Regardless of the proposed objectives, the seed conservation technology is based on the fact that the seed is a living organism whose basic vital functions are not completely interrupted in the hemibiosis state (Bâlteanu, 2003). One of the coordinates of the judicious management of the quantitative and qualitative losses during the storage of the seeds intended for consumption/sowing is their defence by the effect of the harmful organisms specific to the storage. The harmful organisms specific to the storage of seeds of straw grains are constituted mainly by insects and rodents. Most species of insect pests belong to the group of beetles, like wheat mackerel (*Sitophilus granarius*), rice mackerel (*Sitophilus oryzae*), Surinam beetle (*Oryzaephilus surinamensis*), Mauritanian beetle (*Tenebrioides mauritanusus latilusus, latilusophilus*) etc, or lepidoptera: cereal moth (*Sitrotoga cerealella*), wheat moth (*Nemapogon granellus*) or dried fruit moth (*Plodia interpunctella*). Major problems, during storage can be generated by rodents: the gray rat (*Rattus norvegicus*), the black rat (*Rattus rattus*) and the common mouse (*Mus musculus*).

In order to prevent the attack of these harmful organisms, a series of preventive measures are required, which aim to prevent the pests from entering the storage spaces, as well as curative measures aimed at the rigorous control of the potentially harmful organisms, applied according to the treatment approved by the National Phytosanitary Authority (Ministry of Agriculture and Rural Development MARD, 2018).

Materials and Methods

The experimental part of the work was carried out within the Agrosem Tecuci Complex, whose warehouses are exclusively intended for the storage and keeping of seeds for sowing, from most agricultural and horticultural species, for the storage of wheat seeds, respectively, within the operator SC Păunul AN SNC SA, specialized for the storage and keeping of barley seeds.

Given the fact that the two mentioned deposits are authorized by State Institute for Testing and Registration of Varieties, Regional Centre Galați (ITCSMS) for the activity of processing and marketing of seeds, within them, only the certified seeds, produced by authorized economic operators for the production of the seeds, have a minimum degree of infestation with organisms. harmful, the integrated control of the harmful organisms being realized by preventive - curative methods approved by NPA, for the disinsection of the spaces of storage of seeds using an approved product, combined with the preventive treatments, respectively, with the technique of lowering the temperature of storage to the maximum 5ºC, in order to minimize the propagation rate of pests, which gave remarkable results.

The laboratory part of the work was carried out within the ITCSMS Galați laboratory, accredited for sampling the seed lots and carrying out quality tests specific to the official certification of seeds and planting material.

Post-harvest technological flow – storage

The access of seeds to the storage areas (temporary or permanent) authorized by the official territorial authorities is allowed when it has a guaranteed provenance, and once entered the deposit the seed goes through a minimal flow, which must start with the quantitative and qualitative reception of the seeds, after that the seed is managed in the appropriate space for temporary storage, depending on the species, variety, category and provenance (MARD, 2018).

Source: Author, personal contributions

Fig. 1: Deposits of seeds packed in Galati county

In accordance with the provisions of the regulations specific to the seeds, the storage of seeds for straw grains for sowing is applicable to the seeds, which come from a crop that has been the subject of official control in the field and has been declared admitted, by the inspectors of the official authority, on the basis of the document of field inspection, with the decision "permitted seed culture" (MARD, 2010). At harvest, the seed mass is not homogeneous but contains, along with the seeds of the base species, a series of impurities formed from seeds of other crop plants, weed seeds, residues of the basic crop (grain fragments), microorganisms (bacteria, fungi) on the surface of the seeds, in shells or inside the seeds, live insects, plant residues (fragments of stems, leaves, inflorescences), mineral impurities (soil, sand, dust, etc.). The seed mass is formed, mostly, from living organisms (seeds and microorganisms), having a vital activity of greater or lesser intensity, depending on the conditions of storage ensured, which interact both with each other and with the environment, with which they are in - an unstable ecological balance, the characteristics of the seed mass constituting the result of the specific properties of its components. Given that the vast majority of harmful organisms are transmitted through seed and soil, and through their action can cause serious damage, sometimes even by compromising the culture, complex prevention and control measures are required, starting with the proper preparation of storage spaces. The choice of seed storage systems for grain crops depends on the state of the crop, the climatic conditions, the duration for which it is necessary to maintain the viability and vigour of the seeds, humidity, their value, being able to opt for: keeping the seeds in different ways: dry state, cool state, or in a state of no air with the help chemical substances.

Fig. 2: Warehouse for cereals and seed Galati County
Source: Author, own contributions

These systems that can be approached singly or can be combined, depending on the objective proposed, the handiest example being the one in which the seeds are kept in the dry state. The quality of a crop, as well as of other products obtained from the processing, crucially depends on maintaining optimum humidity and air temperature, being absolutely necessary, a regulation of the humidity of the seeds and the temperature of the air in the warehouses, because according to these indices the duration of seed retention also varies.

The germination capacity of cereal seeds can be maintained throughout the year only in cases where the seed moisture has not exceeded 13-14%. Permanent monitoring of the evolution of the temperature and humidity of the seed mass, the appearance of the odour of mould and possibly the pests, represents an essential constant of the overgrowth of the seed lots, the results of the determinations being recorded in the record of the respective seed lot. Analysis were made in laboratory of

Fig. 3: Humidity variation depending on the storage temperature
Source. Authors based on ITCSMS, 2019

Comparing the data from two successive observations gives an image of the evolution of the conditions in the seed mass, which, correlated with that of the temperature of the storage air, allows suitable measurements to be done.

Storage conditions for cereals depending on the type of deposit - cereal storage is performed frequently with individual silos with a capacity ranging from 10 to 200 tons, equipped with loading and unloading equipment. A silo count has an underside, which allows the air to circulate freely. Preservation of cereals during the early days imposes an active aeration system, adapted to the characteristics of the respective storage area, composed of channels located at the floor level. Deposited in bulk constructions vertically or horizontally, the cereals are arranged in a layer dependent on the

humidity. Deposits with active aeration allow the formation of a layer of 2.5 m thickness for a humidity of 14-15%, as long as the spaces are provided with special installations, a thickness of 1.5 m is allowed. **Keeping seeds in the dry state** - drying the seeds up to a humidity, below the critical one and keeping them, in the usual conditions of the environment, packed or unpackaged, in spaces that provide maximum protection against changes in humidity, temperature and other factors that prevents the deterioration of their physiological qualities (Agrimedia, 2012).

The vast majority of registered economic operators for seed production, processing and marketing, use this system with good results. The system does not require warehouses or silos with special installations, does not require supervision that is very attentive or expensive maintenance works and allows the packaging and storage of seeds in packages of different types and sizes. Even when stored for 2-3 years, the seeds of most species maintain their physiological properties at optimal values, except for those with a higher fat content.

Cool seed storage - This is the method that can be considered as an alternative to dry storage systems, which responds best to the pest control requirements. The seeds have a temperature-dependent activity rate and the lower it is below the optimum level for each species, the slower the rate until, at certain negative temperatures, some species (harmful organisms, microorganisms) die. The seeds slow down their life cycle, especially the respiration process, so that at 0-5^{0}C temperatures its effects become of no importance for storage (Ion, 2010). The seeds of dry straw grains can be cooled without affecting their germination, but if their moisture is high, the negative temperatures cause them to lose their germination, the process being influenced by the humidity and the degree of maturity of the seeds, by the temperature at which they are cooled, by the rate of decrease of the temperature, by the duration of maintaining at the respective temperature, by the temperature alternations, etc. In practice, keeping seeds at exaggerated negative temperatures is useless and, if made artificially, it is uneconomical both during the production phase and subsequently, during maintaining the temperature because at removing dry seeds from cold storage tanks wetting them should be avoided, through the condensation that can take place in a humid and warm atmosphere, thus being necessary, the thermal accommodation of the seeds, in a warm and dry space, in tight containers, or their energetic ventilation.

Harmful Organisms Specific to Storage of Seed Lots of Straw Grains. General Context

After the technological conditioning process has been carried out, the raw materials collected in warehouses or silos can be:

- Contaminated with mold:
- Field mold, own mold, which contaminates cereals before harvesting *(Altenaria, Fusarium, Clodosporium);*
- Storage mold, which develops in storage spaces *(Aspergillius, Penicillium, Rhizopus);*
- Mold originated during the alteration process *(Populospora, Sardinia, Fusa-rium graminaruum).*
- Infestated with adults and larvae of beetles *(Tenebrioides mauritanicus L., Cryptolestes sp.),* or other insects *(Tenebrioides mauritanicus, Cryptolestes ferrugineus, Ephestia elutella, acarieni).*

In these infestations, the seeds can have the germ destroyed, although the percentage of direct weight loss is very low. Some pests feed only on the endosperm, others attack only the embryo, and the third category attacks all the anatomical parts of the cereal seeds (Jadaneant, Pop and Calin, 2008). Periodic control of the stored products is necessary, as there is a permanent danger of infestation with the most frequent pests in storage, which are insects. The losses caused by rodents are also recorded at significant values. Each rat can consume approximately 9 kg of cereals annually, and 10 times as much grain becomes unfit for human nutrition (NIS, 2015). Damage caused by harmful factors leads to consumption of products, pollution of the mass of products with products of insect metabolism,

increase of temperature and humidity and creation of favourable conditions for the development of microorganisms.

Fig. 4: The weight of infestation while depositing

Protection of stored agricultural products

The concept of integrated protection of seed lots subjected to storage is based on food safety management systems, according to Regulation (EC) no. 852/2004 of the European Parliament and of the Council of 29 April 2004 on food hygiene and integrates the requirements of modern technologies, in a set of methods and means of combating, based on the natural factors for regulating the population density of harmful organisms, which should not to exceed the Economic Damage Threshold (PED) (MARD, 2018).

The problem of protection of stored products has become very current in agriculture, a large quantity of agricultural products being stored without ensuring the necessary conditions for storage. In many cases, prophylactic measures of disinsection are not performed. The problem of infestation of stored products is old, the overall losses are very high. Numerous specialized studies illustrate the economic role of infestations in the conservation process of plant products and, in particular, cereals. Pest infestation is among the biotic factors that most influence the quality of the stored products. An important aspect is to identify the degree of infestation of the seed mass, prior to preliminary storage, based on samples taken directly from the gross mass of seeds harvested, by the direct observation method (in the visible form, live adults or their larvae are observed, as well as the damaged seeds) or by other procedures that determine the hidden forms of the pests or the cases of infection with different pathogens. Seeds in which pests live have been found (eggs, larvae, chrysalis, visible and latent adults) are considered to be affected by pests and cannot be passed to the next processing / storage stage, until the most appropriate measures are taken for pest control, given that the specific regulations and standards in force do not admit live pests or their larvae in the seed material.

Determination of the economic damage threshold (PED). Modern theories of protection against harmful organisms are based on the economic threshold of damage (PED), which can be defined by the level of losses caused by harmful organisms, the cost / benefit ratio and the resource costs for protection actions. The level of losses may vary, as the cost and benefit of some actions will depend on the actual situation and circumstances (Boboc, 2006). This is essential, taking into account the variability of opportunities and constraints between keeping products in agricultural holdings, processing companies and large warehouses with sophisticated storage conditions of control capabilities. In simple terms, PED is an indicator that helps manufacturers determine if the number of pests is large enough to justify the application of the control measures. Rather, PED is the number of harmful organisms per unit of measurement (m2, kilogram, trap, etc.), which, being unchecked, will in the near future increase and exceed the economic level of damage. In reality, this is the balance between the costs of plant protection and the economic losses caused by harmful organisms. The economic threshold for pests and insects in seed lots to be stored is close to zero, when certified seed lots come from controlled and admitted seed crops, free of living harmful organisms and without signs of infestation. In cases where the PED is

higher than zero and the quality standards require product reconditioning, the cost of pest control works in the storage areas is quite high, due, first of all, to the high prices for the chemical preparations used, to equip them with the necessary equipment, to train the specialists in carrying out the corresponding works and approvals. (Alecu et al, 1997). Prophylactic measures are the most important elements of the system of integrated protection of the stored products and include the operations that are carried out in the empty warehouses, before the introduction of the products (cleaning the deposits, disinfecting them by chemical means, etc.) and have as a basic principle of preventing the penetration of pests into the storage space, the development of a system of monitoring the ways by which they can have access inside the warehouses:

Preventive - curative measures The inspectors of the National Phytosanitary Authority (NPA-ANF) recommend the disinsection of the cereal storage spaces, observing several stages: the hygiene and the clearing of the storage spaces, the sealing of the storage spaces in order to increase the efficiency of the solutions, the treatment solutions, by spraying, with long-acting insecticides. The basic objective of cleaning the rooms and hygiene measures were to eliminate the outbreaks of pests, to prevent the spread of pests from outbreaks established in other places, to limit the extension of the populations of pests, maintenance and cleaning at the workplace. The harvesting machines, air conditioning systems, packaging, as well as means of transport are also cleaned.

Results

Thus, the health status of the seed lots (SS) was evaluated, determinations of humidity (U%), germination capacity (G%) and the presence of live pests (SS) were carried out, by standardized laboratory methods, standardized according to SR EN ISO/IEC 17025: 2000. The preparation of the storage areas related to the keeping of the seed lots certified by the Gloss and the barley of autumn Nectaria, was realized, by treating them with a product approved for disinsection and deratization. The evolution of the health status of Glosa wheat seed batches, stored experimentally in the laboratory of the State Institute for Testing and Registration of Varieties, Regional Centre ITCSMS Galați (figure 5).

Figure 5: Evolution of the health status of Glosa wheat seed (2016-2019)
Source: ITCSMS (2019)

In order for the experimental results to be repeatable, with practical and scientific value, the researches were carried out according to specific techniques and methodologies, described in the specific standards mentioned, as well as in the operational procedures and instructions of the Quality Manual. The evolution of the health status of the Nectaria barley seed lots, experimentally deposited in the Galati ITCSMS laboratory is shown in Figure 6

Figure 6: The evolution of Nectaria barley seed (2016-2019)
Source: ITCSMS Galati data - health quality indices of stored seed lots (2020)

From the analyses carried out it was observed that the indices of humidity (U%), germination (G%) and health status (SS%) (presence of living pests), purity (P%) of the batches of seed certified in the end, analysed, in view of the official certification, had corresponding values. The determination of the presence, in the analysis samples, of the living pests, emphasized that during the four years of storage, the presence of the harmful organisms of the deposit was kept to zero, so the indications of respective quality and the sanitary status had corresponding values. According to the principles of integrated pest control organisms, the method of maintaining the storage temperature, at the level of 5^0C, was used to minimize the propagation rate of pests.

Conclusions

The research on the integrated control of the damaging organisms from the lots of stored grain seeds, was carried out within the mentioned authorized warehouses, finding that the lots of Glosa wheat and Nectaria autumn barley seeds were conditioned and stored according to the specific seed technologies for straw grain for seeding. Pest control of stored grain seed lots has developed as a practical necessity, in order to biologically substantiate the steady increase in agricultural yields, as well as to avoid the risks related to seed trading. Research on the integrated control of harmful organisms from the lots of stored grain seeds, at the level of the two authorized economic operators for seed processing, has revealed "zero" PED values as an indicator of the presence of living harmful organisms in the stored seed lots, in all years of storage. The economic pest threshold for insects in seed lots for storage is close to zero, when certified seed lots come from controlled and admitted seed crops, free of living harmful organisms and without signs of infestation.

Abstract

The purpose of the study is to consider the features of the development of socially oriented non-profit organizations at the regional level and to determine the main directions of support and development of socially oriented non-profit organizations in the Russian Federation. The researchers paid special attention to the problems of legislation and legal support for the activities of non-profit organizations. The main conclusions of this study are based on the key theoretical principles and practical directions of the activities of socially oriented non-profit organizations (establishing, functioning, development). The authors analyzed the activities of one of the largest and most efficient regional socially oriented non-profit organizations. The researchers carried out the SWOT analysis to study the methods of state support for regional non-profit organizations and the effectiveness of cooperation with the philanthropic sector. Based on the study, the authors proposed the ways of development of the non-profit sector and socially oriented non-profit organizations.

Keywords: Non-profit sector, non-profit organizations, socially oriented non-profit organizations, social sphere

Introduction

In the modern conditions of globalization and growing external influence, it is extremely important to develop the national economy, social sphere and well-being of citizens. Special attention should be paid to social problems. The social sphere is negatively affected by the policy aimed at raising the retirement age, the weakening healthcare system and the economic situation.

In 2010, there appeared a concept of non-profit organizations and Russian law started to regulate the actions of such entities. Such organizations include civil society institutions and deal with the social problems. They are not involved in political activities and are not state-owned. Employees of non-profit organizations are fully interested in the development of various areas of the Russian economy and contribute to the efficient work of the company.

In 2010 socially oriented non-profit organizations were treated as a specific type of corporations, which was an important stage in the process of development and structuring of such entities. The socially oriented non-profit organizations perform specific economic functions to strengthen the

economy, to stabilize the situation and to increase the financial literacy of the population. To achieve the goals, the socially oriented non-profit organizations also:

- create new jobs;

- even incomes of various social groups;

- contribute to improving the quality of social services provided to the population.

Social functions include not only providing social services, but also:

- drawing public attention to acute issues so that the citizens could contribute to the process of solving the urgent problems;

- developing the civil society as a whole;

- contributing to the development of the social sector by means of providing high-quality services, taking innovative approaches and working conscientiously;

- contributing to the development of charity and volunteer activities;

- contributing to the development and augmentation of the regional natural resources and human capital, helping citizens to attain self-realization.

The most popular non-profit organizations include public organizations, autonomous non-profit organizations and non-profit foundations (Kovalenko, 2019).

According to the Ministry of Justice of the Russian Federation, in April 2018, there were 455,617 organizations in total. According to the Russian Statistics Agency, in 2014 there were 132,087 socially oriented non-profit organizations in the Russian Federation. The data provided by Rosstat (Russian Federal State Statistics Service) in 2016, are presented in Figure 1.

Figure 1: The number of socially oriented non-profit organizations performing major activities in the Russian Federation (percentage of the total number of organizations).

Thus, today the vast majority of non-profit organizations (approximately two-thirds of all the registered companies) are socially oriented.

Methods

The purpose of this study is to find the ways, methods and tools aimed at improving the work of regional socially oriented non-profit organizations. The study was conducted at two levels. First of all, the authors analyzed the specifics of the area and the sector the socially oriented non-profit organizations are involved in. The researchers determined which organizations should be supported by the government at the federal, regional and municipal levels. Secondly, the authors conducted the research at the level of the socially oriented organization to identify which problems this type of organization has to deal with and to determine the ways to solve these problems.

A great contribution to the development of the issue under study was made by Russian and foreign authors, such as L.I. Jacobson, I.V. Mersiyanova, R. Kramer.

The methodological basis of the study is related to the analysis of the legislative framework and regulatory documents alongside with the comprehensive and systematic analysis of data on the development of the nonprofit sector. The authors applied such general scientific methods and cognitive techniques as a statistical analysis, complex and situational approaches, and generalization. The empirical study is based on the method of web content analysis (the analysis of the information posted on the organization's official websites on the Internet). Within the framework of the first part of the study, the authors formulated some hypotheses, which allowed them to conclude if it was necessary to make some changes in the activities of socially oriented non-profit organizations in the field of economic development of the region:

- the most famous socially oriented non-profit organizations getting state financial support are most involved in practical actions;

- the successful projects of socially oriented non-profit organizations contribute to the development of the social sphere of the region as a whole and improve the quality of social services provided to the population;

- executive bodies of state power provide financial support in the form of grants to the most open and transparent socially oriented non-profit organizations.

To implement the second stage of the study, the authors analyzed the activities of an autonomous non-profit organization, which is one of the largest in the region (Kolesnichenko and Radyukova, 2018), since 2014 it has successfully provided social services and improved living conditions for single elderly people.

To identify the specifics of the organization under study, a SWOT analysis was carried out. A SWOT analysis is related to a situational analysis. Within the framework of this analysis the emphasis is made on the enterprise under study, while the competitive environment and the sector itself serve as the "background" of the study. In general, the authors focused on the "matrix of the SWOT analysis".

Results and Discussion

Let us focus on the general development trends of socially oriented non-profit organizations in 2012-2019. In March 2012, the President of the Russian Federation announced that there was a need to promote public-private partnership in the social sphere. At the same time, it was crucial to provide socially oriented non-profit organizations with financial support from the federal budget and grant systems. Since 2017, there has been a rapid increase in the number of socially oriented non-profit organizations in the subjects of the Russian Federation. Some of the social welfare services are provided by socially oriented non-profit organizations on the basis of an outsourcing agreement. So, the activities of socially oriented non-profit organizations are controlled by the government, which results in the efficient work and high-quality services. It is important to note that due to the external

and internal competition and specific criteria for evaluating the effectiveness of activities, the work efficiency increased and the social sector attracted additional funding.

In 2018, socially oriented non-profit organizations became fundamental for the stable and confident development of the state. According to the statistics, there was a growth in the number of socially oriented non-profit organizations involved in the social sphere. As for the finances, they used their own resources and the money they received thanks to the grant systems, partnerships and crowdfunding projects.

According to the analysis of the activities of the regional socially oriented non-profit organizations, at the end of October 2018 there were 171 registered organizations (98 of those companies were registered in 2018). There were more and more registered organizations. The authors focused on the main characteristics of the non-profit sector and came to the following conclusions.

1. Socially oriented non-profit organizations have deficient legal framework. There are no clear mechanisms for granting privileges to socially oriented non-profit organizations that provide socially useful services.

2. The competitive conditions are not equal for socially oriented non-profit organizations and small and medium-sized businesses. This implies that non-profit organizations do not have the opportunity to obtain debt financing, soft loans etc. In addition, socially oriented non-profit organizations cannot receive property support on a gratuitous (preferential) basis if they receive compensation for social services they render; and regional socially oriented non-profit organizations do not have preferences in public contracting.

3. Poor public awareness of the activities of socially oriented non-profit organizations. There are specific problems related to offline and online work. The information on socially oriented non-profit organizations needs to be available on the Internet so that the companies could be promoted and developed in the future. Thanks to the Internet, it is possible to implement projects and meet like-minded people. However, it takes much time to create and maintain a social networking community and a website of the organization. Many socially oriented non-profit organizations, especially in the regions, hardly use PR promotion tools (Kulkova, 2017).

4. Disunity of the non-profit sector. Some representatives of the socially oriented non-profit organizations claim that there is an “unhealthy competition” in the non-profit sector. There are no established intra-sectoral contacts, organizations rarely interact to exchange their positive experiences to develop the civil sector and solve corresponding social problems.

5. The low level of professionalism of non-profit sector workers is also a great problem. In the commercial sector candidates compete against one another to attain a position, the most qualified personnel are selected, and the employees are paid according to their merits. The situation in the civil sector is different. It mostly employs enthusiasts ready to work for a small salary, or unprofessional volunteers who need additional training. Therefore, in socially oriented non-profit organizations there is always a shortage of experienced personnel in the field of management, office work, marketing, etc. (Zavgorodnyaya, 2018)

6. "Philanthropic hunger" which implies lack of resources needed to carry out certain activities. There is an ongoing process of searching for additional sources of funding. State organizations and socially oriented non-profit organizations providing social services have to meet the same requirements, despite a critical difference in funding and available resources.

Let us analyze the results of the SWOT-analysis of one of the regional socially oriented non-profit organizations. The results of the analysis are presented in Table 1.

Table 1: results of the SWOT-analysis of the activities of the socially oriented non-profit organization

Strengths: Highly qualified personnel; Years the created experience; High uniqueness of the organization; Partner support; Recognition and trust in the organization use of the mechanism of crowd funding; Support from volunteer units; Continuous work on the extension of the partner network.	**Weaknesses:** Specifics of activity; Continuous dependence on external funding
Opportunities: Receiving grant support; Implementation of new system projects; Participation in grant competitions; Involvement of new partners; Holding charitable actions; Continuing staff development; Development of cooperation within the framework of corporate charity.	**Threats:** Macroeconomic instability, Economic recession

As soon as the authors analyzed the strong and weak points of the organization, as well as potential threats and opportunities, they tried to establish links between them.

The results of the SWOT analysis show that the unique competitive advantages of a socially oriented non-profit organization make it possible to maintain and expand the list of competitive advantages in the market in the current macroeconomic situation.

A socially oriented non-profit organization pays special attention to the development of the project format of work, constantly looks for new ways and directions, tries to use accessible information technologies and be in line with the main trends.

Recommendations

One of the latest Federal Laws was adopted to support socially oriented non-profit organizations, to simplify their work system and to make it more convenient both for non-profit organizations themselves and for beneficiaries (Romodina, 2018). Federal Law of December 5, 2017, No. 392 provides for amendments to improve the system of independent expert analysis of the quality of services rendered by socially oriented non-profit organizations. In accordance with the system, an independent expert analysis of the quality of services should also be carried out by the federal medical and social assessment departments. The federal, regional and municipal Public Chambers are responsible for forming public councils to conduct an independent expert analysis. Public service employees (representatives of state and local self-government bodies) working in the sphere where an independent expert analysis is to be carried out, as well as the employees of the organizations involved in this sphere, are not entitled to be members of such public councils. (Kovaleva, Tcukarev and Shibaeva, 2016).

Such a mechanism is convenient for all participants and, above all, is aimed at improving the quality of services provided. Public Chambers also receive an additional privilege - their authority is strengthened and they act as a mediator between the state and the civil society.

To be promoted in the network, socially oriented non-profit organizations need to hire a new employee, which is also problematic due to insufficient financial resources. Volunteers can provide partial or substantial assistance.

The government is responsible for eliminating the above-mentioned problems. Property support can also be provided to socially oriented non-profit organizations. It implies that such organizations are entitled to possess and (or) use on a long-term basis the state property of the region free from any

right or claim of a third party (with the exception of property rights of non-profit organizations). Such property should be used for its intended purpose only. Non-profit organizations rendering socially useful services are provided with property support for at least two years.

Information support may also be provided. In order to implement state policy aimed at supporting regional socially oriented non-profit organizations, the regional administration creates and maintains a website to provide necessary information.

Consultative support is offered to socially oriented non-profit organizations by regional government authorities. They publish methodological materials for socially oriented non-profit organizations. Such materials deal with the issues of interaction with regional government authorities and the activities performed by socially oriented non-profit organizations regulated by the law. The methodological materials should also provide information on how to arrange thematic seminars and hold scientific and practical conferences on the interaction between regional authorities and socially oriented non-profit organizations etc. Two online resources (the Information Portal of Socially Oriented Nonprofit Organizations and the site called "Nonprofit Organizations of the Region") provide consultative support and systemize legislative and methodological information useful to regional nonprofit organizations. On these sites, interested parties can read the sector news, look through a calendar of events, post information on the activities of their organization, find out useful information on competitions, grants and legislative aspects (Zhdanov and Danilov, 2018).

Socially oriented non-profit organizations cannot do without financial resources. Subsidies are the main and most effective form of financial support.

The authors offered some draft recommendations for specific non-profit organizations.

1. Active participation in grant competitions at the regional and federal levels.

It is necessary to regularly monitor the sites that systematize information on current contests the organization can take part in.

2. Interaction with volunteer centers and building a team of permanent volunteers. The implementation of many projects and the activities of the organization depend on the help of volunteers (mainly students of universities and colleges). However, students find it difficult to combine their voluntary work on a regular basis with their studies at the university. The older people also provide some assistance but cannot participate in every event, since their priorities are related to their families, work and personal affairs. If a team is created, the work is coordinated. It should also be noted that experienced volunteers helping the organization, contribute a lot to the effective work. They do not need much time to undergo training courses. Volunteer work connected with the leisure activities helps people to get closer, trust each other and make their communication more open.

3. Studying the mechanisms of work in the field of corporate charity. This is one of the most important directions aimed at the development of the charitable sphere and the promotion of socially oriented non-profit organizations. It is characteristic of large cities and industrial regions (for example, the regions where natural resources are extracted). It implies different ways of interaction and support. However, nowadays this direction is not very popular since it demands a lot of time and effort.

4. The development of social networks of the organization. The direction has always been very popular. The information on the organization's activities is provided and crowdfunding projects are promoted. Increasing audience engagement will help to expand the affiliate network and promote the organization. In this case, it is necessary to focus on priorities as time is limited. There are several ways to gradually improve the work in this area:

- writing posts and content-plans in advance;

- attracting volunteers who can provide information support;

- regular e-mail distribution of projects;

- budgeting for advertising in social networks;

- attracting more followers (real users) in all social networks;

- creating interesting sections to post materials apart from news information.

Conclusions

The modern political strategy of the Russian Federation tends to be social since it is aimed at improving the quality of life and well-being of every citizen.

Since 2012, the government has put a lot of efforts into the formation and development of the "third sector" of economy represented by non-profit organizations.

In the course of time, socially oriented non-profit organizations proved to be trustworthy and reliable market participants. A new type of organization is aimed at creating healthy competition in the sphere of social services, improving the quality of social services and introducing innovations.

Currently, socially oriented nonprofit organizations successfully perform their functions and are involved in almost every sector of economy. Creating healthy competition in the service market and giving beneficiaries an opportunity to make their own choice, socially oriented nonprofit organizations help to improve the quality of services, create new jobs and promote volunteering in our country.

Socially oriented non-profit organizations perform their functions successfully and get the resources they need thanks to the support provided by business structures, wealthy and middle-class citizens and the volunteer sector.

Socially oriented non-profit organizations play an important role and are treated seriously at all state levels.

Taking into account the general tendency to support socially oriented non-profit organizations at the federal and regional levels, the authors claim that in the future the social sector is likely to be promoted and perform its functions successfully in our country.

Abstract

The crop structure of a farm designates its field of activity and, in the case of developing a strategy, it is a component of it, influencing in many aspects the results that will be obtained. Due to its complexity, determined by the multitude of components, the relationships between it and the impact it generates on the economy of agricultural holdings, the culture structure has a special decision charge. In this context, the structure can be viewed as a combination of options, of ways in which the unit is to function. It is absolutely necessary for the process of establishing a culture structure to take into account the relationships of biological, technological and economic nature, whose contents can lead to either a complex structure of production (diversification) or the imposition of narrowing the profile of the production activity (specialization). The following indicators are followed in research: structure of cultures (2015-2018); cultivated area (2015-2018) and total production, prices and total revenues (2015-2018). The conclusion of the research is that choosing an optimal crop structure, it starts from the soil and climate conditions that characterize the agricultural unit, following on one hand, putting them into value, and on the other hand satisfying the requirements of the plants towards these factors, which influences the level of production. Extensive and intensive agriculture determines the organization of different production structures, with particularities that influence the economic results on the farm level.

Practicing culture structure is a natural consequence of the plant biology, especially population’s need for food (population growth and product demand).

Keywords: Agriculture, Culture Structure, Culture Share.

Introduction

The rural development of Romania experienced a complex evolution after the change of the political regime in 1990, being influenced by the national policies regarding the field of land funds and the retrocession by the former owners. The fragmentation of agricultural lands, due to the wrong system of reallocation of the Romanian farmers' lands, affected the performance of the national agricultural production and favored the sale of the Romanian land to foreign investors (Iancu and Stanciu, 2017).

Direct payment schemes to be granted as support mechanisms for agricultural producers, are the following in Romania: Single payment scheme on the agricultural area; Transitional national aid - ANT; Redistributive payment; Payment for climate-friendly agricultural practices; Payment for young farmers; Coupled support scheme; Simplified scheme for small farmers. Payment schemes should be revealed in the impact study.

Since, in general, crops have varied production cycles and that environmental factors know a certain distribution over time, some of the crops, respectively, the varieties, "catch" better conditions. For example, given that, in certain areas, rainfall is concentrated during May-June and early July, early varieties of maize give better results than late ones, which, although having higher efficiency, are affected by drought at the end of the period, production per hectare being decreased (Stanciu, 2017a, b).

The same can be done in the case of field vegetables, in order to counteract the negative effects of late spring frosts and mists that come too early in the fall. In principle, the determination of the production structure of the agricultural holding must take into account the criteria of the technical and economic optimum (Florea et al, 2019). In connection with the transition to the market economy, it is deeply necessary to investigate the economic efficiency of the production and to introduce corrections in the modification of the specialization of enterprises. Schin, Virlanuta and Stanciu (2017), showed that the association of agricultural producers, in various forms, can be a solution for the improvement of technological flows for the agricultural feedstock production, for the processing and selling of food products. As far as agricultural associations from Romania are concerned, there are significant discrepancies between counties and between the crop and animal production sectors. At a national level, there is a moderate concentration degree of producer organisations.

This is done through structural changes in the production process, as well as in the potential of resources for which large investments are usually required. The selection of crops must be made according to the profitability ensured by selling the products that depend on the level of the resources of the companies. Selecting the most profitable crops and determining the profit obtained by combining them is a relatively slow process and a specific research problem.

An analysis of the structure of the main agricultural crops in Romania (table 1), in 2018 compared to the year 2014, shows that:

- grains decreased by 4.14%, from 5,484 thousand ha in 2014 to 5257.20 thousand ha in 2018;
- legumes registered an increase of 170.59% in 2018 compared to the year 2014, especially due to the increase of the cultivated areas with pea beans, an increase with 233.89% in 2018 compared to the year 2014;
- oilseed plants registered an increase with 18.40%, influenced by the growth with 92.25% in the culture of rapeseed.

Regarding the share of the crop groups from the total cultivated area it can be observed the following:

- cereals registered a decrease in share, from 66.44% in 2014 to 62.09% in 2018, decrease influenced by the share decrease of the areas cultivated with maize from 32.66% to 28.82%;
- legumes registered an increase in share, from 0.60% in 2014 to 1.58% in 2018, influenced by the share increase of cultivated areas with peas from 0.44% to 1.42%;
- the oilseed plants registered an increase of the share, from 18.57% in 2014 to 21.44% in 2018, growth influenced by the increase of the surfaces of all crops. (table 1).

Table 1: Share of the main crops from the total agricultural area in Romania (2014 – 2018)

Source: *data processed according to the Statistical Yearbook of Romania 2014 and 2018.*

Analysing the data presented in Table 2 it is noted that, regarding the structure of the main agricultural crops in Galati County, in 2018 the evolution was different from the evolution to the national level, thus:

- cereals showed a decrease of 16.82%, from 283,976 ha in 2014 to 269,848 ha in 2018;
- legumes registered an increase of 446,47% in 2018 compared to 2014, being influenced by the growth of the cultivated areas with peas with 798.09%;
- oilseed plants showed an increase of 14,43%, growth influenced by the increase with 6,39% of the sunflower culture.

Table 2: Share of main crops from the total agricultural area in Galati County (2014 – 2018)

Culture groups / Culture	Years		(+/-)comp. to 2014%	% compared to total agr. area 2014	%compared to total cultivated area 2018
	2014	2018			
Total cultivated area, ha	**283,976**	**269,848**	**- 4.98**		
● Grains	**190,589**	**158,524**	**-16.82**	**67.11**	**58.75**

Source: *data processed according to the Reports of Statistical Office of Galati County,*

Regarding the share of the crop groups from the total cultivated area, in Galati County, it can be observed that:

- grains have decreased in share, from 67,11% in 2014 to 58,75% in 2018, being influenced by the decrease of the share of the wheat cultivated areas from 19,33% to 16,15%;

- leguminous showed an increase of the share, from 0,64% in 2014 to 3,70% in 2018 influenced by the increase of the peas cultivated area from 0,37% to 3,49%;
- oilseed plants registered an increase of the share, from 24,24% in 2014 to 29,19% in 2019.

Considering the structure of the main crops in the total agricultural area used in Galati County, it is required an analysis of it viewed in a rational rotation, recommended for the South Eastern part of Romania (table 3).

Table 3: The share of main crops from the total agricultural area within a rational rotation, in the plain area

Culture groups/Culture	Crop system	
	Irrigated (%)	Not irrigated (%)
Maize	33 - 35	25 - 27
Wheat	10 - 12	12 - 16
Barley	6 - 8	11 - 14
Grains - total	**49 - 55**	**48 - 57**
Soybean	8 - 9	5 - 7
Sunflower	5 - 6	8 - 10
Oilseed plants - total	**13 - 15**	**13 - 17**
Beetroot	4 - 5	3 - 4
Other plants for industrialization - total	**4-5**	**3-4**
Fodder plants	**14-15**	**15-18**

Source: *CEEX PROJECT no, 732 " The technical-economic and management practical guide - Vegetable production"*

From the data presented in Table 2 and Table 3, the following conclusions can be formulated:

In Galati County:

- the share of cereals in the crop structure represented 67,11% in 2014 and 58,75% in 2018, which shows a structure above the recommended share;
- the share of leguminous plants in crop structure represented 0,64% in 2014 and 3,70% in the 2018;
- the share of oilseed plants in crop structure represented 24,24% in 2014 and 29,19% in 2018, a structure above the recommended share.

Case study on PFA PECHEANU CORNEL

The Authorized Physical Person (PFA) is the form of organization of the economic activity performed by an entrepreneur in Romania equivalent to a self-employed individual in UK or USA.

The Authorized Physical Person (PFA) PECHEANU CORNEL was founded in 2006 and operates on the basis of the Romanian commercial law, with headquarters in Namoloasa village, Galaţi County, having an agricultural area of 908,69 ha in 2018, located on the territory of the same locality. The area of arable land owned and used by PFA PECHEANU CORNEL between 2015-2018 has shown a structure of crops presented in table 4 in which it is noticed that cultures of wheat, barley, maize and sunflower are predominant. The land is leased from the rightful owners, based on lease agreements, according to Law no. 16/1994.

The land area currently used has low agricultural potential, the area being disadvantaged due to specific natural conditions, as provided by the National Rural Development Plan 2014-2020, allowing moderate agricultural productions.

The agricultural holding has no possibilities to irrigate the crops, even if in that area has been conducted, before 1989, a project for an irrigation system, abandoned in 1991. From the data presented in table 4 it is noticed that the land area of the agricultural holding, all arable land, has increased during the years 2016, 2017 and 2018, towards the year 2015, with 199.74ha, 223.94 ha and 62.84ha, reaching from 422.17ha in 2015 to 908.69ha in 2018.

Table 4: Crop structure for PFA PECHEANU CORNEL, between 2015 and 2018

Nr. crt.	Culture	2015	2016	2017	2018	Average	(+/-) Towards 2015 (%)
		Area (ha)					
1	Wheat	103.42	305.21	299.15	236.36	236.04	128.54
2	Spring barley	80.44	78.04	195.28	270.42	156.05	236.18
3	Barley (autumn)	-	-	-	38.50	9.63	-
4	Oat	-	31.00	237.16	98.67	91.71	-
5	Maize	54.75	17.91	41.11	30.20	35.99	-44.84
6	Sunflower	56.35	71.05	53.60	128.10	77.28	127.33
7	Soybean	2.70	-	-	-	0.68	-
8	Rapeseed	-	37.56	-	-	9.39	-

11	Sorghum	-	20.30	10.55	28.36	14.80	-
12	Uncultivated land	80.37	-	-	27.38	26.94	-65.93
TOTAL		**422.17**	**621.91**	**845.85**	**908.69**	**699.66**	**115.24**

Source: *data processed according to PFA PECHEANU CORNEL's records.*

The analysis highlights the fact that, during the period 2015-2018, the culture structure has modified, in the sense that certain crops (soybean, rapeseed, peas) are no longer cultivated, but new crops appeared (barley, oats, sorghum). Surface increases are recorded for the autumn wheat crops, maize, sunflower and fodder plants (between 236% for barley and 14,87% for fodder plants). Considering that in the structure of crops a predominant place is occupied by cereals, it can be concluded that the farm is a "cereal type" farm. The following indicators are followed in research: Structure of cultures (2015-2018); The cultivated area, 2015-2018; Total production, prices and total revenues 2015-2018.

The results for the economic activity of agricultural holding PFA PECHEANU CORNEL are presented in tables 5, 6, 7 and 8. The total amount of the obtained products has increased from one year to another as a result of the increase of the cultivated area, but the average production per hectare depended on the climatic conditions.

Table 5: Total production, prices and total income, on crops, realized by PFA PECHEANU CORNEL in 2015

Culture	Area (ha)	Average production (kg/ha)	Quantity (tons)	Average price (RON/ha)	Total revenue (thousand RON)	Income (RON/ha)

Source: *data processed according to PFA PECHEANU CORNEL's records.*

In 2015, due to drought, yields obtained have been far below the average of the years 2015-2018, and the total income has been influenced by the average sales price, which has been above the average price for the years 2015-2018. In 2016, by comparison to the year 2017, the total income realized by the farm were with 48,54% higher, due to the influence of the average productions as well as the average selling price.

Table 7: Total production, prices and total income, on crops, realized by PFA PECHEANU CORNEL in 2017

Culture	**Area (Ha)**	**Average production (kg/ha)**	**Quantity (tons)**	**Average price (RON/ha)**	**Total revenue (thousand RON)**	**Income (RON/ha)**

For some crops, the income per hectare had a significant increase, as it is the case of the sunflower crop, where the income increased by 257.22%, compared to the year 2015 and the case of fodder plants, which increased by 131.47% towards the year 2015. In 2017 compared to the year 2018, the total income registered a decrease by 26.13%, as a result of the change of the crop structure, of the sale prices and of the lower yields compared to the year 2018. In 2018, compared to the year 2017, the total income on the farm increased by 37.75%, as a result of the increase of the used area, but also as an effect of changing the structure of crops, the average selling price and the higher yields.

Conclusions

The structure of cultures, which has a very important role in how it is manifested and in terms of the results it generates, is influenced by natural, economic, technical and technological factors, etc. Taking into account this role, it is necessary to choose and to optimally proportion the different cultures that enter the structure and, implicitly, in the production system.

An optimal culture structure must satisfy several demands in a simultaneous relationship:

- to offer products that, from a quantitative and qualitative point of view, respond to the demand, highlight and protect the natural conditions and other factors of production;

- to allow the organization of culture rotation and to ensure maximum profit for the entrepreneur.

As a result, the option for one structure of cultures or another structure of cultures is a complex process, which is required to be grounded considering both technical and economic knowledge and appropriate methods.

It is rightly appreciated that these conditions manifest themselves as major restrictions, which almost certainly limits the choice of structure, also with a restrictive role intervenes the market of the respective products.

Safety Performance – Node Comparison in Polish Railways Aspect

Rafal WACHNIK

WSB University, Dąbrowa Górnicza, Poland
rwachnik@wsb.edu.pl

Abstract

Article shows comparison of different transport modes safety performance. On basis of which conclusion that railways are the safest mass land transport mode. Additionally one can obtain information about safety performance of polish railway market. 2018 was the safest year, however there are still areas for improvement. On of the most significant risk factors are the involvement of third untheorized personnel and railway crossing users, which generate nearly ¾ of all accidents. Keeping in mind high risk level for the whole market it must be stated that the risk level for passengers is one the lowest in EU member states. One of key factors may be different approach towards qualification of suicides and fatalities in area of unauthorized persons between different member states. Form the human and organizational factors scope - SPAD's seem to be the most crucial elements to be taken care of regarding safety of polish railways.

Keywords: Safety performance, safety monitoring, safety, railways, safety management system, risk management

Safety Performance Regarding Different Transport Modes

Prologue

Safety has always been a key feature of transport especially regarding passenger services and transport of hazardous goods. It is one of the most significant values in railway transport due to its very structured approach and highly organized manner. Railway transports large amount of goods which inflicts operating with heavy vehicles where a slight error can cause catastrophic consequences. The second most important factor in making railways such a safe mean of transport is the human factor – the devotion to railways of people who are involved in it, and high level of competencies required for nearly every post which is involved in operational services. In summary, available historical data on fatal railway accidents shows a solid gradual improvement in railway safety over the past three decades, which has slowed down since the late 1990s. This "softening" of the trend is observable when analysing both absolute and relative figures of fatal train collisions and derailments in Europe. [1]

Due to this aspect, while organizing railway transport there is a high demand for specialized engineers who can aid the safety matters of railway transport not only on the operational level but mainly on the management level. Proper data analysis and giving precise conclusions and safety targets are at stake. Thus, there are a lot of courses dedicated to safety engineering, based on experiences from other branches of technical science and transport modes. They implement such elements of the art like: proactive safety management, risk analysis, accident investigations etc. These courses are provided at a different level of individuals education, from technical college-like level, through dedicated specializations during bachelors and masters studies, up to postgraduate studies and doctorate theses. It seems that the role of well-trained safety engineers will greatly increase in the railway sectors in the following years.

As it is well described in aviation literature, a proper safety-related data analysis is crucial for improving safety. Extracting knowledge from the mistakes made is the minimum requirement for preventing them in future – a cornerstone of safety culture. As one can see from the higher number of railway accidents[i] for analysis last year it seems that also railway companies see the full potential in this area and the grey area of reporting seems to be decreasing.

As it was stated at the beginning, there are some differences between transport modes:

- ✔ Level of organization – in general companies in maritime, aviation and railway are far more structurally organized and larger per company then in road transport, the other aspect is that they usually derive from national operators where road transport seems to be more open and competitive,
- ✔ Level of administrator regulation – there are regulatory bodies in every industry but mostly one can find them outside of road transport, from the aspect of access to the market (licence and safety certificate in railways for the level of company, authorisation of placing in service for technical assets, and competency management for safety-related posts etc.). Other aspects of regulatory supervision and aid of transport are investigation bodies, where throughout Europe one can find them outside of road transport mainly in aviation and railways,
- ✔ A natural approach to internal regulation form organizational culture approach from companies – aviation is built on procedures for nearly every aspect of transport, railways also have a strong internal regulations backbone for operation, lately (from around 2004) also going into the direction of management systems for safety and maintenance.
- ✔ Access for non-professional operators to the transport infrastructure is the only one with open access for "amateur" operators (drivers) to the same infrastructure that professionals operate, with slight resemblance in maritime (but significant differences in size of vessels). In aviation small airplanes, usually operated by nonprofessional pilots, can operate to a certain flight level and in railways there are only professional drivers.
- ✔ All of these differences and far more, like the level of the safety culture of transport users will eventually have its influence on safety performance.

Safety performance regarding different transport modes

European Union's Agency for Railways (EUAR or the Agency) started to compare safety performance between different transport modes a couple of years ago. The most up to date comparison are shown in Figure1 [1]. As one can see from it, aviation is still the safest mode of transport regarding the number of fatalities and travel distance, while the railways remain the safest land transport mode.

Figure4 :Fatalities per billion passenger kilometres for different modes of transport in the EU (2010-2014)[ii] [1]

In the following analysis authors focused on road and railway transports as they are the most common and very accessible for passengers, especially regarding distances up to 500 km. General Safety performance values for each transport modes are given in Table 1.

Table 1 General safety performance data for road transport and railways

Transport mode (data for 2016)	**Number of accidents / incidents**	**Number of fatalities / seriously injured / injured**	**Economic cost (2014 & 2015)**
Road transport	33,664 / 406,622	3,026 /12,109/40,766	PLN 48.2 bln - 2015[8]
Railways	581 / 837	169 / 94 / -	EUR 153.9 mln -2014

One can clearly see that the difference in data is staggering and favouring railways, even having in mind the difference in a number of million passenger-km done by each mode (in 2016[9] - 292 for railways and 390 for road transport). Regarding land transport in Poland, the authors compared number of fatalities with the operational work in railway and in road transport, the comparison is shown in Table 2.

Table 2 : Comparison of safety performance in land transport (number of fatalities and operational work) [iii]

Accident measure for **freight transport**	Accident measure for **passenger transport**	*year **2016***
0,010	0,157	***Road transport***
0,006	0,015	***Railways***

Another interesting field of comparison is a number of fatalities and distance covered by road and railway vehicles. Figure 2 shows the average of fatalities regarding operational work in road transport. Poland's system is unfortunately the last one, with nearly 18 people killed on roads per one billion vehicle-km.

Figure 5 : Road deaths per billion vehicle-km[iv] **[6]**

Figure 3 shows the appropriate measure for railways and one can clearly see that there is a significant reduction in number of fatalities per train-km. These can be treated as equal to vehicle km despite the

fact that trains usually consist of multiple vehicles. Even at the EU level, there is a nearly 21-time reduction in the average number of fatalities. Also, the same applies to Poland – 15 times higher for road transport.

Figure 6 : Railway fatalities per million train-km (2010-2014) [1]

Other interesting aspects of safety performance are external costs of transport which were studied by prof. A. Merkisz-Guranowska team and described in [7]. The summary is given in Table 3, and it also clearly states that rail transport is the best choice for mass land transportation.

Table 3: Comparison of external costs of transport modes [7]

[euro/1000 tkm]	Road transport	Railways	Inland shipping	Short sea shipping
Accidents	5.44	1.46	0	0
Noise level	2.14	3.45	0	0
Pollution emission	7.85	3.80	3	2
Greenhouse gas emissions	0.79	0.50	irrelevant	irrelevant
Infrastructure	2.45	2.90	1	< 1
Congestion costs	5.45	0.24	irrelevant	irrelevant
Summary:	**24.12**	**12.35**	around **4.0**	around **3.0**

Railway safety performance in Poland for 2018

This paragraph is based on the most relevant data for Polish railway market which are published in the latest report of Polish national safety authority – the President of Office of Rail Transport - [97]. First of all, authors focused on a primary measure for safety performance which is the number of accidents[v] to operational work for the whole railway market.

Figure 7: Value of accidents measure

2018 was the safest year since the measure is being calculated with the rate of accidents on railway lines of 2,39. That was despite increase in operational work in the market.

When analysing the accident rate, it should be pointed out that for the improvement of safety it is necessary to cooperate with all parties, both those operating the railway traffic and providing products and services for this market. The periods of disturbing the railway system during investment works and the still high level of influence of third parties on the railway have a negative impact on the level of safety. In 2018, the President of UTK carried out activities aimed at raising the awareness of both railway market entities, service and goods suppliers, but above all, people crossing the tracks in a hazardous or even unlawful manner. This was done through participation in social campaigns, organizing meetings of the Task Force on monitoring the safety level of the railway sector in Poland, promoting a safety culture, as well as stimulating railway market participants to implement solutions, often innovative, improving the level of safety in rail transport. One of the actions taken is the safety improvement program on level crossings.

Figure 8: Common Safety Targets achieved for Poland in 2013-2018

Another important aspect of safety performance are Common Safety Targets calculated in six different categories. These values are then compared to National Reference Values which are also calculated according to European regulation for each member state. These evaluated NRV levels for Poland in

respect of CST values in years 2013-2018 are shown below – Figure 8. As one can see there is a general acceptable level of all CST values, which is a desirable tendency. Unfortunately, risk towards employees is nearly at maximum acceptable level, it's mainly due to high level of infrastructure investments on the market and high level of outsourcing conducted during ground works.

As for specific values that were calculated in 2018, they are shown in Table 4. As it was said before CST 2 and 3.1 are addressed on the basis of SMS's (Safety Management System) of specific companies. CST 5 and 6 require proper attention as well.

Table 4 : Achieved CST values in 2018[3]

Common Safety Targets (CST)		NRV for Poland	CST value for Poland	NRV level
NRV risk to passengers (x 10^{-9})				
CST 1.1.	Fatalities and weighted serious injuries (FWSI) among passengers per billion train kilometres of passenger trains	116,1	16,918	14,6%
CST 1.2.	Fatalities and weighted serious injuries (FWSI) among passengers per billion passenger kilometres	0,849	0,133	15,7%
NRV risk to employees (x 10^{-9})				
CST 2.	Fatalities and weighted serious injuries (FWSI) among employees per billion train kilometres	17,2	16,7	97,1%
NRV risk to level crossing users (x 10^{-9})				
CST 3.1.	Fatalities and weighted serious injuries (FWSI) among level crossing users per billion train kilometres	277	196,064	70,8%
CST 3.2.	Fatalities and weighted serious injuries (FWSI) among passengers per billion passenger kilometres (km) multiplied by the number of level crossings	n.a.	-	-
NRV risk to others (x 10^{-9})				
CST 4.	Fatalities and seriously injured (FWSI) among other people in one billion train kilometres	11,6	0,379	3,3%
NRV risk to unauthorized persons (x 10^{-9})				
CST 5.	Fatalities and seriously injured (FWSI) among unauthorized persons in one billion train kilometres	1210	545,799	45,1%
NRV societal risk (x 10^{-9})				
CST 6.	Fatalities and seriously injured (FWSI) among all people per billion train kilometres	1590	769,493	48,4%

Another positive aspect that was identified in 2018 is the regular growth in a number of incidents per year since 2013. Of course, it is intended to have as low as a possible number of railway accidents unfortunately in the past a significant number of accidents that should have been qualified as incidents were hidden in internal categories of railway undertakings and infrastructure managers. Due to consistent "zero tolerance" policy of the President of Office of Rail Transport since 2013 and putting emphasis on effective implementation of Safety Management Systems railway, actors began to understand that there is no point in hiding incidents, even if there were less investigation and analysis to be done. The companies encouraged by the President of UTK began to implement safety culture policy and their SMS and gradually began to see the benefit of conducting an analysis of all unwanted accidents in their systems. Finally, in 2016 the number of incidents exceeded the number of accidents, which seems to be a natural course of things regarding their significance – least accidents with highest

consequences and most accidents with least consequences. As the companies need to investigate all of those accidents and incidents the most likely outcome is a continuous improvement in safety as one the main goals of each SMS is to prevent accidents and incidents from happening. It seems that the values stabilised at around 1200 incidents per year – Figure 9.

Figure 9: Number of incidents on railway lines in years 2011-2018

There were also other activities of the President of UTK that influenced safety performance i.e. supervision activities. The way was performed in 2013 shifted towards a systematic approach with stronger enforcement actions taken afterward. The other element was a change in approach towards efficiency so that each year there were more activities conducted. In 2016 there was a change in legislation and the President of UTK became responsible for supervision of railway commission (which is responsible for the investigation of every accident and incident). This resulted in additional growth due to the new scope of activities.

The other outcome of consequent supervision was the decrease in a number of found non-compliances. It seems that the railway companies began to understand the point of having their own Safety Management Systems so that they took action and did not wait for a control of a supervision body.

Analysing the change in the noncompliance indicator compared to 2017, one can notice its significant increase in the area of railway sidings. In 2018, it increased by 2.59 points, which is almost 57% difference. Based on further analyses, the President of UTK decided to include railway sidings in additional supervisory activities in the audit plan for the coming years.

Figure 10 : Areas with the largest decrease in the noncompliance's rate in 2018

The largest decrease in the noncompliance rate in 2018 compared to the previous year was recorded for the following thematic areas:

• functioning of the maintenance management system (-1.64);
• the process of transporting dangerous goods by rail (- 0.26);
• technical condition and maintenance process of railway vehicles (-0,22);
• preparation and implementation of the transport process (- 0.18).
Which also seems to be the benefit of proper understanding of companies the requirements that are set out for their management systems.

Figure 11 : Areas with the largest decrease in the noncompliance's rate in 2018

There are also general studies conducted regarding railways safety, one of them focused on the decomposition of primary causes of accidents and incidents. The study was started by Eng. D R. Wachnik during his studies and then was continued by Eng. D K. Chruzik. The latest data come from 2012 are described in [4] and shown on Figure 8. Unfortunately, more than two-thirds of railway accidents have their origin outside of the railway system – it concerns "unauthorized persons on railway tracks" and "level crossing users" which in most cases do not comply with legal restrictions and eventually not only break the law but also cause damage to the railway system.

Figure 12 : Structure of the railway accidents (number of accidents, the percentage) due to their primary reason for covering the period 2009-2012[4]

Unfortunately those studies seem to be up to date still in 2018 as nearly 80% of accidents are caused by persons from outside of the railway system.

As these two subjects unauthorized persons and level crossing user's behaviour is a remaining safety issue also the President of UTK addresses these subjects with supervision activities. These activities were described in detail in [5]. The main approach is to point out any illegal crossing to the infrastructure managers, provide technical controls on level crossing but mostly act on soft aspects like education of the youth during campaign "Railway ABC" which is dedicated towards preschools in places with the highest number of accidents on railway crossings.

Another aspect of the above-mentioned activities is encouraging infrastructure managers to upgrade their level crossing towards a B category (automatic system with barriers) which has lowest number of accidents measure, except man-operated A category. It may seem that A category is a way to go, but one must keep in mind that this measure strongly relies on the number of level crossings, and having in mind the cost of operation of A – level crossing and the possible influence of human factor, the B – level crossing seems to be the optimal choice.

Figure 13 : Accidents measure on railway crossings in years 2013-2018

The last-mentioned aspect is the impact of a human factor on railway accidents, it is most significant regarding SPAD's[vi]. Figure 14 shows the number of SPAD, regardless their qualification in the last 5 years. There has been a large increase in the number of accidents since 2014, which continued in 2018.

Figure 14: Number of SPAD's in years 2013-2018

Figure 16 shows the possible and real outcome of a SPAD, in this specific case a train driver of a freight train missed a STOP sign and entered an occupied track on which the passenger train was already running. It was impossible to avoid the collision and the passenger train was nearly entirely derailed – fortunately, no one was killed or seriously injured. It was one of a couple of similar accidents in 2017 and it clearly shows that even the slightest mistake regarding train operation can result in a catastrophe. This subject needs to be properly analysed as for now it seems that the corrective measures that are applied are ineffective. It is possible that a proper analysis of human factor involvement is a necessity.

Figure 16 : Example of outcome after a SPAD [10]

Accident risk is expressed as the number of outcomes per exposure. Considering all railway fatalities (excluding suicides), the fatality risk per million train-kilometres in the 2011-2015 period was 0.27 fatalities per million train-kilometres in the EU Member States. The figure for 2015 alone is lower at 0.23 fatalities per million train-kilometres. Values of risk vary greatly between Member States, with a more than 30-fold difference between Member State safety outcomes. The distribution of Member States' accident risk, expressed as the fatality risk per million train-kilometres over the 5 years from 2011 to 2015, is shown in Figure 17.

Figure 17: Railway accident fatality risk on EU railways: fatalities per million train-kilometres (2011-2015)

Personal risk for railway passengers can be expressed in terms of passenger fatalities per passenger-kilometre. For the EU-28 over the 5 years from 2011 to 2015 and 2015 alone, the fatality risk range was between 0 and 0.085 fatalities per 100 billion passenger-kilometres respectively. Figure 18 maps the passenger fatality risk over the 5 years from 2011 to 2015 by Member State.

Figure 18 : Map of personal risk on railways: passenger fatalities per 100 billion passenger-kilometres (EU-28, Norway and Switzerland; 2011-2015)

A positive point that can be taken from Figure 19 is the fall in the numbers of unauthorised persons being killed. In the past 5 years there has been a reduction from 804 (2011) to 591 (2015), a fall of 26 %. Whether or not they are 'railway caused', these accidents are a source of appalling personal tragedy, including the impact on railway staff, along with significant delays and unnecessary costs for the rail system as a whole.

In recent years we have considered the use of different methods to normalise suicide fatality statistics, for example by using the correlation with national overall suicide rates, the availability of the railway to the public expressed by total train-kilometres or traffic density. Figure 12b on the following page shows the comparative analyses of suicides/million train-kilometres for 2015, the three 5-year means for 2015-2011, 2014-2010 and 2013-2009 and the 10-year mean for 2015-2006.

Figure 19: All railway fatalities and suicide fatalities on railways (EU-28, Norway and Switzerland; 2011-2015)

Summary

In comparison, railways are the safest mode of land transport, not only regarding pure safety performance indicators but also considering external costs to society and a member state.

As for Polish railways, the year 2018 was the safest since 2008 even despite the growth of the railway market.

There are still elements that need to be taken care of, such as continuous improvement of safety culture so that there can be a consistency in safety statistics and improvement of total safety performance. Another significant element is the analysis of human factor with the involvement of professionals in the area of human performance, since it seems that current corrective activities are insufficient.

Authors would like to summarise this short paragraph concerning railway safety performance that, undoubtedly railways are the mass transport mode to choose, as far as the safety of travel is concerned.

[i] Railway events in this article are understood as serious accidents, accidents, and incidents under the Polish national law.
[ii] Source of data: Passenger kilometre data taken from the EU transport in figures (Statistical Pocketbook 2014, DG MOVE 2014, European Commission). Airline passenger fatalities over EU-28 territory by any operators (Annual Safety Review 2014, EASA), Bus/occupant fatalities estimated from available data in CARE database (European Commission), Vessels passenger fatalities as reported by EU and EFTA MS as per Directive 2009/18/EC for years 2011-2014 (EMSA, 2016)
[iii] Measure was calculated on data from [2][3] and data from Central Statistical Office of Poland (www.stat.gov.pl)
[iv] Average for the latest three years for which both the road deaths and the estimated data on distance travelled are available. 2013-2015 (HR, LV, SE, CH), 2012-2014 (AT, SE, DK, FI, FR, IE, NL, PT, UK, IL, NO), 2011-2013 (BE, PL), 2014-2015 (MT). *Provisional figures for road deaths in 2015. **Road deaths per billion vehicle-km travelled by cars only.
[v] Accident is considered a railway event which results in negative measurable consequences regarding people, environment or generally expressed in cost (above 3,000 euro).
[vi] Signal Passed at Hazard (SPAD) means any occasion when any part of a train proceeds beyond its authorized movement and travels beyond the hazard point. Hazard point is a point at which the train will be in a hazard of an accident (collision, level-crossing accident, accident to a person caused by rolling stock in motion or derailment). It is usually defined in the specifications of the Train Protection System.

Public Procurement Performance: Criteria and Indicators for Ukraine

Abstract

Transparent and efficient public procurement is the basis of financial security, economic growth and social stability in the country. The main purpose of the article is to analyze the performance indicators of public procurement in Ukraine and determine the ways of their improvement. The authors used the method of generalization and systematization (to identify three groups of factors affecting public procurement efficiency), expert survey (to set the limits of indicators and determine the level of customer satisfaction with the choice of winning suppliers through an electronic system ProZorro), statistical analysis (to calculate indicators) and other methods. The effectiveness of public procurement affects the quality of public services and is based on three main factors: accessibility of the public procurement market; quality of organization of procurement activity and quality of performance of the contract. The authors proposed 12 criteria of public procurement performance and substantiated the methodology for their evaluation. An analysis of public procurement performance in Ukraine showed that during 2016-2019, the level of public procurement performance was consistently low, namely the high proportion of unsuccessful procurement, the low level of competition, the increase in the share of contracts being cancelled and contracts to reduce procurement volumes due to lack of financing. The study identified the main problems faced by customers in the procurement activity.

Keywords: public procurement, KPI, transparency, contract performance

JEL Classification: H57, M 48

Introduction

The legislation of Ukraine contains the principles of public procurement, the main ones are to ensure their maximum cost-effectiveness, the impartiality of evaluation and transparency. Public procurement will be able to meet established principles using key criteria and methods for evaluating In Ukraine, for example, this is a problem for the government (Tkachenko, 2016). In 2018, the Ministry of Economic Development and Trade of Ukraine (regulator in the field of public procurement) presented an annual report, which mentioned the efficiency of the procurement area. As positive indicators, the Ministry showed the dynamics of growth in the number and cost of completed purchases, the number

of participants and customers in the ProZorro system. Low levels of competition and a significant proportion of direct contracts without competitive procurement were noted as negative indicators (over 72%). This requires preventive control and further automation of the procurement process (Ministry of Economic Development and Trade of Ukraine Report, 2019). At the same time, the Accounting Chamber of Ukraine, in its conclusions from the analysis of the Ministry's report, noted that the indicators presented in the Ministry's Report do not characterize the efficiency of public procurement (Accounting Chamber Report, 2019). Lack of public procurement performance criteria and methodology for performance evaluation does not allow for an objective assessment. That is why the conclusions of the Accounting Chamber (the body of financial and budgetary control established by the Verkhovna Rada of Ukraine) and the Ministry for Development of Economy, Trade and Agricuture of Ukraine (the authorized body that regulates and implements public procurement policy) differ significantly in the results of the evaluation of public procurement effectiveness in Ukraine.

Literature Review

Public procurement is part of public spending that can ensure the sound management of public finances while performing various functions of the state, aimed at ensuring the sustainable welfare of the population. The economic effect of public procurement is the result of the impact of the Government's strategic objectives on health, education, the environment, and social protection (Tkachenko, 2016). In Ukraine, about 20% of public spending is spent on public procurement (17% on the use of goods and services and 3% on capital expenditures).

Public procurement in research is linked to the impact on the economic growth of the country. Kukhta P. & Piontkivska I. (2015) believe that public spending is not the only determinant of economic growth and cited Sweden as an example, where declining public spending has led to economic growth through high levels of government efficiency, regulatory quality and control of corruption.

According to the calculations of the multiplier of public spending, Dehtyar N., Boyarko I., Deineka O. (2013) identified two cluster groups in studies of the impact of public spending on economic growth in the EU and Ukraine: Group I - the countries with a positive impact of public spending on economic growth (Greece (1.850), United Kingdom (1.819), France (1.751); Group II - the countries with lack of effect of public spending on economic growth (Luxembourg (0.518), Malta (0.862) and Ireland (0.872)).

Piontkivska I. (2016) noted that significant budget savings can be achieved through public spending reform on a “do more, spend less” principle, and identified expenditures where the greatest savings can be achieved, including increasing public procurement transparency.

According to the World Bank report, Ukraine is in the top twenty in terms of government spending and in the last quarter in the quality of government. That is why researchers justify the need to reduce government spending (Dubrovsky, 2018).

The European Commission, as the supreme executive body of the European Union, links the role of public procurement to the quality of public services, the high level of which depends on the efficiency of procurement, as reflected in the European Commission's Procurement Strategy «Making Public Procurement work in and for Europe» (2017). The European public procurement performance experience is based on the OECD / SIGMA methodology of the Organization for Economic Cooperation and Development, the World Bank (Methodology for Assessing Procurement Systems), the European Bank for Reconstruction and Development (EBRD). For evaluation of efficiency, the expert evaluation is applied in three directions: 1) national legislation in the field of public procurement; 2) public procurement practices; 3) verification and facilities of legal protection. Overall rating is determined by the level of compliance: very high compliance (above 90%); high compliance (76-90%); average compliance rate (60-75%); low compliance (50-59%); very low compliance (below 50%).

Bhagat G. (2017) proved the need for optimization the efficiency of procurement. Costantino N., Dotoli M., Falagario M. & Sciancalepore F. (2012) argue for the importance of such public procurement

characteristics as competition, prescribed procedures, and transparency. Patrucco A., Luzzini D. & Ronchi S. (2016) suggested cost, quality, time, compliance, innovation and sustainability as indicators of public procurement performance. The authors of the study argue that public procurement performance will be ensured when the procurement function is recognized as strategic in government. Rizzo I. (2013) relates public procurement effectiveness to the level of corruption, competition and speed of the procurement process. Panda P., Sahu G. & Gupta P. (2010) believe that digitizing all stages of public procurement can ensure their effectiveness. Janke F. & Packova M. (2016) noted that electronic reverse auctions have become popular as a public procurement mechanism, and they are the ones that provide efficiency through competition and the ability to reduce the price during rounds. Milosavljevic M., Dobrota M. & Milanovic N. (2018) consider that the biggest problem with evaluating public procurement performance is the definition of criteria that are prone to systematic error and numerous omissions.

Tas B. (2012, 2017) conducted empirical research and substantiated the impact of the optimal number of bidders on the procurement price of different types of products. Chever L. & Moore J. (2013) compared standard open auctions and open auctions with a supplementary negotiation phase and non-formalized procedures. Decarolis F. (2018) also explored types of auction formats and factors limiting the scope for strategic bidder defaults. Nunes A. & Velame I. (2016) analyzed indicators of cost-effectiveness and time efficiency in public procurement. Thus, in today's scientific environment, an understanding of the importance of transparent and efficient public procurement has emerged as it is capable of providing financial security (Khovrak & Petchenko, 2015; Finogenova et al. 2018; Tsintsadze et al., 2019), economic growth (Dehtyar, et al., 2013; Kaigorodova et al., 2018), development of social responsibility (Kaigorodova et al, 2017; Khoma et. al., 2018; Koziuk et. al., 2019; Trynchuk et. al., 2019; Trunina & Khovrak, 2019; Glonti et. al., 2020) and reduce the risks (Merlo et. al., 2013; Achkasova, 2017; Klapkiv et al., 2017; Pyrkova et al., 2018; Aroshidze, et al., 2019).. This is important for both public and commercial procurement (Wozniak, 2018), (Zimon et al., 2019).

Hypotheses

The effectiveness of public procurement affects the quality of public services and is based on three main factors: accessibility of the public procurement market; quality of organization of procurement activity and quality of performance of the contract.

Methodology and Data

In worldwide practice, key performance indicators (KPIs) are widely used as a tool to measure goals. The KPI formulation process is reflected in ISO 9001: 2015, which defines performance as the degree of achievement of planned results (the ability to navigate results) and efficiency - the ratio between the results achieved and the resources expended.

First of all, it is necessary to separate cost savings, performance and cost-effectiveness (fig. 1), since in the scientific literature these concepts are the same. But this is not correct.

Fig. 1: KPI for measuring public procurement

Thus, performance indicators are the accessibility of the public procurement market; organization of procurement activities and performance of the contract. In order to determine what factors lead to procurement performance, the categories were divided into quantifiable subcategories. As a result, we obtained 12 criteria, the method of calculation of which is described in table 1.

Table 1: Criteria and methodology for evaluating public procurement performance

№	Criteria	Calculation formula	Justification of the criterion
The accessibility of the public procurement market			
1	The proportion of procurement participants to all economic entities in the country, %	The number of entities of the large, medium, small, microenterprises in Ukraine participating in procurement for the year * 100 / The number of entities of the large, medium, small and microenterprises in Ukraine per year.	It is an indicator of the level of awareness, interest and confidence of the business in the field of public procurement. It affects the level of competition in competitive procurement procedures and the amount of cost savings due to the competition factor.
2	Percentage of participants-subjects of medium, small and micro-enterprises in public procurement, %	The number of entities of the medium, small, microenterprises in Ukraine that are involved in the procurement for the year * 100 / The number of entities of the large, medium, small, microenterprises in Ukraine that are involved in the procurement during the year.	Indicates the availability of small and medium-sized businesses in the field of public procurement.
Quality of organization of procurement activity			
3	Share of unsuccessful purchases by quantity, %	(The number of cancelled procurements annually for the year + The number of procurements that did not occur in the year) * 100 / The number of announced procedures per year.	Negatively affects the performance of public procurement of the organization (institution, enterprise).

4	The share of unsuccessful purchases by value, %	(Estimated cost of cancelled purchases for the year + Estimated cost of purchases that have not occurred in a year) * 100 / Estimated cost of announced procedures for the year.	Reduces the economic efficiency of public procurement of an organization (institution, enterprise).
5	Percentage of unsuccessful competitive boundary* procurement procedures by quantity, %	The number of competitive boundary procedures completed per year * 100 / The number of competitive boundary procedures announced per year.	Negatively affects the efficiency of the auction as a mechanism of public procurement.
6	Percentage of unsuccessful competitive boundary procurement procedures by value, %	(Expected cost of cancelled competitive boundary procedures for the year + Expected cost of competitive boundary procedures that did not occur in the year) * 100 / Expected cost of competitive boundary procedures announced for the year.	Reduces the economic efficiency of the auction as a mechanism for public procurement.
7	Percentage of non-competitive boundary procurement procedures,%	(Estimated cost of the negotiated procedure for the year + Estimated cost of the negotiated procedure for the urgent need for the year) * 100 / Estimated cost of competitive boundary procedures for the year.	There is a risk of a negative effect - collusion and rising prices. One of the indicators for the implementation of the Sustainable Development Strategy "Ukraine 2020" is the limit of the share of non-competitive purchases in the total volume of procurement not more than 30% (Decree of the President of Ukraine «On Sustainable Development Strategy« Ukraine - 2020» of 12.01.2015 No. 5/2015).
8	The average number of participants in competitive boundary procurement procedures	The number of tenderers participating in competitive boundary procedures (lots) / The number of competitive boundary procedures.	A high level (4 or more participants) ensures the effectiveness of the auction mechanism in procurement.
9	The proportion of purchases in which the winner is selected only by price criterion, %	The number of competitive procedures and lots with non-price selection criteria for the winner per year * 100 / The number of competitive procedures and lots per year.	Allows choosing an economically advantageous offer from suppliers on the principle of "better quality at a lower price".
Quality of contract performance			
10	Share of terminated contracts by quantity, %	The number of contracts terminated per year * 100 / The number of current contracts per year.	Affects the degree of satisfaction of public and state needs.
11	Share of terminated contracts by value, %	Cost of terminated contracts for the year * 100 / Cost of current contracts for the year.	Affects the cost-effectiveness of public procurement.

12	Share of current contracts with changes in price and volume of purchase, %	The number of current contracts that changed the price and volume of purchase for the year * 100 / The number of original current contracts.	Affects the effectiveness of the public procurement financing mechanism.

Public procurement performance is measured at two levels:
1 – national (1-12);
2 – customer (3-12).

Table 2 shows the results of the analysis of public procurement performance criteria at the national level. Public procurement performance assessments required the establishment of indicators by each criterion, which was identified through the involvement of experts.

The Ukrainian ProZorro system is considered the best reform in Ukraine and transparent at all stages of public procurement. The main achievements of the system are:

- A significant reduction in transaction costs by replacing paper purchases with electronic ones;
- Access to open data through the Public Procurement Analytics module, which enables effective control over the spending of taxpayers' funds;
- Introduction of automatic indicators of a violation of the law in the field of public procurement for the implementation of public financial control;
- The professionalisation of the public procurement field started due to the gradual rejection of the tender committee.

The main problems of purchasing activity are:

- The orientation of the customers not on the result of improving the quality of public services, but on the use of budget funds and compliance of the procurement procedure with the law;
- The main indicator of public procurement effectiveness is the cost savings, the value of which is calculated as the difference between the expected value of the tender and the lowest bidder's bid price, which is unjustified in complex procurement (construction work). Procurement with contracts terminated was made with a saving of 1.4 billion UAH, which is 4.4% of the total cost savings;

Table 2: Public Procurement Performance Indicators in Ukraine

Criteria	2016	2017	2018	2019	Indicator
The proportion of procurement participants to all economic entities in the country, %	3,53	7,07	8,05	-	≥ 10%
Percentage of participants-subjects of medium, small and micro-enterprises in public procurement, %	-	-	-	96,5	≥ 50%
Share of unsuccessful purchases by quantity, %	23,7	14,7	13,2	9,4	≤ 10%
The share of unsuccessful purchases by value, %	34,9	30,3	33,2	32,9	≤ 10%
Percentage of unsuccessful competitive boundary* procurement procedures by quantity, %	52,6	47,6	50,5	43,6	≤ 10%
Percentage of unsuccessful competitive boundary procurement procedures by value, %	49,8	39,1	44,1	43,2	≤ 10%
Percentage of non-competitive boundary procurement procedures,%	18,8	16,1	14,7	15,2	≤ 10%
The average number of participants in competitive boundary procurement procedures	2,86	2,68	2,67	2,76	≥ 4
The proportion of purchases in which the winner is selected only by price criterion, %	-	-	-	0,8	≥ 10%
Share of terminated contracts by quantity, %	5,0	7,0	7,0	7,0	≤ 10%
Share of terminated contracts by value, %	9,0	12,0	5,0	14,0	≤ 10%

Share of current contracts with changes in price and volume of purchase, %	15,0	31,0	20,0	44,0	≤ 10%

** according to the Law on Public Procurement, boundary procurement procedures are purchases of goods and services with an expected value of 200 thousand UAH (approximately 7 thousand EUR), works - 1 million UAH (approximately 36 thousand EUR). The share of unsuccessful purchases (criteria 3, 4) include canceled procurements and purchases that have not taken place and does not include terminated contracts (criteria 10, 11).*

- Low competition and a high proportion of unsuccessful purchases. The Public Procurement Law of Ukraine establishes a boundary procurement requirement for a minimum number of participants (at least two), otherwise, the tender is cancelled. Given the low level of competition, the participants informally agree to simulate the tender to obtain a contract that is not in competition. In such circumstances, both the players and their tender prices are known;

- Customer dissatisfaction with the performance of contracts by the winning tenderers.

The results of the study showed that in general public procurement in Ukraine is ineffective.

The focus of public procurement reform solely on the fight against corruption has led to ineffective control of public procurement by public financial control authorities over the identification of unjustified needs, inflated purchase prices, unjustified rejection of the bidder's best offer for formal reasons, rejection of bidding. This was the result of the imperfection of national legislation. According to the results of an electronic survey of procurement participants on the impact of corruption, it turned out that more than 24.2% of respondents have experienced corruption in procurement, but noted that corruption has decreased; 89% of respondents experienced dumping by competitors (ProZorro, 2020).

We conducted interviews with customers who were trained in the Public Procurement Program at the Kyiv National University of Trade and Economics during September-October 2019. The questionnaire contained two questions: 1. How do you assess the level of satisfaction with the choice of the winning suppliers through an electronic system at the stage of contract performance? 2. What is the main reason for dissatisfaction with the winning suppliers?). 65 interviewees from 33 bidding organizations participated in the interview. According to the research, more than 60% of customers are dissatisfied with suppliers (Fig. 2).

Fig. 2: Distribution of respondents' answers regarding the degree of customer satisfaction with the choice of winning suppliers through an electronic system ProZorro, %

Customers note the fact that bidders are dumping at the auction, knowing that they will not be able to fulfil the terms of the contract. That is why the scheme of making amendments to the signed agreements is quite common in Ukraine. So, after signing the contract with the supplier-winner received a certificate from the Chamber of Commerce and Industry of the actual price requires the customer to make a change to the contract. This is most often done by raising the price per unit and reducing the number of goods. Under these conditions, the contract value does not change. These circumstances force the customer to agree to change the conditions because the customer does not want to start a new tender procedure. Therefore, the effectiveness of public procurement should focus more on the quality of contract performance.

Results and conclusion

The results of the study show that the criteria for the effectiveness of public procurement, the measurement of which is available in the module of analytics of the electronic system ProZorro (2020), are the proportion of procurement participants to all economic entities in the country; share of unsuccessful purchases; share of non-competitive purchases; the average number of participants in the tender; share of contested purchases in favour of the complainant; share of terminated contracts; share of current contracts with changes in the price and volume of purchase.

An analysis of public procurement performance in Ukraine showed that during 2016-2019, the level of public procurement performance was consistently low, namely the high proportion of unsuccessful procurement, the low level of competition, the increase in the share of contracts being cancelled and contracts to reduce procurement volumes due to lack of financing.

Discussion

Increasing the efficiency of public procurement will enable new procurement methods, such as electronic catalogue procurement, joint (centralized) procurement, and the implementation of a life-cycle costing criterion. Also, it is important to use the voluntary certification of reliable suppliers to confirm the level of qualification (including financial and economic status) can significantly improve the quality of contract performance. Priority objectives of regulatory policy should be the adoption of appropriate regulations on the use of "green" procurement, the development of functional and "green" specifications and life cycle cost calculator.

Photovoltaics as A Tool for Managing Household Finances

Mariusz Chudzicki

Czestochowa University of Technology, Częstochowa, Poland
mariusz.chudzicki@pcz.pl

Abstract

This article attempts to assess alternative ways of investing financial surplus by households. One way to increase household income is to invest surpluses in photovoltaic cells. The methods of assessment of investment projects showed a higher profitability of such investment in relation to financial instruments with low risk and income. Despite the positive results of the investment analysis of the project, one should remember about the limitations in this type of surplus investment by the household, which is also presented in this study.

Keywords: photovoltaic installation, household, finance, investments.

Introduction

Currently, in Poland and throughout Europe, we are dealing with the phenomenon of low interest rates. Historically, they are at the lowest level in almost 30 years. On the one hand, this means a relatively low cost of capital for borrowers, on the other, very low income from low-risk financial instruments. The exceptional stability of interest rates in Poland should also be emphasized, as the main rates of the central bank have not changed for 5 years. This tendency will probably continue for many years. This article attempts to assess alternative ways of investing financial surpluses by households in the context of low interest rates on financial market instruments such as bank deposits, bonds and low risk funds. Nominal income from such investments is at most 3 percent, and it should be taken into account that this negligible income is still taxed at a rate of 19 percent, which further aggravates their low attractiveness. The increase in inflation in 2019 caused a further decline in real rates to negative values. A way that can increase household income is to invest their surpluses in photovoltaic micro installations, the profitability of which is presented in this study.

Household as An Entity of The Financial Market

The household sector is heterogeneous, which then leads to different divisions and classifications of households, and to problems in comparative analysis (Hoffmeyer-Zlotnik, Warner 2009, p. 1-26). Not only in Poland but also in the world, scientists are trying to emphasize the importance of household finances (Campbell 2006, p. 1553–1604).

Household finances cover the most numerous group of market stakeholders. Based on the assumption that, according to the classification of the European Central Bank as well as the National Bank of Poland, households are divided into: private individuals, individual entrepreneurs and individual farmers, household finances can also be classified according to this scheme as: personal finances, finances of individual entrepreneurs and individual farmers. Household finance as a scientific subdiscipline includes the study of theoretical phenomena and relationships. It should be noted, however, that it has broad practical application in economic reality. The subject of interest in household finances is extremely extensive, as it relates to: savings, investing, credit, spending (consumption), insurance, taxes, income, pensions, wealth, etc. (Świecka, Musiał 2016, p. 823).

The household is an active participant in the market. The market in economics is understood as an institution enabling transactions between producers and consumers. The market can be divided, taking into account the household, among others into the labor market, goods and services and the financial market (Podolec, Ulman, Wałęga 2008, p. 15-16).

Some households have a surplus of free cash and often decide to invest them hoping for greater profit. Such transactions are carried out on the financial market and are concluded between capital providers and borrowers.

In literature, the financial market is defined in a broad and narrow sense. In a broader sense, the structure of the financial market includes not only money-related activities, their flow but also economic activities based on money trading. In the narrower sense, the financial market contains decisions related to cash, whose task is to protect the value of money held or its increase in future periods. Financial markets enable the creation over time of investment and consumption structures in economic entities and increase the efficiency of resource use in the economy. Financial markets enable investors to diversify the portfolio of assets held, thus limiting the risk of investment, they also provide financial information about business entities in the form of financial statements, especially for listed companies. (Szrama 2010, p. 8-9).

Modern financial markets are very complex, consisting of many different entities issuing and purchasing financial instruments and brokers of trading, as well as modern technical means enabling transactions. Financial markets can be classified according to various criteria, three classifications are of primary importance. The financial goods market can be divided into: money and capital. The first of them lasts only for one year, the market's entity are securities and deposits. In turn, the capital market is based on making long-term transactions such as the purchase of shares or bonds. Households can participate in both markets, primarily as entities depositing financial surpluses. The amount of assets collected in the form of financial instruments by a household is influenced by factors such as (Świecka 2008, p. 28):

– financial tradition and culture,
– level of financial market development,
– at least average propensity to save.

The amount of savings depends on the profitability and efficiency of the household. Namely, this relationship consists in dividing the obtained income into current consumption and savings goals. Increasing monetary resources for consumption causes a decrease in savings and vice versa. In income management, therefore, a so-called "golden mean" should be found that allows shaping the balance between the expenditure and saving sphere of the household. Saving can be voluntary or forced. Voluntary saving consists in voluntary resignation from spending income for consumption purposes. On the other hand, forced saving consists in allocating part of your income to repay e.g. a bank loan (Bywalec 2009, p. 163).

There are six types of saving strategies. The first strategy is a low risk strategy. Households with savings in the form of bonds use this type of strategy. This strategy is used by households with the following socioeconomic and demographic characteristics (Anioła, Gałaś 2013 p. 1-11):

– households of pensioners,
– households whose place of residence is a city,
– educated members of the household are medium or higher,
– households with health problems or disabilities,
– farms with average or higher income.

Another austerity strategy is the so-called conservative strategy. Over half of households in Poland using this strategy, investing all their savings in the form of PLN deposits. Households using this type of strategy are characterized by a lack of cash savings. The conservative type of strategy is characterized by a low saving rate. This strategy is used by households in which:

– members are middle and older,
– farms embedded both in the city and in the countryside,
– households with an average level of income.

The third type of strategy is extremely passive. About 25% of households in Poland use this type of strategy. Households have 100% of their savings in cash. The passive savings strategy is characterized by a very low savings rate. Households using a passive saving strategy use loans and borrowings, however, the value of their debt does not exceed their monthly income. Farms of this type show that they have difficulty making ends meet. This strategy is used by middle-aged households who live in the countryside and are often run by widowers. The fourth type is an extremely conservative strategy. It is used by households that invest their savings in bank deposits and in cash. This strategy is characterized by an average saving rate. Households using this type of strategy are characterized by income stability and thus have no problems with making ends meet. Only one in four households using this strategy must use loans. The extremely conservative strategy is used by households in which members of households are older and middle-aged, the location of households is both the city and the village and the income is obtained from hired work.

The next strategy is a diversification strategy. This type of strategy is used by the smallest number of households, only 0.4%. The type of saving is characterized by a variety of forms of saving and the lowest saving rate. Households using a diversification strategy very rarely use loans. Nevertheless, if they already contract them, the value of this debt is high, usually exceeding their annual income. This strategy is used by households with the following socioeconomic and demographic characteristics:

- low age of household members,
- farms where the head of the family is a man,
- households located in large cities,
- households with minor health problems,
- household members have a secondary or higher education,
- income is earned from hired work or from running your own business.

The last sixth saving strategy is aggressive. About 1.6% of households that are not afraid to take risks use this type of strategy. Farms using this strategy show the highest level of debt exceeding their annual income. This strategy is used by households in which (Anioła, Gałaś 2012 p. 1-11):

- low age of household members,
- high level of education of household members,
- households whose members are single,
- earned income is higher than average,
- households have a low level of disability.

In households, the conservative strategy is the most important and extremely passive based on saving in the form of bank deposits and / or cash. In Poland, households most often use banking services, placing their money in the form of deposits secured by the Bank Guarantee Fund. In contrast, in countries such as the USA, Great Britain, a significant proportion of household funds is allocated to pension funds (Czapiński, Panek 2014 p. 87-92).

In 2018 in Poland, there was an increase in real average monthly total disposable income per person - by 4.3% (in 2017 an increase of 6.3%). This applied to all socioeconomic groups of households, except for households of farmers, in which income in nominal terms remained almost at the same level as in 2017, and in real terms fell by 1.5%. The highest real increase in income was recorded in households of retirees (by 4.4%) and employed persons (by 4.2%). The real decrease in disposable income in the group of farmers' households was mainly due to the real decrease in income from an individual farm compared to 2017 (by 5.3%). The highest share of income from the main source of income was recorded in the households of pensioners (82.7%), and the lowest in the households of farmers (66.6%) (www.stat.gov.pl).

Fig. 1: Structure of average monthly disposable income per capita in households in total in 2018

Source: own study based on www stat.gov.pl.

The average net assets of a household in Poland amounted to 60.6 thousand euros accounted for approx. 58% of the median net assets of a household in the euro area (104.1 thousand euros), the vast majority of households own the main residence (79.2%) and motor vehicles (65.8%). Much less often, respondents declared valuable items (29.4%), other real estate (24.3%) or business property (20.4%) as components of their property. Financial assets have 90.8% of households, with bank deposits being the most popular form of raising funds (84.9% of households), although the average value of assets accumulated in this form is relatively small (about EUR 3 thousand) (www.nbp.pl).

Development of photovoltaic installations in Poland

The solar sector in the country is developing very dynamically, in 2019. increased to 1300 MW, which means a dozen or so growth in recent years. Despite such a large increase in installed power from solar farms, this technology still has great potential for development, especially when compared with other available energy sources. Most investments operate in the Podkarpackie, Śląskie and Kujawsko-Pomorskie voivodeships.

Photovoltaic panels operate on the principle of a photovoltaic effect, for which light is needed, so even on cloudy days photovoltaic works well with electricity production. However, the highest efficiency is achieved in sunny weather, which we have relatively many in Poland, which translates into an average energy yield of 950 kWh per year from one kilowatt solar cell power (about 6 m2). To cover the annual average electricity demand of an average Polish family, it is enough to cover 18m2 of roof with photovoltaic panels. According to the Central Statistical Office, the average energy consumption per person in Poland in 2018 ranged from 824.3 kWh to 904.5 kWh. (www.stat.gov.pl). The small solar plant consists of photovoltaic panels, inverter, cabling and assembly system. The cost of devices is the largest component of the installation price. Comparing these costs to the price of other devices in the home or business, such as central heating furnaces, heat pumps, home sewage treatment plants or interior furnishings, the expenditure on photovoltaic installations is not at all greater. Branded devices that make up the solar power plant have a long warranty. It is at least 10 years for panels and 5 years for inverters. The service life of the devices is also very long, for good solar modules it can reach up to 30 years. In addition, the expense associated with the launch of solar micro-installations begins to pay off immediately, resulting in a significant reduction in electricity bills.

Fig. 2: Production of energy from the 4.32 Wp - 4701 kWh installation

Source: own research.

The legislator, wanting to encourage the installation of photovoltaics, allowed the storage of surplus energy in the network in the summer and collection them in the winter months in order to compensate for slightly worse results of electricity production in the winter. Thanks to this, we can balance our energy demand with production from solar farms throughout the year and reduce electricity bills to subscriptions and fixed fees. Figure 2 shows the distribution of energy production from 4,32 kW installations. Three years of research indicate that the distribution of energy production varies from month to month, however, annual production is very similar. The solar installation on the roof or ground is practically maintenance-free. Branded solar inverters themselves inform about faults, therefore there is no need for continuous personal monitoring of the installation status. Inverters connected to the internet can send information about the failure directly to the service technician so that in the event of a failure he can react quickly and resume the production of free energy. The legislator imposed on power plants an obligation to connect microinstallations with a capacity of up to 40 kW. He also ordered the operator to cover related costs, such as replacing the meter with bidirectional. The requirements for devices and installers are strictly defined in the Act and after their fulfillment and submission of complete documentation, the energy operator has 30 days to connect microinstallations. Prosumer's introduction of energy into the grid is also beneficial for operators for several reasons. They can sell energy from a photovoltaic installation to their nearest customer saving on transfer from a remote power plant. Poland must also comply with international obligations regarding the share of renewable energy in total electricity production. It is also worth paying attention to the fact that the greatest demand for electricity, which is in the summer, occurs during the period of the highest productivity of photovoltaic installations, which will relieve conventional power plants overloaded during this period and reduce the possible need to import electricity.

Cost-Effectiveness of A Photovoltaic Installation

The cost of investing in a photovoltaic system is related to the total power of photovoltaic cells and the place where the installation will be built. Small photovoltaic installations, up to 10 kW, are located on the roofs of buildings. Systems with power above 10 kW are usually mounted on the ground with the help of support structures. Expenses related to the preparation of the installation project are incurred first and represent a small percentage of the entire investment (Fig. 3). As a rule, however, especially for the smallest installations, the project is carried out for free by the contractor, but probably its cost is included in the total cost of installation.

Over 2/3 of expenditure is the purchase of devices with all electrical equipment. The inverter, ensuring the change of the parameters of the current flowing from the panels to those required for home receivers (alternating, 230 V, 50 Hz), costs several thousand zlotys, while other small accessories such as

mounting constructions, cables and assembly - another several thousand. The average unit costs for small installations below 10 kW, assumed on the roofs of buildings, are in the range from 4000 to 5000 PLN / kWp (EUR 930 to 1370). Roof installations are cheaper due to a lower VAT rate of 8% against 23% for ground installations. The total power of electric receivers, together with household appliances and lighting (without electric heating), may exceed 30 kW. Building an installation that satisfies at least half of this power will be expensive and will take up a lot of space. At the same time, it is rare that most of them operate simultaneously, so it is recommended that the peak power of the solar installation for a single-family house should not exceed 5 kW. A system with this power will occupy approx. 33 m2 of roof.

Fig. 3: Expenses related to the solar system

Source: own research.

In the analyzed photovoltaic investment, implemented in the Częstochowa poviat, 16 Sharp panels with 270 Wp capacity were installed. Total installation has a power of 4.32 kWp. The installation includes a 4 kW FRONIUS single phase inverter. The unit cost of the installation was 4.4 thousand. PLN/kWp, the total value of investment outlays is 19 thousand PLN (EUR 4420). Thanks to the 4.32 kW photovoltaic installation, savings with the highest efficiency of the system is PLN 1,800 per year. The final value of the project was omitted in the calculations due to its negligible value. Investment flows also include expenditure on repairing the installation in the middle of the investment's operation. According to producers, the life span of photovoltaic cells is estimated at 30 years and this was the life span of the project used in the analysis. It is worth adding that many products available on the market have a warranty of 25 years, at least 80% of the output power obtained from photovoltaic cells.

Fig. 4: Example relationship between the output power of a solar panel and the length of service life in years

Source: own research.

Figure 4 shows an example of the dependence of the photovoltaic panel output power on its years of use. As you can see, the decrease in power over time is a linear (decreasing) function. This is also the way the system efficiency was adopted in further analysis. From the observations and tests of the photovoltaic installation carried out over the last 3 years, it was not found that such a large decrease in power could improve the efficiency of the installation.

Table 1 presents the results of research on the profitability of solar farms. The discount rate was adopted as the average interest rate on 12-month deposits from five banks that offered the best terms according to the banks' offers at the end of 2017. The net present value (NPV) of the investment is positive, which means that it is more beneficial to implement such an investment than, for example, investing cash in a bank deposit bearing an interest rate of 2%. Internal rate of return (IRR) indicates the profitability of the project in the amount of 7.54 percent, however, one should remember about the limitations of this method, because it assumes reinvesting surpluses according to the obtained rate of return, which in this case will not be possible. The payback periods of the investment under consideration are long and amount to 11 years and almost 14 years for the discounted version of this method.

Table 1: Solar plant profitability test

Year	**2017**	**2018**	**2019**	**2020**		**2044**	**2045**	**2046**	**2047**
Investment outlays	-19000

.

The analysis of these two investment options indicates that in the case of obtaining a subsidy for investments from public funds, the superiority of solar photovoltaic installations against financial investments is indisputable. However, in the absence of such a subsidy, making a photovoltaic investment is no longer so obvious, despite positive financial indicators mainly due to payback periods. This means that the funds will be tied up for a very long period without the possibility of early withdrawal, as practically all financial investments allow.

In order to broaden the research covering investment analysis, surveys were conducted in 2019. The study covered residents of small towns with single-family houses. The research was carried out in two voivodships: Śląskie and Łódzkie. The research shows:

- 94 percent of surveyed households are willing to make a solar investment.
- Usually, the minimum expected return period was 4-5 years.
- Older people are less willing (over 60 years) to undertake such investments, they also expect a shorter payback period.
- All respondents pointed to the need for co-financing from such programs by government programs.
- Only 8% of respondents indicated the possibility of carrying out such an investment without public aid.
- 43 per cent of respondents indicated the possibility of using investments in a solar installation as a way to increase household income.
- 13 per cent of respondents indicated the possibility of using solar investments instead of investing in bank deposits. Such a low result is probably the effect of limited cash resources in Polish households.

Research also carried out among persons who already have such installations. Their implementation allowed to draw the following conclusions:

- The majority are satisfied with having such an installation.
- Respondents point to an increase in electricity consumption at the expense of other energy sources.
- If there were government programs, they would be willing to expand their installations, reducing the consumption of conventional energy sources.
- The biggest limitation in the expansion of renewable energy is the inability to store it and the need to settle accounts with energy suppliers.

Summing up financial analyzes and surveys, it should be stated that photovoltaic investments can be implemented on a large scale if two conditions are met. The first is the support of government programs for this type of investment and the second is the possession of free financial resources by the household.

Summary

The activities of the European Union aimed at increasing the share of energy from renewable sources in the market, and at the same time the uncertainty associated with the exploitation and supply of non-renewable raw materials (coal, gas) point to the great development potential of the solar cell market. Households having a privileged position in this market due to legal regulations may take advantage of the possibilities of increasing their income by constructing such a backyard installation. Undertaking such an investment will depend on the propensity for risk of persons creating a household, however, as research has shown, such an investment will be profitable. Of course, remember about the restrictions of this type of investing surplus by the household. The main disadvantage of this way of using the surplus is the size of investments, which in principle in the case of financial instruments are not limited by a minimum amount, while in the case of a solar installation such investment is at least several thousand zlotys. In addition, exit from financial investments is possible at any time, and in the case of solar investments it is impossible. The advantage is greater income from financial investments, which can be even greater thanks to the use of public funds. Obtaining funding at least 60 percent total expenditure, significantly improves the profitability of investments and minimizes the risk of building the installation. The popularity of photovoltaic investments, and through them the improvement of environmental protection can be achieved not only by financial support from the government or the European Union, but also by raising awareness of the investment possibilities of this type of projects. As indicated in surveys, this awareness in society is small and should be improved by information programs.

Global Debt: Problem Assessment and Some Strategic Development Aspects

Elena K. VORONKOVA

Associate Professor of the Department of Finance and Prices, Moscow, Russian Federation, e-mail: Voronkova.EK@rea.ru

Tatyana E. PAUSHEVA

Associate Professor of the Department of Finance and Prices, Plekhanov Russian University of Economics, Moscow, Russian Federation, e-mail: Pausheva.TE@rea.ru

Abstract

The article analyses the most characteristic trends in the functioning of the world and national economies amid increasing global and sovereign debt dependence. The authors study a number of issues related to the global debt growth: the reasons for it and its manifestation forms, the impact on the economy of certain countries, possible options for resolving sovereign debts. Focus is made on the role of regional interstate associations in reducing risks and threats of debt dependence. The assessment of the economic regionalization policy potential in strengthening the stability of the global economic system is given using the EAEU as an example.

Keywords: Global debt, sovereign debt, regional economic unions, instability.

Introduction

The global debt problem is now impeding the development of the world economy. Large global debt increases the risks for global financial stability and creates limitations for economic growth. Global debt is increasing dangerously amid growing macroeconomic and financial instability, dependence on short-term market expectations, worsening growth prospects in the global economy in the absence of incentives for aggregate demand and stable positive dynamics of its main components, such as manufacturing investment, export, domestic consumption, government spending.

Uncontrolled increase in debt obligations leads to a decrease in the sovereign credit rating, political and economic dependence of borrowing countries on creditor countries. The need to direct more and more funds to pay the external debt diverts resources from key national sustainable development projects and destabilizes the

financial situation in countries. Modern strategies for balanced economic development of states should be aimed at maintaining external debt at a safe level. Amid significant increase in external debt and reducing possibilities for its refinancing, the government debt management policy aimed at timely servicing of public debt at the lowest cost through the optimal selection of debt methods and tools, which does not allow sovereign liquidity or solvency crises, becomes of primary importance. Understanding the nature and development processes of modern debt imbalances, the dependence between fundamental factors, the level and structure of the debt burden, is important to ensure macroeconomic and corporate financial stability, and an efficient economic policy.

The objective of the article is to study the impact of global debt on the state of the world and national economies, analyze the relationship between macroeconomic development and the debt burden level, identify possible development areas for the global economy and individual countries that are able to solve debt problems.

The academic value of this paper consists in stating the problem to find radical solutions for reforming national economies, taking into account the problem of increasing global debt and formulating some proposals in this area. In particular, it becomes necessary to clarify the possibilities of building a balanced regional economy, which allows on a mutually beneficial basis to fully utilize the production factors of individual states and reduce systemic risks caused by debt dependence.
The practical importance of this study is that the research results can be used to justify and implement foreign and domestic debt policy strategies at the macro- and micro levels, as well as in selecting principles and mechanisms for debt financing of the Eurasian Economic Union member states.

Materials and Method

The main provisions of the article are based on the application of modern scientific methodology, presented by the concepts of debt analysis by J. Stiglitz, B. Bernanke, S. Gesell, C. Kennedy and others. Debt problems are studied in the article together with the reproduction of the existing capital structure in the global economy and national economies. The logical approach to considering the evolution of debt relations in a global context, the analysis of quantitative indicators of debt, together with an analysis of the qualitative characteristics of the economic development of certain groups of countries, made it possible to substantiate the challenges of monetary and debt stimulation of the economy.

The debt problems were studied in several interrelated areas: analysis of the sources and features of the global debt structure, identifying the specifics of the national debt level, principles and methods of debt settlement through economic regionalization processes. To analyze the scale and pace of change in global debt, the indicators of international monetary and financial organizations were used: the International Monetary Fund, the World Bank, the Bank for International Settlements,

UNCTAD, the World Economic Forum, as well as statistics from the Eurasian Economic Union and the Bank of Russia.

Results

The modern economy is characterized by an increase in the debt burden. The dynamic development and liberalization of the international financial market has increased the level of dependence of different countries on external financing sources. The potential of the international financial market today can meet almost any need. The diversified assortment and cost of international financing sources, convenient and simple fundraising schemes are attractive. Opportunities of the international financial market, as a source of financial revenues, are widely used by government agencies, financial and non-financial private companies, and international financial organizations.

External and internal financing expands financial opportunities to support national economies. Almost all countries across the world implement debt mechanisms in the course of market reforms. Injecting cash and loans into the national economy encourages economic growth, the spread of financial innovations, and increased concentration of financial markets. In the course of history, debt instruments have proved to be effective in stimulating economic development. Future cash flows, being the result of earning investments through today's debt financing, provide revenue growth and debt repayment opportunities. With the efficient spending of borrowed resources on projects with a high multiplier effect, economic growth accelerates, priority investment objects are implemented, and socio-economic problems are solved. At the same time, monetary and debt stimulation does not always promote investment growth. It all depends on preference levels in terms of liquidity, marginal efficiency of capital, and propensity to consume. If the financial resources of external origin are used inefficiently, debt obligations increase, which leads to extra budget expenditures, reduction of government spending, pressure on the national currency exchange rate and tension in the monetary sphere. Then external debt burden becomes a threat to the sustainability of national economies.
An array of problems is connected with the tension in the global debt market. The growth of global debt affects the international and domestic liquidity of individual markets, causing significant, sometimes sudden, capital flows that expose national markets and create risks to economic and financial stability. Unsustainable household debt and the excessive borrowing of financial institutions in the United States became the reasons for the 2008 global financial crisis. Exceeding the reasonable limits of the sovereign external debt compared to GDP drags countries into debt traps, when a decrease in credit rating due to poor indicators of sovereign or corporate debt increases the external debt service expense and requires more and more borrowings.

Global debt is a serious problem for many countries today. Most national economies, both developed and developing, now have debt some features. Sovereign debts are classified as key systemic risks of the global and national

financial systems. Global debt has grown more than 13 times since the 80s, and over the past decade – by almost 50% reaching a record-breaking $250 trillion in 1Q 2019, which corresponds to 320% of global GDP. In 50 countries of the world, public debt exceeds 70% of GDP, and in 15 countries public debt is above 100% of GDP. Traditionally, advanced economies have accumulated the largest debt. In total, they account for more than half of all loans – about $177 trillion. The United States has been leading in the "debt" race for years. The total debt of the United States today exceeds the country's output, and by 2023 it will reach 117% of GDP. A significant increase in external debt is also observed in China, where the indicator already exceeds 300% of GDP. Argentina and Japan markets are facing similar problems (Fig 1).

Fig. 1: Dynamics of the "public debt/GDP" ratio by groups of countries, in %

One of the reasons for the significant growth of the global debt today has been the large-scale state support of the private sector during the 2008 crisis. Direct state support of financial institutions only during the crisis amounted to $1.6 trillion. The situation is also aggravated by the ultra-low interest rates set by central banks in different countries and lower requirements for creditors.

Over the past decade, the nonfinancial sector is making an increasing contribution to the growth of global debt. The total amount of non-financial debt in countries with systemically important financial sectors as of the end of 2017 equaled more than 250 percent of their total GDP. 2/3 of Chinese debt is corporate debt, represented mainly by state companies. The debt of Chinese companies exceeds 40% of the corporate debt of emerging economies. It is increasingly difficult for the global economy to cope with such huge and poorly managed debt. Under these conditions, the risk of potential defaults, recessions, increases sharply. In 2018, 18 thousand companies went bankrupt in China, while defaults on bonds were five times higher than in 2015.

Discussion

International monetary and financial institutions and national governments are coordinating their efforts to reduce the vulnerability of global and national economies connected with the growing debt, but agree that there can be no universal solution in this sphere. Measures to improve debt management are being developed aimed at increasing the transparency and acceptability of sovereign debt as well as easing the debt burden of poor states. Funding sources are being searched for in order to implement the Sustainable Development Goals (SDG) program in the developing countries, which is expected to require at least $2 trillion per year annually, including through the use of concessional lending schemes and the global SDG fund.

It is proposed that one of the ways to release the developing countries from debt traps, to support the effective mobilization of domestic resources, it to strengthen regional monetary cooperation between developing countries for refinancing, expand intra-regional trade and develop intra-regional value chains, as well as encourage full-scale development of regional payment systems and domestic clearing unions. Quite positive effects of the European Economic Union's monetary policy during the European debt crisis give reason to consider interstate economic regionalization as one of the central strategic formats for the debt development of the world economic system. Let us analyze the potential of regional economic cooperation of developing countries in the context of solving the global debt problem taking the Eurasian Economic Union (EAEU) as an example.

The principles of the EAEU allow creating conditions for mitigating debt contradictions and preventing the transformation of borrowed capital from a long-term financing tool designed to unleash the future growth potential into a potentially risky financial asset. The EAEU is implementing a coordinated macroeconomic policy, which includes the development and realization of joint actions by member states in order to achieve a balanced development of the economies of member states, to ensure their resistance to external influences based on the integration potential of the Union and the competitive advantages of each member state, as well as their effective interaction. Specific quantitative values of macroeconomic indicators showing the sustainability of the economic development in member states were specified (Table 1) for these purposes. These include the size of the annual deficit of the consolidated budget in the general government sector, the debt in the general government sector, and the inflation rate. Considering that the state budget affects investment attractiveness, motivates capital outflows/inflows, it can be assumed that this system of indicators contributes to the optimization and debt burden of the EAEU member states.

Table 1: Macroeconomic indicators of the EAEU sustainable economic development

Indicator	Quantitative value, not higher than
Annual consolidated budget deficit of general government sector	3% of GDP
Debt of general government sector	50% of GDP
Inflation level	5 percentage points of minimum inflation in member states

A high share of foreign currency liabilities in the public debt structure aggravates the problem of the debt dependence of the EAEU member states on external factors. In the EAEU in general, as of October 1, 2019, external debt amounts to $1.2 billion. Its annual increase equaled 0.2%. The external debt of Armenia over the past year has grown by 7.6%, Belarus – by 1.3%, Kyrgyzstan – by 3.0%, Russia – by 1.0%. In Kazakhstan, external debt over this period decreased by 2.2%. The ratio of external debt and GDP is 36.1% on average in the EAEU. The dynamics of this indicator varies across the EAEU member states (Table 2). In Armenia, Belarus and Kyrgyzstan, the debt of government bodies prevails, while in Kazakhstan debt on direct investments (intercompany lending) and in Russia debt of other sectors prevail. All EAEU member states share a common trend of declining debt to external creditors and growing external debt in relation to GDP.

Table 2: Dynamics of the external debt/GDP indicator in the EAEU member states, %

Country	**Years**							
	2012	2013	2014	2015	2016	2017	2018	2019
Armenia	38,1	36,5	35,3	43,7	51,5	53,4	52,8	87,9
Belarus	23,9	22,5	22,5	32,6	41,5	42,1	40,6	64,0
Kyrgyz-stan	11,7	12,2	14,1	17,5	19,2	19,7	19,4	89,7
Kazakh-stan	48,6	45,4	48,6	57,1	58,9	59,7	57,4	101,1
Russia	9,1	9,8	10,8	11,4	11,9	12,0	11,6	28,6

All EAEU member states have adopted public debt management strategies sharing a common target – debt burden optimization, but by different means of implementation, taking into account the heterogeneity in the macroeconomic development of the regional association participants, the level of integration into the world economy, mutual trade volumes, etc.

The Republic of Armenia defines 4 target indicators for public debt management:

1) the average maturity of a state debt is 8-11 years,
2) the share of treasury securities with a maturity next year in the total volume of treasury securities (at the end of the year) – no more than 20%,
3) the share of fixed rate debt in the total debt is not less than 80%,
4) the share of domestic debt in the total debt is at least 20%.

The Republic of Belarus established that
1) procurement of unrelated state loans shall be carried out solely to repay the state debt and replenish gold and foreign currency reserves as well as it shall not exceed half of the annual need for repaying the state debt;
2) payments for servicing the state debt shall be made at the expense of the republican budget;
3) the ratio of public debt to GDP shall not exceed 45 percent.

The Republic of Kazakhstan has introduced the following restrictions to maintain the state, quasi-public and external debt of the country at a safe level:
1) public debt in 2020 should not exceed 27% of GDP, including the governmental debt – 25% of GDP;
2) external debt in the medium term should not exceed 100% of GDP;
3) the upper limit of public debt and the debt of the quasi-public sector shall total no more than 60% of GDP, excluding the mutual obligations of state-controlled organizations and the obligations of controlled non-resident organizations.

The Kyrgyz Republic has recommended that the present value of government debt to GDP, taking into account the remittances of labor migrants, shall not exceed 56% in 2020.

The debt policy of the Russian Federation identifies the following main areas:
1) achieving the optimal ratio of duration and yield of sovereign debt obligations;
2) restoration and increase of credit ratings;
3) the development of reasonable guidelines for the level of credit risk and the improvement of the system for monitoring the risks of external borrowings for corporate borrowers;
4) stimulation of the Russian territorial entities and municipalities to conduct a responsible debt policy;
5) increasing the adaptability of the mechanism for providing state guarantees to the needs of economic growth and diversification of its structure;
6) to ensure that the ratio of public debt to gross domestic product is not higher than 20%.

The security of sovereign debt in the EAEU is also supported by the fiscal policy of member states through control of current expenditures, limiting the budget deficit indicator, and the creation of sovereign wealth funds (in Russia and Kazakhstan). The budget rule in Armenia and Belarus establishes a “debt anchor”, which includes three thresholds for the public debt level – 40%, 50% and 60% and 45%. Kyrgyzstan has started planning to use the “debt anchor” at 70%. Kazakhstan dos not have such “anchor”, however, there is a limit for the costs of paying off and servicing the government debt in the amount of 15% of the republican budget revenues. In the Russian Federation, due to a relatively low rate of public debt, debt ratio standards have not been defined. Such stabilization mechanisms of a budgetary nature, while preventing the excessive growth of government spending and

smoothing out the negative external impact on the budget system of an unfavorable political and economic global environment, have a positive effect on the size of the debt overhang.
To a certain extent, the problems of external debt in the EAEU states are connected with the state of their balance of payments and low adequacy of international reserves. In the EAEU, only Kazakhstan and Russia have a positive trade balance. Only Russia has high coverage of external debt with international reserves (112.1%). In other EAEU member states, this indicator ranges from 18.3% to 26.4%. Although in recent years, all EAEU member states, except Kazakhstan, have observed a positive trend in the dynamics of the international reserves and external debt ratio.

Regional cooperation within the EAEU creates the conditions for flexible debt management, achieving a balance between financial needs and obligations. The EAEU common market is a growth factor for all the member states. The expansion of mutual trade within the Union reduces pressure on the EAEU member states in industrialized countries and allows using relative advantages of national economies amid the most favored nation treatment. If the global economy today is characterized by negative expectations of imbalances in world trade due to trade protectionism escalation, then in the EAEU, the volume of mutual trade is gradually increasing. Following the results of 2019 (January-November), the growth of mutual trade amounted to 0.2%. In 2018, the export of Armenia and Kyrgyzstan to the EAEU member states increased faster than with other countries, and Belarus saw outperforming growth rates of imports from the EAEU member states. As a result, trade costs are reduced, revenues from external deliveries are increased, negative external influence is slowed down and currency risks are reduced, since national currencies are increasingly used for settlements. The share of the dollar in the mutual settlements of the EAEU member states in 2018 amounted to 19.2%, the euro – 6.8%, and the Russian ruble – 72.7%. The stability of the EAEU member states financial income can be achieved thanks to the EAEU internal market, which is extremely important for timely repayment of external and internal state debt in full.

Conclusion

It is quite real that strategies for interstate regional development may start dominating the debt economy today. Studying the functioning and prospects of the EAEU leads to the conclusion that regional economic policy has a higher level of harmonization and provides more visible growth conditions for each member state and, therefore, a solution to the sovereign debt problem, than global or national financial regulation.

Fig. 2: Positions of the EAEU member states in the WEF Global Competitiveness Index

The macroeconomic situation in the EAEU member states has improved over the recent years, the volatility of key macroeconomic indicators has decreased, their position in the world economy is strengthening, which is demonstrated by the dynamics of the global competitiveness indices of the World Economic Forum (WEF) (Fig 2). The EAEU national markets are becoming increasingly attractive for investors. Thus, 90% of Western companies with many years of experience in Russia are confident in the future growth of the Russian market, especially in such sectors as medicine, pharmaceuticals, engineering, energy, construction and consider it strategically important for themselves in the future. More than 2/3 of Kazakh business representatives are optimistic about the prospects for the development of the country's economy and are confident in the corporate income growth. The further rise of the EAEU national markets will allow not only to cope with debt problems, but also to increase credit and investment ratings, will become a new stage in their progressive economic development.

The Importance of Tokenization for The Development of The Art Investment Market

Joanna WIEPROW

WSB University, Wroclaw, Poland
joanna.wieprow@wsb.wroclaw.pl

Abstract

With the financial markets facing high volatility, crises and declining confidence in recent years, alternative forms of wealth creation have been attracting more interest. The art market is the largest segment of the alternative investment market. One of the reasons for investing in this class of assets is the ability to diversify investment portfolio and to ensure protection against inflation. However, there is a number of factors such as low liquidity, having to invest substantial amounts and the lack of international exchange standards which hamper investments to be carried out the art market. Today, devising modern models of investments based on innovative technological solutions is becoming one of the priorities for this market. Drawing on the blockchain technology, tokenization, as a new model, allows for the issuing of tokens. A digital token certifies that a fractional ownership of the work of art, and has been purchased while enabling one to trade the token on the cryptocurrency exchanges.
As its primary goal, the paper attempts to find the answer to the question whether the process of tokenization can play a part in the development of the art market. The indirect goal is to identify the factors constraining investment in this asset class For these two objectives the following theses were put forward: (i) there are numerous factors on the art investment market which hinder its growth; (ii) by removing significant barriers, tokenization of artworks can contribute to the development of the art investment market.

Keywords: blockchain, alternative investments, tokenization, works of art.

Introduction

The analysis of the history of the art market reveals that works of art have been enjoying unwavering demand among collectors and investors. On the one hand, artworks represent a long-term investment while on the other allowing one to achieve non-financial goals and follow his or her passion. Additionally, seeing the issue from the investor's perspective, works of art provide an opportunity for portfolio diversification, they protect against inflation and show low correlation with the financial market. Investments in works of art are part of the alternative investments making up the largest segment of this market.

In 2018 the art market was worth USD 67.4 billion, which is 6% more than the year before (The Art Market Report, 2019). Still, the analyses show that there exist plenty of barriers which affect adversely the art market and hence constrain its development. The most important of these barriers are low liquidity of investments, having to provide substantial funds, low transparency and geographical limitations on access to the market. According to the entities operating at the art market, a pressing priority is to search for models capable of removing these barriers and making investments in this asset class more appealing. The solution to the issues cited may be found in bringing the innovative blockchain technology into the art market. The application of a digital ledger that is decentralized and distributed combined with smart contracts made issuing digital tokens possible, a process referred to as tokenization. Tokenization of artworks is a new investment model which allows one to purchase a fraction of an artwork as security tokens and then to trade them on the cryptocurrency exchanges.

As its primary goal, the paper attempts to find the answer to the question whether the process of tokenization can play a part in the development of the art market. The indirect goal is to identify the

factors constraining investment in this asset class. For these two objectives the following theses were put forward: (i) there are numerous factors on the art investment market which hinder its growth; (ii) by removing significant barriers, tokenization of art works can contribute to the development of the art investment market.

The first section of the paper presents the concept of alternative investments and examines the art market globally. Next, the concept of digital tokens and their types are defined, and the tokenization process is outlined. Further on, the paper identifies the barriers hampering the development of the market in question, and shows how tokenization contributes to making investments more appealing. The paper goes on to show how the removal of the factors indicated can impact the chances for using the model and what are the risks involved in its functioning. To this end, a review of the literature and references was conducted. The number of available publications on tokenization of artworks is understandably very small given that it is a new phenomenon on the financial markets. The paper was written drawing on the analysis carried out based on the latest reports on the global art market and internet portals of entities operating on the art market.

The concept and features of alternative investments

The largest segment of the alternative investment market is the art market, where the objects of trade range from paintings to sculptures, graphics, posters, porcelain, antiques and applied arts, with the artwork price not being dominated by the supply/demand ratio (Cichorska, 2015, p. 71). Alternative investments could be defined as those which do not fall into one of the conventional equity/income/cash categories. "Alternative investments include private equity or venture capital, hedge funds, managed futures, art and antiques, commodities, and derivatives contracts" (Chen, 2019). However, what is still being disputed is what is the clear dividing line between the traditional and alternative investments. How this dividing line is being drawn is directly related to the investor's knowledge and experience regarding the allocation of assets on the financial markets (Borowski, 2012).

Alternative investments are also defined as physical assets having no links to the financial market. With this approach, alternative investments could be seen as investments in physically existing assets, whose rate of return is not correlated with the financial market and which are comprised of: real estate, precious stones and metals, works of art, wine, whisky, luxury goods (e.g. yachts, watches), raw materials and commodities, ornamental materials of natural origin (e.g. amber), collections (e.g. stamps, coins, pens, furniture), comics, national memorabilia (Banasik, 2016, p. 110-113).

Alternative investments are a wide range of products of which the following features should be examined (Aspadarec, 2013):

- low correlation with conventional financial investments such as stocks,
- potentially relatively low liquidity,
- potential difficulty in determining the current market value for assets concerned,
- potentially limited data on risk and rates of return,
- potentially necessary analyses before investing,
- potentially high cost of opening and closing down an investment.

As Chen (2019) stresses, alternative investments tend to show a low correlation with the investments in the conventional asset classes. This feature makes them a suitable tool for diversifying portfolio. They may also generate higher rates of return than a strictly traditional portfolio (Manning 2019). Some authors, meanwhile, emphasize that the alternative investment market grows only in times of economic crisis while in times of economic growth they fail to be an attractive form for wealth creation (Weber, 2011). Investing in fixed assets such as gold, works of art, raw material and property also provides effective protection against inflation. This may also be a feature which makes investing in this asset class appealing.

Another fact worth mentioning is that artworks as part of the segment of alternative investments fall into the subcategory of emotional investments. Borowski (2016, p. 9) describes emotional investments as those for which profit is no longer the key determinant of making the investment since the primary factors taken into consideration are of noneconomic nature – emotions, sentiment or sensorial experience. For the participants of this market, the crucial factors considered when making an investment decision, include such elements as beauty, rareness, origin, nature or the very fact of being able to commune with the particular object.

The Art Investment Market

In 2017 the global art market worth was USD 63.7 billion, an increase of 12% compared to 2016, while the number of transactions itself grew by 8%. The year 2018 saw the sales at USD 67.4 billion, which is 6% more than in 2017. 84% of those sales was centered around the three markets: the USA (44% of sales by value); the UK (21%) and China (19%) (The Art Market Report, 2019). 70% of the global auction sale (between July 2018 and July 2019) was carried out at the following three auction houses: Sotheby's (32.9%) Christie's (25.4%), Phillips (11.9%), (The Contemporary Art Market, 2019, p. 19). Dealer sales in 2018 reached an estimated USD 35.9 billion, up 7% year-on-year. What is significant here is that the global value of online art sale amounted to USD 6 billion in 2018 and was up 11% compared to 2017 (The Art Market Report, 2019).

The studies show that in 2018 works of art whose value exceeded a million dollars accounted for 61% of all sales at the auction market, with 28% accounting for artworks worth more than USD 10 million. Artworks sold for less than a thousand dollars accounted for merely 0.3% (The Art Market Report, 2019). Chart 1 shows the value of sales according to price ranges.

Chart 1: The value of artworks sold on the global market according to price ranges (2018)
Source: self-reported data based on The Art Market Report, (2019, p.157).

For the art market, significant findings come from the Deloitte study carried out on a sample of 322 entities operating on the market. Published in 2019, the report shows that in 2008-2018 the value of sales conducted at auction houses increased by 4.6% annually. CAGR (*Compound Annual Growth Rate*) for Top 100 artists was at 8% in relation to 3% for S&P500. In 2018 52% of people owning artworks reported that in purchasing those assets they were strongly motivated by gaining the possibility to diversify their investment portfolios (Art&Finance Report, 2019). Table1 presents CAGR levels for individual art categories for the five, ten and fifteen-year terms.

Table 1: CAGR level for individual art categories (2013-2018)

Art category	5-year CAGR	10-year CAGR	15-year CAGR
European Old Masters	-2.82%	-1.63%	2.38%
Global Impressionist Art	-3.92%	-0.48%	1.33%
Global Modern Art	2.87%	2.10%	4.15%
Global Post War Art	7.92%	6.69%	7.81%
Global Contemporary	5.70%	4.58%	7.12%
Fine Chinese Paintings and Calligraphy	-5.06%	7.45%	9.31%

Source: self-reported data based on Art&Finance Report (2019, p.135).

That the interest in investing on the art market has been on a rise is clearly evidenced by the growth of assets of the funds engaged in art investments. In principle, art funds are private investment funds whose purpose is to generate profit by purchasing and selling works of art. They are run by professional firm managing art investments or counseling firms which receive fees for management and participates in the fund's profit. The funds investing in art differ in terms of their total amount, duration, investment orientation, strategies and portfolio limitations. Artemundi Global Fund, in business from 2010 to 2015, is one example among financially successful funds. The fund raised USD 211 million from investors. The average purchase price of an artwork stood at over USD 800 thousand. The Fund's investments were tailored to the five-year time horizon, with the average annual rate of return at 17.07%. Tiroche DeLeon Collection Art Vantage registered in Gibraltar is yet another example of the fund, whose portfolio is built on art. As the founders of the Fund say, "Classical portfolio theory recommends an allocation of 3-10% to art; the fund offers an opportunity to investors from around the world to diversify their portfolios while remaining the only fully private fund built on the decisions made by one private collector". Upon opening subscription (2017), the Fund required a minimum investment of USD 500 thousand, other costs-annual management fee at 2% and performance fee at 20% (http://www.tirochedeleon.com/about/investors/). The Fine Art runs several funds, which invest into art. Other funds operating in this way include Fine Art Invest Fund based in Switzerland (https://privateartinvestor.com/category/art-finance/art-funds-art-finance/) or German Artfonds21 (http://artfonds-21.com/).

The Art&Finance Report (2019) draws attention to the factors which the art market participants (broken down into art professionals, collectors and wealth managers) view as having an adverse impact on the reputation of the art market. 75% collectors reported that the lacking transparency is one of the most serious threats to the market's reputation. It is a sharp increase compared to 2017 (62%). The same view is shared by 75% of art professionals and 77% of wealth managers. Chart 2 presents selected factors indicated by the entities operating on the art market.

Chart 2: The most threatening/damaging issues to the reputation of the art market (in %)

Source: self-reported data based on Art&Finance, (2019, p. 206).

As the result of the lack of uniform regulations in Europe the market for art-backed credits is poorly developed unlike that operating in the USA, where its global worth ranges from USD 21 to 24 billion. In Europe, only 32% of banks declares that they will focus on this form of securing credit in the upcoming year, in relation to 80% of the financial institutions in the USA (Art&Finance Report, 2019).

A considerable problem, perceived as particularly harmful, is the fact that the art market is being used for money laundering. In this respect, significant changes regarding the EU Member States were put in place in connection with the V AML Directive on the prevention of the use of the financial system for the purposes of money laundering or terrorist financing. Under the Directive regulations, entities are indicated which are involved in providing currency exchange services between virtual currency and fiat currency, as well as providers of virtual currency accounts who in the past were not required under the EU law to report suspicious transactions (Directive EU 2018/843 of 30 May 2018).

Another issue worth emphasizing is the opinion voiced by the participants of the art market that the implementation of an innovative technology may affect significantly the most vital aspects involved in art investments, such as (Art&Finance, 2019, *key facts*, p. 16):

- improving provenance and traceability,
- creating more transparency,
- improving authenticity,
- imformation and educating,
- improving valuation.

The last ten years have seen the wealth of people owning at least one million dollars double. People's growing wealth witnessed globally may become a driving force for today's art market, already turning into a great opportunity. It is estimated that the value of artworks in the collections owned by UHNWI (Ultra high-net-worth individuals defined as people having a net-worth of at least USD 30 million) amounts to USD1.74 billion, and is expected to go up to USD 2.13 billion in 2023. Although

the forecasts of growth are optimistic, currently the art market has grown in nominal terms by merely 9%. Lacking credibility and transparency have been identified as the key obstacles to its expansion. In order to capitalize on this opportunity, the legal barriers which discourage potential investors should be removed (Art&Finance Report, 2019).

Moreover, the authors of the report (Art&Finance Report, 2019) argue that development of technologies, including that of blockchain, may affect considerably a number of aspects involved in the functioning of the art investment market. Building on the findings produced by the analysis of the studies included in the report, the conclusion to be drawn is that what now becomes one of the market's priority is having to create new investment models based on innovative technological solutions. A promising innovation in this context is the already mentioned blockchain, which allows for solving the important problems plaguing the art market in relation to the lacking transparency for buyers and sellers, transaction security, and the possibility to verify the authenticity of an artwork and that of its origin.

Tokenization of works of art

The blockchain technology entails five key advantages (Schueffel, 2019):

- it makes transactions more transparent to all the parties involved,
- it offers better traceability of transactions,
- it is safer than the conventional methods used for recording transactions,
- improving transaction effectiveness and speed,
- reducing transaction cost.

Bringing the blockchain technology into the world of finance has also positive implications. First of all, this is a situation where the number of intermediaries is being constantly reduced. Furthermore, a blockchain allows for reducing the transaction time. Another advantage is that various asset classes can be offered on the global market. In practical terms, everybody with the Internet access can, in accordance with current law, take up an investment opportunity just emerging, regardless of their current place of stay. Additionally, investment projects can raise interests among a greater number of investors as their offer will be able to reach new segments of investors. It is important to emphasize that blockchain considerably limits the opportunities for market manipulation as every transaction is recorded in a very transparent way in real time, offering no possibility for any alterations later on, while the information about the transaction is made available at any time to all operators concerned, including the supervisory authorities (Schueffel, 2019).

Asset tokenization is a process of issuing digital tokens which is made possible thanks to the decentralized blockchain technology and smart contracts. A token is a transferable item of fixed assets which is not material having only a digital record. In the process of tokenization of assets we encounter the exchange of rights to individual items of wealth for a token. "A token represents an asset or utility that a company has and they usually give it away to their investors during a public sale called Initial Coin Offering (ICO). ICOs are basically crowd sales, the cryptocurrency version of crowdfunding" (Hiscox online art trade 2019).

Among the uses of tokenization there is Security Token Offering (STO). STO offers security tokens, which share the same characteristics as the regulated securities, being subject to legal regulations, and meet all the requirements in this respect. As such, it is a much more secure method of financing given that it requires that the asset tokens be issued in a blockchain network under the regulations on the prospectus. The holders of tokens can therefore own shares in tangible assets (Burke et al. 2019). Security tokens represent such assets as shares in underlying instruments, companies or revenue streams and rights to dividends or interests. In terms of their economic function, security tokens correspond to stocks, bonds or derivatives (*'*Types of tokens. The four mistakes beginner crypto-investors make').

In other words, STO is a digitalization of assets. This is a modern form used for raising capital through a public offering with the tokens sharing similar features to those found in cryptocurrencies. Unlike utility tokens, issued under ICO and not regulated at all, tokenization under STO is subject to legal regulations conditional on the provisions in place in the country concerned. Art will thus become an investment with greater liquidity when it is approved and becomes an object of trade just like securities. That is why security tokens, classified under law as securities, have to meet the relevant legal requirements. It is on account of the securities law, implemented as the method designed for investor protection, that the fractionalized sale of artworks allows numerous investors to trade tokens and co-create works of art (Fractionalized Art Ownership and Securities Law).

The process of artwork tokenization consists of several stages. Following the valuation, verification, confirmation of the authenticity of a given work of art, a bid is made at the investment portal. Before making their decision, investors have a chance to learn about the details of a particular artwork, its history, origin and creator. Next, relying on the blockchain technology, tokens are issued representing fractional ownership of the artwork. The owner issues tokens to be sold at the platform while the investors interested in purchasing the tokens can pay in acceptable fiat currency or cryptocurrency (https://www.maecenas.co/whats-maecenas/). The tokens can be exchanged at any time via cryptocurrency exchanges at which they are listed. The costs associated with storing and insuring the work of art, are paid by its holder (the entity that has the largest share in the ownership of a work of art). Table 2 shows the advantages arising from the tokenization of works of art both for investors and owners of a tokenized artwork.

Table 2: Advantages arising from artwork tokenization for investors and owners

Investors	Ownerships
Holding a fraction of an artwork	Raising capital from the fractional sale of an artwork.
No geographical limitations – greater access.	The chance of reaching a wider group of potential investors.
Low entry threshold/no need for high financial resources.	The chance of taking physical possession of an artwork (provided that one's share is over 50%).
High investment liquidity/the ability of trading tokens on cryptocurrency exchanges.	The ability to make works of art available to the public, e.g. in a museum.
No security and storage costs.	High transparency and transaction security.
The ability to verify the authenticity of an artwork/ high transaction transparency and security.	Satisfying emotional needs.

Source: Author's own study.

"Due to the growing interest in the art market in the last decade, one of the models that emerged on this market is fractional ownership. Fractional ownership of art has been tried and tested over the last 10 years with limited success, from the early European initiatives such as SplitArt and A&F Markets to the Chinese art exchanges that emerged between 2009 and 2011, and were subsequently shut down or consolidated by the Chinese government towards the end of 2011. The question whitch arises is could fractional ownership be a way of attracting new audiences to the art market?" (Art&Finance Report 2019, p. 146).

According to the study, the art market participants continue to take a skeptical attitude towards the fractional investment models. Only 19% of collectors and art professionals shows interest in this

investment form. In contrast, 33% of collectors and 38% of art professionals made the same comment about the traditional art funds. Nor do wealth managers show much confidence in the art tokenization model. Merely 10% of them considers recommending the fractional investment models to their clients. This situation, however, looks slightly different for investors in the age bracket of up to 35. According to the study carried out by ArtTactic, 46% of millennial art buyers would consider fractional ownership of art as a form of investment. For comparison purposes, 29% of buyers from the over 50-age bracket found the new model for investing in art interesting (Hiscox Online Art Trade Report 2019, p.26).

Maecenas is the first blockchain-based platform that allows anyone to buy, sell, and trade part ownership in masterpieces on a liquid exchange. It was on this platform that the first artwork tokenization took place. The year 2018 saw Andy Warhol's graphic sell for USD 5.6 million using the tokenization process. Over 800 individuals entered the auction buying tokens for USD 1.7 million, representing 31.5% of the artwork value ('Maecenas successfully tokenizes first multi-million dollar artwork on the blockchain'). The MeacenasArt token is currently listed on cryptocurrency exchanges, including, for example:

- CoinMarketCap (https://coinmarketcap.com/currencies/maecenas/),
- Etherscan (https://etherscan.io/token/0xfec0cf7fe078a500abf15f1284958f22049c2c7e),
- CoinGecko (https://www.coingecko.com/pl/waluty/maecenas).

One of the platforms created most recently is Artopolie, founded in 2019 offering works created by Pablo Picasso and Claude Monet. Any registered member of the platform can become a fractionalized owner of an artwork. Artopolie purchases a work of art and files an offer at the Securities and Exchange Commission (SEC). After the offer has been approved, Artopolie sells the fractional ownership of the artwork on its platform. 50 dollars will be sufficient to buy a fraction ownership (Artopolie, 2020).

Another example of a blockchain-based platform is Look Latereal, created in 2018. Anyone interested in investing in art through buying or selling part ownerships in artworks can access the platform. Through Look Lateral, one can authenticate and secure permanent collections, e.g. in museums, or artists can raise capital for their various art projects (https://www.looklateral.com/).

The Importance of Tokenization for The Art Market Development

Investing in artworks is considered as high risk. This risk arises from the specific features inherent to this class of assets and the market volatility caused by the ever changing trends. Given that these are long-term investments, predicting the future value of a particular artwork, is quite challenging, as is predicting how the buyers' taste will change and whether the artwork will still be in demand, say in several or a dozen of years. Moreover, considering that some artworks are exceptionally rare, putting a value on them might prove quite difficult. For this kind of investments, it is not infrequent that one needs specialist expertise or has to turn to advisory services. When taking physical possession of an artwork, investors must take into account additional costs relating to having to store, insure and secure the artifact. What investors find to be an extremely difficult problem is low liquidity of this asset class and having to make a substantial investment. This situation pertains not only to the physical purchase of works of art at auction houses or art galleries, but also to the participation in the art investment funds. Another problematic issue is that there are no uniform regulations governing the trade on the art market.

In summing up, one can identify the following barriers to the art market growth:

- low liquidity,
- high enter threshold,/substantial investments,
- the costs involved in storing and insuring artworks, fees to be paid to intermediaries (physical possession of the artwork) or fees and commissions paid to the investment funds,

- difficulty relating to confirming the authenticity of the work,
- geographical limitations/limited access to art,
- low transparency of the art market,
- no uniform laws,
- no institutional supervision over the art market.

As the analysis shows, there are many factors which affect adversely the art market growth in terms of investments. Using innovative technologies can contribute considerably to removing those barriers thus creating completely new investment possibilities. The tokenization of artworks, as a new investment model, could be the answer to the majority of the problems reported by the participants of the market.

Considering the issues addressed in the paper regarding the barriers identified here, as well as the participants' views as to how the technology may affect the art market and the benefits arising from tokenization, one may venture to conclude that the new model of artwork tokenization can alter significantly the rules according to which the art market operates. Some of the advantages arise from the potential offered by blockchain and are conducive to matters concerning the following:

- determining the authenticity of an artwork and its origin,
- transaction speed and transparency,
- transaction security,
- lowering transaction costs,
- global access to the art market (no geographical barriers).

What tokenization, or fractional investments, does is to lower the threshold for entering the art market, thus providing less wealthy investors with the chance of getting access to this market. Trading tokens is easier than trading a physical masterpiece, which in turn contributes immensely to improving the liquidity of the investments in these assets. In addition, holding a token does not entail additional costs such as those arising from the physical possession of a piece of art. Lower are also the costs arising from using intermediaries. For the auction houses, the commission charged amounts to 25% of the sales value, art galleries may set their commission as high as 50% while with tokenization the fee charged by the investment platform ranges from 1% to 8% (https://www.maecenas.co/whats-maecenas/). Hence the art tokenization model plays a part in removing the art market barriers indicated in the paper.

Conclusions

Adopting the blockchain technology is a slow process. It appears that the art world is watching closely the changes as they unfold, awaiting their verification. The area where Blockchain is likely to succeed is where it offers the possibility to register the title and trace the origin of artworks. Meanwhile, the participants of the art market seem cautious when it comes to the tokenization process. As a new investment model, tokenization cannot remove all the barriers which hamper the art market growth such as changing trends or difficulties in putting a value on the works of art. Still, tokenization can play a part in overcoming some key obstacles thereby making art investments more accessible.

Moreover, what certainly presents a serious threat to the art token trade is the overall situation at the cryptocurrency exchanges, where instability, volatility, potential hacking attacks can destabilize the market affecting adversely the investors' attitudes. Furthermore, implementing legal regulations centered around the STO, is one of the most vital determinants for a successful tokenization. Having appropriate legal provisions in palace will ensure investors' safety and increase the level of confidence while making art investments. Although security tokens feature similar characteristics to those of securities, the legal provisions and rules concerned with their issuing have not been implemented in every country. Many countries adjust their provisions to the changing market demands as well as to the development and application possibilities offered by Blockchain.

Nevertheless, there are countries where trading security tokens continues to be banned, e.g. China, South Korea, Ecuador, Algeria (The Ultimate Guide to STO 2019, p. 27).

In referring to the question raised in the Introduction, it is possible to conclude that the artwork tokenization contributes considerably to removing the barriers encountered at the art market, to reducing investment risk and thereby help the art investment market expand. However, when deciding to invest in fractional ownership, one should consider such factors as the overall situation at the cryptocurrency exchanges and the scope of the legal provisions regarding the issuing of security tokens.

Abstract

National projects have become the main strategic instrument for stimulating the economic growth of the Russian economy and improving the level and quality of life of Russian citizens. Financing of national projects is based on a program-oriented approach and involves the allocation of 95% of funding from the federal budget, implies the use of new project mechanisms for the construction of capital objects in various sectors of the economy. In the study, the analysis was carried out on the basis of implementation plans and detailed schedules of national projects. Monitoring for 2019 revealed that the implementation of national projects was relatively effective – not all projects had a high indicator of control events, and in addition, it was often not possible to fully assess the effectiveness of spending the total amount of funding due to the lack of statistics. Based on the collected statistics, the study analyzed expenditures financed under national programs by component elements, which made it possible to develop recommendations on the use of economic growth drivers and structure the types of effects depending on the characteristics of the GDP structure – short-term (from the aggregate demand side), medium-term (from the supply side) and long-term (increasing factor productivity) macro-effects.

Keywords: The System for Financing, The State and Municipal Finance, National Projects, Program-Targeted Method of Funding

Introduction

A special Russian instrument as national projects is a key trend and a strategic instrument for stimulating economic growth in the Russian economy. The idea of national projects in Russia was born as a result of the search for the new strategic points of growth and development of the Russian economy that can not only provide the economy with a new breakthrough socio-economic level of development, but also improve the quality of life of Russian citizens, creating conditions and opportunities for self-realization and development of each Russian resident. National projects were developed during 2018 and currently include sectoral goals and objectives, the list of federal projects, the expected results of their implementation and the parameters of financial support in the context of sources of budget and non-budgetary sources of funding. To ensure the unity of the state strategic planning system the list of Federal projects are included in the sub-program elements of the relevant state programs of the Russian Federation. In 2019-2024, it is planned to allocate more than 25.7 trillion rubles for national projects, of which 29.1% are non-budgetary sources; 51% – means of the Federal budget of the Russian Federation and about 20% - means of regional budgets and state extra-budgetary funds. The main task of the national project financing system in the country is to develop new schemes and mechanisms for financing national projects that can optimally combine different conditions and sources of

financing, as well as attract significant resources to improve the quality and level of socio-economic development and life in the country.

Objectives of the Study

The broad objective of the study is to examine the system and methods of financing national projects, analyze the effect of their implementation on the Russian economy and think about the structure between different budget and extra-budgetary sources of financing national projects in various sectors of the economy in Russia.

Literature Review

Program-Targeted Approach to The System of National Projects Financing

A special Russian instrument as national projects based on the long-term socio-economic development plans of Russia, is an instrument for achieving its goals, and is oriented on a program-targeted approach. Preconditions for the introduction and use of program-targeted approaches to budgeting in the implementation of national projects in the framework of state programs began in Russia in the early twentieth century, long before the development of national projects themselves. During this time, the Government of Russia have rebuilt the system of planning and forecasting socio-economic indicators in the country, as well as the sectoral development of the economy, in order to fully assess the effectiveness of public expenditures from the budget in relation to the main parameters of economic development. However, the process of forming an integrated system for managing state and municipal finances at all levels of the state's budget system is still incomplete. A serious budget reform based on a program-targeted approach has been carried out, which has made it possible to build a budget process in Russia and link the achievement of efficiency between strategic goals, priority tasks of social and economic development and state programs, national and federal projects. National projects in the system of state and municipal finance have become a key mechanism that allows linking strategic and budget planning, increasing budget transparency at all levels of the country's budget system.

A special feature of national projects in Russia is the presence of a special management system that provides for accelerated decision-making management and the allocation of significant financial resources from the federal budget of the Russian Federation for their implementation.

Theoretical Review

The development of public finance management in RF in recent 10 years is due to the following trends:

- increasing the independence of the Executive authorities of the subjects of the Russia,
- reducing the dependence of the consolidated budgets of Russian regions on financial assistance from the federal budget of the Russian Federation,
- development of program-targeted methods of public finance management,
- improving the quality of regional and local financial management.

The transition to program-targeted methods of funding the state budget has been a general global trend in the past decades to improve the system of public finance management. The program budget in many countries of the world economy is the main mechanism for financing national projects in order to effectively spend funds on solving socio-economic problems of regional development.
The use of software instruments makes it possible to increase the flexibility of budget resources management in achieving strategic goals of economic development, helps to minimize costs and improve the efficiency of

providing all types of budget services. Within the framework of program and target planning, the financing of major national projects is implemented by developing a set of measures to equalize disparities in the socio-economic development of various territories and, as a result, to achieve the set goals and objectives laid down in national projects. Results-based management is considered an effective instrument for public finance when the process of its implementation takes place within the framework of changes in the system of public finance management, development of strategic planning, and reform of budget powers and functions of government authorities. All these changes have been taking place in the budget sphere in Russia since the 2000s. they have created a good platform for launching a system of financing national projects in Russia and, as a result, achieving strategic goals and objectives of socio-economic development.

Prerequisites for implementing the system of financing national projects based on the program-target method in the budget process factors:

- international reserves accumulated during the 2000s played a role, but were almost exhausted by 2014, and risks are increasing;
- spending in the 2000s increased significantly, but without linking to priorities, there was bargaining for resources and erosion of budget discipline;
- incentives to increase budget expenditures were maintained, and conditions were not created for improving the efficiency of budget expenditures;
- strategic planning was loosely linked to budget planning, and the structure and dynamics of expenditures were loosely linked to public policy goals;
- there was no assessment of the effect of public policy instruments (budget, tax, tariff, customs, regulatory regulation);
- planning of program and non-program expenditures, as well as capital and current expenditures) was not methodologically linked.

The main issue in the course of financing national projects based on the principles of program-targeted budgeting remains the qualitative improvement of the unified system of performance indicators and its subsequent integration into the budget process. Most countries that have implemented programmatic budgeting have difficulty using performance indicators correctly. These problems include the following issues:

- measuring the parameters of indicators based on their goals of national projects;
- obtaining the necessary volume of high-quality statistical data for their analysis;
- developing a system of indicators for accounting for data of individual activities.

As you know, the most common model worldwide (especially in the OECD countries, the USA, Canada, Australia, and UK) is the budgeting model (or «direct budgeting» model), which takes into account performance when budget funds are linked to either planned indicators or actual results. The application of this model implies a budget in the program format and specification of goals through indicators of expected results. Actual results are of key importance in the process of prioritizing the distribution of financial flows for the next year, but they do not affect the process of determining the amount of budget funds allocated.

In Russia, a demonstration model of program budgeting is practiced, which has the main reference point in the form of the final result. At the same time, the main feature of this model is the lack of connection between information about results and financing, since the indicators of final results are included in state budget documents only as information. Such information mainly contains data on planned and actual indicators and is necessary, first of all, to increase the accountability of state bodies and transparency of the budget process.

At the same time, it should be noted that when determining the sources of funding for national projects to achieve the strategic goals of economic development, not only public investments from the budget are attracted, but also private investments from extra-budgetary sources of funding, including funds of the population.

Methodology

For national projects, the following main focus has been identified for forming a system of their implementation and financing aimed at ensuring breakthrough results:

- defining national projects as a portfolio of priority projects;
- ensuring that expenditures for national projects are separated in the budget classification;
- transformation of state programs that affect the implementation of national projects (programs) into «pilot programs»;
- creating a single information resource that allows you to ensure that full information about the parameters of national projects is available, in accordance with the principle of single data entry.

At the stage of developing national projects, proposals should be formulated that are used in the performance assessment stage and include:

- proposals for a system of goals and objectives for the implementation of national projects with a methodology for calculating new proposed indicators, including determining the methodology for calculating indicators, justifying the possibility of using existing forms of federal statistical observation or the need to adjust these forms;
- proposals for target values of national project indicators, including justification of forecast values of indicators;
- proposals on the structure of the main activities in the framework of national projects and the expected results of their implementation;
- proposals for a system of measures a system of legal regulation measures aimed at achieving the goals of the implementation of national projects;
- proposals on the amount of financial support for the implementation of national projects, taking into account the maximum amount of financial support from the federal budget for the next financial year and planning period.

The transition from forecast targets for socio-economic development to national projects is a multi-stage process of forming proposals based on forecasts to justify national project options at the macro level, supplemented by proposals from regions containing integrated assessments of municipalities. In connection with these circumstances, possible contradictions are inevitable, but the search for solutions should be aimed at achieving agreed measures, decisions that indicate the relationship between the social and economic development targets and results of national projects.

The system of implementation of national projects and subsequent evaluation of their effectiveness includes the following stages at the macro level (Fig.1).

Fig.1: Stages of implementation and evaluation of the effectiveness of national projects

(source: compiled by the authors)

The main priorities for the development of public finance in the implementation of national projects on the principles of project management are:

- digitalization of tax administration and integration of all data sources into a single information space with subsequent automation of its analysis based on modern technologies for processing large data sets;
- strategic prioritization of financing of national projects (in the proportion of 95:5 – federal and regional budgets) that contribute to the transition of the economy to a qualitatively different pace of development and significantly improve the quality of life of the population;
- introduction of the «golden rule», according to which the expansion of the economy's potential and the financing of capital investments are carried out at the expense of a moderate increase in government borrowing based on the principles of long-term sustainability and balance of the country's budget;
- reorientation and prioritization of targeted inter-budget transfers in accordance with a differentiated approach to areas and measures of state support for different types of territories, taking into account the economic specialization of the Russian regions, the identified growth points and infrastructure constraints;
- setting targets for federal projects in the context of Russian regions, which will be reflected in agreements on providing financial support to regional budgets.

Implementation of results-based management principles at the regional level increasing the efficiency of public finances, and introducing modern budget technologies and tools into the budget process (starting with the development of revenue potential and ending with public debt management) have also become priorities for the socio-economic development of Russian regions. National projects should become a simple and effective tool for organizing both project and process activities of public administration

bodies, reflecting the relationship between the resources spent and the results obtained. The achievement of the established values of national project indicators at the regional level will be taken into account when compiling industry ratings of their performance, and in some cases – when evaluating the activities of governors and when financially encouraging regions through grants.

The involvement of regional public authorities in the implementation of national projects in the process of implementing the program principles of budgeting in the regions led to the formation of the following trends in the development of regional finance:

- implementation of budgeting in budget practice, which contributes to the coordination of strategic and tactical goals for the implementation of national projects;
- development of tools for improving the efficiency of budget expenditures by improving the quality of public services and completing the process of developing national projects for the balanced socio-economic development and improving the quality of life of citizens of the country;
- the main guidelines of national projects that have become tools for improving the quality of public finance management are the development of the social sphere, implementation of infrastructure projects, innovative development and modernization of the economy;
- state programs have an active impact on the economic development of certain territories (Crimea, the far East, Kaliningrad, the North Caucasus) and focus on financial support for projects aimed at solving systemic problems in these regions;
- improving the efficiency of public investment and procurement, and improving internal financial control and audit procedures.

Statistics and Data Analysis

In 2019-2024, it is planned to allocate more than 25.7 trillion rubles for national projects, of which 29.1% are non-budgetary sources; 51% – means of the federal budget of the Russian Federation and about 20% - means of regional budgets and state extra-budgetary funds.

National projects are financed on the basis of a decree of the Government of the Russian Federation. Average levels of co-financing for subsidies in the context of national projects, despite the threshold value of 95: 5, where 95% of co-financing is provided from the Federal budget, and 5% from regional and local budgets.

In fact, this minimum ratio is much lower and varies from 60: 40 to 82: 18 depending on the industry specifics of the national project (Fig.2).

Fig.2: Average levels of co-financing for subsidies in the context of national projects

The main task of the national project financing system in the country is to develop new schemes and mechanisms for financing national projects that can optimally combine different conditions and sources of financing, as well as attract significant resources to improve the quality and level of socio-economic development and life in the country on the principles of public-private partnership and initiative budgeting.

Test of Hypotheses

A systematic approach to the consideration of national projects dictates the need to analyze the economic processes that determine their implementation. In this regard, the assessment of the macroeconomic effect of the implementation of national projects is carried out in close relationship with the indicators of socio-economic development of the Russian Federation and the structure of GDP. The methodology for assessing the macroeconomic effect of national projects is based on the methodology for calculating GDP by expenditure method. For this purpose, as part of the assessment of the macroeconomic effect of the implementation of national projects, a General assessment and classification of Federal budget expenditures by economic factors that form the macroeconomic effects of supply and demand in the economy is carried out. The factors that determine the expenditure items of GDP form the demand in the economy (expenditure on final consumption, investment in fixed capital, government expenditure and net exports). In General, from the point of view of the elements of GDP use, these expenditures mainly form the final consumption of households and public institutions. At the same time, a significant share of expenditures, according to the provisions of the national accounting system, can be classified as investment and will contribute to the growth of demand for investment goods and services and the accumulation of fixed capital in the economy.

Results

1. The process of forming an integrated system of state and municipal finance management in 2019 in Russia at all levels of the state budget system has not yet been completed. A serious budget reform has been carried out, which has made it possible to build a budget process and link the achievement of efficiency between strategic goals, priority tasks of social and economic development in Russia and state programs, national and federal projects. National projects in the system of state and municipal finance have become a key mechanism for linking strategic and budget planning and increasing budget transparency at all levels of the country's budget system.

2. The program budget and its tools are the main mechanism for increasing the socio-economic efficiency of state expenditures. Since 2014, the main tool for improving the efficiency of federal budget expenditures has been the use of a program-targeted method for managing budget resources within the framework of state programs, which ensures their concentration on priority areas of socio-economic development.

3. The use of software tools makes it possible to increase the flexibility of budget resources management in achieving strategic goals of economic development, helps to minimize costs and improve the efficiency of providing all types of budget services. In the future, national projects should become a simple and effective tool for organizing both project and process activities of state government, reflecting the relationship between the resources spent and the results obtained within the framework of national projects.

4. Trends in public finance in Russia include increasing the independence of the executive authorities of the Russian regions, reducing the dependence of the consolidated budgets of the Russian regions on financial assistance from the federal budget of the Russian Federation, developing program-oriented methods and improving the quality of public finance management.

5. The specifics of implementing national projects require the creation of a quality standard for public services. National projects should address issues aimed at improving the quality of life, improving the living environment, ensuring equal opportunities for education, medical care and health restoration, developing social activity and protecting socially vulnerable groups. At the same time, personnel issues should be resolved. Creating comfortable living conditions for the population, including transport accessibility, development of telecommunications, engineering, and social infrastructure, and preservation and improvement of the environment and cultural and historical landscape of the territories. All this will help to improve the quality of life of the population and ensure the inclusion of the population in civil society.

6. Despite a number of unresolved issues, such as the inability to fully select all budgeted funds for national projects at the federal level. At the regional level, when financing expenditure obligations in the proportion of 95: 5 and its deviations (Fig. 2), there is often not enough money for the implementation of activities on national projects due to the lack of new project mechanisms and often the lack of funds from municipalities for the development of design and estimate documentation, the conclusion of state expertise bodies for capital construction projects.

7. The implementation of national projects in Russia is carried out on the basis of implementation plans and detailed schedules for their implementation. For planning and forecasting socio-economic performance indicators of national projects, it is carried out on key points, which also include an annual report on the progress of implementation and evaluation of the effectiveness of national projects, a report of the responsible executive on the progress of implementation and a consolidated annual report.

8. According to the results of monitoring, the implementation of national projects for 2019 in Russia was relatively effective – not all national projects have a high indicator of the control events that occurred, in addition, there is no opportunity to assess the effectiveness of spending the total amount of funding for all national projects.

9. The macroeconomic performance of national programs in the medium term is determined by the volume and dynamics of investment expenditures in the structure of their financing, which form a contribution to the operating flow. The total contribution to the use of GDP in 2019 is estimated at 25.7

trillion rubles (including 5.7 trillion rubles – in human capital, 9.9 trillion rubles – in creating a comfortable living environment and 10.1 trillion rubles in creating conditions for economic growth in the country), which is approximately 30% of GDP. According to the estimates, the financing of national projects made a positive and neutral contribution to the GDP growth rate.

10. The positive contribution from the increase in financing of national projects is offset by the negative impact of their inflationary depreciation. At the same time, the implementation of national projects practically does not lead to additional inflationary pressure, even contributes to a certain slowdown in inflation. The analysis of expenditures financed under national programs by component elements allowed us to structure the types of effects depending on the characteristics of the GDP structure – short-term (from the aggregate demand side), medium-term (from the supply side) and long-term (increasing factor productivity) macroeconomic effects.

Discussion of Findings

In international practice, the assessment of the macro-effect of the implementation of program-target planning in the budget process was as follows:

a) analysis of the structural elements of each of the projects as part of in-depth public administration reforms (Great Britain, Australia, New Zealand);

b) within the framework of separate programs for partial modernization of the public administration system that do not affect its fundamental foundations (USA, Canada, Ireland, the Netherlands, Denmark, Sweden, France);

c) within the constraints of the initiatives to improve the system of public finance management (Norway, Germany, Switzerland).

Each of the described methods involves the use of a final tool or driver for regulating the impact on the national project management system. As indicated in the study, in order to increase macro-efficiency from the implementation of national project activities, it is necessary to activate new growth drivers. Any of the state approaches determines the analysis of expenditures financed within the framework of national projects by component elements and types of effects, depending on the characteristics of the GDP structure: short-term effect-formed from the aggregate demand in the economy (wages, interest expenses, depreciation, profit margin); medium-term effect-formed from the supply side (investments in fixed assets, net exports, expenditures of state administration bodies); the long-term effect is formed by the drivers of economic growth (investment, new jobs, labor productivity).
These findings are supported by results of current studies.

Recommendations

The study recommends include:

a) based on the results of the evaluation structural elements of national projects, state and regional authorities should formulate consolidated proposals for:
- a system of goals and objectives for the implementation of national projects with a methodology for calculating new proposed indicators, including determining the methodology for collecting statistical data and calculating indicators, as well as searching for alternative sources of statistics;
- target values of indicators of national projects, including justification of forecast values of indicators;
- structure of the main activities of national projects, their expected results of implementation;
- a system of legal regulation measures aimed at achieving the goals of implementing national projects;
- the amount of financial support for the implementation of national projects, taking into account the maximum amount of financial support from the federal budget in accordance with the federal law on the federal budget for the next financial year and planning period.

b) to increase the macro-efficiency of the implementation of national project activities, it is necessary to activate such growth drivers:
- in the short-term as creating new jobs, increasing the level of remuneration of the population,
- in the medium-term – attracting investment,
- in the long-term – increasing the innovation of infrastructure, social sphere and industry in the country.

In the future, national projects should become a simple and effective instrument for organizing both project and process activities of public authority, reflecting the relationship between the resources spent and the results obtained.

Conclusion

National projects are a key mechanism for strategic and budget planning and increasing budget transparency at all levels of the country's budget system. The process of forming an integrated system of national project management is based on a program-oriented approach and requires the creation of a quality standard for public services to improve the level and quality of life of Russian citizens. As a result of the implementation of national projects for 2019, a number of unresolved issues were identified, such as the inability to fully select all budgeted funds for national projects at the federal level, although at the regional level there is often not enough money for the implementation of activities due to the lack of new project mechanisms and lack of funds at the local level. According to the conducted estimates, the financing of national projects has made a positive and neutral contribution to the GDP growth rate, but not all national projects have a high indicator of the control events that occurred, in addition, it is not possible to assess the effectiveness of spending the total amount of funding for all national projects. In order to increase the macro-efficiency of implementing national project activities, it is necessary to activate such growth drivers in the short-term as creating new jobs, increasing the level of remuneration for the population, attracting investment in the medium-term, and increasing the innovation of infrastructure facilities in the long-term.

Development of The Evaluation Tools of Budget Program Expenditure in The Russian Federation

Alla Y. CHALOVA

PhD, Assistant Professor, Assistant Professor of the Department for Finance and Prices of the of the Plekhanov Russian University of Economics, Moscow, Russia
TCHalova.AY@rea.ru

Abstract

The article is devoted to the methodology of evaluating the effectiveness of program budgets of the Russian Federation's expenditures and the substantiation of approaches to transform the existing methodology for assessing the effectiveness of state budgeting. There were described the existing tools of program budgeting in Russia and their evolution at the macro level, as well as the methods and approaches used to assess the effectiveness of government programs. Not only the author's interpretation of the term "efficiency of the state program" was given, but also the criteria of efficiency are proposed for evaluating state programs. The statistics on the effectiveness of the implementation of state programs in Russia by the integral indicator and on the cash execution of expenses from various sources were summarized. A set of measures is proposed to improve the methodology for assessing the effectiveness of state programs and approaches to managing program budget expenditures. Research also justified the proposal on increasing weight values for significance factors for measures and suggested indicators that have a direct impact on achieving the goal of the state program.

Keywords: Program Budgeting, State Program, State Program Effectiveness, Methodology For Evaluating Effectiveness.

JEL Classification: H11, H43, H50, H59

Introduction and Literature Review

The topicality of the research is determined by the need to develop a unified and understandable comprehensive, scientifically based methodology to measure the impact of program expenditure of the federal budget and other budgets of the budgetary system of the Russian Federation, which allows managing in the area of prioritization and rationale for funding state programs and projects. The concerns of ensuring the most cost-effective budget funds spending of at all levels of the budget system and increasing their impact on economic growth in Russia are associated with a set of unresolved issues that are related to theoretical and methodological basis for evaluating program budget expenditures in the context of the expansion of program budgeting tools.

Since the 2000s, there is a trend in the Russian Federation to accumulate simultaneously used program-targeted financing and management tools. The *federal targeted programs*, in which an attempt was made to ensure the balance between various resources (financial, human, material ones) to achieve the most important state goals and objectives as well as their connection with the priorities of socio-economic development, can be considered as first program budgeting tool at the federal level. Similar programs have been adopted at the territorial levels (*(regional target and municipal target programs*) for targeted financing of priority activities of territorial significance. Since 2005, *departmental target programs* have been included into the practice of budget funding of expenditures to finance sectoral areas and areas of government activity, covering specific profile functions and services of authorities. To enhance public investment and develop public infrastructure, another tool for program financing of budget expenditures, – the federal targeted investment program, has been introduced since 2010. It combined state investment projects related to the creation, reconstruction and modernization of capital construction projects at the expense of the federal budget. The need to

improve the RF citizens' standard of living, the quality of the existing social infrastructure, as well as the quality and accessibility of social services gave birth to a new program financing tool – *priority national projects*, included not only traditional elements of program planning (goals, objectives, events, deadlines), but also target indicators of their performance. So, since 2006, along with the federal targeted investment program, departmental target programs, numerous federal, regional and municipal programs, the following four priority national projects have appeared: "Education", "Health", "Development of the Agro-Industrial Complex", "Affordable and Comfortable Housing and Utilities for Citizens of the Russian Federation".

The development of program tools in the field of budget planning and financing did not stop there. Result-oriented budgeting received a further large-scale boost with the introduction of the program budget into the budget process, i.e. mandatory producing of part of budget expenditures in the format of state programs. So, since 2013, a program structure of expenditures has been introduced in Russia: first at the federal level, and from 2016-2017 – also at the level of constituent entities of the Russian Federation and municipalities. The main goal of introducing state programs was to increase the efficiency of budget expenditures in the context of a limited revenue base for budgets of all levels. The state (municipal) program financing would come both from budgetary funds and from extra-budgetary sources: bank loans, funds of public organizations, private investments, etc. However, the share of budgetary funds in the overall structure of financing sources of state (municipal) programs significantly exceeds the extra-budgetary component. A certain innovation in program management and financing of budget expenditures was the approval in the federal budget of five "pilot" state programs since 2018, for which project management mechanisms have been implemented. This tool, which in fact duplicated the previous ones, was aimed at overcoming the shortcomings of the existing system of functioning and implementation of state programs.

Finally, in 2019, 65 *federal projects* as part of 25 (of the 42 existing) state programs, were approved. These projects were combined according to national strategic development goals into *12 national projects*, as well as a Comprehensive Plan, including 7 federal projects implemented at the expense of the federal budget in as part of *the backbone infrastructure modernization and expansion program.* National projects have become the basic tool for achieving national development goals, as defined in Presidential Decree No.204 of May 7, 2018 and disclosed in the main areas of government activity until 2024. The integration of national projects in the program budgeting system was carried out in order to promote common actions of the state strategic planning and a unified state policy.

As can be seen from the review, program and project approaches, declared to be more effective in financing investment budget expenditures by state and municipal bodies, were each time clothed in new formats (tools), without fundamentally changing the very mechanisms of spending budgetary funds. The "long-livers" of the budgeting system remain federal target programs and national projects of the first wave, which have not been officially canceled and for which the required reports are regularly prepared (*Figure 1*).

Fig. 1: Structure of the state program

Such a "program and project compote" in the absence of a systematic mechanism for financing the above-mentioned state budgeting formats makes it very difficult not only the execution of expenses for these formats, but also an objective assessment of their effectiveness. This creates a multiplicity of models and hierarchical branches of management: the implementation of national projects is managed according to one model, the main directions of government and state programs - according to another, federal target programs (FTP) - according to the third. This creates duplicate processes that are identical in tasks and not integrated into a single system, which distorts managerial motivation. Under these conditions, expectations of new changes are being formed, in connection with which the desire to deeply develop some kind of tool does not arise.

At the same time, a large number of different plans and road maps are in operation. Despite the correct vector of actions and transformations undertaken by public authorities in the field of reforming budget planning and financing, budget spending does not yet have a proper impact on indicators of the social and economic sector, and the evaluation of programmatic expenditure formats is not standardized up to the level of a unified methodology with a transparent algorithm and criteria. This requires the authorities to reload the existing mechanisms for implementing state programs and the projects being part of them, including change in the methodology for their evaluation.

Hypotheses

What has been achieved so far in the field of development of program budgeting in the Russian Federation and implementation of high-quality goal-setting when planning budget expenses. For example, government pilot programs set goals that meet the SMART method. However, they are failing to combine goals and resources on a systematic basis. As a result, there are situations that arise in practice, when funds are spent efficiently (internal efficiency is high), while they are not aimed at achieving the goals set in the state program (effectiveness is low). The multi-level system for the implementation of activities and the achievement of targets within the framework of the state program is diffused ("blurred"), inaccurate and has a number of substantive problems and shortcomings.

So, the evaluation of the effectiveness of the implementation of state programs is carried out by its responsible executives (ministries and departments) on the basis of independently established

indicators and the methodology for evaluating effectiveness developed by them, is subjective and does not allow to really assess the progress of the implementation of state programs. In addition, when assessing the effectiveness of state programs, the volume of increasing receivables from responsible executives, as well as the increase in the cost of construction in progress, in which budget funds are actually frozen, but which does not affect the growth of the economy, are not taken into account.

In this regard, a reload of approaches to assessing the effectiveness of state programs in Russia is required in the direction of unification of the evaluated performance criteria for all state programs and their structural elements, as well as weight values awarded to them. We also believe that an increase in weight values for significance factors for measures and indicators that have a direct impact on achieving the goal of the state program, and a decrease in weight values for coefficients for events and indicators of secondary importance, i.e. having an indirect effect on the achievement of the program targets, it will provide a more adequate assessment of the effectiveness of the implementation of government programs and their impact on economic growth and improving the life of the Russian population.

Methodology and Data

The methodology for assessing the performance of a state program from an economic point of view is an algorithm to evaluate whether budget funds for approved specific activities both in the process and as a result of the implementation of the state program are being spent in an efficient manner. Based on the review of economic literature, there are three main areas that unite the whole variety of approaches to assessing the effectiveness of government programs:

1. The method of cost-benefit analysis (CBA - cost benefit analysis), the founders of which are C. Weiss and M. Scriven. To apply this method, it is necessary to evaluate all the required costs and possible benefits from the implementation of government programs in monetary terms. However, it is usually difficult to evaluate the social effect in monetary terms in practice. A modification of this technique is the discounted cash flows method, which is used to assess the effectiveness of investment projects. V. Livshits, A. Shakhnazarov and S. Smolyak believe that, in calculating the benefits that will be obtained from the implementation of government programs, all deferred income are to be considered.
2. The cost-effectiveness analysis (CEA) differs from the above method in that it eliminates the need to calculate all socio-economic effects in monetary terms. As an indicator, it uses the amount of resources per unit of result. However, this approach too would have disadvantages. If, when applying the first method, the comparison of net present value is carried out with zero, and the profitability index – with unity, then in the CBA, cost benefit analysis, there is no normative value with which to compare the obtained efficiency indicator. Still, we can widely use this approach to select the most effective program from the many existing ones.
3. The method of integrated assessment - a variation of wCEA, weighted CEA, used by the World Bank and in foreign practice as a whole. The essence of this approach is that weights are assigned to each direction of the program. The social effect is its conditional expression through an aggregated indicator. In this case, weights are set for the goals and objectives of the program, planning, management and monitoring, effectiveness and performance, that is, those areas that determine the requirements for the program and allow you to objectively form an idea of its quality.

In the Russian Federation there is used the methodology for assessing the performance developed by the Ministry of Economic Development of the Russian Federation. It involves evaluating by the following directions:

1) the degree of conformity of the established and achieved targets and indicators of state programs;
2) analysis of the execution of control events of state programs;

3) analysis of the fulfillment of expenditure obligations of the Russian Federation related to the implementation of state programs;
4) an assessment of the activities of promoters in terms of the development and implementation of state programs.
5) calculation of the integral indicator for assessing the performance of the state program in quantitative terms.

Consider the assessment methodology in the direction of the analysis of compliance with established and achieved target indicators and indicators of the state program (table 1).

Table 1: Methodology for analyzing the compliance of established and achieved target indicators and indicators of state programs

Overall assessment of achievement of planned values of indicators	$OD_{п} = \frac{к_1 * \frac{\sum_{i=1}^{M} ОД_{пi}}{M} + к_2 * \frac{\sum_{j=1}^{N} ОД_{пj}}{N}}{к_1 + к_2}$
Overall assessment of the achievement of the planned value of the q-th target indicator of the state program level, which is not an indicator of the Decrees of the President of the Russian Federation	$ОД_{п_i} = \frac{к_3 * \frac{\sum_{i=1}^{L} ОД_{П(ГП)_q}}{L} + к_4 * \frac{\sum_{w=1}^{P} ОД_{П(ПП)_w}}{P}}{к_3 + к_4}$
A general assessment of the achievement of the planned value of the j-th target indicator of the state program (subprogram, federal target program), corresponding and ensuring the achievement of the Decrees of the President of the Russian Federation	$ОД_{п_j} = \frac{к_3' * \frac{\sum_{q=1}^{L} ОД_{П(ГП)_q}}{L} + к_4' * \frac{\sum_{w=1}^{P} ОД_{П(ПП)_w}}{P}}{к_3' + к_4'}$
A general assessment of the achievement of the planned value of the w-th target indicator of the subprogramme level (federal target program), corresponding and ensuring the achievement of the Decrees of the President of the Russian Federation	$ОД_{П(ПП)_w} = СД_w * СД_{Д_w}$
The degree of achievement of the planned value of the w-th target of the state program	for indicators whose desired development trend is an increase in the value: $СД_w = \frac{ЗП_{Ф_w}}{ЗП_{П_w}}$
	for indicators whose desired development trend is a decrease in the value: $СД_w = \frac{ЗП_{П_w}}{ЗП_{Ф_w}}$
The degree of dynamics of the values of the w-th target indicator of the state program	for indicators whose desired trend is an increase in values: $СД_{Д_w} = \frac{ЗП_{Ф_w}}{ЗП_{Ф_{предыдw}}}$
	for indicators whose desired trend is a decrease in values: $СД_{Д_w} = \frac{ЗП_{Ф_{предыдw}}}{ЗП_{Ф_w}}$

The next stage is the analysis of the execution of control events of state programs, the methodology of which is presented in table 2.

Table 2: Methodology for the analysis of the execution of control events of state programs

General assessment of the implementation of the main activities of state programs in the reporting year	$OP_{OM} = \frac{\kappa_5 \frac{\sum_{i=1}^{M} H_{KC_i}}{M} + \kappa_6 \frac{\sum_{j=1}^{N} H_{KC_j}}{N}}{\kappa_5 + \kappa_6}$
Assessment of the onset of the q-th control event provided for in the implementation plan for the main activities of the state program, the implementation of which provides for the allocation of budgetary allocations	$H_{KC_i} = \frac{\kappa_7 \frac{\sum_{q=1}^{L} H_{KC_{(ПР)q}}}{L} + \kappa_8 \frac{\sum_{w=1}^{P} H_{KC(ДПГ)_w}}{P}}{\kappa_7 + \kappa_8}$
Assessment of the onset of the j-th control event for the main activities of the state program, the implementation of which does not provide for the allocation of budgetary allocations	$H_{KC_j} = \frac{\kappa_7' \frac{\sum_{q=1}^{L} H_{KC_{(ПР)q}}}{L} + \kappa_8' \frac{\sum_{w=1}^{P} H_{KC(ДПГ)_w}}{P}}{\kappa_7' + \kappa_8'}$
Assessment of control events for key events	$H_{KC_{(ПР)q}} = \frac{KC_{ФПР_q}}{KC_{ППР_q}}$
Evaluation of the onset of the w-th control event provided for in the detailed plan for the implementation schedule and not included in the implementation plan for the main activities of the state program, the implementation of which provides for the allocation of budgetary allocations	$H_{KC_{(ДПГ)w}} = \frac{KC_{ФДПГ_w}}{KC_{ПДПГ_w}}$

An interpretation of all indicators is presented *in Appendix 1*.

Evaluation of cash execution of state programs is carried out according to the following formula:

$$K_{уи} = \frac{\sum_{i=1}^{N} \frac{Касса_{OM}}{СБР_{OM}}}{N} \quad (1)$$

Performance evaluation of a responsible executor:

$$ОЭД = \frac{\sum_{j=1}^{T} \frac{КР_{факт\,j}}{КР_{план\,j}}}{T} \quad (2)$$

And finally, the integral indicator is calculated according to the following formula:

$$ГП_{ОЭ} = \kappa_9 * ОД_n + \kappa_{10} * OP_{OM} + \kappa_{11} * K_{уи} + \kappa_{12} * ОЭД \quad (3)$$

The integral indicator provides an assessment of the effectiveness of the implementation of the state program in quantitative terms and is based on the degree of achievement of indicators (indicators) at the level of the state program as a whole, its subprograms and federal target programs, the effectiveness of the implementation of the main activities, the level of cash execution and the performance of the responsible executive. The highest weighted value is given to the coefficient of achieving the planned values of the indicators of the state program, subprograms and federal target programs (K9) – 40 percent, the smallest – to the coefficient of the level of use of budgetary allocations in the implementation of the state program (K11) – 10 percent (Appendix 1). This generally contradicts modern practice of evaluating the effectiveness of the implementation of state programs by the Ministry of Finance of the Russian Federation in terms of the use of federal budget funds, in which the key criterion remains the amount of cash execution of program budget expenditures.

However, in 2018, changes were made to the assessment of the integral indicator in terms of dividing the degree of achievement of indicators at the state program level as a whole and at the level of its constituent elements (subprograms and federal target programs) with the assignment of different weighting factors (previously it was estimated by one indicator and, accordingly, one weighting factor), which in our opinion should increase the objectivity of this indicator. Thus, the integrated performance assessment for each state program since 2018 is estimated as a weighted average of 5 indicators (weighting coefficient of achieving the planned values of indicators (indicators) of the state program - 0,7; weighting coefficient of achieving the planned values of indicators (indicators) of subprograms (federal target programs) - 0,1; weighting coefficient for evaluating the effectiveness of the implementation of the main activities - 0,1; weighting coefficient for the level of use of budgetary allocations - 0,05; weighting coefficient evaluating the performance of the responsible officer - 0,05). Thus, the weight of the assessment of achieving the planned values of program indicators in the aggregate was increased from 40 to 80 percent in the overall assessment of the effectiveness of the state program. This confirms the thesis that when assessing the effectiveness of state programs, a significant factor is the level of achievement of planned values of indicators of the state program, even in the case of the presentation of forecast (preliminary) data

A key aspect of the methodology used in assessing the effectiveness of state programs is the use of weighting coefficients for achieving one or another indicator of the methodology, both at intermediate stages of evaluation for each criterion being evaluated, and at the level of the integral indicator. At the same time, the same significance factors are graded in relation to the individual estimated indicators of the methodology (indicators and control events) for various structural elements of the state program (subprograms, target programs, etc.) according to the criterion of their compliance or non-compliance with the goals of the Decree of the President of the Russian Federation, as well as the implementation plan of measures . Moreover, the weight of the coefficient of significance of achieving the indicator or the implementation of the control event within the state program that is not related to the Presidential Decree is significantly higher than the weight of the same coefficient for the estimated indicator that is not related to the implementation of the Decree of the President of the Russian Federation. Since during the period of implementation of state programs since the approval of the methodology under consideration both the new decree of the President of the Russian Federation was adopted, so a significant number of other regulatory legal acts with a huge list of targets, often not comparable, this creates significant problems when assessing the effectiveness of state programs, makes the methodology too bulky and difficult to use. In addition, the exclusion from the evaluation of indicators for which the responsible executors did not provide the actual values of their performance leads to an overestimation of the effectiveness of state programs, does not stimulate the responsible executors to update the list of indicators.

In connection with the integration of federal projects into the structure of the state program, the following additional problems arise when using this approach: there are no indicators to assess the contribution of the federal project to achieving the goals of the state program, there is no direct relationship between the key targets (indicators) of federal projects and the corresponding state program.

Speaking about the effectiveness of financing and implementation of state programs, it should be noted that the evaluation of state programs is a tool that allows you to create a view of the progress of the programs being implemented and helps to obtain information for making budget decisions regarding their further implementation. At the same time, the cost-effectiveness of the state program implies the implementation of all the main activities to achieve the specified targets (indicators), taking into account the use of the approved budgetary allocations on the planned dates. From this it is clear that the effectiveness of the state program is directly related to the cost effectiveness of program budget expenses.

In modern financial science and budget legislation there is no consensus on what is meant by the cost effectiveness of budget expenditures. In the public sector, it must be borne in mind that the cost is the entire amount of budgetary funds allocated to achieve the goals and objectives of the budgetary policy of the authority. Moreover, the allocated resources are determined by the budget law and

should be justified and sufficient to achieve the goals and objectives of the state program. The results of budget spending are usually of socially significant nature and should reflect the achievement of goals. The extent to which goals are achieved can be different, i.e. it demonstrates the level of compliance of the actual result with the planned goals and objectives, which is characterized by the indicator of "effectiveness". However, in our opinion, the concept of "*efficiency of a state program (project)*" is a much wider and more comprehensive concept from the point of view of not just the final result of the use of budget funds, which, no doubt, is an extremely significant factor, but also from the standpoint of conformity and priorities of spending budget funds for strategic (national) development goals, as well as the impact of the results of such spending on specific indicators of society and the state of the economy.

In this regard, the concept of "*efficiency of a state program (project)*" should be understood as the maximum compliance of the results of the activities implemented in this program with the planned growth of socio-economic development indicators for a certain period and the final needs of the population (maximum achievement of the final target indicators of the program), while ensuring timely financing of these activities in the prescribed amount. At the same time, an assessment of the effectiveness of budget expenditures under the state program should express the ratio of the degree of achievement of socially significant results (effects) to the level of actual use of budget funds with the purpose not to minimize costs, but to maximize the beneficial effect (economic, social, budgetary)

Since the term "efficiency" evolves the precise definition of the criteria for evaluation, such benchmark indicators must be determined to evaluate the efficiency of the program and projected expenditure. These criteria must meet the following requirements:

1) a clear statement of the goals of the state program (project), focused on its final measurable result;
2) justifying calculations of the amount of budget funds spent for the implementation of each of the provided goals and objectives of the state program (project);
3) the absence of duplicate expenses during the implementation of one goal (task);
4) the presence of an estimated relationship between the amount of budget funds for the state program (project) and the expected results of their use in budget reporting forms;
5) comparability of socially significant indicators and performance indicators of the state program (project).

Conclusion and Discussion

A statistical evaluation of the effectiveness of the implementation of state programs in the Russian Federation was carried out on the basis of the approved range of distribution of state programs in the following efficiency categories: high degree of implementation efficiency, degree of implementation efficiency above the average level, degree of implementation efficiency below the average level, low degree of implementation efficiency. The results are presented in table 3. As can be seen from the table, the criteria for the degree of effectiveness of state programs from year to year are constantly changing due to the constant change in the list of indicators and weighting coefficients in the evaluation methodology. At the same time, there is a steady increase in percentage criteria for such categories of state programs implementation efficiency as a high degree of implementation efficiency and a degree of implementation efficiency above the average level. At the same time, in relation to percentage values for the efficiency categories of the implementation of state programs with a degree below the average level and a low degree of implementation efficiency since 2018. That is, after changing the composition of the evaluated indicators in the methodology and the weight values of the coefficients, a tendency of their significant mitigation.

Table 3: Performance criteria for the implementation of government programs in the Russian Federation in 2015-2018, in percent

The degree of effectiveness of the state program	2015	2016	2017	2018	2019
high	more 92,7	more 91,9	more 92,7	more 94,6	more 94,2
above average	77,6-91,4	83,5-87,9	88,4-92,3	85,3-94,5	90,1-94,1
below the average	73,2-76,9	76,5-81,8	82,8-87,2	57,6-85,2	56,8-90,0
low	45,5-63,0	56,8-74,8	78,4-80,8	less 57,5	less 56,8

The results of evaluating the effectiveness of the implementation of state programs in the Russian Federation by the integral indicator according to the methodology of the Ministry of Economic Development of Russia for 2015 - 2018 are presented in table 4.

Table 4: Evaluation of the effectiveness of the implementation of state programs in the Russian Federation in 2015 - 2018, number of state programs

The degree of effectiveness of the state program	2015	2016	2017	2018	2019 (preliminary estimate)
high	3	6	6	22	23
above average	16	12	12	13	7
below the average	5	13	12	4	12
low	8	6	6	1	0

Despite the tightening of percentage assessment criteria for the upper values of the presented range, and as a result, an increase in the number of state programs with a high degree of efficiency and a decrease with a low degree of efficiency, the impact of state programs on the rate of economic growth in Russia remains extremely low. This is evidenced by the unsatisfactory significance of the dynamics of real incomes of the population, the growth rate of the Russian economy, the mortality rate and so on.

Statistical observations of the implementation of federal and regional programs and national projects integrated in them in Russia demonstrate a significant decrease in their cash execution from year to year, failure to achieve a number of planned indicators or lack of real results when formally achieved. Given that the financing of state programs comes from various sources, the assessment of their financial support should be carried out not only from the federal budget, but also from the budgets of the constituent entities of the Russian Federation, budgets of state extra-budgetary funds, as well as from extra-budgetary sources (table 5).

Table 5: Evaluation of cash execution of government programs in the Russian Federation by resource sources in 2015-2018, in percent

Source of financial support for the state program	**2015**	**2016**	**2017**	**2018**
Total	85,7	104,7	101,2	113,5
Federal budget	99,6	98,6	101,7	103,9
Consolidated budgets of the subjects of the Russian Federation	90,0	90,8	93,2	63,5
State extrabudgetary funds	95,3	103,8	96,6	90,1
Extrabudgetary Sources	47,4	214,5	58,8	162,7

The data in table 5 demonstrate a steady increase in the level of cash execution of state programs from 2017 from the federal budget relative to planned values. In relation to the execution of state programs at the expense of the consolidated budgets of the subjects of the Russian Federation (territorial budgets) and funds from extrabudgetary sources, extremely unstable dynamics is observed. We believe that in assessing the overall effectiveness of the implementation of state programs, it is advisable to include an assessment of the fulfillment of expenditure obligations at the expense of all sources of financial support for all participants in state programs, taking into account the financing of budgets of the constituent entities of the Russian Federation and extrabudgetary sources.

Of course, the federal budget plays a decisive role in the effectiveness of the implementation of state programs. However, if we evaluate the cash execution of federal budget expenditures for the implementation of state programs (including expenses for the implementation of pilot state programs) in relation to the approved indicators of the consolidated budget list, then for the period from 2015-2019. there is a steady downward trend (Table 6).

Table 6: The level of cash execution of expenditures of the federal budget of the Russian Federation for the implementation of state programs regarding the indicators of the consolidated budget list, in%

at the end of the reporting period	2016	2017	2018	2019
% execution	98,3	96,8	95,6	94,1

Expenditures for the implementation of national projects (programs) and the Comprehensive plan were fulfilled by 91.4% of the consolidated list, which is 2.8 percentage points lower than the average level of execution of federal budget expenditures in 2019 (94.2%). At the same time, 7 out of 12 national projects were completed below the indicated level. As a result, the total amount of unfulfilled assignments for national projects (programs) and the Comprehensive Plan amounted to 149.8 billion rubles, or 8.6% of the total budget list at the end of 2019. (table 7).

Table 7: Implementation of state programs and national projects in Russia in 2019

State programs	*Execution of government programs, in%*			
	more than 100	*94,2 - 99,9*	*90,1 - 94,1*	*56,8- 90,0*
Number of state programs	1	22	7	12
Total (42)	***94,1***			
National projects	*Execution of national projects, in%*			
	100 and more	*93,1 - 99,1*	*90-93*	*Less than 90*
Number of national projects	0	7	1	4
Total (12)	***91,4***			

The reasons for the unsatisfactory implementation of program tools in the field of state budgeting were the lack of a systematic mechanism for their formation, fulfillment, and evaluation. In particular, a number of state programs are not balanced in terms of goals and objectives; the target dates for the implementation of activities in individual programs are constantly shifting. So, by the end of the approved term of the next state program, the level of its implementation often is so low that its implementation is delayed for the next planning period. Such situation does not lead to an increase in the effectiveness of budget financing in terms of targeted and efficient use of the federal budget and other budgets of the budget system of the Russian Federation, but it also discredits the very idea of program budgeting in Russian practice, reduces the degree of trust and interest in government projects on the part of business.

The problems of implementing program tools for financing public expenditures can be grouped in accordance with the root causes of their occurrence as follows:

1) increasing the types and forms of program-target management documents;
2) the blurred concept of the consumer of the state program results and the lack of feedback on the program implementation results;
3) combining program-specific management and budgeting based on results;
4) combining change management and process administration procedures;
5) the public administration system focused on control, but not results;
6) reduced manageability of state programs as a result of including federal projects in their structure;
7) the formation of a significant number of requests for changing the passports of national and federal projects, providing for the adjustment of indicators and results, the redistribution of their financial support;
8) inferiority of the procedure for a comprehensive assessment of the effectiveness of state programs.

The result of these problems created a paradoxical phenomenon: despite the low performance or non-performance of individual expenditures for state programs and federal projects that are part of them, the planned targets of individual indicators were met or exceeded. Moreover, a number of results of federal projects do not affect the achievement of any target indicator of national projects.

The inferiority of complex procedures evaluation of the effectiveness of state programs leads to the fact that the evaluation of the effectiveness and efficiency of the state program implementation is based primarily on the principle of "plan - fact" and is largely similar to monitoring the fulfillment of instructions from the management of the relevant control units. The following paradoxical situation can arise in a situation where the conditional customer of the results of the state program is the agency that administers it: Evaluation of the effectiveness of the direct results is actually based on the data of the responsible performer, who forms plans on its own and provides information on their implementation. As a result, in most cases, the existing system of monitoring the implementation of state programs does not lead to management actions that are adequate to the actual situation.

The problems of program budgeting identified in the course of the study confirm the thesis about the need to “reload” state programs as a management tool. Each specific state program should be considered as a tool for managing changes in the relevant field of activity. It must respond to urgent challenges based on the real needs of society, citizens and business.

To improve the efficiency of program budgeting in Russia at the state level, we propose the following strategic directions (vectors) for the development of a methodology for evaluating state programs and tools for managing them.

1. To ensure the manageability of the federal budget expenditure results, it is necessary to take an inventory of existing formats for planning and budget spending, to combine program and project tools with similar goals, objectives and performance indicators. This should significantly simplify the budget process for responsible performers of expenditure obligations and increase the level of cash fulfillment of expenses.
2. To obtain objective results of evaluating the effectiveness of program expenditures, it is necessary to fully match the target indicators of each federal project that is part of a specific state program with the profile orientation of the target indicators (indicators) of this program. At the same time, the content of the main measures for assessing the effectiveness of the state program should be fully consistent not only with the goals of its separate federal projects, but also with the goals of the state program as a whole.
3. To determine the *significant factor* for each main event of the state program and its constituent federal projects, which should be used to evaluate the performance of the main activities. For example, measures that lead to the achievement of strategic (national) development goals (for example, increasing life expectancy) and that have a direct impact on the achievement of the state

program goal should have a greater weight in the model for assessing its effectiveness compared to activities related to additional goals and having an indirect effect on the achievement of the final goal of the project (program).

4. To conduct a thorough decomposition of indicators of national projects at the territorial level, as well as federal projects that are part of them. I.e., the target indicators of the federal project of the corresponding state program should be adapted for each region individually, taking into account its territorial features, available resources, and living standards of the population. At the same time, it is necessary to take into account differences in the starting conditions of regions when implementing national projects assigned to them.

5. To carry out a gradual transition from monitoring the occurrence of control events under the state program to monitoring the immediate and intermediate results of the state program.

6. Given the high dependence of volumes of financing of state programs from the approved indicators of the summary budget list in approving the budget law, it is proposed to assess the impact of new funding on the change in the integral indicator of the efficiency of the state program when changing the indicators of the summary budget list. If the assessment shows a significant decrease in efficiency in terms of an integral indicator, a program adjustment is required in terms of its indicators and the volume of planned measures. Otherwise, an assessment of the effectiveness of the state program completion with the changed volumes of its financing will give a negative result.

7. To transform the methodology of evaluation of state programs and their component projects through the division of its efficiency into two components: "financial efficiency of the state program" as a separate indicator, the purpose of which will be a direct assessment of the management quality of financing state programs, and "socio-economic efficiency of the state program", which involves assessing the degree of impact of state program measures and the timeliness and completeness of their implementation on specific indicators of economic and social development and the degree of customer satisfaction of the services provided under the program. This measure will allow to focus on the high-quality results of measures in managing the implementation of the state program. The financial efficiency of the state program, calculated at the end of the reporting period, will allow identifying possible ways to optimize the volume and format of its financing, while not harming the quality component of the implementation process and achieving the goals of the program.

8. To review the measures of responsibility for failure to achieve the indicators of national projects, which are fixed in agreements between the federal center and the regions on obtaining subsidies for co-financing regional projects. According to the current regulatory documents, the subject of the Russian Federation, in case of failure to achieve the results of the national project, must return 10% of the financial equivalent of the lost effect to the federal budget. At the same time, the effect of financing may appear beyond the time limits set for achieving national project indicators. In this regard, a preliminary comprehensive and objective assessment of the reasons and factors of the failure to achieve the planned indicators is required, which should be enshrined in the grant agreement.

These recommendations are aimed at improving the effectiveness of program-oriented management, objectivity of approaches to assessing the effectiveness of state programs and their "reloading" from the side of a positive multiplier effect on economic growth and improving the life quality of the Russian population.

Appendix 1

Interpretation of indicators of the methodology for assessing the effectiveness of a state program approved by the Ministry of Economic Development of the Russian Federation

$ОД_n$- a general assessment of the achievement of the planned values of the indicators of the state program, as well as subprograms and federal target programs;
$ОД_{ni}$- a general assessment of the achievement of the planned value of the i-th target indicator of the state program, as well as subprograms and federal target programs, which is not an indicator of Decrees of the President of the Russian Federation dated 05.05.2012 No. 596-606;
M - the number of target indicators of the state program (subprogram, federal target program), which are not indicators of Decrees of the President of the Russian Federation dated 05.05.2012 No. 596-606;
κ_1- significance coefficient for indicators of the state program (subprogram, federal target program), which are not indicators of Decrees of the President of the Russian Federation dated 05.05.2012 No. 596-606 (κ_1= 1);
$ОД_{nj}$ – a general assessment of the achievement of the planned value of the j-th target indicator of the state program (subprogram, federal target program), corresponding and ensuring the achievement of Decrees of the President of the Russian Federation of 05.05.2012 No. 596-606;
N – the number of target indicators of the state program (subprogram, federal target program), relevant and ensuring the achievement of Decrees of the President of the Russian Federation of 05.05.2012 No. 596-606;
κ_2 – significance coefficient for indicators of the state program (subprogram, federal target program), relevant and ensuring the achievement of the Decrees of the President of the Russian Federation of 05.05.2012 No. 596-606 (κ_2 = 1,2). In the absence of such indicators – ($\kappa_2 = 0$);
$ОД_{П(ГП)_q}$ – общая оценка достижения планового значения q-ого целевого показателя уровня государственной программы, не являющегося показателем Указов Президента РФ от 7.05.2012 г. №№ 596-606;
L – the number of target indicators of the state program level that are not indicators of the Decrees of the President of the Russian Federation dated 05.05.2012 No. 596-606;
κ_3 – significance coefficient for indicators of the level of the state program that are not indicators of Decrees of the President of the Russian Federation of 05.05.2012 No. 596-606 ($\kappa_3 = 1{,}5$);
$ОД_{П(ПП)_w}$ – general assessment of the achievement of the planned value of the w-th target indicator of the level of the subprogram (federal target program), which is not an indicator of Decrees of the President of the Russian Federation dated 05.05.2012 No. 596-606;
P – the number of target indicators for the level of the subprogram (federal target program), which are not indicators of the Decrees of the President of the Russian Federation dated 05.05.2012 No. 596-606;
κ_4 – significance coefficient for indicators of the level of the subprogramme (federal target program), which are not indicators of Decrees of the President of the Russian Federation dated May 7, 2012 No. 596-606 ($\kappa_4 = 1$);
$\kappa_3{}'$ – the coefficient of significance for indicators of the level of the state program, relevant and ensuring the achievement of Decrees of the President of the Russian Federation of 05.05.2012, No. 596-606. In the absence of such indicators - ($\kappa_3{}' = 0$);
$\kappa_4{}'$ – significance coefficient for indicators of the level of the subprogram (federal target program), relevant and ensuring the achievement of the Decrees of the President of the Russian Federation of 05.05.2012 No. 596-606. ($\kappa_4{}' = 1$) In the absence of such indicators - ($\kappa_4{}' = 0$);
$СД_w$ – degree of achievement of the planned value of the w-th target indicator of the state program (subprograms, federal target programs) in the reporting year;
$СД_{Д_w}$ – the degree of dynamics of the value of the w-th target indicator of the state program (subprograms, federal target programs);
$ЗП_{Ф_w}$ – the value of the w-th target indicator of the state program (subprograms, federal target programs), actually achieved at the end of the reporting period;

$ЗП_{П_w}$ – the planned value of the w-th target indicator of the state program (subprograms, federal target programs) for the reporting year;
$ЗП_{Ф_w}$ – the value of the w-th target indicator of the state program (subprograms, federal target programs), actually achieved at the end of the reporting period;
$ЗП_{Ф_{предыдw}}$ – the actual value of the w-th target indicator of the state program (subprograms, federal target programs) for the year preceding the reporting year;
OP_{OM} – general assessment of the implementation of the main activities of the state program in the reporting year;
H_{KC_i} – assessment of the occurrence of the i-th control event for the main activities of the state program, the implementation of which provides for the allocation of budgetary allocations;
M – the number of control events for the main activities of the state program, the implementation of which provides for the allocation of budgetary allocations;
κ_5 – coefficient of significance of control events for the main activities of the state program, the implementation of which provides for the allocation of budgetary allocations (κ_5=1). In the absence of such control events – ($\kappa_5 = 0$)
H_{KC_j} – assessment of the onset of the j-th control event for the main activities of the state program, the implementation of which does not provide for the allocation of budgetary allocations;
N – the number of control events for the main activities of the state program, the implementation of which does not provide for the allocation of budgetary allocations;
κ_6 – coefficient of significance of control events for the main activities of the state program, the implementation of which does not provide for the allocation of budgetary allocations (κ_6=1,2). In the absence of such control events – ($\kappa_6 = 0$);
$H_{KC_{(ПР)q}}$ – assessment of the onset of the q-th control event provided for in the implementation plan for the main activities of the state program, the implementation of which involves the allocation of budgetary allocations;
L – the number of control events provided for in the implementation plan for the main activities of the state program, the implementation of which involves the allocation of budgetary allocations;
κ_7 – the coefficient of significance of control events provided for in the implementation plan for the main activities of the state program, the implementation of which provides for the allocation of budgetary allocations ($\kappa_7 = 1{,}5$). In the absence of such control events - ($\kappa_7 = 0$);
$H_{KC(ДПГ)_w}$- assessment of the occurrence of the w-th control event provided for in the detailed plan for the implementation schedule and not included in the implementation plan for the main activities of the state program, the implementation of which provides for the allocation of budgetary allocations;
P – the number of control events provided for in the detailed plan for the implementation schedule and not included in the implementation plan for the main activities of the state program, the implementation of which provides for the allocation of budgetary allocations;
κ_8 – the coefficient of significance of control events provided for in the detailed plan for the implementation schedule and not included in the implementation plan for the main activities of the state program, the implementation of which provides for the allocation of budgetary allocations ($\kappa_8 = 1$). In the absence of such control events - ($\kappa_8 = 0$);
$H_{KC_{(ПР)q}}$ - assessment of the onset of the q-th control event provided for in the implementation plan for the main activities of the state program, the implementation of which involves the allocation of budgetary allocations;
L – the number of control events provided for in the implementation plan for the main activities of the state program, the implementation of which involves the allocation of budgetary allocations;
$\kappa_7{}'$ - the coefficient of significance of control events provided for in the implementation plan for the main activities of the state program, the implementation of which does not provide for the allocation of budgetary allocations;
$H_{KC(ДПГ)_w}$- assessment of the occurrence of the w-th control event provided for in the detailed plan for the implementation schedule and not included in the implementation plan for the main activities of the state program, the implementation of which provides for the allocation of budgetary allocations;

$\kappa_8{}'$ - the coefficient of significance of control events provided for in the detailed plan for the implementation schedule and not included in the implementation plan for the main activities of the state program, the implementation of which does not provide for the allocation of budgetary allocations ($\kappa_8{}' = 1$). In the absence of such control events - ($\kappa_8{}' = 0$)

$КС_{ФПР_q}$ – actual value for the q-th control event provided for in the plan for the implementation of the state program in the reporting year;

$КС_{ППР_q}$ - planned value for the q-th control event provided for in the plan for the implementation of the state program in the reporting year;

$КС_{ФДПГ_w}$ – the actual value for the w-th control event provided for in the detailed schedule of the implementation of the state program in the reporting year and not included in the plan for its implementation;

$КС_{ПДПГ_w}$ – planned value for the w-th control event provided only in the detailed schedule for the implementation of the state program in the reporting year and not included in the plan for its implementation;

$К_{уи}$ – level of use of budget allocations in the implementation of the state program;

$Касса_{ОМ}$ – cash expenses of the federal budget for the implementation of the main activities of the state program;

$СБР_{ОМ}$ – the amount of budget allocations for the implementation of the main activities of the state program according to the consolidated budget list;

$ОЭД$ – assessment of the performance of the executive of the state program in the reporting year;

$КР_{факт j}$ – actual value of the j-th criterion for assessing the performance of a responsible executor;

$КР_{план j}$ – planned value of the j-th criterion for evaluating the performance of the responsible executive;

T – number of evaluation criteria.

$ГП_{ОЭ}$ – integrated assessment of the effectiveness of the implementation of the state program;

κ_9 – weight coefficient of the overall assessment of the achievement of the planned values of the indicators of the state programs (subprograms and federal target programs) ($\kappa_9 = 0{,}4$);

$ОД_n$ - a general assessment of the achievement of the planned values of the indicators of the state program, as well as indicators of subprograms and federal target programs;

κ_{10} – weight coefficient of the overall assessment of the effectiveness of the implementation of the main activities of the state program in the reporting year ($\kappa_{10} = 0{,}3$);

$ОР_{ОМ}$ – general assessment of the effectiveness of the implementation of the main activities of the state program in the reporting year;

κ_{11} – weight coefficient of the use of budgetary appropriations in the implementation of the state program ($\kappa_{11} = 0{,}1$);

$К_{уи}$ – level of use of budget allocations in the implementation of the state program;

κ_{12} – weighting coefficient for evaluating the performance of the responsible executive of the state program in the reporting year ($\kappa_{12} = 0{,}2$).

Do Eco-Innovations Boost Entrepreneurship Development?

Abstract

In an entrepreneurship development, not only the system, structure and strategy are of paramount importance, but also the entrepreneurial culture. Entrepreneurs all around the world have continuously helped improve the global economy. The paper is aimed to identify the relationships between countries performance in eco-innovations implementations and indicators of enterprises development in the EU-28 countries. Set of dependent variables includes indicators of business units' quantity (existing and new enterprises), indicators of financial potential of enterprises development (investment and capitalization parameters), indicators of added value, created in national economy and indicators of employment structure. Set of independent variables is presented by Eco-Innovation Index and its structural components that illustrate inputs, activities, outputs, socio-economic and resource efficiency outcomes of eco-innovation practices. Research period covers 2010-2016. Calculations are realized with using random-effects GLS regression in Stata software package and intended at testing the following hypotheses: 1) intensification of the process of eco-innovation implementation is associated with a decrease in the number of enterprises due to enhancing requirements for their competitiveness; 2) the effects of progress in implementing eco-innovation are reflected in increasing the country's investment attractiveness and increasing company capitalization; 3) eco-innovation reduces the share of value added created by the real sector of the national economy; 4) implementation of eco-innovation has a positive impact on employment in entrepreneurship; 5) the impact of eco-innovation on entrepreneurship development is differentiated depending on the country's overall level of eco-innovation progress.

Keywords: entrepreneurship, business, eco-innovations, employment, value added, capitalization, investment.

Introduction

Nowadays sustainability of development stands core position not only in research of economic, social and environmental issues on country level, but in the context of entrepreneurship development, including innovative activities and progress. On the one hand, growth in economic impact on environment determinates enhancing research & development efforts (Haseeb et al., 2019b) and vice versa intellectual resources development creates conditions for economic growth and innovations

implementation (Golovchanskaya et al., 2018). Traditionally entrepreneurship and start-ups are considered as drivers of innovative economic growth (Khan, 2018; Pomianek, 2018; Vidic, 2018). Bhandari (2019) illustrates that innovations lead to sustainability. Interconnection of business performance and corporate social responsibility is confirmed by scope of studies (Adámek, 2018; Mayorova, 2019; Manzoor et al., 2019; Cismas et al., 2019; Fadyeyeva, 2019; Szanto, 2019) while linkage of environmental responsibility and entrepreneurship development is not so obvious (Myroshnychenko et al., 2019). Thus, research purpose is to ground interrelationships of eco-innovations and entrepreneurship development.

Literature Review

Before clarification of certain relevant factors affecting entrepreneurial activity, it is necessary to underline core perspectives of indicators of entrepreneurial performance and systematize indicators of eco-innovations measurement.

Nowadays entrepreneurial performance is no more measured only with financial indicators like sales, profit or variation of ratio of returns, but by far more important triggers of business development become orientation on sustainable development issues: namely, implementation of innovations, environmental-friendly technologies and resources, adoption of corporate social responsibility concept, active participation in local community development etc.

Nevertheless, there are still a lot of empirical research results aiming at assessing of drivers and inhibitors of only economic perspective of entrepreneurial performance. Namely, Korcsmáros and Šimova (2018), Bilan et al. (2019a), Cepel et al. (2019), Lesáková, Ondrušová, Vinczeová (2019), Svabova and Durica (2019) in their research tried to identify important economic factors that influence SME business environment in Czech and the Slovak Republic. They found out that SMEs development highly depends on financial conditions and credit availability. In addition, Ahmad and Atniesha (2018) grounded key role of the volume and structure of SMEs financing at start-up stage of their development. In turn, Boiko and Samusevych (2017), Ślusarczyk (2018), Mukherjee (2018), Bilan et al. (2018b), Liu et al. (2019) and Andrejovska (2019) mentioned tax incentives and tax competition as key factors of business performance and entrepreneurial development. Rahmatiah, Wiroto, and Taan (2019) based on Indonesian case pointed out that favorable social conditions is one of the core prerequisites of youth entrepreneurship. Kasztelnik and Brown (2019), Bilan et al. (2019d), Vasylieva et al. (2019a) also argued that social factors matter for business performance.

There is also a group of scientists arguing that institutional framework and regulatory quality significantly matter for entrepreneurial development. Namely, Marikina (2018) found that effective regulatory conditions help to reach environmental sustainability in Balkan states. Bilan et al. (2019c) also found empirical evidences that institutional conditions have impact on social and economic sectors, and certainly entrepreneurial environment. Zajkowski and Domańska (2019) identified that regional Business Support Institutions influence creation of new business entities.

Plenty of scientists found empirical evidences that innovations, creativity and new technologies have positive impact on entrepreneurial development. Specifically, Carrillo (2019) proved that expansion of R&D expenditure positively affected country economic development and business competitiveness. While Karbowski (2019) revealed that cooperative and non-cooperative R&D strategies influence product innovation and business performance. Moreover, Potjanajaruwita and Girdwichai (2019), Bilan et al. (2019b) also mentioned that information technologies and creative innovations matter for business sustainable development. In turn, Drejeris and Oželienė (2019) empirically proved that technological perspective might be added to the set of traditional corporate sustainable development dimensions (economic, social, environmental and institutional). Kyrychenko et al. (2018), Zakharkina et al. (2018), Mikhaylova et al. (2019), Susanto, Abdullah, and Wardi (2019), Mekhum (2020) also proved that innovations are core trigger of entrepreneurial development. Crucial role of Industry 4.0 in ensuring of SMEs performance and sustainability is confirmed by Haseeb et al. (2019a).

Despite existence of plenty researches that proved significance of innovations for entrepreneurial development, there are also some empirical evidence of the opposite trend. Certainly, Taçoğlu, Ceylan and Kazançoğlu (2019) while analyzing determinants of textile industry development in Turkey pointed out that open-mindedness and employee qualification are the most influential factors of business development, while product design and product innovation have no significant impact on performance indicators. Meanwhile, Kaur and Mehta (2019) also did not observe significant gap of productivity, employment and output between high-tech and low-tech manufacturing industries.

Nevertheless, there are also set of researches aiming at clarification of ecological and environmental factors' effect on entrepreneurial development. Namely, Dabyltayeva and Rakhymzhan (2019) underline that active implementation of green economy concept in Kazakhstan allow achieving positive macroeconomic effects and ensure qualitative transformation of business environment. Meanwhile, Salam and Senasu (2019) aimed at constructing of business sustainable development measurement system that includes economic, social and environmental dimensions. They underlined such influential environmental determinants of entrepreneurial development as environment management system parameters, energy use and greenhouse gas emission, waste and wastewater management. Additionally, Akhtar (2019) and Pechancová et al. (2019) also revealed that active adoption of environmental management system has positive and significant impact on business competitiveness and company performance. Moreover, Sokolenko, Tiutiunyk, Leus (2017), Bilan et al. (2018a), Mentel et al. (2018), Yevdokimov et al. (2018), Vasylieva et al. (2019b), Lyeonov et al. (2019), Dwikuncoro and Ratajczak (2019), Pisar & Bilkova (2019) also support the idea that greenhouse gas emission, renewable and traditional energy consumption influence entrepreneurial sustainable development. Meanwhile, Chygryn et al. (2018) argued that emission of green bonds might positively influence business environmental performance.

Ślusarczyk (2011) proves that limitations of negative impact of industry on the environment as the part of EU protection policy lead to the reduction of business competitive advantages and might determinate slowdown of national economy. Pohludka, Stverkova, and Ślusarczyk (2018), Vaitkevicius et al. (2019) highlight an importance of sustainable business development through the implementation of enterprise resource planning system that has positive impact on company's financial performance. In addition to existent positive influence of internal business innovations (i.e. supply chain management) on the company's competitive advantages (Harsasi and Minrohayati, 2017) some extensions of its effects on the growth of social and environmental sustainability of enterprises were revealed by Kot, Haque and Kozlovski (2019).

In order to investigate eco-innovations influence of entrepreneurship development the following hypotheses have been put forward:

H1: eco-innovations implementation has an inverse relationship with the number of enterprises in economy;
H2: progress in eco-innovations lead to an increase of financial indicators of entrepreneurship development;
H3: eco-innovative development inhibits share of value added in real economy;
H4: eco-innovations have a positive relationship with employment in entrepreneurship;
H5: linkage of eco-innovations and entrepreneurship indicators depends on the general level of country's eco-innovation progress.

Research Methodology

The purpose of the study is to identify the relationship between the country's eco-innovation level and entrepreneurial development. Background of research is presented by Eco-Innovation Index, which was developed by European Commission for illustration of EU countries performance in eco-innovations implementation and achievement of sustainability progress. Such Index consists of 16 components characterizing different directions of ecological innovations both on state and enterprises levels that are aggregated into 5 groups. Thus, set of factor variables of current research is presented by following indicators:

– Eco-Innovation Index – general level of country's eco-innovation progress measured in reference to EU-average level, where higher value of index illustrates better country's position;
– Eco-innovation inputs: 1) Governments environmental and energy research and development appropriations and outlays, % of GDP (R&D appropriations); 2) Total research and development personnel and researchers, % of total employment (R&D personnel); 3) Total value of green early stage investments, USD/capita (Green investments);
– Eco-innovation activities: 1) Enterprises that introduced an innovation with environmental benefits obtained within the enterprise, % of total firms (Enterprise environmental benefits); 2) Enterprises that introduced an innovation with environmental benefits obtained by the end user, % of total firms (User environmental benefits); 3) ISO 14001 registered organizations, per mln population (ISO 14001);
– Eco-innovation outputs: 1) Eco-innovation related patents, per mln population (Patents); 2) Eco-innovation related academic publications, per mln population (Academic publications); 3) Eco-innovation related media coverage, per numbers of electronic media (Media coverage);
– Resource efficiency outcomes: 1) Material productivity, GDP/Domestic Material Consumption (Material); 2) Water productivity, GDP/Water Footprint (Water); 3) Energy productivity, GDP/gross inland energy consumption (Energy); GHG emissions intensity, CO2e/GDP (GHG emissions);
– Socio-economic outcomes: 1) Exports of products from eco-industries, % of total exports (Exports); 2) Employment in eco-industries and circular economy, % of total employment (Employment); 3) Revenue in eco-industries and circular economy, % of total revenue (Turnover).
Entrepreneurship development is presented by different dimensions:
– Business quantity indicators: 1) Population of active enterprises, number (Active); 2) New limited liability corporations, number (New business); 3) Density of new registrations per 1,000 people (Density);
– Added value indicators: 1) Value added in agriculture, % of GDP (Agriculture); 2) Value added in industry, % of GDP (Industry); 3) Value added in manufacturing, % of GDP (Manufacturing);
– Employment indicators: 1) Contributing family workers, % of total employment (Family workers); 2) Self-employed workers, % of total employment (Self-employed); 3) Wage and salaried workers, % of total employment (Employees);
– Financial indicators of entrepreneurship development: 1) Foreign direct investment net inflows, % of GDP (FDI); 2) Market capitalization of listed domestic companies, % of GDP (Market capitalization).
Country sample consists of 28 countries that are European Union members. Research period covers 2010-2016, based on statistical data from European Commission and World Bank databases. Empirical research is realized by panel data regression analysis in Stata software package. Application of the Breusch and Pagan Lagrangian multiplier test to the sample of statistics showed the presence of random effects, therefore random-effects GLS regression was chosen as the method of calculation.

Results

The overall impact of the change in the country's Eco-Innovation Index position on the dynamics of entrepreneurship development indicators is demonstrated by the results presented in Table 1.

Table 1: Results of Eco-Innovations Index impact on entrepreneurship development

Dependent variables		EU-28 countries	Eco-innovations leaders	Eco-innovations performers	Catching up eco-innovations

*Note: *** – p<0.01; ** – p<0.05; * – p<0.1.*

The Eco-Innovation Index assessment methodology provides the classification of countries into three groups by eco-innovation activity level: eco-innovations leaders, eco-innovations performers and countries, catching up eco-innovations. Thus, in order to compare the intensity of the impact of eco-innovation on the parameters of entrepreneurial development at different stages of country's eco-innovation development, the relationships between the indicators was also evaluated in terms of different groups of countries.

The evaluation results show that the maximal impact eco-innovations have on the employment structure in the economy. Thus, the growth of the country's progress in the implementation of eco-innovation leads to an increase in the share of wage and salaried employees, at the same time having inverse relationship with the parameters of self-employed and family workers. Such relationships illustrate increase of opportunities for additional employment of workers as a result of eco-innovative economy development. On the other hand, the results show a decrease in the share of value added created by the real sector of the economy (agriculture), which is caused by a decrease in the level of use of resources in the eco-innovative approach to doing business. At the same time, there is no significant results of the impact of eco-innovations on quantitative and financial parameters of entrepreneurship development.

Calculations for countries with different levels of eco-innovation activity revealed the following patterns:

– eco-innovation leaders are characterized by the lack of significant impact of eco-innovation progress on quantitative indicators of entrepreneurship development, while the countries that are catching up eco-innovators show a strong positive effect in these terms. Eco-innovations performers have the weak relationship between eco-innovation and number of enterprises;
– changes in value added as a result of eco-innovation are only confirmed for eco-innovations leaders. Positive effect of value added in industry illustrates the results of production based on more efficient use of resources;
– the results of assessing the impact of eco-innovation on employment obtained for eco-innovation performers and countries catching up eco-innovations are similar to the trends found in estimating the total sample, while eco-innovation leaders do not show a statistically significant correlation between indicators, which may be the result of an already formed employment structure at earlier stages;
– the impact of eco-innovation on financial performance of business development has been confirmed only for eco-innovation leaders. The reversed identified impact may be the result of the transformation of the priorities of doing business from financial to non-financial indicators in the conditions of significant level of eco-innovation progress.

At the same time, the results of assessing the impact of separate components of the Eco-Innovation Index on business development are interesting. Table 2 shows the results of the impact of different dimensions areas and indicators of Eco-Innovation Index on quantitative parameters of business development and value added indicators. Thus, increase in eco-innovation inputs determinates the growth of new enterprises density both in general and through the channel of R&D personnel growth.

On the other hand, growth of green investments has an inverse impact on the number of active enterprises.

Growth of companies certified by ISO 14001 requirements stimulates an increase in quantity of new and existing enterprises, while expansion of environmental benefits achieved by enterprises for their own goals leads to the reduction in active enterprises quantity. Improvements in eco-innovation outputs does not determinate rise of business number, whereas resource efficiency and socio-economic outcomes indicators demonstrated positive significant relationships with new and existing business quantity in terms of influence of separate indicators. Thus, improving the country's performance in the direction of GHG emissions is a driving factor for the growth of active enterprises number in the economy, while water productivity has strong significant impact on the creation of new business units. At the same time material productivity is the factor inhibiting new enterprises creation in terms of their density. On the other hand, development of socio-economic outcomes forms a background for the rise of new business density.

The growth of eco-innovation inputs has no significant impact on value added in any of the studied economic sectors. Along with this, the share of value added in the industry is reducing due to the influence of environmental benefits, creates by enterprises for final user and share of value added in agriculture is mostly inhibited by intensification the process of ISO 14001 certifying.

An impact of eco-innovations outputs on the value added in economy in presented with decrease of value added in agriculture in a result of academic publications and media coverage indicators. Most indicators of resource efficiency outcomes demonstrate strong inverse relationship with value added by real economy, except material productivity improvement that leads to the growth of manufacturing value added to GDP ratio. Identified direct linkage between socio-economic outcomes of eco-innovations and value added in industry and manufacturing represents the contribution of eco-innovative enterprises in real production growth.

Changes in employment structure and financial opportunities of business development under the influence of eco-innovations parameters are presented by the data of Table 3.

Table 3: Results of eco-innovations impact on indicators of employment structure and financial indicators of entrepreneurship development

*Note: *** – p<0.01; ** – p<0.05; * – p<0.1.*

The calculations showed that almost all indicators of the country's eco-innovative development are determinants of changes in employment structure, except eco-innovations inputs. Results obtained for the dimension of eco-innovation activity demonstrate significant positive impact of eco-innovations on the growth of the share of wage and salaried workers simultaneously with the reducing of the share of self-employed and family workers. Resource efficiency and socio-economic outcomes indicators are characterized by similar effects of employment structure changes to the previous results.

It should be noted that revealed connections between eco-innovations and business financial indicators are multidirectional in the scope of dimensions and indicators of eco-innovations. So stimulating effect of eco-innovations implementation on the growth of financial potential for enterprises is presented by socio-economic and resource efficiency outcomes, while eco-innovations inputs, activities and outputs have rather negative impact.

Conclusions

According to formulated research hypotheses calculations were divided into 5 sections, which illustrated effects of eco-innovations implementation in different dimensions of entrepreneurship development to check out the hypotheses of the research. Obtained results allowed confirming H4 and H5 completely. H3 is mostly confirmed at the level of separate eco-innovations dimensions, while revealed effects are not consistent for the countries in different eco-innovation progress. Results research aimed to test H1 and H2 did not allow drawing unambiguous conclusions about the direction and strength of existing linkage and should be completed by additional studies. In general, it can be summarized that eco-innovations have limited positive impact on business development in the context of employment growth, increasing the competitiveness of existing enterprises and a certain increase in the financial attractiveness of investments. It was found that in the early stages of eco-innovation progress of the country there is a more intense impact of eco-innovation on business development than in countries with a formed eco-innovation economy. In general, research shows that eco-innovation has a moderately stimulating effect on entrepreneurship development in terms of ensuring the growth of companies' number and employment. On the other hand, strong impact of eco-innovation on the financial performance of entrepreneurial development is not revealed. These results are of great practical importance in terms of improving the coordination of economic and environmental policies of countries.

Limitations and future directions of the study

Obtained results reflect relationships in the sample of countries from the European Union. To identify more general trends, the sample of the research have to be broadened by geography and level of economic development of countries. In the context of further research, the most promising area is to study the specifics of the relationship between eco-innovation outcomes and entrepreneurship development. The current study allowed suggesting that resource and economic outcomes might have the greatest potential to influence the financial performance of companies that should be realized with additional investigations.

Acknowledgments

The research was supported by the Ministry of Education and Science of Ukraine and performed the results of the project "Structural-functional multiplex model of ecological tax system building in Ukraine in the context of national security" (registration number 0119U100759).

Abstract

Systematization of the scientific researches indicated the absence of unique and generally acknowledged term to define the essence of green brand of companies. Thus, absence of unique definition prevents the effective promotion of environmentally friendly activity and increases the level of distrust in society. In view of this, this study is aimed to provide the bibliometric analysis investigating the scientific research papers related to green branding issues in order to contribute to the theoretical development in this field and popularize green brands among the academic community and online users. The authors have formulated a hypothesis that green brands positioning is more effective than sustainable brands, eco-brands or sustainability brands for promoting green company policy. To develop formulated hypothesis, Google Trends analysis, Google Ngram Viewer overview, Scopus and VOSviewer bibliometric analyses were used. The current study involved data from 214 papers investigating the issues on green brands published from 2001 to 2019. The findings from VOSviewer identified 9 clusters of papers with 124 links where green brands were investigated from the different points of views. The obtained results have proved the formulated hypothesis. Moreover, it was justified green brands' web-search requests were the most popular when online users look for information to increase their awareness level on environmentally friendly issues. Furthermore, the authors found out the outstanding research interest to green brands was in 2017, while the USA was most of all interested in this issue. Finally, this study provided directions for future researches in order to popularize green brand positioning.

Keywords: bibliometric analysis, green brand, Scopus, VosViewer.

Introduction

It is a world tendency that companies increase the volume of green investments to investigate and implement the modern environmentally friendly methods of production and distribution as well as eco-programs and shares to position themselves as a green brand. Increasing the green consumer number indicates the necessity to consider the principles of sustainable development in the process of formulation of the marketing mix and transform sustainability into the marketing strategic instrument that intensifies the competitive advantages of the company. The different terms could be used to describe the environmentally friendly intentions of business activity.

Thus, the following terms such as «green brand», «sustainable brand», «sustainability brand», «eco-brand» are used by companies promoting themselves, Internet users looking for information on environmentally friendly topics and researchers investigating in this field. In view of this, it was noticed the increasing number of scientific publications in the field of green branding. The focus on green brand in the analyzed publications, allow formulating the hypothesis that for promoting green company policy green brand positioning is more effective than sustainable brands, eco-brands or sustainability brands. In accordance, the huge number of scientific papers on issues of green branding allows testing the formulated hypothesis by the methods of bibliometric analysis. Thus, this article is aimed to analyze the structure and dynamic of scientific publications in the field of green brands. It should be noted that nowadays Internet is the most powerful platform for satisfying many people's needs by searching any information, doing business, promoting brands etc. in turn, the web-research analysis makes it possible to identify the preferences of the potential clients, formulate the effective strategy to promote green brands taking into account the trend fluctuations. Using the modern tools of analysis on the base of the contemporary analytical database formulates the preconditions to win higher company positions in the search engines and, as a result, the companies have the opportunities to set their trends.

Literature Review

Using Google Ngram Viewer online tool (Ngram, 2020) it has been founded, that the scientific interest to green brand appeared after the 1860s which is associated with the machine production transition and distributive marketing development (Fig 1). Whereas, the term «sustainable brand» appeared after the 1980s while the political and academic communities became to take more attention to the issues of sustainable development.

Fig. 1: The frequency of using sustainable and green brand in scientific papers to 2000 (Ngram, 2020)

The systematization of scientific sources indicates that the tools of Internet analytics have been growing in popularity as in the business, as in the academic community. In the scientific paper (DRAKE et al., 2012) the American scientists Michael S. Drake, Darren T. Roulstone и Jacob R. Thornock proposed to use Google Trends to investigate the factors influencing on the decision-making process by the potential investors. In turn, Choi H. and Varian H. in their work (CHOI et al., 2012) demonstrated how Search Engine data could be used to predict economic performance. Moreover, in the scientific paper (Kirichenko et al., 2013). The description of the modern Search Engines to investigate the dynamic pattern of the population's interest to some events in the society and in the government was presented. Zaharov V.P. emphasized on the linguistic mechanism of web-search request formulating (Zakharov, 2005). Furthermore, the authors of research (Klimchuk et al., 2014) investigated the popularity of project management theme in banking among Internet users by the means of online requests analysis. The research studies (Greco, 2018; GrenÄÃ-kovÃ¡ et al., 2019) were aimed to investigate the online analytical tools to analyze big data.

The studies in the field of green branding and sustainable development were included in the current paper (Mikalauskiene et al., 2019; Medani, 2019; Lušňáková et al., 2019; Kwilinski et al., 2019b; Kot et al., 2019). Thereby, the researches in the papers (Madden, 2012; Atkočiūnienė et al., 2019; Chygryn et al., 2018; Dabija et al., 2019; Derevianko, 2019) have analyzed how sustainable development and green image of companies related to macroeconomic stability and companies' performance. The authors emphasized that the more people are aware of sustainable development necessity, the more they concern about environmental problems and try to protect the environment. As a result, it influences economic stability increasing the economic growth of the country.

In the following papers (Purgat, 2018; Zhao et al.,2019; Yuri et al., 2018; Shevchenko et al., 2016; Roszko-Wójtowicz et al., 2019; Kiseľáková et al., 2019) the EU experience in providing the support of sustainable development and a new model of green brand popularization were investigated. In the frame of the mentioned papers, the authors considered the determinants of sustainable development and measured the average innovativeness change in green economy over time in the EU member states. In the scientific article (Bethlendi et al., 2019; Bilan et al., 2018; Kološta et al., 2019; Sotnyk et al., 2013; Haseeb et al., 2019) the authors investigated the relationship between brand management and economic stability, where the strong impact of brand management on company development has been found.

In view of this, in the paper (Kwilinski et al., 2019a) the marketing tools and innovative approaches to popularize green brands were proposed. The researches in their publication (Pechancová et al., 2019; Hasan et al., 2019; Csaba Fogarassy et al., 2018; Cebula et al., 2018; Bilan et al., 2018a; Onishi et al.,2018; Popkova et al., 2018; Sokolenko et al., 2017; Sotnyk et al., 2014) investigate the environmental management systems as effective tools to boost the development of companies' green brands. The analysis of green GDP of green activities in developing and developed countries was conducted in the researches (Stjepanović et al., 2019; Bilan et al., 2019; Lyulyov et al., 2017; Vasylieva et al., 2019b; Moskovicz et al., 2018; Vasilyeva et al., 2019a). The systematization of mentioned above scientific papers indicates that the issues on positioning green brands are investigated from a holistic perspective. In view of this, under the studying the following hypothesis was checked:

H1. Green brand is more effective for promoting green company policy positioning than sustainable brand, eco-brand or sustainability brand.

Methodology

In the frame of this paper, the most relevant data retrieval to look for the highlighted research questions was conducted into several steps. Firstly, based on the Scopus database (Scopus, 2020), a search request of publications including the following keywords such as «green brand», «sustainable brand», «eco-brand», «sustainability brand». As a result, the current study involved data from 214 papers published in 7 languages conducted from 2001 to 2019. The Scopus bibliometric analysis on the issue of the green brand was conducted from the view of the dynamic of publication activity and citations, considering the most interested researchers in this issue, related subject areas for green brands research as well as countries.

Furthermore, in the current article, the analysis of keywords popularity was conducted with Google Trends analytical tool (Google, 2019) which is a simple and convenient web-application to analyze the popularity and seasonality of web-search requests. It should be noted, that the results demonstrated the frequency of web-search request to the total number of research requests in the different world part and languages in order to estimate the impact of geographical features on the popularity of the web-search or the topic in general; to specify how optimize the content of the site to get more traffic; to monitor the popularity of the different goods, news in the Internet; to analyze the dynamic of web-search requests during the time period and detect the seasonal dependence, etc.

Thereafter, investigating the thematic scope of the chosen publications was conducted by VOSviewer bibliometric tool that allowed building a terminological map on the base of keywords co-occurrence in the names and abstracts of the scientific papers. It is worth to note that the results of VOSviewer

bibliometric analysis are visualized by a thematic map that is formulated with the clusters. Moreover, each cluster has its own color that shows which keywords are used in the same study. The distance between circles shows the frequency of using the keywords. It means the shorter distance is, the more frequently the keywords used in study. Furthermore, the more the size of circles, the more citations and co-occurrence keywords could be in the study. In turn, in the frame of this paper, the minimal number of co-occurrence key words was chosen three. As a result, for each of 45 words, the total strength of the co-occurrence links with the other key words was calculated.

Results

In purpose to investigate the most appropriate keywords for the companies providing environmentally friendly activity, the Google Trends analysis has been conducted. Thus, using this tool frequency of web-search requests of the following keywords such as «green brand», «sustainable brand», «eco-brand» were analyzed s from September 2016 to July 2019 (Fig 2)

Fig. 2: The popularity dynamic of web-search requests in Google Engine from 2016 to 2019 (Google Trends, 2019)

The obtained results indicated that «green brand» (46 points) web-search requests were more popular than «sustainable brand» (26 points) or «eco-brand» (25 points). However, we could assume that the «green brand» web-search requests the Internet involved not only information on ecological issues, but design or color. In view of this, we concretized our parameters and analyzed the above-mentioned requests in the categories «Business and industry» as well as «Science». According to the results, we found out that the most popular web-search request in the category «Business and industry» were «sustainable brands», while in the category «Science» were «green brand» web-search requests. Thereby, relying on the empirical observation it was founded that the business sector and academic community had different definitions describing the environmentally friendly and responsible brands. In turn, these contradictions rise the complexities in the process of promoting environmentally friendly brands.

Systematization and summarization of scientific resources in the investigated field (Pham et al., 2019; Nemmiche et al., 2019: Mentel et al., 2018; Hitka et al., 2019; Danaj et al., 2018; Bilan et al., 2019c; Baldo, 2018.) indicated that the concept of green brands demands more attention while the academic community has taken more attention to researches in «green marketing». It should be noted that in the studies (Tresna et al., 2019; Bilan et al., 2019; Vaitkevicius et al., 2019) considered «green brands» to be some messengers to transfer information about unique and ecologically clean brand features that decrease the negative impacts on the environment. On the other hand, in the research papers (Yakubu et al., 2019; Sriyana, 2019; Skačkauskienė et al., 2019; Huang et al., 2014) «sustainable brands» described as the brands designed that increase the company income while developing social welfare

and preserve the environment providing green investments in their activities. According to Fig 3, it was found that green brand keywords most of all used in the articles on issues of green marketing and sustainability investigations.

Fig. 3: Bibliometric coupling of the keywords in the investigated articles

2001-2019 (VOSviewer 2020)

In this paper, the thematic scope of investigating papers was conducted by the bibliometric tool VOSviewer allowing build the terminological map on the base of coupling keywords in the names and abstracts of the chosen articles. Having limited frequency of keywords to three items, it was detected 45 items gathered into 9 clusters, joined by 124 links (the total link strength was 178) that link keywords according to thematic proximity (Fig 3). This map visualizes the frequency of using the keywords (the size of circle), link strength (the closer, the more strength) and different conjunctions of keywords as inside clusters, as outside them. According to the developed map (Fig 3) the following circles consist of (in decreasing quantity of keywords): 1) brand credibility, brand equity, brand image, communications, corporate branding, identity, image, strategy; 2) brand extension, branding, brands, consumer behavior, environmental sustainability, green marketing and trust; 3) brand loyalty, green brand, green brand loyalty, green perceived risk, green perceived value, social media; 4) corporate social responsibility, green advertising, green brands, greenwashing, legitimacy, stakeholders; 5) green brand attachment, green brand equity, green brand image, green satisfaction, green trust; 6) brand, climate change, conjoint analysis; 7) green brand knowledge, green brand positioning, sustainability, sustainable brands: 8) city branding, green branding; 9) brand attitude, organic food.

Based on the Scopus analytical tool, it was founded that the publication activity in the field of green brand has a positive tendency (Fig 4). Furthermore, it has been established that the hugest share of publication on green brands were in the United States (17%), China (12%), India and Taiwan (10%), Australia (7%), South Korea (6%) as well as United Kingdom (5%).

Fig. 4: The dynamic of published articles for 2001-2019 (Scopus, 2020)

Moreover, the citation level of the investigated articles increases every year. Studies on green brand become more popular and have higher value for society. In 2018 255 articles were published while it has been the highest explosive growth for analyzed period. According to the Fig 5, the boom in publishing activities was in 2010, when the first preparatory committee to 2012 United Nation Conference on Sustainable Development in Rio de Janeiro (RIO+20) took place. It should be noted that this conference was aimed to agree the political declarations on the getting the sustainable development goals as wake to collectively find the methods to solve the problems in the field of sustainable development such as decreasing of poverty in the world, promoting the development of social justice and reserving the environment etc. Furthermore, the most important issues were the development of green economy in order to achieve sustainable development goals and complete for the poverty among people as well as improve the global collaboration in the field of sustainable development. In turn, in 2015 Agenda for Sustainable Development was adopted which set 17 sustainable development goals. However, the agenda provided no methods and ways to achieve the formulated sustainable development goals. In the wake of this, the number of researchers investigating the directions and special tools to achieve the target goals has been increasing every year.

Fig. 5: The dynamic of citations of published articles for 2001-2019 (Scopus, 2020)

In the publications (Abaas et al., 2018, Akhtar, 2019) the authors indicated that to develop green brands and satisfy society's needs companies collaborated with professionals from different subject areas. In accordance with Fig 6 in the academy society green brands appeared to be a multidisciplinary issue and considered from the view of business, social science, economics, environmental science,

engineering, energy, agricultural, biological, computer sciences, psychology as well as art and humanities. Moreover, it has been found out that about 64% of analyzed study papers on green brands were investigated from business management and accounting perspectives (Zhuang Xiong, 2019; Haninun et al., 2018; Leonov et al., 2019; Csaba Fogarassy et al., 2018). Furthermore, the researchers in their studies (Armenia Androniceanu, 2019; Wroblowska, 2019; Vasilyeva et al., 2018a; Teletov et al., 2019) indicated that generation Z become more ecologically aware and concerned about the damaging environmental influences. Taking this into account, they trust just the environmentally friendly companies which aimed to reserve environment making income.

Fig. 6: The analyzed study articles by the research areas published from 2001 to 2019 (Scopus, 2020)

In the frame of this study, top-10 highly cited articles based on the total number of citations were considered in order to compare the impact of total citation per article with the field-weighted citation impact per article for the previous three years (Table 1). It should be noted that field-weighted citation impact allows estimating whether the article cited well compare to the similar ones. Furthermore, the value of field-weighted citation impact depends on the year of article publication, the type of article as well as the associated disciplines with considering article. According to Table 1, the ranks of the article by the total number and field-weighted citation ratio differed. While the most cited article titled "Pro-environmental products: Marketing influence on consumer purchase decision" by Pickett-Baker, J., Ozaki, R. had the total number of citations 386, its field-weighted citation ratio was 5.37. In turn, the article "The drivers of green brand equity: Green brand image, green satisfaction, and green trust" by Chen, Y.-S. which the total number of citations was 338 had higher field-weighted citation impact which was 11.45. In the wake of the above mentioned, it has been found out that the impact of investigated article total citations didn't mean that this article has the same impact level to set the directions for future investigations in the field of green brand providing.

Table 1: Impact of top-10 articles based on total number of citations and field-weight (Scopus, 2020)

Rank	Author(s)	Title	Citations	Field-weighted citation impact
1	Chen, Y.-S.	The drivers of green brand equity: Green brand image, green satisfaction, and green trust	338	11.45
2	Pickett-Baker, J., Ozaki, R.	Pro-environmental products: Marketing influence on consumer purchase decision	386	5.37
3	Namkung, Y., Jang, S.S.	Effects of restaurant green practices on brand equity formation: Do green practices really matter?	78	3.51

Fig. 7: The co-occurrence network of authors of the articles on the base extended set of keywords (VOSviewer, 2020)

Moreover, to formulate the network of authors who had strong impacts on the green policy investigation, we analyzed the publications based on the following keywords as "green marketing", "green policy", the environmental policy" as well as "green brand". As a result, based on 31083 publications from 2001 to 2019 the VOSviewer analytical analysis visualized the 41 clusters with 7098 links (the total link strength was 10656) among which the Chinese researchers had stronger link strengths. However, comparing the countries (Scopus, 2020) indicated that the biggest part of publications was conducted in the United States (Fig 8).

Fig. 8: The analyzed study articles by the countries published from 2001 to 2019 (Scopus, 2020)

Conclusions

The existence of the different definitions to describe the environmentally friendly aspects of companies' activities increases the level of misunderstanding among the consumers as well as the stakeholders. Moreover, the marketers could use «green brand», «sustainable brand», «eco-brand», «sustainability brand» to popularize and promote their brands. In the frame of this article, on the base of Scopus and VOSviewer analytical tools we made the bibliometric analysis of publications in the field of green brand in order to find out the structure and dynamics of publications on green brand development.

According to the obtained results on the base of the Scopus analytical tool, it has been found that the quantity of publication on green brand issues increased. In this study, 214 articles presented on the Scopus database from 2001 to 2019 were analyzed. Furthermore, the level of citation increased too, which means green brand issues became more important and relevant for society. In turn, in the frame of this article, it has been highlighted the more attention is taken to the issues of climate change, the more academic community is interested in investigating the green brands in their researches. It was found that the most active in view of publication activity in green brand issues were the USA, China and India. Moreover, we highlighted the most cited articles which indicate the directions to future investigation in the field of green branding.

The analysis of the thematic direction of investigated articles on the base of the VOSviewer analytical tool indicated 45 items gathered into nine clusters of research with 124 links where the total link strenghts was 178. In turn, it proved the formulated hypothesis that for promoting green company policy green brand positioning is more effective than sustainable brands, eco-brands or sustainability brands. More than, analysis of the web-search requests based on Google Trends tool emphasized that Internet users most of all used the keywords «green brand» to find any information on ecological issues.

Limitations of the Study

The obtained results of investigations proved that green brand positioning considered to be more popular in the scientific papers provided in the Scopus database. However, as this study covers only the publications based on the Scopus database, it is appropriate to extend the current study by analysing the publications from the Web of Science database in order to find the unique and generally acknowledged term to define the essence of the green brand of the companies.

Future Directions of The Research

According to the results of the VOSviewer and Scopus analyses investigating the articles from the Scopus database, we found out the most influencing articles in the field of green brand development that could be the basis for future investigations in the field of environmentally friendly brand positioning. The provided results in the frame of this study have practical importance and could be considered for future investigations. However, because of analyzing the articles published just on the Scopus database there is existent question “Is term “green” is the best to popularize the brand as environmentally friendly among the main stakeholders such as consumers, investors, partners, etc.?” In this way, this study could be used as direction for future bibliometric investigations in order to find out and popularize the unique and generally acknowledged term to define the essence of the green brand of the companies.

Abstract

Financial issues are one of the important factors influencing new public management and relations with stakeholders. The purpose of this study is identifying and formalization of hidden structural links between the level of financial inclusion and new public management in the context of a business environment. This was done through a two-step analysis of 22 World Bank indicators: G 20 Financial Inclusion Indicators (6), Worldwide Governance Indicators (6), Doing Business (10) for 93 countries with different levels of economic development in 2014. In the first phase, using the principal component method 9 most relevant indicators were selected, three in each group that participated in the next phase of the study. Financial Inclusion Indicators remained the following: Account, ATMs per 100,000 adults and POS terminals per 100,000; from the Worldwide Governance Indicators - Control of Corruption, Government Effectiveness and Rule of Law; from the Doing Business-Global group: Ease of doing business, Paying taxes and Resolving insolvency. In the second phase of the study, two systems of simultaneous structural equations were built. They help to identify the hidden links between financial inclusion and new public management in the context of a business environment. It has been found that financial inclusion of the population has a stronger statistically significant direct impact on the business environment than on new public management. As the level of financial inclusion of the population per unit of business environment increases, it will improve 7,234 times, while new public management will improve 0,470 times.

Keywords: Financial Inclusion, New Public Management, Business Environment, Public Administration.

Introduction

Financial inclusion is an important component of economic development and reducing the overall poverty level in the country, and can also be a means of preventing the phenomenon of social exclusion. The human right to use formal financial products and services should be a priority when the financial system is organizing. However, when it comes to financial inclusion, it cannot be limited to its relationship with the financial sector. In accordance with the key principles underlying the new public management concept defined in 1993 in one of the OECD publications (public functions are delegated to private entities under contractual agreements or based on partnerships; prompt and flexible response to the needs of customers and users of public services; maximum satisfaction of their requests; decentralization of management of finances, personnel, quality of work;

delegation of powers and responsibilities from the central to the lower levels of public administration; activities of local authorities and non-governmental organizations in the development and implementation of strategic goals of public policy; establishment through the system of evaluation of the results of personal responsibility for the quality of management; endowing the grassroots with authority to effectively make decisions and solve local problems; employees, increasing the responsibility of organizations for achieving results; functioning of state institutions in market conditions through competition, client choice through tendering, etc .; expanding their area of responsibility; widespread implementation of strategic planning and other innovations), the ability of the population to be active financial actors is encouraged and promotes the free development of the government sector and the business environment. These vectors of social life combine that the level of financial inclusion of the population, the level of implementation of the concept of new public management and assessment of the business environment. These categories are complex, so they are usually formed by the integrated assessment of the phenomenon under study. The nature of the management of the financial system is complex and heterogeneous. An inclusive financial system needs special encouragement in the use of financial services by all groups of society in the conditions of well-organized government and business environment.

Overview of Research Studies

To quantify the degree of financial inclusion of the population in the work of Cámara and Tuesta (2017) it is proposed to calculate an appropriate index, which will consist of those positions of financial activity of the population that are relevant to the particular situation. In general, the index of financial inclusion can be viewed from the standpoint of the following blocks: accessibility (possibility to have access to branches of banks and other financial institutions, ATMs, self-service terminals); usability (ability to freely manage personal accounts, savings, loans); obstacles (distance to the point of service, trust in financial institutions, operating expenses, workflow). As noted above, the category of financial inclusion of the population is complex and includes a number of other defining concepts such as the financial health of the society, the level of financial knowledge (financial literacy), financial behavior, transparency of financial data and activities of financial institutions, etc. Directly or indirectly, these aspects of determining financial inclusion of the population were discussed in the works. Luan and Tung (2019), Rungsrisawat and Pamornmast, C. (2019), Sadalia et al. (2019), Schönfeld et al (2018), Bolek et al (2018), Shkvarchuk and Slav'yuk (2019), Nguyen and Rozsa (2019), Bilan et al (2019), Gavurova et al (2019), Singh and Lall (2018), Alikariev and Poliakh, S. (2018), Ivanova et al (2017), Issa et al (2019).

A number of scientific works are also devoted to defining the connection of the concept of new public management with different segments of the economy. In particular, how the public services for the business environment could be effectively employed in the development environment of Industry 4.0 is presented in Ślusarczyk and Adnan (2019); on the activities of multinational corporations in the conditions of active implementation of different management concepts, including new public management, are discussed in the works of Ohunakin et al (2019), Li (2018), Kargol-Wasiluk and Wildowicz-Giegiel (2018), Korecko et al (2019), Farhshatova et al (2019).

There should be highlighted a series of scientific papers dedicated to the isolation of microeconomic and macroeconomic factors, which have a decisive influence on the formation of a quality business environment in terms of providing a sufficient regulatory framework and openness of activities of governing bodies across countries: Czech Republic - Smékalová et al, 2017) Egypt and others African Countries - Asaleye (2019), Wagdi and Hasaneen (2019), Bakari et al (2018), Serbia - Stevanovic et al (2017), Baltic Countries and Slovakia - Krajnakova et al (2018), Raišienė et al (2018), Korcsmáros and Shimova (2018), Poland - Gorączkowska (2018), Greece - Taliouris and Trihas (2017), Israel – Braw et al. (2018); USA - Kasztelnik and Gaines (2019), India - Chakr awal and Goyal (2018), Russia - Usenko et al (2017); Indonesia - Costini and Rahar (2019).

The activities of small and medium-sized enterprises also play a very important role in shaping an effective business environment. Correct risk management by entrepreneurs, the influence of credit risk during a crisis and sufficient funds for SMEs, technological factors - these and other factors form

the basis for the development of this segment of business. Various aspects of these issues are reflected in the following scientific papers: Belás et al (2018), Kozubikova and Kotaskova (2019), Belas et al (2019), Meresa and Haftu (2019).

Today, a legal framework has been formed in various countries around the world to regulate the management of sovereign and guaranteed sovereign debt and other obligations in order to promote financial stability. The set of measures undertaken by governments allows to regulate this process at the expense not only of direct government only, but also of involvement of the non-state sector (financial institutions, private sector) - Gružauskas and Grmanová (2018), Nastiti et al (2019), Zhussupova (2019) , Karintseva and Benetyte (2018), Bhowmik (2018), Urbina (2018), Mirzanti et al (2018).

Methodology and Data

The next step of the analysis is to formalize the links between financial inclusion, new public management and the business environment within the help of structural equation modeling. In the first stage, the most significant indicators in the study should be selected, grouped into three groups, reflecting the level of financial inclusion of the population, new public management and the business environment.

Principal Component Analysis, PCA is at the part of factor analysis. A more detailed description of the analysis can be found in the works of Harman (1976) Lawley and Maxwell (1971), Mulaik (1972), Morrison (1967) and others. Factor analysis is used to solve two main problems: reducing the number of variables (data reduction); defining the structure of relationships between variables, their classification.

The principal component method allows to identify a number of components (factors) that explains all the variance and correlations of the initial values. The selected components (their number can be both set individually and programmatically obtained) are ranked in descending order of the proportion of total variance explained by each component. It is generally accepted that those components that account for more than 70% of the total variance can be called the most influential among the entire sample. The principle of selecting is next – the first component is to choose exactly the direction in the space of initial variables, in which the set of objects (points) under study has the greatest variation (variance). Each subsequent component is calculated to have its direction parallel to the first component and to account for as much of the residual dispersion as possible. This process continues until all the components that determine 100% of the variance of the studied variables are found. In addition, it is possible to determine the required number of factors by using a scree plot, where, on the basis of the eigenvalues of factors, Cattell (1966) suggested to find a place on the graph when the velocity of decreasing eigenvalues, when looking at the graph from left to right, decreases significantly. Anything left on the right side of the checkpoint is called "debris" that does not have a significant effect on the result. After determining the optimal number of factors, it is necessary to analyze the eigenvalues of the factors - these are the variances that are allocated to each of the factors.

The next step of the analysis is to formalize the links between financial inclusion, new public management and the business environment whith the help of structural equation modeling. The first to develop this field in the world was Professor and Director of the Institute for Advanced Study in the Integrative Sciences, George Mason University, Virginia J. Warfield. In 1973, based on the foundations of discrete mathematics, the scientist developed a methodology for structural equation modeling that allows us to investigate a variety of complex systems based on the detection of hidden relationships between them. The first resonances of J. Warfield's scientific work, where he used the developed methodology, were devoted to the analysis of complex socio-economic systems of Warfield (1976). For a long time, this technique was closed to the general public, as it was considered very complicated, from the stage of input data formation, to the process of interpretation of the results. Later, when the necessary mathematical calculations were automated with the help of special software, the high cost of such products became a new obstacle to the popularization of this method

of modeling. Today, however, these problems have come to the fore and it is safe to say that the use of structural modeling is one of the most popular methods of scientific research in various fields of human life.

Among the main tasks for which modern scientists apply structural modeling are the following: causal modeling or path analysis (establishing between causal relationships, testing hypotheses of causality, determining explicit and latent (implicit variables); factor analysis (determining the structure of factor loadings and correlation relationships between factors); second-order factor analysis (this analysis is a modification of the previous one and allows you to build a correlation matrix between common factors); regression modes whether (the analysis of regression coefficients, provided that they can be fixed and equal to each other, is considered as a modified multivariate linear regression analysis); modeling of the correlation structure (testing the hypothesis that the correlation matrix has a certain form); modeling the structure of averages (simultaneous analysis of variances and covariates).

Thus, structural modeling reveals some hidden factors, the links between them, to some extent, explain the structure of the phenomenon under study.

From the point of view of mathematical representation of systems of structural equations, systems of independent (1) and interdependent (recursive, joint, simultaneous) (2) equations are distinguished.

$$\begin{cases} Y_1 = a_{11}x_1 + a_{12}x_2 + \ldots + a_{1n}x_n + \varepsilon_1 \\ Y_2 = a_{21}x_1 + a_{22}x_2 + \ldots + a_{2n}x_n + \varepsilon_2, \\ \ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots \\ Y_m = a_{m1}x_1 + a_{m2}x_2 + \ldots + a_{mn}x_n + \varepsilon_m. \end{cases} \quad (1)$$

$$\begin{cases} Y_1 = a_{11}x_1 + a_{12}x_2 + \ldots + a_{1n}x_n + \varepsilon_1 \\ Y_2 = b_{21}Y_1 + a_{21}x_1 + a_{22}x_2 + \ldots + a_{2n}x_n + \varepsilon_2, \\ Y_3 = b_{31}Y_1 + b_{32}Y_2 + a_{21}x_1 + a_{22}x_2 + \ldots + a_{2n}x_n + \varepsilon_2, \\ \ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots \\ Y_m = b_{m1}Y_1 + b_{m,m-1}Y_{m-1} + a_{m1}x_1 + a_{m2}x_2 + \ldots + a_{mn}x_n + \varepsilon_m. \end{cases} \quad (2)$$

The main difference between the presented systems of equations is the nature of the representation of variables. Unlike independent systems, where each equation of a system is actually a separate regression equation, in systems of interdependent equations, both dependent (Y_n) and independent variables (x_n) simultaneously play the role of each other in different equations. Therefore, each subsequent equation of this system cannot be considered without the previous one. It is the systems of simultaneous structural equations that have become most widespread in scientific research, as they allow us to detect the presence of those hidden relationships between the variables being studied.

Considering the basic terminology of the system of simultaneous structural equations, it should be noted that instead of dependent (Y_n) and independent (factor) (x_n) variables, it is customary to use such synonyms, respectively, as endogenous and exogenous variables. In fact, the number of endogenous variables depends on the number of equations in the system and depending on the specifics of the study, the variables can replace each other. Each endogenous and exogenous variables have the coefficients b_{ik} and a_{ij}, respectively. These are the structural coefficients of the model. In addition, in each equation of the system there is a residual value ε_j, while the free term is absent.

The process of modeling consists of a few steps. In the first step, it is necessary to present the structure of dependencies between explicit and latent variables using visual tools, usually graphically (path diagram). This is necessary in order to clearly understand the nature of the complexity of the model, which simplifies the process of entering the necessary parameters during the calculation in special software. In the second step, you must set all the required parameters for the calculation. In the next step, in the corresponding software module in which the structural equations are constructed, the obtained variances and covariations are automatically checked. If they meet all the requirements of the research process, then the program goes to the next step. In the fourth step, it is necessary to substitute the obtained structural coefficients of the model and the residuals into the general form of representation of the structural dependencies between the variables. In the fifth final stage, based on a set of different statistics, the quality of the model is evaluated and the adequacy of the results obtained. To evaluate the quality of the built models, there are three main indicators: maximum residue cosine, RMS index, graphical representation of the distribution of residues and reflector matrix.

The maximum cosine residual criterion indicates how well the iteration process has converged. If the value of this indicator is close to zero, it means the successful completion of the iteration process. The RMS index measures the quality of the model fit. Model fit is considered qualitative if the index is less than 0.05. If the index value exceeds 0.1, then the constructed model does not adequately describe the data. The reflector matrix is used to test the model for resistance to scaling the input measurement. A model is considered more stable if the values of the elements of a given matrix are close to each other.

We used indicators from the World Bank databases as input variables: G 20 Financial Inclusion Indicators (6), Worldwide Governance Indicators (6), Doing Business (10) for 93 countries with different levels of economic development in 2014 (this year's choice is explained the presence of complete statistical information). The input indicators and their symbols are presented in the Tab 1.

Tab 1: Input variables

№	Name of variable	Sense of variable	Legend
1	Account (% age 15+)	Denotes the percentage of respondents, ages 15+, who report having an account	x1
2	ATMs per 100,000 adults	Denotes the total number of ATMs for every 100,000 adults in the reporting country	x2
3	Branches per 100,000 adults	Denotes the number of branches of commercial banks for every 100,000 adults in the reporting country	x3
4	Deposit accounts per 1,000 adults	Denotes the total number of deposit accounts that are held by resident nonfinancial corporations	x4
5	POS terminals per 100,000 adults	Denotes the number of point of sale (POS) terminals per 100,000 adults.	x5
6	Outstanding loans per 1,000 adults	Denotes the total number of loan accounts that are obtained by resident nonfinancial corporations	x6
7	Control of Corruption	Control of Corruption captures perceptions of the extent to which public power is exercised for private gain, including both petty and grand forms of corruption	b1
8	Government Effectiveness	Government Effectiveness captures perceptions of the quality of public services, the quality of the civil service and the degree of its independence from political pressures, the quality of policy formulation and	b2

		implementation, and the credibility of the government's commitment to such policies	
9	Political Stability and Absence of Violence/Terrorism	Political Stability and Absence of Violence/Terrorism measures perceptions of the likelihood of political instability and/or politically-motivated violence, including terrorism	b3
10	Regulatory Quality	Regulatory Quality captures perceptions of the ability of the government to formulate and implement sound policies and regulations that permit and promote private sector development	b4
11	Rule of Law	Rule of Law captures perceptions of the extent to which agents have confidence in and abide by the rules of society, and in particular the quality of contract enforcement, property rights, the police, and the courts	b5
12	Voice and Accountability	Voice and Accountability captures perceptions of the extent to which a country's citizens are able to participate in selecting their governmen	b6
13	Dealing with construction permits)	The score for dealing with construction permits is the simple average of the scores for each of the component indicators: the procedures, time, cost to deal with construction permits	a1
14	Enforcing contracts	The score for enforcing contracts is the simple average of the scores for each of the component indicators: the procedures, time and cost for resolving a commercial dispute through a local first-instance court	a2
15	Getting Credit total	The total score for getting credit is the sum of the strength of legal rights index and the depth of credit information index	a3
16	Getting electricity	The score for getting electricity is the simple average of the scores for each of the component indicators: the procedures, time, cost for a business to obtain a permanent electricity connection and supply for a standardized warehouse	a4
17	Global: Ease of doing business	The ease of doing business score is the simple average of the scores for each of the Doing Business topics: starting a business, dealing with construction permits, getting electricity, registering property, getting credit, protecting minority investors, paying taxes, trading across borders, enforcing contracts and resolving insolvency	a5
18	Paying taxes	The score for paying taxes is the simple average of the scores for each of the component indicators, the payments, time and total tax and contribution rate for a company to comply with tax laws in an econom	a6
19	Protecting minority investors	The score for protecting minority investors benchmarks economies with respect to the regulatory best practice on the indicator set	a7
20	Resolving insolvency	The score for resolving insolvency is the simple average of the scores for each of the	a8

		component indicators: the recovery rate of insolvency proceedings involving domestic entities	
21	Starting a business	The score for starting a business is the simple average of the scores for each of the component indicators: the procedures, time and cost for an entrepreneur to start and formally operate a business, as well as the paid-in minimum capital requirement	a9
22	Trading across borders	Doing Business measures the time and cost associated with exporting and importing a standardized cargo of goods by sea transport	a10

Results and Discussion

As a result of the principal component method, 9 were selected from 22 inputs (three in each group). The number of selected factors and factor loadings for each indicator are presented in the Tab 2.

Tab 2: Factor loadings

Legend	**Factors**	
	Factor 1	Factor 2
x1	**-0,841**	
x2	**-0,834**	
x3	-0,661	
x4	**-0,729**	
x5	**-0,844**	
x6	0,348	
b1	**-0,959**	
b2	**-0,961**	
b3	**-0,835**	
b4	**-0,952**	
b5	**-0,984**	
b6	**-0,866**	
a1	-0,676	-0,178
a2	-0,622	0,351
a3	-0,659	-0,117
a4	-0,635	-0,521
a5	**-0,995**	-0,027
a6	**-0,737**	0,106
a7	-0,587	0,361
a8	**-0,733**	0,046
a9	-0,593	0,579
a10	-0,689	-0,478

In the first and second cases, for a group of financial inclusion indicators and new public management, based on the eigenvalues of factors (3.2, representing 54% of the aggregate variance, and 5.17, representing 86% of the aggregate variance, respectively), one factor is optimal. In the third case (a group of indicators describing the business environment), two factors are identified - a cumulative eigenvalue of which is 6.07, accounting for 60.7% of the total variance.

Given the values of the factor loadings of each indicator: Account (-0.841), ATMs per 100,000 adults (-0,834) and POS terminals per 100,000 adults (-0,844) remain for further analysis in the first group; from the second group - Control of Corruption (-0,959), Government Effectiveness (-0,961) and Rule of Law (-0,984); from the third group - Global: Ease of doing business (-0,995), Paying taxes (-0,737) and Resolving insolvency (-0,733).

For structural modeling, we introduce into the study three latent variables: to denote a group of indicators of financial inclusion of the population - FIN, for a group of indicators new public management - GOV, for a group of indicators that describe the business environment - BUS. Each of these latent variables includes the corresponding explicit metrics selected using the principal component method. We conduct a two-step study of the nature of the relationship between latent variables (Fig. 1).

The results obtained from structural modeling for both cases are presented in the following form (Tab 3)

Tab 3: The results of structural modeling for both cases

Case 1			
Direction of connection	Estimation parameter	t-statistics	p-level
FIN->GOV	0,905	8,552	0,000
FIN->BUS	-0,974	-0,545	0,586
GOV->BUS	9,065	5,112	0,000
Case 2			
FIN->GOV	0,470	3,780	0,000
FIN->BUS	7,234	6,813	0,000
BUS -> GOV	0,060	4,261	0,000

1 case

2 case

Fig 1: Regression dependencies between latent variables for two cases where ZETA1, ZETA2 are residual values

The systems of structural equations for both cases are as follows:

$$\begin{cases} BUS = -0{,}974FIN + 9{,}065GOV + 12{,}903 \\ GOV = 0{,}905FIN + 0{,}188 \end{cases} \tag{3}$$

$$\begin{cases} GOV = 0{,}470FIN + 0{,}060BUS + 0{,}086 \\ BUS = 7{,}234FIN + 28{,}386 \end{cases} \tag{4}$$

The adequacy of the constructed models can be estimated using the maximum cosine of residuals, RMS index (Tab 4)

Tab 4: Criteria for assessing the adequacy of models

	Case 1	Case 2
MAX Cos	1,190	0,000
RMS	0,054	0,044

As we can see, from the obtained values, in the second case, the value of the cosine maximum is zero. This means successful completion of the index iteration process. The RMS is less than 0.05, which indicates the high quality of the model fit.

The reflector matrices and the graphical representation of the residue distribution (Tab 5) also confirm the quality of the second model.

Tab 5: Reflector matrix and graphical representation of residue distribution for two cases

Case 1

	x1	x2	x5	b1	b2	b5	a5	a6
x1	-0,000	-0,099	7,172	0,005	-0,006	-0,002	-0,011	0,023
x2	-0,006	0,000	-5,422	0,003	0,001	0,002	-0,011	-0,022

Thus, in view of the results obtained, it can be seen that financial inclusion of the population has a stronger statistically significant direct impact on the business environment than on new public management. As the level of financial inclusion of the population per unit of business environment increases, it will improve 7,234 times, while new public management will improve 0,470 times.

Conducting an analysis from the standpoint of identifying implicit functional relationships between groups of metrics, one should focus on exploring the interrelationships between explicit variables. In particular, it concerns checking the impact of the most significant variables characterizing the business environment and new public management on the level of financial inclusion. For this purpose it is necessary to determine the integral index of financial inclusion of the population.

Given the existing methods for deriving an integrated indicator based on several interrelated indicators, the following are the most popular ones:

- method of additive convolution of criteria;
- the method of multiplicative convolution of criteria;
- method of uniform optimality.

The first two methods are not included in the category of so-called universal, because their application has certain requirements. Yes, the method of additive convolution of criteria is used in cases where we are sure that all our studied indicators have a linear and additive effect on the system. In our study we cannot confidently accept this hypothesis, so we have to exclude the use of this method. With regard to the second method, the multiplicative convolution of criteria, the main assumption here is the following: the main convolution indicators should be relative values. As for the method of uniform optimality, there are no special requirements for its application. Given the specifics of our input indicators, we can use the latter two methods to obtain an integral indicator, however, given the popularity of use in the financial sector, let us focus on the latter.

Thus, the role of the dependent variable will be played by the Financial Inclusion Index (IFI), and the independent variables - Control of Corruption (b1), Government Effectiveness (b2), Rule of Law (b5), Global: Ease of doing business (a5) - variables having the highest values of factor loadings.

We obtain the following multivariate regression model:

$$IFI = 0{,}339 - 0{,}032b1 + 0{,}067b2 - 0{,}032b5 + 0{,}003a5 .$$

So, we have the following results:

- with the increase of the corruption assessment index in the country per unit financial inclusion of the population will decrease by 0,032, which indicates the negative impact of corruption on the financial involvement of the population;
- with increasing government efficiency per unit, financial inclusion of the population will increase by 0,067, which indicates a close positive relationship between government and the desire and willingness of the population to be active users of financial services;
- with the increase of the index of development of legislation in the country per unit financial inclusion of the population will decrease by 0,032, which indicates the negative impact of complex regulatory support on the general level of financial involvement of the population;
- with the increase of the global index of ease of doing business in the country per unit financial inclusion of the population will increase by 0,003, which indicates the positive impact of business on financial inclusion of the population.

Conclusion

Today, there is a clear understanding of the concept of "financial inclusion" as a prerequisite for sustained poverty reduction and economic growth. However, the relationship between financial

inclusion and the already traditional concept of sustainable new public management and the business environment development index has not yet been sufficiently studied and considered in a single context. This situation started to improve and became especially relevant in the post-crisis period, when research into these issues could help to understand the causes of negative financial and administrative structural changes. According to the purpose of this study, it was necessary to identify and formalize hidden structural links between the level of financial inclusion and new public management in the context of a business environment. This was done through a two-step analysis of 22 World Bank indicators: G 20 Financial Inclusion Indicators (6), Worldwide Governance Indicators (6), Doing Business (10) for 93 countries with different levels of economic development in 2014. In the first phase, using the principal component method The most relevant indicators were selected, three in each group that participated in the next phase of the study. Financial Inclusion Indicators remained the following: Account, ATMs per 100,000 adults and POS terminals per 100,000; from the Worldwide Governance Indicators - Control of Corruption, Government Effectiveness and Rule of Law; from the Doing Business-Global group: Ease of doing business, Paying taxes and Resolving insolvency. In the second phase of the study, two systems of simultaneous structural equations were built to identify the hidden links between financial inclusion and new public management in the context of a business environment. It has been found that financial inclusion of the population has a stronger statistically significant direct impact on the business environment than on new public management. As the level of financial inclusion of the population per unit of business environment increases, it will improve 7,234 times, while new public management will improve 0,470 times. The results obtained can form the basis for formulating recommendations to state and local government bodies in formulating management decisions in the area of financial involvement of the population.

Abstract

In the context of increasing social and economic tensions, one of the reasons for the low level of economic development of both individual countries and the world as a whole, is the activation of economic entities and households towards concealing their income and shadowing their output. The aim of this study is to develop a methodological toolkit for evaluating the effectiveness of public policies to counteract the shadow economy. This paper empirically investigates the economic and social effects of implementing an effective policy of the de-shadowing economy. The developed approach assumes an assessment of the integral index of public policy effectiveness, which is based on the following components: regulatory efficiency, procedural efficiency, substantive efficiency and transactive efficiency. Based on the panel regression models, the most prioritized measures of the de-shadowing economy were identified (formation of a sufficient level of tax morality, reduction of corruption in state bodies, raising awareness of the main goals of economic reforms, etc.). The scientific contribution of the article consists in the fact that the current studies of the effectiveness of the policy of de-shadowing the economy are fragmentary and limited to studies of the effectiveness of its individual components. The established inter dependence can help to increase the effectiveness of measures to stimulate business entities to withdraw funds from the shadow and improving the performance of the official economic sector. Also, modern information technologies can counteract the emergence and help in subsequent monitoring of the shadow economy. Contemporary times are marked by the digital blood circulation of data, which makes the virtualization of the world, apart from globalization, a marker of the level of development of the economies of individual countries. Economy 4.0 with set of technical and technological solutions includes cloud data collection and computing, mobile technologies, analysis of large data sets (Big Data), social media in business and finally Block chain technology will reduce shadow economy.

Keywords: De-Shadowing of The Economy, Public Policy, Efficiency, Economic Development, Instruments, Economy 4.0

Introduction

Excessive state regulation of the economy, high level of corruption, low income of economic entities, excessive tax burden, low level of efficiency of the institutional environment in the country are leading to an increase in the size of the shadow economy worldwide. According to international experts, the level of shadow economy varies within 10-40% of GDP (for Advance Economies its value is 10-20% of GDP, in Emerging economies - 30-35 % of GDP, in CIS countries it exceeds 40%) and is a threat to the economic development of countries (Schneider and Buehn, 2017).

The annual increase in the size of the shadow economy leads to the formation at both national and international levels of institutional and regulatory policies to counteract the shadow economy. The current system of counteraction the shadow withdrawal of funds abroad has a three-tier structure: the national financial monitoring system (Financial Action Task Force on Money Laundering), The Committee of Experts on the Evaluation of Anti-Money Laundering Measures and the Financing of Terrorism (MONEYVAL), The Eurasian group on combating money laundering and financing of terrorism (EAG)); regional revenue shadowing system (Eastern and Southern Africa Anti-Money Laundering Group (ESAAMLG), The Caribbean Financial Action Task Force (CFATF), Latin America Anti-Money Laundering Group (GAFILAT), OUF Banking Supervision Group, Central African Republic Anti-Money Laundering Group (GABAK)); a supranational monitoring and control system.

These institutions have developed a wide range of initiatives to counteract the shadowing of revenues by lowering tax bases, investing funds through shell companies, attracting foreign loans with the subsequent bankruptcy of companies, overestimating or lowering the customs value of goods, etc. One of the main instruments for the de-shadowing of the economy in the EU countries is the Directive 2015/849 of the European Parliament and of the Council of 20 May 2015 on the prevention of the use of the financial system for the purposes of money laundering or terrorist financing.

However, despite the considerable diversity of anti-money laundering organizations and the regulatory acts that they have developed, there is no methodological toolkit to form an effective strategy for unshadowing the economy. Thus, it becomes urgent to develop a methodology for assessing the effectiveness of public instruments to de-shadowing the national economy and determine their impact on the social and economic development of the country.

Literature Review

The theoretical and practical aspects of the functioning of the shadow economy, the methodological tools of its assessment and the mechanisms of minimizing the share of the shadow sector in the economy have been studied by many scientists. The international scientific community pays the greatest attention to the issues related to the functioning of the shadow economy, the identification of its causes and the factors that stimulate its spread. Thus, the development of individual theories of shadow economy and the study of the causes of the informal economy sector devoted to the work of such scientists as: Schneider (2017), Bhattacharyya (1999), Loayza (1996), Williams and Martinez (2014), Geertz (1978), Bilan et. al. (2019 a, g, f), Ginevicius et. al. (2018), Lubacha-Sember et. al. (2017), Rahimi (2016), AUgbaka et. al. (2019), Greco (2018).

A considerable amount of scientific work is devoted to the study of the determinants of the shadow economy growth. Thus, the works of Sookram et. al., (2009), Williams and Nadin (2012) investigate the shadowing of the economy in the context of its relation to the labor market in the country: inefficient labor relations, low wages, worsening working conditions becomes the reasons for shadow employment increase. The impact of economic development indicators on the level of shadow economy have been investigated by Miłek (2018), Omidi et. al. (2017), Shkolnyk et. al. (2018), Ślusarczyk and Haque (2019), Vasilyeva et. al. (2019a), Vasylyeva et. al. (2014), Yoshimori (2019), Zainol et. al. (2018). The impact of digitalization on the level of shadowing of the economy was investigated by Afonasova et. al. (2019), Bilan et. al. (2019b, d), Melnyk et. al. (2016, 2019), Zakharkina et. al. (2018), Nathan et. al. (2019), Petrushenko et. al. (2018), Kendiukhov and Tvaronavičienė (2017), Khusaini (2019), Leonov et. al. (2019).

The quality of functioning of the institutional component of public policy and confidence level in the government as a prerequisite for the growth of the share of the shadow economy are considered by Schneider (2017), Ipatov et. al. (2018). Thus, Schneider determines the low level of competence of official institutions, the quality of the regulatory framework, the level of bureaucracy, the quality of the judiciary, the compliance with the law by factors of shadowing the economy in the countries of Central and Eastern Europe. Bilan et. al. (2018), Chygrynet. al. (2018), Dobrovič et. al. (2018), Gashenko et. al. (2017), Ipatov and Grebeniuk (2018), Masri et. al. (2019), Mróz (2019), Tiutiunyk (2019), Vysochyna et. al. (2015) argued that countries where fiscal regulation of the economy is carried out on a democratic basis have a lower level of shadowing.

The most influential factors behind the increase in the level of shadowing are the level of fiscal burden. Krumplyte (2008), based on examples of foreign experience, shows that countries with high tax burden (52-55%) are more competitive and have a low shadow economy (Sweden, Denmark, Finland). Countries with relatively low tax rates (up to 20 percent) have a shadow economy over 60 percent of GDP (Georgia, Mexico). The impact of this factor is described by the Laffer curve, which shows that a relatively low tax burden determines low levels of the shadow economy while increasing the tax burden above an optimum level determines a high proportion of the shadow sector, which in turn reduces the amount of tax revenues to the state budget (Schneider, 2017).

In general, for industrial countries, the following factors influence on the level of the shadow economy (Al-Tkhayneh et. al., 2019; Boyko and Roienko, 2014; Brychko et. al., 2019; Dobrovič et. al., 2017; Gren et. al., 2019; Kostyuchenko et. al., 2018; Levchenko et. al., 2019; Marikina, 2018; Marková et. al., 2017; Musa et. al., 2018; Petrenko et. al., 2017; Skare et. al., 2019; Ślusarczyk and Grondys, 2019;): high level of tax burden and excessive social security contributions; increasing unemployment and limiting to the maximum number of working hours per week; excessive government regulation of the labor market, increasing the retirement age; frequency and intensity of regulation of the official sector of the economy. Countries with high level of shadow economy tend to show low level of willingness to pay taxes, low level of government tolerance, lack of respect and loyalty to NGOs, and are characterized by excessive corruption and commitment.

The theoretical aspects of public administration of the national economy have been investigated in the works of Sokolenkoet. al. (2017); Stanczyk-Hugiet and Maciejczyk (2019); Sukhonos and Makarenko (2017); Tiutiunyk (2018); Bercu et. al. (2019); Bilan et. al. (2019c, e); Brychko and Semenog (2018); Kasztelnik and Gaines (2019); Kolarova et. al. (2019); Koraus et. al. (2017); Kot et. al. (2019); Levchenko et. al. (2018) and others. In the process of developing measures to de-shadow the economy, the authors differently determine the tools to counteract the shadow withdrawal. Thus, some authors define financial policy as the basis for legalizing shadow income, while some authors define tax policy as the main instrument for the shadowing of the economy.

At the same time, there are currently no comprehensive studies on the development of tools for assessing the effectiveness of instruments of the de-shadowing national economy.

Material and Methods

On the basis of the generalization of existing approaches to determining the most effective instruments for the de-shading of the economy, we can conclude that there is a multiple nature. Such diversity of counteraction instruments testifies to the feasibility of applying an individual approach to the development of a policy of unshadowing economy. The authorities should determine the feasibility of applying a particular instrument of unshadowing the national economy and form an appropriate regulatory framework for their use, depending on the level of economic development of the country, the level of risk of shadowing of income, the most influential factors of shadowing that are specific to a particular country.

Considering the above mentioned, we propose to define the public policy of counteracting the shadow economy as a system of goals, tasks and measures that determine the volume and forms of

influence of the official sector of the economy on the channels of shadow withdrawal, aimed at reducing the share of informal financial transactions.

Assessment of the effectiveness of public policy is a very important element in the system of economic management and at the same time it is difficult from the point of view of implementation of the process. However, despite the presence of a large number of state institutions responsible for implementing the policy of unshadowing the economy, the efficiency of their work is rather poor. The reasons for this situation are the objective factors related to the significant influence of the external (international) environment on economic entities and subjective ones, among which corruption and bureaucracy in the country, low level of trust in the government, lack of historically formed principles and tax morals play an important role.

Effective implementation of the policy of de-shadowing the economy should include not only measures to identify the facts of income shadowing, but also measures aimed at raising the level of tax morality among the population, reducing the level of corruption in the bodies that are directly involved in the process of unshadowing the economy (tax authorities, public administration, control services, etc.).

In this context, understanding the goals and key objectives of economic reform, in particular tax one, is important. Awareness of the importance of taxes as key components of budget filling, the causes and consequences of changing the tax burden, are important tools to combat tax evasion.

One of the conditions for successful implementation of the policy of unshadowing the economy is to reduce the tax gaps - the difference between the sum of actual and potentially possible tax revenues. Taking into account the fact that tax payments are one of the main budget-forming elements, they also determine the ability of the state to fulfill its powers by financing economic, environmental and social activities. However, to date, the problem of effective planning of public expenditures is quite acute, due to the inability to finance certain items under the influence of the shadow economy and the emergence of income gaps. Thus, increasing the efficiency of measures to de-shade the economy will provide an opportunity for accurate planning and regulation of the budget process, targeted use of funds and full financing of planned budget items.

In the process of establishing a state policy to counteract the shadowing of an economy, the fact that a large part of illegal operations is carried out with the direct involvement or support of employees of state or local authorities is generally not taken into account. Thus, reducing the level of corruption in public institutions, increasing the transparency of their activity before the public, reducing the contradictions of the regulatory framework should be considered as one of the main components of the effective functioning of the economy.
Importance is gained in implementing in the executive authorities an effective approach in determining the priority areas of their activities. Quite often, the actual activity of public authorities in the sphere of the unshadowing of the economy does not correlate with those tasks, which are declared in the normative-legal acts of the respective direction.

We propose to evaluate the effectiveness of the policy of counteracting the shadow economy in the context of the following components: regulatory efficiency - as an indicator of the conformity of the results of implementation of state measures to the previously defined goals; procedural efficiency - the effectiveness of ways to achieve the intended result; substantive efficiency - the consistency of interests of the state and economic entities; transactive efficiency - efficiency of realization of auxiliary components in the sphere of counteraction of shadowing of economy.

Thus, the analysis allows to determine the main components of the evaluation of the effectiveness of the policy of the de-shadowing economy, the characteristics of which are shown in table 1.

Table 1: Indicators of effectiveness of the public policy of unshadowing the economy by main components

Effectiveness	Indicator	Characteristic
Regulatory efficiency	The rate of change in the ratio of tax revenues to GDP, the rate of change in the level of corruption	Characterizes the amount of non-receipt of tax payments by the appropriate level budget.
Procedural efficiency	Rate of change in the cost of financing measures to counteract the shadowing of the economy, the level of change in the effectiveness of the process of financial monitoring	It describes the ability of state and local authorities to use their powers to develop the official sector of the economy.
Transactive efficiency	The level of time spent on tax payments, the level of digitization of the economy	It reflects the efficiency of building the tax system in the country in accordance with the principles of openness and transparency based on the calculation of the index of development of e-government, openness of state data, budgetary transparency, etc.
Substantive efficiency	The tax progressiveness index, the tax burden, the rate of change in the level of awareness of the main goals of economic reforms, the rate of change in the level of tax morale	Characterizes the level of stability and fairness of the tax system in the country on the basis of the level of tax competitiveness, the quality of individual components of the tax system.

Evaluating the effectiveness of existing policy to counteract the shadowing of the economy requires the use of a large amount of information, which in the conditions of low data transparency, democratization of society can significantly complicate this process and reduce the reliability of the obtained results. At the same time, taking into account the fact that macroeconomic indicators are at the heart of the calculation of the vast majority of components, the application of this approach provides an opportunity for international comparison, comparisons at the national level, identification and use of best practices for the de-shadowing measures.

We propose to calculate the integral indicator of the effectiveness of the public policy to counteract the shadowing of the economy by the following formula:

$$IndiScore = \sum_{j=1}^{n} I_j = \sum_{j=1}^{n} \frac{x_i - \underline{x}}{\bar{x} - \underline{x}} \times 100 \quad (1)$$

where I_j – normalized values of the j-th component; x_i – the actual value of the i-th component; $\bar{x}$ and $\underline{x}$- the maximum and minimum values of the element.

Results

The results of the evaluation of policy efficiency of unshadowing economic activity of businesses in the context of the European Union and Ukraine, given in the Table 2, let us to determine the average level of public policy effectiveness. Thus, the average efficiency for the analyzed countries is 0.68 (Figure 1). For France, Lithuania, Bulgaria, Finland, Hungary, the effectiveness of public policy exceeds 0.75, while for some countries (Croatia, Latvia, Czech Republic) its value is much lower than the average. For Ukraine, as the only non-EU country, the indicator of the policy efficiency of the counteracting the shadow economy does not exceed 0.5.

Table 2: The results of the evaluation of policy efficiency of unshadowing economic activity of businesses

Analysis showed the lowest effectiveness of the regulatory component, which indicates that the actual results of the public policy did not correspond to the planned indicators. The reason for this situation may be, on the one hand, the imperfection of the planning procedures and, on the other, the inefficiency of the implementation of the planned measures. The most effective in terms of counteracting the shadowing of the economy is the transactive component (average efficiency index of 0.7), which is based on reducing the level of shadow activity of economic entities by digitizing the economy, increasing the transparency of financial transactions. Given the active use of digital technologies by the vast majority of economically developed countries, the use of online technologies

in the process of financial monitoring and control is a key to increasing transparency in the activities of both economic entities and public authorities.

Figure 1: Effectiveness of public policy to counteract the shadow economy

Determination of the most priority, in terms of increasing the effectiveness of the policy of unshadowing the economy, indicators will be made in the context of components (regulatory and substantive), which have the least average. Taking into account the fact that the implementation of public policy is generally of a long-term nature, we will carry out a Fully Modified least squares regression using. The results of the calculations are shown in table 3.

Table 3: The funding of Fully Modified least squares regression for Ukraine

Variable	Coefficient	Std. Error	t-Statistic	Prob.
The ratio of tax revenues to GDP	0.02147	0.00324	0.47854	0.6578
The level of corruption	0.05354	0.00424	6.24786	0.0000
The tax progressiveness index	-0.01479	0.01257	-0.33678	0.3214
The level of tax burden	0.01478	0.03245	-5.15478	0.0001
The level of awareness of the main goals of economic reforms	-0.03595	0.00478	-6.14751	0.0000
the level of tax morale	-0.05945	0.02775	-4.69756	0.0000
R-squared		0.974564		
Adjusted R-squared		0.931475		
S.E. of regression		0.907014		
Long-run variance		1.365786		

The results of the analysis revealed a statistically significant correlation between the level of shadow economy and the level of corruption, the level of awareness of the main goals of public policy and the level of tax morale. In terms of the ratio of tax revenues to GDP and the tax progressiveness index, the probability is less than 5%, which indicates that there is no statistically significant correlation between the analyzed indicators. Thus, an increase of 1% of the tax burden leads to an increase in the level of shadowing of the economy by 1.48%, an increase in the level of corruption is accompanied by an increase in the shadowing by 5.3%, the level of awareness of the main goals of economic reforms to a reduction of the level of shadowing by 3.5%, and the level of tax morale up to 5.9%.

Conclusion

This study is aimed at analyzing the effectiveness of public policy to counteract the shadowing of the economy. The study was based on an analysis of four major groups of policy effectiveness components: normative, procedural, transactive and substantive. The results of the analysis made it possible to evaluate the effectiveness of state measures aimed at reducing the level of shadow economy and to identify the areas that have the most significant impact on them: the level of corruption, the level of awareness of the basic goals of economic reforms and the level of tax morality. The calculations conclude that in most EU countries the level of public policy effectiveness is average, while in Ukraine it is quite low. The calculations confirm the results of previous researchers (Levchenko, 2018; Dobrovič, 2018) on the low level of effectiveness of public policy to counteract the shadowing of the economy in countries with transitive economies and the average level in EU countries. The study substantiates the feasibility of improving the effectiveness of measures within the framework of regulatory effectiveness. The results of the study have implications for representatives of the scientific community as well as for public authorities in the world. First, they form the basis for further scientific research in the context of identifying priority actions to improve the effectiveness of public policy. Secondly, it is possible to predict the value of the level of shadowing of the economy due to changes in certain directions of public policy.

Abstract

The development of the financial sector is inextricably linked to the functioning of other sectors of the national economy and is interdependent with the parameters of the business environment. Stormy and dynamic changes create new challenges for running economic activity. Doing business must include processes aimed at improving the competitiveness of enterprises and ensuring economic growth. The purpose of the paper is to analyze the correlation between the spread of FinTech innovations and the parameters of business environment development, using Spearman's rank correlation methodology. To quantify the spread of technological innovation in the financial sector, it is proposed to use the Technological Financial Services Index (TFSI) – an integral indicator proposed by the authors. Twelve international indexes, such as Social Progress Index, Gini Index, Index of Economic Freedom, Global Competitiveness Index, Human Development Index and others, are used to evaluate the parameters of the business environment. The correlation analysis of the business environment parameters and the technological financial services index provided the following conclusions: 1) the highest level of correlation is between the technologization of financial services and the ICT development and digital readiness; 2) technological development is the main determinant of FinTech innovations, while the level of economic development does not have a decisive influence on the spread of FinTech innovations; 3) the parameters of the political and social environment strongly correlate with the technologization of financial services; 4) the lack of linkage to innovation in financial services is only specific to the environmental dimension of business environment.

Keywords: Business Environment, Fintech, Financial Services, Information Technologies, Correlation Analysis.

Introduction

The development of the financial sector is inextricably linked to the functioning of other sectors of the national economy and is interdependent with the parameters of the business environment. On the one hand, financial institutions, by acting as intermediaries, facilitate and accelerate commodity exchange, ensure the distribution of financial resources through stock market and credit market mechanisms.

The technological development of the financial sector has a positive impact on the efficiency of the business environment. FinTech innovations accelerate the payment process, simplify the process of obtaining loans, reduce transaction costs, which directly affects the business environment of enterprises and institutions of the real and public sectors.

On the other hand, the business environment can create barriers or, on the contrary, favorable conditions for the development of financial and technological innovations. For example, lack of information technology dissemination, lack of secure or high-quality access to computer networks will slow the implementation of FinTech innovations.

Thus, the purpose of the paper is to analyze the correlation between the spread of FinTech innovations and the parameters of business environment development, using Spearman's rank correlation methodology and the analysis of the field of correlation between the parameters of the business environment and the technologization of financial services.

Literature Review

In the financial sector, as in any other sector of the national economy, innovation is a way of ensuring the competitiveness and efficiency of a financial institution. The role of innovation in economic development, improving efficiency and profitability, ensuring sustainable development and competitiveness is confirmed by numerous scientific studies (Kirikkaleli and Ozun (2019), Goncharenko et al (2019), Sineviciene et al (2018), Zygmunt (2019), Khan (2018)). However, previously the financial sector, including the banking sector, could work effectively using traditional business models, but now the transition to a new technological mode – Industry 4.0 made it impossible to stay away from transformation processes (Brychko and Semenog (2018), Postelnicu and Câlea (2019), Pisar and Bilkova (2019)). At the present stage innovations are primarily related to the use of information technology, which includes the automation of production and general management, the use of cloud technologies, Big Data analysis, the use of artificial intelligence and automated decision-making systems (Beyi (2018), Afonasova et al (2019)).

The need for technological innovation in the financial services market has been driven by several key global market trends (Grencikova et al (2019)). As noted, the first trend is the digitization of all aspects of public life, industrial activity and services (Bilan, Đšuzmenko et al (2019)). The second trend is the decline in confidence in the banking sector, the destabilization of the banking system after the global financial crisis (Bilan, Y., Brychko et al (2019), (Buriak et al (2019), Brychko et al (2019), Vasilyeva et al (2013), Vasilyeva et al (2016)), and the efforts of financial services consumers to find alternative ways of investing and saving, and alternative sources of capital formation and lending (Bilan et al (2018), Buriak et al (2015), Gavurova et al.(2019), Kozmenko and Vasyl'yeva (2008), Leonov et al (2014), Leonov et al (2012),). The third trend is changes in consumer demand, the desire to receive 'everything at once', i.e. to have online access to services, quickly conduct financial transactions and so on (Grytsenko et al (2010), Lyeonov and Liuta (2016), Vasylieva and Chmutova (2015)).

The results of the diffusion of technological innovation in the financial sphere have several manifestations. First, the technological basis of conducting financial transactions has changed, the share of non-cash payments has increased, and online banking and mobile banking have developed (Basri (2018), Redda et al (2017)). In the real economy, such changes have contributed to the intensive development of e-commerce and promotion and marketing by social networks (Hu et al (2019), Roy et al (2017), Hendriyani and Raharja (2018), Khwaja et al (2019), Kunesova and Micik (2019), Zatonatska (2018)). Secondly, the digitalization in the financial sector has led to a change in the financial intermediation concept and in the emergence of peer-to-peer and crowdfunding platforms, FinTech startups. FinTech startups offer individual financial services, replacing traditional financial intermediaries (Drugov et al (2019), Njegovanović (2018)). Lack of venture funding has led to the development of crowdfunding platforms. Peer-to-peer platforms are an alternative source of lending to individuals and small businesses (Bilan, Rubanov et al (2019)). Therefore, the essential feature of the financial sector nowadays is the widespread adoption of information technology and its use both for financial services provision and organization of financial institutions' activity – process and organizational innovation (Big Data, electronic payment technologies, blockchain technology, online and mobile banking), and for changing financial services – product innovation (Giebe et al (2019), Veselovsky et al (2018), Knezevic (2018), Karaoulanis (2018)).

The processes of financial sector development are inextricably linked to the properties of the country's micro and macroeconomic environment and are influenced by general trends in the global financial market and regulatory policies in this field (Vasilyeva, T., Kuzmenko et al (2019), Djalilov et al (2015)). On the other hand, financial innovations also affect the business environment, creating both new opportunities and threats. Among the main risks of spreading FinTech innovations are limited control by the state, insufficient protection of the interests of consumers and investors, lack of effective risk management, employment problems as a result of reducing the need for staff of financial institutions, the possibility of data loss through cyberattacks are some of the main issues of using innovative financial and technological services at the present stage (Lyulyov and Shvindina (2017), Tkachenko et al (2019), Postelnicu and Câlea (2019), Milon et al (2018)). In addition, some technological innovations may be used in money laundering and other illegal activities as a result of lack of clear legislation and financial monitoring mechanisms (Bilan, Vasylieva et al (2019b), Kostyuchenko et al (2018), Leonov, Yarovenko et al (2019), Levchenko et al (2019)).

In addition, studies show that the level of financial and technological innovation implementation by banks and other financial institutions has significant differences in different countries and regions of the world. The interstate and interregional differences in investment and innovation activity and technological readiness to innovations by economic entities is confirmed by the scientific studies in particular (Bilan, Vasylieva et al (2019a), Koišová et al (2018), Wierzbicka (2018), Vashchenko et al (2018), Roszko-Wójtowicz and Białek (2019)). The higher innovation activity is common in the countries with higher levels of economic development, and vice versa (Kapidani and Luci (2019), Formánek (2019), Szarowská (2018)).

Thus, most studies on the diffusion of innovations in the financial sector consider them in relation to the overall state of the financial market, economic development, technological level and the scope of innovation (Li (2019), Skare and Porada-Rochoń (2019), Kohnová et al (2019)). At the same time, the interdependence of all components of the business environment, including the social, demographic, political, ecological and other dimensions, cannot be ignored. The specificity of modern innovative development is the penetration of technology in all spheres of society, including public administration and the social sphere (Ślusarczyk and Haque (2019), Kozubikova and Kotaskova (2019)). Several studies have substantiated the correlation between economic and social indicators (Vasilyeva et al (2018)). It therefore requires a deeper study of the correlation links between the different dimensions of the external business environment and innovation in the financial sector.

Methodology

The main methodological toolkit used in this study is the Spearman's rank correlation. Spearman's rank correlation is a non-parametric measure of statistical dependence between two variables, ranked in an increasing or decreasing order. Spearman's correlation coefficient determines the strength and the direction of monotonic relationship between two ranked variables, rather than the strength and direction of linear relationship, which is what Pearson's correlation determines.

The following are some of the methodological aspects of the application of correlation analysis in this study.

First of all, in order to carry out a correlation analysis between the indicators of business environment development and diffusion of FinTech innovations it is necessary to determine the list of quantitative parameters and to form the information base of the research. To quantify the two components between which the correlation is analyzed, it is proposed to use an index method that allows comparative analysis of indicators of different countries without further normalization and provides a generalized assessment of many indicators in a particular area (Alikariev and Poliakh (2018), Janoskova and Kral (2019), Kiseľáková et al (2018)). Therefore, it is necessary to select the appropriate index parameters to characterize all dimensions of the business environment and technological development of the financial sector.

To quantify the spread of technological innovation in the financial sector, it is proposed to use the Technological Financial Services Index (TFSI) – an integral indicator proposed by the authors. It is based on a linear model of calculating the level of technologization of financial services using the weighted sum method. Eight indicators, weighted by the appropriate weighting factor, are included in the index calculation. These indicators include the financial component expressed as the share of population with an account in a financial institution or mobile money provider (weight coefficient based on the the Fishburn formula – 0.04167), the technological component expressed as the share of the population using the Internet at least once a week (weight coefficient 0.04167) and six comprehensive indicators that include the share of population who use internet banking (weight coefficient 0.22222), the share of population conducting other financial transactions (securities transactions, insurance) via the Internet (weight coefficient 0.19444), the e-commerce share in total sales (weight coefficient 0.08333), the share of population who use electronic payments (automatic and online) (weight coefficient 0.15278), the share of population who use mobile phones to pay bills (weight coefficient 0.15278), the share of traditional loans substitution by alternative on-line financing, (crowdfunding and peer-to-peer) (weight coefficient 0.11111).

Moving on to the characteristics of a business environment, first, it is necessary to distinguish its constituent elements or parameters, and secondly, to identify indicators (indexes) by which these parameters can be evaluated and analyzed.

For the purpose of analysis, we will present the structure of the business environment by the degree of its influence on the activity of economic entities and the ability to control the factors of the business environment by the business entity. According to this division, the business environment can be distinguished to the internal (controlled) business environment, external controlled (direct impact) and external uncontrolled (indirect impact) business environment.

The internal business environment reflects the company's management system, including the international management system, technological level, cost, personnel, financial, investment and marketing policies. An external controlled environment encompasses the interaction of the enterprise with customers, suppliers, intermediaries, partners and competitors. At this level, there may be an interaction between the company and the FinTech segment. That is, the use of innovative financial services by enterprises is an example of their interaction with the external environment. The degree of use of FinTech in the activity of the enterprise will be determined primarily by the factors of the external uncontrolled environment.

The external uncontrolled business environment includes general economic development (economic dimension), politics and law (political dimension), social and cultural development (sociocultural dimension), development of science and technology (technological dimension), demographic situation (demographic dimension), environmental protection (ecological dimension). As indicators to evaluate the parameters of the business environment, we use the most famous international indexes, which are calculated by international organizations and experts. The characteristics of the indicators selected for analysis are presented in Table 1.

Table 1: Indexed parameters of external business environment

Index	Methodology	Source / developers
Social Progress Index	Twelve components in three categories: - Basic human needs (nutrition and basic medical care, water and sanitation, shelter, personal safety); - Foundations of wellbeing (access to basic knowledge, access to information and communications, health and wellness, environmental quality); - Opportunity (personal rights, personal freedom and choice, tolerance and inclusion, access to advanced education)	Social Progress Imperative

Human Development Index (HDI)	The HDI is the geometric mean of normalized indices for three dimensions of human development: - Health (assessed by life expectancy at birth); - Education (mean of years of schooling for adults aged 25 years and more and expected years of schooling for children of school entering age); - Standard of living (gross national income per capita)	United Nations Development Programme
Global Competitiveness Index (GCI)	The overall GCI includes three sub-indexes and their corresponding pillars: - Basic requirements sub-index (institutions, infrastructure, macroeconomic environment, health and primary education); - Efficiency enhancers sub-index (higher education and training, goods market efficiency, labor market efficiency, financial market development, technological readiness, market size); - Innovation and sophistication factors sub-index (business sophistication, innovation)	World Economic Forum
Index of Economic Freedom	The Index is based on 12 factors, grouped into four broad categories (pillars): - Rule of Law (property rights, government integrity, judicial effectiveness); - Government Size (government spending, tax burden, fiscal health); - Regulatory Efficiency (business freedom, labor freedom, monetary freedom); - Open Markets (trade freedom, investment freedom, financial freedom) (Miller et al. 2016)	The Wall Street Journal and the Heritage Foundation
Gini Index	Statistical measure of economic inequality, measuring income distribution among a population	Eurostat
Environmental Performance Index	The Index is based on 20 performance indicators in 9 policy categories: health impacts; air quality; water and sanitation; water resources; agriculture; forests; fisheries; biodiversity and habitat; climate and energy	Yale Center for Environmental Law and Policy; Center for International Earth Science Information Network; World Economic Forum
Ease of doing business	Ease of doing business ranking includes ten areas: starting a business, dealing with construction permits, getting electricity, registering property, getting credit, protecting minority investors, paying taxes, trading across borders, enforcing contracts and resolving insolvency	World Bank Group
Democracy Index	The Index is based on five categories and 60 indicators within these categories: electoral process and pluralism; civil liberties; the functioning of government; political participation; and political culture	Economist Intelligence Unit
Corruption Perceptions Index (CPI)	The CPI is calculated using 13 different data sources from 12 different institutions that capture perceptions of corruption within the past two years	Transparency International
Digital Readiness Score	Includes 7 index groups: technology adoption, start-up, human capital, technology infrastructure, business and	Cisco Corporate Affairs

	government investment, ease of doing business, basic needs (Yoo et al. 2018)	
Digital Economy and Society Index (DESI)	DESI is composed of 5 principal dimensions, each divided in a set of sub-dimensions, which are in turn composed by individual indicators. The dimensions are: Connectivity, Digital Skills, Use of Internet, Integration of Digital Technology, Digital Public Services	European Commission
ICT Development Index (IDI)	The IDI is a composite index that combines 11 indicators. The Index divided into the following three sub-indices: ICT access sub-index; ICT use sub-index; ICT skills sub-index	International Telecommunication Union

Given the complex nature of most of the indices under consideration, they can be used to characterize multiple dimensions of the business environment. Taking into account the methodology of index calculation discussed in Table 1, Fig. 1 presents the proposed relationship between business environment measurements and the indices selected to characterize them. Note that straight lines are used to indicate the full correspondence of the indicator to the selected business environment parameter. The dotted line indicates the partial correspondence of the index to this dimension of the business environment.

Fig. 1: Indicators of analysis of external business environment

Therefore, the following international indices and indicators are used to characterize business environment measurements:

- Economic dimension: Index of Economic Freedom, Gini Index, Ease of doing business, Global Competitiveness Index;
- Political dimension: Democracy Index, Corruption Perceptions Index, optional – Index of Economic Freedom;
- Sociocultural dimension: Social Progress Index, optional – Corruption Perceptions Index, Human Development Index;
- Demographic dimension: Human Development Index, optional – Social Progress Index;
- Technological dimension: Digital Readiness Score, ICT Development Index, Digital Economy and Society Index;
- Ecological dimension: Environmental Performance Index.

Results and Discussion

The practical implementation of the proposed approach to the analysis of the relationship between the level of technological financial services and the parameters of business environment development was carried out on the basis of statistics for 2016 for 28 countries in the European region: Austria, Belgium, Bulgaria, Croatia, Czech Republic, Denmark , Estonia, Finland, France, Germany, Greece, Hungary, Ireland, Italy, Latvia, Lithuania, Luxembourg, Malta, Netherlands, Norway, Poland, Portugal, Romania, Slovakia, Slovenia, Spain, Sweden and UK.

The formation of such a sample of countries and the selection of the study period are due to the limited statistical data for calculating the technological financial services index. Accordingly, for the parameters of the business environment, the index values were also selected for the listed European countries for 2016. This will ensure the comparability of the data and the adequacy of the results. Thus, we analyze the correlation relationships between the technological financial services index and business environment parameters using Spearman's rank correlation methodology and the analysis of correlation fields of business environment parameters and the technological financial services index. The results of modeling correlation relationships based on the correlation fields are presented in Fig. 2-4.

Fig. 2: Correlation fields of the Technological Financial Services Index and indicators of economic dimension of external business environment

As can be seen from Fig. 2 the relationship between the technological financial services and the economic dimension of the business environment cannot be described by linear dependence. While it is generally possible to find a direct link between the technologization of financial services and global competitiveness, economic freedom and ease of doing indices, and reversed relationship with the Gini index, the variance in the correlation of variables is quite wide. According to the results obtained by constructing the correlation field, the Gini coefficient has the lowest level of correlation with the level of technologization of financial services. It may indicate that innovations in the financial sector do not have a significant impact on the distribution of income between different segments of society, and vice versa.

Among the analyzed indicators of economic dimension of the business environment, the Global Competitiveness Index shows the highest level of correlation with the Technological Financial Services Index. According to the value of the coefficient of determination, the relationship between these variables is described by a linear function for 67% of cases. However, the higher correlation level of this pair of indices, compared to other indicators selected to characterize the economic dimension of the business environment, may be related to the complexity of the Global Competitiveness Index itself. The GCI it includes not only economic but also other components whose impact on the results of correlation analysis can be decisive.

Regarding the next set of indicators characterizing the technological and innovative dimension of the business environment, we can say that there is a clear relationship between the technological financial services and indices of digital readiness, ICT development, digital economy and society.

According to the formed correlation field (Fig. 3), all three analyzed indicators of technological development have a direct linear dependence with the indicator of technologization of financial services. The determination coefficient in all three cases ranges from 0.77 to 0.81, which means that the established dependency is valid in about 80% of the cases and shows a strong correlation of the variables.

Fig. 3: Correlation fields of the TFSI and indicators of ecological and technological dimensions of external business environment

Regarding the environmental dimension indicator (Environmental Performance Index) it is not possible to detect its correlation with the technologization of financial services according to the correlation field.

The next group of indicators presented in Fig. 4 demonstrates the correlation between the technological financial services index and the indicators of social, political and demographic dimensions of the external business environment. First of all, it can be noted that all the indicators considered have a strong correlation with the technological financial services index. The strongest correlation link is traced between the TFSI and the Corruption Perceptions Index.

Fig. 4: Correlation fields of the TFSI and indicators of political, sociocultural and demographic dimensions of external business environment

The high level of linkage between the technologization of financial services and the level of corruption can be explained as follows: the lower the level of cash payments, the lower the shadow economy and the share of payments that goes uncontrolled outside the banking system. Thus, it can be assumed that the correlation between the studied indicators is more indicative of a positive impact of the technologization of financial services on the rate of the Corruption Perceptions Index than vice versa. It can also be noted that, as the previous findings have shown, there is a close direct relationship between the general level of digitization in the country and the digitization of the financial sector in particular, so a significant correlation between the index of technological financial services and the corruption perception index may be associated with a decrease in the level of corruption in all areas of society, including government agencies, through the digitization and automation of many services and processes in the public sector (when issuing permits, conducting inspections, etc.).

For an in-depth analysis of the linkage of technologization of financial services to business environment parameters, we calculate Spearman's rank correlation indicators and test their statistical significance according to p-value and Student's t test. The results of Spearman's rank correlation analysis are presented in Table 2.

Note that due to the complexity of the Global Competitiveness Index and its coverage of various dimensions of the business environment, including not only economic, but also social, demographic,

technological and others, the correlation coefficients were analyzed both for integral values of the GCI and its 12 pillars.

Table 2: Spearman's correlation analysis results

Variables in correlation with the TFSI	Spearman Rank Order Correlations	t(N-2)	p-value	Tightness and nature of the relationship	Statistical significance
Global Competitiveness Index	0,838604	7,849694	0,000000	Strong, direct	Significant
1st pillar. Institutions	0,887247	9,807368	0,000000	Very strong, direct	Significant

Digital Readiness Score	0,893533	8,899826	0,000000	Very strong, direct	Significant
Environmental Performance Index	0,368363	2,020360	0,053759	Absent	Not significant

Thus, the results of the analysis of the correlation field and the calculation of the Spearman correlation coefficients for the relationship between the business environment parameters and the technological financial services index revealed that there is a statistically significant correlation between the majority of the variables.

The lack of linkage to innovation in financial services is only specific to the environmental dimension (Environmental Performance Index) and the 10th pillar of the Global Competitiveness Index ("Market Size").

The lack of relevance to the environmental dimension is logical and understandable given the specifics of the variables chosen, since the FinTech innovations are a service industry and, most of all, automated online operations, so they do not require the use of natural resources.

In addition, the following conclusions were drawn from the study.

The highest level of correlation between the technologization of financial services and the ICT development and digital readiness is expected. The correlation was confirmed by three different indexes, calculated using slightly different methods and characterizing different aspects of technological innovation diffusion and its perception by society. However, all three indices showed virtually identical results both in modelling the correlation field and in calculating the Spearman correlation coefficients, and confirmed the existence of a very strong, direct, statistically significant correlation with the technological financial services index.

Economic environment parameters, such as the Economic Freedom Index, Ease of doing business and Gini Index, confirmed the existence of a statistically significant link with the Technological Financial Services Index. At the same time, the strength of this link is lower than the correlation of the TFSI and indicators of technological, political and sociocultural dimensions. Therefore, we can conclude that not financial or economic but technological development is the main determinant of FinTech innovations. The level of economic development does not have a decisive influence on the spread of FinTech innovations.

At the same time, it should be noted that due to limited statistical data, only the countries of the European region were included in the analyzed sample. These countries have at least an average level of financial and economic development, which ensures that they have the minimum necessary conditions for diffusion of FinTech innovations. In our opinion, this could have affected the results of the correlation analysis. It can be assumed that the diffusion of FinTech innovations requires a certain level of economic development, which, in the future, will not have a decisive influence over other factors. Insufficient level of economic development in other non-sampled countries can be a significant factor of the low level of technologization of financial services. This can be considered as a major drawback and limitation of the proposed model and the direction of further research.

The parameters of the political and social environment strongly correlate with the technologization of financial services. This is confirmed by the Spearman correlation coefficient values for the Corruption Perceptions Index (0.89); the 1st pillar of Global Competitiveness Index ("Institutions") (0.89); the Social Progress Index (0.82); Democracy Index (0.81). Therefore, important conditions for the development of FinTech innovations and technologization of financial services are the protection of intellectual property and investor rights, the legal regulation of economic relations, the stability of the political system, the independence of the judiciary etc. The factors that characterize human development, including access to information resources, educational attainment, protection of civil rights and freedoms, are also significant.

Conclusions

The correlation analysis of the business environment parameters and the technological financial services index provided the following conclusions:

- the highest level of correlation is between the technologization of financial services and the ICT development and digital readiness, which is confirmed by three different indexes - Digital Economy and Society Index, Digital Readiness Score, Environmental Performance Index;
- technological development is the main determinant of FinTech innovations, while the level of economic development does not have a decisive influence on the spread of FinTech innovations;
- the parameters of the political and social environment strongly correlate with the technologization of financial services;
- the lack of linkage to innovation in financial services is only specific to the environmental dimension of business environment.

Meeting the Housing Needs of Seniors In the Poznań Agglomeration

Anna JANCZ

Poznań University of Economics and Business, Institute of Economics, Department of Microeconomics, Poznań, Poland, anna.jancz@ue.poznan.pl

Abstract

The aim of the article was to recognize whether, within the framework of the conducted housing policies in the municipalities of the Poznań agglomeration, actions are taken to meet the housing needs of the seniors. To this end, provisions concerning housing policies were analysed in the strategic and development documents of the surveyed commune.The research shows that the communes' activities focus primarily on adapting the social infrastructure and the cultural offer for spending free time to the needs of the elderly, which is to counteract the social exclusion of the elderly in the commune. Senior housing policy in the analysed municipalities is insufficiently implemented.

Keywords: housing policy, senior housing, senior, elderly

Introduction

Poland is a country with an ageing society. The increasing proportion of seniors in the overall population structure, which has been observed for many years, can influence the adaptation of many areas of everyday life to the needs of older people.

One of the areas in which changes should be observed is the real estate market. The key activity of the state authorities in this respect seems to be the creation of the country's senior policy, including housing. The current national housing policy is subordinated to the creation of demand for the purchase of real estate mainly by young people, which in the long run may not necessarily have a positive impact on the proper development of the real estate market.

The issues of housing policy are discussed in national and world literature. One of the country's developed in these analyzed housing conditions in the context of the housing situation in Poland is Mieszkalnictwo w Polsce. Analiza wybranych obszarów polityki mieszkaniowej w Polsce prepared by Habitat for Humanity Poland. In the report analyzing the results of experts, solutions to the housing problems of Poles, paying attention to the condition of housing and problems related to the management of state resources. In addition, the results of public opinion polls and the opinions of local government authorities included in it. Case studies were also carried out for four cities in Poland, which analyzed how housing policy is conducted. Qualitative research results available for leading providers of housing services and housing. The conducted research concerns that the housing needs of Poles are not fully met. Housing goals do not cover all areas where deficits are defined, e.g. too few flats for the least affluent (Habitat for Humanity, 2015).

The housing situation in Poland is monitored by the state authorities through censuses of residents and apartments (once every four years), based on possible problems related to the description of housing conditions related to service (GUS, 2019a). In addition, Główny Urząd Statystyczny publishes once a year a study on housing relations in Poland.

Issues conducted in residential Poland have been conducted for a long time. The emerging solutions focus primarily on searching for housing needs, the main problems related to housing, related and managed development of housing services, as well as municipal problems in the field of housing

design - financial aspect (Cesarski, 2013; Groeger, 2016; Herbst, 2013; Kucharska- Stasiak, 2008; Lis, 2011; Muzioł-Węcławowicz, 2013; Rącka and Bieda, 2017; Trojanek, 2015). Issues related to meeting the housing needs of older people are rarely addressed (Kłobukowska, 2014; Rataj, Iwański and Bugajska, 2018; REAS, 2015; Zrałek, 2012).

In foreign literature, housing issues are also addressed. Many studies have been created in this field in various countries (Aalbers, 2004; Aalbers & Christophers, 2014; Allen and other, 2004; Anderson, 2004; Gibb, 2015; Hochstenbach, 2017; Lopez & Paredes, 2018; McKeea, Muirb & Moorec, 2017; Paris, Gray and Muir 2003; Pato and Pereira 2016; Yates, 2013).

The study aimed to identify whether, within the framework of local policies (in regional development strategies and long-term programs of municipal housing management), the communes' activities are aimed at meeting the housing needs of the seniors. The analysis was carried out on the basis of strategic-development documents of 17 communes of the Poznań county and the city of Poznań (the communes of the Poznań county together with Poznań constitute at the same time the area of the Poznań agglomeration), based on which it can be concluded whether the authorities of local government units take into account the housing needs of the oldest people in their communes when creating local policy. It is believed that the housing needs of older people are marginalized in the documents examined.

Assumptions of housing policy in Poland

The satisfaction of housing needs is considered to be one of the basic human needs (Kucharska-Stasiak, 2016; Dziworska, 2017). These needs belong to the group of subjective needs-striving for a certain comfort of life or social status (Tanaś et al. 2019, Trojanek 2013). Living is a special good. It plays a significant role and is essential in the life of every person. Unfortunately, not every household can guarantee its own housing needs (Główka, 2009).

However, the satisfaction of housing needs is not entirely achievable. Even in the event of an increase in income and a drop in apartment prices, the difference between potential and effective demand would never be equal to zero. As regards the price elasticity of demand, it should be pointed out that a change in the price of a residential property may result in a less than proportional change in demand. Most often, the flexibility index is less than unity. This is due to the lack of a substitute for the good that is the apartment (Trojanek, 2008).

The issue of the right to live was first raised by T. Toeplitz in the interwar period. The provisions of these considerations were first included in 1948 in the Universal Declaration of Human Rights (Lis, 2008; Tolwiński, 1975).

In Poland, the housing policy is shaped based on the provisions of the Constitution of the Republic of Poland . Indicate the provision of Article 75, point A, point A, B, C and D. 1 of the document indicated, reading as follows: "public authorities pursue policies to meet the housing needs of citizens, in particular, to combat homelessness, support the development of social housing and support citizens' efforts to obtain their own housing". Special attention shall be paid to the tenant of the housing stock. The authorities of the country were obliged to adopt a separate resolution, defining first of all the rights protecting tenants. This is due to the point. 2 of the indicated Constitution (Constitution of the Republic of Poland of 2 April 1997).

The housing policy conducted in Poland is a part of the social policy of the state, in which the mentioned constitutional postulates for action should be indicated . It is, therefore, the responsibility of the State to provide assistance to anyone who does not have housing needs met. As in other countries , Poland's housing policy is initiated by central authorities (Brenk, Chaczko and Pląsek, 2018; Cesarski, 2016; Lis, 2012; Lis, 2015; Muzioł-Więcławowicz, 2015).

Actions in the field of housing policy are to a large extent delegated to the level of communes, then districts, and are implemented in cooperation with social organisations or private entities.

As far as social housing is concerned, a commune is obliged to provide shelter, run and provide places in protected flats, direct to a social welfare home and pay for the stay of a commune resident in that home, set up and maintain a social welfare centre, run and provide places in social welfare homes and support centres of a commune-wide range and direct persons requiring care to tchem and to provide shelter to foreigners referred to in Article 53 paragraph 1 point 15 and Article 53s paragraph 2 point 4 of the Act of 13 June 2003 on foreigners, providing shelter to foreigners who have obtained a permit for a tolerated stay on the territory of the Republic of Poland (MRPiPS, 2020).

The Ministry of Funds and Regional Policy (responsible, among others, for the state's housing policy), within the framework of the conducted housing policy, which is the point of these considerations, has identified four areas of action, which include (MFiPR 2020): Narodowy Program Mieszkaniowy, housing aid, support for term modernization and renovation, housing cooperative.

Narodowy Program Mieszkaniowy is currently the most important and recent document, describing in a comprehensive way the specific objectives and activities of the authorities that create the country's housing policy. In Poland's housing policy, Narodowy Program Mieszkaniowy has included provisions taking into account the housing situation of seniors. So far, the state aid provided by the State has been social welfare homes and protected housing. Moreover, the housing situation of the elderly has not been addressed before in any strategic documents of the country. The elderly person's place in the housing market was rather marginalised.

It, therefore, seems important to pay attention to seniors in an ageing society. The indicated age group may report additional needs when choosing an apartment due to certain movement restrictions or health problems. Thus, there may be a need to provide different types of housing that will provide care at home.

In the housing policy, the term senior housing was cited for the first time. The concept is defined as a resource adapted spatially, environmentally and technically to the needs of seniors.

It is important from the point of view of the issues raised that attention should be paid to whether the implemented senior policy includes housing policy aspects. It turns out that the document addresses the issue of adaptation of the current housing to the demographic situation, possibilities, including financial possibilities and needs of the seniors. One of the instruments planned to be introduced is a reversed mortgage and a life annuity, which are intended to enable seniors to benefit from additional benefits paid under the ownership of the apartment transferred after death. At this point in time, work is underway on the appropriate shape of this instrument.

Currently, seniors can apply for a sheltered apartment within their own homes, where they benefit from a preferential rent. In addition, the first proposals are made to create housing estates dedicated to the elderly with appropriate infrastructure and services (MRPiPS, 2020).

One of the objectives of the senior policy is "to promote spatial architectural planning that is adapted to all (universal design) and takes into account the needs of different age groups (including the elderly)".

Among the submitted recommendations is indicated (MRPiPS, 2020):

- working with seniors and social organisations on the assessment of public places and buildings in terms of accessibility for elderly and preparing plans and proposals for changes that take into account the needs of seniors,

- raising awareness of the energy efficiency of senior's homes and buildings and the risk of energy poverty,

- public transport planning, taking into account the needs of elderly (location of stops, running hours, frequency of trips, transfers),

- introduction of measures to shorten the waiting period for service in public places (office, library),

- implementing universal design principles at every level,

- support for the construction of apartment complexes as well as for the change of existing ones, as specially adapted infrastructure and services for the elderly.

Strategic and development documents of voivodeship, county and commune should take into account the provisions of national regulations.

Demographic Diagnosis of The Poznań Agglomeration

The Poznań agglomeration consists of 17 communes of the Poznań county and the city of Poznań, which is the centre of the agglomeration. In the agglomeration, there are urban, urban-rural and rural municipalities. The first of these groups are the following local government units: Luboń and Puszczykowo, the urban-rural communes: Buk, Kostrzyn, Kórnik, Mosina, Murowana Goślina, Pobiedziska, Stęszew and Swarzędz, and the rural communes: Czerwonak, Dopiewo, Kleszczewo, Komorniki, Tarnowo Podgórne Rokietnica and Suchy Las (powiat.poznan.pl).

The Poznań agglomeration is characterized by high demographic potential. At the end of 2018, the Poznań agglomeration was inhabited by 926,746 people, of which 42.2% were from the Poznań district and the remaining 57.8% were residents of Poznań (GUS, 2020). According to the data for 2018 available at the end of 2019, the agglomeration was inhabited by 29.8% of the population of Greater Poland Voivodeship, while the natural growth was 2.7 persons per 1000 inhabitants, while for Greater Poland Voivodeship it was 1.0 persons per 1000 inhabitants and for Poland, in the same period, it was negative and amounted to -0.7 persons per 1000 inhabitants. The population density is, in turn, 338 persons/km2 in the Poznań agglomeration (for the Greater Poland Voivodeship 117 persons/km2, for Poland 123 persons/km2) (GUS 2019b).

It should be pointed out that in the case of Poznań and cities with a similar level of development (e.g. Wrocław, Kraków), which form agglomerations with neighbouring communes, characteristic phenomena are observed which are related to the movement of population within the agglomeration and changes in the age structure (Kayser, 2012).

In the Poznań agglomeration, the migration of people from the central city to the neighbouring communes is observed - a developing suburbanisation process. These movements concern mainly the place of residence of wealthy city dwellers of working age, who continue to benefit from the conditions of Poznań's close location and the city's well-educated offer such as commuting, children's education, studies and leisure activities (Kayser, 2012).

The fact of migration from Poznań, or in fact its direction, is confirmed by the results of the analysis conducted by J. Tanaś in 2014. As the author points out, people who in the years 1995-2010 moved out of Poznań, lived mainly in the Poznań district (1995 – 47.11% of the total migration to the Poznań district from Poznań, 2000 – 61,04%, 2005 – 67,40%, 2010 – 65,26%). The share of people moving out of Poznań to neighbouring communes in the analyzed period was on an upward trend. In turn, the migrants who registered in Poznań at the same time came mainly from the territory of Poland (not including Greater Poland Voivodeship and Poznań County). Their share in the years 1995 – 42.15%, 2000 – 42.85%, 2005 – 46.15%, 2010 – 43.72%. Only 20% on average of the new

registrations in Poznań in the same period concerned people coming from the Poznań district (Tanaś, 2014).

The main directions of migration of the inhabitants of Poznań to the district of Poznań should be indicated as Swarzędz, Luboń and Puszczykowo, Murowana Goślina and Pobiedziska and the communes: Swarzędz, Komorniki, Czerwonak, Dopiewo, Tarnowo Podgórne and Suchy Las as rural areas located closest to Poznań. The rarest people from Poznań moved to the municipalities of Buk and Stęszew (Tanaś, 2014).

Figure 1 presents the age structure according to economic age groups separately for Poznań county and Poznań at the end of 2018.

Fig. 1: Age structure of the population by economic age groups as a percentage of the population in Poznań and the communes of the Poznań count in 2018

Source: Own study based on GUS, 2020.

In Poznań, the share of people in the post-working age is higher than in the communes of the Poznań count. The age structure of the inhabitants of the communes located near Poznań is younger than that of Poznań - both the youngest inhabitants in pre-production age and those in production age. However, the share of elderly people in the total population of the Poznań count is high.

Figure 2 shows the share of people in the post-production age bracket in the communes of the Poznań district and in Poznań in the years 2008-2018.

Fig. 1: Share of people at post-production age in communes of Poznań county and in Poznań in 2008-2018

Source: Own study based on GUS data (2020).

The share of people in the post-production age in 2008-2018 increased both in Poznań and in the communes of the Poznań count. However, the share of people of post-production age in the count of Poznań is lower than in Poznań. At the end of 2008, it was 11.9%, while at the end of 2018 it increased to 16%. In Poznań, the share of people at the beginning of the analysed period was already 18.2% and at the end of 2018 24.5%. Therefore, the process of population ageing concerns both the inhabitants of Poznań and the communes of the Poznań count.

Housing policy of municipalities in the Poznań Agglomeration – analysis of strategic and development documents

The subchapter presents the results of the analysis of strategic and development documents of the Poznań agglomeration communesr in the context of the conducted housing policy. Only the municipal development strategies valid for 2019 and long-term municipal housing programmes were examined (table 1). The review of the documents has been limited to records of actions taken by municipal authorities to ensure adequate housing conditions for the elderly. First of all, it was analysed whether the territorial self-government units' authorities take into account the housing needs of older people when setting the direction of development. In the context of the discussed issues, the following provisions on local housing policy are presented, taking into account the needs of the elderly.

Table 1: Records in the development strategies for gminas of the Poznań county taking into account the process of an ageing population

No.	Name of the local government unit	Name of the strategy of development and housing development programme	Record in the document
1.	Czerwonak	-*Strategia Rozwoju Gminy Czerwonak na*	-lack of infrastructure for the elderly (nursing homes for the elderly, palliative care facilities, temporary stay for the elderly related to

		lata 2012-2020 *-Wieloletni program gospodarowania mieszkaniowym zasobem Gminy Czerwonak w latach 2017 – 2021*	rehabilitation and care), - signalled willingness to broaden and improve the level of services provided for the elderly by developing a system of assistance for the elderly and increasing their accessibility to protected housing, - municipal programme of support and prevention of social marginalization of elderly people, - counteracting the isolation and social exclusion of seniors by developing and promoting the activities of the Senior Citizen's Club, systematic cooperation with Social Welfare Houses and Health Care Centres in neighbouring municipalities and promoting the value of the participation of seniors in social life, - building (launching) a Daily Residence and Rehabilitation House, - currently, there is no infrastructure such as a daycare home for seniors, - The vision of the commune indicates the creation of favourable living conditions for all inhabitants, - development of housing and support for municipalities in the construction of housing for people requiring social assistance
2.	Buk	- no current strategy available *-Wieloletni program gospodarowania mieszkaniowym zasobem Gminy Buk na lata 2014 – 2019*	- lack of records
3.	Dopiewo	*-Strategia rozwoju gminy Dopiewo na lata 2016-2025* *-Wieloletni program gospodarowania mieszkaniowym zasobem Gminy Dopiewo na lata 2016-2020*	- the general trend for people in the post-working age bracket in the commune is at the level of a steady growth of 100 people per year on average, however, the commune authorities assume the need to incur higher costs in the future related to social and caring functions for the group of seniors
4.	Kleszczewo	- no current documents available	-

5.	Komorniki	-*Strategia rozwoju gminy Komorniki 2013-2020* -*Program gospodarowania mieszkaniowym zasobem Gminy Komorniki na lata 2020 – 2024*	- willingness to organise a Day Care Home for the Elderly in Plewiska in an adapted facility after Herbapol
6.	Kostrzyn	-*Strategia rozwoju gminy Kostrzyn na lata 2015-2022* -*Wieloletni program gospodarowania mieszkaniowym zasobem Gminy Kostrzyn na lata 2016 -2020*	- the commune wants to be a friendly place to live for its residents, guaranteeing comfortable living, rest and recreation conditions (vision)
7.	Kórnik	-*Strategia rozwoju miasta i gminy Kórnik 2017-2025* -no available programme	- building a house for intergenerational integration
8.	Luboń	-*Strategia rozwoju miasta Luboń na lata 2019-2028* -no available programme	- the functioning of the day care centre
9.	Mosina	-*Strategia Rozwoju Gminy Mosina na lata 2014 do 2020+* -no available programme	- the social welfare infrastructure is planned to be expanded by providing in-patient day care for the elderly, disabled and lonely and by providing hot meals for those in need of support, - The Social Welfare Centre in Mosina carries out tasks in the field of feeding various groups of people, including the elderly, - the development of various forms of housing construction is planned
10.	Murowana Goślina	-*Strategia Rozwoju Miasta i Gminy Murowana Goślina na lata 2013-2020* -*Wieloletni program gospodarowania* *mieszkaniowym zasobem* *Gminy Murowana*	- drawing attention to the elderly in the editorial office of the commune vision: Brick Guesthouse attractive for residents: The competitiveness of the commune will be based on the offer of residence attractive for the existing residents as well as for those who intend to settle in the vicinity of Poznań. It is important that the offer of accommodation is competitive for young people, attractive for families, friendly for the elderly and disabled,

		Goślina na lata 2015 do 2020	- the creation and functioning of a day house for the elderly is planned (adaptation of the existing premises, elimination of architectural barriers), - the market offer of flats in terms of construction costs and housing prices must take into account the capabilities of different social groups with housing needs
11.	Pobiedziska	*-Strategia Rozwoju Miasta i Gminy Pobiedziska na lata 2012-2020* *-Wieloletni Program Gospodarowania Mieszkaniowym Zasobem Gminy* *Pobiedziska na lata 2017 – 2022*	- the development of social infrastructure, i.e. diversified social and health services for the elderly, is planned, - there is thought of increasing activities in the field of community support, institutional care, e.g. creation of a new nursing home, - Pobiedziska has the "Hospes Hospiti Sacer" Welfare House, which has 18 places for the elderly, including the disabled and chronically ill.
12.	Puszczykowo	*-Strategia Rozwoju Miasta Puszczykowo na lata 2010-2020* *-Wieloletni program gospodarowania mieszkaniowym zasobem gminy Miasta* *Puszczykowo w latach 2016 – 2020*	- lack of records
13.	Rokietnica	*-Strategia Rozwoju Gminu Rokietnica na lata 2014-2020* -no available programme	- there are plans to create infrastructure for the needs of disabled and elderly people (including rehabilitation facilities, occupational therapy workshops, day homes), - the housing policy is mainly geared towards young people (it is indicated in the document that the municipality is mainly settled by young people - the dependency ratio is favourable in comparison with other municipalities)
14.	Stęszew	*-Strategia Rozwoju Gminy Stęszew na lata 2016-2026* *-Wieloletni program gospodarowania mieszkaniowym zasobem gminy Stęszew na lata 2016-2020*	- it is planned to improve care for the elderly by creating day homes for seniors
15.	Suchy Las	*-Strategia rozwoju gminy Suchy Las na lata*	- undertaking activities aimed at improving housing management and developing various

		2013-2022 *-Programu gospodarowania mieszkaniowym zasobem Gminy Suchy Las na lata 2016-2020*	forms of housing construction in the municipality, - adaptation of the social housing base to social needs (the main idea behind this objective is to verify and adapt the existing housing stock to the needs of social housing)
16.	Swarzędz	*-Strategia rozwoju społeczno-gospodarczego gminy Swarzędz, Swarzędz 2020 (rok 2011)* *-Wieloletni Program Gospodarowania Mieszkaniowym Zasobem Gminy* *Swarzędz na lata 2020-2024*	- a system of assistance and support for the disabled, children and the elderly is planned (counteracting social exclusion) - the housing market in the municipality is considered by the authorities to be diverse (inhabited by different age groups)
17.	Tarnowo Podgórne	*-Strategia rozwoju gminy Tarnowo Podgórne, 2009* *-Wieloletni program gospodarowania mieszkaniowym zasobem Gminy Tarnowo Podgórne na lata 2016-2020*	- lack of records

Source: Authors' own calculations based on the development strategy for communes of Poznań county, 2020

The analysed strategies signal the problem of an ageing society. All the strategies under analysis note the problem of increasing the participation of seniors in the population structures from year to year, which is included in the strategic development goals.

The entries in the documents indicate that the hitherto influential population who decided to live in the areas of the analysed communes are mainly young and middle-aged people, who constitute the demographic development potential of the area. It should also be pointed out that the communes note that the most significant problems as a result of the ageing society will be observed in Poznań, from where young and middle-aged people migrate (purchase of a cheaper flat or construction of a detached house on the outskirts of Poznań).

When pointing out the main priorities for the development of communes, which take into account the needs of the elderly, some universal and at the same time, convergent areas of undertaken activities should be indicated. These include the objectives of activating the elderly and preventing social exclusion (providing medical and rehabilitation services, organising cultural activities for the elderly and the leisure sphere, setting up universities of the third age and senior citizens' circles, ensuring adequate public transport, and removing architectural barriers).

Records concerning the housing sphere in strategic documents appear much less frequently or are generalized. In the visions of these strategies, the authorities usually indicate that the area of their

municipalities is friendly to residents of different ages. The solutions included in the documents include the desire to increase the number of places for temporary stay of seniors in care facilities mainly offered by social assistance, to extend the offer of day homes for seniors, to increase access to protected and social housing, to eliminate architectural barriers to the public housing stock, and to develop various forms of housing construction.

The long-term housing programs drawn up by territorial self-government units' authorities contain, first of all, provisions concerning the guarantee of statutory tasks imposed on gminas - such as a plan of renovation of the gmina housing stock, plans to increase the available number of protected or social housing. None of the documents cited in this respect contained information concerning assistance to the elderly.

Activity in these areas will undoubtedly have an impact on ensuring an appropriate quality of life for the elderly in terms of guaranteed services. The analysis of the documents shows that housing policy for seniors exists, but is currently not a priority area. Municipalities focus on regulating land ownership, creating local plans. Instead, there is a lack of provisions in the strategies concerning the use of land for investment projects concerning strictly senior citizens' homes or the adaptation of existing housing for the needs of the elderly. Municipalities focus on and develop tasks in the field of social policy assurance.

When analysing the strategic and development document of the city of Poznań, it should be pointed out that in January 2017 it was updated (Strategia Rozwoju Miasta Poznania 2020+). The new provisions introduced in the document were influenced by the changes noticed in the macroeconomic environment of Poland, including Poznań. Five areas of global conditions determining the development of the city of Poznań were indicated. One of them was the phenomenon of an ageing society. This problem has and may continue to have an impact on the demographic and economic development of the city, which is noticed by the city authorities. It is assumed that the city will be increasingly inhabited by the elderly: well educated and entrepreneurial. They will be specialists in various industries and will sell or pass on their companies to their children. These people may report a higher quality of life requirements than existing seniors. They may also want to continue their professional career or train younger people (passing on the skills and experience gained so far).

Poznań is a city focused on meeting the housing needs of seniors. Residential investments have already been made here, which have been exclusively intended for the elderly. From the activities undertaken by the city authorities in the scope of satisfying the housing needs of the elderly, the cooperation of the city of Poznań with Towarzystwo Budownictwa Społecznego Sp. z o.o. should be indicated above all (PTBS). The program consisted of concluding contracts for participation in the costs of construction of flats in PTBS resources by the city in exchange for the delivery of a council flat by an elderly person to the city. The PTBS residential building and its premises have been technically and architecturally adapted to be inhabited by the elderly (elevators, thresholdless passages, handles, driveways, floors in different colours to allow orientation, proximity to greenery and public transport). The old building on Grabowa Street was revitalized, while a completely new one was built on Drewlańska Street.

Flats for seniors are also created thanks to the city's cooperation with the municipal company ZKZL. In its investment plans, the company has planned to allocate part of the flats from the ground floors of the buildings to the elderly or disabled people.

The provisions of the strategy and the initiative taken prove that the authorities of the city of Poznań are constantly monitoring the demographic situation of the city and trying to meet it by creating newer and newer initiatives. The housing policy of the city of Poznań, due to the importance of the city, is conducted on a much wider scale than in suburban gminas oriented in terms of development mainly towards young people undergoing the suburbanization process.

Conclusion

Everyone needs housing. The housing policy of the state has aimed at providing equal opportunities in access to housing for people in difficult financial situation. Setting housing policy goals should take into account the housing needs of people at risk of social exclusion. One of the groups of people who may need help from the state in the future in guaranteeing housing are the elderly.

The problem of population aging is now widespread, it also applies to Poznań, where the percentage of elderly people has recently been constantly increasing. Senior policy in the Poznań agglomeration is conducted in the field of social welfare, shaping services exclusively for seniors, organization of free time and adaptation of public buildings for the elderly and disabled. Social assistance is implemented through the functioning of social welfare homes, feeding the elderly or the functioning of daycare homes. However, in the majority of the surveyed gminas, no activities are undertaken in the area of investing in housing for seniors and these issues are not properly covered by strategic and developmental documents.

Perhaps during the period of creating strategic documents, interest in the housing situation of the elderly was not significant enough. In addition, mainly young people move to suburban communes, it is possible that up to now there was no need to guarantee housing for the elderly.

In Poznań, interest in the housing situation of seniors is greater. One of the most important initiatives implemented in the Poznań agglomeration is the City's cooperation with PTBS Sp. z o. o. and providing independent housing with preferential rent to seniors as part of the provision of communal housing.

Records in the development strategies of the Poznań agglomeration's communes, taking into account current and projected demographic changes and the awareness of the municipalities' authorities of the impact of population ageing on the further development of municipalities may lead to more and more recent initiatives in this area and directions of development. Cooperation between private entities and municipal authorities also seems to be crucial here, which may affect the level of housing needs of current and future seniors according to their expectations.

Consumers Revealed Preferences In The Secondary Housing Market In Poznań

Justyna Tanaś

WSB University in Poznań, Poznań, Poland
justyna.tanas@wsb.poznan.pl

Abstract

Many studies on buyers' characteristics and their housing market preferences are of a qualitative nature. Surveys are performed to classify the attributes of potential buyers, which are typically targeted. The study aims to evaluate the buyer's characteristics as well as the preferences reported on the secondary housing market in Poznań. To this end, information was collected on transactions concluded on the secondary market in Poznań in 2010-2016. Instead, the information contained in the land and mortgage registers (Section II-ownership and Section IV-mortgage) was used to assess the gender, the age of the buyers and the form of financing the buying of real estate. Additionally, the information was supplemented with Cadastare data and Google Street View. The analysis shows that the largest number of flats were purchased in Nowe Miasto and Grunwald. Among the buyers, young people up to 35 years old dominated (they constituted about 48% of the buyers). The area of 2/3 of the apartments ranged from 30 to 60 m², and 2/3 of the total were apartments located in buildings built in the traditional technology. What is essential, the majority of flats purchased with a loan (ca. 54%) constituted in the analysed period. The results obtained may serve as a basis for further consideration of the demographic conditions of demand on the Poznań housing market.

Keywords : Buyers' Preferences, The Housing Market, Revealed Vs Stated Preferences.

Introduction

The choices made by consumers on the market are the result of their preferences and budget constraints. Different motivations are at the basis of the final decisions, which determine a given a choice from the alternatives under consideration. Consumers' preferences are, to put it simply, their subjective assessments of the characteristics of the goods in question that form the basis of their choice at the time of purchase. Research on consumer preferences is necessary to determine what rationale the purchaser has when deciding to buy a given good (Gluszak & Marona, 2017; M. Trojanek, 2013).

Residential real estate is a specific property that is traded in a specific market. This is due to such characteristics of the property as high price to be paid for it, high strength, variety and stability in place (Galster, 1996). This makes the measurement of preferences in the real estate market complicated, and this is an essential issue because housing satisfies one of the basic life needs of a person (Jansen, Sylvia J.T., Coolen, & Goetgeluk, 2011). Since the 1950s, when Rossi (1955) began researching the motives of families in deciding to move, many publications on the factors determining choices in the housing market have been produced (Borth & Summers, 2018; Coulter, Van Ham, & Feijten, 2011).

Most of the research on the characteristics of buyers conducted in Poland, as well as their preferences concerning the residential market, is of a qualitative nature. Most often surveys are conducted, usually targeted, to identify the profile of a potential buyer. The authors draw attention to demographic features such as age, gender and income as determinants of preferences. Some people study housing preferences in relation to the family life cycle and housing mobility. Most of the research focuses on the characteristics of the apartments, such as cost, size and location.

The goal of the article is to identify the profile of buyers of housing (residential) properties and to investigate the preferences identified in the secondary market in Poznań. In order to achieve this objective, information on purchases entered into the secondary market in Poznań in 2010-2016 was gathered. Then, the information provided in the land and mortgage registers was used to determine the gender, age of the buyers and way of financing the purchase of the real estate. In addition, the database was supplemented with Cadastre data and Google Street View in order to obtain more detailed information about the apartments being purchased.

Literature Review

Methods For Examining Consumer Preferences

The problem of measuring preferences is the area of interest and research of scientists from many disciplines (de Koning, Filatova, & Bin, 2017; Jansen, Sylvia J.T. et al., 2011). Because of this interdisciplinarity, several different strategies and preference research models have arisen, from simple direct questions from respondents to sophisticated strategies that enable researchers to examine the reasons behind their choices. It can be assessed in many different ways what customers desire. Each approach is based on a set of limiting assumptions and thus serves a specific aim.

Classification of approaches to housing preference research can be done using several different schemes (Timmermans, Molin, & van Noortwijk, 1994). In principle, there are two broad approaches to preference survey - methods for analysing revealed preferences and methods for analysing stated preferences. The research on preferences revealed is based on actual market decisions of consumers (Tanaś, Trojanek, & Trojanek, 2019; R. Trojanek, 2013). The analysis of such preferences is primarily based on historical data. In turn, the stated preferences concern the market behaviour of consumers.

However, it should be remembered that both approaches have certain limitations. They are listed in Table 1.

Table 1: Potential limitations of methods of analysis of preferences revealed and stated

Preferences revealed	Stated preferences
1. Hard to distinguish individual interests from (market) constraints; 2. They are based on the belief that customers are always making rational decisions and are always looking for optimal solutions, which is unlikely; 3. The study may exclude major explanatory factors; 4. Many characteristics are associated which can lead to incorrect conclusions/indicators;	1. The approach may not be accurate because people may express transient expectations or beliefs in a real housing market that can not be realized; 2. The approach assumes that respondents may express their desires while being indifferent or may rely on specific conditions; 3. Factors such as social motivation, risk aversion, and reduction of cognitive dissonance may affect the result of this process.

Source: Jansen S. J.T i in. (red.), (2011) The Measurement and Analysis of Housing Preference and Choice, Springer, s. 20

Both methods have common assumptions:

1) first, they assume that the properties and their surroundings can be described in terms of a set of features (attributes);
2) Secondly, they assume that individuals or households derive usefulness from each attribute.

Different approaches offer different outcomes Therefore, the selection of a particular approach can not be based on the benefit of one method over another, but should be influenced by the sort of information which the researcher is interested in. Nevertheless, many economists share the view that by studying

the choices they make, much more can be learned about human interests than by listening to what they say (Bernheim, 2009). Molin and others (Molin, Oppewal, & Timmermans, 1996) claimed that individuals can disclose their desires only in the act of actual choice, as confirmed by the anthropologist M. Mead's assertion that "what people say, what they do and what they say they do, are completely different things".

Typically the micro-and macro-levels are concerned with variables examined in the housing preferences studies so far. The investigations had been focused on the preference stated and revealed in these studies. Ge and Hako (2006) studied the characteristics of residential preference trends, residential selection criteria and residential satisfaction, and their interrelationships, using questionnaire surveys of two Japanese cities. It turned out that the size of the apartment could predict residential satisfaction (Hwang & Albrecht, 1987), and could affect people's mobility (Diaz-Serrano & Stoyanova, 2010).

Other characteristics of housing preferences involved external environmental quality (Cellmer & Trojanek, 2019; Del Giudice et al., 2017; Kopsch, 2016; Naish, Tan, & Demirbilek, 2011; Szopińska & Krajewska, 2014; R. Trojanek & Huderek-Glapska, 2018; R. Trojanek, Tanas, Raslanas & Banaitis, 2017), green spaces (2016; McCord et al., 2014; Olbińska, 2018; R. Trojanek, Tanas, Raslanas & Banaitis, 2017) location (Kryvobokov & Wilhelmsson, 2007), security and town centre proximity, mass transit (Gadziński & Radzimski, 2016), office proximity, medical and educational facilities (Ceccato & Wilhelmsson, 2011; Wu, 2010). Besides, the preferences examined included factors such as a building's architectural style (Akalin et al., 2009; Stamps, 1999), security, comfort, and flat layout (Wang and Li, 2006; Wu, 2010). Factors such as safety function, expected resale value (Iqbal & Wilhelmsson, 2018), facilities were also examined.

Moreover, in turn, the analysed preferences included factors such as the architectural style of a building (Akalin et al., 2009; Stamps, 1999), safety, comfort, the layout of flat (Wang and Li, 2006; Wu, 2010). Such factors as the role of safety, the expected value of resale (Iqbal & Wilhelmsson, 2018; Renigier-Biłozor, Walacik, Źróbek, & d'Amato, 2018), facilities have also been studied, as well as the price of dwelling, location, distance from shops, schools (Turnbull, Zahirovic-Herbert, & Zheng, 2018; Wen, Zhang, & Zhang, 2014), and other premises, and the size of the house (Borth & Summers, 2018).

Overview of studies in the housing market preferences in Poland

The vast majority of studies of purchasers' preferences on the residential market in Poland carried out over the last few years are studies on local markets usually of the largest cities. The most frequently conducted surveys of preferences stated with the use of a survey questionnaire (Jancz, 2019). In many cases, it was a survey among young buyers, as the respondents were students. A summary of research conducted in recent years on preferences in the real housing market in Poland is presented in Table 2.

Table 2: Summary of studies on buyers' preferences in the housing market in Poland

Test Methodology and Data Sources

This research, as already described, aims to define the profile of buyers in the secondary housing market in Poznań and to explore their preferences. For this reason, data about transactions concluded on the secondary market in Poznań in 2010-2016 were collected from the Property Price and Value Database. Then, as a result of a time-consuming process of reviewing sections II and IV of the land and mortgage registers of the properties that were the subject of trading, the sex, the age of the buyers and the method of financing the property's purchase, among others, were decided. To get more accurate information about the apartments being bought, the database was supplemented with data from the Land and Building Register and using Google Street View. After the database was tidied up (which was necessary due to, e.g. incomplete information on some transactions or lack of the land and mortgage register number), 13779 real estate transactions were finally accepted for analysis. Their number in particular years are shown in Table 3.

Table 3: The number of transactions of residential properties in Poznań in 2010-2016

Year	Number of transactions covered
2010	1826
2011	1792
2012	1710
2013	1853
2014	1881
2015	2683
2016	2034
Total	**13779**

Source: Author's own work.

The developed database contained information on the dwellings being traded and their buyers. The apartments were described in terms of such features as the location by district, area of the premises, construction technology, age of the building, building height and transaction price. As far as buyers are concerned, information was obtained on their gender, age, and how to finance the purchase of property (credit or cash).

Results

Characteristics of purchasers of residential real estate

The purchasers of premises were divided into four primary groups (types), namely: marriages, women, men and others (this group includes, e.g. siblings). Figure 1 shows the share of particular types of purchasers in the total number of transactions in the whole analysed period, while Figure 2 shows the share of particular types of purchasers in particular years of analysis.

Figure 1: The structure of buyers according to the type in the years 2010-2016.
Source: Author's own work.

Figure 2: The structure of buyers by type in individual years covered by the analysis
Source: Author's own work.

The most significant number of flats in the analysed period was purchased by married couples (39.15%). On average, every third apartment was bought by a woman. Slightly less frequent buyers were men (21.63% of all transactions).

In particular, years covered by the analysis, one can observe slight fluctuations in the shares of particular types of purchasers in the total number of transactions in a given year.

When analysing the share of individual groups of purchasers in subsequent years, it can be seen that marriages dominated in the first two years, after which their share in the total number of transactions generally followed a downward trend (except for the last year of analysis). In turn, until 2015, the share of women has gradually increased (only in 2016 can we see a decrease of about 3 p.p.). In the group of men, on the other hand, it is difficult to indicate a specific trend.

First, the buyers' structure was evaluated according to their age. The buyers were split into groups of 10 years. In the case of marriages, the "average age of the partners" has been defined as the arithmetic mean of the age of the husband and wife. Figure 3 shows the proportion of particular age groups in the overall number of transactions.

Figure 3: The structure of buyers according to age in the years 2010-2016.
Source: Author's own work.

The analysis of the age distribution of buyers indicates that most apartments were bought by people between 25 and 30 years old. The youngest buyers constituted about 5% of the buyers. It can be seen that the older the age range, the lower the share in the total number of transactions.

Among men purchasing apartments, the largest group were people aged 25-30, then 31-35. Among women, the proportion of subsequent age groups was slightly higher than that of men. In turn, among married couples, the share of individual age groups was more evenly distributed.

Interesting conclusions are provided by the analysis of the method of financing the purchase of a flat by young buyers on the secondary market (Figure 4).

Figure 4: The method of financing a flat by buyers at the age of over 60 in the years 2010-2016.
Source: Author's own work.

In the entire analyzed period, slightly more than half of the purchased apartments were purchased with a loan (Figure 4). However, the analysis of transactions made in particular years shows that in general, the share of apartments purchased for cash has been growing year on year (except in 2016). The share of transactions with funds coming from credit in the 7 years covered by the analysis dropped by 16 p. p. Analysing the method of financing within particular groups of purchasers, it can be observed that married couples definitely most often purchased apartments with funds coming from credit. Among this group, over 55% of the apartments were purchased with the participation of an external financing source. Among men, transactions involving credit also dominated. In turn, the trend among women was the opposite - slightly more than half of the apartments were purchased for cash.

Purchaser Preferences In The Secondary Housing Market In Poznań

On the basis of the collected data, the preferences of the revealed purchasers of flats were analyzed taking into account: location of flats according to the districts of Poznań, area of purchased flats, construction technology, age of the building, building height and transaction price.

The data presented in Figure 5 may indicate preferences of particular groups of buyers for the districts of Poznań.

Figure 5: The percentage of flats bought by particular groups in the districts of Poznań in the years 2010-2016

Source: Author's own work.

Most apartments were purchased in the New Town district, then in Grunwald, and rarely in Wilda. In particular years, the share of transactions in the Old Town and the Wilda district was steadily growing, while in the remaining districts the values of these shares fluctuated, but generalised, a decline in interest in apartments in these areas can be observed. Women were more willing to buy apartments in the Grunwald and Wilda districts, while couples in the Old and New Town. The location in the Old Town was the least popular among men. In turn, Figure 6 shows the apartments purchased by area.

Figure 6: Flats purchased by buyers according to their floor space in the years 2010-2016.

Source: Author's own work.

Figure 6 shows that the most frequently purchased apartments were those of 45-60 m^2, followed by 60-75 m^2. The largest and smallest apartments were the least popular. Analysing the individual years, one can see that the share of the largest flats increased slightly, but still decreased - the smallest ones.

Figure 7 shows buyers' preferences for construction technology.

Figure 7: Flats purchased by buyers according to the construction technology in the years 2010-2016

Source: Author's own work.

Taking into account the construction technology - 2/3 of all transactions were apartments located in buildings constructed in the traditional technology. In particular years, the share of the purchased flats in traditional technology was increasing, while it was decreasing - in the large plate one.

The age of buildings in which flats were most often purchased was also analysed (Table 4).

Table 4: Flats purchased by buyers according to the age of building in the years 2010-2016

Type of buyer/ Age of building in years	Up to 25	25-30	31-35	36-40	41-45	46-50	51-55	56-60	61-65	More than 65	The average age of a building
Married Couples	37	40	38	39	39	40	40	38	37	28	39
Women	40	45	42	40	42	43	43	34	33	34	41
Men	45	42	44	42	46	40	47	45	41	46	43
Total	42	42	41	40	41	41	42	37	36	34	41

Source: Author's own work.

The average age of buildings in which the apartments purchased in Poznań at the aisles of the examined period were located was 47.3 years. The average age of buildings was the lowest for apartments purchased by married couples and the highest for men.

Figure 8 shows the preferences for the number of floors of buildings.

Figure 8: Flats purchased by senior buyers according to the number of floors in the years 2010-2016

Source: Author's own work.

Taking into account the height of the buildings, 2/3 of the purchased apartments were located in low buildings (up to 5 storeys). There were no significant discrepancies between the different groups of buyers on this issue.

Table 5 shows the average transaction price of the apartment being purchased and the average area depending on the group of buyers.

Table 5: Average prices of flats and its average floor space purchased by buyers in the years 2010-2016

Type of buyer	Average price (PLN)	Average area (m^2)
Married Couples	266 280, 23	53,05
Women	244 677,75	48,02
Men	255 481,17	50,92

Source: Author's own work.

Within buyers, it was married couples who on average bought apartments at the highest overall transaction price. This is presumably because it was it the group that bought apartments with a bigger area on average (about 53.05 m^2).

Conclusions

The purpose of this study was to determine the profile of buyers on the residential market in Poznań and their preferences. The analysis shows that in the years 2010 - 2016 in Poznań in the secondary market:

- ✓ Most flats were purchased by married couples (about 40%), followed by women (about 31%) and men (about 22%),
- ✓ The most flats were purchased in the New Town district (about 30%) and Grunwald (about 26%),

- ✓ Among the buyers, young people up to 35 years old dominated (they constituted about 48% of the buyers),
- ✓ The area of 2/3 of the flats ranged from 30 to 60 m²,
- ✓ 2/3 of the total were apartments located in buildings built in traditional technology,
- ✓ In the analysed period, the majority of flats were purchased with a loan (about 54%),
- ✓ the older the purchasers, the greater the proportion of flats purchased for cash.

The results of the revealed preferences survey are worth comparing with the survey of declared buyers' preferences conducted on the Poznań market (Strączkowski, 2010). Taking into account the preferred construction technology and height of buildings, the results are convergent. However, in terms of the area of flats purchased, age of buildings or location by district, the results obtained slightly differ. It should be noted, however, that the discrepancies indicated may be related to a different period covered by the analysis (preferences change over time), but certainly they also mainly result from the adopted research methods. In this study, the preferences revealed to the whole population were examined, whereas in the quoted studies the sample selection was non-random, purposeful and included interviews with 56 intermediaries, who expressed their opinions on the preferences of the whole population.

It should be borne in mind that the method of analysing preferences revealed has certain limitations. The choices made in the analyzed market may have resulted not only from the buyers' preferences alone but to a large extent they may have been due to financial constraints. The described conclusions have been prepared on the basis of data on completed transactions, derived from notarial deeds and supplemented with data from land and mortgage registers.

It should, therefore, be taken into account that the analysis may have omitted other essential factors which influenced the choice of purchasers and about which it was not possible to obtain information from the sources used in this study (e.g. standard of housing, accessibility of playgrounds for children, proximity of green areas or recreation places, etc.). The author sees a need to supplement the results obtained with the use of this method, e.g. by conducting a survey among people who bought a flat in the analysed period. Such a survey would allow getting to know the motives of the buyers when making such an important decision.

Undoubtedly, the results would also provide vital information for developers in terms of planning an appropriate residential offer, as well as other real estate market participants, such as valuers or real estate agents.

Importance of Perpetual Usufruct Right in The Structure of Rights to Municipal Real Estate in Poland

Maria TROJANEK

WSB University in Poznań, Poznań, Poland
maria.trojanek@wsb.poznan.pl

Abstract

The institution of perpetual usufruct in the Polish legal system was introduced in 1961, at a time when, according to the political system assumptions, the dominant form of ownership was state property. It was intended by the legislator to regulate ownership relations between the state and private sector entities, initially mainly in the field of housing. These regulations have been amended many times; hence the current legal regulations differ significantly from those introduced in 1961. The study aims to present the significance of this law in the management of municipal real estate in selected cities, as well as to indicate the consequences of the instability of legal regulations (here: another regulation of the transformation of the right of perpetual usufruct of land intended for housing purposes into the right of ownership of such land) in terms of the reduction of the commune's assets (real estate stock) and the reduction of budget revenues from annual fees, which in consequence will not be without influence on the financial situation of communes. The deliberations take into account the current legal status, refer to the literature on the subject and present the share of land given over for perpetual usufruct to natural persons and housing cooperatives in selected cities in Olsztyn. area and legal changes in the field of municipal land management in selected cities in Poland. The interviews show that the introduced changes in legal regulations will reduce the share of perpetual usufruct in the structure of legal forms of municipal land ownership. This is the result of transforming the right of perpetual usufruct by law into the ownership right.

Keywords: Perpetual Usufruct, Property Rights, Municipal Land.

Introduction

Perpetual usufruct was introduced into the Polish legal system in 1961 by the Act on land management in cities and housing estates (consolidated text in Journal of Laws of 1961, No. 22, item 159, as amended), at a time when, according to the political system assumptions, the dominant form of ownership was state property. Article 41 of the quoted Act stated that various temporary, long-term forms of management of state property existing at the date of its entry into force were replaced by the right of perpetual usufruct (Sejm Rzyczypospolitej Polskiej, 1961; Truszkiewicz, 2006). Besides, the right of perpetual usufruct guaranteed that real estate owned by the State Treasury could be used by non-state entities while remaining the property of the State. This law regulates the issues of development on other people's land, i.e. State Treasury (SP) land, and since 1990 also land owned by municipalities, and since 1999 also land owned by other local government units or their associations. The right of perpetual usufruct enables natural and legal persons to use real estate in public property for a long time (40 or 99 years) to satisfy various social purposes, primarily to carry out housing investments (Kokot, 2009). The current legal regulations of perpetual usufruct differ from those introduced in 1961 by the Act on land management in cities and housing estates (Sejm Rzyczypospolitej Polskiej, 1964). Although the political and political and political reasons for the introduction of this right have disappeared, the right of perpetual usufruct still plays an essential role in the system of property law, although the scope of this right has been limited

since 1997 due to the possibility of transformation, and since 2018 the right of perpetual usufruct of land developed for housing purposes is transformed from the "office" (land) into the ownership right (Article 1(1) of the Act of July 20, 2018, on transformation of the right of perpetual usufruct of land developed for housing purposes - Dz.U. 2018, item 1716).

The right of perpetual usufruct played an essential role in the processes of systemic changes concerning the functioning of the economy and the State, especially in the processes of the enfranchisement of state and municipal legal entities. The right of perpetual usufruct is a right in rem, derived from the Roman law of emphyteusis. The institution of a long-term lease is a form of ownership that is common not only in Europe, but also in the economies of other continents (Asia, North America, and Australia), although it is applied to a different extent and detailed regulations vary across countries and in time (Caesar, Donner, & Kopsch, 2019; Dale-Johnson, 2001; Foryś & Gaca, 2018; Gerber, Nahrath, & Hartmann, 2017; Giglio, Maggiori, & Stroebel, 2015; Głuszak, 2008; Irumba, 2015; Löhr, 2017; R. Trojanek, Tanas, & Trojanek, 2019; Tyvimaa, Gibler, & Zahirovic-Herbert, 2015).

Features of the right of perpetual usufruct

The right of perpetual usufruct is a right on somebody else's property (land owned by the State Treasury, local government units and their unions), giving the perpetual usufructuary (natural persons or legal persons) rights similar to the right of ownership. The right in question is, like the right of ownership, a transferable right (it means that it can be traded), a transferable right (it means that it can be contributed as an in-kind contribution to a company), and an inherited right (it means that it can be, for example, an object of donation or inheritance). However, there are differences between the right of ownership and the right of perpetual usufruct, which apply (M. Trojanek, Anholcer, Banaitis, & Trojanek, 2018):

- the duration of these rights. The right of perpetual usufruct is temporary, and the land is given away for 99 years. In specific situations where the commercial purpose does not require that the land be given up for 99 years, a shorter period may be allowed, but at least for 40 years,

- the properties of the buildings and structures on the ground. Buildings and other equipment erected on the land for perpetual usufruct are the property of the perpetual user,

- the possibility of extending this right. During the last five years before the expiry of the perpetual usufruct right reserved in the contract, the user may demand an extension of this right for a period from forty to ninety years. Refusal of extension is only acceptable for critical public interests (e.g. construction of sewage treatment plants),

- the method of accounting for buildings or other equipment erected on the ground. If the perpetual usufruct expires as a result of the expiry of the period established in the contract or as a result of termination of the contract before that period, the perpetual usufructuary is entitled to remuneration corresponding to the market value of the buildings and equipment as at the date of expiry of the perpetual usufruct right,

- the need to pay for the use of the land. The perpetual usufructuary pays the first fee (from 15% to 25%) of the real estate price and annual fees for the entire duration of the perpetual usufruct right (from 0.3% to 3% of the real estate price). The amount of the first fee and annual fees depends on the purpose for which the property has been let for perpetual usufruct as specified in the agreement. For example, the commissioning of land property for residential purposes requires the first fee of 15% and annual fees of 1%, whereas if the property is let for perpetual usufruct for commercial purposes, the fees are 25% and 3% of the property price respectively,

- rules of charging for the use of land. The annual perpetual usufruct fee may be updated no more frequently than once every three years, provided that there is a change in the value of the property,

- the possibility to terminate the contract before the expiry of the deadline set in the contract. An agreement for the perpetual usufruct of land may be terminated before the expiry of the deadline specified therein, if the perpetual usufructuary uses the land in a manner contrary to its purpose as specified in the agreement, in particular, if, contrary to the agreement, the buildings and equipment specified therein have not been erected,

- of the subject of the rotation. The right of perpetual usufruct is connected with the right of ownership of buildings of other facilities) located on the land given over for perpetual usufruct. The right of perpetual usufruct is transferable. The transfer of the right of perpetual usufruct of developed land transfers the ownership of the buildings to the buyer. This means that the right of perpetual usufruct cannot be traded separately from the ownership of the building erected on the land by the perpetual user.

Perpetual usufruct may be established only on land that is publicly owned, i.e. the State Treasury, local government units or their associations.

Municipal land under perpetual usufruct

Initially, the right of perpetual usufruct supported housing construction (single and multi-family), providing land on favourable terms. Overtime (since 1969), the subject matter of this right has been significantly extended (it could be established for housing and boarding house construction, craft workshops or small manufacturing plants).

Perpetual usufruct may be established only on land that is in public ownership (Treasury State and local government units or their associations). As of December 31 2018, the land use structure is presented in Figure 1.

Figure 1: The land use structure in Poland in 2018

Source: Report on the condition of Treasury property as at 31.12.2018.

The perpetual usufruct of 485,965 ha of land owned by the State Treasury, which accounts for 4.85% of the total land of the State Treasury. The municipalities owned 1.041.386 hectares, of which 75.432 hectares were transferred for perpetual usufruct, which accounted for 7.24% of the land owned by the municipalities. Perpetual users of communal land are natural persons -21.810 ha (28.92%), housing cooperatives -10.487 ha (13.90 %), legal persons 4.220 ha (5.59 %), remaining persons – 38.915 ha (51.59 %).

Figure 2 : The structure of perpetual users of communal land

Source: Own study based on the Local Database, www.stat.gov.pl

The share of land owned by powiats and voivodships in the total land under perpetual usufruct is small (about 154 ha is the land owned by powiats, and about 34 ha is the land owned by voivodships). Due to the changes introduced (since 1997) in legal regulations giving the possibility to transform the right of perpetual usufruct into ownership, the area of land under perpetual usufruct is decreasing. The scale of these changes is illustrated by the following data: in the years 2002-2003, there were 96,000 hectares of communal land under perpetual usufruct, while in 2017 (as of December 31, 2011) the area decreased by over 20,500 hectares. The share of land transferred to natural persons and housing cooperatives in the total land given over for perpetual in the capital cities of voivodships in Poland in figure 3.

Figure 3 : The share of land transferred to natural persons and housing cooperatives in the total land given over for perpetual in the capital cities of voivodships in Poland

Source: Municipal land area according to legal forms of use, Central Office of Geodesy and Cartography, 2018

It is worth noting that the share of land transferred for perpetual usufruct to natural persons and housing cooperatives in the total land transferred for perpetual usufruct varies considerably in individual cities with county rights. There are cities in which this ratio is only 12% (Toruń) and 90% (Olsztyn).

Since 2002, the area of land under perpetual usufruct has significantly decreased. Due to subsequent amendments to the Acts governing the transformation of the right of perpetual usufruct of land developed for housing purposes (Act 2018), this process will intensify as, in accordance with the provisions of this Act, land put into use for housing purposes as of January 1, 2019, became by law the property of existing perpetual usufructuaries. This applies primarily to land given for perpetual usufruct to natural persons and housing cooperatives. It is estimated that, on a nationwide scale, the area of municipal land will decrease by more than 32 thousand hectares. The right of perpetual usufruct, due to its legal nature (features of this right), causes certain financial effects in real estate and income of both perpetual usufructuaries and public property owners. The principles of transforming the right of perpetual usufruct into the ownership right from financial consequences are primarily unfavourable for municipal budgets. The cities which lose the most are those who have given up a significant part of their land for residential purposes, and these properties have a high market value. The consequence of this transformation process is a reduction of assets (gminas cease to be landowners), and this fact influences the financial situation of individual cities (gminas). This applies in particular to cities with poviat rights, which is mainly due to the high share of land given over for perpetual usufruct in the budgets of these cities. The receipts from perpetual usufruct fees in the budgets of cities with poviat rights amount to over PLN 1 billion; they are characterised by small variability, although they show a systematic growth. The situation concerning the share of receipts from perpetual usufruct in particular cities varies. For example, in 2018 the following amounts were received by the cities' budgets: PLN 35 910 581 (Cracow); PLN 38 700 000 (Poznań); PLN 547 861 740 (Warsaw); PLN 6 761 363 (Częstochowa); PLN 622 220 (Chełm); PLN 13 826 552 (Białystok).

Conclusion

The right of perpetual usufruct governs the development of someone else's land (public property). The legislator intended to provide an accessible way of acquiring land primarily for housing purposes. Over time, the scope of purposes for which state land may be given away was extended. Thus, the law met specific social objectives. On the other hand, it gave the possibility to shape certain investments, contributed to the development of cities or gave the possibility to use real estate for specific developmental purposes.

In the period of political transformation, the right of perpetual usufruct played an essential role in the process of the enfranchisement of state and municipal legal entities. Therefore, the right of perpetual usufruct was not only an instrument to implement the state housing policy, but also to carry out public tasks.

However, from the very beginning of the introduction of the Act of 1961, it has been the subject of a multithreaded discussion, the provisions regulating this Act have been amended many times. The study presents the role of the right of perpetual usufruct as a form of management of land properties owned by municipalities (here: cities). It was pointed out that the last introduced change in the regulations will result in significant depletion of municipal land resources and property, and in consequence, will affect their financial condition. The scale of these changes in individual gminas (cities) will be differentiated depending on the amount of land held for perpetual usufruct by natural persons and housing cooperatives for perpetual usufruct, the value of this land and the annual fees paid for perpetual usufruct. The financial consequences of the introduced changes will result in a total loss of revenue from the annual fees. In return, the cities (municipalities) will receive revenue from the transformation fee (20 times the annual perpetual usufruct fees set at the level in force in 2018), which may result in potentially higher revenue if the transformation fee is paid once. The loss of revenue should be increased by the amounts resulting from the possibility to increase the annual fees due to the statutory possibility for municipalities to update these fees.

Communes, especially urban communes, will be deprived of permanent income. The legislator has not provided for any compensation for the lost income, which will have an impact on the financial standing of gminas. However, the solutions introduced are beneficial for perpetual usufructuaries, as by law, perpetual usufruct is transformed into ownership on preferential (non-market) terms.

Abstract

The current trends in green products promotion characterizes by the relevant necessity of implementation the omni-channel approach for unification customer experience across all marketing channels. The goal of the article is to investigate the structural and functional environment of the formation and development the marketing and omnichannel strategies, to search the opportunity for its implementation in green marketing strategies. The authors used the methods of bibliometric analysis for determining vectors of perspective development of marketing strategies and omnichannel theory as a tool for green goods and services promotion. The main hypothesis of investigation is the studying the increasing tendency on analyzing of marketing strategies by the scientists. In order to formulate the terminological basis of the implementation the omnichannel strategies in green marketing, a bibliometric analysis of the spread of the concept of "green marketing" and "omnichannel strategies" in scientific articles indexed by the Scopus science base was performed. These authors reviewed more than 1670 papers from Scopus base. The period for the analysis was chosen since 2000 till 2019. Used the Scopus screening tools showed that in 2006 the numbers of articles which focused on marketing strategies began to increase. On the international level the investigated area represented by the next countries: United States, United Kingdom, China, Australia, India etc. Using the VOS viewer program were identified 12 clusters of the scientific papers which investigated marketing strategies from the different points of views. In the paper justified that in the condition when the scale of green products supply and using are constantly increasing the traditional multichannel strategies can lead to confusion for customers about the products offer. In that case using the omnichannel strategies could optimize consumers engagement, meet high customer expectations, enable better service, provide actionable data integrated.

Keywords: Green Marketing, Customer, Marketing Channel, Brand, Omnichannel Strategy.

Introduction

Today there is a sustainable trend on markets toward to using of the different multi and cross channel approaches to communicate with buyers and consumers. But nowadays production development and market tendencies characterize by fundamental consumer's needs which determine to use omni-channel approach that provides a unified experience for the customer across all channels. The omni-channel strategy may be especially successful for the sphere of green products and services promotion. It will

be possible due to the new market requests in the condition of the dynamic convergence global marketplace in which customers are being provided with new quality of green goods from the different companies and industries.

Literature Review

Last tendencies characterized by the necessity of implementation more than one of the distribution channels for green products promotion. The marketing strategy must be increasingly complicated. Today more than 80% of customers demand to get an integrated shopping experience for the different channels they can use when buying from the one supplier [E-tailing Group].

Traditionally the marketing strategies analyzing from the different points of view. Thus, the scientists in the paper (Çera et al., 2019; Osama Ben Rajab, 2019; Lubis, A., 2018) investigated the social factors and their influence on marketing strategies. In the paper (Nikodemska-Wołowik et al., 2019; Shih & Yang, 2019) that the behavioral determinants and their trends are the key element in the enterprises marketing strategies. From another point of view the authors (Rallabandi Srinivasu, G.V.S.R. Anjaneyulu, 2019; Atta Mills et al., 2020) proved that development of the basic management functions improving quality in commercial and social institutions, and as a result the companies policy creates the environment for the customer behavior. In the papers (Dabyltayeva, N., Rakhymzhan, G. 2019; Pechancová et al., 2019; Aliyas et al., 2018; Yevdokimov et al., 2018; Bilan et al., 2018; Cebula et al., 2018; Sokolenko et al., 2017) the scientists investigate the environment management systems and their place in green economy development. Besides, Yevdokimova et al. (2018), Lyulyov et al. (2019), Vasylieva et al. (2019), Mentel et al. (2018), Lyeonov et al. (2019), Shvindina (2019), Serhii et al. (2014) and Aliyas et al. (2018) emphasized the role of sustainable development and social responsibility in modern marketing concepts. The place of innovations and the barriers on the way of increasing market competitiveness are analyzed by the scientists Szymańsk, E., Dziedzic, E., & Rutkowski, A. (2017), Bondar et al. (2015), Bilan et al. (2019c), Vasylieva et al (2014) and Hvolkova et al. (2019). Agota Giedrė Raišienė et al. (2019), Grenaakova et al. (2019), Myroshnychenko et al. (2019) and Malega et al. (2019) proved the influence of the changes in attitudes to stakeholder collaboration in the process of marketing policy creation and competitiveness. The linking between educational aspects and marketing categories are investigated in the papers of Dvorský (2019) and Adebayo et al. (2019). The marketing strategies provided on the level of national economy are analyzing by the scientists Lyulyov et al. (2018) and Raftowicz-Filipkiewicz (2014), Bilan et al. (2019). Mikołajczak (2019) emphasized that the factors, which strongly influence on promotion marketing strategies in NGOs'. They include initiatives and activities for several years, events in favor of external benefit takers, close commercial cooperation, lack of investments and constant financial sources, regular actions combined with flexible working time. At the same time, the Hossain et al. (2018), Němcová (2019), He Shuquan (2019, 2018) and Hadbaa, H., (2019) Vaitkevicius et al. (2019) Starostová et al. (2018) investigate the determinants which influencing on consumer behavior using the examples from their countries. In the researches provided by Arribas et al. (2019) and Hadbaa (2019) analyses the behavioral factors in the decision-making process. The scientists Vysochyna (2018) and Tiutiunyk (2019) was determined conflicting influence of different determinants of fiscal policy on dynamic of promotion of goods and services. The industry segment in the field of marketing instrument implementation was investigated by the authors Gavurova et al., (2018); Huamin (2019); Horváth, (2019). In the paper (Chygryn et al., 2018) justified that the principled of sustainable development have to implemented in management and marketing strategies. The papers (Bilan, 2019a, 2019b) are using the behavioral aspects and trust cycle for representing the level of synchronization the financial and commercial cycles. The author Njegovanović A., (2018) justified that the future of decision-making and choosing of future marketing strategy are linked to artificial intelligence and the necessity for implementation new knowledge.

The omnichannel marketing, first, characterized by multiplicity of information channels about the products and services. The first use of the term "channels multiplicity" was used in 2016 by Van Bruggen et Al., which was determined by increasing of using technology and information streams. According to Donald Carroll and Inés Guzmá (Carroll, 2015) omni-channel model can be created on the base of synchronized operating modeling where all the company's channels are having the same

rights and represent a single configuration and view to the consumers and the one corresponding way of doing business. In this model, companies change their points of view to the customer, identifying they specific and one unified features. It is open up a possibility for companies to respond in a permanent way to the customer's fast-moving evolving needs. Verhoef P., Kannan P.K., Inman J. (Verhoef, 2015) determined the omnichannel strategy as the synergetic simultaneous management of the multifarious existent channel and customer touchpoint, in the way then the customer experience and expectation across the channels of promotion and performance over channels is optimized.

Giovanni Vaia and Diletta Cerolini (Vaia, 2016) noted that the omnichannel strategies redefine a customer experience creating a synergy between consumer and brand. Concurrently the brand doesn't lose value but follow the needs of customer and communicate with him.

However, using the omnichannel strategies for green goods promotion is the relevant way how to engage green consumer and involve their to the processes of green consumption using the instruments of digital marketing.

Methodology

The main hypothesis of investigation is the studying the increasing tendency on analyzing of marketing strategies by the scientists. For this purpose were identifying the quantity tendency of the scientific papers which focused on the analyses of issues connected with omnichannel marketing strategies; the emphasizing the main subject areas under analyses of marketing strategies was done; clustering the papers on the main directions for investigations with purpose to identify the further options for analyses were provided.

For the analysis were chosen the following keywords: green marketing, omnichannel strategy, neuromarketing, digital marketing. The research process was divided on two steps. First, were determined the main clusters and their scale which were formed in the procedure. In the process were identified 12 clusters of the scientific papers. These are the clusters connected with the green marketing strategy, neuromarketing, consumer behavior. On the second stage was analyzed the cluster which include omnichannel category with the linked categories, such as, green marketing, environmental management, neuromarketing, consumer behavior etc. The time for analysis was chosen 2000-2019.

This study reviewed 3500 papers from Scopus. The analyze was done by providing the software of VOSviewer using the dates from the Scopus. The VOSviewer allowed to allocate and visualize the network of definitions which used and co-citation during the investigation of omnichannel strategies in green marketing. The provided analyses proved the statement about the perspectives of implementation omnichannel strategy for the green goods promotion using the instruments of digital marketing.

Results

In order to formulate the terminological basis of the implementation the omnichannel strategies in green marketing, a bibliometric analysis of the spread of the concept of "marketing strategy" and "omnichannel strategies" in scientific articles indexed by the Scopus science base was performed.

Using the Scopus analyzing tools were reviewed more than 1650 papers from the scientific Scopus base. The period for the analysis was chosen since 2000 till 2019. The Scopus screening tools showed that in 2006 the numbers of articles which focused on marketing strategies began to increase. In 2019 in comparison with 2000 the quantity of articles increased more approximately on 600 percent (figure 1).

Fig. 1: The results of the publication trend analysis in the field of omnichannel strategies in marketing

Sources: created by the authors on the base of Scopus

On the international level the investigated area represented by the next countries: United States (4260 papers), United Kingdom (1336), China (1094), Australia (718), India (682), Taiwan (652), Canada (470), Spain (462), South Korea (437), Italy (414). The most quantity of academic researches concentrate in such academic institutions: Hong Kong Polytechnic University; Texas A&M University; Pennsylvania State University; Purdue University; Griffith University; Texas Tech University; University of Florida; Cornell University.

Fig. 2: International academic representation of the category "omnichannel marketing strategy"

Sources: created by the authors on the base of Scopus

The main subject areas (Figure 3) which connected with the marketing strategies are business, management and accounting, social science, computer science, economics, econometrics and finance, engineering, medicine etc.

Fig. 3: The subject area in Scopus for analyzing the "omnichannel marketing strategy"
Sources: compiled by the authors using data from Scopus

It has to be noted that the percentage of the environmental science is 8%. It tells about low level of implementation the marketing strategies in the sphere of environmental economics, sustainable development and green production.

In the table 1 systemized the authors whose scientific interests relate to the omnichannel marketing. Considering the scientific trends (figure 1, 2, table 1) it has to be noted that the spreading of the omnichannel strategy connected first of all the digitalization the retail processes, neuromarketing and green marketing.

The citation analysis revealed the most authoritative researchers as well as the 12 clusters of research teams that had the greatest influence on the development of omnichannel theory (Figure 4). The big cluster includes the categories connected with the categories of omnichannel strategies and digital marketing, such as: big data, omnichannel management, omnichannel retailing, internet of things, customer experience, e-commerce, digitalization etc. Considerable cluster connected with the green marketing categories: environmental marketing, sustainable marketing, environmental concern, environmental attitude, green products, green consumer, green consumer behavior, willingness to pay, green marketing strategy, purchase intention, green supply chain, green brand image etc. The significant cluster chained with the neuromarketing and contain the next categories: marketing research, brain activity, circular economy etc. The "sustainability" cluster includes concepts: green marketing strategies, environmental management, green products etc. Determined interconnections tell about the huge possibilities for using the approaches and opportunities omnichannel strategies for promotion the green good and services.

The figure 5 shows analyzed the cluster which include omnichannel category where also the linked categories are: green marketing, environmental management, neuromarketing, consumer behavior etc. The provided analyses proved the statement about the perspectives of implementation omnichannel strategy for the green goods promotion using the instruments of digital and neuro marketing.

Fig. 5: The results of bibliometric analysis of structural and functional environment of formation and development of the omnichannel theory with close areas

Sources: compiled by the authors using the data from Scopus and VOSviewer tool.

Until recently most of the green companies focused their marketing strategies on green products, their quality and features. In that cases the main target is the promotion of a brand fostering. This general approach remains through the many years at campaign-level mentality and using corresponding basic marketing capabilities. For green products promotion the communication channels are conceived separately, and the environmental marketing strategies could be different according to the consumers used. But in the condition then the scale of green products supply and using are constantly increasing such strategies can lead to confusion for customers about the offer. At the same time nowadays the competition among green companies is high and the possibilities of choice for the customers are continuous multiplied.

The omnichannel strategies redefine a customer experience creating a synergy between consumer and brand. The brand doesn't lose value but follow the needs of customer and communicate with him.

In that case it is important to distinguish the features between multichannel and omnichannel marketing. The multichannel marketing proposes to use various channels with the identic messages that will be reaching as many consumers as possible for brand promotion. In the case of omnichannel marketing the channels can interact between each other when the brand is sending the messages to a consumer across the whole channels.

According to statistics (Omnichannel, 2019), customers who interacted with an omnichannel campaign using three or more channels had higher involvement than those who interacted with the single channel of promotion. In the comparison of the single-channel (where the rate is 5,4%), the omnichannel engagement rate - 18,96%.

Conclusion

The omnichannel strategy in green marketing today can bring the list of the benefits for companies, who provide green production. So, an omnichannel strategies allows businesses to cooperate with consumers through their required ways, increasing involvement and targeting communication. The companies can reach more wide audience because they can procure more consistent message across the whole marketing channels and provide a broad information for the customers. Such strategies make the marketing channels different for consumers and can improve communications for better engagement by the finding the necessary information for buying through a diversified field of channels. Beyond that, the customer-focused approach will be being provided for each consumer. In addition to, any mismatches between information form the store units and from on-line stores could create uncertainty over the process of buying and will turn aside the consumer from making a commitment. In that case multichannel systems equalize such customer expectations and allow companies to fulfill their obligations before the consumer. So, the omnichannel strategies allow companies to have an engagement in market communication processes and be responsible to consumer needs in a timely manner through different marketing channels. The interaction between such channels will give the opportunity for the consumer to finish the communication on one channel and seamless find it on another channel. In that case companies have more information about the customer service the and can use an optimized marketing channel. Integrated multi-channel channels can gather various marketing information and dates about consumers. Such dates help to provide continuous understanding about the customer journey, allowing companies to improve communication processes and identify their inefficiencies at a faster way. As a result, enhanced business practices could result to a higher customer satisfaction and loyalty.

Managing the Image of An Educational Institution in The Social Media Era

Waldemar JEDRZEJCZYK

Czestochowa University of Technology, Faculty of Management, Czestochowa, Poland, waldemar.jedrzejczyk@wz.pcz.pl

Abstract

This article presents the use of social media in marketing activities, which aim at creating a positive image of the organization. Social media play an increasingly important role in the contemporary marketing. The attributes of social media predestine them to be used in the process of image creation. They are used in practical areas. Therefore, it does not to be checked or proven that social media should be applied in image management, but rather if social media are used in a diligent and effective manner? Market economy principles apply not only to business organizations but also, increasingly, to other types of organizations, including educational institutions. Similarly to enterprises, educational institutions must also build a positive image of the organization, which will translate to good reputation in the long term. The main purpose of this article is assessing the scale of using social media in the process of managing (creating) the image of educational institutions. In the presented results of empirical studies, the analysed entity was limited to one type of educational institutions – secondary schools. The research has shown that all analyzed schools use social media and the school's website as tools to promote and build their image in the local community, which is undoubtedly a strength. However, low effectiveness of using these tools is the weak point.

Keywords: Image of The Organization, Social Media, Marketing Communication, Educational Institutions, Secondary Schools.

Introduction

The image of an organization is how the stakeholders see it, it is the depiction of the organization in the environment in which it operates (Alvesson, 1990; Chaturvedi and Gupta, 2014). The image may be deliberately and intentionally created by the organization. Image management is a process that requires developing a general concept and an action plan. The image concept should constitute an element of the overall marketing concept, strictly related with other elements.

Social media play an increasingly important role in the contemporary marketing (Kaushik, 2012). The attributes of social media predestine them to be used (in communication with stakeholders) in the process of image creation. Organizational practice demonstrates that they are used in practical areas. Numerous research proves that business organizations attach great importance to social media in conducted marketing activities, which aim at building the organization's image – for example, during a national survey covering 152 enterprises, the management responsible for using the Internet in marketing activities, or for initiating and maintaining the company's relations with customers using new technologies assessed the importance of such activities at 4.36 (the average grade) on a scale from 1 (small importance) to 5 (large importance) (Mazurek-Łopacińska and Sobocińska, 2017, p. 350). Therefore, it does not to be checked or proven that social media should be applied in image management, but rather if social media are used in a diligent and effective manner?

Market economy principles apply not only to business organizations but also, increasingly, to other types of organizations, including educational institutions. Similarly to enterprises, educational institutions must also maintain good relations with their stakeholders (Kazoleas et al., 2001). They have to build a positive image of the organization, which will translate to good reputation in the long term (Alves and Raposo, 2010; Ryńca and Radomska, 2018).

The article consists of two main parts. The first part presents a synthetic description of the process of managing the image of the organization. It describes the basic stages of the process, as well as the methods of creating the organization's image for various groups of stakeholders. The distinguished elements were referred to the process of managing the image of educational institutions. In addition, part one also presents the most important characteristics of social media, which predestine them to manage the image of organizations. Part two presents the results of own research. This article has been prepared for analytical and research purposes. It was drawn up based on an educational approach, with the use of source literature and results of empirical studies.

The main purpose of this article is assessing the scale of using social media in the process of managing (creating) the image of educational institutions. In the presented results of empirical studies, the analysed entity was limited to one type of educational institutions – secondary schools.

The Process of Managing the Organization's Image

The process of managing the organization's image is not an easy task, mainly due to substantial complexity of this phenomenon. The image may be may be different in various groups of the organization's environment. It does not have a static nature, because it changes along with the change of stakeholders' views and tastes. To a large extent, it is shaped regardless of the organization – the entity, to which it refers, and does not always reflect the reality. It may be shaped through quality of products and services, as well as promotional activities. Shaping the image is a long-term, continuous process, which requires a methodical approach (Massey, 2016). The process of managing the organization's image may be divided into the following stages (Schuler, 2004, Świeczak, 2017, p. 91):

1. Defining the goals of building the desirable image of the organization;
2. Defining the main stakeholders of the organization;
3. Analysing the present image of the organization;
4. Defining the determinants of the organization's image;
5. Selecting the instruments for creating the image and channels of communication with stakeholders;
6. Defining the team and persons responsible for executing image-related tasks;
7. Implementing and executing the image management strategy;
8. Supervision over results achieved.

The proposed stages in the image management process allow identifying areas – both in the organization's environment where it is essential to undertake actions to create, strengthen, or change the organization's image, and in the organization itself, where activities significantly affect the organization's image.

The image allows differentiating the organization from the comparison, in the organization-environment relation. An important role in shaping this relation is played by stakeholders, who may affect the organization, or are affected by its activity (Frandsen, 2017). Every organization has its groups of stakeholders, which may include various entities e.g. natural persons, communities, institutions, enterprises, public offices. Individual groups of stakeholders may have stronger or weaker relations with the given organization. The manner of creating the image depends on the power of this relation (Scott and Lane, 2000). Possible methods of creating the organization's image for various groups of stakeholders are presented in figure 1.

Fig. 1: Methods of creating the organization's image for various groups of stakeholders
Source: own elaboration

In the first model version, the organization's image, developed in the defined group of stakeholders, is created directly on the basis of the organization's identity. The organization has a potentially significant influence on the created image. In the second version, the organization's image is created not only on the basis of the organization's identity but also based on images of other groups of stakeholders, whereas the influencing power of individual factors depends on the power of relations between entities. In the third model version, the organization's image is created only on the basis of images of other groups of stakeholders. This is applied when the organization and stakeholders do not have direct relations. In such event the organization has no possibility to influence the image.

The Image Management Process of Educational Institutions

Execution of the process of managing the image of educational institutions, in particular managing the image of secondary schools is relatively easier than the analogical process carried out in business organizations. In case of educational institutions, the situation is relatively simple in the following stages of the management process:

Stage 1. It is easy to define the main goal of marketing activities – the main goal is to attracting candidates during recruitment.
Stage 2. It is easy to precisely define the most important groups of stakeholders – in the process of building a positive image of the organization, a very important role is played by proper definition of groups of stakeholders, in particular customers. The principal groups of stakeholders of secondary schools are presented in figure 2.
Stage 4. It is relatively easy to define the most important determinants of the image – for this purpose, in its on-going marketing activity the school should expose elements with the most importance for the student, such as: educational offer, teaching level, teaching staff, premises, technical facilities.
Stage 5. The task concerning the selection of tools for image creation is also relatively simple. The portfolio of methods should definitely include social media. There is no need to conduct own research to realize that all youth in a secondary school uses and is present in various social media on

a mass scale – they create own communities. In effect, it is relatively easy to define the profile of the customer – student.

Stage 6. It is relatively easy to define the persons engaged in image-related activities – they should include not only school principals, but also all teachers since they are in direct contact with the most important school stakeholders – the students.

Fig. 2: Principal groups of stakeholders of the secondary school
Source: own elaboration

Schools have strongest connections with own students and their parents, whereas this is a direct dependency. This group of stakeholders may be influenced by the school to the largest extent – variant 'a' of the image creation model. In turn, the group of stakeholders, which receives the school's largest attention, are potential students – graduates of lower level schools. To continue operation, schools must attract these stakeholders. The image amongst this group of stakeholders is most important for the school and relations with this group are weak – variant 'b' of the image creation model. Schools should therefore pay special attention to stakeholders, with whom potential students have best contact. This means current students at the school, in particular from junior classes, who only last year attended the lower level school with the younger potential candidates. This means that schools should make their own students the image ambassadors, because such action may be most effective. However, other groups of stakeholders should not be completely ignored, because they may also influence the school's image and its reputation to a larger or smaller degree.

Although the process of managing the image of educational institutions, in particular secondary schools, is relatively easier than an analogical process carried out in business organizations, this does not mean that image management in these institutions is conducted effectively. The difficulty in managing the image of secondary schools results from a flat organizational structure. A school is managed by a principal, usually assisted by one or two deputies. Other employees are subject teachers and administration staff. The main burden on management is on the school principal, who must create appropriate organizational, personnel and economic conditions for effective and efficient performance of educational activities in the school (Komorowski, 2009, p. 10). Execution of these tasks requires a wide range of competencies - both conceptual, social as well as professional – in various management areas, mainly in regard to educational processes, human resources, finance and marketing, both at the strategic and operational level (Gawrecki, 2003, p. 120). Therefore, the role of

the school principal should be fulfilled by a top class manager. And here is the problem – such managers are completely not at interested in working in a school for financial reasons. A school will never offer salaries comparable with large companies. It is a general educational practice – in the Polish reality – to employ school teachers as principals. An advantage of this solution is a very good knowledge of the specificity of the managed organization, and a disadvantage is a lack of numerous management skills.

The competency gap of school principals usually covers also the area of image management, in particular with the use of new technologies. This issue is not easy to solve. Personnel restrictions pose a barrier. A school cannot afford to hire a marketing specialist, who would also be responsible for image management. The principal is often supported by teachers. However, this is usually an *ad hoc* support. In the area of image management with the use of social media, relevant tasks are usually outsourced to IT teachers. However, they also lack required competencies.

Execution of tasks related with using social media in the organization's practice requires defined competencies – both organizational and individual. Source literature mentions publications, where competencies of so-called social media specialists are defined (Moretti and Tuan, 2014; Cao and Poorani, 2015). This specialist should have the following competencies:

- Knowledge of various types of social media,
- Ability to effectively mover around social media, combined with content analysis,
- Ability to create multimedia communication,
- Ability to design campaigns in interactive media,
- Ability to generate traffic in social media,
- Ability to monitor undertaken activities,
- Ability to strengthen the image of the organization.

The above skills cover technical, media, communication, social, and marketing competencies. This is also reflected on the job market. Many organizations are seeking specialists in this area.

Knowledge of school principals on competencies desired in the image management area will surely contribute to reducing the competency gap and increasing the effectiveness of this process.

Why are Social Media Predestined to Manage the Organization's Image?

Social media comprise a developed set of communication tools, based on Internet applications and mobile technologies, which constitute a breakthrough in the area of interpersonal communication (Bingham and Conner, 2010, p. 6). The methods of communication between people have changed radically and, going beyond hitherto social communication, have transformed it into an interactive dialogue. The basic characteristics of social media, which differentiate them from traditional media, include (Heinonen, 2011; Laroche et al., 2012; Fill and Turnbull, 2016, p. 605):

- Large potential to trigger activity of users, which means that content published in the network about e.g. a particular organization are generated not only by this organization but also its stakeholders. This means that how the organization is perceived depends not only on the organization but also on its environment.
- Ability to direct the message to a wide group of recipients, as well as a narrow group of recipients, or a defined addressee.
- High speed of information transfer – social media constitute an environment where an immediate reaction of users is possible.
- A lot of types of social media, followed by substantial abilities to satisfy very different needs of users.

The specific ownership of social media translates to their usability. SM are increasingly used in organizations mainly for the purpose of marketing communication, both in relations with advertising

as well as connected with public relations (Mangold and Faulds, 2009). The effectiveness of using social media in marketing/ public relations activities depends on the adopted strategy of conducted marketing activities. There are several concepts of a marketing-mix, whereas the most popular and frequently use in business are the following concepts: 4P, 4C and 7P. It seems that the most predestined concept in the area of use of social media is the 4C formula, since it concentrates on the client's point of view and perspective, and not on the organization. Conducting activities consistent with the 4C formula requires (Kietzmann et al., 2011, pp. 241-251):

- Recognizing and understanding the mechanisms of social media functioning (cognise);
- Building a strategy on the application of social media in marketing communication – social media, which allow executing assumed goals should be selected (congruity);
- Defining the policy and rules of listening to the dialogue of customers in social media, and appointing responsible persons (curate);
- Monitoring information in social media about the given organization (chase).

Assessment of the Scale of Using Social Media in the Process of Managing (Creating) the Image by Educational Institutions – Research Results

Research Method

The main goal of the conducted empirical studies is to prepare a model approach to effective management of the image of educational institutions[i]. Three principal research questions are asked in relations to the main goal, in order to facilitate achieving this goal:

1. Is the potential of social media in the management of the image of educational institutions used in an effective manner?
2. What are the main reasons of ineffective use of social media in managing the image of educational institutions?
3. How to manage the image of educational institutions using social media, so that the process of creating the image was effective?

Responses to such questions were sought in a survey addressed to defined groups of respondents. Research was conducted in the years 2015-2019. In search for the answer to the research question in empirical studies, emphasis was placed on those elements of the process of shaping the image, which depend on the organization and which should be combined with the use of social media. Three sub-processes were analysed:

1. Building of organization's identity,
2. Communicating the organization's identity to stakeholders,
3. Obtaining feedback from stakeholders on the current image of the organization.

Within each sub-process, attempts were made to define and assess activities undertaken by analysed schools in the image building process with the use of social media.

This article presents results of research, which allowed obtaining a partial answer to the first research question. The main goal of this article is to assess the scale of use of social media in the process of managing (creating) the image of educational institutions. Educational institutions are divided into schools and educational facilities. Schools are in the definitive majority. Due to the substantial differentiation of types of schools (every educational level has its specificity) it was adopted that the subject of the research will cover secondary schools.

Empirical research was conducted on two principal research populations. The first population comprised employees of secondary schools (principals, vice-principals, teachers), and the second one – main stakeholders – students and their parents. Schools were located in Poland in the Łódzkie voivodeship. 201 employees participated in the research, including three principals, five vice-principals and one hundred and ninety three teachers from thirteen secondary schools, as well as 1465

students from these schools and 467 parents of students. Research was conducted in 13 schools – in schools where principals agreed to conduct this research. In every school the study population included both school staff as well as current students and their parents.

Research Results: Employee's Perspective

Currently schools undertake promotions in the local environment (96% of respondents). In their marketing activities, they use various methods and techniques. Most frequently used promotion methods include: so-called open doors (95% of respondents), the school's website (89% of respondents), participation in educational fairs (65% of respondents), information placed in social media (60% of respondents), local media i.e. press, television, radio (55% of respondents) – figure 3. Social media and traditional media are mainly used by schools to inform about their successes, executed projects and school events. Sharing photographs and films as well as discussion forums were stated as the most useful functions of social media, which the school may use in its promotional activities (70% and 52% of respondents, respectively). In the opinion of the staff, currently undertaken promotional activities are effective (95 % of respondents).

Fig. 3: Promotion methods used by schools according to employees' opinions
Source: own elaboration

All analyzed secondary schools are already using social media, but the level of this use varies. All schools have accounts on at least one social media portal, and most – on at least two social media portals. The post popular social media service amongst secondary schools is Facebook – all schools use it. You Tube is also very popular. Other social media such as Messenger, Instagram or Snapchat are used much less. It seems that schools still do not appreciate these applications, while they should. They have huge potential due to very big popularity amongst young people. In general, social media are seen as a good communication channel between the school and its stakeholders, in particular students and their parents (92% of respondents). The effectiveness of promotional activities carried out using social media is also deemed as high (87 % of respondents).

Research Results: Main Stakeholders' Perspective

The use of social media in the process of building the school's image is highly justified. At the moment, students have an almost unlimited access to the Internet (89% of respondents), which they mainly use in their natural environment – at home (95% of respondents) and in school (48% of respondents)[ii]. More or less, almost all students use social media – they have an account in at least one portal and use it daily (98% of respondents). Social media are most frequently used in the following areas:

- education – expanding knowledge required in school, expanding knowledge within one's own interests, hobbies, doing homework, preparing for tests, searching other information, learning via the Internet, e-learning courses, reading blogs;

- communication – using social media, using email, viewing forums and participating in discussions on forums, contacting friends;
- entertainment – listening to music, watching movies, playing games;
- e-shopping – using Internet stores.

Within the scope of activity in social media, many students also share their opinions on Internet forums and blogs, and comment on posted content (44% of respondents).

Students are already aware that schools started to compete for them (96% of respondents). Most information on a given school reaches its stakeholders mainly through the school's website (61% of respondents), open days (54% of respondents), social media (49% of respondents) as well as local media (32% of respondents). Whereas the most effective promotion methods applied by schools are recognized as: open doors (53% of respondents), the school's website (45% of respondents) an social media (22% of respondents).

Fig. 4: Promotion methods used by schools according to main stakeholders' opinions
Source: own elaboration

The data presented allows for two principal conclusions: 1) digital communication tools are also included in the portfolio of methods of promotion applied by schools; 2) schools do not fully use the potential of applied methods, in particular digital tools. This mostly visible in the case of social media. Less than half of respondents who receive information about the school via social media see this as an effective form of promotion. In general, promotional activity of schools is positively assessed by their main stakeholders, meaning both students and their parents (82% and 70% of respondents, respectively). The above data should definitely be of interest to schools.

Discussion and Conclusions

All organizations must be aware that the Internet is currently the one media where promotional activities must be concentrated in the coming years. The significance of the Internet in promotional activities is continuously growing at the cost of traditional media. Traditional forms of advertising are more and more often replaced by more specialised and better addressed digital tools, which allow reaching selected groups of clients with more customized information in the form of an interactive multimedia dialogue. The following portals are most frequently used by organizations:

Facebook, Google+, LinkedIn, Twitter, YouTube, Instagram, Snapchat and blogs. Usability of social media in organizations is increasing systematically. This concerns all types of organizations, including educational institutions. This is confirmed by numerous publications e.g. examples of good practices in using social media in higher schools presented in: Lavrusik (2009), Rosmala and Rosmala (2012), Tess (2013). This phenomenon is treated as a trend, which started to be referred to as social media marketing.

In the client's market era, the need to care for the image becomes an axiom. This concerns not only businesses but also public and social organizations, including educational institutions. Caring for the image and building it consciously is becoming a general practice in schools. The image also forms a significant element of the school's strategy, shapes its diversity, distinguishes it amongst the competition, and is decisive in terms of how the school functions and how it is perceived in the local community. The image is one of the most important factors that decide about choosing a particular school.

The activity of stakeholders in social media may be divided into two types: 1) activity in the form of posted comments and opinions about the school, both positive and negative, which has direct effect on the school's image; and 2) activity in the form of expressing interest in content posted by school staff, as well as general topics related with the school, its educational offer and promotional activities, which directly affect the school's image. Both types of activity are significant for the school's functioning. Obtaining information about how stakeholders perceive the school allows conducting an evaluation of activities undertaken by the school and their future modifications. Whereas data concerning the interests of stakeholders give a wider picture and may be used in operational studies, e.g. to detect new trends in the environment.

All analyzed schools use social media and the school's website as tools to promote and build their image in the local community, which is undoubtedly a strength. However, low effectiveness of using these tools is the weak point. The current scale of using social media in schools may be surprising, taking into account the nature of this tool. Actually, for the first time in history organizations may use tools with huge potential, for which they do not have to pay, and which offer unlimited access – a condition to use these tools is access to the Internet. They may also be certain that this tool is used by stakeholders, especially when the main stakeholders are young people.

Discussed studies should be continued on a wider territorial scale. It would also be interesting to check whether the school's location (town/village) and size affect the applied communication tools and their effectiveness. Additionally, it would be interesting to conduct a comparative analysis of the studied phenomenon against analogical studies conducted in other countries. However, these activities would require new empirical studies and broad literature analyses. Due to the volume- and time-related limitations related with this article, this issue should be deemed as a limitation of presented study.

[i] Research is conducted by a research team managed by Waldemar Jędrzejczyk, the author of this article. The principal study area concerns the issue of competences, both those currently desirable as well as prospective, referring to sectors, kinds and types of organizations, professional groups, and key positions in organizations. In the area of the organization's competences to create the image using social media, the main owner is Marta Konieczna-Kucharska.

[ii] This trend is also confirmed by studies conducted by other research centres and institutions e.g. the NASK national research institute: *Raport z badania. Nastolatki 3.0*, NASK, Warsaw 2017.

Development Factors of Polish Subsidiaries in The United States

Abstract

The paper presents results of a firm-level survey carried out between 2016 and 2017 among Polish companies who made foreign direct investment in the United States. The purpose of this paper is to identify FDI development determinants among Polish enterprises in the US market as well as to find out about the discrepancies in their perception between representatives of different business sectors i.e. enterprises from traditional and new technologies industries. The results of the study indicate that regardless of the sector, Polish enterprises seek the determinants of development of their subsidiaries in the USA primarily in the internal factors, i.e. unique and sustainable ownership-specific advantages. The ownership advantages – together with external location factors such as the demand, the ease of doing business and the business environment – affect most the development of Polish direct investment companies in the USA. There were significant differences between the assessment made by traditional and new technologies enterprises in relation to resource factors, efficiency factors and the competition in the USA.

Keywords: Foreign Direct Investment, FDI, Development Determinants, Multinational Enterprises, MNES

Introduction

In the era of accelerated internationalization, involving capital abroad in the form of foreign direct investment (FDI) seems to be a natural way leading to an enterprise development. Foreign capital expansion, which until recently had been a privilege available only to corporations originating from highly developed countries, is now becoming a tool that is frequently used also by enterprises from developing countries and by the so-called latecomers in the global economy. While the former ones originate generally from moderate or low-income economies with still modest levels of internationalization, the latter ones represent countries already partially advanced on their way to win the "developed" status (Storper et al, 1998).

In spite of their current status, enterprises from both groups keep aiming at shaping their ways to gain their share of "business success" in international markets. Likewise, Polish companies are continuing to boldly follow this development path. According to the data published in the last World Investment Report (UNCTAD, 2019), by the end of 2018, Polish companies had invested abroad capital in the form of FDI with a value of $28,510 million, which is over 106 times more than at the end of 2000 ($268 million, nominal values). 1838 companies based in Poland held shares/stakes in 3941 entities abroad, which means an increase of almost 38% compared to 2010 (Statistics Poland, 2019). Despite an intensive growth in FDI outward stock, it must be clearly emphasized that most Polish subsidiaries have been located in European countries (NBP, 2018; Statistics Poland, 2019) – which means in a geographically and culturally similar environment. Among the non-European countries attracting Polish capital, the USA is a leading destination. Entering the US market – one of the most advanced and competitive economies in the world – may however be a major challenge for many companies, especially for latecomers in international business. This brings us to a fundamental and potentially interesting research question: what are the development determinants of Polish FDI in the USA?

The aim of the paper is to identify FDI development determinants among Polish enterprises in the US market as well as to find out about the discrepancies in their perception between representatives of different business sectors i.e. enterprises from traditional and new technologies industries.

Literature Review

The internationalization of economic activity is guided by various premises that lead enterprises to undertaking activities focused on foreign expansion. They originate in the enterprise but take into account a broad spectrum of both internal and external factors, which determine the potential, the position and probable chances of a company to succeed in the implementation of planned projects depending on the area of activity, a chosen direction of expansion, its form or the final destination of planned foreign activity (Kuzel, 2018). In this context, these initial internal internationalization premises (motives) are inextricably linked with the factors that encourage choosing a specific place for business development (location determinants). The right combination of these factors maximizes the chances of success in foreign expansion.

Conceptually, the described relation is best explained by the so-called OLI paradigm (Dunning, 1979; 1988). According to the OLI paradigm, three conditions must be satisfied if a company is to engage in overseas operations in the form of FDI: 1) the possession of unique and sustainable ownership-specific "O" advantages (in comparison with other firms in a given market), 2) the presence of superior market benefits (internalization "I" advantages) in exploring the above mentioned advantages directly rather than through an arm's length relationship, and 3) the existence of location "L" advantages in a host country (Dunning and Lundan, 2008). While the "O" advantages and the "I" advantages are firm-specific and represent mainly endogenous factors such as product differentiation ability, marketing, logistics and management skills, trademarks and brand names, access to raw materials, economies of scale, access to capital, technology, patents, etc., the "L" advantages are country-specific and refer to the host country factors exogenous to multinational enterprises (MNEs).

Translating that into the experience of Polish enterprises in the US market, it should first be pointed out that – as far as the authors are aware – there are no papers directly related to the issues discussed in this paper. Hence, to put our considerations into the context of the literature on the subject, the main focus has been on the review of the work on Polish FDI motives and FDI location determinants in the USA.

Quoting J.H. Duning's (2000; Dunning and Lundan, 2008), this basic division of FDI by their main motive of foreign expansion, four main types can be distinguished, i.e. market seeking, resource seeking, efficiency seeking, and strategic asset seeking investment. Research results have demonstrated that in the case of FDI undertaken by Polish enterprises, it is possible to demonstrate virtually all types of investment, although market seeking investment clearly is the dominant group (Götz, 2011; Gorynia et al, 2013; Jaworek, 2013; Kowalewski and Radło, 2014; Trąpczyński, 2015; Kuzel, 2017; Jaworek et al, 2018a). It seems that attributing Polish FDI mainly to market motives should be confirmed by the assessment of market-related factors as one of the most important factors for the operation of foreign subsidiaries in the United States. Therefore, the first hypothesis states that:

Hypothesis 1: Irrespective of an enterprise's business sector, i.e. enterprises from traditional or new technologies industries, market factors (especially those related to market demand) were the most important factors for Polish direct investors who had entered the US market.

It seems that the multitude of determinants not only justifies, but even requires analysing them in groups, so that they can be subjected to a more comprehensive assessment and comparison. In this paper has adopted the division proposed by J.H. Dunning (2006; Dunning and Lundan, 2008), who distinguishes between three broad groups of host country FDI determinants. The first group is made up of institutional and legal factors including for example taxation and trade policies. The next group constitutes economic determinants that can be divided into market, resource, efficiency and strategic asset-related investment. The last group is made up of business facilitation factors that lie within the competence of host countries (Jaworek et al, 2018b).

Analysing various papers on FDI location determinants in the USA, it can be seen that the majority of them consider economic factors to be the most important (table 1), and among them those related to the market, i.e. the extremely large US market, the search for new markets, and the need to be close to customers (Sokoya and Tillery, 1992) or in more general terms, the "market potential" (Ajami and Ricks, 1981; Friedman et al, 1992; Zitta and Powers, 2003; Ekanayake and Kornecki, 2011; Underwood, 2012). The factors identified in the group of economic determinants were also related to: the quality of the labour force along with the efforts by the local authorities to improve it (Axarloglou, 2004; 2005; Zitta and Powers, 2003; Ekanayake and Kornecki, 2011; Underwood, 2012), manufacturing wage rate and transportation infrastructure (Friedman et al, 1992), and minimizing transaction costs by the choice of site and investment size (Solocha et al, 1990). Factors from the other two groups – institutional and legal framework, and business facilitation (table 1) – appeared much less frequently in the quoted papers.

Table 1: Summary of literature on FDI location determinants in the United States

Determinants (groups)	Author(s) / year
Institutional and legal framework	Tallman, 1988; Chernotsky, 1991; Hines, Jr., 1996; Coughlin and Segev, 2000; Zitta and Powers, 2003; Wijeweera et al, 2007; Globerman and Shapiro, 2009; Ekanayake and Kornecki, 2011
Economic determinants (market, resource, efficiency, and strategic asset-related investment)	Ajami and Ricks, 1981; Chernotsky, 1987; Solocha et al,, 1990; Kogut and Chang, 1991; Sokoya and Tillery, 1992; Friedman et al, 1992; Grosse and Trevino, 1996; Ulgado, 1996; Coughlin and Segev, 2000; Zitta and Powers, 2003; Axarloglou, 2004; Axarloglou, 2005; Ekanayake and Kornecki, 2011; Underwood, 2012
Business facilitation	Head et al, 1995; Coughlin and Segev, 2000; Axarloglou, 2004; Halvorsen, 2012

Source: compiled by the authors.

In this text, the focus is on companies already present in the United States and on the recognition of their development determinants, referring to both internal factors of an enterprise, as well as location determinants. We also take into account the potential importance of enterprise diversity in terms of their resources as well as their perception of external factors. That is why the second research hypothesis takes the following form:

Hypothesis 2: The importance of FDI development determinants has varied depending on the business sector of analysed enterprises, i.e. enterprises from traditional and new technologies industries.

Methodology

The results presented in this paper come from a survey conducted between 2016 and 2017. It covered Polish enterprises which had undertaken direct investment in the United States. The database was created based on own insightful knowledge of the Polish Embassy in Washington and on public information. It contained a list of 82 Polish investors, who had created a total of 92 direct investment entities in the USA. 19 questionnaires were filled out correctly, which meant a return rate of 25%.

Taking into account the specific nature of the respondents, the results were not only presented in relation to the whole population, but also taking into account the singularities of the surveyed entities, splitting them into two groups, namely enterprises doing business in the area of new technologies and entities operating in traditional industries. The first group comprised entities doing business within two different sections: "Information and Communication" and "Professional, Scientific and Technical

activities". The second group included entities operating in the following sections: "Mining and Quarrying", "Industrial Processing" and "Wholesale and Retail Trade; Motor Vehicle Repair". The share of the respondents in each group was 63.2% and 36.8% respectively.

The questions in the research questionnaire regarding the individual factors' impact on the development of Polish direct investment companies in the USA were closed-ended questions. The respondents determined the impact of individual factors using a seven-point scale with a range from -3 to +3, where: -3 meant a strong negative impact, -2 – a negative impact, -1 – a slightly negative impact, 0 – no impact (neutral factor), +1 – a slightly positive impact, +2 – a positive impact, and +3 – a strong positive impact. The impact strength of individual variables was determined using a weighted arithmetic mean, hereinafter referred to as the impact indicator (i). The level of an index value determined the position of individual indicators in the value hierarchy.

Research Results

The respondents assessed a total of 40 potential development determinants, which were divided into two main groups. First of all, the determinants in the form their resources, the so-called internal factors – i.e. unique and sustainable ownership-specific advantages – and external location factors, i.e. country factors exogenous to the analysed enterprises. The first group of factors was assigned to four sets: production/services, marketing, organization and management as well as finance. Most of these factors were resources contributed by parent companies to their subsidiaries, including the factors falling under the category of the so-called ownership advantages related to non-classic production factors. The location factors were divided according to the J.H. Dunning's classification into three groups: institutional and legal framework, economic determinants and business facilitation (table 2).

Having analysed the results of the entire population, the factor that had the greatest impact on the development of the subsidiaries in the USA was market demand (1st place with an impact ratio i=2.44). Despite the fact that respondents ranked external factor of location as first, their indications reflected their tendency to see the determinants of their development within their own organization. Out of the 15 factors that positively influenced the development of direct investment enterprises in the USA, as many as 10 belonged to factors in the form of these companies' internal resources: leadership (2nd place, i=2.00), organization of production/service processes and product/service innovation (3rd place, i=1.88), applied technologies (4th place, i=1.88), organizational culture (6th place, i=1.74), management team competences (7th place, i=1.68), product quality, employee qualifications and management team commitment (9th place, i=1.50) as well as company financial capital (11th place, i=1.44). Factors related to the ease of doing business in the USA (5th place, i=1.79) and the business environment (8th place, i=1.65) were also ranked high. This proves that the development of subsidiaries is largely determined by the ownership advantages of the surveyed enterprises, including the possession of innovative products and services that, together with favourable location determinants, affect the success of an enterprise in foreign markets.

Analysing the responses in these two groups, it must be pointed out that the results differed slightly. The determinant related to the demand on the US market had the biggest and definitely the most positive impact on the development of Polish new technology enterprises (i=2.82). These companies also indicated that applied technologies had a strong positive impact on their development (2nd place, i=2.25). Among the 14 factors that positively influenced the development of enterprises from new technologies industries, there were as many as 10 determinants in the form of the internal potential of these enterprises, including product/service innovation (3rd place, i=2.09); organization of production processes and employee qualifications (4th place, i=2.00), leadership (6th place, i=1.83), product/service quality (7th place, i=1.82), organizational culture (8th place; i=1.67), management team commitment (9th place, i=1.64), management team competences (10th place, i=1.58), company image (12th, i=1.33) and company financial capital (13th place, i=1.30). These results may indicate that investments in the USA made by entities with specific high-quality products and services, which result from the application of the right technologies, the work of qualified employees and competent management of the discussed investments by a committed management teams. This, together with the

large size of the American market, the ease of doing business there (5th place, i=1.92) and a favourable business environment (7th place, i=1.82), impacts a company's success.

Companies from traditional industries also ranked high the impact of internal factors on the development of their enterprises in the USA. Among the 13 determinants exerting a strong positive or positive impact on that development, they indicated as many as 7 internal factors. Enterprises from this group ranked leadership first (i=2.29) as a factor with a strong positive impact. Three other factors, including market demand in the USA, management team competencies and organizational culture (i=1.86), ranked second. Similarly to the group of technologically advanced enterprises, respondents from traditional industries also recognized the positive impact of the organization of production processes (3rd place, i=1.71), product/service innovation (5th place, i=1.57) and applied technologies (6th place; i=1.50) on the development of their enterprises. In their opinion, a company's financial capital was also important (4th place, i=1.67). The enterprises stressed, similarly to the previous group, the importance of the factor related to the ease of doing business (5th place, i=1.57). It is worth mentioning that in contrast to the previous group of companies, the following external resource factors proved to be important for traditional enterprises: factors related to the ability to supply natural resources, materials and semi-finished products, energy resources (3rd place, i=1.71) and factors related to the ability to supply new technologies, management systems and other new intangible assets (6th place, i=1.50). It can be argued that apart from market determinants, these entities were also guided by resource motives when making those decisions. These companies ranked factors such as employee qualifications and product/service quality slightly lower than those from the new technologies industries attributing to them only a slightly positive impact on their development.

Other factors in both groups of enterprises were ranked lower, meaning that they had a slight positive impact, no impact at all or even a negative impact.

Table 2: Development determinants of Polish enterprises in the United States (survey results)

DEVELOPMENT DETERMINANTS	Enterprises					
	New technologies		Traditional industries		Total	
	Index	Pos.	Index	Pos.	Index	Pos.
A. FACTORS INSIDE AN ENTERPRISE						
I. PRODUCTION/SERVICES

Guidance notes: Pos. – factor position; i – impact indicator taking the value from -3 to 3.
Source: own study based on survey results.

Based on the analysis of the responses, it can be concluded that they were largely convergent. However, significant differences have emerged in relation to some factors. Two of them were the assessment of competition in the USA and other foreign markets. Traditional enterprises perceived these factors to be hampering or without any impact on their development (i=-0.71 and i=-0.20 respectively), while new technology entities treat competition as a development factor (i=1.08 and i=1.17 respectively). The philosophy of competition perception can explain such assessment. New technology entities often use competition to improve their standard of services and better reach their customers. Strong

competition forces them to grow constantly, means avoiding stagnation and often inspires them to take action.

Other significant differences were noted in the assessment of resource factors. For traditional entities, an important development factor was the ability to supply both classic production factors (i=1.71) as well as those related to new technologies, management systems and intangible assets (i=1.57). Surprising is the fact that new technologies enterprises rated these factors much lower (i=0.00 and i=0.55 respectively).

Another significant difference in the assessment of development factors was related to the availability of external capital (venture capital, private equity, business angels). Both new technologies and traditional enterprises recognized that it is a factor which impacts their development, but the impact was believed to be insignificant for the latter group. This fact can be explained by the very nature of this type of financing. As a rule, venture capital funds and business angels finance new technologies companies with an innovative product and the American market is considered to be one of the largest markets of high risk investors.

Ranking the market factor very high, i.e. a market demand in the USA, in both groups of enterprises, proves that the expectations of enterprises in regards to foreign expansion expressed in the motives that affect investor's decisions contribute the most to the development of their subsidiaries, and consequently the entire company. Therefore, there is no reason to reject the hypothesis which says that regardless of the enterprise type, the market factor related to market demand was the most important development determinant of Polish enterprises in the USA.

In addition, the differences in the assessment of resource factors, efficiency factors and the competition in the USA indicated by traditional and new technologies enterprises, demonstrate that there are grounds for accepting the hypothesis which says that the importance of FDI development determinants varied depending on the sector of the analysed companies, i.e. enterprises from traditional and new technologies industries.

Conclusions

The experience of Polish enterprises investing in the USA is intrinsically interesting as it describes latecomers in the global economy conquering one of the most demanding markets in the world. Apart from companies following the traditional path of internationalization, for which the USA are the next stage on their path towards international expansion, the paper focuses on enterprises from the sector of new technologies with relatively little experience in international business.

The results of the study indicate that regardless of the sector, Polish enterprises seek the determinants of development of their subsidiaries in the USA primarily in the internal factors, i.e. unique and sustainable ownership-specific advantages, such as for example leadership, product and service innovation or applied technologies. These ownership advantages – together with external location factors such as the demand in the USA (ranked as the major development determinant), the ease of doing business and the business environment – affect most the development of Polish FDI there.

The research results also found that there were the differences in the assessment of competition in the USA and in foreign markets. New technologies enterprises perceived these factors as stimulating, while traditional companies indicated that the factors had no impact or even inhibited their development. The differences were also noted in the assessment of resource factors. For traditional entities, the ability to supply both classic production factors as well as those related to new technologies, management systems and intangible assets was an important development factor. New technologies enterprises, however, rated these factors much lower. While classic production factors, such as natural resources, semi-finished products and energy resources, are not sought after by new technology companies, ranking low the ability to supply new technologies may come as a surprise. This can be explained by the surveyed enterprises' resources: without valuable intangible assets, having own technology or even an idea for a new product, undertaking operations in the USA seems to be an irrational step.

This study has contributed to the understanding of FDI development determinants among Polish enterprises in the US market. While no significant differences between the two groups were identified in relation to enterprise internal factors, there were some important differences in the assessment of FDI location determinants depending on the business sector analysed. The study has also presented the problem from the perspective of investors from Central and Eastern Europe, who have not received a lot of attention from empirical researchers in the past decades. Moreover, the study has focused on firm-level survey studies, which makes it unique and gives it a significant cognitive value making it an important contribution to the existing literature.

Abstract

Achievement of energy efficiency is a major challenge due to the complexity and size of customers, including national, regional, and local authorities, households, and industry. The energy savings shown so far in individual countries are usually smaller than declared. The problem is aggravated by the continuous technological progress, social development, and population growth. The goal of energy saving remains in opposition to the growing demand for products and services. Therefore, EU energy efficiency regulations may not fully address the existing dilemmas for many market players, including primarily for private companies. On the one hand, the objective of those entities is to meet the needs of consumers, and on the other hand, they should focus on reducing energy consumption. Consequently, a research problem has been identified concerning the possibilities of increasing energy savings in companies and trade associations operating within the European Union. All raw data used for the study comes from a data set that was developed for consultation of the EED Directive by the European Commission. The purpose of study is indicate the attitude of companies operating in the European Union towards energy efficiency regulations.

Keywords: Energy Saving, Energy Efficiency, Business Operations

Introduction

Energy is an important resource for any developing economy and its low price and sufficient availability are even more important. In the light of climate and economic change, energy resources are becoming increasingly important, both globally and nationally, for economic growth, sustainable development, and social well-being. Energy is used by national and local authorities, households, and, most importantly, industry. The role of energy is particularly noticeable in manufacturing processes that can have a negative impact on the environment. External regulations and related environmental goals mean that reduction of energy consumption requires dynamic and effective corrective actions. Effective use of energy is therefore becoming one of the biggest economic and climate challenges.

Energy efficiency is also a strategic priority for the European Union's energy and climate policy. A proper energy policy is a prerequisite for sustainable development. Technological and demographic developments limit the available energy resources and force us to take measures to ensure energy security. Both the way energy is obtained and the way it is used are important. The area of production of goods and services requires a special focus on both energy sources and the level of its consumption due to the high level of energy consumption in the operations of production companies. Effective implementation of an energy efficiency policy is a major challenge for them. High investment costs, lack of experience, access to finance, and reluctance to change must be overcome. On the other hand, only some companies are required to carry out energy audits to verify their achievement of energy efficiency. Organizational and financial constraints effectively inhibit the level of energy savings in

companies therefore, formal and accessible solutions are needed to support and facilitate energy efficiency in manufacturing and service activities.

The effectiveness of available regulations in the field of energy saving in operations of businesses is a research problem of the article, where purpose is to identify and assess the attitudes of enterprises operating in the European Union towards regulations on achieving energy efficiency. The content of paper divided into sections. Section 1 describes the theoretical basis of the problem and identifies the EU documents that underpin the achievement of energy efficiency in the EU. Section 2 covers empirical research aimed to identify the attitudes of companies to energy efficiency regulations. Section 3 summarizes the results of the study and the conclusions drawn.

Theoretical framework of the problem

The concept of energy efficiency

As a result of economic growth, global energy consumption is growing out of proportion to the size of the population (Cruz-Lovera C. et al., 2017; Manzano-Agugliaro F. et al., 2015). According to a report by the International Energy Agency, global energy consumption increased by 92% between 1971 and 2014 (International Energy Agency, 2016). This results in a lower availability of energy for all types of consumers, including enterprises (Kumaraswamy S. and George S., 2019).

There are many definitions of and approaches to energy efficiency in the literature. Ganda F. and Ngwakwe C. (2014) believe that these technologies and strategies solve problems related to energy consumption and the associated costs and environmental impacts. Patterson M. (1996) supplements the fact that energy efficiency makes it possible to produce the same product or service with reduced energy consumption. Cui Q. et al. (2014) define this concept as a determination of performance based on a comparison of the energy input and output or as a comparison of the energy input to the energy production and expressing it in monetary value (Galvin R., 2014, Mikita M. et al., 2017). As defined by Erbach G. (2015), energy efficiency means the level of energy consumption for production purposes and is usually expressed, as a percentage, as the amount of mechanical energy produced by a given energy source. According to Salvia A. L. and Schneider L. L. (2019), "energy efficiency refers to a group of practices to improve the use of energy sources, reaching the same results - or even better ones - with lower energy consumption."

An improvement in energy efficiency consists primarily in reducing the resources needed for energy production and at the same time reducing carbon dioxide emissions. It is also related to the reduction of consumption of non-renewable energy sources and alleviation of energy poverty in the society (Ganda F. and Ngwakwe C.C., 2014).

Energy efficiency is an important part of the strategy for combating climate change and also serves to improve energy security and to optimize energy resources. It consists in using less energy to produce the same or improved product, service, or process (Science for Environment Policy, 2015; Allouhi A. et al., 2015). On the other hand, efficiency of energy sources enables production of an identical or better product or service using reduced energy resources (Dahlstrom K. and Ekins P., 2005).

The objective of energy efficiency is to generate benefits while saving energy by (Erbach G., 2015):

- off-peak energy use by different entities;
- use of renewable energy sources; and
- application of solutions that limit energy consumption.

Pursuit of energy efficiency should constitute the foundation for actions for sustainable development. Rational use of available energy sources and minimization of damage to people and the environment force maximum use of energy while minimizing its consumption (Kot and Ślusarczyk, 2013).

Improvement of energy efficiency leads to reduced environmental pollution and improved competitiveness of national economies.

Energy Efficiency Regulations

Improvement of energy efficiency is an important part of national and international environmental strategies, mainly involving reduction of greenhouse gas emissions. Effective achievement of environmental objectives requires the use of simple and understandable tools (Medina A. et al., 2016). Governments and non-governmental organizations (NGOs) focus on improving energy efficiency by improving access to renewable energy and combating climate change (Ürge-Vorsatz D. and Metz B., 2009). On the other hand, regulations on strategies to reduce energy consumption and carbon dioxide emissions adopted by European countries are based on an energy efficiency certificate that has been devised. The energy policy adopted in 2007 under the "Horizon 2020" program sets energy efficiency targets to be met by the end of 2020, including energy savings of 20% compared to 2005, an increase in the use of renewable energy of at least 20% of total energy consumption, and a 20% reduction in greenhouse gas emissions compared to 1990 (Energy Policy, 2018). The energy efficiency improvement target to be achieved by 2020 assumed 1.5% energy savings annually. In the period of 2007-2017, primary energy consumption decreased on average by over 2% per year (Peryt S. et al., 2019). The fastest rate of energy efficiency improvement was recorded in industry. Each member state set its own energy efficiency targets and had to take its own actions and put in place additional measures to achieve this objective.

Energy efficiency is important for environmental protection and is linked to the ETS Directive (2009/29/EC) on limits of greenhouse gas emission from electricity and industry. The need to comply with emission quotas set forth in external regulations may motivate companies for investments in energy efficiency, especially when they can significantly reduce pollution levels.

The Energy Efficiency Directive 2012/27/EU (EED) was also prepared in 2012 to promote energy efficiency within the European Union. Its objective is to support measures aimed to increase savings resulting from energy supply and consumption. According to the EU Directive, energy efficiency means the ratio of the level of service and production to the energy used. Saving energy, on the other hand, means a reduction of the energy consumption needed for the same production. The document contains both definitions and tools for the pursuit of energy efficiency by the various entities in the national economy.

Effectiveness of energy efficiency legislation makes it possible to reduce resource consumption by introducing specific laws. Penalties for high energy consumption stimulate innovation and introduction of new technologies to reduce energy consumption, as well as use of alternative energy sources. It has been shown that without external pressures, such as market forces or legislation, it is almost impossible to improve efficiency (Dahmus J. B., 2014). An important measure that results in an improvement of energy efficiency is stimulation and motivation of public and private entities with the aim to increase energy savings. Understanding and availability of regulatory solutions can also have a significant contribution to increasing energy savings in companies.

Empirical Analysis

Scope and subject matter of the study

In order to identify the attitudes of businesses towards regulations and laws pertaining to increase in energy savings, their opinions on the Energy Efficiency Directive (2012/27/EU) were examined. The study uses external primary data intended for the Public Consultation for the Review of Directive 2012/27/EU. The raw data was collected in an Excel file. The main objective of the study was to assess the views on the application of the energy efficiency concept in a group of companies operating within the European Union. Taking this into account, only a group of businesses and business associations was surveyed. Thus, a further study covered 172 research questionnaires. The structure of the research

sample was the following: 79% of industry and business associations and 21% of private companies. Slightly more than 26% of the respondents indicated that their main activity was located in Belgium, about 11% indicated Germany, 9% France, and about 5-6% of the respondents conducted their operations in Sweden, Spain, or Austria. Only two thirds of the surveyed entities declared that they dealt with energy issues. The study used basic inference methods, including response frequency distributions, p-value for the single-sided chi-square test investigating the significance of the differences between indication frequencies, and graphical methods.

Assessment of the possibilities to strive for energy efficiency in business operations

Among the surveyed respondents, there was generally no significant difference in the assessment of their countries' guidelines for properly defining the concept of energy efficiency of products and services: the group of respondents who indicated that the guidelines were sufficient in this respect and the group who were of a different opinion were the same and equal to 30%. The lack of clarity in this respect may result from the respondents' assessment of ongoing information campaigns or public initiatives that would concern clarification of the nature of public procurement of energy-efficient products and services. Nearly 75% of the respondents admitted that they did not encounter any activities in this area. Detailed information on the issues discussed above is presented in Figure 1.

Fig. 1: General characteristics of the surveyed respondents.

Source: prepared by the authors.

At the same time, the results observed with regard to the low level of energy savings in the European Union show some barriers and challenges to the effective implementation of Article 7 of the Directive (Fig. 2). The most common challenges for companies are the selection or implementation of the right set of measures that will enable achieving 1.5% of annual energy savings (26% of the indications), the high degree of flexibility in applying the measures of the energy efficiency obligation scheme and alternative measures or the lack of sufficient knowledge and skills of the parties involved in implementing Article 7 (10% each), as well as the strong opposition from energy suppliers and distributors to the establishment of an energy efficiency obligation scheme, the lack of effective enforcement of the commitments made, the lack of the end-users awareness of energy efficiency obligation schemes or alternative measures, and the high administrative burden associated with introduction of such schemes (7-9% each).

1. To select or introduce the right set of measures for achieving 1.5% energy savings (annually)
2. Too great flexibility to use a wide range of measures: energy efficiency obligation scheme and alternative measures
3. Strong opposition from energy suppliers and distributors to set up an energy efficiency obligation scheme
4. Lack of effective enforcement
5. Lack of sufficient knowledge and skills of involved parties
6. Lack of awareness (by the end-users) of the energy efficiency obligation schemes or alternative measures
7. Developing the calculation methodology in line with the requirements of Annex V
8. Ensuring sound and independent monitoring and verification of energy savings
9. Avoiding double counting
10. High administrative burden
11. Ensuring consistent application of the requirements with other energy efficiency legislation (e.g. building codes)
12. Limited timeframe (2014-2020) that makes it hard to attract investment for long term measures
13. Other

Figure 2: Challenges and barriers to achievement of energy efficiency by companies operating within the European Union

Source: prepared by the authors.

At the same time, more than 43% of the surveyed entities believed that the provisions of the EED on metering and billing are sufficient (less than 23% of the respondents expressed a different opinion) and almost 50% of the surveyed entities indicated that the requirement of frequent and individual billing should be dependent on the technical possibilities and the cost-efficiency of such undertaking, but only one in five respondents indicated that it would affect the potential for energy savings and consumer empowerment. Nevertheless, more than 80% of the respondents were of the opinion that there should be specific provisions to facilitate investments in specific areas of energy efficiency, with very frequent references to measures related to energy consumption by the industry (36%). In addition, a half of the respondents thought that solutions related public procurement of energy-efficient products and services should also apply to public authorities at the regional and local levels, but only 17% believed that the guidelines currently in force sufficiently define the very concept of "energy-efficiency of products, services."

The respondents also indicated that energy efficiency obligation schemes can bring some benefits (Fig. 3).

Inclusion in their operations of the principle of sustainable energy acquisition and consumption can translate into greater consumer awareness of the potential of energy efficiency (71%), development of

new financing models (56%), creation of a better business and administrative environment for future innovations in energy services (55%), lower bills for consumers (51%), possibility of aggregating several small investments into one larger one (46%), better relations between energy suppliers, distributors, and customers (35%), lower costs of energy generation and transmission (23%), and increased competition in the energy market (22%).

Figure 3: Benefits for companies from adaptation to the principle of energy efficiency

Source: prepared by the authors.

Study of Significant Differences Between Selected Groups

A detailed analysis of respondents' views on the energy efficiency issues discussed above indicates that these views are largely dependent on the views of the respondents as regards their countries' guidelines that enable proper description of energy-efficient products and services. Significant differences in this respect occur between industry and business associations and private companies, but this is mainly due to the fact that the opinions in this respect are much more often expressed by the surveyed associations than by private companies (see Table 1).

Table 1: Opinions about the level of guidelines for describing energy efficiency of products and services in particular groups of surveyed entities

	Industry	Private	p-value for a one-sided chi-square test investigating the significance of the differences between frequencies of indication
Insufficient	32.94%	15.79%	0.069752
I have no opinion	31.76%	68.42%	0.001493
sufficient	35.29%	15.79%	0.049327

In addition, those respondents who saw the information campaigns on energy efficiency more than twice as often indicated that the guidelines in their countries were sufficient in this respect and, on the other hand, those who did not see such campaigns more than four times as often indicated lack of sufficient guidelines on the energy efficiency of products (see Table 2). Both the supporters and the opponents of the opinion that there is a sufficient level of guidance for properly defining the energy efficiency of products and services, most often indicated as barriers and challenges to the effective

implementation of Article 7 the need to choose the right set of measures to achieve 1.5% annual energy savings (35% of the indications among the supporters and 24% among the opponents) and strong opposition from energy suppliers and distributors to the establishment of an energy efficiency obligation scheme (13% and 17% of the indications, respectively). Lack of sufficient knowledge and skills of the parties involved and the need to ensure reliable and independent monitoring and verification of energy savings (about 10% each) were indicated as other significant barriers by the supporters of the claim that the guidelines in the area of energy efficiency are sufficient. The other group of respondents, on the other hand, indicated that there was too much flexibility in applying the various measures of the energy efficiency obligation scheme and alternative measures (21% of the indications) or that there was a lack of effective enforcement of the adopted obligations (14%). Detailed information on the frequency of indications of particular barriers and the significance of the differences between the two discussed groups of respondents is presented in Table 2.

Table 2: Frequency of identification of selected barriers and challenges to effective implementation of Article 7 of the EED depending on the opinion concerning the sufficient level of the current energy efficiency guidelines

Barrier	Opinion on the level of the current guidelines in the area of energy efficiency		P-value for a one-sided chi-square test investigating the significance of the differences between frequencies of indication
	sufficient	insufficient	
To select or introduce the right set of measures for achieving 1.5% energy savings	35.48%	24.14%	0.168937
Too great flexibility to use a wide range of measures: energy efficiency obligation scheme and alternative measures	3.23%	20.69%	0.017613
Strong opposition from energy suppliers and distributors to set up an energy efficiency obligation scheme	12.90%	17.24%	0.319078
Lack of effective enforcement;	6.45%	13.79%	0.171754
Lack of sufficient knowledge and skills of involved parties	9.68%	0.00%	0.042828
Lack of awareness (by the end-users) of the energy efficiency obligation schemes or alternative measures	6.45%	0.00%	0.08208
Developing the calculation methodology in line with the requirements of Annex V	3.23%	10.34%	0.134641
Ensuring sound and independent monitoring and verification of energy savings	9.68%	0.00%	0.042828
Avoiding double counting	0.00%	0.00%	-
High administrative burden;	6.45%	6.90%	0.472477
Ensuring consistent application of the requirements with other energy efficiency legislation (e.g. building codes)	0.00%	3.45%	0.148559
Limited timeframe (2014-2020) that makes it hard to attract investment for long term measures	0.00%	0.00%	-
Other	6.45%	3.45%	0.296875

Respondents who were in favor of the statement that the existing guidelines in the area of energy efficiency were sufficient also indicated more frequently (p-value<0.0047) that the provisions of the EED on metering and billing are sufficient, but at the same time more frequently (p-value<0.0143) they were of the opinion that the requirement of individual metering and frequent billing should be made dependent on technical possibilities and cost-effectiveness in this area. Also, they significantly more frequently (p-value<0.0077) believed that the requirements of the EED concerning smart metering systems for electricity and natural gas and the feedback on their consumption, as well as common

minimum functionalities, such as those related to the frequency of updating of readings and their delivery directly to customers, would ensure a sufficient level of harmonization at the EU level. They also statistically more often (p-value<0,0072) believed that there was sufficient guidance and framework in place to properly understand the very concept of energy-efficient products and services. The respondents who had a negative view on the sufficient level of guidelines related to energy efficiency significantly more often (p-value<0.058) expressed the opinion that the sheer technical and/or economic possibility of being energy-efficient had a positive impact on potential energy savings and consumer empowerment. Also, they significantly more often (p-value<7.3E-05) agreed with the statements that measures related to public procurement of energy-efficient products and services should also become mandatory for public authorities at the regional and local levels. Detailed information on the above opinions of the supporters and opponents of the claim concerning sufficient scope of guidelines describing the energy efficiency of products and services is presented in Figure 4.

Fig. 4: Opinions concerning selected energy efficiency issues depending on the opinion on the level of guidelines enabling adequate description of the energy efficiency of products and services.

Source: prepared by the authors.

Both supporters and opponents of the claim of sufficient level of current energy efficiency guidelines are in principle the same supporters of the opinion that there should be specific detailed regulations to facilitate investments in specific areas of energy efficiency. In general, there are also no significant differences in the areas where such provisions should apply. Only in the case of the area related to improvement of the efficiency of household appliances and equipment, 35% of the respondents who believed that the current level of guidelines related to energy efficiency was sufficient were in favor of specific regulations in this area, compared to only 8% of those with the opposite view. Also, the first group of respondents significantly more often indicated the need to prepare detailed regulations facilitating investment in the urban and community infrastructure with respect to transport, energy recovery, heat recovery, and waste energy. Detailed information in this respect is presented in Table 3.

Table 3: Assessment of the importance of areas where there should be regulations to facilitate energy-efficient investments

Areas indicated	Opinion on the level of the current guidelines in the area of energy efficiency		p-value for a one-sided chi-square test investigating the significance of the differences between frequencies of indication
	sufficient	insufficient	
Building renovation	65.22%	73.08%	0.275673
Efficient appliances and equipment in households	34.78%	7.69%	0.009433
District heating and cooling network development	26.09%	15.38%	0.176788
Energy use by industries	30.43%	34.62%	0.377734
SMEs	21.74%	34.62%	0.159691
Companies	8.70%	23.08%	0.087029
City and community infrastructures in relation to transport, waste heat recovery, waste-to-energy	43.48%	11.54%	0.005747
Other	21.74%	38.46%	0.102481

As a potential benefit of the functioning of energy efficiency obligation schemes, those who considered that the current guidelines in their countries already allowed for a proper definition of the concept of energy-efficient products and services were significantly more likely to indicate lower energy bills for

consumers (p-value<8.55E-06), greater consumer awareness of the potential for energy efficiency (p<0.0467), the possibility of developing new financial models (p-value<0,0005), stimulating energy-efficient renovation of buildings (p-value<0,012), and increasing competitiveness in energy markets (p-value<0.0022) (cf. Fig. 5).

Fig. 5: Potential benefits of energy efficiency obligation schemes

Summary of the results

The most important conclusion of the study is that not all business entities are interested in energy efficiency in their operations. The analysis has shown a number of obstacles that may influence such a development of the studied problem. First of all, these entities lack a concrete set of measures and tools to enable the effective implementation of the energy efficiency concept in line with EU requirements; secondly, there are many gaps and misunderstandings in awareness and knowledge of the issue. On the part of companies, the need to introduce formal simplifications in the implementation of investments related to energy consumption in production and service provision processes is particularly evident. The biggest challenge is therefore to supplement the Directive with programs that will support the implementation of innovative energy saving solutions. At the same time, the surveyed entities hope that the regulations in force will primarily increase consumers' energy awareness and will allow them to optimize their energy consumption and thus improve their competitive position. The study also made it possible to identify some differences between the surveyed entities. Those entities that considered the current guidelines to be sufficient in the area of energy efficiency most often pointed to lack of sufficient knowledge and skills and lack of a robust system for monitoring and verifying energy savings as an important barrier. At the same time, they believed that the EED's metering and billing rules are sufficient, but the requirement for individual metering and billing should be made conditional on technical feasibility and cost-effectiveness. The other group, on the other hand, did not consider the current rules to be sufficient, mainly due to too much flexibility in the application of the various measures of the energy efficiency obligation scheme and alternative measures. Furthermore, such companies thought that the technical and/or economic feasibility of being energy efficient itself has a positive impact on potential energy savings and consumer empowerment.

Achievement of energy efficiency in companies is constrained by a number of considerations, including mainly lack of experience and skills. The provisions of the Energy Efficiency Directive are not sufficiently clear and understandable, while the proposed energy saving tools are not adapted to current possibilities of functioning in a competitive market. As a result, achievement of the planned energy

savings and reduction of energy consumption requires additional actions and forms of external support not only to companies but also to other market players.

Abstract

All organizations strive to achieve and maintain the highest possible level of employees' motivation. It may be achieved by using of tangible or intangible motivation tools. Highly motivated employees bring many different benefits for the organization. School and other educational institutions are organizations where possibility to use financial motivation tools is considerably limited. It is then especially important for school leaders to understand motivational processes and factors important for their motivation and motivation of employees. High motivation of school managers results in job satisfaction and motivation of teachers. The motivation of teachers undoubtedly affects students' learning and performance which is the main aim of schools as organizations.

Keywords: Educational Leadership, Job, Motivation, Teachers, School.

Introduction

Job is defined in many scientific disciplines. This term comes from the Latin word "*labor"* which originally means "an effort". Generally speaking , the literature concludes that the job is a set of activities performed by a human in order to produce goods and services in return for remuneration. The meaning of work in human life is defined as a degree of general importance that the subjective experience of working has in the life of an individual, at any given time. These subjective experience is divided into three main groups. They include:

- The individual experiences as job – employees in this category are committed to performing their work only for the material benefits such as for example salary and other material benefits.
- A career – viewing work as a career causes that employees are willing to put their effort into work - related activities for future gain understood as prospects of taking higher positions in professional hierarchy.
- A calling – people feel job satisfaction and obtain a sense of fulfillment from performed activities, they do not see work as way of making money but way of doing something valuable (Bellah, Madsen, Sullivan, Swidler, & Tipton,1985; Parry, 2006; Wrzesniewski, McCauley, Rozin, & Schwartz, 1997).

Referring to work as a sphere of life in which employee spends a considerable part of his or her life, it can be concluded that working environment plays an important role in meeting specific human needs. According to Maslow's theory there are five types of needs that are arranged in a hierarchical order such as:

- **Physiological needs** – (i.e. our body craves food, clothing, warmth) this basic group of needs can be fulfilled by received fair remunerations for job.
- **Safety needs** – teachers seek to establish stability and consistency in chaotic world which can be achieved by a guarantee of permanent employment.

- **Love/belongingness needs** – these needs come into play if the psychological and safety needs are already satisfied. It can be understood as establishing positive relationships with supervisors and co-workers and a sense of belonging to workplace.
- **Esteem needs** – understood as the need of esteem and prestige. The needs of this level can be satisfied by public praises or giving an employee ambitious and responsible tasks to be performed.
- **Self – actualization needs** – it means to satisfy human ambitions, constantly striving for personal and professional development. The school can help to meet this needs by organizing courses/training which to enable learn new qualifications and skills (Griffin, 2012).

These needs are arranged from the most to the least pressing needs. Meeting the needs on the higher level (self – actualization needs) causes that a teacher sees the sense of his or her professional and private life. It is important to stress that motivational systems in organizations should take into account complexity of human needs and their importance to motivation in organizational context. It is especially important in education as schools are places with very specific social context important for specific motivation (Schunk, Meece, Pintrich, 2020). It is also important from more general point of view of education as a social change agent that can promote certain models of action, in that case certain ways of motivation that can be transferred from educational context to other social domains (Gonida, Lemos, 2019).

Job Motivation – General Information

According to Butkus and Green *motivation* is derived from the Latin word *"motivate"* which means to persuade to move and act to satisfy the needs. Kreitner and Kinicki also underline that word *motivation* comes from the Latin *"movere"* which means to move (Butkus, Green, 1999). Literature presents many definitions of motivation as a psychological phenomenon (several of them showed in Table no. 1). On the basis of literature review motivation is understood as a set of energetic forces that originate both within as well as beyond an individual's being, to initiate work – related behaviour, and to determine its form, direction, intensity and duration (Pinder, 1998). Motivation is understood as a behaviour focused on specific goals. Employee is motivated when she or he expects that his/her way of action will lead him/her to achieve the specific objectives and valuable prizes satisfying her/his needs. According to A. Pocztowski motivation is an internal process during which the employee (Zając, 2014) :

1. Realizes his/her unmet needs.
2. Recognizes the opportunities to meet the needs.
3. Undertakes the actions aimed at achieving particular goals.
4. Achieves a certain level of completed tasks, which then is evaluated.
5. Receives awards or punishments for his tasks, which meet or do not meet her/his needs.
6. Assesses the degree of meeting his/her needs which, in turn, leads to creating a new needs or to modifying existing.

The literature distinguishes two kinds of motivation which involves positive and negative motivation. Positive motivation means encouraging employees to do their work in the best possible manner as well as to improve their performance by receiving financial and non – financial rewards. In contrast, negative motivation means the act of forcing workers to work by using threats and punishments e.g. threat of loss a part of salary after performing improper tasks, risk of reprimand, a shift to less well-paid jobs or lower position at work.

The aim of positive and negative motivation is to inspire employees to work. However, these concepts differ in their approaches. The positive motivation concept assumes that rewards and other facilities are provided for workers better performance. Whereas negative motivation tries to induce the workers by cutting their wages and other facilities. This kind of motivation is based on concept that if employees fail in achieving the desired results, they should be punished.

Motivation to work may have a very diverse nature. Employee is motivated to work which meets her/his expectations or needs as well as gives him/her perspectives. On the other hand, a worker can be

motivated by salary, promotions or other praises. Motivation can be divided into two different types of motivation such as (McCullagh, 2005):

- **Intrinsic (internal) motivation** – is understood as an individual need of pride with something. A worker is intrinsically motivated when she/he seeks satisfaction of curiosity or personal challenge in the job instead of working to achieve external, mainly material rewards (Nduka, Obiekwe, 2016). An employee's engagement in tasks requires a sense of inner satisfaction or pleasure. According to Hackman and Oldham workers have strong internal motivation when they are aware of a responsibility for their job's outcomes, realize the meaning of work and they have knowledge about the actual results of job activities (Hackman & Oldham,1980). In educational contexts such kind of motivation is especially important as aims of educational organizations are specific and material situation of schools are generally difficult which makes material (external) motivation more difficult (Łuczyński, 2011).
- **Extrinsic (external) motivation** - it is an opposition of internal type of motivation. It necessitates the effort on activities for the sake of external rewards such as bigger salary or other material job benefits (Amabile, 1993). It is undoubtedly not a good method of motivation in educational organizations context.

Internal and external motivation has different effects on each other: individuals focus on intrinsic outcomes while others are centered on extrinsic or even both. According to Furnham et al. introverts are more extrinsically motivated while extraverts are more intrinsically motivated (Furnham, Forde, Ferrari, 1998). In order to increase employee motivation and satisfaction, the organization should concentrate on internal factors because only these factors contribute to productivity growth. At the same time, the organizations should not neglect external factors because it may lead to increased employees' dissatisfaction and result in counterproductive behaviours of employees.

It seems to be important from practical point of view that motivation is a complex phenomenon influenced by many different factors. It influences ways of understanding motivation and its definitions in literature that underline different aspects of motivational process, that can be seen in Table 1 below.

Table 1: Definitions of motivation in literature

Authors	Definition of motivation
S.P. Robbins	Motivation is defined as a willingness to exert high levels of effort toward organisational goals, conditioned by the effort's ability to satisfy some needs.
J.A.F. Stoner, Ch. Wankel	Motivation is understood as a something what arouses, steers and maintains human behaviour.
A.A. Huczynski, D.A. Buchanan	Motivation is defined as a decision making process through which the individual chooses desired outcomes and sets in motion a pattern of behaviours appropriate to acquiring them.
L. H. Haber	Motivation is defined as an action to perform on individual approach to worker, knowing his needs and expectations as well as creating good working conditions. These activities contribute to achieving the objective of the company.
J. Reykowski	Process of psychological regulation which determines human effort for achieving particular goals.

Source: own elaboration

Tangible employee motivation tools include all motivators that are given to workers in an intangible form but which can be converted to money (some of them are shown in the picture no.1). However, intangible motivation tools cannot be converted into cash but they have a substantial psychological value for employees.

Figure 1: Tangible employee motivation tools

Source: own elaboration

Research conducted by Linder shows that different motivational factors affect workers performance. This factors are ranked in the following order: (1) interesting work, (2) good salary, (3) full appreciation of work done, (4) job security, (5) good working conditions, (6) promotions and growth in the organization, (8) feeling of being in on things, (9) personal loyalty to employees, (10) tactful discipline as well as (11) sympathetic help with personal problems (Linder, James, 1998).

Teacher's Motivation

Motivation is one of the most important factors increasing the efficiency and effectiveness of work (Yousaf, Latif, Aslam, Saddiqui, 2014). Teacher's motivation is understood as something 'what attracts individuals to teaching, how long they remain in their initial teacher education courses and subsequently the teaching profession, and the extent to which they engage with their courses and the teaching profession' (Sinclair, 2008). Motivation is a complex psychological process. Teachers have different needs which are determined by such factors as for example: their age, sex, life/job experience, social status, expectations, financial conditions etc. Teacher motivation is a key determinant for student motivation and teaching effectiveness in the classroom (Han, Yin, 2016; Hattie, 2012).

Teachers' motivation is affected by job satisfaction, reward system, training and development as well as work situational factors (Nyakundi, 2012). Schools and other educational institutions are places where possibility to use financial motivation tools is considerably limited. Teachers' salary consists of basic pay and remuneration for additional work as well as supplements: years of experience, class teacher's duties and other incentives (in other companies called the bonus).

The research conducted by B. Taradejna presented expectations motivating teachers to take up work at school. According to study which included about 260 respondents the most important factors which determined teachers to choose the teaching profession are: opportunities to pursue their passion at work as well as possibilities for personal and professional development (Taradejna, 2011). Also the opportunity to improve qualifications and professional development has enormous potential for teachers' everyday motivation. The school manager/leader may encourage teachers to constantly improve their professional qualifications through such activities as for example:

- Creating a good working ambience in the pedagogical council which help to identify teachers with their school as specific educational institution.
- Creating a convenient weekly lesson schedule for teachers that suits their individual needs.

- Co - financing some of the continuing professional development courses important for teachers in their professional career.
- Proposing attractive forms of increasing teachers' skills and qualifications within internal professional development schemes developed at the school level.

Penc distinguished several activities of the motivation process which can be used by school leaders or managers to motivate their teachers. One of them is formal recognition of different teachers' qualifications/needs/predispositions to adapt work to employee expectations (eg. during job interview) as well as maintaining good climate at work (Penc,1996). Friendly atmosphere at school means a good relationship between headmaster and all school workers, mutual respect as well as mutual kindness at the interpersonal level. A good social climate or atmosphere at work determines workers creativity and speed of response to changes in the workplace. It satisfies many important needs connected with work among which are: esteem needs, safety needs and affiliation needs. In addition, employees expect oral praises (individual or public) and professional support from their school headteacher (Watt, Richardson, Smith, 2017).

Working environment of school can strongly influence employees' professional motivation. It includes different aspects such as equal opportunities, equal rights and equal possibilities to act professionally within school as organization for all teachers. On material level, it also needs to build a healthy workplace, understood as using the modern equipment/tools/ergonomic furniture at work, lighting and functional design of classes, number of students in class, conditions in teachers' room, relationship with co – workers, responsibility and autonomy. Understanding complexity of factors contributing to motivation is one of most difficult aspects of building adequate competencies of school leaders.

Conclusions

Good school leadership needs different interpersonal competencies but those connected with motivation seem to be one of crucial for good school functioning. Understanding motivation and its functioning in organizational context is very important. Good school leaders know how to motivate by understanding complexity of this process.

Motivation specifies the reason why teachers decide to do their job with commitment as well as effort which employees put in the performance of their duties and how long they are willing to sustain their job (Han, Yin, 2016). Teacher motivation affects student performance while motivation is affected by job satisfaction, reward system, training and development as well as work situational factors (Nyakundi, 2012).

Teachers play a significant role in the learning process of students (Muhammad, Farrid, 2011). Building a school motivation system may guarantee its efficient functioning. School manager (headmaster) is expected to have such a style of managing the educational institution which influencing the workers' commitment and job satisfaction that contribute to high motivation in everyday work.

Abstract

Communication skills seem to be crucial element of contemporary leadership skills, especially educational leadership. In traditional schools, communication was predominantly one-way, e.g. directed from teachers to students. Therefore, such schools were often dubbed schools of monologue. In contemporary schools, more and more communication is two-way or even multi-directional, which shows that all the participants of educational process are involved in the communication. It is one of the steps taken in order to build a school community. The issues discussed in this paper include communication and its impact on the creation of democratic school communities. The authors arrives at their final conclusions by means of discussing two aspects that are immanently related to communication, i.e. management styles and self-education.

Keywords: Communication, School Community, Democratic School, Management Style, Self-Education

Introduction

Before 1989, working in Polish schooling consisted mainly in student education and socialisation. These were, however, corrupted by the ideology of that time. The party imposed a default development pattern upon people so that they are formed by manipulated knowledge and, quite paradoxically, anti-social models of existence in society. In the time of transformation, schools functioned in very much the same way as they did in the socialist era, albeit without the shackles of total oppression. The tokens of liberty in education were: the demonopolisation of schooling, the decentralisation and autonomy of schools. A contemporary school keeps evolving, but the goal is not only to care about education, socialisation, and individual development, but also to initiate changes in the society. A starting point for such changes could be the creation of democratic schools. The reference to democracy here is not only to imply the system of the school itself, but also to characterise the attitude of people. A significant role in schools should be played by civic education on both theoretical and practical levels. The development of democratic attitudes should be started from the area of communication, as its impact on self-perception, outlook, and reality creation is immense. The principle of mature and responsible existence in society is self-development.

The aim of this article is to present communication as a determinant in the construction of school community. Communication is perceived as one of key factors or competencies of leadership in every organization (Mumby, Kuhn, 2018), but especially educational leadership or management in school context (Bush, 2011). It is undoubtedly very important aspect of school functioning as central educational skill (Raptou, Stamatis, Raptis, 2017). It is also a crucial competency of people working in schools as specific organizations (Morreale, & Pearson, 2008). Two aspects related to communication have been scrutinised: the management style and self-education. The reference to management style may suggest that this article is primarily related to those who manage schools, i.e. headmasters and teachers. What is more, if there is no self-education effort or conscious self-development, it is difficult to speak of a proper communication that could facilitate the creation of a

school community. This kind of communication is more of a pretence.

Attempts at defining communication

The discussion on communication should be started from a scrutiny of the term itself. The concept of communication appears and is discussed on a variety of fields, including sciences such as information technology or cybernetics, and reaching humanities and social studies, e.g. linguistics, psychology, sociology, management, or political science. Communication can have an external or internal form. The internal communication is oriented towards the surroundings. The internal communication – or autocommunication – is oriented towards one's inner self. The definitions of communication available in literature on the subject can be divided on the basis of how broad the definition is. In the narrower definition, communication is understood as a process of information exchange between two people (Griffin, 2002; Grzesiuk, Korpolewska, 1988). M.Filipiak makes a distinction between *communicating something*, *communicating with somebody*, and *communication* itself. Thus, "*communicating something* is a one-way flow (with the addressee listening to the speaker), *communicating with somebody* is a two-way flow (with both interlocutors conversing), and *communication* is a flow in general (with the information circulating in the system)" (Filipiak, 2004, p.13). The broader takes at the term emphasise other aspects of communication. For instance, Z. Nęcki defines communicating as "an exchange of verbal, vocal, and non-verbal signs (symbols) undertaken in a specific context aimed at reaching a higher level of communication" (Nęcki, 1996, p. 109). At the same time, J. Stewart claims that "interpersonal communication is the type or kind of communication that happens when the people involved talk and listen in ways that maximise the presence of the personal" (Stewart, 2000, p. 37). Then he proceeds to explain the definition, highlighting the significance of *people* and *contact*. People's characteristics are enumerated to distinguish them from other living creatures. These characteristics include: „1. **Uniqueness** – every human being is a special and irreplaceable part of a communication situation, 2. A person is more than a combination of observable, measurable elements. The immeasurable consists of *feelings*, *emotions*, or *soul*, 3. People can **choose**. Instead of reacting, we can respond. We cannot turn time back or move to another planet, but our future is never totally determined by our past, 4. People are **reflective**. We are aware of not only what is around us; we are also aware of our own consciousness, 5. People are **addressable**, which means one can talk *to* us or *with* us, not only *about* us, and we can reciprocate that" (Stewart, 2000, p. 44). By „type or kind of communication", Stewart means something that occurs between people, and not something one person does to another" (Stewart, 2000, p. 45). This shows that communication is relative and has influence on others.

Stewart's definition presented above is a starting point for the author's discussion, as it allows one to acknowledge the depth of communication processes and their significance, as well as provides the basis for a real community to exist. Thus, we arrive at the very etymology of the word *communication*, which was derived from "a Latin word *communis* ("common"), signifying an attempt to establish connectivity (community) with somebody" (Pilarczyk, 2002, p. 7)

Communication and Management Style

Every management style brings about a specific method of communication. The style of one's preference is decided by the traits of the managers, their personality, qualifications, and management skills (Żukowski, 1997). Both a manager and those who are managed have an impact on the effectiveness of the management style applied. A management style "is a complex set of relationships between the behaviour and personal traits of the manager, the characteristics of the team to manage, and the context in which the manager and the team work. (…) The management style applied is copied on all subordinate levels on the organisation hierarchy" (Penc, 2000, p.148). The management style is suggestive of the constellation of relationships in a given professional team.

There are many typologies of management style in the literature on the subject. The first scholar to scrutinise this issue was K. Lewin. He developed a classic management style typology, distinguishing between: 1) an autocratic leader, under whose management every employee has a manager-specified role in a defined field. The manager is the one controlling employees' activity. The manager single-

handedly defines goals for the organisation and does not base employee evaluation on objective criteria, 2) a democratic leader, who discusses the goals and the effectiveness of the team members with the team and takes into account objective factors for employee assessment, 3) a laissez-faire leader, whose approach is characterised by the freedom of actions, also those of the employees. The manager has a passive, friendly attitude towards the subordinates and avoids evaluating them (Teczke, 1988). In 1930s, R. Lippit and R. White conducted a significant study. The study analysed children's reactions to the three leadership styles: the autocratic, democratic, and laissez-faire leadership. The autocratic leader used commands to manage the group. A democratic leader allowed his group to talk and make decisions. The laissez-faire maximised the children's freedom of action and minimised the manager's impact on the group (Bielski, 2001). The results showed that in the autocratic model, the amount of work done by the kids was the highest, but the effort was virtually non-existent once the leader left. In the democratic model, the quality of the work was the highest and the intensity of work dropped just insignificantly in the absence of the leader. The laissez-faire model did not bring any positive results in any area (Bielski, 2001). Some scholars (e.g. F. Fiedler) prefer situational leadership and believe the effectiveness of each style is dependent on the acceptance of the subordinates the manager has, the nature of the tasks, and the extent of formal superiority the manager has (Bielski, 2001). The effectiveness of a given style is decided by the circumstances.

J. Penc described two management styles: classic management and new management. The former is characterised by rigid rules and extensive bureaucracy. The latter is about flexibility, support, and partnership (Penc, 2010). It is assumed that the classic management style is in correlation with a one-way model of communication. A certain kind of asymmetry can be observed in the one-way communication process: the speaker addresses the listener, there is no feedback, the speaker does not wait for the addressee's reaction after the command was uttered, the manager does not explain the "why" behind the decision (Frydrychowicz, 2009). The modern style is based on a two-way (interactive) or a three-way (relational) communication model. The characteristic features of interactive communication include: feedback, increased symmetry of the relationship between the manager and employee, and more frequent consideration given to employees' standpoint and vice versa. This creates the environment for the regulation and modification of behaviour and for the development of sensitivity to the person we are interacting with (Frydrychowicz, 2009). The three-way communication, also known as relational or transactional communication, consists mainly in concentrating on the subject of the communication, and not on the individuals and their behaviour. The communication between the speaker and the addressee is based on creating a common platform for understanding, constructing meanings together, developing a kind of closeness enhanced by the communication subject, establishing mutual respect for others' roles. This communication leads to being open in a cognitive and emotional way (Frydrychowicz, 2009).

From the management point of view, communication has an impact on the effectiveness and quality of the way the organisation functions. It creates the organisational culture – the personality of a given company or unit (Lis, 2007). Schools are organisations in which the management is an important field. The key roles are held by headmasters, teachers, and more and more often also parents and pupils. Communication is perceived as key competence important for good school management or leadership (Dorczak, 2019). The management style assumed brings about a specific communication style, and high-quality communication in the organisation helps in managing it, positively impacting the motivation, involvement, and integration of employees as well as their completion of tasks and goals (Frydrychowicz, 2009). Striving for perfection in communication may contribute to the development of a school and every human being.

Communication and (self-)education

The relational (three-way) communication described above requires adequate communication skills. Therefore, it is not easy to apply it in practice. In order to acquire the skills related to the highest communication level, it is essential that one is constantly focused on their own development. The question of self-education arises as the one of utmost importance. Considering the very concept of human life, one can conclude that people start undergoing education processes right after they are born. Later schools, starting from lower levels of nursery or kindergartens as places of socialization

help to develop communication skills and enable individual to develop themselves (Zakova, 2019). Until a young person is fully mature, they are hardly or not at all capable of being involved in any conscious self-education processes. Crucially enough, „the dominating, primary factor responsible for preparing the foundations for self-education" (Pacek, 1977, p. 14–19) is always education itself. The education process is conducted with the participation of two significant figures. While the educator manages pupils' activities and takes responsibility for them, the pupil is the focus of the educator's effort. Pupils' behaviour reflects the impact of educator's activities. Pupils' involvement in the education process can vary in degree and type (Sowiński, 2006). In this discussion, the author would like to address the role of the educator. In adult life, self-education processes are of primary importance. It is the "I" that decides whether the influences from the surroundings are internalised or not. What is more, in order to be able to direct somebody towards self-education, one should make an effort to develop themselves as well. F. W. Foerster claims that „one of the most important conditions for effective development of pupils' characters is self-development on the part of the educator, since the educator can only discover in pupils that which he can discover in himself. Therefore, the most important education method is the indirect one, i.e. the one which educates and reforms one's will is first applied to oneself and one's own reservations, and only after that to pupils" (Matwijów, 1994, p. 25). Self-education activities are most often undertaken in order to become a better person, not least morally. Before one can get to that point, however, a certain route must be taken. S. Pacek described self-education potential using a classification of initial behaviour. He distinguished between five levels: 1) egocentric, 2) unsteady, 3) spontaneously exploratory, 4) creative, and 5) harmonious.
The egocentric level is characterised by no developmental dynamism. Its sole orientation is towards one's needs. The attitude towards the world is on one hand conflict with the world, and on the other hand, dependence on it. The characteristics of the egocentric level include the lack of sensitivity, empathy, internal conflicts, and guilt. The unstable level is characterised by the instability of attitudes and preferences, the lack of a clear development path, internal conflicts that are solved very randomly, and emotional attachment to other people. The spontaneously exploratory level is distinguished by the presence of dynamisms oriented towards the internal: evaluation and self-evaluation. The instability is replaced by the sense of responsibility and a kind of existential anxiety is observed. On the creative level, one hierarchy of values and aims is developed to a large extent. Internal conflicts and tensions still appear, but self-consciousness is very well developed. Individuals are more autonomous and are oriented pro-socially. The are reflective regarding self-perfection. The last level, called harmonious, deals with dynamisms at the highest degree: authenticity, responsibility, self-consciousness, and autonomy. Reaching this level is very difficult but not impossible (Żurowska-Berkowicz, 2012). All these levels form a pyramid, in which the broadest and lowest egocentric level forms the base, and is followed by unstable, spontaneously exploratory, creative, and harmonious levels to form the triangle.

Self-education contributes to one's developmental changes. The development is directed from a basic level – psychological level, focused on needs and oriented towards specific goods and the associated lower values, and characterised by strong egocentrism, a taker's attitude, and entitledness – to the spiritual level, consisting in exploring higher values, experiencing them, and having a desire related to a given value. The characteristic feature of this level is transgression, the transcendence of the ego, the "objectivised attitude", i.e. orientation to the subject of cognition, love, relationships with other people (Węgrzecka, 2012). The effort to develop, the ability to reflect, and the awareness of the responsibility for one's word dissolve communication barriers. The most common communication obstacles as listed by M. Świeca are:

1) Judgement – criticism, abuse, predication, judgemental praise. Imposing one's on values upon the interlocutor, formulating solutions to the interlocutor's problems, applying one's own criteria to judge other people – this is all often frowned upon.
2) deciding for others – making others dependent on us and depriving them from the power to make decisions autonomously. This is manifested by ordering, threatening, and moralising. This can compromise understanding even despite the sincere willingness to help because the partner may feel they have limited control over their situation.
3) Premature interpretation of motives – guessing people's point before they verbalise it themselves. Teachers are likely to see the motive they are afraid of, and not the motive the

pupil is concealing – e.g. when a pupil is smiling in front of the teacher, he or she may feel nice, be afraid, be ashamed, and not necessarily sarcastic or ironic.

4) Perception filter – we see mainly that which we want to see and hear what we want to hear. Limited perception is a distorted one. The rejected information is that which may undermine our positive self-perception or contradict the data stored in our brains.
5) The contradiction between body language and words – the utterance conveys something different than the body.

Self-education pertains to the work on speaking consciously, and listening to others consciously, too. P. Thomson claimed there were six levels of listening. The first one is the "unconscious look" – it happens when somebody unreflectively drifts away. The listening does not occur as the listener is busy with his own thoughts unrelated to the subject of the conversation. The second level is automatic response, with no willingness to get involved in the conversation. The third level is listening half-heartedly, i.e. the listener remembers only the last utterance, kept busy by his inner dialogue. On the fourth level, the recipients begin to listen. They can answer the question that was asked. The two final levels consist in the deeper understanding and processing of the input received. The understanding on the fifth level allows one to explain the subject to a third party. On the sixth level, the person can teach others (Machaj, 2006). Such deep communication is vital in every context but especially in education as it can best help to develop such personalized communication (Kaur, Cui, Luu, 2019).

Conclusions

The foundation of the efficient functioning of all organisations is formed by the people who make them. Skilful communication with others based on respect and interest facilitates the exchange of ideas, experience, or knowledge and motivates people to be more involved in the work they do (Szczygieł, 2012). The Gospel of John reads this: *In the beginning was the Word, and the Word was with God, and the Word was God. The same was in the beginning with God. All things were made by him; and without him was not any thing made that was made. In him was life; and the life was the light of men (…)* (The Jerusalem Bible, 2006, p. 1475). The religious context of that passage aside, it is worth to analyse the "word" part. This *passus* of the Gospel Prologue shows the power of the word. The word is *the beginning, the cause of things, life and light*. The last two nouns especially highlight the positive aspect of words. Nevertheless, if that is so, words can be negative as well; they can be *death* and *darkness*. This shows that the power of words is serious enough to affect the mental and physical health of individuals.

The 21st century has brought about the democratisation of management which calls for teamwork in management on all organisation levels. The people at the top of the ladder should be close to what is happening right at the bottom, and the lower level employees should be familiar with the goal of the organisation, its mission, vision, and strategy (Koźmiński, Piotrowski, 1998). Because of this situation, the structures are flattened and deformalised, and all employees participate in the management of the unit. Each of the presented communication models has its advantages and drawbacks. All three communication types can virtually occur; yet most commonly there is a hierarchical order to them. In order to build a school community, relational communication reached and perfected through self-education seems to be the most adequate type. This allows people to reach the highest communication level – the synergic one, which is devoid of the primitive win/lose dichotomy.

Management of Projects and Project Portfolios Co-Financed from The EU in Public Universities

Waldemar SZCZEPANIAK

Czestochowa University of Technology, Faculty of Management, Czestochowa, Poland
waldemar.szczepaniak@wz.pcz.pl

Abstract

EU projects play an important role in the development of public universities. Therefore, it is so important to ensure an appropriate level of management of these specific undertakings. Changes in the financing of project management costs co-financed from the European Union funds brought a new financial perspective, necessitated the search for new solutions in this area. The aim of the study was to assess the possibilities of managing EU projects and portfolios composed of these projects at public universities. For this purpose, methods of analysing literature sources were used and quantitative research was carried out using a questionnaire for EU project managers implemented in public universities in the previous and current financial perspective. In the course of the research, it was found that it is necessary to search for solutions combining the advantages of managing multiple projects simultaneously with the management of single EU projects at public universities

Keywords: Public Universities, Portfolio Management, Project Management.

Introduction

EU projects are a specific type of initiatives financed with the European Union funds available under multiannual financial perspectives. However, not only the source of origin distinguishes this group of projects, but also a strong concentration on guidelines for their implementation, including cost eligibility, information and promotion. Additionally, when these projects are implemented in public entities, such as universities, which also operate within a specific legal and financial framework, their management requires moving within a narrow range of acceptable activities. Therefore, it seems reasonable to look for solutions to improve the process of managing EU projects in public universities.

New financial perspective of the European Union for the years 2014-2020 brought many changes. In Poland, previous Operational Programs have been replaced by new ones, and universities have received a dedicated priority axis under the Operational Program Knowledge Education Development (OPKED), which replaced the Human Capital Operational Program (HCOP). In addition, significant funds can be obtained by universities as part of the Smart Growth Operational Program (SGOP), which replaced the Innovative Economy Operational Program (IEOP). There were also changes in the scope of financing costs, particularly unfavorable are changes in the scope of extending the catalogue of indirect costs and at the same time keeping their proportion unchanged. In the 2014-2020 perspective, both costs of remuneration and delegation of project management staff, as well as information and promotion costs can be financed only as indirect costs. Therefore, it is necessary to search for new solutions that will allow more efficient use of limited funds for project management. One of these solutions may be turning to portfolio management.

In order to achieve research goal defined in this way, an analysis of literature and results of own research were carried out. First part of the article presents a review of literature on project management and portfolio management. Next part presents methodology of own research and then analysis of results obtained. Last part includes a summary of research results and indicates directions of future activities in the field of managing EU projects at universities.

Projects and their role in HEI

Projects can be analysed from a static and dynamic point of view. Statically, project is a presentation of a description of implementation of a task (action, problem) with indicating its implementation within a specified time (Stabryła, 2006). It is presented usually as a preliminary document describing intentions and proposals for implementation of a specific task (Werewka, 2012). On the other hand, in dynamic terms, project is an organized sequence of many actions aimed at achieving a specific and measurable effect structured in time. It is addressed to specific group of recipients and requires involvement of limited human, material and financial resources (Bonikowska et al., 2006).

Project prepared in a form of description of the concept of implementing an action, requires involvement of specific resources in order to be implemented. Therefore, many projects remain only at the conceptual stage, and only certain projects are implemented. Main factor here are financial resources, involvement of which is an inseparable element of implementation of many projects. Each project has a clearly defined goal, which should be achieved within a specified time, within adopted budget and at an assumed quality level. In addition, projects are characterized by high level of complexity, autonomy (partial or complete independence) and uniqueness (Malinowski, 2013; Kopczyński, 2014).

Definitions and characteristics clearly indicate that projects require an adequate level of management (Mesjasz-Lech, 2015). Project management is a set of activities consisting of planning, organizing, directing and controlling focused on implementation of project objectives, enabling use of resources, both material and human, assigned to the project (Łada and Kozarkiewicz, 2005). Project management is a complex process (Padalkar and Gopinath 2016) requires consideration of aspects such as costs, time, quality, material resources, staff and communication, and risk. (Sanderson, 2012; Jun et al., 2011; Carr and Tah, 2001; Manikowski, 2013).

Projects co-financed by the European Union are an example of projects closely linked to various guidelines, both on the national and EU level. These projects are implemented as part of EU policies and are intended primarily to support socio-economic development of member states. In addition, these projects are characterized by significant resources necessary for their implementation and involvement of many participants (Domiter and Marciszewska, 2013).

On the other hand, portfolio of projects is a set of projects which implementation takes place at the same time and were particular projects are linked with the same source of financing, existence of a synergy effect or mutual balance (Martinsuo, 2013; Tonchia, 2018,). In the process of project portfolio management, projects for the portfolio are selected, method of their financing is determined, monitoring tools are chosen and implementation stages are design in a way to enable organization to achieve its goals (Kozarkiewicz, 2012, Kaiser et al., 2015, Killen et al., 2012).

Among various concepts aimed at increasing effectiveness of operations in the multiple-projects environment, the idea of creating a project management office is worth mentioning (Ko and Kim, 2019). This solution allows you to centralize all tasks directly related to project management in the organization. Thanks to this, it is possible to identify theoretical and practical knowledge and its subsequent use in particular projects contributing to increasing their efficiency (Unger et al., 2012, Jonas et al., 2012). It is also recommended to include project portfolio management in project management offices (Spałek, 2012). It should be emphasized that in many Polish public universities there are already project management offices (Chluska and Szczepaniak, 2017).

Review of the literature shows that there are not many publications on the relationship between the single-project management and project portfolio management (Martinsuo and Lehtonen, 2010). Therefore, it can be pointed out that there is a cognitive gap in the area of solutions combining elements of single-project management and portfolio management (Maceta and Berssaneti, 2019), especially at public universities.

Methodology of Research

Presented discussion has been based on the analysis of literature and results of quantitative research. First survey on project management was carried out among EU project managers implemented by public technical universities in Poland in the previous financial perspective of the European Union. Based on data from the SIMIK National Information System 07-13, 659 projects that were carried out by December 31, 2015 at public technical universities from the EU financial perspective for 2007-2013 were identified. These projects had to be implemented individually or as part of a consortium / partnership where the university was a leader. Population defined in this way formed a base for selecting respondents for the survey. Selection was deliberate and random. 20% of projects were drawn at each of 18 public technical universities. Systematic draw was adopted as a drawing scheme. The sample obtained is a result of choosing every k-th unit from the community (k=5). Survey was prepared online and posted on webankieta.pl platform. An invitation to complete the survey was sent to 132 EU project managers, of which 85 fully completed the survey, which resulted in a relatively high 65% rate of return.

However, the second survey was a preliminary study and was based on results of unstructured interviews with heads of units responsible for project management at public universities (Szczepaniak, 2017). Based on advantages and disadvantages of project portfolio management identified during the qualitative study, a survey questionnaire was developed and a survey was conducted among persons managing EU projects at public technical universities in the 2014-2020 financial perspective. This study was aimed at identifying factors determining transition from the level of individual project management to the level of project portfolio management at public universities. The survey was prepared in an online form and published on webankieta.pl platform. Selection of respondents was random, invitation to complete the survey was sent to 28 EU project managers at universities. These managers were identified based on project websites. 15 EU project managers responded to the invitation to complete the survey, which meant a rate of return of 53.6%. The article presents partial results of the study, which concerned rationale for portfolio management at universities. This research approach allowed to take advantage of rich experience of EU project managers from previous financial perspective and new challenges brought by the financial perspective for 2014-2020.

Research Findings and Discussion

Each project requires involvement of a team responsible for managing it. It is natural that in the case of complex projects, which are undoubtedly projects co-financed from EU funds, apart from the project manager, other people are appointed to the management team. Results of the study regarding size of EU project management teams are summarized in Table 1.

Table 1: Size of EU project management teams at public technical universities

Number of people appointed to the project management team	Number	Share (in %)
1	5	5,9
2-5	55	64,7
6-10	20	23,5
More than 10	5	5,9

Source: own study based on research, n=85.

In the case of examined projects, management teams most often consisted of two to five people (64.7% of responses). Only in 5 projects (5.9% of respondents) project management was focused exclusively in the hands of project manager. The same number of projects were managed by teams of more than ten people. For the remaining 23.5% of projects, project management teams consisted of six to ten people.

Project management process is multi-stage and multi-faceted. In the project you can manage all its components or only selected ones. Therefore, in the further part of survey, managers were asked whether indicated elements of the project were managed in their projects. The answers received are summarized in Table 2.

Table 2: Management of individual components of the project

Has the following aspects been managed in your project?	Yes		No		I do not know/ Hard to say	
	Number	Share (in %)	Number	Share (in %)	Number	Share (in %)
Quality	63	74,1	15	17,7	7	8,2
Costs	81	95,3	0	0,0	4	4,7
Time of implementation	79	92,9	4	4,7	2	2,4
Risk	48	56,5	25	29,4	12	14,1
Human resources	74	87,1	7	8,2	4	4,7
Communication	57	67,1	12	14,1	16	18,8

Source: own study based on research, n=85.

Vast majority of EU project managers (74.1% of respondents) indicated that quality was managed within their project. This is a very important issue primarily from the point of view of final beneficiaries who are interested in receiving the highest quality project products and results. High quality of results obtained is also an important element in creating the image of a university implementing the project.

Costs are another element of project, which are at the same one of main constraint in the implementation of each project. Answers given by respondents in the area of project cost management are generally not surprising. Over 95% of respondents indicated that costs were managed in their projects. Remaining 4.7% of managers surveyed could not answer this question unequivocally. Importantly, none of respondents indicated that they did not manage costs. Effective project cost management should ensure that costs are fully eligible.

Implementation of each EU project should take place in accordance with adopted schedule. Project implementation time is another main constraint of each project. Answers given by respondents clearly indicate that implementation time is managed within EU projects. Almost 93% of surveyed managers indicated that in their projects they managed implementation time. Only 4.7% of surveyed managers replied that they did not manage realization time in their projects. On the other hand, 2.4% of respondents had difficulty in providing a clear answer to this question. Effective time management in the project should ensure timely implementation of planned activities and achievement of intended specific effects in the grant agreement.

Implementation of each project involves a certain level of risk. The longer implementation time and the higher budget, the greater risks associated with successful completion of a project. Answers given by respondents indicate that majority of managers (56.5% of respondents) managed risk in their projects. 14.1% of managers had difficulty in answering this question. What is more, 29.4% of respondents said that risk was not managed in their projects. Lower percentage of risk managers in projects is not surprising. For example, in HCOP, part of application regarding risk of failure to achieve project assumptions was not filled in for projects with a value below PLN 2 million.

Human resources management is another important aspect of project management. Implementation of EU project is associated with management of personnel being part of management team but also of staff responsible for implementation of content-based tasks. In connection with this, project managers were asked if they managed human resources in their projects. Respondents' answers confirm important role of human resources in EU projects. 87.1% of respondents said that human resources

management played an important role in their projects. Only 8.2% of managers surveyed replied that they did not manage personnel in their projects. However, 4.7% were unable to provide an unequivocal answer to this question.

Management of human resources in the project is also associated with communication management. Among the surveyed managers, 67.1% indicated that in their project they managed communication. A lower percentage of EU projects in which communication was managed may result from specific communication paths at the university. Respondents asked to assess the correctness of the statement saying about official communication related to implementation of the project at the university pointed to its truthfulness. Their answers are summarized in Table 3.

Table 3: Assessment of correctness of the statement regarding communication related to the project

Communication related to the implementation of the project at the university takes place by business	Number	Share (in %)
I definitely agree	35	41,2
I rather agree	40	47,1
I have no opinion	4	4,7
I rather disagree	6	7,1
I strongly disagree	0	0,0

Source: own study based on research, n=85.

Results obtained indicate that majority of respondents – 47.1%, rather agree with this statement, and 41.2% of EU project managers strongly agree with this statement. Only 4.7% of respondents did not have an opinion on this issue, and 7.1% rather disagree with this statement. This confirms existence of a business route as part of project-related communication, which in some cases may limit possibilities of full communication management.

Presented research results regarding possibilities of managing EU projects have shown that:
- 74.1% of respondents said that they managed quality in their project,
- 95.3% of respondents said that they managed costs in their project,
- 92.9% of respondents said that they managed implementation time in their project,
- 56.5% of respondents said that they managed risk in their project,
- 87.1% of respondents said that they managed human resources in their project,
- 67.1% of respondents said that they managed communication in their project.

It was therefore confirmed that EU projects were managed at public technical universities. This statement allows to evaluate possibilities of managing EU project portfolios, understood as groups of EU projects implemented under a given Operational Program. The adoption of such a criterion for combining EU projects in a portfolio is justified by similar objectives and one source of financing. It also results from existence of common guidelines, manuals, guides and other documents dedicated to relevant Operational Programs.

During the second survey, one of questions asked to respondents concerned assessment of the issue whether project portfolios should be managed at the university. Results obtained are summarized in Table 4.

Table 4: Evaluation of a need to manage project portfolios at the university

Do you think portfolios of projects should be managed at the university?	Number	Share (in %)
Yes	12	80,0
No	3	20,0

Source: own study based on research, n=15.

Respondents' answers indicate that there is a need to manage project portfolios at public universities. The vast majority of EU project managers indicated that they should manage project portfolios at the university. In further part of the survey, the question was asked whether their project could be part of project portfolio at the university. Answers obtained are presented in Table 5.

Table 5: Evaluation of the possibility of including projects in the portfolio

Could your project be part of project portfolio at the university?	Number	Share (in %)
Yes	10	66,7
No	5	33,3

Source: own study based on research, n=15.

Among surveyed EU project managers, almost 67% stated that the project they were managing could represent part of project portfolio at the university. Obtained answers indicate that at most universities several projects are implemented under particular Operational Program, which is confirmed by analysis of ranking lists as part of competitions dedicated to universities in Poland. At the same time, it proves the need to search for new solutions in the field of managing EU projects in public universities.

Conclusion

In the management of a project that takes advantage of external financing under the European Union's structural funds, a strong emphasis is placed on efficient and effective use of funds within contracted time frame, taking into account objectives of allocated funds. Therefore, effective management plays an important role in the implementation of any EU project. It is to ensure that project objectives will be achieved in accordance with the budget and schedule, and products and results produced will be of adequate quality.

Process of managing EU projects begins when application for funding is prepared. Then, after receiving the funding, management processes are strongly intensified until the project is closed. After the end of implementation period, EU projects enter a sustainability period, within which management actions are also necessary.

Empirical studies carried out indicate that strong emphasis has been placed in public universities on ensuring an adequate level of management of EU projects. These activities are aimed at ensuring an appropriate level of product and project results quality within the time specified in the schedule and with full cost eligibility. To achieve these goals, additional efforts are required in human resources and communication management as well as in risk management. New financial perspective also means new challenges faced by public universities participating in the absorption of EU funds. Restrictions on financing management costs in projects, visible primarily in the Operational Program Knowledge Education Development, where these costs were included in indirect costs, lead to a situation in which it is necessary to search for new solutions in the scope of managing EU projects at universities.

These solutions should be developed in a direction of seeking opportunities to combine advantages of managing individual projects with benefits of portfolio management. Particularly important role should be played by project management cells at universities, which bring together qualified employees supporting administrative service process of such projects. However, each project should be managed by an independent manager. This solution will enable an individual approach in the implementation of each project while providing professional service by a team of employees involved in the implementation of many projects.

Sustainable Quality of Life and Knowledge Management

Michał DZIADKIEWICZ

Czestochowa University of Technology, Czestochowa, Poland
michal.dziadkiewicz@wz.pcz.pl

Abstract

The purpose of the article is to identify the factors which affect the quality of life in terms of knowledge management at the individual level. A literature review pointed to the existence of a research gap in this field. It has been assumed that the knowledge management context is understood as a desire to acquire knowledge in the field of addiction prevention as well as health and life, but also as a desire to obtain information on solutions to improve the quality of life. Conclusions were drawn on the basis of the results of a survey carried out among the residents of the Department of Housing Management - Social Housing Association called ZGM "TBS" in Czestochowa. The obtained data was subjected to statistical analysis, which included the use of logit analysis. The study allowed to identify statistically significant factors affecting the quality of life in the context of knowledge management.

Keywords: Knowledge Management, Sustainable Quality of Life, Municipal Housing Management.

Introduction

Knowledge in times of information society has become an indispensable resource of every organization. However, the ability to acquire, accumulate, process, generally speaking – to manage knowledge – is very important for every human being, in every field of his/her activity. In this context, it can be assumed that knowledge management affects the quality of life. This issue is particularly significant in terms of health and safety of both society and individuals.

The method of cognitive-critical analysis of the literature on the subject of quality of life and knowledge management was used to prepare the theoretical part. This allowed to indicate the research gap that can be identified between the studied areas, i.e. knowledge management at the individual level with regard to the quality of life. On the other hand, the conclusions presented in the empirical part were formulated on the basis of the survey results obtained from the residents of the Social Housing Association „TBS" in Czestochowa. The data obtained was further subjected to statistical analysis, in which logit analysis was used.

With reference to the issues thus adopted, the following conditions were defined for the identification of factors affecting sustainable quality of life in the context of knowledge management, namely:

- there is an increased need to broaden the knowledge of improving health and life, including addiction prevention,
- organization of regular meetings with residents contributes to raising awareness in the area of life quality,
- there is a growing interest in solutions to improve the quality of life.

On this basis, the main thesis was raised that knowledge management is of key importance for shaping the quality of life.

Quality of Life – A Review of Definitions

The quality of life of the population is the most important indicator of the efficiency and effectiveness of the economy, in the regions and local governments. In a single economic and social space, the most important goal of the state is to create and maintain conditions for the convergence of its regional levels (Kuznetsov, Rastova, Rastov, 2017). The quality of life of the population is determined by the achieved level of development of society, reflecting the level of realization of people's reasonable needs and the degree of satisfaction of their life plans in accordance with economic and social standards (Walczak and Tomczak, 2011). Therefore, the quality of life is one of the aspects of the concept of sustainable development, which is analyzed in three dimensions: economic, social and ecological. In economic terms, it relates to GDP growth that will ensure the right amount of goods and services. In social terms, it concerns the satisfaction of basic social needs, improving the quality of life and reducing unemployment. However, in ecological terms it refers to the improvement of the natural environment and the preservation of natural capital and protection of biodiversity (Zakrzewska, 2019).

Quality of life is a very complex concept that refers to many aspects of human life and depends on many individual and social factors, and the boundaries between individual approaches are fluid. This is an in¬terdisciplinary issue, so it is impossible to formulate a simple definition and uniform methodological criteria for its assessment (Kowalska and Szemik, 2016, Camarero, 2019). In research practice, the measurement of life quality is defined as multidimensional, requiring the combination of knowledge from various fields. Therefore, the subject matter related to it is of interest to many fields of science.

Quality of life is a result of the individual's attitude towards its own psychological and physical well-being, material existence, interpersonal relations possessed, possibilities of personal development and a sense of subjectivity (Walczak and Tomczak, 2011; Tetsuya et al, 2006 ; Padilla et al, 1983; Stempień, 2018). According to the World Health Organization, the individual's quality of life should be understood in the context of their perception of life situation, related to the cultural context and the system of values accepted by the society in which the individual lives, and in relation to life goals, expectations and interests (WHOQOL, 1993). According to E. Skrzypek, „the quality of a person's life is the sum of his/her efforts, struggles, the fight often taken against oneself, it is the ability to make right choices, it is also the ability to compromise, and above all it is the ability to make decisions and take their consequences with all responsibility. It is also quality perceived by the environment, manifested in how we live, how we dress, what we ride, how we eat, how we spend our free time, how we relate to other people, whether we are open to human problems" (Skrzypek, 2001). The quality of life includes all those elements of human life that are related to the fact of human existence, being someone and feeling various emotional states, resulting e.g. from having a family, colleagues and friends (Katana, 2016). It is an existential approach which focuses on distinguishing between two life orientations that can relate to the desire to live and the desire to own (Suchodolski, 1990). Quality of life can also be considered as a sense of accomplishment in connection with the implementation of development and life tasks (Kowalska and Szemik, 2016).

The quality of life defined in the category of needs is associated with the satisfaction of individual needs, including, among other things, the degree of satisfaction with family and professional life, neighborly relations, social relations, health status, the way of spending one's leisure time, education received, occupation and general standards affecting the quality of life within a given local community. R. Kolman defines the quality of life as a degree of satisfying material and

spiritual needs that translate into the standard of human life and society. According to him, the quality of life is the level of expectations satisfying the individual against the requirements of normality, as well as the predictability of life and actions in everyday situations (Kolman, 2000).

It is assumed that the quality of life is determined by two categories of factors, namely: objective conditions and subjective conditions of well-being. The first category includes economic and social conditions, while the second category includes the beliefs, feelings, desires and aspirations of the individual related to existential values (Trzebiatowski, 2011; Rapley, 2003; Sompolska-Rzechuła, 2013, Burkhart-Kriesel, 2017). Factors affecting the quality of human life include objective factors and subjective factors. Objective factors include, among others: the objective reality in which the individual lives, as well as the socio-economic and demographic structure of the population (Katana, 2016). Therefore, it will be an objective assessment of such indicators as, among others: life expectancy, crime rate, unemployment rate, amount of the gross domestic product, poverty rate, solarization rate, weekly number of hours (Chanda, 2015; David, 2017). However, subjective factors are primarily values and content understood as life satisfaction, expectations, aspirations, assessment of perspectives as well as perception of the past and adopted reference points. The following things are important here: a sense of community, a sense of security, perception of one's own financial situation, family relationships, a sense of justice, a hobby, a sense of class identity. The interaction of these factors affects the sense of life satisfaction (Sőrés and Pető, 2015).

Knowledge Management in The Context of Life Quality

The quality of life in subjective categories is interpreted through the prism of human moral and ideological problems, attitudes towards life, as well as preferred values (Sompolska-Rzechuła, 2013). In this view, knowledge as a resource, the desire to acquire knowledge and the ability to use it to preserve or improve the quality of life is a key factor according to the author. In the literature, knowledge and knowledge management relate primarily to organizations. This is understandable, because in today's information society knowledge is a valuable resource of dynamic nature that is a source of market competitiveness. Knowledge, however, can not only contribute to the development of any organization, but can also be a subjective factor in the quality of life of the individual. According to the author, many analogies can be found.

In the literature on the subject "knowledge is the ability to use data and information for a specific action" (Brdulak, 2005). Researchers of the problem of knowledge, noticing the difference but also the interdependence between the triad: data - information - knowledge, explain it using a model created by D. Tobin functioning under the name of the so-called knowledge hierarchy. The foundation is the data which, by linking together, creates information, whereas the information used in practice transforms into knowledge (Hey, 2012).

Knowledge at the individual level also includes skills and motivations. As in the company, the source of knowledge is man and the broadly understood human capital associated with him/her. An important factor, and also a soft component of intellectual capital, is the attitude towards knowledge. According to Skiba and Kwiatek, human attitudes towards knowledge are generally relatively persistent dispositions to assess and value it. In this definition, the object of attitude is knowledge. An important feature of this definition is the fact that attitude in this approach is a phenomenon rooted in the human psyche and the meaning assigned to specific components of a given attitude is an important issue (Skiba and Kwiatek, 2017).

Acquiring knowledge and activity level in this action is a kind of indicator of how valuable the attitude towards knowledge can be. It should be clearly emphasized here that two basic conditions must be met simultaneously in order to generate a true internal motivation that encourages

intellectual effort and knowledge acquisition, or a motivation that encourages the implementation of specific actions and adopting the right attitude towards knowledge. Firstly, the objectives of the action, the expected results, intentions and actions taken must present a specific value for the individual. Secondly, those particular goals should enable the achievement of measurable benefits or serve a specific need - they must therefore be assessed positively (Kwok and Gao, 2005). It is worth emphasizing at this point that regardless of whether the attitude towards knowledge and its acquisition is positive or negative, it has a fundamental impact on the quality of life.

Research Methodology and Procedures

To verify the adopted assumptions, a diagnostic survey using a survey technique was conducted among the residents of the Social Housing Association (abbreviated ZGM "TBS") in Czestochowa.

The study used a structured questionnaire that was created as a result of consultations of the appointed research team, which included five employees of the Faculty of Management of the Czestochowa University of Technology with the Management Board of ZGM TBS in Czestochowa. The prepared questionnaire form contained 22 main research problems related to various aspects of life quality in the city of Czestochowa.

The questionnaire was distributed via internal communication channels in August and September 2019 to the residents of six branches of ZGM TBS in Czestochowa. Due to the low rate of returned surveys, which was at the level of only 100 correctly completed forms, the study period was extended (the end of October - the beginning of November) and the direct interview method (PAPI) was used (For its correct course, it was determined that the sample size should be at the n=384 level, which was estimated on the basis of the sample size formula for a very large population, assuming that the confidence level 1-2 is 0.90 and the maximum error of estimate e = 5%). The final sample size was $n = 531$ of correct answers.

The starting point for statistical analysis was the econometric modeling instrumentation in the form of a multivariate ordered logit model (Kufel, 2007). The use of logit analysis was aimed at determining potential knowledge management factors affecting the quality of life of the residents of the ZGM TBS housing stock in Czestochowa. The estimated models included only zero - one variables coded on the basis of the subjects' answers (dependent variables). It has been assumed that the dependent variable (Y) defines the subject in the following way:

— $y_i = 1$, if i-th resident of the ZGM TBS housing stock declares willingness to acquire knowledge,
— $y_j = 0$, if j-th resident of the ZGM TBS stock is not interested in acquiring knowledge.

It should be emphasized that these variables were referred to four questions from the questionnaire, identified for the purposes of this scientific study as:

— $\boldsymbol{Y1}$ - interest in the knowledge of addiction prevention,
— $\boldsymbol{Y2}$ - interest in the knowledge regarding health and preventive medicine,
— $\boldsymbol{Y3}$ - interest in participating in educational meetings about improving the quality of life,
— $\boldsymbol{Y4}$ - solutions to improve quality.

The input set of independent variables (X) included variables characterizing the inhabitants of the ZGM TBS housing stock in Czestochowa. For the purposes of the study, the following were selected as explanatory variables: gender, age, level of education, marital status, and status in ZGM TBS. Variants of responses, together with the reference group, are given in Table 1.

Table 1: List of explanatory variables (own calculations)

Statistical data of the respondent		Independent variable	% Value	Reference group
Gender	Female	F	57%	
	Male	M	43%	*
Age	18-24 years old	A1824	4%	*
	25-39 years old	A2539	25%	
	40-59 years old	A4059	42%	
	60 years old and above	AP60	29%	
Education	Graduate	EG	31%	
	high school	EHS	36%	
	Professional	EP	25%	
	primary school	EPS	7%	*
Marital status	Single	S	15%	
	Married	MA	46%	*
	Widowed	W	16%	
	Divorced	D	11%	
	Separated	S	4%	
	Partnership	P	7%	
Status	Housing Association member	HA	39%	
	Tenant	T	61%	*

The research sample consists of 302 women and 229 men (reference group). The subjects (i.e. respondents) of the study were both members (39% of the surveyed population) and tenants themselves (61% of the surveyed population - reference group) of ZGM TBS in Czestochowa. The study mainly involved people over 40, of which 42% are people aged 40-59, while 29.4% are people over 60 years of age. The smallest group consists of young people, up to 24 years of age - 4%, who were selected as the so-called reference group. Taking into account the next category of variables, i.e. the level of education, the smallest share in the sample was recorded in the group of persons with elementary (primary) or lower secondary education - 7% (reference group). The most numerous group in this category was recorded among persons with secondary education (36%). Most of the people participating in the study were married - 46.6% (reference group), then single people (widowers / widows - 16%, bachelors / maidens - 15%, divorced people - 11%).

Research Results and Discussion

For the purposes of the study, eight logit models were estimated using the Gretl program, two for each of the considered explanatory variables (full logit model including all explanatory variables and a reduced logit model including only those variables that show significance features). The developed logit models were created based on the structure of answers to research questions defined as explained (i.e. dependent) variables. Table 2 presents the results of estimated models for the variable $Y1$.

NZ	−0.779200	0.352136	−2.213	0.0269**	

Explanation, significance level of parameters: *** $\alpha = 0{,}01$, ** $\alpha = 0{,}05$, * $\alpha = 0{,}1$

Looking at the obtained results (Table 2), it can be stated that age and status in the housing resources of ZGM TBS in Czestochowa are not statistically significant factors determining the desire to acquire knowledge of addiction prevention. In the case of data analysis in groups distinguished in terms of education, a statistical relationship can be observed in the case of EP (full and reduced model). Comparing this to the other groups, it can be stated that the probability of acquiring knowledge in the field of addiction prevention will be lower in this case. A similar situation (full model) is shaped for the variable F (gender) and NZ (informal relationships).

In the reduced model, these variables show a statistically greater relationship (level of significance $\alpha = 0{,}05$). Analysis of the obtained material showed that the inhabitants of the ZGM TBS housing stock in Czestochowa are most interested in acquiring knowledge of healthy lifestyle prophylaxis, in particular diet (52% of respondents). It should be emphasized here that both model 1 and 2 are characterized by the correctness of matching, as evidenced by the value of the likelihood ratio test (24.8 - p = 0.02 and 15.16 - p = 0.0017, respectively). On this basis, the null hypothesis of the total assessment irrelevance of the parameters of these models should be rejected.

However, taking into account the second of the analyzed variables - $Y2$, interest in the knowledge of health and preventive care (see Table 3), it should be observed that each of the selected groups

of explanatory variables has features of statistical significance. It can therefore be concluded that this factor plays a large role in improving the quality of life of the inhabitants of the ZGM TBS housing stock in Czestochowa. This is because these variables, as in the case of model 1 and 2, are characterized by the correctness of matching, which is also the basis for rejection of the null hypothesis.

Confirmation of the great interest in the knowledge of health and preventive care is the fact that the inhabitants of the ZGM TBS housing stock are mainly interested in acquiring knowledge in the field of hypertension, heart attack, stroke and therefore diseases that affect people over 40 years of age. In addition, questionnaire analysis showed that respondents were interested in the knowledge of physical activity and healthy eating, as well as ways to manage stress.

The results of the estimated models (models 5 and 6) are slightly different for the $Y3$ variable of interest in participating in educational meetings in the field of improving the quality of life (Table 4).

*Explanation, significance level of parameters: *** α=0,01, ** α=0,05, * α=0,1*

Analyzing the estimated models for the $Y3$ variable, it can be stated that:

- in the case of the full model (model 5): age and education did not prove to be a statistically significant factor determining the probability of occurrence of the examined factor (participation in educational meetings about improving the quality of life), a low significance level can be seen for the criteria of gender and status in the housing stock of ZGM TBS; a high level of significance can be observed for variable D, and therefore people who, due to the greater amount of time, will be happy to acquire knowledge during educational meetings,
- in the case of the reduced model (model 6): statistical significance was demonstrated by the variables F and HA, with higher probability of occurrence of the examined factor in persons from the point of view of status in the ZGM TBS housing resources.

In both models 5 and 6, the correct credibility of the model is clearly visible, therefore the null hypothesis should be rejected in favor of the H1 hypothesis. Delving into the respondents' preferences, the most desirable educational meeting is participation in workshops with a dietitian as well as a doctor. The respondents were also willing to meet with a lawyer and a psychologist.
In the next modeling (model 7), similarly to models 1 and 5, age did not show statistical significance. The status in the housing stock of ZGM TBS did not play a significant role either (as

in model 1). Statistical significance can be seen in the case of three groups of factors, i.e. gender and then education (EP) and marital status (D). It is these three variables that were analyzed in the reduced model (model 8). From the point of view of improving the quality of life, the highest probability of occurrence of the examined factor ($Y4$) can be seen in the case of gender (Table 5).

Table 5: Results of estimated logit models for the $Y4$ variable (own calculations)

D	0.598202	0.349594	1.711	0.0871*	The adjusted R-squared 0.0062
HA	0.438543	0.285185	1.538	0.1241	

Explanation, significance level of parameters: *** $\alpha = 0{,}01$, ** $\alpha = 0{,}05$, * $\alpha = 0{,}1$

The analysis of the questionnaire explicitly shows that the residents of the ZGM TBS housing stock are interested in the installation of gas sensors, as well as video surveillance. In their opinion, these two factors mainly affect their safety and thus improve the quality of life. In addition, the respondents indicated that social campaigns such as: "Be safe, senior" or "Internet safety " (action directed at children) have an impact on improving this quality.

Conclusions

The objective of the study was to identify statistically significant factors affecting the quality of life in the context of knowledge management, the implementation of which required the use of logit modeling. The estimated logit models (full and reduced) showed that interest in the knowledge of addiction prevention, knowledge concerning health and preventive medicine, interest in participation in educational meetings about improving the quality of life as well as

learning solutions that improve quality have a significant impact on improving the quality of life in the ZGM TBS housing stock in Czestochowa. It should be emphasized that the relatively higher quality of the estimated models can be seen in the case of models 5 and 6. In these models the number of 'correct prediction' cases is 72.6%. This means that in the case of the $Y3$ variable, the prediction corresponds to the actual state to the greatest extent. In other models the following may be observed: model 1 - 64.3%, model 2 - 62%, model 3 - 68.5%, model 4 - 66.9%, model 7 - 59.3% and model 8 - 56.1 %. To sum up, the overall case classification turned out to be correct, which can be considered a satisfactory result. This means that most of the accepted explanatory variables have a statistically significant effect on the dependent variables found.

Abstract

The purpose of the article is to determine the strategy of development and effective principles of regulation of biofuels production in Ukraine at the competitive level.

To systematize historical trends in the development of world and domestic energy, a dialectical method has been used. Using the monographic method, the priority principles of formation and mechanisms of regulation of energy policy and biofuels production are investigated. The forecasting method is used to formulate conceptual foundations of regulation and strategy for the development of competitive production of biofuels, and abstract-logical – for the theoretical generalization and formulation of conclusions. To ensure a solution to raised the problem, the well-known strategic planning tool – SWOT-analysis was used.

Based on the SWOT-analysis and the results of the study, a comprehensive mechanism for increasing the rate of industrial production of biofuels in Ukraine at a competitive level has been formed, containing the following priority regulatory measures: technology transfer and innovation; harmonization of the legal framework with the European Union; introduction of energy-saving and energy-efficient technologies; proper consulting and audit; attraction of highly skilled personnel; cluster approaches; provision of principles of nature conservation; development of foreign economic activity in the biofuels industry. The state regulatory strategy for the development of competitive biofuels production involves the comprehensive application of economic, legal and administrative regulatory methods.

For the first time, the principles of regulatory policy (consistency, flexibility, homeostaticity, synergy, competence) that are based on system-wide properties (system unity, development, complexity, compatibility, invariance, information unity) are developed in the field of stimulation of

production and consumption of biofuels. The direct process of their implementation in the fuel and energy complex of our country should be carried out on three main levels of management: macro-, meso- and micro-levels.

Adherence to the developed strategic principles of state regulatory policy will transfer the state to the energy saving type of economy and reduce energy intensity of production, increase the share of renewable energy resources in the national structure of energy consumption, ensure the formation of competitive production of biofuels in Ukraine, create favorable conditions for attracting to the agro-industrial complex external and internal investment inflows, the introduction of the latest innovative technologies and modern experience of effective work of the agricultural sector on the basis of diversification and clustering of production.

Keywords*:* Management, Fossil Fuel, Energy Dependence, Biofuels Industry, Competitiveness, SWOT-Analysis, Principles of Regulation, System Properties.

Introduction

The advanced countries of the world in the current economic environment are intensively developing rational ways of balancing their own structure of consumption of energy resources to ensure the independent functioning of the national economy by reducing the supply of imported energy. The complex of practical questions on significant reduction of energy consumption will be effectively solved only if the identified problem is clearly delineated in a structured system, localized on a territorial principle, comprehensive study of relationships with environmental factors, identified sources and causes of energy leakage. Constant exacerbations and conflicts at the state level in the supply of fossil energy are forcing the national economies of developed countries to constantly focus their research on shaping the competitiveness of biofuels. The development and implementation of diversified programs aimed at supporting domestic and international biofuels production seek to find effective and sustainable ways to overcome obstacles in bioenergy development, to create a balanced management system for scientific knowledge and research to promote innovation in this field. This process will lead to rational and efficient use of energy resources to sell produced products at national and world markets, as well as to stabilize the growth of demand for different types of biofuels, which should become a necessary component in the overall structure of needs of different categories of consumers.

The current conditions indicate that Ukraine has an irrational structure of energy resources use, so the problem of improving the management efficiency in energy consumption and reducing the energy consumption of produced products is quite relevant in theoretical and practical terms. The very volatile and unpredictable situation in the gas and natural gas markets and the possible negative changes in their further appreciation, as well as the need to dramatically improve the environmental status of cities and rural areas, require accelerated development of industrial production and consumption of biofuels, in particular for motor transport , agricultural machinery, housing and communal services, etc. Therefore, it is relevant to study and use the world experience in the development of the biofuels industry, as well as to put into practice state mechanisms of regulation and facilitate cooperation with developed countries in the field of development and implementation of highly efficient technologies of competitive production of biofuels in our country, bringing their technical and economic levels world standards.

The global demand for energy and related services to meet social, economic and human development, well-being and health is increasing. Energy is a central requirement in our daily lives to improve human development, leading to economic growth and productivity. Returning to renewable energy sources to help mitigate climate change is a great approach to sustainable development and meeting the energy needs of future generations [1]. Reducing energy demand and improving energy efficiency are two of the main goals sought in many national and international programs (such as EU 20-20-20 goals) in the transformation of energy systems [2].

Materials and Methods

Since the oil crisis of 1973, biofuels have been used extensively for many years to increase energy independence, reduce the cost of importing fossil fuels, and strengthen the agrarian sector of the economy [3]. Biofuels have the potential to change the transport and agricultural sectors of decarbonized societies. However, the stability of these fuels has been questioned in recent years due to the compromise of food against fuel, carbon accounting and land use [4].

However, the IEA estimates that bioenergy is one of the most effective and promising alternative energy destinations. The technologies for the production and use of bioenergy resources meet the requirements of the Paris Climate Agreement (COP 21) on environmental protection. The rapid and steady pace of development of the bioenergy industry over the last decades is due to a number of factors, the key ones being the widespread use of state programs to limit greenhouse gas emissions and environmental protection, reducing traditional energy resources while accompanying rising energy prices, improving the competitiveness of energy and energy. . The successful development of the biofuels industry abroad is driven by stable and diverse support from the state. Forms of support vary from country to country, but generally boil down to tax breaks and vacations; providing interest-free loans; setting a fixed tariff for green electricity; public financing of research and development works and pilot projects, etc. [5].

It should be noted that in the world, Ukraine is one of the most energy-intensive industries, so the competitiveness of production is directly dependent on the prices of fossil fuels, whose value is constantly increasing. The rise in prices over the last decade for fossil fuels has led to an increase in the competitiveness of renewable energy resources, in particular biofuels.

In agricultural enterprises, the cost of production is increasing annually, which is largely due to the constant appreciation of used energy materials produced from natural resources, such as fuel and lubricants, fertilizers, and natural gas. It is possible to reduce these resources at the expense of their alternative production from agricultural products, the technologies of which have been elaborated by world and national science, practically applied in many countries of the world and experimentally tested in Ukraine [6]. In spite of this, there is an extremely unsatisfactory rate of development of the biofuels market today, despite the adoption of a number of legislative acts aimed at solving this problem. The lack of consistency and consistency in the organizational and economic mechanisms for the development of the biofuel industry is conditioned by the lack of political will for their full implementation, as well as economic and political interests that have emerged in the energy market of Ukraine and other countries [7].

The wide range of urgent problems of pursuing a rigid state government policy in the field of bioenergy and the lack of incentive measures for biofuels producers have led to a slowdown in investment in the industry and the curtailment of the biofuels market in Ukraine in recent years. In order to create favorable investment climate for the development of bioenergy in Ukraine and to develop the market of biofuels, the state policy should be aimed at introducing an effective mechanism for supporting the production and use of biological fuels. The effectiveness of this mechanism is based on the optimal correlation between the administrative and market instruments of regulation of the bioenergy segment of the fuel and energy complex. The decisive role in shaping the state policy of bioenergy development in Ukraine belongs to the processes of development and adoption of legislation aimed at introducing tax, credit and price instruments, which will be more directed to the sphere of regulation of demand for biofuels [8].

The scarcity of its own energy sources compels the government to decide on increasing their imports. However, in the context of reducing fossil fuels in the world and the rapid increase in prices for them, solving energy problems through imports alone is not sufficient, which requires the introduction of effective regulatory instruments aimed at developing national biofuels. The current processes of European integration and the low level of consumption of renewable energy resources, in particular biofuels, in the structure of energy consumption requires the development of perfect regulatory principles and a coherent strategy for the sustainable development of national energy policy and

independence, which are now one of the weakest links in state regulation in Ukraine. [9].

The creation of a new environmentally friendly energy sector will facilitate the deployment of rational diversification processes for energy resources and the strengthening of Ukraine's energy and economic security. Along with the market mechanism of self-regulation, the state should also be the main regulating subject of a market economy. Especially versatile and purposeful should be the functions of public authorities in the context of economic reform, especially where the rights of private property are not clearly defined, as a result of which private owners lack the motivation to use their capital for the benefit of society as a whole, including the development of a sustainable energy sector. This is forcing the state regulatory bodies of Ukraine to pay greater attention to energy efficiency and energy conservation policies while respecting the environmentally friendly use of energy resources. Among the unresolved tasks of the state policy in the regulation of the fuel and energy complex is the urgent solution of the problem of reforming the national energy supply through the introduction of effective mechanisms of state regulation in accordance with world practice and EU requirements.

This process requires that, a set of priority measures will be implemented as soon as possible that will allow: to make the transition to competitive internal and external energy markets; to create an efficient internal infrastructure; introduce transparent market rules for energy activities; increase the level of financial discipline and responsibility and introduce mechanisms of insurance of non-payment risks for the used energy resources; to provide systematic control over pricing processes in the energy sector; introduce a system of mixed state and market regulation of the activities of energy market entities; to carry out systematic regulatory control over the activity of natural monopolies; increase the share of renewable energy resources in the national energy mix, giving priority to biofuels. The dynamic development of bioenergy requires a comprehensive optimization of this process, taking into account the needs of the energy and food sectors of the economy, as well as state regulation of export of biofuels.

The purpose of the research is to identify a strategy for the development and regulation of biofuels in Ukraine at the competitive level.

The conducted research is based on fundamental principles of economic theory, scientific developments of domestic and foreign scientists on the issues of state and market regulation of the development of competitive biofuel production, as well as the current legislative base of Ukraine. The study used general and specific scientific methods and techniques. In particular, a dialectical method was applied to systematize the historical trends of world and domestic energy development. Priority principles of formation and mechanisms of regulation of energy policy and biofuel production were investigated using the monographic method. The prediction method is used to formulate conceptual bases for regulation and strategy for the development of competitive biofuel production, and abstract-logical - for the implementation of theoretical generalization and formulation of conclusions. The well-known strategic planning tool - SWOT-analysis was used to solve the problem. The methodological underpinnings of SWOT analysis are a comprehensive assessment based on a matrix of interrelationships of the strengths and weaknesses of the industry, as well as a consideration of a range of factors of available opportunities and threats to the environment.

Results and Discussion

The system of urgent problems of rational use of energy resources under conditions of intensive increase of production of foodstuffs, improvement of their qualitative characteristics and formation of food security are among the priority tasks of the world economy. Today, however, an energy crisis that has swept almost the entire world has combined food and energy issues into an interconnected scenario for the continued sustainable development of the planet's future existence. Thus, an increasing number of countries are declaring their interest in accelerating the production of various types of energy from renewable energy sources, and the biofuels industry is now one of the fundamental positions in the economy of any energy-dependent country and in the development of

consumer services and materials markets.

Effective solution of the problem of energy supply is a key, paramount task of a sustainable, ie harmonious with nature and society, development of each state, implementation of its independent foreign policy, internal political and social stability, raising the economic and cultural standard of living of the population. As a consequence, the role of energy in solving sustainable development challenges is growing. The steady rise in world prices for traditional energy and energy produced in recent years has been exacerbated by the impact of the problem of energy supply on these factors, especially in countries with fragile economic status to which Ukraine belongs.

Changes in approaches to the formulation of states' energy policy are taking place in the world: the transition from the outdated model of functioning of the energy sector, dominated by large producers, fossil fuels, inefficient networks, imperfect competition in the markets of natural gas, electricity, coal - to a new model in which creates a competitive environment, equalizes opportunities for development and minimizes the dominance of one of the types of energy production or sources and / or routes of fuel supply. At the same time, it is preferable to increase energy efficiency and use of energy from renewable and alternative sources. This poses new economic and technological challenges for Ukraine, opens new opportunities for finding and implementing innovative developments in the field of fossil fuel production and transformation, transformation, supply and consumption, necessitating the formation of a new state energy policy [10].

The inevitable process of liberalization of prices for energy resources should take place in stages, but in the current unstable economic and political situation, our country is not immune to the trigger effect - a sharp increase in prices, which can lead to shock therapy for the whole economy. At the present stage of development, the disparity in prices for energy, industrial and agricultural products in Ukraine determines the prospect of introducing innovative technologies for the use of plant products. Industrial biofuel production process makes agricultural products analogous to industrial or energy. Given the rather strong potential of the scientific, technical and industrial base in the agricultural sector of Ukraine regarding the cultivation of agricultural biomass, the biofuel industry has a high level of economic efficiency, which gives every reason to allocate it to a separate branch of energy.

The Law of Ukraine “On Alternative Fuels” aims at supporting and developing the production of biofuels. In particular, in Art. 9 of this law states that the organizational and economic measure to increase production (production) and consumption of alternative fuels is to stimulate investment and the introduction of new technologies. The growth of investments aimed at the production of biofuels will be a decisive factor in adjusting the production process, the transition of agricultural enterprises to their consumption and the creation of an economic mechanism to regulate market relations in the field of alternative fuels [11]. Therefore, the regulation of the biofuels industry should be viewed through the prism of optimizing production, finding the most profitable areas of entrepreneurship and rational maneuvering of financial flows. In order to achieve sustainable biofuel production, it is necessary to develop an effective development strategy based on which the high economic efficiency of the bioenergy industry will be achieved and optimal ratios will be created in the domestic and foreign markets. However, the biofuel production process is currently under conditions that are not specific to global market trends and relationships. Regulatory decisions should be avoided in returning to the old framework of the planning and administrative system, with its almost comprehensive planning and tight regulation of the established limits. Addressing the problematic aspects of biofuel production will depend on the coordination of joint action, that is, on political and administrative consolidation in government.

Properly developed managerial strategic decisions on the implementation of energy conversion of biological raw materials contribute to the development of diversification processes in the production activities of the agro-industrial complex, ensure the entry into the market of production of new types of basic and by-products, reduce the negative impact on the environment at the regional and national levels, which results economic and financial condition of the agro-industrial industry and the country as a whole [12].

Therefore, in order to formulate an effective strategy for managing and regulating the processes of bioenergy conversion, a selection of appropriate effective analytical tools has been made, among which SWOT analysis is at the forefront. This kind of analysis is one of the necessary elements of scientific research to create sound prerequisites for the development of different levels of strategic and marketing plans, in particular for the formation of competitive biofuels production in Ukraine. The results of the SWOT analysis (Table 1) make it possible to objectively evaluate the internal forces and resource potential of the industry to realize the potential of the existing external capabilities and to confront the various threats that are constantly emerging in the changing market conditions. As a result of a comprehensive justification of the weaknesses, a system of internal deficiencies is identified that needs immediate elimination or minimization.

Table 1: Matrix of SWOT-analysis of strategy for development and regulation of biofuels production in Ukraine

Indicators of the matrix		Environment	
		Opportunities 1. Energy independence of agro-industrial complex and expansion of consumption of biofuels. 2. Inflow of internal and external investments and development of national production of biofuels. 3. Increasing employment and reducing the negative manifestations of seasonality of production.	**Threats** 1. Traditional energy subsidies and low biofuels consumption. 2. Lack of state support and legal nihilism in the field of bioenergy. 3. Increased competition and higher standards in biofuel production.
Internal environment	**Strengths** 1. Energy dependence and unregulated prices for traditional energy sources. 2. High biomass potential for biofuel production. 3. Reduction of waste accumulation and improvement of environmental situation.	Field of SO 1. Reduction of energy dependence and sustainable development of the agricultural sector of the country's economy. 2. Development of national production of biofuels on the basis of favorable investment climate. 3. Improvement of conditions of agricultural production and ecological situation in the country.	Field of ST 1. Development of the state program of development of biofuel production. 2. Stop the government's lobbying for traditional energy and adopt effective laws on the development of biofuels production. 3. Formation of ecologically clean production on the basis of development of competitive biofuel production.
	Weak sides 1. High energy intensity and cost of agricultural products and seasonality of production. 2. Low level of innovation and investment development. 3. Export of plant products for processing into different types of biofuels.	Field of WO 1. Bringing energy production indices of national production to the world level based on biofuel consumption. 2. Formation of competitive biofuel production on the basis of innovation and investment development. 3. Decrease of export of plant products abroad and increase of employment of the population in the country, especially in the agrarian sector of economy.	Field of WT 1. Low production of competitive agro-industrial products and rising unemployment. 2. Development of Ukraine as a raw material appendage of Europe. 3. Use of fertile lands of Ukraine for biomass cultivation and food security problems.

Source: created by the authors

Thus, at the intersection of the Sectors Strengths - Opportunities sectors, the most effective areas of strategic activity are formed, which provide the comparative advantages of the industry. As we can see, due to the considerable energy dependence of the Ukrainian economy on the import of traditional energy sources, it is strategically necessary to develop national production of biofuels based on the high economically viable biomass potential.

This process will ensure, first and foremost, the energy independence of the country's agro-industrial complex, expanding further the consumption of biofuels in other sectors of the national economy. Secondly, based on the creation of a favorable investment climate, there will be an inflow into the agricultural sector of domestic and foreign investment economies, which will allow the export of biofuels to the European energy market in the future. Thirdly, the formation of a competitive biofuel industry will help increase the employment rate of rural population and reduce the seasonality of agricultural production, as well as create real prerequisites for reducing waste accumulation and improving the environmental situation in the regions and in Ukraine as a whole.

An assessment of the Strengths - Threats sector indicates the feasibility or refusal of the further development of the area of activity or industry in question. The process of forming a competitive national biofuel production requires the development of a state support program to increase the pace of development of the biofuels industry, to end the government's lobbying of traditional energy in the form of subsidies and to minimize the problem of food security in Ukraine.

A study of the Weaknesses - Opportunities sector creates the prerequisites for identifying key challenges that need to be effectively addressed, as unfulfilled opportunities can translate into potential threats. As a result, the development of competitive biofuel production in Ukraine needs to be carried out on the basis of innovation and investment development, which will allow to reduce or stop the export of vegetable raw materials for processing to biofuels abroad and will provide a rational process of energy use with bringing the energy production indicators to the level of energy intensity. .

It also requires a thorough analysis of the Weaknesses - Threats sector, where emerging relationships create various risks that can halt the industry's development and lead to a loss of production and subsequently to bankruptcy. In this case, the main risks are related to the low level of production of competitive agro-industrial products, the further development of Ukraine as a raw material appendage of the European Union, the increasing risk of using fertile land of Ukraine for biomass production.

In the process of becoming biofuel production in market conditions, its financing should be made on the basis of internal and external resources. Internal resources include active savings of the owner, which are directed to the creation and development of the biofuel business; current receipts to support existing production and further depreciation. External resources include received funds from various financial institutions (banks, credit and investment companies), as well as funds that may come from business colleagues, stakeholders, sponsors, etc.

According to the Law of Ukraine “On the Principles of State Regulatory Policy in the Field of Economic Activity”, six basic principles of state regulatory policy have been established: 1) expediency; 2) adequacy; 3) efficiency; 4) balance; 5) predictability; 6) transparency and consideration of public opinion [13]. In order to form and develop competitive biofuel production in Ukraine, we are offered to use, in addition to the above-mentioned principles of state regulatory policy, principles based on system-wide properties (Table 2).

Table 2: Characterization of proposed regulatory principles and system-wide properties for competitive biofuel production

The essence of the proposed principles of regulation	The essence of system-wide properties
1. Funnels - the persistence of accounting policies used to compare reporting information. 2. Flexibility - the ability to change their directions in the process of business planning due to the emergence of unforeseen circumstances and adaptation to market requirements. 3. Homeostatic - the creation of economic and organizational mechanisms of self-regulation and stabilization in the production system, so that it is able to perform its functions in a stable manner within the tolerances and withstand dysfunctional influences. 4. Synergism - the use of several mutually agreed methods (strategies) has a greater effect than the sum of the effects of the isolated application of each method (strategy). 5. Competencies - the presence of special professional knowledge, skills and professional experience acquired as a result of professional training and professional activity.	1. System unity - is ensured by close links between technological processes of biofuel production (from the formation of raw materials to the sale of finished energy products to consumers); 2. Development - based on the expansion and improvement of the production of various types of biofuels and the formation of their competitive production in the long term in both the internal and external markets for energy. 3. Complexity - due to the integrated use of raw materials for the introduction of waste-free technologies in the production of biofuels. 4. Compatibility - is ensured by the joint operation of production systems on the basis of traditional energy carriers, biofuels analogues and their mixtures in different ratios. 5. Invariance - creation of universal or typical energy systems that provide a continuous process of increasing the share of biofuels consumption in the structure of national energy consumption. 6. Information unity - providing objective information on the economic, energy and socio-environmental characteristics of consumption of traditional and biological fuels.

Source: created by the authors

The direct implementation of these principles and system-wide properties in the fuel and energy complex of our country must be carried out at three main levels of management: macro-, meso- and micro-levels. At the macro level, it is necessary to ensure a system-wide change in national energy consumption, increasing the share of the use of renewable energy sources, in particular biofuels. On the mezzanine level, the consumption of biofuels is increased in the context of natural and economic regions, taking into account the regional structure of consumption of traditional energy sources (principles of behavioral economy). At the micro level there is a thorough analysis of the indices of local energy supply in each region and the possibilities of realizing economically feasible biofuel production potential.

Indirect stimulation of competitiveness in the field of biofuel production will be achieved on the basis of tax rebates on investments in the active part of fixed capital, reduction of the term of depreciation, introduction of tax incentives in financing scientific works of research institutes, insurance of risks and insurance of risks. An important role in the structural changes of the economy will be played by the introduction of the contract system, whose functions and methods in a market economy are gaining new meaning. Government institutions order the required products (services), at market prices. Instead, private capital may lease to the state factories, factories, equipment, research centers, etc.

One of the main directions of improvement of domestic biofuel production is a balanced process of its transfer to the path of intensification and innovation-investment development, ensuring optimization of acreage for the formation of raw materials base. By developing a sound and scientifically sound economic support system, the cost of producing biofuels can be reduced. The use of agricultural products for the production of biological energy will increase the consumption of

cheap renewable energy, thereby increasing national competitiveness.

Therefore, increasing the energy efficiency of the national economy requires that in the shortest possible time a set of priority measures will be implemented that will allow: to make the transition to competitive internal and external energy markets by forming an efficient internal infrastructure; to use transparent market rules of activity in the field of energy; increase the level of financial discipline and responsibility for ensuring timely calculations for the use of energy resources, as well as preventing barterization; introduce mechanisms of insurance of non-payment risks; ensure systematic control over pricing processes in the energy sector; introduce a system of mixed state and market regulation of the activity of the subjects of energy markets; apply systematic control over the activity of natural monopolies by the regulatory body; to increase the share of renewable energy sources in the national energy consumption structure, giving priority to biological fuels.

Conclusions

Thus, based on the conducted SWOT-analysis and the results of the research, a comprehensive mechanism for increasing the rate of industrial production of biofuels in Ukraine at a competitive level was formed, which contains the following priority regulatory measures: 1) technology transfer and innovation; 2) harmonization of the legal framework with the European Union; 3) implementation of energy saving and energy efficient technologies; 4) proper consulting and audit; 5) attracting highly qualified personnel; 6) cluster approaches; 7) ensuring the principles of nature protection; 8) development of foreign economic activity in the biofuel sector, etc. Adherence to the existing and developed strategic principles of the state regulatory policy will ensure intensive development and development of competitive biofuel production in Ukraine, create favorable conditions for attraction to the agro-industrial complex of external and internal investment revenues, introduction of the latest innovative technologies and modern economic activities production.

The strategy of state regulation of the development of competitive biofuel production in Ukraine envisages the process of complex application of the basic methods of regulation. The main economic will include: the cessation of subsidizing traditional energy sources; reduction of bank lending rates for producers and consumers of biofuels; exemption from taxation of part (at least 50%) of the profit received from the consumption of biofuels; introduction of innovations and attraction of investments). Legal methods will include: the adoption of an environmental tax on emissions of harmful substances from the consumption of traditional energy sources; creation of central and regional bodies of state executive power for production and consumption of biofuels; adopting a differentiated approach in increasing the addition of bioethanol and biodiesel to gasoline and diesel, giving priority to bioethanol. Administrative methods should ensure: the introduction of a state duty or limits on the export of bioenergy raw materials; development of European Union harmonized state standards and certification in the biofuels industry; licensing of consulting and auditing firms; adopting differentiated standards for production and consumption of biofuels in the context of regions and natural and economic areas of Ukraine.

The development of biofuel production is essential for the restructuring of the fuel and energy complex and the further integration of Ukraine into the EU. It is necessary to develop a set of measures for implementing economic policy in the field of bioenergy in order to achieve a radical revival in the implementation of innovations and to create effective incentives for spreading the innovative model of economic behavior of Ukrainian business. Increasing the rate of development of the bioenergy industry in our country makes it possible to comprehensively solve a number of energy, economic and environmental problems.

Abstract

This article provides the analysis of the actual state and level of agricultural lands use, presents the reasons of these lands degradation. It systemizes the factors creating obstacles for activating investments aimed to agricultural lands fertility restoring. Also, the article presents different capital investments of agricultural enterprises oriented to lands reclamation, such as drainage, irrigation, amelioration, creation of highly productive hayfields, pasturages etc. It is proposed to evaluate land resources of agricultural enterprises according to fair value that will contribute to better transparency and credibility of financial reporting. For this purpose it is necessary to elaborate the methodology of agricultural lands evaluation taking into account the indices of soils rating, crop yield in every region. It is justified that for increasing investments to restoring agricultural land potential fertility it is necessary to implement the corrective coefficients at the calculation of the land tax and the tax for group 4 of tax payers (former fixed agricultural tax). It is wise to calculate corrective coefficients on the base of agricultural soils grade rating in the beginning and in the end of reporting period that should be multiply on the normative monetary value of the region. The action of this index should be foreseen to the period of five years. It is defined that activation of investments to agricultural lands fertility preservation and improvement should be realized on the base of the state programme for land use and protection based on plots markets with the respect of the legislation and under the independent monitoring of agro-ecological characteristics, property rights, and economic activities. It is justified that the investments into agro-technical measures aimed to increasing fertility of agricultural lands should be based on the co-financing by agricultural enterprises, united territorial communities and the state budget.

Keywords*:* Agricultural Lands, Capital Investments, Restoring of Lands Fertility, Normative Monetary Evaluation of Land.

Introduction

In Ukraine 32, 5 million ha of lands are used for agricultural purposes, so almost 54% of the territory is tilled. It is one of the biggest indices in the worlds. There are more than 25 million of land users and owners. According to the FAO data, Ukraine is on the 9-th place in the world with its 32,5 million ha of agricultural surface behind India, Russian Federation, United States of America, China, Brasilia and Australia.

Being a production mean in the agriculture, the land has its specific peculiarities that differ it from other production means, namely, if other production means are results of a previous human work, the land is a gift of the nature, a product of its natural and historical development that lasted during many centuries. The land is reproduced by the work. It is a natural condition for human creative activity, it can't be substituted, and the productive process is impossible without it; it is limited in the space. But it doesn't mean that its capacities needed for agricultural production are exhausted; the use of the land as production mean is related to its constant location, in the same time other production means don't have this relation, land plots are not homogenous as for to their quality, that depends on the content of nutritive matters in the soil; they are not homogenous as for relief and other characteristics. It is an objective factor that should be taken into account by enterprises for planning their productive programmes; at a proper use the land is not exhausted, its quality doesn't degrade, but in difference with other production means created by work, it can be improved permanently. This peculiarity of the land is conditioned by such characteristic as its fertility that is the most important characteristic of the land and consists in its capacity to provide necessary nutritive matters to plants during their vegetation and development. In the conditions of market relations the land can be a commodity with a range of peculiarities that differs it from all other commodities.

Analysis of recent researches and publications

_The largest share in investments structure in the agriculture belongs to real investments, which are called placement of funds. It should be noted that placement of funds is an investment into fixed capital (fixed assets), including costs of new construction, expansion, reconstruction, technical re-equipment, updating of existing resource potential, purchase of machinery and equipment. Some researchers conflate placement of funds and real investments, but the latter are larger because they include investments into intangible assets and formation of inventories [1].

The main areas of funds placement in the agrarian sector are: construction of industrial and non-production facilities; purchase of equipment (agricultural machines, tractors), equipment and vehicles, planting of perennial plantations and their cultivation to the operational (fruitful) age; formation of main herd of productive and working animals; land improvement measures (without buildings).

By generalizing the approaches to the definition of investments, their versatility was established: investments as all kinds of property and intellectual values that are invested into objects of business and other activities [2]; investments as costs [3]; investments as incomes by J.M. Keynes [4, 5]; investments as a process, investment operations [6-8]; investments as long-term funds placement Y. Morozov [9]; investments as a use of savings [10].

The specificity of the agrarian sector economy influences the implementation of many economic and social phenomena and processes, including the investment activity of agricultural enterprises, among which it is advisable to distinguish the following: greater, than in other sectors duration of technological and financial cycles due to the objective properties of agriculture; close relationship of production processes in agriculture with natural processes; the high level of risks of investment in the agricultural sector is largely determined, in addition to the natural factor, by the instability of domestic agricultural markets; the strategic importance of the agriculture in the socio-economic development of rural areas and the country requires active government intervention in investment activities; the multiplier effect that arises not only in the economy but also in the social sphere as well

as in the environment; the specificity of the institutional environment is conditioned by the complexity of modern agriculture.

Under the investment activity of agricultural enterprises we understand the task oriented process of regulatory, organizational, economic and financial influence of an economic entity on the formation (not related to current consumption) and the transformation of resources from one form to another, which contributes to obtaining of additional profit, achievement of another economic, industrial or non-economic potential long-term effect, creation of conditions for extended reproduction.

The main resources of agricultural production essentially include: land resources (their surface and quality), climatic conditions, and availability of water resources. When characterizing the land resource as a production factor in the market conditions, it is necessary to take into account the fact that this resource becomes decisive in shaping the level of competitiveness of agricultural products. That is why it is necessary to study the issue of investing into the increasing of agricultural land fertility in today's economic conditions.

The land investment processes are studied in the works of Ukrainian scientists [11, 12], in particular, the scenarios of prolongation or withdrawal of the moratorium as an institutional prerequisite for ability or inability to use land assets as collateral for obtaining credit resources are analyzed, the issues of implementation of public-private partnership agreements for investments into the reproduction of agricultural lands are considered. However, in the context of the formation of the land market in the country, it seems necessary to form a systematic approach to the choice of priorities for attracting investments into the reproduction of agricultural lands.

Materials and methods

The purpose of the study is to summarize the peculiarities of the investment potential of lands belonging to agricultural enterprises and to justify the optimal ways of attracting investments into increasing the fertility of agricultural land in the conditions of transformation processes in land relations.

The study was based on the use of the following methods: balance method for the study of the nutrients balance dynamics of agricultural lands involved into production; statistical analysis for the study of the capital investments dynamics of agricultural enterprises and their share in the overall structure of agricultural enterprises' investment; calculation and constructive method for justifying sources of investment resources formation for restoration of agricultural lands fertility. The data of the State statistic service of Ukraine and the State Geocadastre of Ukraine, the results of researches of Ukrainian scientists and the author's own observations, obtained through the survey of agricultural producers were used as a database for this study.

Research Results

According to the results of scientists' researches, in terms of acidity, salinity, alkalinity, water logging, technogenic pollution, some of Ukrainian lands are in pre-crisis and sometimes in crisis condition with a tendency to deteriorate [13]. In addition to the above mentioned reasons, other degradation processes have spread to agricultural land.

It should be noted that the volumes mineral fertilizers application decreased from 148 kg / ha of active substance in 1986–1990 to 76–96 kg / ha in 2011–2015. Only 0.5 tons of manure are applied to 1 ha of arable land instead of 9.4 tons as it was in 1985, which led to the formation of a stable negative balance of humus, nitrogen, phosphorus and potassium in agro-ecosystems (Table 1).

Table 1: Dynamics of nutrients balance in the Ukrainian agriculture

Balance articles	Balance of nutrients, kg/ha of active substance			
	Nitrogen	Phosphorus	Potassium	Total (NPK)
1986–1990				
Intake	89,5	56,1	102,7	248,3
Removal	92,6	31,2	103,2	227,0
Balance	-3,1	24,9	-0,5	21,3
1996–2000				
Intake	26,0	10,4	15,3	51,7
Removal	56,5	18,2	53,7	128,4
Balance	-30,5	-7,8	-38,4	- 76,7
2001–2005				
Intake	21,8	5,9	8,7	36,4

Source: Done according to the data of the State Geocadastre of Ukraine.

Thus, today agricultural producers obtain high yields of agricultural crops mainly due to natural soil fertility, which can decline significantly in 5-10 years, since the average humus content in soils of Ukraine decreased from 3.64% in 1961 to 3.16% for today.

Obviously, the improvement of agricultural land can be carried out by both tenant farmer and by landlord, which must be conditioned by the lease contract. According to the Law of Ukraine "On Land Lease", if the tenant farmer is engaged in land improvement, he is reimbursed for the costs of such measures; if land improvement is done without the consent of the landlord, then such costs are not reimbursed to the tenant [14].

The capital investments of agricultural enterprises include works on a radical improvement of land (drainage, irrigation and other reclamation works, creation of high-yielding meadows, pastures, etc.). These may be capital expenditures of inventory nature: construction of water, anti-erosion, hydro-technical, anti-settlement and other structures (dams, canals, irrigation and drainage networks), cultural and technical measures for surface improvement of land for agricultural use of non-inventory nature (not connected with building) and terraced slopes. Technical works on agricultural lands that do not require drainage include: planning of land plots, clearing of land from forests, shrubs, stumps, boulders and stones, leveling of lands after cutting, cutting and cultivation of mounds, milling, plowing of virgin land and fallow lands that has not been carried out for more than 5 years, with tillage and rolling of these lands, cleaning of water reservoirs, etc. Reclamation works belong to building works (water management building). The following capital investments are allocated for irrigation of lands: creation of new irrigation systems, including for irrigation of hayfields and pastures, areas under rice and vegetables; for complex reconstruction of irrigation systems and restructuring of the collector-drainage network; land drainage (new drained lands, restoration and reconstruction of existing drained lands, including closed drainage; watering of pastures (new

pastures), reconstruction of water structures on existing pastures; construction of main agricultural water supply systems.

It is known that the Ministry of Agrarian Policy has foreseen the amount of 350 million UAH in the State Budget for 2018 under the budget program 2801170 "Financing of measures for protection, reproduction and increase of soil fertility". It is planned to use this amount for carrying out the following measures on the area of 500 thousand hectares: liming of acid soils - 350 thousand hectares; gypsum plastering of alkaline soils - 150 thousand hectares. It has been proved that neutralization of soil solution due to chemical reclamation, according to data of scientific institutions of the National academy of agrarian sciences of Ukraine, provides yield increase in terms of grains within 3–3,5 hundredweights / ha, or 1200–1400 UAH / ha. Thus, the Procedure of using the funds provided in the state budget for financing measures for protection, reproduction and increase of soil fertility in the amount of 350 million UAH from the state budget will be spent on liming - 245 million UAH, gypsuming of soils - 105 million UAH. It should be noted that for the first time in Ukraine the funds from the State budget have been allocated for the aforementioned agro-technical measures.

During the studied period, the area of liming of soils increased by 63.7%, gypsum in almost three times. However, the volumes of limestone flour and gypsum application remain minimal, which does not give reason to claim a positive effect from the implementation of the aforementioned agro-technical measures.

We believe that most land tenants (pais) have undertaken measures to increase the fertility of agricultural land, if there were long-term perspectives for their production activities. In current conditions, it is very difficult to finance independently such measures to increase the fertility of land, especially for small agricultural enterprises. It is established that during 2010-2018 years the volume of capital investments applied by enterprises of the agrarian corporate sector increased in 5.6 times and in 2018 this amount was 193090 thousand UAH. (Fig. 1). However, in the structure of capital investments of agricultural enterprises they make up less than 0.5%.

Fig. 1: Dynamics of the volumes of capital investments applied by enterprises of the agrarian corporate sector in increasing agricultural lands fertility (thousand UAH.) and their share in the total investments of agricultural enterprises

Source: Done according to the data of the State Statistics Service of Ukraine.

So, we can conclude that restoring the fertility of agricultural land is not a priority for investing economic entities in the field of agribusiness. According to the results of surveys of agricultural enterprises heads in Kyiv, Cherkasy, Kirovograd and Khmelnitsky regions (435 interviewed), the main factor of such situation is a high probability of agricultural lands owners or tenants change in

the conditions of introduction of the agricultural land market, this answer was received from 76% of respondents; 17% mentioned the probability of economic entity failure; the absence of incentive measures implemented by the State and the united territorial communities was indicated by 6%, and 1% of respondents indicated the absence of agricultural land quality monitoring systems.

It should be noted that land is the only component of agricultural capital that is not reported as an object of accounting and reporting. So, this situation makes it impossible to make appropriate calculations of the return on capital investments, as well as the accounting of capital investments aimed at increasing soil fertility, that have a direct impact on the change in the residual value of agricultural land as an asset of an economic entity. It is estimated that at the current level of market prices near $ 25 billion of such assets are not reflected. To be more precise, this figure is a $ 24.51 billion that presents a potential for growth of the national wealth of Ukraine [15].

If we consider the land capital in comparison with the main macroeconomic indicators, it is a fifth part of GDP and more than all gold value reserve of Ukraine, which at the beginning of 2019 was at the level of $ 20.8 billion. At the same time, unlike gold value reserves, that are more than a half formed by IMF loans, the land resources are Ukraine's own capital that ensures the country's income, its food security, and its competitiveness at external stocks and food markets.

It should be noted that at present time only about 3% of agricultural lands and rights to use them are evaluated and put on the balance of agricultural enterprises of all legal forms of economic activity, which is only $ 150 million. In order to identify the reasons of a low accounting discipline related to land and rights of their lease, we carried out a survey of farms accountants (109 people).

The following restraining factors of land value assessment were identified: problems of identification of land assets - 23% of respondents; lack of recommendations for self-assessment - 11%; high cost of the peer review procedure - 9%; lack of the state motivation and control - 26%; orientation to shadow business and unwillingness to evaluate these assets - 31%. So, today in Ukraine we can notice a low level of accounting of agricultural lands directly by producers (only $ 150 million in the financial statements) and in parallel its low reflection in the system of national accounts in the macroeconomic statistics.

The main problem in estimating the value of lands is the contradiction in the consideration of capital, national wealth in the International Financial Reporting Standards and in the system of property rights to them. This leads to the key problems of capitalization of Ukraine's land-based national wealth: accounting and evaluation procedures and a clear identification of property rights to assets; its concerns the rights to both physical and non-physical objects.

In 2018, an updated version of the Conceptual Framework for Financial Reporting has been published, according to which, since 2020, the International Financial Reporting Standards will treat assets as a set of rights and not only as physical objects. In addition, in 2019, International Financial Reporting Standard 16 "Lease" has come into force; it clearly recognizes that, at the date of the lease start, the tenant recognizes an asset for the right to use and a lease obligation (paragraph 22 of IFRS 16 "Lease"). In this regard, it is necessary to adapt the domestic accounting standards and the provisions of the Tax Code to the International Financial Reporting Standards.

It should be noted that according to the Law of Ukraine "On land evaluation" №1378-IV of 11.12.2003 (as amended), depending on the purpose and methods applied the assessment is divided into the following types: soil rating; economic evaluation of lands; monetary evaluation of land plots [16]. The economic evaluation is the basis of the regulatory monetary evaluation of agricultural lands, but its principles are outdated [17]. In the current context, such a method of assessment is expensive, since it must be carried out at the same time throughout the country and difficult, since there is no comprehensive data on the activities of agricultural enterprises.

We believe that it is advisable to develop a scientifically justified methodology for agricultural lands evaluation that should take into account soil rating indices, crop yields for each region. Yields will be

differentiated and translated into income for a specific type of farmland. The proposed approach will equalize the situation, and land with higher fertility rates will justly be more expensive.

The economic evaluation of agricultural lands is a natural extension of their qualitative assessment, and can be considered as a basis for conducting a comparative efficiency of agricultural lands use at an average level of economic intensity. It should be emphasized that the yield capacity is a complex productive, quantitative and qualitative indicator, its analysis will allow to generalize the impact of natural and climatic factors on the land use efficiency. Obviously, the land evaluation is becoming a necessary procedure today, since without information on its market value it is not possible to carry out properly operations related to land plots, in particular, to obtain a loan. AS for the land in Ukraine, the concept of "independent evaluation" is transformed into the concept of "expert monetary evaluation".

A new regulatory monetary evaluation (NME) for agricultural lands is currently being implemented in Ukraine. It should be noted that the information base for NMEs of such lands, including lands under farm buildings and yards, is information of the State Geocadastre (quantitative and qualitative characteristics of lands, soil rating, economic evaluation of lands), documents related to land management. However, this process is complicated since the last soils rating and the economic evaluation of lands were carried out in the 1980s. Therefore, without carrying out a new stage of soils survey, that will affect soils rating indices and, accordingly, the economic evaluation of lands, it is difficult to speak about the objectivity of NMEs, even in view of the new Methodology No. 831 “Methodology for regulatory monetary evaluation of agricultural lands”.

It is known that the regulatory monetary evaluation is intended to determine the amount of land tax and rent for lands of state and communal property (clause 289.1 of the Tax Code of Ukraine) [18]. However, the analysis of regulations shows that the use of the regulatory monetary evaluation is not the basis for the presentation of agricultural lands in the financial statements forms.

Today, a moratorium on the sale of agricultural lands is acting in Ukraine, so the market for such lands does not work, and therefore, the market prices for arable land are not formed. However, due to certain subjective circumstances, some individual farms of the corporate sector of the agrarian economy have to carry out the expert monetary evaluation of agricultural lands; to their opinion this evaluation is market-relevant. We believe there are several root causes for this: the need to reduce financial risks. The urgency of this issue in Ukraine is confirmed by the fact that during 2014-2016 years, nearly 600-700 thousand hectares of land changed their owners. Therefore, all these agreements will require a preliminary objective evaluation; the necessity of involving an appraiser in accounting re-evaluation of non-current assets and current biological assets (Article 7 of the Law of Ukraine “On evaluation of property, property rights and professional evaluation activity in Ukraine”) is provided by the law [19]; the requirement of commercial banks to provide an independent evaluation of property and property rights when drawing up a loan and a collateral agreement; equal distribution of capital structure in the process of merging are foreseen as well.

When assessing the market value of agricultural lands the following features should be taken into account: the need to maintain the fertility of the upper layer of agricultural land, it means soil, through the use of scientifically sound agricultural technology and respect of certain requirements to the methods of production (compliance with grazing standards, establishment of appropriate crop rotation systems, applying of an appropriate quantity of fertilizers, etc.), leaving of fallow lands, creating protective forest belts, etc.; a direct dependence of the structure of agricultural lands on physical and geographical characteristics of the area (geomorphological, soil, hydrological, climatic and other features); high risks of agricultural production due to natural factors and force majeure (droughts, floods, early winter frosts, snowstorms, epizootic diseases emergence, other natural disasters); a significant impact on the incomes from agricultural production of fluctuations in prices for agricultural products, fuel and lubricants, agricultural machinery; a seasonal nature of production and prices in the agricultural market; the lack of actual farmland turnover; the deficiency of significant investments in agricultural production; a low population density in areas distant from large industrial centers; a poorly developed infrastructure of the land resources market.

To assess land rights under the Ukrainian law, the comparative and profitable approaches are envisaged. So, the comparative approach (similar to sales) often can be used just to obtain information. Obtaining of an objective result is complicated due to the inaccessibility of market information, significant individual characteristics of plots and history of their use.

The method of comparing sales for analogue objects is practically undeveloped now, as the practice of its use is not yet available. However, the technology of applying this method to agricultural lands should not fundamentally differ from the technology of the market value assessment of other categories of land (land in cities, suburban areas) by the sales comparison method. Thus, when making adjustments, in addition to the elements of comparison, listed in the sales comparison method, such characteristics as soil type and its technological properties, soil credit score (differential land rent I), availability of reclamation facilities, structure of sowing areas, distance from sales markets, environmental status (differential land rent II) may be taken into account. Other factors, such as preferences of local people in production and consumption of certain types of agricultural products, etc. (surplus land rent) should be considered as well.

It should be noted that the domestic regulatory documents do not give the rules and requirements for the procedure of amendments introduction to the evaluation of agricultural lands in view of their specificity.

An income approach based on the capitalization of future cash flows from land use is the main one, which takes into account all the features of the agricultural area and real provisional future profits from its use.

The estimation of agricultural land by the methods of income approach can be carried out both on the basis of direct capitalization of rent payments for land, and with the help of capitalization of net operational income, which is formed as a result of agricultural production and is a land rent. We believe that the assessment of agricultural lands value and its reporting will provide: cost savings as it optimizes capital investments; increasing of the capitalization of agricultural enterprises, especially highly concentrated ones; formation of the information base, since it requires periodic professional evaluation and professional management of it; attracting of capital and investors. IPO's initial public offering as a fundraising tool is now somewhat obsolete, since private investors prefer to understand the real value of business, confirmed by independent consultants; increase in income, and in particular, by export of products. An independent evaluation uses market analysis and real-costs calculation to justify the objective level of agricultural prices and to optimize value-added tax (VAT). This tax is a significant part of the cash flow of agricultural enterprises in Ukraine because it remains at the disposal of the enterprise to finance capital investments under the legislation. During 2010-2018, the use of VAT as a source of investments for the development of agricultural enterprises is characterized by two stages: the first - 2010-2015: the taxation of volume of sales carried out by agricultural enterprises on the principle of "zero rate »; the second stage - 2016 - to date: the use of the mechanism of "quasi-accumulation" of VAT in relation to agricultural enterprises. It should be noted that during 2010-2015, the share of VAT in the structure of agricultural producers' revenue was from 8.1 to 13.4%. In year 2015, that was the last for the full functioning of the VAT-accumulation regime, the amount of VAT support increased to more than UAH 42 billion, which was aimed at enhancing the renewing of material and technical base of enterprises. However, in 2018 only UAH 4.2 billion were allocated for the development of the agrarian sector economy through the use of the mechanism of "quasi-accumulation" of VAT in the form of the direct state support, mainly for the development of the poultry industry.

Therefore, an independent evaluation can be used as a justification of costs volume for fiscal authorities, the size of VAT base as a whole; and for the optimization of top management remuneration. It is obvious that the increasing market capitalization (value) of a business is one of the key indicators of business efficiency, and serves the basis for cash remuneration of enterprise management; for the optimization of insurance payments, whose amount is calculated depending on the market value of agricultural assets; for the formation of reliable financial statements according to the International Financial Reporting Standards when attracting foreign investments. An international audit of such reporting requires a prior evaluation of main production means and other assets

(including biological current assets and agricultural lands) by an independent evaluator; and optimization of the amount of collateral whose market value requires an independent evaluation in all Ukrainian banks. To enter the foreign capital market, agricultural enterprises should prepare financial statements that will be understood by potential foreign investors. A fair presentation and disclosure of assets, liabilities and equity in financial statements done according to the International Financial Reporting Standards will enable interested users to form an informed view of the entity's performance during a particular reporting period and the effectiveness of its management's decisions.

We believe that it should be reasonable to carry out the evaluation of agricultural organization's land resources at fair value, as an amount of money sufficient to purchase an asset or to fulfill obligation of an agreement between informed, really interested, independent each from other parties. The evaluation of assets and liabilities at fair value will increase the transparency of financial statements and the reliability of information provided in them about the financial and economic activities of economic entity.

The use of the market value of land plot for preparing the information on the value of land resources of agricultural enterprises will allow increasing the reliability of financial statements. In addition, in the analysis of financial and economic activity of agricultural enterprises, a real evaluation of land resources will have a positive impact on the regulatory indicators of liquidity and financial sustainability, which is especially important in the conditions of financial crisis and growing need for investment.

An important way for formation of preconditions for intensification of investments in reproduction of potential fertility of agricultural lands requires the use of correction coefficients in the calculation of land tax and tax paid by the 4th group of tax payers (the former fixed agricultural tax). Obviously, the current mechanism for calculating the above taxes does not encourage the application of efforts for the improvement of the potential fertility of agricultural land. Conversely, managers of big agricultural enterprises have an economic interest in reducing fertility, as it will lead to a reduction of tax paid to united territorial community (UTC) budget and the value of rent to potential landlords.

We believe that for this purpose it is necessary to develop the system of coefficients correction in calculating the value of agricultural lands, which will be effective in determining the value of 1 hectare of agricultural lands that is the basis for calculating the tax of group 4. For their calculation it is necessary to carry out (once every 5 years) the agrochemical certification of the lands as a component of the agricultural census. It is advisable to base the calculation of the adjustment coefficient on the value of agricultural lands in the beginning and in the end of reporting period, and by multiplying it on the amount of the regulatory monetary assessment existing in the region, the value of the land, that will serve a basis for calculating land tax and leasing fees will be determined. It is advisable to anticipate the validity of this indicator for a five-year period.

At the same time, an unpaid amount of the land tax that had to be paid to united territorial communities' budget and the amount of leasing fees due to the use of the reduction coefficient, which is an evidence of improvement of soil quality (increased rating), should partially, indirectly compensate the cost spent for fertility reproduction of agricultural soils that are temporarily used by business entities. On the contrary, when the increasing coefficient is applied the value of money incomes to budget of the united territorial community increases.

The Budget Code of Ukraine provides for the distribution of funds from the environmental tax in the following ratio: 20% to the state budget and 80% to budgets of the local level, in particular 25% to the rural and city budgets and 55% - to regional budgets.

We believe that the creation of a special Fund for the economic encouraging of agricultural lands fertility increase is an important source of financing the restoration of farmland in addition to the environmental tax, rent payments for the use of natural resources. The sources of its pumping up can be penalties for violations of environmental legislation, as well as additional penalties for non-respect

of soil quality standards that should be developed by the institutions of the State Enterprise "Ukrderzhrodyushchy".

One of the positive changes at the legislative level that will contribute to the increase of soil fertility is the adoption by the Cabinet of Ministers of Ukraine of the Draft Resolution on Amendments to the Model of Land Lease Agreement [20]. This regulatory act provide a new mechanism of management of land use and protection, preservation and reproduction of soil fertility, namely: fixing in the lease agreement the indicators of quality characteristics of the soil in the moment of its transfer to the lease, compensation to landlord-owner of the losses in case of deterioration of soil quality in rented land plot or rendering it in an unusable condition for target purpose; setting the term of payment of the rent for the use of the land plot and strengthening of responsibility in case of its late payment (fine, penalty). However, this regulation does not specify the mechanism for reimbursement of the costs of agrochemical research. To our opinion, their value should be compensated evenly at the expense of the tenant and the lessor.

An important way to increase soil fertility is to fight against its acidity and salinization. The cost of implementing measures to protect, to reproduce and to increase the fertility of soils per hectare (according to the State Institute of Soil Conservation) is on average more than 1500 UAH / ha. Taking into account financial capacity of agricultural enterprises in carrying out these measures and their importance for restoring the fertility of lands, the amount for compensation of their costs is provided by the State Budget of Ukraine. The procedure for the use of funds is envisaged within 40-50%, namely: the foreseen amount for liming of soils is 700 UAH / ha; for gypsum is 700 UAH / ha. This ratio of the size and cost of these activities is optimal, because the main component of the cost of chemical reclamation is the cost of reclamation assests (within 200 UAH / t) and their transportation that is up to 75%, which requires large sums of money before the works.

To our opinion, agro-technical measures in Ukraine should be co-financed by agricultural enterprises, united territorial communities and the State budget under the State program "Financing measures for the protection, reproduction and increase of soil fertility" on a parity basis. Their implementation is mandatory. The quality control of the aforementioned agro-technical measures is entrusted to the environmental inspection.

An important factor that, although indirectly, but contributes to increasing the fertility of agricultural land, is the dissemination of knowledge about current resource-saving technologies. The necessity of training is due to the fact that agricultural professionals feel the need of scientific and advisory services, especially for farmers in order to learn how to restore the fertility of farmland.

Conclusions

It has been proved that activation of investment processes aimed to the reproduction of agricultural land fertility cannot be ensured independently by agricultural enterprise itself. This is due to the fact that farmers, due to their poor financial and economic condition, are not able to direct funds to soil protection measures. Unless immediate actions are taken, soil degradation processes can become irreversible. In view of this, a system of economic incentives to increase the fertility of farmland leased by business entities should be implemented at the State level, primarily through administrative levers and a valid tax system. Since the reproduction of farmland is nationwide, targeted programs should also be fully funded.

At the level of united territorial communities, it is advisable to develop appropriate programs for soil fertility reproduction and conservation. With the combined efforts of the State, united territorial communities, agricultural enterprises the process of reproduction and conservation of soil fertility can be ensured. After all, irresponsible intensive use of the land fund without effective measures to restore it as a productive resource and a renewable ecosystem of the environment has not yet been eradicated. That is why an effective mechanism that foresees the interest of producers in preserving the fertility of Ukrainian soils will ensure a positive result.

Thus, the formation of effective legal regulation of land relations and the implementation of effective tools to stimulate producers to expand the reproduction of land resources fertility will help to prevent soils erosion; to accumulate organic substances; to control the balance of humus and nutrients in the soil; to provide the implementation of directives on water protection, nitrate content in agricultural products and food, use of fertilizers, plant protection, etc.

Abstract

As discovered the tendency to increasing of biofuel production in 2007–2017 was more than doubled due to organizational support for the development of the bioenergy industry in Ukraine, introduction of new technologies and innovative approaches, and application of foreign experience. The prevailing use of gas or oil causes the energy dependence of the economy on the external energy market, which is affected by geopolitical changes. It is proved that the level of self-sufficiency of the Ukrainian economy with fuel and energy resources can be increased due to the use of biofuel, which is produced from biomass. It has been proved that the competitiveness of the biofuel supply chain is achieved by increasing the efficiency of actors functioning at each level, entering of new actors to the market, expanding the internal market and its individual segments. The development of small forms of agrarian business in the bioenergy sector is leading to the growth of the economy and in particular of the agricultural sector, creation of new jobs and expansion of the tax base. The value chains have been constructed and the pricing factors at the bioenergy market have been clarified. A methodological approach is proposed to determine the economic feasibility of directing agricultural products to different areas of industrial use, including their processing for biofuel. It has been found that in the process of forming the technological chain of production, marketing and final consumption of solid biofuels, the confirmation of quality (compliance with standards and certification of pellets), as well as the increase in added value by the manufacturer, play a crucial role. The viability of bioenergy resources production through the cumulative added value formed in the respective technological chains has been determined.

Keywords*:* Supply Chain, Biomass, Biofuel, Added Value, Producers-Assemblers.

Introduction

The Ukraine has sufficient economic and organizational conditions for the development of bioenergy, which are characterized by favorable natural and climatic factors, a strong potential of the agrarian sector, the excess of man power and other factors. At the same time, despite a high resource potential of biomass energy, today there is a high internal demand of energy, which is mainly satisfied by traditional fuels and significant import of energy resources. Thus, fossil resources: natural gas, coal and petroleum products are the most demanded in Ukraine today, they represent over 70% of domestic energy consumption. Biofuels make up only a tiny fraction of the country's overall energy balance.

The restraining factors for the development of the Ukrainian bio-energy market are explained by a number of circumstances, which are conditioned, first of all, to economic and geopolitical processes. Achieving the level of European countries in the production of biofuels requires the mobilization of actors working for the development of biofuel supply chain, increasing their efficiency and increasing the state support, intensifying the processes of attracting domestic and foreign investments in this industry. That is why, under the current conditions, researches devoted to the specificity of biofuel supply chains in Ukraine are important. They identified unresolved issues and allowed to substantiate the ways of their development in terms of added value creation, creation of new employments and solving the problem of import dependence on energy resources. In this research we pay a special attention to the production of biofuels, which will allow the state adapting flexibly to the influence of external factors on energy supply, that are conditioned by the technological development, changes in environmental and energy policy of the leading countries, and the implementation of sustainable development principles and competitiveness of operators in the agricultural sector.

Supply Chain Literature

The concept of "supply chain" is widespread in the scientific literature, and is most often considered through a set of participants (business operators), who bring products (services) to the consumer, logistics warehouses, wholesalers, retailers, other intermediaries and buyers. Therefore, the supply chain consists of all operators who directly or indirectly participate in meeting requirements and needs of potential and actual consumers of the goods [1, p.3]. In addition, some scientific sources point out that the supply chain is a set of three or more organizations that are directly linked to each other and move up and down the flow of goods, services, finances and information from sources of acquisition to end consumer [2].

We find in scientific literature three traditional stages of the supply chain in any production and sell process: procurement, production and distribution [3]. The supply chain can have different complexity level, it depends on participants number and diversity of business processes but in the chain we always see a central organization that manages the entire supply chain or influences its sustainability.

Some researches apply a wider approach, so they believe that the supply chain includes physical, informational, financial flows, as well as management knowledge and experience, aimed at meeting needs of end consumers of goods and services [4]. Thus, according to this definition, the supply chain encompasses processes that include a wide range of activities, including business processes for supply, production, transportation and sale of goods and services. In addition, they highlight an element of the supply chain, such as after-sales support. The integrated supply chain model can contain three interconnected flows: material flows (which include - purchase, transformation and distribution), information flows (electronic data exchange or formed links) and financial flows that include payment for delivered products and services to subcontractors, suppliers of goods and services, as well as payment by the consumer for purchased product to trade organizations [5]. It is obvious that physical distribution is an important part of supply chain, and information and financial components are just as important as physical flow. Nowadays, areas of activity related to increasing the level of consumer satisfaction, recycling of wastes and environmental protection are especially important in the concept of the supply chain. It should be noted that reverse logistics refers to programs or competencies aimed at moving products backwards in the supply chain (e.g. from consumer to manufacturer), and appropriate measures may include product return, recycling, waste disposal, recovery [6].

It should be noted that the supply chain according to the object approach is a set of organizations – manufacturing enterprises, logistics operators, processing enterprises, wholesale and retail organizations, which interact in material, financial and information flows, as well as in service flows from sources of raw materials to final consumer. At the same time, in the process approach, the supply chain is a set of flows and corresponding co-operative and coordination processes between different participants in the value chain to meet requirements of consumers in goods and services [7, 8].

Based on the above mentioned notion, we consider "supply chain" as a set of all activities and processes related to the flow of goods and information from the stage of production of raw materials to the final consumer of the product (service), and its purposeful development is carried out on the basis of organization, planning, control and regulation of commodity flow, in order to create added value and to meet in the best way needs of consumers. As for the value chain, it is first and foremost a combination of supply chains and demand chains, which is aimed to the transformation of raw materials as input through various value-adding processes and to selling of finished goods to consumers with maximum value at the lowest total cost.

The relevance of the study on the functioning of the supply chain of biofuels is confirmed by data from the World Bioenergy Association (WBA) that in 2017 the volume of energy supply from biomass was 55.6 EJ. Energy supplies have declined, however, accounting for up to 70% of total renewable energy [9]. The orientation of most countries in the world towards biofuel production is driven by the desire to implement sustainable development principles in agriculture [10]. It is believed that the production and use of bioenergy and biofuels may have a less negative impact on the environment than oil counterparts[11]. As a result, the world's leading countries have developed appropriate legislation and strategic programs to expand the biofuels industry. For example, in the US, the Energy Independence and Security Act, passed in 2007, to bring the country's annual biofuel production to 36 billion gallons by 2022[12]. Under these conditions, researchers emphasize the development of measures to avoid adverse effects on the food supply of the population, this law stipulates that 16 of the 36 billion gallons of biofuels must be produced from non-starch raw materials in 2022 [13,14]. For Ukraine, there is also debate about balancing food supply and biomass energy production, but today there is no rational use of crop residues and organic waste in the country. It should be noted that only 6% of total grain production is used for ethanol production [15] and for Ukraine this figure does not even reach 1%. In addition, the creation of a modern biofuel production facility in the country requires considerable investment, which cannot be considered as a rapid process, but studying the issues of functioning of the supply chains of biofuels and the directions of their expansion is extremely relevant for domestic practice. This is confirmed by the fact that biofuel production capacity worldwide is less than 1 billion gallons, but the industry will grow, requiring development of sustainable biomass and bioenergy supply chains, reducing production costs, reducing the environmental footprint and reducing the environmental footprint. obtaining social benefits [16,17,18].

It should be noted that until the last decade in Ukraine there were no systematic, coordinated scientific researches on the development of the bioenergy market, and only on February 28, 2007 the Targeted comprehensive program of scientific researches "Biomass as a fuel raw material" was approved, but the study of bioenergy production processes is widespread. , the raw material base of processing technologies, etc., and the features of functioning of the bioenergy supply chains remain unaddressed.

It should be noted that until the last decade in Ukraine there were no systematic, coordinated scientific researches on the development of the bioenergy market, and only on February 28, 2007 the Targeted comprehensive program of scientific researches "Biomass as a fuel raw material" was approved, but the study of bioenergy production processes is widespread. , the raw material base of processing technologies, etc., and the features of functioning of the bioenergy supply chains remain unaddressed.

Research Methodology

The purpose of the research is an assessment of the country's energy supply and determination of the share of biofuels production, typing of biofuel supply chains in Ukraine by key classification features and justification of proposals for enhancing their sustainability and competitiveness on the basis of increasing added value and creating new employments in the country.

The study was carried out on the basis of the fundamental provisions of the chain approach concept, developed by M. Porter [19], Gereffi, G [20], Morris, M. and R. Kaplinsky, [21,22]. The methodological approach of the study was based on the works of the above-mentioned scientists, as well as on analytical studies of national scientists, on the summarized opinions of experts and practitioners in the field of biofuel production. Scientific publications of leading world and national scientists in the field of formation and functioning of supply chains, data of statistical authorities related to production, processing, sale and consumption of biofuel in Ukraine were used for the study. Additional information on value chain initiatives in the production and sale of biofuels at the location of individual actors not registered by the State Committee of Statistics of Ukraine was obtained through a survey of chain participants, technical assistance projects, associations and international donor organizations acting in Ukraine. These collected data were used for the empirical studies devoted to peculiarities of supply chains functioning in the production of biofuels.

The study takes into account the integrated approach to the functioning of the biofuel supply chain, which takes into account the economic and organizational factors of stimulating the use of biomass for energy production at the macro and micro levels, in particular in the context of the economic and political interests of the country, eliminating contradictions in choosing the direction of biomass use , harmonization of economic interests in the technological chain between producers of bio raw materials and energy resources, taking into account the variability of use ystannya biomass-based size accumulative value added per unit of basic production resource. Methods of substantiating the economic feasibility of different corn supply chains for grain, which include the production of bio-raw materials, processing of biofuels, production of biogas from silage of corn, use as feed in the production of milk and pig meat, supply to the foreign market and sale on the domestic market provides for the calculation of cumulative value added, which will allow at the micro level to carry out economic activities more effectively, and at the macro level - to activate the functioning of nationals On the market of biogas and biofuels.

Research Results

The general tendency to decreasing capacity of the fuel and energy market in Ukraine as a whole and in almost all types of bioenergy resources, as for production, so for import was discovered. The exception is biofuels, where production and consumption volumes increased in 2.4 and 1.7 times respectively during 2007–2017, as a result of stepping up of its use (Table 1).

Table1: Dynamic of energy balance indices of Ukraine in thousand tonne of oil equivalent, (toe)

Energy resources	Production	Import	Export	Final consumption
2007				
Total of energy resources	84998	64975	7901	85955
Including bioenergy resources	59850	59709	2538	48007
where:				
- Coal and peat	38018	8899	2492	11772
- Raw petrol	4478	10361	4	21
- Petrol products		4976	4282	13761
- Natural gaz	15865	40449	3	35069
- Biofuel	1489		39	1145

2017				
Total of energy resources	58851	35261	1944	50086
Including bioenergy resources	34935	35257	1494	32155

Total of bioenergy resources	58,4	59,0	58,9	67,0
Biofuel	2,4	×	13,9	1,7

Source: done by authors according to the data of the State service of Ukraine

The data provided in Table 1 indicate a tendency to increase the volume of biofuel production and waste, since in 2007 this indicator amounted to 1489 thousand tons, toe, and in 2017 - 3618 thousand tons, toe. This indicates that in Ukraine there is a growing dynamics of the bioenergy industry development, which is achieved due to technological development of biofuel production processes, introduction of innovative approaches and use of foreign experience. However, the capacity of the biofuels market remains low, which proves the lack of efficient instruments for state support of the biofuels industry.

The positive fact is that the production of wind and solar energy also tends to increase, so in 2017 the figure was 149 thousand tons, toe, and in 2007 it was only 4 thousand tons, toe. High green tariffs, availability of land and sufficient insulation in almost all regions of Ukraine, availability of infrastructure to connect SES to energy systems, and the most important, the support from the state and the business community are the main factors in the development of production of this energy.

It is also discovered that for the period from 2007 to 2017 the indicators of biofuels and waste also increased: the indices of primary energy supply in the form of biofuels and waste increased in 2017 to 3046 thousand tons, toe, in comparison of 1522 thousand tons, toe in 2011 and 1508 thousand tons in 2007.

As in any other market, the bioenergy market has a value chain - the allocation of market participants according to the stages of added value creation from primary raw materials to final consumers. The study found that a complete value chain has been formed in the bioenergy market, since all the links in the value chain are represented; in addition, different business models are presented in the market - from one unit to full vertical integration (from own raw materials to heat production for final consumers). It should be noted that in the formation of the supply chain of biofuel in the country, the model "manufacturer-dealer" is dominating.

The results of the analysis show that the majority of market participants (quantitatively) are engaged in the production of chips, pellets and briquettes, and deliver finished products directly to final consumers. At the same time, the study did not identify powerful biofuels traders in the domestic market that could dominate and act as powerful operators in the formation of the product offer.

It is defined that the majority of biofuel producers are moving up the value chain (trying to control access to raw materials, upstream), it can be supposed that additional resources are needed to move down the chain (to heat production). This proves the willingness of private capital to participate actively in the procurement and growing of raw materials.

The bioenergy market in Ukraine is young and under development; there are only a few powerful players in the market that specialize in one particular part of value chain. So there are few players in the market that are really focused on a particular value chain; most of them are working on multiple parts, or are actively expanding to other parts, some parts can be relatively recently created to define the strategy clearly. We believe that the lack of specialized players is a limiting factor for the future development of the biofuels industry, as companies specialized in certain segments play the role of drivers for the development of other relevant units, actively shape supply and stimulate consumer demand.

It has been defined that the supply chain of biofuels has a limited number and there are no procurement units for some types. Due to the opacity of the market, there is a limited number of companies in the domestic market that present themselves as feedstock for biofuel production.

The limiting factor in the effective functioning of the biofuel supply chain is the fact that today the chain part consisting of biomass heat producers is not shaped (small number of quantified players). Another limiting factor is the lack of clear rules of the game in this market segment and its expansion can be transformed into a market development strategy. The lack of market shape causes significant volumes of biofuel exports, which does not allow addressing fully the issue of value added generation from the functioning of the chain and the creation of additional jobs.

We will carry out the financial and economic calculations of added value in the formation of biofuel supply chain based on the use of maize grain as a raw material. It should be noted that this crop is a strategic food and feed crop and can also be used as a raw material in biofuel production. We have developed a methodological approach, calculating the economic feasibility of using a certain type of product for different purposes of production, but when using agricultural products for biofuel production it is necessary to take into account the levels of food security for certain types of products. We believe that the assessment of the economic potential of energetic crops wastes should be based on the calculation of the optimal amount of wastes for biofuels by individual types and should foresee the implementation of the restrictive criteria for the size of minimum sown areas and livestock for the effective provision of existing bio-raw material processing facilities.

In order to determine the added value in the production and sale of gain corn, we used the indicator of the actual area harvested in the farms of the corporate sector of the agrarian economy for 2018, which is reflected in the appropriate statistical form. In determining the volume of sales of grain corn in the domestic market and the level of purchase prices, as well as prices for milk, pigs (live weight), we used the data of the State Statistics Service of Ukraine, which are obtained on the basis of the state statistical observation according to the form №21-general (monthly) "Report on sales of agricultural products". We have used also the information on the volume of corn exports and the level of export prices based on data from the State Fiscal Service.

In determining the volume of milk production, it was we have supposed that agricultural enterprises grow the silage corn at a standard yield 500 centners / ha instead of grain corn. When doing calculations related to milk production and pig production, we used data from the State Statistics Service related to the level of feeds consumption per 1 quintal of milk and of pig growth, which are reflected in the form № 24 (annual) "Livestock Status".
The value of expenses (in the context of relevant articles) for the production of grain corn, silage corn, milk, and pig meat in live weight was formed on the basis of the Ukrainian State Statistics Service data, based on the form № 50-agriculture "Main economic indicators of agricultural enterprises for 2018 ", and partly on the results of the State statistical observation according the form № 2-farms “Main indicators of economic activity of farms and small agricultural enterprises for 2018".

The rate of manure yield per capita of pigs and cows, as well as the ratio of corn grain weight to by-products, the yield of pellets per weight unit of corn stalks was based on the normative values, which are reflected in the relevant reference literature. For the calculations related to the added value rate formation when processing silage into biogas we used the results of the study done by a leading expert in this field G. Geletukha [23]. The calculations related to the added value formation according to different options of gain corn supply chain formation are presented in Table 2.

Table 2: Calculation of added value at production and sale of grain corn in 2018, thousand UAH / ha of harvested area

Supply chain	Income amount	Expenses without consideration of salaries, depreciation, rental costs	Added value
Sales of maize at the domestic market and use of crop residues as organic fertilizer	28,7	12,2	16,5
Production of biogas from corn silage	76,8	40,0	36,8
Export of corn and production of pellets from stems	40,4	19,2	21,2
Production of corn for silage and use as feed in milk production	73,7	44,9	28,8
Production of corn for grain and use as feed in pig production	57,7	33,3	24,4
Production of corn for the domestic market and production of pellets from stems	39,9	20,4	19,5

Source: *Calculated by the authors*

The calculations provided in Table 2 show that the highest value added per 1 ha of sowing is obtained by growing corn on silage and using it as raw material in biogas production. The experts estimate that from one ton of corn silage from 200 to 400 m^3 of biogas can be obtained, and the yield of biogas from one ton of dry matter of corn stalks will be 420 m^3. The presence of maize repair forms allows the effective use of leaf stem for biogas, obtained by their processing (fermentation). It is known that this type of biofuel with a high efficiency can be transformed into other types of energy, in particular, when used as fuel for gas generators, the efficiency reaches up to 83%. As a result of biogas production in special bioreactors, so-called methane tanks, high quality organic fertilizers (biohumus) are obtained [24].

It is known that growing corn for biofuel production requires mineral fertilizers and plant protection products, so such growing technologies are particularly energy intensive and require cost optimization. Obviously, scientific selection of corn hybrids for the use of grains for biofuels, in order to adapt to the conditions of a particular region of the country, will reduce the cost of both starch and biofuels.

At the same time, the economic attractiveness of the use of corn for energy purposes threatens to reduce food and feed. That is why the EU adopted the Law on Renewable Energy Sources (EEG 2012) establishing the maximum share of corn mass in nutrient substrate for biogas plants 60%. Therefore, today, EU countries consider sugar beets as an alternative to corn [25]. We believe that the most efficient way to stimulate the construction of biogas complexes in agriculture in the country should be the introduction of graduation for a certain capacities and of "green" tariff for small bioenergy producers.

For example, in Germany in 2019, with a near-total abandonment of solid green tariffs, a guaranteed tariff of 0.214 Euros / kWh for 20 years applies to biogas stations with a capacity of less than 75 kW operating on animal husbandry wastes (but not less than 80%). For the larger producers, a long-term (10 years) low-interest lending is guaranteed, with subsidies for the ability to operate at the request of previously installed capacity.

In view of an important role of corn grain in feed base it is advisable to consider the economic feasibility of its alternative use in the production of pig and dairy cattle. It should be noted that since 1993 the number of cows in agricultural enterprises has stabilized and as of January 1, 2019 there were 467.9 thousand heads that is more in 1.3 thousand heads (0.3%) than the previous year. The lifestock of pigs in 01.01.2019 on pig farms was 3395.6 thousand heads, which is in 92 thousand heads (2.8%) more than in the corresponding period of the previous year. Therefore, it can be concluded that dairy farming and pig breeding at agricultural enterprises are in crisis situation.

It should be noted that the use of grain corn as a feed is also facilitated by the acceptable price ratio between milk, pig production and feeds where grain corn presents an important share. Thus, in 2018 the price ratio between milk and corn was 1: 1.6, estimated value providing extended reproduction was 1: 1.1, the price ration between pig production and grain corn was 1: 12.9, estimated value 1: 8. Thus, this ratio of corn, milk, and pig production prices indicates that there are prerequisites for the economic viability of using corn for milk and pig production in the condition of efficient state support. For this purpose, it is advisable to introduce the following instruments: to restore the special VAT tax regime for dairy farmers and pig producers; to develop and adopt the Law of Ukraine "On the National Program of Breeding in Livestock by 2030"; to provide targeted state support for cattle and pig breeders; to carry out the identification of farm animals; to improve the mechanism of interest rate compensation support by dividing them at the national and regional level by credits involved in the construction and reconstruction of livestock premises and the processing of livestock products; to improve the contractual base of integration relations in terms of partnership activities in the chain "production-processing-wholesale-sales"; to create preconditions for motivation of processors to establish long-term raw material zones by providing producers with preferential credits, leasing possibilities, including leasing of milk production equipment; assistance in land leasing under long-term lease and arrangement of tax holidays for the implementation of investment projects in cattle and pig production; to consider the possibility of support to livestock production through the establishment of government subsidies for the use of equivalent prices for livestock products, which would ensure an equal return on equal investment in productive capital.

It is established that one of the problems limiting the development of the biogas, solid and liquid biofuels market at the micro level is insufficient supply of biological raw materials for the production of heat and electricity. Such capacities are used mainly by agricultural and processing enterprises that have their own raw material base and by this way they solve the problem of utilization of by-products, in particular manure of farm animals, solid fuel wastes (sunflower husk).

Obviously, if a producer disposes of solid fuel waste, it incurs additional costs in form of environmental payments (the purchase of permits), their cost depends on the volume of such waste, and in form of payments for their loading and unloading at landfills.

Therefore, the following business models can be distinguished in the market:

1. Manufacturers-buyers. Companies providing services to owners of raw materials (mainly forestry) in harvesting timber or exporting primary logging waste. They are producers of biofuels, they have their own facilities for processing raw materials, production and storage of biofuels, but this model requires significant capitalization (equipment), scale (coverage of forestry) and transparency (the right to collect and to buy raw materials).
2. Full cycle energy service companies. Companies supplying heat to final consumers, mainly to territorial communities. These companies are producers of biofuels and have their own raw materials (such as planting energy plants). The model is based on vertical integration, which encompasses all added value along the entire value chain. An important issue in this model is the development of long-term partnerships with final consumers, capital investments in growing of raw materials and creation of transparent conditions for heat supply.
3. Biomass trade companies that cooperate with different biofuel producers (different types, different volumes, etc.); enter into long-term contracts for the supply of biofuels to heat producers or final consumers. The economic interest of this model is based on the difference between the time of purchase (production season) and the time of sale (heating season) and scale (wholesale and retail

sales). The strategic development of this model requires considerable working capital and establishing relationships (with producers and consumers of biofuels).

The limited price competitiveness and funding for relevant technologies and projects remain major challenges to increasing biofuels consumption. [26] We share the view of some researchers that existing subsidies to traditional energy sources and other distortions of market mechanisms make it difficult to address these challenges. A number of measures and incentives have been developed in Ukraine to expand the production and use of biofuels, but most of them are under implementation. In this situation, more efficient public policy and efficient legislation are needed to promote consumers' interest in using biofuels and to achieve their full environmental, economic and social benefits [27].

Thus, the Law of Ukraine "On Amendments to Certain Legislative Acts of Ukraine on Promoting the Production and Use of Biological Fuels", which stimulates the production of motor gasoline with bioethanol additives (reformulated gasoline), formally acted in 2007, excise tax on such fuels was reduced from 60 to 30 Euros / ton. Zero excise duty on fuel bioethanol produced in the country was set as well. However, because of a number of objective and subjective reasons, the preferences for biofuels suppliers have not been fully implemented.

In 2010, at the meeting of the EU Council of Ministers of energy, Ukraine was unanimously admitted to the EU's Energy Community, accordingly, the country committed itself to the implementation of European fuel rules and standards, including the use of biofuels. Accordingly, in 2012, the Ukrainian Parliament adopted the Law of Ukraine "On Amendments to Certain Laws of Ukraine on the Production and Use of Motor Fuels with the Content of Biocomponents". According to this Law, since January 1, 2014, a mandatory rate of bioethanol content of at least 5% in fuel produced and sold in the territory of Ukraine was introduced. And since 2016, the alcohol content should be at least 7%. However, in 2015 the Ukrainian Parliament abolished the aforementioned Law.

In 2013-2014, bioethanol production was practically ceased due to the introduction of excise duty on alternative motor fuels at the level of 99 EUR / ton by adopting the Law of Ukraine “On Amendments to the Tax Code of Ukraine (on taxation of alternative motor fuels and reducing the cost of fuel)”. According to leading scientists, for the dynamic development of bioethanol production it is necessary to abolish the requirements for licensing of bioethanol, the bill for its transportation, the excise duty on biodiesel, and to define the concept of bioethanol as a separate complex chemical product, and not as a subspecies of ethyl alcohol [28]. Due to political and economic instability, the country has stopped the development of production and use of alternative energy sources.

We believe that one of the factors that influenced the cessation of biofuel production and, consequently, the decline in rape production, that is the main energy crop, is the rise in world food prices. The IMF estimates that the increase in food prices by from 15 to 30% is the result of growing cereals for biofuel production. On the other hand, the ethanol production as a major substitute of automotive fuel, is able to curb rising of oil prices and to help to reduce inflation in major oil importing countries. Bank of America Merrill Lynch estimates that the cessation of biofuels production will lead to increase in oil and gasoline prices by 15% [29].

The "green" tariffs for electricity produced at enterprises from alternative energy sources (except blast furnace and coke oven gas, and using only hydroenergy produced by mini and small hydropower stations) have been and remain main incitement for the production of electricity from solid biofuels in Ukraine.

The coefficients of the “green” tariff for each type of electricity according to the date of commissioning of electricity objects into operation are set by the relevant Laws of Ukraine. On June 4, 2015, a new version of the Law on Green Tariffs № 2010-d was adopted, establishing the following:

for electricity from biomass and for biogas, the green tariff is determined taking into account the coefficients foreseen for facilities put into operation on 31.12.2014, namely is increased by 10% compared to the current one, which is 12.39 euro cents / kW hours;

at the green tariff, electricity is purchased in full, except the amount consumed for own needs of electricity entity producing electricity from alternative sources;

the "green" tariff is revised according to the euro exchange rate on a quarterly basis (once a quarter at the NBU average rate for 30 days preceding the last quarterly meeting of the National Commission for State Regulation of Energy and Utilities);

dependence on euro is valid until 2030, but does not concern objects put into service after 01.01.2025;

when using equipment of Ukrainian production, a “green” tariff is set at a premium of 5% (for 30% of “local component”) and 10% (for 50% of “local component”).

The additional factors contributing to the expansion of biofuels and the reduction of natural gas consumption since 2014, and influencing on the pricing of biofuels, were the increase in gas prices for households and utilities, the setting of administrative limits for gas consumption: reduction by 30% in industrial consumption, state institutions and housing enterprises, by 10% for the population. If in 2014 the price of gas provided at the consumption maximum 2500 m^3 per year was 0.7254 UAH per 1 m^3, then, starting from May 1, 2016, the price increased to 6,879 UAH per 1 m^3, from April 1, 2017 to November 1, 2018 the price of natural gas for needs of the population is set at 6.9595 UAH per 1 m^3, and from November 1, 2018 to December 31, 2019 the price of natural gas used by the population is set at 8.54892 UAH per 1 m^3 [30]. In the face of rising prices for fossil fuels, households and businesses are looking for alternative sources with a lower cost per unit of energy (Fig. 1).

Fig. 1: Dynamics of unit cost of energy in fuel (energy source material) in Ukraine, UAH per 1 GJ without VAT

Source: done by the authors according to the data of the State service of Ukraine

It is revealed that one of the most important factors of the pricing process is the level of purchasing power of biofuel consumer. In the process of interaction with final users and building marketing communications system, the attention should be paid to the cost benefits they can receive. On the other hand, biofuel production volumes in the country cannot be increased immediately. This requires investment and time.

In a context of scarcity, under the influence of public policy and the increase in cost of traditional energy sources, prices for biofuels also rise, making processing all new types of biomass cost effective. Starting around 2016, when active participants in the biofuels market demonstrated the benefits of using vegetable waste, their producers are increasingly setting high prices for them. As a result, in 2016 prices of raw materials for the production of solid fuel pellets and briquettes increased by 10-15%, and doubled in 2017-2018. The distance at which producing companies have to collect straw and husks is also important. For example, the cost of 1 ton of straw at a delivery radius of 25 km is approximately 750 UAH. This price includes the entire cycle from collection of straw to shipment at warehouse.

The second factor influencing the pricing process for biofuels is the price of traditional energy source materials. Biofuel is a substitute product for traditional energy sources. Accordingly, the price level in the biofuel market correlates with changes in the oil, gas and coal markets. The more expensive are oil and coal, the more advantageous it is to burn biofuels. And vice versa.

However, the observation of biofuels markets over last 3-4 years shows that, at least in the short and medium term, this correlation works only upward. Thus, as a result of the oil and oil products price jump in August 2005, the market price of fuel pellets increased by 15-20%. When oil prices dropped again from $ 80 to $ 50 for a barrel, the biofuel prices continued to increase gradually. Obviously, this is due to government regulation on one hand, and with relative inelasticity of demand for biofuels on the other.
The State policy aimed at reducing of greenhouse gas emissions; in particular through the development of bioenergy, underpin such a rapid increase in demand for biofuels. Fuel pellets are one of the most technological sources of clean energy. However, FAO points out that the demand for biofuels is largely artificial. Manufacturers receive tax breaks and discounts, and there are standards for mandatory ethanol add when selling gasoline and biodiesel add when selling diesel.

The Ukrainian scientists have determined the economic parameters under which it is advisable to produce biofuels. The starting points for determining these parameters are the price level: for oil and fuel produced from it (diesel, gasoline, heating oil); on appropriate bio-raw materials; for by-products in the production of biofuels; as well as the level of costs for biofuel production, etc. [31]. Therefore, it is necessary to first determine the approximate production volumes, the indicative market prices for biofuels, clearly understand all stages from the production of biomass to its supply in the form of biofuels to final consumers, the list of necessary equipment, the number of staff, the distance of transportation of raw materials and finished products; to calculate on this base cost items at each stage of the supply chain. Obviously, the total cost determines the cost of 1 ton or 1 m^3 of biofuels. Further, using guidelines, the cost per unit of biofuels is translated into the price of heat energy unit, which allows comparing the efficiency of its production from different energy sources.

In order to identify the opportunities and threats of the biofuels market in Ukraine in more detail, as well as to identify its strengths and weaknesses, we will use a cross-matrix of SWOT analysis (Table 2).

Table 2: Matrix of SWOT analysis of biofuels market in Ukraine

	Opportunities (O)	Threats (T)
	- high level of interest; - development of domestic demand; - certification of products; - access to international export markets; - support of participants; - creation of clusters; - credit lines; - transfer of experience; - state support for development; - image creation; - production diversification; - investment growth; - introduction of modern technologies; - saving of natural energy resources and natural gas; - participation in international and domestic exhibitions;	- shortcomings in the legislation; - a strong lobby in the gas industry; - unstable quality of biofuels; - unstable political situation; - reorientation of biomass suppliers towards more profitable activities; - lack of financial resources; - increasing influence of natural factors; - insufficient awareness of the population; - demographic and social crisis of rural areas
Strengths (S)	SO- strategies	ST- strategies
- great biomass potential; - a lot of grain waste; - availability of wood; - high cost of traditional energy sources; - relatively low competition in the industry; - positive dynamics of the sector development; - "green" tariff; - favorable natural and climatic conditions; - high potential of cultivation of energy crops; - implementation of foreign experience in the construction and production of biogas complexes; - protection and maintenance of soil reproduction; - preservation of the ecology of the environment; - increasing employment and development of rural areas;	1. Creation of value chain for certain types of biofuels; 2. Involvement of existing consumers and companies that are currently supplying biofuels with the new timber supply chain; 3. Creating examples of real cooperation between farmers and industry. 4. Search for potential partners and financing opportunities; 5. Create clusters to bring together small and medium players in this market	1. Increasing the level of knowledge regarding the correct technology for production and storage of biomass 2. Stimulation of biofuel production; 3. Formation of marketing support for promotion of bioenergy products; 4. Involvement of regional / regional / local decision-makers at political level to promote energy sector promotion and protection activities. 5. Overcoming barriers and obstacles hindering the creation of innovative value chains 6. Combating the shadow timber market. 7. Establishment of a network of logistic centers and a regulated exchange for the sale of biofuels of different types with quality monitoring and guarantee of security of supply
Weak sides (W)	WO- strategies	WT- strategies
- imperfect institutional	1. Determining the best business	1. Development of new

support; - unsatisfactory financial condition; - significant biomass production is exported as raw material; - unstable supplies; - seasonal shortage of biomass; - high cost of logistics services; - low level of state support; - underdevelopment of the marketing system in agricultural enterprises; - lack of approved methods of checking the quality of delivered biofuels; - lack of developed infrastructure for storage and processing of agricultural biomass.	model and optimizing its functioning. 2. Marketing research on the introduction of new business in the field of bioenergy 3. Establishment of centers for training of professionals regarding the specificities of the sector and transfer of experience in the future; 4. Awareness raising on the potential benefits of biomass energy use both among farmers / agar enterprises and among potential consumers, companies that can expand their biofuel procurement and supply activities and communities 5. Wide dissemination of information to create a positive image among all stakeholders, potential players in the supply chain and members of the community.	technical capabilities to achieve the economic value of raw materials; 2. Exploring the possibility of using biomass to produce alternative products such as organic fertilizer, biocomposites, biofilters, compost, etc.

Source: Generalized by the authors.

It is obvious that the volatility of the external market for energy resources, the decline in traditional fuel stocks and other factors increase the risks of energy supply to the import-dependent countries, including. and Ukraine. On the other hand, favorable public policy, rising cost of traditional energy sources, except for the situation at the beginning of 2020, lead to higher prices for biofuels, and therefore cost-effective processing of all new types of biomass. In general, these trends lead to conditions for the expansion of production and consumption of different types of biofuels.

At the state level, setting up biofuel production and consumption in the country causes the manifestation of a synergistic effect, which is most characterized by economic, social and environmental factors (implementation of sustainable development principles in rural areas, creation of new jobs, creation of added value at each level of the supply chain, increased revenues budget at different levels - state, region, rural area; productive use of biomass, waste, etc.).

At the micro level - direct producers, the effect is manifested in the diversification of revenue generation, the development of a new line of business, which is additional and based on its own raw material base; gaining the benefits of consumers (agricultural producers), if they are producers and consumers, they receive tangible benefits from the use of biofuels.

Conclusions

It is established that for an efficient development of the bioenergy market in Ukraine a number of problems should be solved at both micro and macro levels. At the micro level the problem consists in low level of supply of bio-raw materials, in particular for available processing capacities into thermal and electric energy. This problem can be explained by a lack of balance of economic interests between agricultural producers of bio-raw materials and their processors. This problem can be solves by the establishment of commissions for reconciliation of economic interests between producers and processors of bio-raw materials, whose obligatory participants should be independent experts. The other mean of solving the problem is ensuring the equal profit per unit of area for agricultural producer compared to other types of products produced by him. At the macro level the problem consists in energy dependency and environmental problems at country and at world level that can be

solved by stimulating the development of alternative fuel markets by differentiating green tariffs depending on the country's economic conditions and the extent of fossil energy depletion.

Based on the calculations, the cumulative added value in different corn supply chains has been determined; they involve the production of biological raw materials, their processing into biofuel, use as feed in the production of milk and pig meat, supply to the foreign market and domestic sales, it takes into account partial return of nutrients to the soil when using stems of the plant as an organic fertilizer and digestate obtained as a result of biogas production per 1 ha of biological raw materials growing. It has been established that in process chain of production, marketing and final consumption of solid biofuels, the confirmation of quality (compliance with standards and certification of pellets) and the increase of added value by the manufacturer play a crucial role.

The Maturity of Outsourcing Used Within Polish Enterprises - Research Results

Jakub DRZEWIECKI

Wroclaw University of Economics, Department of Organization and Management Theory,

Wroclaw, Poland

jakub.drzewiecki@ue.wroc.pl

Abstract

The goal of the paper is to present research results concerning the maturity level of outsourcing used in Polish companies. The article begins with a brief presentation of outsourcing maturity criteria identified by the author that were used to create a research tool. Then, the methodology of the research and characterization of research sample is presented. Main part of the paper shows the results and conclusions that can be drawn based on the accumulated data, including the analysis of outsourcing maturity in enterprises of different size. The research results have enabled to draw two main conclusions. Firstly, the overall level of outsourcing maturity in Polish companies is low. This approach to outsourcing naturally limits not only its scope, but also potential benefits it could bring for the client. Secondly, the specificity of outsourcing maturity used in small companies should be noted. Somewhat chaotic, ad-hoc approach to outsourcing, proved by lowest outsourcing maturity levels among small companies, may result, among others, from the limited possibilities of resource access in comparison to bigger entities. This approach to outsourcing in Polish companies naturally limits not only its scope, but also the potential benefits it could bring for the client. Particularly, it indicates also that the vendor is treated rather as an outside company that provides resources, than a partner that could – to some extent – improve client`s overall efficiency and effectiveness (e.g. by process optimization or new business opportunities).

Keywords: Outsourcing, Maturity, Contract, Vendor.

Introduction

The fact, that outsourcing is one of the most frequently used methods of management in Polish companies (Lisiński *et al*., 2012; Kuczera, 2013), should come as no surprise; for it enables to achieve many various organizational benefits, such as increasing efficiency and effectiveness of processes, as well as new possibilities for establishing relations with environment (including customer and / or client). However, the modern way of approaching outsourcing not only as a method of cost optimization, but also as a tool that supports strategy implementation (Gay, Essinger, 2000; Power *et al*., 2010; Vitasek *et al*., 2013) and business model change (Drzewiecki, 2019) suggests that implementing outsourcing nowadays may be even more demanding than before. This perception of outsourcing requires a thorough analysis of its consequences, because implementing this method may result in significant changes in such vital areas, as: organizational structure, value creation an value delivery process, shape of organizational boundaries, and even organizational culture. This fact raises a question of the way Polish companies approach the problem of outsourcing implementation, which is reflected by the outsourcing maturity concept presented in the paper.

Therefore, the goal of the paper is to present the research results concerning level of outsourcing maturity used in Polish companies. The article begins with a brief presentation of the identified outsourcing maturity criteria that were used to design a research tool. Then, the methodology of research and characterization of research sample is presented. Main part of the paper shows the results and conclusions that can be drawn based on the accumulated data, including the thorough analysis of outsourcing maturity in enterprises of different size.

Outsourcing maturity criteria: framework and research tool

Based on thorough literature review, as well as author`s preliminary and pilot research, a framework of outsourcing maturity was created. It is based on four main areas, as shown in figure 1:

Figure: own work based on: (Drzewiecki, 2019, p.147).

Fig. 1: Outsourcing maturity framework used in the research

The first area of outsourcing maturity determinants stems from using the strategic outsourcing (Alexander, Young, 1996; Greaver, 1999). Most frequent approaches to this issue are: defining a specific set of outsourcing goals, alignment of strategy and outsourcing goals, identifying the level at which using outsourcing contributes to strategy implementation, or certain characteristics of outsourcing (Power *et al.*, 2010, p.25; Gay, Essinger, 2000, pp.39-45). Main problem with this approach to outsourcing maturity is that the company itself may not be conscious of its strategy, yet not even the strategic goals. Moreover, the links between outsourcing and the value it adds to the client`s products and / or services may be difficult to assess, especially in cases, where the value is created within a network, hence – when the process of value creation is somewhat vague and dispersed. Therefore, the strategic outsourcing perspective has to be supplemented by a second set of outsourcing maturity determinants, which encompasses the way outsourcing process is organized and managed.

An important aspect of outsourcing process is time and other resources spent for: gathering information and analytical activities, for it influences outsourcing efficiency. In first phase, the information should encompass: outsourcing goals, expected benefits, outsourcing risks and opportunity cost level (Bidwell, 2012). In second phase, the analytical activities should enable to make an optimal (or, rather, "satisficing" (Simon, 1972)) vendor choice. In this context, such outsourcing process characteristics, as the way the information about vendor is gathered, as well as the way its experience and quality of provided products and / or services is assessed, become crucial. When it comes to outsourcing process organization, one of the options is creating a team that would be responsible for the implementation of this method, as well as to use the assistance of consulting companies. Again, such organizational choices increase the level of resources needed to carry out the process, but, at the same time, allow to achieve many benefits, such as: lowering the risks of failure (e.g. by using different sources of information or gaining additional knowledge) or adding value to the service and / or final product (Power *et al.*, 2010, pp.43-44). Finally, vendor`s participation in outsourcing process may also be beneficial for the client, but it requires a certain level of trust between two sides of the outsourcing agreement (Vitasek *et al.*, 2013).

The organizational aspects of outsourcing described above impact both its efficiency and effectiveness. At the same time, they are not the only factors that influence the possibility of successful outsourcing. Hence, the third determinant of outsourcing maturity used in the research is the form of an outsourcing contract, with emphasis on: contract duration, metrics of assessing partner`s work and partner gratification model. The outsourcing contract duration not only indicates the frequency of transactions between client and vendor (Williamson, Ouchi, 1981; Williamson, 1998); it also influences the level of risk. Long term contract may be an incentive for a vendor to invest in streamlining the processes provided for the client (Vitasek *et al*., 2013). Another crucial aspect of outsourcing contract is the partner gratification model (Vitasek *et al*., 2013; Power *et al*., 2010), which should be strictly linked to the metrics of assessing level of services and / or products provided by the partner (e.g. in the form of SLA, SLI etc.). Both of these aspects of contract are going to influence not only the level of vendor`s motivation, but also the nature of relationship between parties, which is the premise for fourth and last set of outsourcing maturity determinants.

From the client`s perspective, the relationship is perceived here as one of the control mechanisms, usually described as *relational governance* (Dyer, Singh, 1998; Lee, Cavusgil, 2006) which enables the client to influence the vendor`s behaviour. Hence, the outsourcing relationship may be viewed at as a significant complement of the contract that includes – among others – the informal aspects of the cooperation (Goo, Nam, 2007; Poppo, Zenger, 2002). The importance of relationship in outsourcing stems mainly from the lack of possibility to specify a complete contract (one that would consider all the possible scenarios, which is the result of both decision-makers` bounded rationality and uncertainty (Hart 1988)) as well as the cost of partner change (Gulati, Sytch, 2007; Hansen, Rasmussen, 2013). Two main characteristics of outsourcing relationship crucial in this context are: trust and engagement (Babin *et al*., 2017; Child, 2001; Kern, Willcocks, 2000, p.329), since they enable, among others, to: lower transaction cost (mostly by reducing the uncertainty cost regarding outsourcing partner`s opportunistic behaviour), shorten and simplify the outsourcing process (e.g. the negotiation phase), reduce contract complexity, as well as to better understand partner`s goals and choices (Babar *et al*., 2007; McEvily *et al*., 2003).

Four areas of determinants identified during the research described above served as the foundation for a set of specific 18 criteria that would enable to assess outsourcing maturity (in the form of a research tool), along with corresponding variables, as shown in table 1:

Table 1: Brief description of outsourcing maturity criteria used in the research

No.	Criterion description	Substantiation of applying the criterion to measure outsourcing maturity level	Name of the corresponding variable	Variable Code
1	Using long term contract	Influences the durability of relationship, signifies possible strategic impact of outsourcing, as well as possibly higher level of trust	Long term contract	LT
2	Sharing benefit between client and vendor	Highly influences the level of vendor`s motivation and engagement, may signify the importance of the contract for both parties	Benefit sharing	BS
3	Sharing risk between parties	As above	Risk sharing	RS
4	Sharing human resources between client and the vendor	Requires to considerate functional strategies of client (here: the HR strategy), may influence the way this strategy is implemented. Indicates possible need for fit between client and vendor in such	HR sharing	HS

		areas, as organizational culture and communication (e.g. communication routines).		
5	Sharing physical resources between client and vendor	As above	Physical resources sharing	PS
6	Vendor`s participation in the investment needed to carry out outsourcing project	Requires to take into consideration functional strategies of outsourcing client as well as investment process. Increases vendor`s engagement in the relationship. Requires higher level of cooperation between parties (e.g. by making joint decisions concerning the investment).	Joint investments	SI
7	Analyzing possible outsourcing risk	Enables to better understand the outsourcing rationale, as well as to match outsourcing goals to client`s strategy. Increase in cost of outsourcing process. Influences contract formulation phase of outsourcing process.	Outsourcing risk analysis	OR
8	Analyzing level of opportunity cost	As above	Opportunity cost analysis	OC
9	Analyzing the quality level of products and / or services provided by vendor	May be crucial for using outsourcing as a strategy implementation tool (the issue of importance of provided services and / or goods for client`s value creation process). Influences the model of vendor gratification, hence – the contract shape. The results of the analysis may influence vendor`s image, and, as a consequence, level of trust between parties. Important for evaluating the metrics within an outsourcing contract.	Quality of products / services analysis	QP
10	Analyzing the level of vendor`s experience	As above	Vendor experience analysis	VE
11	Gathering information about the vendor from other companies (e.g. former / current client, business partners etc.)	Crucial in case of strategic outsourcing, influences the perceived risk of getting into the relationship. May influence: contract duration, vendor gratification model and metrics.	Gathering additional information about vendor	GI
12	Consulting vendor about the product and / or service requirements specified within the contract	May influence outsourcing effectiveness and efficiency (e.g. by utilizing vendor`s experience), and enable to better address client`s goals (strategy). Possibly shortens the outsourcing process, signifies	Vendor consultations about the requirements	VC

		the higher level of trust between the parties. Enables to specify the contract more precisely and adapt it to both parties` needs.		
13	Consulting vendor about outsourcing agreement draft	As above	Vendor consultations about agreement draft	VA
14	Creating the team responsible for negotiations with a vendor	As above	Creating a team to negotiate with a vendor	CT
15	Creating the team responsible for the project together with a vendor	As above	Creating a team with the vendor	CV
16	Organizing informal meetings with vendor`s employees	Enables to gather additional information from vendor, influences the efficiency of communication during outsourcing process, may result in changes within the contract (e.g. metrics)	Informal meetings with vendor	IM
17	Exchanging the information of strategic importance (e.g. strategic goals, plans) as well as information crucial for company`s results	Enables to match vendor`s strategy to client`s needs, may streamline the outsourcing process. Enables more precise description of requirements.	Exchanging strategic information	EI
18	Hiring consultant(s) during outsourcing process	May enable to improve both efficiency and effectiveness of outsourcing. Influences the shape of outsourcing contract, may be beneficial for contract specificity, enables to gain additional knowledge (e.g. about legal aspects of outsourcing) and to avoid some risks of not matching the contract to client`s needs and / or specifications.	Hiring consultant(s)	HC

Source: own work

Respondents were to assess the frequency of each of 18 solutions used during outsourcing project carried out in their company and described in table 1. During the assessment, 6-point Liker scale was used; the scale ranged from 0 (“never”) to 5 (“very frequently”).

Methodology of the research and characterization of research sample

The research tool was a survey questionnaire. Four channels of communication were used in order to initiate contact with the respondents: traditional mail, e-mail, direct contact and via telephone (using CATI). The research sample included 281 cases and was purposive. Alongside the criterion of outsourcing implementation, the research included only Polish enterprises (Drzewiecki, 2018, p.199).

The characteristics of the research sample in the cross-section of selected quality features (organizational and legal frame, scope of diversification, and business area) are presented in table 2:

Table 2: The characteristics of the research sample in the cross-section of selected features

Organizational and legal frame of business activity	Size of enterprise			Sum (%)
	Small	Medium	Big	
State owned enterprise	1	2	7	10 (3.6%)
Joint stock company	3	5	19	27 (9.6%)
Civil law partnership	21	50	13	84 (29.9%)
General partnership	12	9	4	25 (8.9%)
Limited partnership	0	0	1	1 (0.3%)
Limited liability company	22	20	24	66 (23.5%)
Business run by a natural person	44	23	1	68 (24.2%)
Sum	**103**	**109**	**69**	**281**
Area of business				
Activity only on domestic market	66	72	30	168 (59.8%)
Activity mostly on foreign markets	2	3	5	10 (3.6%)
Activity mostly on domestic market	35	34	34	103 (36.6%)
Degree of diversification				
Enterprise operating in one sector	53	52	21	126 (44.8%)
Enterprise operating in several related sectors	45	53	31	129 (45.9%)
Enterprise operating in several unrelated sectors	4	3	7	14 (5%)
Enterprise operating in a dozen or so sectors	1	1	10	12 (4.3%)

Source: (Drzewiecki, 2018, p.199-200).

Almost one third of the research sample were comprised of civil law partnerships, around one fourth – limited liability companies and businesses run by a natural person. Roughly every tenth of researched companies was organized in the form of a joint stock company; in total, share-holding companies equaled to one third of cases. Most of the subjects comprising the research sample (nearly 60%) operated the business only on a domestic (Polish) market. The degree of diversification of investigated subjects should be evaluated as low: more than 90% of enterprises operated its business either in one branch or at most few related branches (Drzewiecki, 2018, p.200).

Research Results

In order to evaluate the level of outsourcing maturity, average and median values were calculated for each of the 18 variables used in the research (see table 1). Table 3 presents these results (in the sample as well as according to company size):

Table 3: Outsourcing maturity: in the sample and according to company size

Variable code	Variable name	Sample data (n=281)		Data according to company size*					
				Small (n=103)		Medium (n=109)		Large (n=69)	
		Avg.	Med.	Avg.	Med.	Avg.	Med.	Avg.	Med.
LT	Long term contract	1,75	2	1,15	1	2,16	2	2,01	2
BS	Benefit sharing	0,96	1	0,79	1	1,00	1	1,16	1
RS	Risk sharing	1,06	1	1,02	1	1,05	1	1,16	1
HS	HR sharing	1,37	1	1,12	1	1,47	1	1,62	2
PS	Physical resources sharing	1,10	1	0,78	0	1,22	1	1,41	1
SI	Joint investments	1,16	1	0,74	0	1,42	2	1,41	1
OR	Outsourcing risk analysis	1,61	2	1,48	1	1,59	2	1,87	2
OC	Opportunity cost analysis	1,88	2	1,62	1	1,96	2	2,14	2
QP	Quality of products / services analysis	2,43	2	2,23	2	2,43	2	2,72	3
VE	Vendor experience analysis	2,17	2	1,75	1	2,37	3	2,48	3
GI	Gathering additional information about vendor	1,79	2	1,50	1	1,94	2	1,99	2
VC	Vendor consultations about the requirements	1,67	2	1,61	1	1,64	2	1,80	2

HC	Hiring consultant(s)	0,93	1	0,77	0	0,85	1	1,28	1

**Based on two criteria defined in EU regulations: employment size and annual turnover.*

Source: own work

Overall, research results in the sample confirmed **low level of outsourcing maturity used within researched companies** according to criteria taken into account and resulting from the framework described earlier. When it comes to vendor gratification model, Polish companies are not keen to share both risk and benefits with their outsourcing partners. Also, the average values for variables responsible for measuring the frequency of resource sharing (HS, PS and SI) were one of the lowest, in comparison to the rest of variables. Polish outsourcing clients prefer rather formal communication, which may signify that they rarely use various forms of informal relationships with vendor`s workers as one of the control mechanisms. Also, they very rarely decide to hire consultants, which may be the result of lack of financial resources (relevant especially for small companies). In case of only two variables (QP, quality of vendor`s products and / or services analysis, as well as VE - vendor experience analysis), the

average amount was higher than 2. Even though these activities seem obvious and can be found in virtually any outsourcing process framework, values between 2 and 2,5 still have to be assessed as low in this context.

The research results suggest that most of the Polish companies sooner or later encounter problems during outsourcing contract execution, which is going to negatively affect both outsourcing efficiency and effectiveness. Lack of organizational routines such as risk and profit sharing is neither going to encourage the vendor to be engaged in the relationship, nor to increase partner`s motivation. Low level of mature outsourcing solutions popularity suggests also a low level of trust in interorganizational relationships, which naturally increases transaction costs, and, again, negatively influences potential benefits of using this particular management method. Relatively low average values of variables responsible for measuring frequency of analytical activities carried out during outsourcing (2 to 2,5 on a scale of 5) indicate also somewhat chaotic approach to the way outsourcing should be managed and organized. This is especially relevant to small companies.

What also has to be noticed are the differences in outsourcing maturity levels between companies of different size. Statistically proven (by applying Kruskal-Wallis test which enabled to confirm specificity of small enterprises in this regard) differences between average values of variables shown in table 3 indicate, that the way outsourcing is approached and carried out is specific for small companies. This group of enterprises seems to experience some kind of "vicious circle" of outsourcing. They do not have access to the level of resources (mostly: time, financial, HR) that would enable them to carry out outsourcing process "the right way" (e.g. by putting more effort to analytical activities in order to reduce outsourcing failure risk). What is more, they are also not able afford to seek for help from consulting companies which could streamline the whole process. This results in a less controlled approach to outsourcing implementation and, as a consequence, negatively impacts not only *ex ante* risks, but also *ex post* results of cooperation with a vendor. Additional problems during the whole process generate more transaction cost, which influences overall level of company`s resources.

At this stage of the research, a correlation analysis was carried out in order to identify the relations between variables used to measure outsourcing maturity. Its results proved the existence of a number of statistically valid correlations between the 18 variables used in the research. Hence, an additional analysis was carried out, which would enable to aggregate the variables in order not only to inquire more about the nature of these relations, but also to clarify the research framework.

In the course of this analysis, the following statistical methods were used:

- factor analysis – to acquire the new set of aggregated variables and
- reliability analysis – to confirm the correct way the variables were aggregated.

In order to establish the number of aggregated variables (factors), two criteria were taken into consideration: levels of eigenvalues (over 1) and the criterion of Catell`s scree test (Catell, 1966). After identifying the number of factors, the Varimax method was used to rotate the variables, which enabled to match each of the 18 variables to one of the factors. Then, reliability analysis was carried out by calculating the α-Cronbach indexes for each of the identified factors. The results of this analysis are presented in table 4:

Table 4: Brief description of four aggregated variables for outsourcing maturity

Aggregated variable symbol	α-Cronbach index value	Variables constituting the aggregated variable	Aggregated variable characteristics
OM1	0,89	Benefit sharing (BS) Risk sharing (RS) HR sharing (HS) Physical resources sharing (PS) Joint investments (JI) Informal meetings with the vendor (IM) Exchanging strategic information and knowledge (EI)	Form of the contract, model of vendor gratification and information exchange between outsourcing partners
OM2	0,80	Long term contract (LT)	Contract duration
OM3	0,91	Outsourcing risk analysis (OR) Opportunity cost analysis (OC) Quality of products / services analysis (QP) Vendor experience analysis (VE)	Analytical activities that accompany the outsourcing process
OM4	0,91	Gathering additional information about vendor (AI) Vendor consultations about the requirements (VC) Vendor consultations about agreement draft (VA) Creating a team to negotiate with a vendor (CT) Creating a team with the vendor (CV) Hiring consultant(s) (HC)	Outsourcing process organization and management

Source: own work

The results of the factor analysis carried out for the 18 variables of outsourcing maturity enabled to identify four of the following aggregated variables. Table 5 presents the research results of outsourcing maturity using new set of four aggregated variables:

Table 5: Aggregated variables data: in the sample and according to enterprise size

Aggregated variable name [variable code]	Sample data (*N*=281)		Data according to company size					
			Small (*N*=103)		Medium (*N*=69)		Large (*N*=109)	
	Avg.	*Stand. dev.*	*Avg.*	*Stand. dev.*	*Avg.*	*Stand. dev.*	*Avg.*	*Stand. dev.*
Form of the contract, model of vendor gratification and information exchange between outsourcing partners [OM1]	1,15	0,93	0,91	0,78	1,26	0,81	1,36	1,21
Contract duration [OM2]	1,60	1,26	1,08	1,01	1,96	1,20	1,80	1,31

Analytical activities that accompany the outsourcing process [OM3]	2,02	1,27	1,77	1,40	2,09	1,08	2,30	1,28
Outsourcing process organization and management [OM4]	1,35	1,08	1,10	1,07	1,41	0,91	1,61	1,27

***Source**: own work*

The research results presented in table 5 have proven previous conclusions regarding outsourcing maturity. Now, the specificity of small companies in this context becomes even more visible. The lowest average values were observed for variable OM1 (contract form, gratification model), especially in case of small business entities. Also, when it comes to variable OM3 (regarding the analytical activities that accompany outsourcing process), its average value was lower than 2 only for small companies. Again, the research results presented in table 5 have proven that the size of an enterprise is positively correlated to the outsourcing maturity.

Summary

The research results have enabled to draw two main conclusions. First one is that the overall level of outsourcing maturity in Polish companies is low. This approach to outsourcing naturally limits not only its scope, but also the potential benefits it could bring for the client. Particularly, it indicates also that the vendor is treated rather as an outside company that provides resources, than a partner that could – to some extent – improve client`s overall efficiency and effectiveness (e.g. by process optimization or new business opportunities).

The second main conclusion that stems from the research is the specificity of outsourcing maturity used in small companies. As it was stated before, this somewhat chaotic, *ad-hoc* approach to outsourcing, proved by the lowest outsourcing maturity levels, may result, among others, from the limited possibilities of resource access in comparison to bigger entities. The above conclusions become particularly important in the light of the statistically verified relationship between the level of outsourcing maturity and its effectiveness. Indeed, small enterprises, characterized by the lowest level of outsourcing maturity, assessed outsourcing effectiveness as the lowest. The reasons for this state of affairs can stem from, among others, the differences in awareness of how to use this method, as well as managerial routines, processes and procedures, in entities of different size.

Abstract

The effective and efficient laboratories' exposure plays an important role for producing market ready graduates of any engineering are science degree program. The main purpose of the labs, a short form used hereafter for laboratories, is to provide the opportunity to the students to practice the knowledge they gained in the classrooms and from their own understanding. This require for higher education institutions offering degree programs in engineering and science, particularly, to strive always to enhance the quality as well as proper management of the labs. This study presents the analysis of labs in a higher education institutions and suggest solutions; following those labs would have managed properly and students will benefit at maximum of the purpose of the labs.

Keywords: Traditional Managing, Responsibility Matrix, Labs Management Organizational Chart, Teaching/Laboratory Assistants

Introduction

The engineering professionals have always, as their professional responsibility, been endeavoring to harnessing and adapting the well-known fundamental resources; materials, energy, technology, and information that has been considered the creation of technology. The ultimate objective and goal of engineering education is to prepare students to apply engineering theories and laws to deal with the forces and materials of nature. The ABET (2020) defined outcomes for an engineering degree program that a student will have:

"1. an ability to identify, formulate, and solve complex engineering problems by applying principles of engineering, science, and mathematics
2. an ability to apply engineering design to produce solutions that meet specified needs with consideration of public health, safety, and welfare, as well as global, cultural, social, environmental, and economic factors
3. an ability to communicate effectively with a range of audiences
4. an ability to recognize ethical and professional responsibilities in engineering situations and make informed judgments, which must consider the impact of engineering solutions in global, economic, environmental, and societal contexts

5. an ability to function effectively on a team whose members together provide leadership, create a collaborative and inclusive environment, establish goals, plan tasks, and meet objectives
6. an ability to develop and conduct appropriate experimentation, analyze and interpret data, and use engineering judgment to draw conclusions
7. an ability to acquire and apply new knowledge as needed, using appropriate learning strategies."

A careful analysis of the above listed ABET SOs reveals that labs are mandatory resources in a higher education institution offering engineering programs. For example, SO 6 requires a lab to develop a

student's skill to conduct appropriate experiments and SO 5 could also be achieved when students work in a team in labs.

This study was conducted to identify problems in managing engineering degree program supporting labs. The data and the information about style of managing the labs was collected from responsible personnel of engineering labs in three different higher education institutions. This data and style was analyzed to propose *to-do-things* to make labs more productive and provide inducing environment to achieve the student learning outcomes in an engineering degree program. The name of the institutions and personnel are not listed here rather we will use HEI-1, HEI-2, and HEI-3 to present of findings for three labs in different institutions.

Data Collection

Organization Structures

In this section we present the data collection methodology and management style in three labs. The management structure chart for HEI-1 is given in Figure 1. The institution HEI-1 is offering four different programs and there are more than fourteen different labs including computer, science, and engineering.

Figure 1: Management structure chart for HEI-1

The management structure chart to manage the labs in institution HEI-2 is given in Figure 2. The institution HEI-2 is offering four different programs and there are different labs including computer, science, and engineering.

Figure 2: Management structure chart for HEI-2

The management structure chart to manage the labs in institution HEI-3 is given in Figure 3. The institution HEI-3 is offering different programs and there are more than thirteen different labs including computer, science, and engineering.

Figure 3: Management structure chart for HEI-3

Responsibility Matrices

The responsibility matrix to manage the labs for readiness for day-to-day effective conduct of the labs in institution HEI-1 is given in Table 1.

Questionnaire used for Data Collection

The important feature such as accuracy and systematic of data collection has always been critical to conducting scientific or social research as presented in Karim (2017). The data collection allows us to collect information that we want to collect about our study participants. The methods of data collection depend on the investigation and research types and may include documents review, observation, questioning, measuring, or a combination of different methods. The questionnaires, one of data collection tools, are designed to collect data from a group of people coming under the purview of the study. The questionnaire is designed to collect data from large. diverse and widely scattered groups of people. Therefore, it is a device for securing answers to questions by using a form which the respondent himself fills in. We have used a questionnaire to collect data form the those who have been involved in using or managing the labs in three institutions. The questionnaire form; 4 – 1 for (4 Yes), (3 Partially Yes), (2 Partially No) and 1 (No), used and ratings collected is given in Table 4. There were 10 TAs in three institutions and 47 faculty members who participated in the survey.

Table 4: Questionnaire Form for data collection

Questions	**Ratings**			
	4	**3**	**2**	**1**
1. Is the college supporting well in developing and improving the lab as whole?	10	20	20	50
2. Are the learning outcomes of each lab courses clearly defined and are they conducted according to the mentioned learning outcomes?	5	15	55	25
3. Are you happy with your department wise organizational structure for reporting the lab issues?	10	10	50	30
4. Are the responsibilities of each person involved in labs clearly defined?	50	20	20	10
5. As a student working in lab, are you satisfied with your learning outcome?	10	20	40	30
6. Are you happy working with the college as a lab assistant and TA?	3	3	1	3
7. Do you think the lab equipment are properly repaired and refreshed?	2	15	20	10

Data Analysis and Proposed Management Style

Data Analysis is the process of systematically applying statistical and/or logical techniques to describe and illustrate, condense and recap, and evaluate data. According to Shamoo (2003), various analytic procedures *"provide a way of drawing inductive inferences from data and distinguishing the signal (the phenomenon of interest) from the noise (statistical fluctuations) present in the data"*. In Table 5, we provide the analysis of data presented in Table 4.

Table 5: Data analysis and explanation of finding

	This question was asked to identify the level of support and importance given to the improvement of the labs in college. *The analysis of data shows that more than 70% are not satisfied with the support and importance provided by the responsible management personnel.*
	This question was asked to identify importance given to the conduct of labs during the preparation of the curriculum i.e. at the time of developing a syllabus. *The analysis of data shows that only 20% of the participants only are of the opinion that labs are not considered during the development of curriculum.*
	This question was framed to know the type of reporting and organizational structure of the lab managing personnel. It plays an important role to resolve lab issues occurs. *The analysis of data shows that only 20% of the participants only are of the opinion that reporting and organization structure of the lab managing personnel.* .
	This question was asked to identify clarity in the job descriptions of those who are involved in managing the labs for effective contribution in an engineering degree program. *The analysis of the data presents that 70% rated it satisfactory that job roles were clearly defined for the employees involved in the lab management.*

	This question was asked from the students about their satisfaction with the labs readiness for meeting the student outcomes of a program. *The analysis of the data presents that only 30% rated it satisfactory that labs are properly maintained.*
	This question was asked from the TAs about their satisfaction with the working as managing the labs etc. *The analysis of the data presents that only 60% rated it satisfactory.*
	This question is actually asked from the faculty about their satisfaction with the timely procurement of the equipment. *The analysis of the data presents that only 36% rated it satisfactory*

We summarize the main issues identified after the analysis of the collected data as follows:

1. Lab courses are not distributed as per the qualification of the TAs.
2. The learning outcomes for the labs in lab-base courses are not stated.
3. The students' feedback for the faculty/TA is not satisfactory due to faulty or non-availability equipment in labs.
4. There is no properly specified process for financial decisions for replacement or repair of equipment.
5. There is no effective organizational structure for labs' maintenance.
6. There is no proper responsibility matrix present in the institutions for conducting the labs efficiently.

Recommendation for Effective Labs Management

The investigators of this study proposed an organizational structure as shown in Figure 4. The proposed structure will be useful for effective management of the labs for its contribution to meet the students' outcome positively.

Figure 4: Proposed organizational structure

A Lab Director should be appointed as responsible for all labs in an engineering college. The Lab Director and Program Coordinators can decide the learning outcomes of labs and higher decisions regarding laboratories can be made by these personnel. The Lab Director should make sure that the syllabus for labs is proper and as per the requirement of an engineering degree program level. The Program Coordinators should be assigned for each department and they can discuss with their faculty about the experiments to be conducted and also about the learning outcomes of each experiment. Once the syllabus of lab is prepared properly, it should be passed on to the concerned lab assistants to go through it.

Before each semester starts, the Lab Technicians and Lab Assistants should make sure that all the equipment and component are properly working. A log should be maintained to mark the number of working and faulty equipment. The labs should be refreshed with new components in case of any faulty components are there.

Finance for this kind of purposes should be immediately available. For this purpose, reporting of faulty equipment should be done at least two weeks before a semester starts so that the management has enough time to get new one.

If this organizational structure is maintained properly, a lab can run smoothly without many issues.
A responsivity matrix has also been proposed as given in Table 6 *(LD – Lab Director, PC – Program Coordinator, FM – Faculty Member, LA – Lab Assistant, LT – Lab Technician, and CS – Cleaning Staff)*

Table 6: Proposed responsibility matrix

Items	**LD**	**PC**	**FM**	**LA**	**LT**	**CS**
Lab issues	✓	✓	✓	✓		
Lab preparation and running		✓	✓	✓	✓	
Equipment repairing and maintenance				✓	✓	
Lab timing and scheduling	✓	✓	✓			
Lab supervision			✓	✓	✓	
Cleaning labs						✓

The responsibilities of each personnel involved in using and managing labs should be clearly defined. The Lab Director, responsible for readiness of all labs, should be aware of important changes that happen in labs and also should be updated with the status of equipment and experiments conducted as well. The developments and operations of labs should be decided by him or should be prepared by LD to be presented to higher administration following the prescribed processes in the institutions.

Conclusion

We conducted an analysis of the labs management and maintenance in three institutions offering engineering degree program those include the practical as part of the curriculum. After the analysis and findings of the shortcomings in under investigation institutions we also proposed the organizational structure and responsibility matrix. We are confident that the proposed structure and matrix will help in achieving the outcomes of the labs.

Abstract

The article discusses the use of scenario analysis for the analysis of investment attractiveness. With the help of this analysis, a predictive assessment of the state of the organization is carried out with various variants of combinations of factors determining its activity. This method is also the most promising among the existing instruments of strategic economic analysis, since it allows providing the management of an economic entity with ready-made schemes of actions in case of changing conditions of its activity. Scenario analysis is used in decision making even without the support of modern software, purely on an intuitive level.

Keywords: Scenario Method, Investment Attractiveness, Inflation Rate, Economic Efficiency

Introduction

To ensure the competitiveness of Russian enterprises, both in foreign and domestic markets, great attention must be paid to investments. In order for the enterprise to be able to successfully respond to changes taking place in the country and in the world, it is necessary to introduce innovations, to fully utilize the full potential of the enterprise, both economic and technical. This requires significant investment. For this, both the company's own funds and borrowed capital can be used. In order to competently distribute the received funds, it is necessary to evaluate the investment attractiveness (Nandi S. et al., 2019; Laužikas M. et al., 2019; Shaitura S.V. et al., 2018.)

Due to the lack of a clear structure in the system of methods for assessing investment attractiveness, its effective practical application is difficult (Kaźmierczyk J. 2019.; Masood O. et al., 2019; Movchan I.B. et al.,2019; Benešová D. et al., 2019.)

If the analysis of investment attractiveness is carried out competently, then it can form the basis of effective interaction between the source of financing and its consumer.

(Ige O., 2019; Molchanov N.N. et al. 2017; Shatunova O. et al., 2019; Ivanova V. et al., 2019; Turen S. et al. 2019; Petrushina L.O. 2015.)

According to the authors, the identified shortcomings in the process of investment attractiveness can be offset by the use of scenario analysis.

In the system of methods of strategic economic analysis, we can distinguish traditional (statistical), economic-mathematical and special ones. Techniques demanded during the assessment of the investment attractiveness of the organization can be divided into quantitative and qualitative. Quantitative methods include those methods whose use is measurable, objective and unambiguous. While the qualitative ones will differ in subjectivity both in the interpretation of the results and in the nature of the performance.

The main part of the methods of economic analysis of investment attractiveness belongs to the first group, with the exception of heuristic methods (expert assessment methods, brainstorming) and most special (SWOT, PEST, SNW, portfolio, scenario, comparative).

One of the most comprehensive methods of analyzing investment attractiveness is scenario analysis. It is used for predictive assessment of the state of the organization in various combinations of factors that determine its activities. This method is also the most promising among the existing tools of strategic economic analysis, since it allows you to provide the management of an economic entity with ready-made action plans in the event of changes in the conditions of its activity. Scenario analysis is used when making decisions even without the support of modern software, purely on an intuitive level, when the responsible persons are faced with the question: "What happens if?". The possibilities of this method make it necessary to develop and Refine a single scheme for its implementation.
Methods

In the process of practical adaptation of the methodology of the scenario method of strategic economic analysis for assessing the investment attractiveness of a commercial organization, we developed the following step-by-step algorithm of actions:

1 step Organizational stage

2 step Defining predefined constraints

3 step Assessment of factor impact and risks

4 step Forecasting

5 step Adjustment of the organization's development strategy taking into account the forecasts made

6 step Assessment of the investment attractiveness of the organization.

Results and Discussion

We will perform a consistent implementation of the methodology for assessing the investment attractiveness of a commercial organization, based on the reports of Planeta LLC.

Stage 1-organizational. Organization of evaluation of investment attractiveness of a commercial organization through a scenario approach. At this stage, it is necessary to assign responsible persons for each of the elements of the algorithm, set intermediate and control deadlines for the implementation of tasks.

Step 2-define the specified restrictions. At this stage, it is necessary to find out the investment targets and analyze the financial and management reports of the organization to identify current trends in the development of activities. In the period 2020-2022, the market for machine-building products for

agriculture is projected to grow by 12-15 % annually. The market of machine-building products for agriculture has an inflationary model of development, in many respects its volume is determined by the level of set prices. Due to the lack of the organization's own funds, as well as the existing debt to pay long-term obligations, it is necessary to attract 4285714.28 euros of investment to Finance the expansion of the field of activity. Table 1 shows the expected indicators of an organization's investment attractiveness set by a potential investor.

Table 1: Indicators of investment attractiveness of the organization

Indicator	Value
Payback period, years	no more 5
Share of equity, %	no less 7,6

According to the received data, a number of main trends were identified in the activity of Planeta LLC. Planet LLC is located in the city of Voronezh, Russia. The company belongs to medium-sized enterprises with 82 employees. The subject of activity of Planet LLC is the wholesale and retail trade in agricultural machinery and other consumer goods.

1. Active investment activity – implementation of expanded reproduction, acquisition of more modern equipment, implementation of services in new areas of production of complex equipment for agriculture.

2. The financial condition of the organization is stable enough from the point of view of making a profit, but the company is insolvent and financially unstable. Financing activities primarily through long-term and short-term Bank loans, increasing the cost of servicing loans, a low share of equity, reduced liquidity, solvency, and financial stability.

3. Jump in profitability and business activity of the organization, mainly due to the growth of net profit.

Forecasting of changes in the value of the organization was performed from the moment of investment investments-in 2020 – until 2022.

Stage 3-factor impact and risk assessment. One of the indicators of an organization's investment attractiveness is the growth rate of its value. One of the key factors determining the value of a business is revenue. The second indicator of investment attractiveness, the payback period, is calculated on the basis of the derivative of the same indicator – the net profit received minus the planned current expenses after the project launch. Revenue is affected by a large number of factors.

The main performance indicators that form the organization's revenue are the number of customers and the average receipt. These parameters are affected by the following factors:

- rate of inflation;
- currency fluctuations (euros);
- number of market consumers;
- success in attracting new customers in the market;

The considered parameters are mainly determined by the external conditions of the organization's functioning. The impact of each of them on the organization's performance can be estimated, but to eliminate the consequences of the expected negative outcomes, it is necessary to create a program of measures to manage internal factors that primarily determine the level of investment attractiveness of the studied organization for a potential investor. One of the indicators of investment attractiveness in this study is the condition for increasing the cost of equity. The amount of equity can be determined through the leverage of the financial lever, the cost and cost levels, and the amount of current assets. Let's take as a basis for these indicators the DuPont investment attractiveness model.

The expression of the cost of equity through a number of interrelated factors allows you to minimize the set of factors that need to be taken into account in the subsequent calculation of scenarios for changes in the investment attractiveness of the organization. The matrix of possible outcomes of factor influence is presented below (table 2).

When constructing the matrix, the cost level, the level of conditional fixed costs, and the level of conditional variable costs are assumed to be equal to the values of the last studied period, i.e., 2018. The inflation rate refers to external factors with a high degree of uncertainty, so using correlation and regression analysis, we will build a forecast of the inflation rate for the period from 2020 to 2022, taking into account possible economic development options.

Table 2: Prediction of inflation based on correlation and regression analysis

the probability of failure of the Year	Actual Values, %	Forecast, %	
		Polynomial trend line	Trend line
2016	5,4		
2017	2,5		
2018	4,3		
2019 (forecast based on results 9 month)	5,5		
2020		10,08	4,95
2021		16,44	5,16
2022		24,85	5,37

Calculations show that if you use a polynomial trend line as the most reliable one ( ),that is, a fairly serious increase in inflation is predicted: in 2020 - 10.08%, in 2021-16.44% and in 2022 - 24.85%. If you use a linear one, there is a slight increase from 4.95% to 5.37%, but the approximation coefficient for a linear trend line is too low ( ),to use the obtained data in further calculations.

However, given the state policy aimed at reducing inflation, we propose to consider three outcome given the increase in inflation from the minimum determined by a linear trend line to the maximum defined by the polynomial trend lines. The second outcome is the arithmetic mean between the first and second.

Since there are only parameters of the first and second level of uncertainty among the considered factors, a fairly accurate matrix of a small format is formed. If there are factors of the third level of uncertainty, it is possible to include in the matrix the boundary and average values of the range of possible influence, which will allow you to create an optimistic, pessimistic and realistic development scenarios and, thus, limit the number of scenarios considered.

Table 3: Matrix of possible outcomes of factor influence for «Planet» LLC

Factor	№ outcome	2020 г.	2021 г.	2022 г.
Inflation rate, %	1	4,95	5,16	5,37
	2	7,51	10,79	15,11
	3	10,07	16,43	24,85
Cost level, %	1	87,9	87,9	87,9
Level of fixed costs, %	1	6,51	6,51	6,51
Level of conditionally variable costs, %	1	2,81	2,81	2,81
Early repayment of a loan, euro.	1	0	0	0
	2	4285714,28	4285714,28	4285714,28

Taking the outcomes of external factors as strictly set limits of activity, for each of the scenarios, you can choose a set of values of internal factors that the company will need to adhere to in order to maintain the necessary level of investment attractiveness. In addition, by automating calculations and setting possible values for each of the indicators, it is easy to deduce the number of optimal scenarios in their total number, which will determine the current level of investment attractiveness of the organization for a particular investor.

To determine the number of scenarios being developed, we use the basic combinatorics formula.

In this case, the group will be the number of all possible scenarios for the development of each specific factor. Thus, the total number of all possible scenarios for the development of the organization's activities, taking into account the factors considered, is 6 and is determined mainly by the number of possible options for the development of the inflationary influence factor, the timeliness of the investment project and the financial policy of the organization. Using the tools of budgeting, trend analysis, extrapolation, etc. we form a model of the organization's development, tied to different values of factor features.

Stage 4 - preparation of forecast scenarios. From the point of view of assessing investment attractiveness, as well as taking into account the interest of most investors in increasing the cost of equity, the calculations used a model developed by us that links the external and key internal parameters of the organization's activities, including such specific characteristics as the number of buyers, the average check, etc.

The initial data for using the scenario approach when evaluating the investment attractiveness of Planeta LLC are given in table 4.

The results of calculations for each of the 6 scenarios of revenue, net profit, total assets, average annual value of current assets and equity are disclosed in table 5.

Table 4: Initial data on Planet LLC for the period from 2016 to 2018, euro

Усл. Обозн.	Indicator	2016 г.	2017 г.	2018 г.
OA	Current assets	9317786	11955786	14881614

C2 abs	Contingent costs	1625933	2117321	2674043
C3 abs	Conditionally variable costs	609767,1	793007,1	1020514
C1	Cost level	0,87	0,86	0,88
C2	Level of fixed costs	0,08	0,08	0,07
C3	Level of conditionally variable costs	0,03	0,03	0,03

Evaluating the investment attractiveness of a commercial organization using a scenario approach, if technical capabilities are available, allows you to take into account both changes related to internal factors of activity and possible risks associated with external factors. It is enough only to include the considered risks as part of the restrictions (table 5) that determine the business development for the forecast period.

The disadvantage of the proposed method is that it increases the complexity when a sufficiently large number of parameters are included in the calculation. For example, including an increase in the amount of investment due to higher exchange rates as a risk factor (some products and equipment are purchased abroad). This factor has only two possible outcomes in the forecast period: either the amount of investment is growing or not. However, this is enough to double the number of calculated scenarios from 6 to 12.

Stage 5-adjustment of the organization's development strategy taking into account the forecasts made. Taking into account the set restrictions and possible options for the development of factors, the number of neutral (not taking into account possible measures to minimize risks) scenarios corresponding to indicators of investment attractiveness is determined.

Since we selected the payback period and the share of equity as indicators of the organization's investment attractiveness (Table 1), we will consider the choice of a scenario based on these criteria, and we also need to estimate the amount of expected cash receipts from the selected project and calculate the discounted value of each stream that is expected.

Table 5: Calculation of the cost of equity of Planet LLC, taking into account the influence of factors, Euro

	6	End inflation 3, the loan is repaid	1393638,143	2217914,71	3101728,14

The value obtained during the calculation characterizes the amount of money brought to the moment of investment and the amount of income from investments. And now we can compare this amount with the size of the investment.

The forecast of the equity share is shown in table 6.

Table 6: Forecast of the share of equity in the property of Planet LLC, 2020-2022

Script number	Scenario description	Amount of equity, euro			Share of equity, 2020 г.	Share of equity, 2021 г	Share of equity, 2022 г
		2020 г.	2021 г.	2022 г.			
1	End inflation 1, loan is not repaid	1357356,714	2101814,43	2847758,71	0,08	0,12	0,15
2	End inflation 2, loan is not repaid	1375497,429	2159864,57	2974743,43	0,08	0,12	0,16
3	End inflation 3, loan is not repaid	1393638,143	2217914,71	3101728,14	0,08	0,12	0,16
4	End inflation 1, the loan is repaid	1357356,714	2101814,43	2847758,71	0,10	0,15	0,20
5	End inflation 2, the loan is repaid	1375497,429	2159864,57	2974743,43	0,11	0,16	0,20
6	End inflation 3, the loan is repaid	1393638,143	2217914,71	3101728,14	0,11	0,16	0,21

The payback period is usually understood as the number of years required to return the initial investment. This method is very actively used when we are talking about high-risk investments. Then the main criterion for decision-making is the speed with which the investment pays off. The calculation of the payback period, as well as the return on investment, is shown in table 7.

Table 7: Calculation of the payback period and return on investment of LLC Planet for 2020-2022

Script number	**Scenario description**	**NPV, евро**			**NCF, евро**	**Payback period, years**	**Return on investment**
		2020 г.	**2021 г.**	**2022 г.**			
1,4	End inflation 1	707928,571	673191,86	637610,57	2018731	2,12	0,16
2,5	End inflation 2	707928,571	638939,14	534296,29	1881164	2,28	0,15
3,6	End inflation 3	707928,571	608003,29	454200	1770131,85	2,42	0,14

The analysis made it possible to determine possible directions for strengthening the investment attractiveness of the organization, since, according to the preliminary assessment, only one of the 6 scenarios corresponds to the investor's expectations. Thus, the most optimal scenario for the selected criteria is scenario № 4. Let's choose it as a base for further risk assessment: the equity share of 20% is achieved with a minimum payback period of 2.12 years, in addition, the return on investment is maximum and is 16%.

Taking into account the possibility of unrecorded risks, the stage of strategic economic analysis based on the scenario method, involving the development of anti-crisis measures, is vital for the organization. Suggestions for improving the quality of an organization's asset management contribute to an increase in the number of optimal scenarios.

The management response matrix (Table 8) is a table that contains the main signal indicators that reflect the implementation of a particular scenario.

Table 8: Response matrix of the management of Planet LLC, euro

Script number	Scenario description	Total assets	Revenue	Net profit	Borrowed capital	Equity
1	End inflation 1, loan is not repaid	18849130,14	38404760,86	745944,28	16001371,4	2847758,7
2	End inflation 2, loan is not repaid	18976114,86	41953839	814878,85	16001371,4	2974743,4
3	End inflation 3, loan is not repaid	19103099,57	45502917	883813,42	16001371,4	3101728,1
4	End inflation 1, the loan is repaid	14563415,86	38404760,86	745944,28	11715657,1	2847758,7
5	End inflation 2, the loan is repaid	14690400,57	41953839	814878,85	11715657,1	2974743,4
6	End inflation 3, the loan is repaid	14817385,29	45502917	883813,42	11715657,1	3101728,1

However, it should be noted that neither the level of detail of the forecasts carried out nor the number of factors accepted for calculation provide an absolute guarantee that the development of the organization's activities will take place according to one of the considered scenarios. The response matrix serves only as a tool for orientation when drawing up current and medium-term plans and adjusting long-term plans of the organization, which allows reducing the number of considered alternatives taking into account already actual events, and clarifying forecast indicators.

Stage 6-assessment of investment attractiveness. During the analysis, it was determined that there are 6 scenarios for the development of the organization's activities, and this differentiation is due to the presence of a large number of possible outcomes for each period within the forecast of the factor effect of consumer price inflation on services. The revenue indicator is crucial in terms of determining the payback period of the project, as well as in calculating the cost of the business, as it participates in the formation of the company's market stability, its financial condition, and Fund return.

Conclusions and Recommendations

Thus, the scenario approach differs favorably from many existing tools by its universality, or rather, the proposed algorithm takes into account the need to adapt to the specifics of a particular organization's activity. The result of the implementation of the proposed algorithm is the percentage of probability of occurrence relevant for the subject of the scenario assessment for the development of financial and economic activity of object of investments, integrating the actual performance of different versions of the forecast of changes in main determinants of the business. The matrix of responses received as a result of the implementation of the model serves only as a tool of orientation in the preparation of the current and medium-term adjustment and long-term plans of the organization, allowing to reduce the number of alternatives given the fact, already coming events, Refine prognostic indicators. In addition, in the process of testing the method, a number of properties of factors included in the simulation model of the organization's activities were identified, which differently affect the number of calculated scenarios.

Are the Millennial Banking Customers Willing to Use Digital Banking? A Case from Indonesia

Indah WAHYUNINGSIH
Universitas Indonesia, Indonesia, indah.wahyuningsih@ui.ac.id

Abdul MUTA'ALI
Universitas Indonesia, Indonesia, moetaalingua@gmail.com

Abstract

This study aims to determine and analyze the factors that influence the intention of millennial banking customers to use digital banking services by involving conventional banking customers and Islamic banking customers. This research was conducted using a survey method through a questionnaire with a Likert scale of 5 categories in which all statements in the questionnaire were arranged according to the extended UTAUT (Unified Theory of Acceptance and Use of Technology) framework by adding innovativeness, trust, and security variables to adjust the context of the use of digital banking services. In addition, this study also used a dummy variable gender. This study involved 234 respondents consisting of conventional and Islamic banking customers aged 19-39 years and had never used digital banking services. The sampling technique used was non-probability sampling with the type of purposive sampling. Data collected through a questionnaire were then analyzed using multiple linear regressions. The result show that performance expectancy, innovativeness, trust and security provide significant effects on the intention of millennial banking customers to use digital banking. However, gender differences, effort expectancy, social influence and facilitating condition did not play salient role in affecting the millennial banking customers' intention to use digital baking

Keywords: Digital Banking, Millennial Banking Customers, UTAUT.

Introduction

The rapid technological advances in the Industrial Era 4.0 with the existence of Big Data, Artificial Intelligence (AI), the Internet of Things (IoT) have encouraged changes in people's behavior patterns in using financial services. This phenomenon has led to the emergence of new financial service providers who offer new innovations in financial services. According to the McKinsey and Company report compiled by Dietz, Khanna, Olanrewaju, and Rajgopal (2016), if banks do not mitigate fintech attacks, 10-40 percent of bank revenues will be at risk by 2025.

The banking industry is forced to improve and innovate to face the competition with others financial services. There are two responses that banks can do. First, digitizing services in order to provide faster, easier and cheaper services to customers. Second, integrating banking services with customers' daily lives (DBS, 2016). By doing and creating new products that are relevant to the market, as well as new experiences to customers, the bank will become a new disruptor. At present, service to banking customers in Indonesia is still product-oriented (product-centric mindset), so banks need to align strategies for providing customer-oriented financial services (customer-centered mindset).

Indonesia ranks second after Vietnam with 55 percent of non-digital consumers saying that they are willing to use digital banking services in the next 6 months. Meanwhile, according to the 2018 Oracle Financial Services Global Retail Banking Survey, banking customers have switched to digital services, where 67 percent of global customers have actively used digital platforms and frequently access their bank accounts digitally through mobile banking and etc (Pugh, 2018).

Therefore it is important to find out more about factors that influence the intention of banking customers to use digital banking services in Indonesia.

This study used the Unified Theory of Acceptance and Use of Technology (UTAUT) framework developed by Venkatesh et al. (2003) which is a model of technology acceptance and use which synthesizes various elements that exist in eight models of technology acceptance and use that have existed before. In addition, the study modified UTAUT by including innovativeness, trust and security variables to adjust to the context of the acceptance and use of digital banking services and also used a dummy variable in the form of customers' gender to determine whether gender differences affect the intention of millennial banking customers to use digital banking services. This study also involves banking customers in the millennial category, so that this research has a novelty and different from previous studies that have been conducted such as by Yu (2012), Tangkalayanan and Tubtiang (2015), Slade, Dwivedi, Piercy, and Williams (2015), Rahi, Ghani, and Ngah (2019), and Merhi, Hone, and Tarhini (2019).

This study aims to determine and analyze the factors that influence the intention of millennial banking customers to use digital banking services in Indonesia. In addition, this study also aims to determine and analyze the relationship and significance of the factors that influence the intention of millennial banking customers to use digital banking services in Indonesia. This research is expected to be able to contribute to the banking industry, both conventional banking and Islamic banking, by becoming a consideration in developing strategies to dealing with changes in people's behavior patterns in using financial services and in facing competition with other financial service providers. So that the financial industry is able to attract banking customers to use digital banking services. As for the regulator in this case the Financial Services Authority, is expected to be a material consideration in formulating appropriate policies for the banking industry in the face of competition with other financial service providers.

Millennial Banking Customers' Intention to Use Digital Banking

According to Tapscott (1998) millennial generation is referred to as digital generation born in 1976 - 2000. On the other hand, according to the Central Statistics Agency (BPS) 2018 millennial generation is the generation born between 1980 – 2000. In this study, the millennial generation referred to the Central Statistics Agency is the generation born between 1980 - 2000 who are currently aged 19 - 39 years. The main character of millennial generation is familiar with the digital world, so the banking industry is required to adapt to the needs of those who tend to want flexibility and speed (DBS, 2016).

The Oracle Global Retail Banking Survey 2018 states that 69 percent of customers want the entire financial lifecycle to be accessed digitally (Pugh, 2018). The research also outlines several things that encourage customers to switch to digital services, where high rates of return (interest) and customer experience are important considerations in customers financial decisions. Thus, it will be easy for customers to switch to alternative services that offer high returns (interest) and a better experience.

Bank is still the best option in terms of trust, but in the aspect of customer experience, the rate of return (interest) and benefits, the bank is inferior to other financial options. Digital banking enable prospective customers and/or bank customers to obtain information, conduct communications, registration, account opening, banking transactions and account closures, including obtaining other information and conducting transactions other than banking products, including financial advice (financial advisory), investment, electronic-based trading system transactions (e-commerce), and other needs of banking customers (Financial Services Authority, 2016). Therefore it is important to find out more about what factors influence the intention of millennial banking customers to use digital banking services in Indonesia.

This study used the UTAUT model developed by Venkatesh et al. (2003) to understand millennial banking customer's behavioral intention. The UTAUT model was developed to overcome limitations on models of acceptance and use of technology that had existed before, such as the theory of

reasoned action (TRA) developed by Fishbein and Ajzen (1975), technology acceptance model (TAM) by Davis (1989), theory of planned behavior (TPB) by Ajzen (1991), the innovation diffusion theory (IDT) by Rogers (2010) and the theory of perceived risk (TPR) by Featherman and Pavlou (2003). Vankatesh et al. (2003) propose a new model that unites various models of the acceptance and use of existing technology, the model is called the Unified Theory of Acceptance and Use of Technology (UTAUT).

The UTAUT model is a model of technology acceptance and use that synthesizes various elements that exist in eight models of technology acceptance and use that have existed before. The eight models are theory of reasoned action (TRA) developed by Fishbein and Ajzen (1975), technology acceptance model (TAM) by Davis (1989), motivation model (MM) by Davis, Bagozzi, and Warshaw (1992), theory of planned behavior (TPB) by Ajzen (1991), an integrated model of technology acceptance and planned behavior (TAM-TPB) by Taylor and Todd (1995), model of PC utilization (MPTU) by Thompson, Higgins and Howell (1991) , the innovation diffusion theory (IDT) by Rogers (2010), and social cognitive theory (SCT) by Bandura (1986).

According to Venkatesh et al. (2003), the UTAUT model proved to be more successful in predicting technology acceptance and use by 70 percent when compared to the eight previous models. So this study uses the UTAUT model developed by Venkatesh et al. (2003). The UTAUT model has four constructs namely performance expectancy, effort expectancy, social influence, and facilitating conditions. These four constructs succeed in predicting the use and acceptance of technology accurately (Venkatesh et al., 2013). So according to Venkatesh et al. (2003) this model is better compared to other models. In addition, this model has also been validated by being applied in various countries and in various contexts, such as internet technology, internet banking, mobile banking, e-government and others (Merhi et al., 2019).

Figure 1: Research Model; Extended UTAUT with Innovativeness, Trust and Privacy

Source: Venkatesh (2003); Self-Developed

This research extends the UTAUT model by adding innovativeness, trust, and security variables in the construct model. The innovativeness variable was added to determine the extent to which banking customers are open to new experiences and try new technologies in this case digital banking services, as an expression of trends towards innovation and novelty (Slade et al., 2015). However according to Slade et al. (2015), innovation has not been incorporated into any technology acceptance model. Therefore, as a service that offers innovation in the form of new experiences by providing banking

services that are comprehensive, easy, accessible at any time and from anywhere and effective and efficient, in understanding the intentions of banking customers, innovation variables need to be added to the model.

Unlike acceptance of other technologies that simply use the UTAUT model, digital banking services are fraught with security risks, financial transactions that are confidential, involving personal information of customers and so forth. Therefore, the modification of the UTAUT model needs to be done by adding trust and security variables, thereby increasing the ability of the model to explain customers' intentions to use digital banking services.

Methodology

This research was conducted using a survey method through a questionnaire with a Likert scale of 5 categories, where 1 = Strongly Disagree, 2 = Disagree, 3 = Quite Agree, 4 = Agree, and 5 = Strongly Agree. The Likert scale is used to measure how strongly the respondent agrees and disagrees with the statement. The sampling technique used is non-probability sampling with the type of purposive sampling. According to Bentler and Chou (1987), the minimum number of samples needed is represented by the number of question items multiplied by five.

In this study, the construct used consisted of 8 variables, namely, performance expectancy (4 indicators), effort expectancy (4 indicators), social influence (4 indicators), facilitating conditions (4 indicators), behavioral intention (5 indicators) that adapted from Venkatesh, et.al (2003) and additional variables, namely, innovativeness (4 indicators), trust (4 indicators), security (4 indicators). In addition, this study also uses a dummy variable, namely gender of the customers to find out whether gender differences affect the intentions of banking customers in the millennial category to use digital banking services. Thus, in this study there were 33 indicators or statement items, in which 33 x 5 = 165 samples, the minimum number of samples in this study refers to Bentler and Chou (1987) is 165 samples. This study involved 234 respondents consisting of conventional banking customers and Islamic banking customers aged 19-39 years and had never used digital banking services. The respondents were spread in Java, Sulawesi, Sumatera, Kalimantan, and also Maluku Island as Indonesia's largest islands.

The data collected was analyzed using Statistical Package for Social Science for MacOS (SPSS for MacOS Version 23.0). Descriptive analysis used frequency and percentage to examine the profile of the respondents. Individual t-test, simultaneous F-test and multiple linear regressions were used in this study. The level of significance at probability level of 5% was used.

The mathematical equation used in this study is as follows (Gujarati and Porter, 2017):

$$\mathrm{BI} = \beta_0 + \beta_1\, D_\mathrm{Gender} + \beta_2\, \mathrm{PE} + \beta_3\, \mathrm{EE} + \beta_4\, \mathrm{SI} + \beta_5\, \mathrm{FC} + \beta_6\, \mathrm{IN} + \beta_7\, \mathrm{TR} + \beta_8\, \mathrm{SC} + \varepsilon \quad (1)$$

Where:

BI	: Millennial banking customers' behavioral intention to use Digital Banking
β_0	: Intercept
D_Gender	: Dummy variable for respondents gender
PE	: Performance Expectancy
EE	: Effort Expectancy
SI	: Social Influence
FC	: Facilitating Conditions
IN	: Innovativeness
TR	: Trust
SC	: Security
ε	: Error term

Results and Discussions

There were 234 respondents involved in this study, the completed questionnaires were received and consider valid for further statistical analyses. The sample composed of male (41.5 percent) and female (58.5 percent). In addition, the age distribution presents that most of the millennial banking customers in this research were aged from 19-29 with 69.7 percent. The participants were asked about their education level, about 73.9 percent have a bachelor degree. About 23.1 percent of the respondents were student and most of them are muslim with 97.9 percent. The respondent were also asked about their income per month, 33.3 percent were bellow IDR 1.5 Million and 30.8 percent were between IDR 2.5 – IDR 5 Million. Most of the respondents used conventional bank with 67.5 percent of them and the rest 32.5 percent were customers of Islamic Bank. The table 1 summarize the main results.

Table 1: Demographic Respondents

Variables	Category	Frequency	Percentage (%)
Gender	Male	97	41.5
	Female	137	58.5
Age	19-29	163	69.7
	30 – 39	71	30.3
Education Level	High school	42	17.9
	Bachelor degree	173	73.9
	Master or doctoral degree	19	8.1
Profession	Student	54	23.1
	Civil Servant	38	16.2
	Teacher/Lecturer	25	10.7
	BUMN Employee	2	0.9
	General Employee	32	13.7
	Entrepreneur	18	7.7
	Other	65	27.8
Religion	Muslim	229	97.9
	Protestant	4	1.7
	Hindu	1	0.4
Income per Month	< IDR 1.5 Million	78	33.3
	IDR 1.5 – IDR 2.5 Million	46	19.7
	IDR 2.5 – IDR 5 Million	72	30.8
	IDR 5 – IDR 10 Million	29	12.4
	> IDR 10 Million	9	3.8
Bank Used	Conventional Bank	158	67.5
	Islamic Bank	76	32.5

Source: Computed by Author (2020)

Multiple regression analysis was conducted to examine the relationship between adoption factor for online banking and consumer intention to use online banking. It is a constructive statistical technique that can be used to analyze the associations between a set of independent variables and a single dependent variable (Hair et al., 2005). The result of multiple regression analysis summarize in the table 2.

$$BI = 1.930 - 0.050\ D_Gender + 0.243\ PE - 0.130\ EE + 0.049\ SI - 0.067\ FC + 0.269\ IN + 0.160\ TR + 0.452\ SC + \varepsilon \quad (2)$$

The value of intercept is 1.930, it means that the average value of millennial banking customers' intention with gender female and if the performance expectancy, effort expectancy, social influence,

facilitating condition, innovativeness, trust and security are relatively low. Then, the value of β_1 = -0.050, the data shows that the intention of millennial males in adopting digital banking is 0.050

points lower than the females. The value of β_2 = 0.243, it means that every increasing in performance expectancy as much as one point will increase the millennial banking customers' intention amounts 0.243 point. The value of β_3 = -0.130, it means that every increasing in effort expectancy as much as one point will decrease the amounts of millennial banking customers' intention 0.130 point.

Table 2: Result of Multiple Regression Analysis

Independent Variables	Standardized Coefficient (β)	Std. Error	t-value	Sig.
Dummy Gender	-0.050	0.269	-1.457	0.147
Performance Expectancy	0.243	0.073	4.480	0.000
Effort Expectancy	-0.130	0.089	-1.927	0.055
Social Influence	0.049	0.050	1.103	0.271
Facilitating Condition	-0.067	0.082	-1.072	0.285
Innovativeness	0.269	0.068	4.871	0.000
Trust	0.160	0.078	2.537	0.012
Security	0.452	0.068	7.352	0.000
Intercept (β_0)	1.930			
F-Value	88.287			
R-Square	0.758			
Sample (n)	234			
Significant Level (α)	0.000			

Source: Computed by Author (2020)

The value of β_4 = 0.049, it means every increase in social influence as much as one point will increase the amounts of millennial banking customers' intention 0.049 point. The value of β_5 = -0.067, means every increase in facilitating condition as much as one point will decrease the amounts of millennial banking customers' intention 0.067 point. The value of β_6 = 0.269, means every increase in innovativeness as much as one point will decrease the amounts of millennial banking customers' intention 0.269 point. The value of β_7 = 0.160, means every increase in trust as much as one point will decrease the amounts of millennial banking customers' intention 0.160 point. The value of β_8 = 0.452, means every increase in security as much as one point will decrease the amounts of millennial banking customers' intention 0.452 point.

Simultaneously, based on significant level (α) shows that the p-value of α is 0,000 < 0.05. It could be concluded that independent variables which are performance expectancy, effort expectancy, social influence, facilitating condition, innovativeness, trust and security provide significant effects on dependent variable millennial banking customer's intention to use digital banking. All independent variables used can explain variation of their dependent variable as big as 75.8 percent which can be known from R-square value. Whereas, the remaining as big as 24.2 percent is explained by other variables outside the model.

Based on individual test of β_1, it is known that p-value = 0.147 > 0.05 then referring to hypothesis H0: $\beta_1 = 0$ and H1: $\beta_1 \neq 0$ is decided that H0 is accepted or in other words there is no significant differences in millennial banking customer's intention between male banking customers and female banking customers. The results of this study support research conducted by Afandi (2020), this study states that there is no significant difference in intention between millennial banking customers who are male and female to use Fintech Landing services.

The individual test of β_2 show that p-value = 0.000 > 0.05 then referring to hypothesis H0: $\beta_2 = 0$ and H1: $\beta_2 \neq 0$ is decided that H0 is rejected or in other words there is a significant effects of performance expectancy on millennial banking customer's intention to use digital baking.

Performance expectancy is a construct aimed at measuring the extent to which the use of technology will benefit users in carrying out certain activities (Venkatesh et al., 2012). Performance expectancy is the most powerful predictor of predicting user intentions in accepting and using technology (Venkatesh et al. 2003). In the context of digital banking services, including mobile banking (Yu, 2012), online banking and internet banking (Alalwan, Dwivedi, Rana, and Algharabat, 2018), mobile payment (Slade et al., 2015), payment bank (Gupta, Manrai, and Goel, 2019), performance expectancy is determined as a significant factor in customers' intention to accept and use the service.

The result of individual test of β_3 show that p-value = 0.055 > 0.05 then referring to hypothesis H0: $\beta_3 = 0$ and H1: $\beta_3 \neq 0$ is decided that H0 is accepted or in other words there is no significant effects of effort expectancy on millennial banking customer's intention to use digital baking. According to Venkatesh et al. (2003), effort expectancy is associated with the level of ease for users in using a technology. In other words, in the context of banking customers, effort expectancy is related to the level of customer convenience in using digital banking services. Therefore, this construct is related to the perceived ease of use in the technology acceptance model (TAM) developed by Davis (1989).
However, this study empirically found that there is no significant effects of effort expectancy on millennial banking customer's intention to use digital baking. The result in accordance with study conducted by Yu (2012). The reason is that mobile technology has advanced rapidly and the convergence of such technologies and financial services has evolved over time. As a result, consumers have rich experience using mobile phones, the internet and also already have experience with electronic banking services so they are familiar with digital banking.

The value of β_4 show that p-value = 0.271 > 0.05 then referring to hypothesis H0: $\beta_4 = 0$ and H1: $\beta_4 \neq 0$ is decided that H0 is accepted or in other words there is no significant effects of social influence on millennial banking customer's intention to use digital baking. Social influence is defined as the extent to which an individual views that important people around him believe that the individual must use existing technology (Venkatesh et al., 2003). In other words, information and confidence provided by people around the customer could influence the awareness and intention of banking customers to use digital banking services. The result of this study show that social influence does not significantly effect user intentions to use digital banking in accordance with research conducted by Alalwan et al. (2018a) and Mehri et al. (2019).

The individual test of β_5 shows that p-value = 0.285 > 0.05 then refers to hypothesis H0: $\beta_5 = 0$ and H1: $\beta_5 \neq 0$ decided that H0 is accepted or in other words there is no significant effects of facilitating condition on millennial banking customers' intention to use digital baking. According to Venkatesh et al. (2003), facilitating condition is defined as the condition of the availability of technical infrastructure that facilitates individuals in supporting the use of a technology. Facilitating conditions refer to customer perceptions about the resources and facilities available in receiving and using a technology (Vankatesh et al, 2012). However, the result of this study show that facilitating did not play a salient role in affecting the millennial banking customers' intention to use digital baking. This results are consistent with the work of Arenas, Peral, and Ramón (2015).

The result of individual test of β_6 shows that p-value = 0.000 < 0.05 then refers to hypothesis H0: $\beta_6 = 0$ and H1: $\beta_6 \neq 0$ decided that H0 is rejected or in other words there is a significant effects of innovativeness on millennial banking customers' intention to use digital baking. According to Hirschman (1980), innovativeness is defined as the extent to which banking customers are open to new experiences and trying new technologies in this case digital banking services, as an expression of trends towards innovation and novelty. The result of this study show that innovativeness play a salient role in affecting the millennial banking customers' intention to use digital baking. This results are consistent with the work of Slade et al. (2015) and Alalwan, Baabdullah, Rana, Tamilmani, and Dwivedi (2018).

The value of β_7 shows that p-value = 0.012 < 0.05 then refers to hypothesis H0: $\beta_7 = 0$ and H1: $\beta_7 \neq$

0 decided that H0 is rejected or in other words there is a significant effects of trust on millennial banking customers' intention to use digital baking. According to Giovanis et al. (2018), trust refers to the assumption or belief of a potential user that a service provider will fulfill its obligations. In the context of digital trust banking services is a vital variable in the acceptance and use of technology. Trust is needed to reduce the uncertainty of financial transactions so that banking customers are motivated to use digital banking services. This results are consistent with the work of Alalwan et al. (2018b), Oliveira et al. (2014), Merhi et al. (2019).

The individual test of β_8 shows that p-value = 0.000 < 0.05 then refers to hypothesis H0: $\beta_8 = 0$ and H1: $\beta_8 \neq 0$ decided that H0 is rejected or in other words there is a significant effects of security on millennial banking customers' intention to use digital baking. Feeling safe in conducting financial transactions digitally is important to minimize concerns about the use of technology in banking services (Salisbury, Pearson, Pearson, and Miller, 2001). The higher the level of security provided, the higher the user's intention to accept and use a technology. This results are consistent with the work of Merhi et al. (2019) and Oliveira et al. (2014)

Conclusion

The extended UTAUT with innovativeness, trust and security framework has ability to explain variation of the intention of millennial banking customers to use digital banking as big as 75.8 percent, whereas, the remaining as big as 24.2 percent is explained other variables outside the model. The result of this study also show that performance expectancy, innovativeness, trust and security provide significant effects on dependent variable millennial banking customers' intention to use digital banking. However, gender differences, effort expectancy, social influence and facilitating condition did not play salient role in affecting the millennial banking customers' intention to use digital baking. independent variables the performance expectancy, effort expectancy, social influence, facilitating condition, innovativeness, trust and security provide significant effects on dependent variable millennial banking customers' intention to use digital banking.

This study has several implications which could be reflection to the banking industry, both conventional banking and Islamic banking, by becoming consideration develops strategies to dealing with customers' behavior patterns in using financial services and in facing competition with other financial service providers such as fintech. So that the financial industry is able to attract millennial banking customers to use digital banking services. As for the regulator in this case the Financial Services Authority, is expected to be a consideration in formulating policies for the banking industry in the face of competition with other financial service providers. In addition, this research has limitations which the framework used in this research was first UTAUT1, therefore, on the future research is suggested to used UTAUT2 that developed by Venkatesh et al. (2012) and try other data analysis technique.

Assessing Relation Between The Sukuk Market And Islamic Banks To Strengthen The Islamic Financial System: Evidence In Indonesia

Moh. Herman Eko SANTOSO
Universitas Indonesia, Jakarta-Indonesia, santoso.mhe@gmail.com

Abdul MUTA'ALI
Universitas Indonesia, Jakarta-Indonesia, moetaalingua@gmail.com

Abstract

If the company needs source of funding by staying compliant with Islamic law, the options available are taking financing in Islamic banks or by issuing sukuk. Both financial instruments are sources of Islamic funding th at are currently growing and being widely studied by researchers. Along with its development the question arises how the existence of Islamic banks whose main business is in the financing sector with the continued growth of sukuk issued by corporations. This study examines the relationship between these two Islamic funding instruments by examining the impact of the growth of corporate sukuk on the ratio of Islamic banking in Indonesia. This research uses secondary data of monthly time series sourced from the Indonesian Financial authority publication report. Testing data in this study uses quantitative methods with the Vector Auto Regression (VAR) model and the Granger Causality Test. This study also uses Impulse Response Function (IRF) and Variance Decomposition (VD) for further analysis. The results of this study indicate that the growth of the corporate sukuk market has a relationship with the ratio of Islamic banking. The increase in the volume of outstanding sukuk has a positive effect on Islamic bank CAR, but has a negative effect on Islamic bank FDR. While sukuk yield variables produce a positive relationship with Islamic bank FDR but have a negative relationship with Islamic bank CAR. So that the growth of corporate sukuk is relevant to be considered as an exogenous factor affecting the ratio of Islamic banking in Indonesia.

Keywords: Sukuk Growth, Islamic Bank, Ratio, Vector Auto Regression

Introduction

Capital Adequacy Ratio (CAR) is one of the main assessment components used by regulators as a buffer against credit risk faced by banks. Based on Bank Indonesia Regulation Number: 13/1 / PBI / 2011 and Regulation of the Financial Services Authority Number 4 /POJK.03/2016 Concerning the Rating of Commercial Banks, banks are required to conduct individual Bank Soundness assessments using a risk-based approach Bank Rating) with the scope of the assessment of factors: risk profile; Good Corporate Governance; earnings; and capital. According to Wibowo and Syaichu (2013) CAR can increase customer confidence in banks, as well as being the last reserve to protect banks against the risk of any risky productive assets. A high CAR value will provide the bank's ability to finance operational activities so that it can contribute to increasing profitability.

Based on research Nuviyanti and Anggono (2014) states that profitability ratios namely Return on Equity and Return on Assets are the two variables that significantly influence the CAR in commercial banks, then (Jaara *et al.*, 2017) found that bank size, leverage, loan loss reserve, net interest margin, and loan asset ratio have a significant influence on the CAR in banks. While the results of the study (Abusharba *et al.*, 2013); (Andhika and Suprayogi, 2017) show that profitability ratios (ROA and ROE), liquidity (FDR), and problematic financing (NPF) have a significant relationship with CAR at Islamic commercial banks (BUS) in Indonesia. Furthermore, the results of the study Almanaseer and AlSlehat (2016) show that Murabahah (Cost plus), Mudharaba (Profit sharing) and Bai Ajil (deferred sale) financing have an impact on the profitability of the Islamic banking sector.

Based on Sharia Banking Statistics reports issued by the Financial Services Authority of the Republic of Indonesia (OJK), it shows a positive trend in the development of Islamic banking CAR in Indonesia for the past 7 years. The increase in the value of the CAR ratio of Islamic banks indicates the performance of Indonesian Islamic banking which is also getting better. Growth can also be seen with an increase in the value of Islamic banking assets that continue to increase. Recorded in June 2019 Islamic banking assets in Indonesia amounted to IDR 499 trillion, the value is equivalent to 5.95% compared to the total assets of the Indonesian Islamic financial industry. With this value, it placed the Islamic banking in second place after the Islamic capital market sector which contributed 15.49% compared to the total Islamic financial assets in Indonesia. Sharia capital market assets include state sukuk, corporate sukuk and sharia mutual funds.

Indonesia's Islamic capital market sector has grown and developed in the last decade, especially corporate sukuk. Sukuk was first issued by Indosat in 2002, based on the report of OJK there is currently no 145 Sukuk circulating in the Indonesian market with a total value circulating RP30 trillion. In the future, corporate sukuk is projected to continue to grow in line with the government's seriousness through the policies contained in the 2019-2024 Sharia Economics Masterplan for Indonesia to support and encourage efforts to develop corporate sukuk as an alternative source of financing.

Sukuk can be an alternative source of funding for the government and corporation both for general financing and financing certain investment activities or projects (Huda and dkk, 2017). So that the Islamic financial industry provides 2 types of funding instruments that can be selected by companies / corporations in meeting the needs of providing funds, namely through financing in Islamic banking or through the issuance of sukuk. In a study conducted by Mimouni, et al., (2019) on banks and markets it was mentioned that the crisis had a bad impact on lending or in other words that the crisis had the side effect of increasing the potential risk to banks. But on the other hand Sukuk is not affected by the global crisis shocks. Even in some developing countries, after the 2008 global crisis financing through bonds has relatively increased faster than bank financing. Other research conducted by Smaoui, et al., (2017) states that the relationship between sukuk and Islamic bank financing is a substitute. Which means that sukuk growth will likely replace the existence of Islamic bank financing as an instrument providing funding in the Islamic financial system.

This is the basis for examining the impact of the growth of corporate sukuk on the CAR ratio level in Islamic banking in Indonesia. Does the growth of corporate sukuk have a negative or positive effect on the level of CAR in Islamic banking in Indonesia. In addition to capital, liquidity ratios are also calculated in this study taking into account that bank capital and liquidity are needed to maintain bank loans, with capital having a significant positive effect on loans after banks maintain sufficient liquid funds (Thornton and Tommaso, 2019). In addition, bank regulators have understood the importance of adequate liquidity funding and bank capital. Thus, they introduced regulations that obliged banks to maintain adequate liquidity and capital (Dahir *et al.*, 2019). It is hoped that the results of this study will be beneficial for regulators and related parties in determining the right policies to stimulate the growth of the sukuk market while at the same time minimizing the impact caused by the growth of these sukuk on Islamic banking.

Islamic Banking

According to Ayub (2007) and Abdul-Majid, Falahaty and Jusoh (2017) Islamic banking is different from conventional banks, especially in the prohibition of usury, interest-based transactions, gharar, prohibitions in Islamic Sharia, and other unethical practices and to participate in achieving the objectives of the Islamic Economy . Ascarya and Yumanita (2005) defines a Islamic Bank is a bank that conducts business activities based on Sharia principles, namely rules of agreement based on Islamic law between banks and other parties for depositing funds and / or financing business activities, or other activities that are declared in accordance with Sharia.

In its current and future business activities, Islamic banks have the potential to be exposed to risks along with the increase in risk exposures in line with the ever-increasing product and service

developments. So that in the end will affect the soundness of the bank. Through Bank Indonesia Regulation Number: 9/1 / PBI / 2007 Concerning the Rating System for Commercial Banks Based on Islamic Principles, regulators stipulate Islamic Commercial Banks are required to conduct an assessment of bank soundness, which includes the following factors: Capital; Asset quality; Profitability; Liquidity; Sensitivity to market risk, and Management.

Bank Capital

In a banking institution, every aspect of its activities is closely correlated with the availability of bank capital (Raluca, 2011). The provision of a minimum capital ratio is useful to reduce the possibility of failures and systemic risks that endanger liquidity, monetary policy, financial market stability and economic stability (Abou-El-Sood (2016); Nguyen, Gan and Li (2019); Baldwin, Alhalboni and Helmi (2019)) . In addition, bank capital is also an indicator to determine their ability to provide loans (Kick, Malinkovich and Merkl (2020); Dahir, et al., (2019)).

The Islamic Financial Services Board (IFSB) is an equivalent committee to the Basel committee for Islamic finance that is responsible for setting regulatory standards equivalent to Basel standards. Based on IFSB (2013) the total capital required for Institutions offering Islamic Financial Services (IIFS) is the amount of Tier 1 and Tier 2 capital. For Islamic banking, capital is influenced by bank size factors, bank deposit structure, bank competition, and deposit insurance (Smaoui, Salah and Diallo, 2019).

Bank Liquidity

Liquidity for the banking sector is related to solvency. Banks convert liquid liabilities (deposits) into loans. Liquidity shows the ability of banks to meet obligations, repay deposits, and represent the ability to repay their investment and loan portfolios. Banks are said to have an adequate level of liquidity when they can increase the funds needed by selling assets at reasonable prices (Jaara *et al.*, 2017).

According to Dabiri, et al., (2017) liquidity and profitability in the financial sector plays an important role, liquidity is needed to meet the obligations of its creditors. Thus, financial institutions need to maintain a large amount of their assets in cash to meet their short-term obligations. Liquidity ratios measure liquid assets available in banks relative to total assets. The higher the liquid assets, the lower the risk of illiquid. Unemployed liquidity is also undesirable because they produce very little or no return (Jalil and Biswas, 2018).

Sukuk

The word sukuk is a plural form for certificates (sakk) of ownership of certain assets given by the borrower to the lender as proof of ownership. Therefore, Sukuk is a debt instrument that requires the creation of assets owned proportionally by lenders and fund providers (Safari, Ariff and Mohamad, 2014). Sukuk differs from conventional bonds because sukuk represents an inseparable part of ownership of assets, usufructs, projects and services. Sukuk also shows the partnership relationship between the issuer and the investor in a business or joint venture project. Meanwhile, conventional bonds are debt obligations, which can be guaranteed with certain basic assets or without collateral in the form of a promise to pay. Thus, Sukuk holders have a part of the underlying assets in each sukuk transaction depending on the level of investment participation (Alam, et al., (2013); Zakaria, et al., (2012)).

In sukuk classification, Safari, Ariff and Mohamad, (2014) classifies sukuk by issuer into 3, namely:

1. Sukuk issued by the government in the category of risk free
2. Sukuk issued by SPC (Special Purpose Company)
3. Sukuk issued by private companies or institutions with a high risk category.

Table 1: Previous Research Relevant

Author	Year	Invention
Houcem Smaoui, Karim Mimouni & Akram Temimi	(2020)	The development of the sukuk market has a negative impact on the risk of bankruptcy in Islamic Banking, while the risk of Conventional Bank remains unchanged.
Houcem Smaoui, Hatem Ghouma	(2019)	The development of the sukuk market has an adverse effect on the capital of Islamic banks. Sukuk market development has stimulated competition between Islamic Bank, and encourages maintaining lower capital ratio.
Karim Mimouni, Houcem Smaoui, Akram Temimi, Moh'd Al-Azzam	(2019)	Sukuk issuance has a negative impact on bank performance as measured using NIM / NPM. Sukuk issuance is a substitute for the banking system. Sukuk has a negative impact on Islamic Bank's performance while Conventional Bank is not affected.
Houcem Smaoui, Karim Mimouni, & Akram Temimi	(2017)	Sukuk and Islamic bank financing are substitutes. A well-developed banking sector is a barrier to the development of Sukuk market.

Reserch Method

This study uses time series secondary data from 2016 to 2019. Data sourced from OJK Report and from the Indonesia Bond Pricing Agency (IBPA) Report. The variables used in this study use the dependent variable in the form of Capital Adequacy Ratio and Financing to Deposit Ratio, while the independent variable uses corporate sukuk outstanding and corporate sukuk yields.

Table 2: Variable Description

Category	Variable Name	Symbol
Dependent	CAR	CAR
	FDR	FDR
Independent	Corporate Sukuk Outstanding	OUTS
	Corporate Sukuk Yield	YIELD

Data analysis uses the approach of Vector Auto Regression approach. The VAR model is a model for two or more time series in which each variable is modeled as a linear function of the past values of all variables, plus a disturbance that has zero means given all the past values of the observed variables (Wooldridge, 2013). The VAR model is used for data variables that are not stationary at the level but are stationary at first differences and no cointegration is found on the variables (Gujarati and Porter, 2009). The IRF approach is also used to assess the response of the dependent variable to shock by the independent variable. Meanwhile VD provides the proportion of movement in the dependent variable caused by shocks 'on the variable itself' compared to shocks with other variables (Mitsaliyandito, Arundina and Kasri, 2017).

Empirical Results

Augmented Dickey Fuller (ADF). If the t-statistic ADF value is smaller than the critical Mc Kinnon (1, 5, 10 percent), then H0 is rejected or in other words, the data is stationary. The test results are as follows:

Table 3: Results of Stationary Test

	Variable	Level		First Difference	
		ADF Value	Critical Value (5%)	ADF Value	Critical Value (5%)
CAR	CAR	-1.014681	-2.935001	-6.069738	-2.936942
	OUTS	-0.208209	-2.935001	-6.342352	-2.936942
	YIELD	-2.127815	-2.935001	-5.463968	-2.936942
FDR	FDR	-1.438943	-2.935001	-7.738082	-2.936942
	OUTS	-0.208209	-2.935001	-6.342352	-2.936942
	YIELD	-2.127815	-2.935001	-5.463968	-2.936942

Source: Data processed (2020)

Tables 3 show that the dependent variables CAR and FDR are not stationary at the level, but at the first difference level all variables have been stationary, so that further testing can be done that is determining the optimum lag length. The optimum lag value that can be used, namely from Akaike Information Criterion (AIC) and Schwarz Information Criterion (SIC). This research uses optimal lag determination by looking at the minimum value from the SIC. The test results are as follows:

Table 4: Results of Optimal Lag Determination

Lag	CAR		FDR	
	Value AIC	Value SC	Value AIC	Value SC
0	-5.446073	-5.314113	-7.227618	-7.095658
1	**-11.06596***	**-10.53812***	-12.52334	**-11.99550***

Source: Data processed (2020)

In table 4, the optimum lag length value of the two dependent variables is obtained in lag 1 which will be used to estimate VAR in the next step. Cointegration relationships between variables will also be the basis for determining the estimation model that will be used. If there is no cointegration model then the VAR model is more suitable for use (Afandi and Amin, 2019). The cointegration test results are as follows:

Table 5: Results of Cointegration Test

	Hypothesized No. of CE(s)	Eigenvalue	Trace Statistic	0.05 Critical Value
CAR	None	0.229809	16.62759	29.79707
	At most 1	0.121633	6.182939	15.49471
	At most 2	0.024575	0.995291	3.841466
FDR	None	0.145771	11.05025	29.79707
	At most 1	0.082695	4.748009	15.49471
	At most 2	0.031866	1.295407	3.841466

Source: Data processed (2020)

Tables 5 show the trace statistic value is smaller than the critical value of 0.05 or that the two dependent variables have no cointegration relationship. Then the granger causality test stage has been carried out, with the results shown in the following table:

Table 6: Results of Granger Causality Test

	Null Hypothesis:	Obs.	F-Statistic	Prob.
CAR	LOGOUTS does not Granger Cause LOGCAR LOGCAR does not Granger Cause LOGOUTS	41	0.08828 3.76838	0.7680 0.0597
	LOGYIELD does not Granger Cause LOGCAR LOGCAR does not Granger Cause LOGYIELD	41	0.21667 0.10760	0.6442 0.7447
	LOGYIELD does not Granger Cause LOGOUTS LOGOUTS does not Granger Cause LOGYIELD	41	0.37259 0.23983	0.5452 0.6271
FDR	LOGOUTS does not Granger Cause LOGFDR LOGFDR does not Granger Cause LOGOUTS	41	0.82429 0.25232	0.3697 0.6183
	LOGYIELD does not Granger Cause LOGFDR LOGFDR does not Granger Cause LOGYIELD	41	0.52809 0.00339	0.4719 0.9539
	LOGYIELD does not Granger Cause LOGOUTS LOGOUTS does not Granger Cause LOGYIELD	41	0.37259 0.23983	0.5452 0.6271

Source: Data processed (2020)

Ho in the Granger causality test is that there is no causality relationship between the two variables tested. The criterion for starting Ho is if the F-Statistic value is greater than the critical value of 10%, or it can also be used the probability is smaller than the critical value of 0.05. The test results show, statistically the independent variables each do not significantly affect the two dependent variables or vice versa. Furthermore, the stability test results are shown in the following table:

Table 7: Results of VAR Stability Test

CAR		FDR	
Root	**Modulus**	**Root**	**Modulus**
0.975528	0.975528	0.983909	0.983909
0.810662 - 0.060417i	0.812910	0.817712 - 0.113771i	0.825589
0.810662 + 0.060417i	0.812910	0.817712 + 0.113771i	0.825589

Source: Data processed (2020)

The evaluation criteria in this stability test are modulus value smaller than 1 (one). Based on Table 7, it can be concluded that the model used in this study is valid. So that the analysis of the IRF and VD output used in this study is valid.

Results of VAR Estimation Test

This study uses significance with a 95% confidence value, that is the t-statistic value for the critical value of 5% which has a meaning that is, H0 is said to be rejected if the absolute value of t-statistic is greater than the t-ADF value, then the variable is declared to have a significant effect. The test results are as follows:

Table 8: Results of VAR Test for CAR

Variable	Coefficient	T- Statistics
CAR(-1)	0.950385	9.69464
OUTS(-1)	0.004259	0.10465
YIELD(-1)	-0.029428	-0.36838
C	0.201641	0.96342
R-squared	0.938518	
Adj. R-squared	0.933533	

Source: Data processed (2020)

The estimation results of the VAR model state that, if an increase in outstanding corporate sukuk has a positive effect on Islamic bank CAR by 0.004%. Meanwhile, if corporate sukuk yields rise, the CAR of Islamic banks will decrease by -0.029%. Adj. R-squared states that in this equation the CAR variable can be explained by the variable outstanding and corporate sukuk yield of 93.35%.

Table 9: Results of VAR Test for FDR

Variable	Coefficient	T- Statistics
FDR(-1)	0.793433	7.53752
OUTS(-1)	-0.019454	-1.32650
YIELD(-1)	0.047709	1.20992
C	0.855644	1.87854
R-squared	0.915331	
Adj. R-squared	0.908466	

Source: Data processed (2020)

The estimation results of the VAR model in Table 9 mean that, an increase in outstanding corporate sukuk negatively affects the FDR value of Islamic banks by -0.019%. Meanwhile, if the yield of corporate sukuk rises, FDR of Islamic banks will also increase by 0.048%. The FDR variable in the equation can be explained by the outstanding variable and corporate sukuk yield of 90.85% according to the value Adj. R-squared.

Results of Impulse Response Function Analysis

IRF analysis will explain the impact of a shock on one variable on another. The IRF analysis also functions to see how long the influence lasts. The horizontal axis is the period in months, while the vertical axis shows the response value in percentages.

Source: Data processed (2020)

Picture 1: Results of IRF Output for CAR

The graph above shows the CAR's response to the shock of the Outstanding variable which showed a positive trend (+) for 4 months and then returned to its equilibrium point. Whereas CAR responds to the variable yield shock with a downward trend entering the 3rd period.

Source: Data processed (2020)

Picture 2: Results of IRF Output for FDR

The graph above shows the response of FDR to the shock variable Outstanding and yield. This means that when there is a shock on the outstanding sukuk or corporate sukuk yield, it will take around 3 months for the FDR to return to its equilibrium point.

Results of Analysis of Variance Decomposition

VD Analysis aims to measure the amount of contribution or composition of the influence of each independent variable on the dependent variable.

Table 10: Results of VD Output for CAR

Variance Decomposition of LOGCAR:				
Period	S.E.	LOGCAR	LOGOUTS	LOGYIELD
1	0.030851	100.0000	0.000000	0.000000
2	0.042417	99.95639	0.000662	0.042948
3	0.050505	99.87461	0.005139	0.120247
4	0.056713	99.76763	0.017281	0.215092
5	0.061695	99.64307	0.040284	0.316645
6	0.065805	99.50575	0.076166	0.418083
7	0.069264	99.35901	0.125702	0.515287
8	0.072221	99.20547	0.188578	0.605953

Source: Data processed (2020)

The results of the VD Analysis output show that the yield of the corparate sukuk is the more dominant variable contributing to fluctuations in CAR and FDR.

Effect of Sukuk on Islamic Bank Capital

A series of tests and analyzes have been carried out, and we have arrived at the results that the growth of corporate sukuk through an outstanding increase has a positive relationship with the capital of Islamic banks in Indonesia. The opposite result was shown by sukuk yield which had a negative impact on Islamic banks CAR, this result was also supported by previous research conducted by Smaoui, Mimouni and Temimi (2020). In the results of his research it was said that the development of the sukuk market had an adverse effect on the capital of Islamic banks, with the explanation that the development of the sukuk market would increase competition between Islamic banks by forcing them to increase their portfolio asset risk by reducing their capital ratios to the minimum level needed. This is their effort to get higher profit margins.

Effect of Sukuk on Islamic Bank Liquidity

Based on this research it turns out that the sukuk market growth represented by outstanding corporate sukuk turns out to have a negative impact on the FDR of Islamic banks in Indonesia. While sukuk yields have a positive relationship with FDR of Islamic banks. The results of a study conducted by Braima (2017) which states that the ratio of Financing to deposits shows the ability of banks to support the growth of their financing business with owned savings funds. This higher ratio means that there is less savings left to fund additional funding, implying lower liquidity.

Conclusion

Sukuk and Islamic banks are part of the Islamic financial system. For Islamic banks, financing is the main business source of income for the sustainability of the bank. Financing expansion undertaken by Islamic banks must continue to prioritize risk mitigation that may be faced. The results of this study indicate significant findings for the development of the Islamic financial market in Indonesia. The growth of the corporate sukuk market turns out to have an influence on the Islamic banking ratio. The increasing outstanding or high volume of corporate sukuk issuance turns out to have a positive relationship with the capital ratio of Islamic banks, but on the other hand it produces a negative relationship with the liquidity ratio of Islamic banks. Meanwhile, the improved performance of the corporate sukuk market, which was marked by an increase in sukuk yields, turned out to have a negative relationship with the capital of Islamic banks as well as having a positive impact on the

liquidity ratio of Islamic banks in Indonesia. This result can be a reference that should be considered as an exogenous factor that can influence the ratio of Islamic banking.

Our findings can illustrate that there is indeed a potential that Islamic sukuk growth and banking are not in line. There is a potential adverse relationship due to the growth of corporate sukuk towards Islamic banking ratio in Indonesia. This is important for the authorities and decision makers to formulate policies in strengthening the Islamic capital market and Islamic banking together with the aim of creating a strong Islamic financial system. The potential for further research is very open to digging deeper into why and how this can happen and projecting future conditions will be like what.

Acknowledgment

This research was received financial support from Universitas Indonesia through Publikasi Terindeks Internasional (PUTI) Grant 2020.

Abstract

Financing of SME's has been a centre of debate among the academia as well as policymakers for almost a century. In general, financing involves risks; however, the level of risk associated with mature firms is low compared to business start-ups. Therefore, to attract more investors, these start-ups have to pay higher bank rates than established firms. This research explores the importance of crowdfunding as a new form of financing for traditional ventures, and how it has become a unique and different type of financing compared to the traditional form of financing. This study describes different kinds and prototypes of crowdfunding that currently exists in society, and it illustrates the overall market scenario of crowdfunding in Pakistan. This article examined the Pakistani crowdfunding market with the mainstream market. The analysis highlights that awareness among the community about crowdfunding in Pakistan is getting popular and positive results are numerous. However, despite being a new concept, its market size is comparatively smaller than the venture capital market and the banking industry.

Keywords: Entrepreneurship, Crowdfunding, Financing, SMES, Venture Capital

Introduction

Policymakers and academia have been debating rigorously about entrepreneurial venture financing for over half of the past century (Bolton, 1981; Gray and Stanworth, 1991). Axiomatically, entrepreneurial ventures have encountered persistent difficulties in securing the monetary means that are obligatory for potential expansion and development. At the start of 20th century, different strategies were initiated by governments around the world to stimulate both the quality and the size of financing that was conveniently accessible for the small-scale entrepreneurial ventures (Silver et al., 2016; Ponikvar et al., 2017).

In the 1980s and 1990s, the ICT-sector start-ups exclusively enjoyed the easy availability of a large quality of venture capital compared to other sectors. After March 2000, the interest of venture capitalists drastically dropped in the start-ups and growing entrepreneurial firms in most of the industrialized countries due to the dot-com crash (Ponikvar et al., 2017). Over the past decade, a strong upswing has been experienced by the informal venture capital in form of business angels, whereas downsizing has been noticed in formal venture capital markets (Thompson et al., 2009).

The catalyst reason behind the increase in the popularity of informal venture capital is due to the strong dependency of the entrepreneurial ventures on financial institutions loans and overdrafts (Berger and Black, 2011; Hall, 2010). The only source of financing for the small-scale firms in Europe, Asia, and rest of the world are financial institutions. Due to the recent financial crisis, severe detrimental effects have been noticed especially at the time when these firms try to expand (Schizas et al., 2012). Therefore, an emerging concept in comparison to the traditional source of financing is evolved called crowdfunding. According to Asia Institute of Finance (2017) "Crowdfunding is expected to pick up pace in the near future as a critical source of alternative financing for micro, small and medium enterprises (SMEs)".

Keeping in mind the problem of entrepreneurial ventures that seek outside capital, it is the aim of this research to study the role and importance of crowdfunding and how it's become unique as well as different from traditional sources of financing. We presented the current status of crowdfunding market globally, which was more specific in Pakistan, and highlighted crowdfunding platforms areas of focus, revenue earning models, and key factors to develop a crowdfunding market. A brief comparative analysis of the Pakistan crowdfunding market was made with another mainstream market i.e. China. It also discusses two prominent platforms, their vision, objectives, and overall functions. The study concludes by presenting the future outlook of the crowdfunding market in Pakistan.

Role of Financing in Entrepreneurial Ventures

The role of the principal-agent theory reflects a theoretical understanding of departure at the point of conducting research on the financing of SMEs (Jensen and Meckling, 1976). The core hurdle for the SMEs looking for financing is the information asymmetric problem, which exist among financiers and entrepreneurs (Hall 2000; Hsu, 2004). Pragmatically, it is usually apparent that financers feel reluctant while investing at the nascent stages of financing due to the high level of risk related to the firm. Such levels of risk exist due to the lack of information sharing, and it is hard to accurately predict the firm's future market potential. To overcome the problem of moral hazards and information asymmetry, the financer's and entrepreneurs develop contracts and improve the frequency of interactions among each other (Shane and Stuart, 2002; Mason and Harrison, 2000).

Another important feature of financing in the SMEs is the pecking order theory or the pecking order framework (Myers and Majluf, 1984). This theory states that entrepreneurs tend to select that particular types of financing that empowers them to preserve the control. For example, financial institution loans are desired over private equity loans (de Jong et al., 2011; Howorth, 2001; Berggren et al., 2000). Control aversion is the basic concept of this theory, which means entrepreneur's speculate that they are losing their control to external factors (Sætre, 2003; Lindström and Olofsson, 2001). The primary factors were discussed using the pecking order theory, which determines an entrepreneur's financial behavior. According to this theory, "the entrepreneurs select to nurture more slowly- or not at all- to avoid the thinking that they are losing control" (Howorth, 2001).

The problem of information asymmetry becomes more severe at the initial phases of a firm's development due to the encountering perennial problems in access of outside financing. As a result, they lean more on alternative sources of capital (Table 1). Insider finance becomes the sole source of financing at current stage (Berger and Udell, 1998; Cassar, 2004). Insider finance includes the founder's own savings and other connected personnel, such as family, friends, and fools traditionally referred to as 3F (Cliff Ennico, 2002; Bygrave et al., 2003). Owner's personal saving includes property, credit cards, and homes, while finance from 3Fs includes gifts, loans, or firm equity ownership (Cliff Ennico, 2002).

Table 1: Sources of capital for entrepreneurial ventures

Origin	Explanation	Financing category
Owner	Owner's own savings	Equity
3F	Family, friends, and fools	Equity or short term debt
Business angels	Business angel invested in firm	Equity
Government allowance	Accept allowances and subsidies	Short-medium term grants
Factoring	Received cash through the selling of invoices	Short term debt
Financial institutions	Banks provided loan facility	Medium-long term debt
Purchase through hire and leasing	purchase assets through instalments	Medium-term deferred payment
Organizations credit card	On short term basis providing the cash credits facility	Short term debt
Suppliers	Purchasing the raw material on credit	Short term debt
Venture capital firms	Investment by the VC firms in a newly develop firm	Equity

A Background and Overview of Crowdfunding

Crowdfunding started mass targeting in 2006 in the United Kingdom, 2007 in the United States, and in other markets after the global financial crisis in 2008, which included emerging and developing economies (Kirby and Worner, 2014). The global financial crisis caused a lot of damage to the confidence of the financial system, which included the banking sector and as a result, the crowdfunding industry got an opportunity to fill the gap. Since then, crowdfunding has shown accelerated growth in markets across the income range with high demand at both ends of the operation. The number of online platforms raised with a notable rate of 350% worldwide and currently, approximate 2,000 crowdfunding platforms is working online globally (Gałkiewicz and Gałkiewicz, 2018).

Crowdfunding typically describes a system of financing where small volumes of funds are raised from large numbers of individuals or legal entities to support businesses financially, specific projects, individual utilization, or other needs. It bypasses conventional financial mediators and uses online web-based platforms to connect founders with funders. Definitions of crowdfunding may vary, but they often include the following key points: (i) raising funds in small amounts, (ii) from individuals to many, and (iii) uses digital technology. The key out-of-line effect of crowdfunding is that the intermediation from long-established financial institutions is downsized to a minimum as funds are routed directly from funders to founders through a specified platform (Turner et al., 2010).

Crowdfunding is a fairly new concept but has grown substantially over the last few years, which witnessed a whopping growth (UNDP 2017). Just eight years ago, $880 million was reported as the crowdfunding market value in 2010, which depicted a pretty small market with a minimal growth rate. From 2013 to 2014, the industry increased by 167% and reached $16.2 billion. In 2015, the industry maintained at a high growth rate and raised funding that more than doubled, which amounted to $34.4 billion (UNDP 2017; Scott-Briggs Angela, 2016). The crowdfunding market raised a total of $48 billion in 2016, the Asian Pacific (APAC) market is expected to reach $42.39 billion by 2021, and Europe, the Middle East, and Africa (EMEA) are growing at Compound Annual Growth Rate (hereafter CAGR) of 14.70%. According to the Global Crowdfunding Market 2017-2021 report, the crowdfunding market is projected to grow at a CAGR of 17% between the period of 2017-2021, and the estimated value of the industry will be $90-96 billion by 2025 (technavio, 2016; Ali Mohsin, 2018).

The term crowdfunding has appeared as a facilitator for businesses of all kinds and shapes to receive funding by asking the crowd instead of specialized investors and financial institutions (Bouncken et al., 2015; Kleemann et al., 2008).

Crowdfunding Models

The different online crowdfunding platforms usually feature four main categories: donations, rewards, debts, and equity (Kirby and Worner, 2014). Funders commonly select the category that is aligned with their goals based on expected returns.

Table 2: Characteristics of different crowdfunding models

Crowdfunding Model	Business Model	Characteristics	Advantages	Disadvantages
Donation	Donation-based (Philanthropic)	Backers contribute without supposing any financial benefit.	Zero risk factor	Zero guarantees being given to the contributors about the interest deposit.
	Rewards-based	Two kinds of gifts received by the funders in form of thanks given or a sample of the product.	Level of risk is very minimum, but there is no guarantee for any monetary profit.	A small amount of gain is expected but did not obtain any security, and there is no check and balance system.
Investing	Equity-based	A number of shares received by the backers or collects a substantial amount of share from the profit.	It is expected that profit earned from the venture can be shared with the donors. There is a huge potential for monetary gain.	There is a chance of losing the invested capital. At the time of insolvency, the position of the equity holders becomes a subordinate to their creditors.
	Lending-based	Backers obtain a certificate of obligation that remunerates a static interest rate and pay the principal amount on a stated timetable.	Fixed rate of return is pre-decided among creditors and debtors. In the case of insolvency, the equity holders become senior to debt holders.	Subordinates might possibly become a senior creditor. The rate of failure in start-ups becomes higher, which reflects the risk of losing a portion of investment being done as an equity..
	Royalty-based	In comparison to other models, this one is not very popular. Backers obtain a portion in the form of unit trusts.	Profit earnings are limitless, but the rate of earning is pre-decided by the rate of interest.	There is a possibility that the invested amount could be lost. Even though the investment pays a lower amount of earnings than equity investment, that's why such loss of risk is parallel in comparison to an equity investment.

Source: The World Bank (2013).

Investment Stages and Crowdfunding

There are different models presented by different research scholars related to the investment stages of the venture capital and business angels, but the models presented by Tyebjee and Bruno (1984); Fried et al., (1994) and Paul et al., (2007) about investment stages are slightly different as shown in figure (1). According to them, the first stage is the deal origin, which is handled in crowdfunding for the projects that seek funding and use the crowdfunding platform for financial support. In order to attract the potential investors, deal origination is one of the important stages for the financiers, which keeps the equality among the projects, such as how to differentiate good projects from the bad ones.

Screening and due diligence are expected as one of the crucial stages in crowdfunding, because most of the projects that seek the funding are turned down due to the lack of potential. To overcome this issue, crowdfunding does not provide a true and accurate mechanism for this issue in the shape of clear and proper regulations.

In the contracting stage, the investor and investee are much clearer about the terms and conditions of the contract, because information about funding and rewards are clearly stated by the financiers without any negotiations.

Next, managing is considered one of the important stages where investors use their knowledge and networks by making their firms more value added (Politis, 2008). In crowdfunding, this stage does not exist in their true form, because when the founder has received the financial support from the backer then there is no proper interaction between each other.

Finally, in most of the contracts when the financiers will to exit, which is fairly well explained and limited in scope. Once, the financers receive a reward in shape of a product or a certain amount of money at a particular point of time, then contract automatically expires. However, the reward is one of the necessary elements in crowdfunding logic, therefore, some consideration must be given to the investors level of satisfaction by offering different kind of rewards (Silver et al., 2016).

To comprehend crowdfunding under the umbrella of the above investment process, it is evident that crowdfunding provides a very vivid mechanism for managing such stages in the investment process but not for all the stages.

Method

This study is exclusively conceptual, in that it explains theoretical viewpoints that have the latent to highlights the latest developments in entrepreneurial ventures especially in crowdfunding in one of the emerging economy i.e. Pakistan. It is neither a quantitative nor a qualitative analysis or investigation of crowdfunding market; rather, it will establish a strong foundation in developing the crowdfunding market and assist the government in developing the sound policies and practices for this nascent yet emerging stream of investment. Due to the absences of qualitative and mixed-methods design and empirical analysis, it is expected that rigorous propositions and directional hypothesis will be tested by collecting empirical data, which will be grounded in part in the conceptual directions presented in this study.

Crowdfunding in Pakistan

Once Scott Belsky said, "It's not about ideas. It's about making ideas happen." Certainly, owning an idea is a big asset but developing it in a reality is what counts (Ebtihaj, 2017). Pakistan is low-income country but has a tremendous potential for initiating its own digital turnaround that is sustainable. One of the biggest strengths the country is blessed with is a pool of talented, energetic, and competent youth. As per the Higher Education Commission of Pakistan, each year 25k IT graduates become part of the practical world. The boom in IT and telecom sectors embrace digital technology as a powerful tool, which is not only limited to simple communication but sparked as a life-changing catalyst (Khan Rizwan, 2016). The confluence of several enablers, such as increasing internet/smartphone penetration and the snowballing usage of mobile technology for performing everyday functions is expected to digitize the financial services value chain which will cater to the unbanked population which has long been neglected by the financial institutions. In the same scenario, Pakistan, the 6th populous on face of map, is open for innovative penetration. Therefore, innovative technology and business process re-engineering have an opportunity to create solutions, fulfil gaps and succeed (Hussain, 2017).

The young and energetic entrepreneurs initiated new businesses with sparkling ideas but during nascent stages. As there is a high level of risk, entrepreneurs are struggling for the expansion of businesses, because sources of funding are limited. However, various initiatives are being taken by the industry giants, provincial, and federal governments to support young entrepreneurs in their designated area in terms of financial and technical help. Due to strict and vague regulations, it's become tough for the start-ups to grow and expand although governments and financial institutions especially State Bank of Pakistan have started interest-free karobar loan schemes to facilitate these start-ups. In this aspect, crowdfunding evolves as a catalyst that supplements government and financial institution efforts (Khan Rizwan, 2016). Due to the complex mechanisms of equity crowdfunding, reward-based crowdfunding has become popular among the small-scale investors. Two portals emerged as core engines for the entrepreneurs, for example, Kickstarter and Indiegogo, where they can showcase their prototype and unique ideas to compete for funds. The traditional sources of means, such as social media and cellular messages, are still used by most of the entrepreneurs to raise the necessary funding for their projects. Two renowned personalities, Abdul Sattar Edhi and Imran Khan, both adopted crowd-funding by using their personal charisma locally and internationally. Even though financial constraints were there, they acted and adopted more or less in ways acceptable to the state (Ahmad Naveed, 2017). Recently, the American stock index provider classified Pakistan as an emerging market, whereas Morgan Stanley Capital International (hereafter MSCI) announced it as the best performing market in Asia. This type of improvement did not happen overnight. It took a large span of time to bring a lasting change (Ebtihaj, 2017). According to AlliedCrowds statistics Pakistan ranked 22th among the list of crowdfunding in developing countries with an estimated annual sum of $5.4 million (Khan Rizwan, 2016).

Fundraising platforms in Pakistan

Pakistan is a country that has a young population, which two-thirds of its 207 million people are below 30 years old, who are inspired and motivated for change. According to UNDP, 23% of youth are willing to pursue their own businesses in Pakistan, but the prevailing landscape, the requirements, and the procedures hamper the implementation of ideas to materialize (Hussain, 2017). Table 3 shows the list of the top 8 crowdfunding platforms in Pakistan including two of them are honorary members, such as the Edhi Foundation and the Shaukat Khanum Cancer Hospital.

Table 3: Crowdfunding platforms in Pakistan

Name	Sector	Focus area	Nature of platform	Region	URL
Transparent Hands	Healthcare	Basic health facilities	Donation	Domestic/International	https://www.transparenthands.org/

Seedout

Seedout is a crowdfunding platform that was initiated in 2013 in Pakistan. The vision for the platform is to raise funds from a large community to facilitate micro-entrepreneurs. The developer of Seedout argues that the core objective is to alleviate poverty, empower micro- entrepreneurs, uplift the living standards of the entrepreneurs and their families, furnish sustainable business, bring economic stability, and promote education. Entrepreneurs participating in Seedout belong to a low-income class. Seedout purely focusses on charitable based projects. Seedout hosts projects of diverse categories, such as clothing, entertainment, agriculture, food, health, housing, retail, manufacturing, services, transportation, and wholesale. The Seedout team evaluates potential micro-entrepreneur personal information before launching the proposed project for the funding goal. Once the team declares the venture satisfactory, then it develops an entrepreneur profile and launches the project. After that, Seedout asks the potential entrepreneur for a written description and photographs about the

project, which can be furnished if required by the potential contributor. For such activities, Seedout does not charge any fees from the entrepreneurs. Seedout collects contribution from the contributors via two streams, which are donating money to the entrepreneur's project directly or donating money to Seedout. Furthermore, there are three ways that entrepreneurs can collect the contributions, which are charities, *zakat*, and *sadaqah ("Zakat (Arabic) is the taxation of income and wealth of a Muslim, it is a form of obligatory alms-giving and the collected amount is paid to poor Muslims. It is the payment that is made annually under Islamic law on certain kinds of property and is used for charitable and religious purposes, one of the five pillars of Islam" [(Arshad Nadia, 2017)]. "Sadaqah or saddka (Arabic) is an Islamic term that means 'voluntary charity'. This concept encompasses any act of giving out the compassion, love, friendship (fraternity), religious duty or generosity" [(Arshad Nadia, 2017)]).*Donations to Seedout means that contributors assign the responsibility to Seedout to distribute the contributors pool of money where it deems best (Arshad Nadia, 2017; Seedout, 2015).

Once the project successfully achieves its target funding, Seedout provides the necessary training and mentoring sessions for the concerned entrepreneurs before handing over the desired amount. After the initiation of the business, Seedout waits for three months, and afterwards 1% of the donation is returned each month to Seedout. Seedout has an excellent project success rate that ranges from 70-80%. Currently, there are a total of 171 projects worth of $127,776 being floated on Seedout, which 18 are active projects and 153 projects are 100% funded by the contributors (Ahmad Naveed, 2017; Arshad Nadia, 2017). More detailed information about the way Seedout functions can be viewed from their respective website, which is available in Table 2.

Transparent Hands

Transparent Hands (hereafter THs), is a crowdfunding platform that started its operations in 2014 in Pakistan. The aim of the THs is to facilitate Pakistan's underprivileged community by paying the medical bills of patients' who undergo critical surgeries (TransparentHands, 2015). Using a four step process, THs facilitates the patients. In the first step, a contract is signed with the renowned hospitals in Pakistan. In the second step, the THs receive a list of the registered patients recommended by different hospitals, and then they send these patients to those contractual hospitals in-order to verify the patient, prepare a diagnosis report, and develop a medical bill with an estimated cost. After that, THs allocate a unique number to the concerned patient and upload their picture, case history, and other medical treatment information along with the requested amount for the donors through their crowdfunding platform. In the third step, potential donors evaluate the patient's medical credentials and fund the campaign by using a credit card or a bank transfer. In the final step, once the requested amount is raised successfully, THs stops the campaign and transfer the payment to the concerned hospital for the patient's treatment. In order to update all the donors, the recovered patients share their respective success stories along with the necessary documents via the THs web portal (Moin Rameeza, 2015).

From its inception till now, THs have financed more than 264 surgeries and spent $229,000. A total of 35 organizations support THs, and it has 12 medical partners and has organized 19 medical camps. THs recovers their development/service charges by deducting 15% from the total amount of each campaign (TransparentHands, 2015).

The team of the THs argue that it will continue to serve humanity by offering them the best healthcare across the country in addition to its plan to extend humanitarian services, which include human rights and education (Transparent Hands, 2015). More detailed information about the way Transparent Hands functions can be viewed on its website, which is available in Table 2.

A brief comparison between the Pakistani crowdfunding market with the Chinese mainstream market

As previously discussed, the Pakistani crowdfunding market is at the initial stages, and regulatory agencies are working overnight to develop clear and transparent regulations, so that the doors of opportunities will open for the outside investors and entrepreneurs to launch new start-ups and invest in unique and viable projects. In this part of the paper, we compare the Pakistani market with another developing market i.e., China. As per the market analysts, the Chinese crowdfunding market is flourishing phenomenally and witnessed the largest market growth in the world. Since 2007, after the emergences of crowdfunding in the United Kingdom, many would have never thought that China would become the largest market in 10 years. Peer-to-peer lending in China gained popularity in 2011, and the market size reached US $52.44 billion in 2015 (Zhang et al., 2016; Aveni and Jenik, 2017). After one year, the Chinese crowdfunding market far outperformed North America with a threshold of US $100 billion and a total crowdfunded loan volume that amounted to US 36.16 billion (Aveni and Jenik, 2017). The exceptional progress in the industry enriched the access of finance for the potential entrepreneurs and SME's. Figure 2 interprets the growth rate of crowdfunding in China. Furthermore, according to the World Bank report 2013, crowdfunding's potential for the developing world estimates that Chinese crowdfunding market will generate US $50 billion or 52% of the global total in crowdfunding by 2025 (Shira, 2017).

Fig. 2: The Chinese crowdfunding market

Source: (Aveni and Jenik, 2017).

There has been a surge in online crowdfunding platforms in recent years in the country. According to Premier Li Keqiang at a recent meeting of top leaders on education, science, and technology, "New ideas, such as crowdsourcing, will be promoted to bring more social forces into play" (Chinadaily, 2015). By the end of December 2017, the number of domestic crowdfunding platforms totalled 209, which covered 18 provinces and cities. The number of equity crowdfunding platforms were 71, the commodity crowdfunding platforms were 95, the donated crowdfunding platforms were 9, and another 34 were equity + reward multi-mode platforms. By the end of 2017, crowdfunding fund-raising amounted to 58.4 billion yuan (historical accumulated). In the year of 2017, crowdfunding fund-raising amounted to 22.02 billion yuan. The three leading platforms in 2017 were Kaishiba Crowdfunding, Jingdong Crowdfunding, and Taobao Crowdfunding. The amount of funds was 2.9 billion, 1.7 billion and 1.6 billion respectively. Some other crowdfunding platforms also had outstanding performances (JRZJ, 2018). Table 4 shows the list of top crowdfunding platforms in China.

Table 4: Crowdfunding platforms in China

Name	Sector	Focus area	Nature of platform	Region	URL

Source: (JRZJ, 2018).

The industry has experienced tremendous growth especially in P2P lending and crowdfunding. Therefore, the governmental agencies adopted a wait-and-see strategy towards establishing regulations for this nascent industry. From 2007, the government agencies allowed P2P platforms and other online financial companies to execute their operations without setting any legal structure. The self-generated policies and ad-hoc oversight by the local authorities bring the problem of

inconsistencies in most of the platforms functioning in the different parts of the region, which resulted in failures and the emergence of scandals, which include the E'zubao Ponzi scheme. To overcome such inconsistencies, the regulative authorities tightened the policies more in 2015. Figure 3 defines the regulative policies milestone. Such regulative changes make the market more competitive and transparent for the entrepreneurs and investors. As a result, more than 3,000 P2P platforms wind up their businesses, and the number of P2P Platforms became 2,488 in 2016 (Aveni and Jenik, 2017).

Fig. 3: Policy interventions by the state council

Source: (Aveni and Jenik, 2017)

The prevailing comparison in Table 5 will shed light on a few of the important aspects that will help the stakeholders, the government, and regulatory agencies in developing vivid policies for the crowdfunding market in Pakistan.

Table 5: Key differences and improvements b/w two countries

Area	Pakistan	China
The role of Government	Government agencies, such as SECP established incubators and accelerators with the collaboration of the provincial government and educational institutions (Quadri and Ayesha, 2014).	In 2015, the government took very decisive steps in the form of policy intervention and pilot drafts for P2P lending and the crowdfunding market. (Liang, 2015).
Supporting Talent	To encourage and support the young talent to acquire the entrepreneurial skills by creating avenues and platforms for the promotion and reinforcement of entrepreneurship in the country (JRZJ, 2018).	The Chinese government strongly fuelled the entrepreneurship activities inside the country by engaging e-commerce giants, such as Taobao, JD, and Xiaomi (Joffe, 2017).
Access to markets	The government should develop a centralized platform or directory that showcases Pakistan's potential markets to the outside investors. Such acts	To flourish the market further and bring momentum in equity crowdfunding, the regulative agencies should develop confidence and trust among

	will develop a high level of trust in the minds of outside investors (JRZJ, 2018).	investors and open new ways/channels for the potential financing of businesses at different stages of the start-up development cycle (Liang, 2015).
Education	Education can foster an ecosystem of entrepreneurship based on learning (World Bank, 2013). Pakistan spent nearly Rs 790 billion ($6.8 billion) on education in 2016, and the education budget has gone up by an average of 17.5% every year since 2010 (Ali and Naviwala, 2017).	China spent nearly 4 trillion yuan ($590 billion) on education in 2016, which was upto 7.57 percent from the year before. It was the 5th consecutive year that the country spent above 4 percent of GDP on education (Yan, 2017).
Women	To educate and develop the entrepreneurial skills among women, the provincial governments first step was to make a technology based incubator called Plan 9. Plan 9 developed a platforms called a capacity building platform to aspire women entrepreneurs, and it has trained 100 women over a period of six months with the aim to increase the female labour force participation rate (Qadeer 2017),	The Chinese government estimates that 55 percent of the country's internet firms were founded by women. Even if these figures are debatable, there is no doubt that China's start-up industry has brought about some of the most successful businesswomen in the world, such as Jean Liu and Hu Weiwei (Sieren 2017).

Key Factors That Facilitate the Development of Crowdfunding

The following are the key factors that help crowdfunding being embraced in developing countries.

1. The government should develop a clear and profound regulatory framework that leverages the transparency and improves the scale and speed of the technology, which will enhance the internet connectivity and clearly discuss different aspects of crowdfunding, start-up promotions, and investor protection (BR Research, 2017; World Bank, 2013).
2. To harness the demographic and technological trends by developing a profound mechanism where social media can integrate among the community, strong market players could adopt a penetration strategy and strong internet usage, which will also become a bridge for collaboration and cultural shifts (World Bank, 2013).
3. To facilitate capital formation, a strong regulated online marketplace is necessary where investor protection can be achieved by proper training and education (World Bank, 2013).
4. To create a promising channel for opportunity and oversight, it has become necessary for the entrepreneurs to collaborate and participate in different hubs and events, such as business plan competitions, education institutions, incubators, accelerators, and co-working spaces (World Bank, 2013).
5. The Country State Bank should bring changes in legislation to reduce the barriers for the entrepreneurs in access to finance, and such provisions will accelerate the business growth (Hussain, 2017).

6. Entrepreneurs should perform comprehensive research about crowdfunding before launching any projects and must adopt sound marketing techniques for project promotion (Khan Rizwan, 2016).
7. Local citizens are totally unaware of the role and importance of crowdfunding in the development of society. Digital and print media can play their role in educating the society about start-ups and crowdfunding.

The culture of trust will evolve as a result of the above factors, which are the core element for the funding of companies, projects, and causes mediated primarily through web-based interactions.

Conclusion

Crowdfunding is a unique concept that gives a method of integrating investors demand through financial support and the management of the risk, but it requires a definite share of magnanimity and social entrepreneurship commitment. To make this idea valid, there is a valid reason, where the internet more specifically has become a great source for connecting and engaging people that have unique and common interests on a worldwide basis.

This write-up is one of the first to address and assess the current trends of crowdfunding in Pakistan. We have analyzed the overall market based on suggestive evidence and a comparison with a mainstream market in China, which reflects the prevailing environment and procedures available for the entrepreneurs and contributors that motivate them to invest in the crowdfunding market. The current environment that exists in the country supports and convinces entrepreneurs to initiate a donation-based platform rather than other crowdfunding models.

The current market scenario strongly witnessed that soon reward based and equity-based crowdfunding platforms will start their operations once the government and regulatory agencies streamline the overall mechanisms of crowdfunding in a country that is hampering in the developmental process of crowdfunding. Even though market conditions are quite favourable but vague and complicated regulations make it tough for the local people to understand and invest inside in the crowdfunding market.

We are confident that a comparative study of the two markets will further shed light on the importance of crowdfunding especially in developing a strong and profound foundation inside in the country for P2P and the crowdfunding market. All crowdfunding platforms, especially Seedout and Transparent Hands, have been quite successful in promoting the crowdfunding concept as well as a donation base model and expanding the boundaries of their operations across the country.

In summary, this leads to the conclusion that the concept of crowdfunding is new and at such an initial stage's that there are a few numbers of platforms currently operating in Pakistan. However, the FinTech industry, which is booming drastically will popularize the concept of crowdfunding among the community and will change the financing scenario for the start-ups.

Limitations and Future Research Work

This research contributes to the eminent field of crowdfunding in one of the developing countries, such as Pakistan. However, there are few limitations that make room for further research. The most obvious one is that our sample size is very limited. We selected Pakistan, because it's a new market in crowdfunding industry. Secondly, the availability of literature is quite rare, and accessible information usually originates from the news, magazine reports, and discussions that occur during table talk. Thirdly, there is no proper research publication available about the crowdfunding market in Pakistan. Fourthly, the discussions and conclusions made here cannot be generalized, because the environment of the crowdfunding market varies from country to country.

Further interesting trends in market development can be explored through an in-depth analysis by conducting a qualitative and quantitative study. A comparison study is also possible between Pakistan and another developing country by analyzing the two markets through an (S.W.O.T) analysis.

Abstract

The essential role of entrepreneurship for economic growth and prosperity determines a constant effort made by researchers and decision-makers in creating and developing suitable business structures to enhance its effects on the economy and society. In this respect, business accelerators, focused mainly on a critical mass of successful entrepreneurs, are able to stimulate and accelerate the development of a significant number of innovative, high growth projects, with a significant impact on the market. In this paper, using the results of a survey applied to a considerable number of start-ups around the world made available by Entrepreneurship Database Program (EDP), we analysed the association between the expected profit margin and the founder's age, and respectively, cumulative work experience. We found that expectations of reaching a certain profit margin are not strongly dependent on the age or work experience of start-up's founder. In line with other contribution in the field, we consider the aim of accelerated growth is not necessarily linked to the youth and limited experience of high growth-focused entrepreneurs.

Keywords: Entrepreneurs, Age, Work Experience, Profit Expectation

Introduction

Entrepreneurship has a key role in economic development, individual and social prosperity, and technological progress. Identifying those entrepreneurial determinants able to strengthen the support measures and to capitalize on the growth and profit ambitions are of great importance. Thus, incubators and accelerators are exceptional opportunities for young companies in order to transform ideas into successful start-ups, orienting energies to the market and avoiding the typical mistakes of the start.

In this paper, based on the results of a survey involving a large number of new ventures' entrepreneurs from all over the world, enrolled in various business accelerator programs we attempt

to identify the existence and intensity of a relationship between the entrepreneur's age and work experience, on one hand, and expected financial performance of the firm, on the other hand.

Firm's objectives and performance

Assessing business performance is an essential issue for researchers, entrepreneurs and managers. Currently, standard indicators used to measure business performance, such as profit, turnover, customer portfolio, return on investment, improvements in product quality, are preferred, as they also express how a business has hit or missed strategic pre-settled goals. Pérez and Canino (2009) confirms that the most endorsed indicators associated with performance in the literature are quantitative ones, describing in particular the business expansion and financial performance: the growth of the company / or turnover (31% of cases), followed by profitability indicators (over 18 % of cases), profit (14%,) or liquidity 7%.

However, in the early years of a business, surviving and gaining a market position are truly successful, when insufficient managerial experience and high costs are combined with instability and fierce competition. Thus, a widespread use of financial performance indicators can generate an incomplete picture of young firm performance (Hillman and Keim, 2001). These indicators do not take into account the efforts and achievements such as competition, entering new markets, reaching organizational goals - strengthening the team, retaining key personnel, etc. showing, rather, underperformance, crisis or insolvency circumstances, being unsuitable indicators to measure the success of start-ups (Herron and Robinson, 1993). A combination of objective and subjective techniques, quantitative information and individual perspectives on performance seems more appropriate (Naman and Slevin, 1993), (Zulkiffli and Perera, 2011). It could allow comparisons between firms in various contexts such as relative performance of industry, time horizon, culture or economic conditions, supplementing the understanding of entrepreneurial ambitions.

Age and work experience as predictors of entrepreneurial performance

There is a popular yet unproven concept that youths are more capable of generating revolutionary ideas, as they are more dynamic, open to novelty, less preoccupied by social obligations and responsibilities (family, savings, retirement etc). Several studies argue that young people often have unique advantages in approaching entrepreneurial activity: high level of optimism and confidence, willingness to assume risks and naturally inclined towards change and modernization (Koellinger, et al., 2007), (Haltiwanger, et al., 2013), (Hatos et al., 2015). Consequently, they could be interested in entrepreneurship because they perceive it as a challenging endeavour, different from common and boring jobs, specific to older generations (Badulescu et al, 2015).

However, the ability to discover opportunities is often best enhanced by experience, market knowledge, accumulation of resources, useful in influencing business success and resilience (Azoulay, et al., 2018). Experience and education are parts of human and social capital (Dodescu and Badulescu, 2010) and they can enhance the accumulation of financial capital (Gruber, et al., 2008), (Lafontaine and Shaw, 2014) being critical in high technology domains. Also, young people may be reluctantly treated by creditors (especially banks) when they apply for a loan (Andersen and Meisner Nielsen, 2012). In this case, there is the alternative of business angels, where a higher seniority of the firm's founder may be a disadvantage, as these investors are usually looking for extremely dynamic start-ups and they are less interested in medium- and long-term stability (Gompers, et al., 2010), (Badulescu, 2013).

Even if the age, skills' accumulation and the availability of adequate financial capital do not guarantee the entrepreneurial success, nor the risky decisions are inevitably successful. There is, rather, a complex and often unfavourable relationship between optimism and performance, between entrepreneurial over-confidence and business longevity (Koellinger, et al., 2007).

Research Methodology and Results

Our research is based on the data series made available by Entrepreneurship Database Program (EDP) housed at Emory University, which include application data collected from programs that opened applications in the 2013-2018 window. The main database contain data from 19,418 ventures whose founders applied through more than 280 different programs run by more than 90 different organizations (Entrepreneurship Database Program & Aspen Networks of Development Entrepreneurs (EDP), 2019).

We try to find the answers to several questions such as: Are younger (i.e. under 25) entrepreneurs more eager to set higher profit targets? Are entrepreneurs with a relevant work experience (i.e. 5-20 years) more cautious than younger ones? Is there a connection between the age, respectively the work experience of the firm's founder, and the setting up of a certain profit margin target?

In preparing the dataset we identified and removed several records considered extreme or implausible, or due to the impossibility of identifying the firm's year of establishment. Overall, of the total of 19418 records, 18743 valid ones were taken into account. We find a high percentage of for-profit entities (14886, i.e. up to 80% of the total), followed by the non-profit entities (11%), but also undecided (4%), others (6%) or unfilled responses. In terms of education, a large majority of founding entrepreneurs has tertiary education (around 75% of the total) followed by high school, associate and vocational (16%) and few (up to 1%) up to Middle school (including Pimary school, Less than 9, None) education. The rest (8%) are No answer (around 8%).

We were then interested in selecting only for-profit companies, leaving us (after removing 663 non-answers) with 14.223 records, i.e. over 77% of the total. In Table 1 we present the expected annual profit margins with regard to the founder's age and, respectively, work experience.

Table 1: The expected annual profit margins related to founder's age, respective, to work experience

Expected profit margin	Founder's age (years)				Founder's work experience (years)		
	16-25	26-45	46-65	>66	<=5	5-20	>20
0% - 10%	127	645	137	4	507	353	53
11% - 15%	170	856	164	21	657	485	69
16% - 20%	278	1508	303	21	1043	966	101
More than 20%	690	4003	813	44	2813	2453	284
None	881	3247	565	46	2705	1819	215
Grand Total	2146	10259	1982	136	7725	6076	722

Source: Own calculation based on dataset

In order to analyse the association between the expected profit margin and the founder's age, and respectively the founder's cumulative work experience, we converted the quantitative variables (founder's age /experience) into ordinal data. The expected profit margin was divided in 5 ordered ranks (0% - 10%, 11% - 15%, 16% - 20%, More than 20%, None), the founder's age was grouped into 4 ranks (16-25 years old, 26-45, 46-65, >65), and experience into 3 categories (up to 5 years of experience; 5-25 years' experience, and above 25 years' experience). No expected counts in either contingency table were below 5, allowing the use of Pearson's chi-squared test. The association was tested by means of chi-squared tests and Cramér's V statistics, based on interpretation suggested by Cohen (1988).

Regarding the relationship between the expected profit margin and the founder's age is was observed a very highly significant association ($p<0.001$, $\chi2=105.274$, df=12, N=14,523), even the effect size is weak (Cramér's V=0.049, $p<0.001$), below Cohen's suggested threshold of 0.058 for a 4x5 contingency table. In the case of the association between the expected profit margin and the founder's

cumulative work experience, similar results was obtained - a very highly significant association ($p<0.001$, $\chi2=63.499$, df=12, N=14,523), but a weak effect size (Cramér's V=0.047, $p<0.001$), below Cohen's suggested threshold of 0.071 for a 3x5 contingency table.

Thus, based on the analysed data, we can affirm that the expected profit margin is influenced by the age or work experience of the founder of the company (very significant results of the chi-square test). On the other hand, however, we found a weak association between the independent variables (age and experience, respectively) and the dependent ones (the anticipated profit margin). In other words, independent variables have a low predictive value.

Conclusions

Identifying those entrepreneurial determinants able to strengthen the support measures and to capitalize on the growth and profit ambitions are of great importance for economic growth, innovation, employment and for the decrease of regional disparities. In this paper we have considered two of these determinants - age and work experience and we attempt to find tried to see if they really count in targeting an expected level of profit. The results of the research show that, although they influence setting certain financial performance objectives, the entrepreneur's age and experience are not powerful predictors thereof. Moreover, we cannot say whether young and inexperienced entrepreneurs are more optimistic in setting ambitious aims, nor conversely whether age and experience lead to having more reserved goals. The impossibility to verify the actual achievement of the proposed targets, but also the lack of some qualitative information regarding the founder's work experience (relevance, type) could constitute as a serious limitation of our research. In future studies, we intend to expand the analysis of the determinants of entrepreneurial and high-growth ambitions by addressing the above-mentioned limitations.

Abstract

The paper concludes that the share of new knowledge embodied in technologies, equipment, personnel training, manufacturing organization in developed countries is about 70%-90% of GDP growth. Introduction of innovations has become a key factor of market competition giving progressive companies an opportunity to reach excess profits based on assignment of intellectual rent arisen by the monopoly usage of more advanced technologies. Nowadays, Russia faces a problem to form advanced engineering and manufacturing systems. At the same time, the Russian economy does not have an operating system of state stimulation of innovation development. The factors constraining the innovation-oriented development of Russia are revealed thus: expensive energy resources, inefficient taxation system, insufficient money supply, unused human capital, quality of administration. The necessary measures which ensure the transition to a balanced economy with sustainable growth of the main indicators of national production and consumption have been identified.

Keywords: Innovative Development, Innovation, State Policy, Innovative Activity.

Introduction

The transition to a balanced economy, ensuring a steady growth of the main indicators of national production and consumption, is possible only with development of high value-added manufacturing and high-tech industries. Innovation was the main factor that ensured economic progress at all times. At present, in all countries, posing themselves as highly developed countries, the contribution of innovation to GDP growth has an upward trend. In the EU, on average, the value of innovation factor reached half of all components providing GDP growth at the beginning of the 21st century. In Germany and Austria, it has recently reached 67%. At the same time, it was not the market, but targeted management efforts that ensured the West European (especially German) innovation effect.

The research purpose is to identify the factors affecting innovation development of the Russian economy and determining the directions for neutralizing their influence.

Research Material and Methods

During the research process, there were used the following research methods: universal methods of scientific cognition including the empirical and theoretical levels of scientific knowledge, analysis and synthesis, a systematic approach, and conceptual modeling. In addition, such methods of scientific research as dynamic and structural analysis, and the construction of logic circuits were used. The information and empirical part of the research was formed on the basis of data provided by

the Federal State Statistics Service; research results of the World Bank; analytical reviews published in periodicals, domestic and foreign literary sources, and materials of scientific research institutes.

The works of the following Russian and foreign scientists and economists are devoted to innovation issues and innovation activities: S.Yu. Glaziev (2010, 2014), V.V. Ivanter (2005), V.L. Inozemtsev (2000), Ch. Greenhalgh (2010), and G.M. Peter Swann (2009).

Practical significance of the research is concerned with developing recommendations that can be used to improve the process of strategic planning and current management of developing the national innovation system of Russia. The authors' theoretical ideas and research results are applicable to the activities of government bodies at various levels.

Research Results

Back in the 1960s, science in the West actually functioned independently of the economy sphere. With the exception of the military-industrial complex, it was not involved in the development of economic sectors. As the researches notes, during this period, state scientific policy had cultural features. Reorientation of scientific research for satisfying practical needs and economic challenges began in the West in the second half of the 1960s. Science has become defined as a factor of economic growth. In accordance with this approach, developments are primarily stimulated that are aimed at increasing the growth and competitiveness of products. Finally, in the late 1990s, science and technology policy was transformed into an innovative one in the West.

Unlike business, states consider R&D as a sector with long-term economic returns. Active support of renewable energy engineering programs illustrates this fact. The German 100,000 solar roof program implies state subsidies for research on solar energy in the amount of 0.51 billion Euros.

Special attention is paid to seed-stage financing of the development and implementation of innovations, which, as a rule, constitute up to 30% of the total project cost. In the West, the system of innovative incentives includes such traditional financing instruments as targeted subsidies, grants, mortgage lending, etc. A state innovation procurement practice builds confidence of product implementation and contributes to the success of its rapid introduction into production. This kind of procurement provides in the EU countries 16% of gross domestic product (Yakunin, 2008).

At the same time, there is a significant lag in the financing of scientific research in Russia compared to developed countries. In the 1990s, Russia's scientific policy was based on 'the Gaidar imperative' – 'Science will wait'. In terms of percentage of science expenditure in GDP, Russia is ranked in the upper thirties, along with Greece, New Zealand and Slovenia (Malinetskyi, 2015).

In addition, there is a 'technological lag'. The results of basic research are embodied in specific technologies in about half a century. Applied developments come to industry and change it in 15–20 years' time. This is clearly shown by innovations in the defense complex - on average, 10 years pass from the start of financing a new weapon project to supply it to an army.

It is necessary to pursue a reasonable industrial policy for solving these problems.

A policy of reduction of extraction and consumption of natural resources and energy to the level of the national industry needs should be put in place. At the same time, the right to extract oil and gas should be granted to companies on a competitive basis with payment to them per unit of extracted raw materials; the products themselves should belong to the state.

The prices of gasoline, fuel oil, gas, electricity and utility services at least should be halved due to the removal of adventitious costs, inefficient management and excessive taxes on domestic energy consumption. This would be the most important factor in raising the competitiveness of Russian industry and increasing the well-being of the population (Minakova, Bukreeva, Masalov, Galchenko and Kharlanova, 2019).

It is advisable to change the order of interaction of the state with mining companies: the right to extract oil, gas, etc. should be given to companies on a competitive basis with a fixed fee per unit of extracted raw materials. At the same time, the raw material remains under state ownership and must be sold at world prices without involving offshore companies and intermediaries.

The Russian tax system needs to be improved. First of all, it is necessary to modernize the income tax and value added tax.

The introduction of a progressive income tax is one of the main measures to improve the socio-economic situation in Russia. According to the calculations of the Institute of Social and Economic Studies of Population of the Russian Academy of Sciences, if Russia had an average European progressive tax scale, Russia's GDP would be 30-50% higher than in reality (Rusrand, 2017). The greater the income of the population, the greater the demand for goods will be thus ensuring GDP growth. At the same time, Keynes's Psychological Law of Consumption states 'when aggregate real income is increased, aggregate consumption is increased, but not by as much as income'. As a rule, these funds are transferred overseas for purchasing real estate, luxury goods such as yachts and football clubs, or simply deposited in foreign banks, which also does not contribute to the production and GDP growth in Russia.

In such conditions, the introduction of progressive taxation will increase the marginal propensity to consume in the Russian economy. The last one will ensure the growth of GDP, including industrial production.

The next measure is taxation. Enterprises allocated their income for investing in production development, R&D and development of new technologies should be exempted from taxation. Special attention should be paid to the value added tax (VAT).This tax burdens high-tech products with high added value and stimulates the development of resource-based industries.

In 2019, the standard VAT rate in Russia was raised to 20% (In accordance with Federal Law No. 303-FZ of 03August 2018) (Nalog, 2019). At the same time, the actual collection of VAT does not exceed 30% (Rusrand, 2017). According to some economists, it is advisable to establish a unified VAT rate equal to 8%; reduce the number of VAT exemptions; calculate VAT as a product of value added and tax rate; cancel the VAT refund for exporting raw materials; 50% of VAT reinvested regionally. The implementation of the proposed measures will improve business climate, significantly reduce the number of subsidized regions, increase the collection of VAT from 30% to 90% and give the budget an additional RUB 2.0-2.5 trillion (Rusrand, 2017).

The reasonability of the proposed measure is confirmed by the report 'U.S. corporate tax policy for the 21st century' of the Office of Tax Policy of the US Department of the Treasury.

The most important factor constraining the industrial innovation in Russia is the quality of labour forces. This is partly a consequence of the degradation of the Russian educational system. The Russian educational system is based on training of humanities scholars and middle-ranking managers. Training of specialists in natural science and technology is carried out only by state universities, the share of the experts in these fields is reducing, and as a result, the number of professional personnel capable of contributing to the development of the domestic industry is rapidly declining. According to the statistics of recipient countries, Russia's loss from 'brain drain' is evaluated by several million educated people, including 250 thousand scientists in advanced fields (Shevyakov and Kiruta, 2019).

Therefore, this problem can be solved by generating a demand for innovations from the real sector of the economy. In order to overcome scientific, technical and technological stagnation, our own R&D expenditures should be doubled. This task should be achieved by combining the growth of government allocations by pursuing appropriate scientific and technical policies with stimulating innovative activity of the private sector through tax incentives, infrastructure development and credit expansion. Russia should demonstrate at least a two-fold increase in scientific research budget financing.

Countries having experienced so-called economical miracles confirm the need for forced increase investments up to 35–45% of GDP. These investments will move the economy to a new technology stage. Thus, China's ten-fold increase in GDP from 1993 to 2016 was followed by an increase in investments by 28 times, money supply and bank credit on the manufacturing sector – by 19 and 15 times, respectively (Glaziev, 2018).

This implies the need to reorient monetary policy to the needs of economic development through the creation of a multi-channel mechanism for targeted credit emissions under the obligations of the state and enterprises to master advanced technologies and expand production.

Conclusion

Russia will not have a chance to join the list of global leaders without advanced technologies in economy. The ability of the national economy to update its technological base and upgrade the technical level of enterprises is a key factor for improving and realizing its competitive potential.

This implies the need of reorienting monetary and fiscal policy for the needs of economic development and incentives for enterprises introducing new technologies.

The economic development policy should review:

- the reduction of interest rates and the creation of mechanisms for refinancing of capital investment and innovation activities;
- the introduction of progressive income taxation, the modernization of the VAT system, tax exemption for enterprises investing business profit in manufacturing expansion, R&D implementation and introducing new technologies.

The research paper is written as part of the state grant for 2020 (№0851-2020-0034).

Abstract

The paper reveals the results of the unipolar world order implemented since the 1990s of the XX century after the collapse of the USSR. The research determines the prerequisites for modernization of the current world order and highlights the centres of resistance of the American centrist model. First of all, it is China which over the past 15 years accumulated considerable resources and potential and developed its own tactics of influencing counterparties with the aim of building an allied network; then Latin America, Iran, North Korea and Russia. Russia has significant potential in certain areas. In particular, the territory of Russia is the most important factor to occupy leadership positions in the world. Natural resources are another criterion for determining the potential of a country. By this criterion, the position of Russia in the world is even higher; it is the most resource-rich actor for putting forward an independent new world alternative. Russia is most affected by socio-economic and political factors. But unlike geographic, these factors can be changed in a targeted way.

Keywords: unipolar world order, bipolar system of international relations, American centrist model, world alternative.

Introduction

Starting from 1991 to the present, the world economy remains unipolar. The result of a unipolar world was an increasing inequality between countries. So, from the moment of the collapse of the socialist system, income inequality, or the gap between the richest and poorest groups has been growing markedly. According to the report on human development of 2017, many African countries are balancing on the verge of mass starvation. In Guinea, one out of every five children under five years of age, and in Madagascar every third child is underweight. According to the report on human development 2013, in the fifteen-year period after the collapse of the USSR, the death toll in one thousand children increased in Zimbabwe by 38.2%, Swaziland by 49.1% and Botswana by 113.8%.

The quality and volume of educational services provided differ fundamentally in the regions of the world. About 800 million people over 15 years of age remain illiterate - 18% of the world's adult population. 76 countries of the modern world do not provide legal guarantees of free primary education.

The country gap in life expectancy is growing. It is twofold between Japan with the highest life expectancy and Afghanistan with one of the lowest rate of life expectancy (Golos, 2017). One of the

significant, producing a high level of conflict in the world of modern challenges is the growth of xenophobia. Back in the 1980s there was no such problem on a planetary scale. The average level of xenophobia in the world was less than 5% of respondents, indicating a fundamental undesirability for themselves to live next to immigrants. Currently, this share in the world's population is already about 28% (Golos, 2017).

Drug use as the most dangerous social vice in the world is in a growth trend. After the American invasion of Afghanistan, opium production increased by almost 2.5 times compared to the initial level (Sulakshin and Bagdasaryan, 2016).

This implies the relevance of the problem of the changing world order. A new world order will be opposed to a unipolar model of the world order. It seems important to analyze the possible alternatives to the existing model of the world order and to study the potential opportunities and Russia's place in it.

Research Material and Methods

The theory of a multipolar world was developed in the papers of Kissinger H. (2009, 2011), Brzezinski Zb. (2009), Waltz K.C. (1993, 2000), Huntington S. (1993, 1999), Kegley Ch.W. and Raymond G. (1994).

The research works of Bogaturov A.D. (2009, 2017), Sulakshin S.S. (2016), and Ponomareva E.G. (2016) cover the modern model of international relations. The purpose of the research is to study of the essential prerequisites and directions of transformation of the global economic model. The study is based on the methodology of the general theory of systems, and such methods for studying complex social objects as synthesis, comparison, system analysis, analogy, the construction of scientifically based hypotheses, etc.

Research results

The United States ensured a unipolar world order by maintaining overwhelming leadership in four key areas: military-technological, financial-economic, geopolitical, and information-ideological. The fundamental basis was the axiomatic nature of the statement about the exclusive position of the United States and its messianic role in the world. A distinctive feature of American foreign policy is its offensive and expansionist nature. Along with the expansionism of the United States, a 'complex of American superiority' developed, which increasingly resembled arrogance (Shakleina, 2002).

Almost all the presidents of the Cold War era supported the idea of 'American exclusivity' and the US special mission to spread their own ideals and values as the main ideological argument in the fight against the Soviet threat. In the 1990s of the 20th century American political scientists developed several clear doctrines of demonstrating and affirming the US dominant position in international relations. According to the concept of power hegemony (W. Wohlforth, C. Bell and Zb. Brzezinski), preference is given to the power tools to strengthen the leadership positions of the United States in the world. The ignoring interest of partners and closest allies by the US is allowed.

The consequence of such a policy of the United States was the growth of conflictogenity in the world. Despite a more than twofold reduction in militarized interstate disputes, the number of intrastate conflicts almost reached the level of the final phase of the Cold War, when the bipolar world order disappeared. There was no significant reduction in mortality as a result of military conflicts.

It happens amid the decline of influence of UN's legal principles on the world politics. The most important of them is a state sovereignty - the cornerstone of world politics since the middle of the XVII century.

The bipolar system of international relations was based on the military parity between the Soviet Union and the United States. When the Soviet Union collapsed, Russia as a sole successor state

retained the right to possess the Soviet arsenal of strategic nuclear weapons (including nuclear arsenals removed from the territory of Belarus, Kazakhstan, and Ukraine). Due to this, today we can talk about maintaining parity between Russia and the United States, but only in strategic weapons. A number of scientists call this situation residual bipolarity (Bolotin, 2001). The other seven countries (great Britain, France, China, India, Pakistan, Israel, and North Korea) have nuclear weapons, but their stocks allow only talking about the possibility of nuclear deterrence, but not parity with either the US or Russia (Minakova, Parkhomchuk, Golovin and Bukreeva, 2018).

After the dissolution of the USSR and the socialist camp with the subsequent collapse of the bipolar system of international relations, Russia's sphere of influence in the world began rapidly to reduce. The Soviet Union actively expanded the allied network around the world, primarily due to powerful ideological (communist and socialist alternative, political support), financial (credits, arms transfers, trade ties within the CMEA, etc.) and intangible (academic exchanges, cultural cooperation, etc.) resources and incentives. The USSR's 'soft power' could be estimated by the number of countries chosen the Soviet life model. According to the Soviet propaganda, these countries could are divided into socialist and socialist-oriented ones. As of 1985, they accounted for 37% of the territory, 40% of the population, and 22% of GDP (Bolotin, 2001). Nowadays, Russia's foreign presence is limited to curtain former Soviet republics (Belarus, Armenia, Azerbaijan, Kyrgyzstan, Tajikistan, Kazakhstan and Uzbekistan) and regions involved in conflicts (Transdniester, South Ossetia and Abkhazia). As for far-abroad countries, only Syria, Serbia and Venezuela are quite loyal to Russia influence. At the same time, the United States over the past 20 years has not only preserved, but also significantly increased its military presence in the world.

The current unipolarity model demonstrates curtain signs of coming global restructuring. First of all, it is increasing the resistance of some countries or groups of countries to rules, institutions and regulatory mechanisms within a unipolar world order.

In recent years Latin America has become another significant area of resistance to the American-centric model of the world order. Since 2010, four states of the Bolivarian alternative (Venezuela, Cuba, Nicaragua and Ecuador) have agreed to replace the US dollars with the virtual currency equivalent (the sucres) for trade payments among themselves. In 2010, after the adoption of the Customs Code, the stage of formation of the customs union of Mercosur's member countries was completed. The organization has started creating conditions for the transition to a new currency union, Argentina and Brazil have already managed to test a number of mutual trade settlements in a single currency. In addition, the Mercosur's countries have reduced their dependence on trade with the United States (an average of 18%), increasing intra-continental trade.

Being the traditional hotbeds of anti-Americanism Iran and North Korea have high-level resistance to American hegemony. A large potential for resistance to the established rules of world order is shown by such regional integration blocs as the Association of Southeast Asian Nations (ASEAN), the Shanghai Cooperation Organization (SCO) and organizations such the CIS operated in the post-Soviet space (CSTO and others). These organizations develop new alternative models of trade, economic and military-political relations among the member states.

Russia with a great potential in certain areas is a significant pole of resistance to US dominance. In particular, the territory of Russia is the most important factor to occupy leadership positions in the world. Natural resources are another criterion for determining the potential of a country. By this criterion, the position of Russia in the world is even higher. According to some courses, Russia possesses 22% of the world's total natural resources. The Russia's share in the world's supplies of natural resources is estimated by the following indicators: 12% oil, 32% gas, 11% coal, 31% potassium salts, 21% cobalt, 25% iron, 15% zinc, 10% lead, 33% nickel, 18.2% tungsten, 7.6% tin, 10.7% platinoids, 5.3% uranium, 8.2% antimony (Minakova, Parkhomchuk, Golovin and Bukreeva, 2018). The well-known American Internet resource 247 Wall Street calculated the financial value of the natural potentials of the countries. The calculated resources included: oil, natural gas, coal, wood, gold, silver, copper, uranium, iron ore and phosphates. The calculations were based on statistics from the US Geological Survey, the US Energy Information Administration, Bloomberg, and financial

visualizations. A dozen of the world's most resource-rich countries were identified (247wallst, 2012). With an indicator of 24.4% Russia (USD75.7 trillion) took an unconditional 1st place in this rating. The USA with an indicator of 14.5% is in the second position in the ranking. Thus, Russia beats America in a resource fight. Consequently, in order to maintain its dominant position, the United States must take steps that undermine Russia's resource capabilities. This is one of the main reasons for the increasing external pressure on Russia.

The resource potential makes Russia the most secured actor for developing an independent new world alternative. China, being the world's second-largest economy and the world's largest country in terms of population, ranks only sixth in terms of natural resources. In this regard, it is vulnerable to the prospect of a long-term resource competition with the United States. China's resource potential is 2 times less than the American one and 3.3 times less than the Russian one (247wallst, 2012). Hence, China's resource strategy may consist of either intercepting Russian resources or establishing an alliance with Russia. Weak Russia will lead China to the first scenario. Strong Russia will be obviously chosen as a strategic partner. The liberal model of the state currently prevents Russia from realizing its natural potentials. The preservation of this model in Russia is beneficial to its geopolitical opponents, especially to the USA.

China is the biggest threat to American hegemony. It has been making a major contribution to the growth of the world economy over the past few years.

In the last 15 years China has accumulated considerable resources and potential and developed its own tactics of influencing counterparties with the aim of building an allied network. Thus, it has managed to convert its increased economic opportunities into political influence in many African countries, Latin America, Mongolia, etc. The Chinese leadership does not allow American capital enter its strategic industries and major companies. Despite serious international pressure, China is not going to give up protectionist measures in the interests of national producers and the undervalued exchange rate of national currency - the renminbi (yuan). Moreover, the Chinese leadership openly promotes the decline of the US dollar in world trade in favor of other currencies and the revision of management rules and quoting in international financial institutions - the International Monetary Fund and the World Bank.

However, China alone will not succeed in overthrowing the United States from the podium of leadership. The chances of China are even less in the global struggle against the geopolitical power of the United States and its allies. A real challenge to the West can be thrown by the joint geopolitical powers of Russia and China. The calculations of the countries' potentials prove this fact.

One of the calculated comparative integral indices is the national combined power index. It uses data from the International futures (IFS) computer model as the basis for evaluating countries' potential. The model was developed by Barry B. Hughes, the Professor at the University of Denver, it is one of the most authoritative projects for predicting the future (Don, 2014). For calculating a country's power index, the following variables are taken into account: GDP, defense spending, population, and technology. According to the received trends, the center of geopolitical power is moving from the West to the East. By 2060, the United States will lose global leadership. They will be bypassed not only by China (this will happen in 2030), but also by India. Rapid breakthroughs in the ranking will be made by Indonesia - from 12th place to 4th and Pakistan-from 19th to 7th (OECD Economic Policy Papers, 2012). Russia will also reach the level of world leaders in terms of total power. In this situation, the model of the unipolar world can no longer be implemented. There will be a transition from a system of country hierarchy to a system of country equality and dialogue.

Conclusion

Thus, the globalization of the modern world does not mean the homogenization of countries' development indicators, but leads to the further delamination and inequality. The gap between the world leaders and the rest of the world in terms of indicators reflecting the dynamics of the standard

of living, the quality of life, scientific and technological progress, after the collapse of the Soviet Union, has significantly increased.

It is logical to assume that in the nearest time the struggle between the US and China will intensify, and the pressure on the Arab countries will be increase. The fight against the possible alternative will be conducted not by highly cost-effective strong arm tactics, but will be transformed into an information technology and ideological sphere. In the next 50 years, the convergence of large countries of the East (China, India) and some countries of the Middle East (Pakistan, Iran) is likely to occur, despite the fact that the contradictions between these countries are still quite strong. China and Turkey, apparently, will strengthen their presence and influence in the countries of Central Asia, and compete in this area with the Western countries.

In case of the turn away from of the liberal model, Russia with its potential can become one of the world leaders. It is highly likely that in the medium term, cooperation in the BRICS and SCO will be actualized, which will begin to gain more weight in the international arena, as well as other attempts will be made to create associations and unions of countries striving to build their policies independently of the United States.

Position of Electromobility in the Mateusz Morawiecki's Government Policy vs Energy System and its Security

Piotr KWIATKIEWICZ

University of Zielona Gora

Abstract

The Polish fuel sector within the hydrocarbon area is confined to mid- and downstream. The first of the two is losing support due to the decline of Poland's significance as a transit state for the Russian export. Given lack of upstream capacity, the position of the latter is also very weak. The excess supply of refinery services across the European continent reduces its development opportunities. The electrical power engineering alike, leaves much to be desired. The production area is dominated by entities more than half a century old. The over-exploited and useless power units are not replaced by any new ones featuring the power close to the withdrawn items. Majority of professional power plants are coal operated. The climate changes and the resulting restrictive UE policy in terms of greenhouse gases emission, including carbon dioxide, successfully contribute to the decarbonisation of the power production in the region. This process will cover also Poland. Awareness of the issue seems to emerge from the government's state of mind. The electromobility plan meets all the preconditions to become an element of support to the power transformation process in Poland. The car market is well developed and plays a significant role. Although used cars imported privately dominate in the streets, the share of new vehicles rises on a year to year basis. CO_2 emission-based restrictions and penalties imposed on the manufacturers lead to the eventual removal of traditional combustion engines driven cars. The rising number of PHEV and EV indicates not only the higher demand for electric power, an increase in its production in other words, but a complete remake of the distribution infrastructure as well. The problem is clear to see in big agglomeration suburbs inhabited by wealthy society. Microgeneration development seems to be the only hope here.

Introduction

The National Electromobility Development Plan (NEDP) was signed in February 2017[1)]. It was given the status of an agreement the signatories of which were the following government institutions: Ministry of Development, Ministry of Energy, Polish Development Fund, National Centre for Research and Development, National Fund for Environment Protection and Water Management and the representatives of the Association of Polish Cities. It was part of the concept entitled Strategy for Responsible Development[2)]. It is the vision of Mr Mateusz Morawiecki, then Minister of Development and Finance and presently Prime Minister, on the direction of activities granting the stable and fast rise of welfare of the Polish citizens and arriving at a competitive position in Europe.

The focus on Electromobility was not accidental. It contained a propaganda message which exposed the option for modernity and high-tech by the conservative government. The plan suggested a fast progress in the domain of advanced technologies meant as counter argument to the massive criticism linked to the resistance against decarbonisation project. Electromobility was to help Poland built a strong position on the emerging market; within the area where there was no need to catch up with the huge backlogs resulting from the Eastern Block heritage, etc. It created a field for economic competitiveness where Poland had the same position as its Western counterparts, hence the idea of making the said Plan into the flywheel of the country's subsequent development.

Methodological Assumptions

The logical connection between the electromobility and the energy sector transformation trends is very clear and does not call for any explanations unlike the issue of correlation between the progress of electromobility implementation and the transformations within the said economy sector. This combination gives way to both elements being created by one power centre. The said centre supervises the legislation work to present the legal grounds for motor industry segment development focusing on electric vehicles and, at the same time, does it in the event of the entities present in the domestic fuel and energy market and also controls it. The latter function results from it being the body representing the institution of the State, and at the same time, in the Polish circumstances – it appears as a shareholder – owner of major companies operating within this sector.

The basic research related question raised in connection with the analysed issue, concerns the taken measures and subsequently their cohesion. The reciprocal relations between the market and the PRE strategy targets implementation seem very interesting to be determined. The circumstances that remain to be explained is the role electromobility plays in the Polish energy transformation process.

Reaching out to the institutional analysis frequently referred to in social studies, but also very popular in political and economy studies, Polish fuel concerns and energy companies, passenger cars segment in the motor market as electromobility pioneer and also energy distribution infrastructure have become the focus of researchers. The latter of the enumerated elements can be deemed the progress measurement tool of the implemented processes.

The Energy Market in Poland

The daily demand for the oil and its products reaches nearly 700 000 bbl (Dudley, 2019). The dozen-percent rise that has occurred over the last five years explains the customs system sealing. Also, the recent Poland's economic growth does not remain unnoticed. Due to the abovementioned changes to the duel import system, its share in the demand sharp rise is difficult to determine.

Fig. 1: GDP growth / crude oil consumption

Author's own survey based on BP and the Central Statistics Bureau

Oil is imported from the Russian Federation by the Friendship Pipeline. It is about 65% of raw material that Poland uses. It is supplemented by swap purchase from the Persian Gulf area. The imported oil is processed in local refineries whose output satisfies the national market on 100%. The domestic oil drilling oscillates around 1 % and is of little importance to the economy.

The situation of natural gas is quite to the contrary. The annual demand for this fuel reaches 20 bln m^3 and keeps rising (Dudley, 2019). This progress results from a growing number of households that turn to gas consumption due to pro-environmental administration decisions and an improvement of living standards as a consequence of the said economic development (see, Fig.1). Approximately 20% of natural gas is produced on site, 65% come from import contract concluded with Gazprom and transferred by a network of pipelines, and about a dozen percent comes to Poland on board ships in the LNG form. Among the suppliers, the US companies are the key ones followed by the ones from Canada and Qatar.

Over 80 % of the coal mined in the UE was from Poland which amounts to about 65 million tonnes. However, the demand for this raw material is much bigger; its consumption reaches 75 million tonnes. The difference is covered by import, mainly from Russia. This situation is determined by the peculiarity of Polish coal mines. High production cost and very deeply seated deposits are the main reasons for the quantity and activity limitation.

Polish Oil Concerns and Their Transformation

Two Polish major oil companies: Grupa Lotos S.A and PKN Orlen S.A. are of key importance at home. Both companies operate within mid- and downstream. The upstream operation run by the subsidiaries has a marginal significance for their business, their share in EBTIDA alike. The first of the two is smaller; it operates a modern refinery processing over 11mln bbl/y and a network of 495 petrol stations. It is based in Gdańsk and sells only in Poland. PKN Orlen operates in a number of countries. Its refineries are not as advanced as those owned by Lotos yet its total procession capacity is three times higher and arrives at 33,5 mln tonnes a year (ORLEN, 2018). Orlen owns 2 800 petrol stations, of which 1787 in Poland, 582 in Germany, 409 in the Czech Republic and 25 in Lithuania (ORLEN, 2018). Its capitalisation reaches USD 8 billion and is two-and-a-half times higher than that of Grupa Lotos S.A. (*Money.pl*, 2020) Both concerns have entered the fusion process. It is a political decision made by the major owner, the Polish State and is not rid of a propaganda aspect. Their key position in the sector results from their total wholesale market domination. Their joint share is over 80%. This situation reflects the legal regulations in place and the role the State has taken as a regulator of oil products turnover. The possessions of Grupa Lotos S.A. and PKN Orlen S.A. in wholesale theoretically guarantees their wellbeing in case a gradual retail reduction occurs due to the rise of interest in alternative fuels against the traditional combustion engine driven vehicles. Those concerns have been using concessions for power distribution over the area under their control. In 2014, PKN Orlen was granted the licence for their products marketing, thus becoming a supplier (Decision by the Energy Regulation Authority Chairman, 2014). They also adopted the role of a manufacturer owning a 2153MWt & 345MWe heating power plant. In September 2019, PKN Orlen announced their intention to acquire the Energa Group – energy producer and distributor to over 3 million consumers. In December 2019, Orlen placed a stock call to sell the shares of the acquired company (Sofuł, 2019). Having been focused on oil processing and petroleum-derived product sales for many years, the Concern is clearly diversifying their operations. Today, the electric power they produce, and market makes up 15 % of EBITDA (Lis, 2019). This trend of changes might be regarded as unambiguous and in line with the assumptions which have the electric energy the only fuel of the future. Statoil – Equinor are undergoing analogous transformation yet much more advanced in terms of the implemented stages. The correlation with the electromobility programme is very clear, yet the fusion with Grupa Lotos interferes with the transformation ideas.

The Motor Market – Passenger Car Segment

In early 2018, in Poland there were 23 million registered cars. Since the start of the decade, the growth dynamics has not changed much. It can be assumed that the market defined by the number of items in the passenger car segment has been expanding since 2015 at the pace of 3,8% y./y.

Fig. 2: The increase in car number in Poland since 2010.

The change is of both quantity and quality nature. The latter parameter concerns the car age and standard. A vital element of the discussed transformation is the replacement of old vehicles by newer generation cars.

In 2018, over 1.16 million cars were deregistered (CEPiK), while in the first quarter of 2019 – over 360 thousand (CEPiK). The number of cars that were allowed to drive the roads for the first time was 531 889 and 139 809 respectively, which seems to reflect the dynamics of the changes present in the passenger car age structure in Poland.

Also, in the event of car import, there is a clear element which can be described as the transition to the subsequent technological car generation. On one hand it is a natural process as a consequence of sometimes limited wear&tear, depreciation period and car durability, but also the technological advancement and associated changes to valid standards on the other. Very slowly, yet on a systematic basis, the percentage of imported cars younger than 4 years is growing (PZPM).

The Motor Market, Passenger Car Segment – Development Perspectives and Their Basic Determinants

The above mentioned short- and medium-term perspective of the generation change of cars in Poland along with the rising number of vehicles, is the factor stimulating the demand for liquid fuels. This will refer to petroleum and diesel oil in similar proportions. With time, however, it seems to be of more certainty that the demand will differ as to the choice in favour of petrol and the drop in diesel consumption. Both the pace and dynamics of the process will progress in relation to the extent of pro-environmental awareness among the society and the respective regulations. It is not difficult to notice in the said processes the effects of the changes occurring in the passenger car market and of the transformations started by the introduction of new types of drives. It is interesting to see the rising share of hybrid cars. The reports focus exclusively on the plug-in types (hereafter PHEV - Plug-in Hybrid Electric Vehicles / PK comm.), the y/y/ records display 29%. Trying to estimate the future demand for fuels, vehicles featuring the combustion-and-electric drive with no access to chargers (hereafter: HEV - Hybrid Electric Vehicles / PK comm.) will appear in significant numbers.

Their share in the secondary market is becoming more and more clear. In August 2019, in the most popular Internet motor announcements service, it reached 2%, in the event of new cars it was over 12%. If this trend is maintained, the quantity of passenger cars with compression ignition will be outnumbered by vehicles powered by engine petrol followed by LPG, CNG and possibly also ethanol-based fuels.

The preferences under the "Law on Electromobility and Alternative Fuels"[1] or the Order concerning supplements to electric cars do not seem to be able to change much. The scale of the planned supplements will only allow to be used in case of short-range small cars. It may merely serve as an additional stimulus to raise interest in electricity powered vehicles.

Analysing the factors influencing the domestic market, the cultural aspects should also be taken into consideration. The variable which must not be neglected is the attitude of the subsequent generations to owning a car (Hysa, 2016). The so-called Y-Generation forms a considerable barrier, i.e. persons born in 1980s and early 1990s. Analytical surveys of the HR areas indicate no manifestation of the said need (Stachowska, 2012).

The UE legislation and the changes trends makes the endogenic factor of market shaping, which is a result of Poland's membership in the UE structures. Almost all of the Union bodies, the European Commission including, have been very clearly manifesting their concern about the natural environment and the need to counteract the ongoing climatic changes. This is well reflected in the resolutions concerning the acceptable fumes emission standards. They determine the work in the motor industry, both in the design and construction sector and the fuel manufacturers as well. The trends of the ongoing transformations can be spotted as early as the applications for changes or replacement of the present regulations[2]. The base guidelines were specified already in April 2019 (European Commission).

The technological solutions are external elements affecting the market. Their availability on the target market determine the popularity of a given vehicle or model type. And this is the place where logistics issues are exposed followed by the so called environmental factor, such as CNG system presence will not be a supply advantage if in the nearest area of the potential customer there is no station to fill the tank with the "blue fuel", a garage or workshop specialising in particular repairs, etc.

CO_2 emission limitation as electromobility development stimulus

The conclusion of the Paris Agreement on greenhouse gases reduction, including CO_2 made the EU member states initiate actions to achieve the aim (Ministerstwo Aktywów Państwowych, 2017). An outline of new regulations likely to efficiently reduce the road transport emission was put forth already in 2017. Those propositions were included in the so called third package entitled "pure mobility". The European Parliament made a respective statement in October 2018. The member states negotiations were going on until January 2019. Their results were codified on 15th April 2019. The basic assumption of the then adopted order saw drop of the CO_2 emission into the atmosphere in 2030 by 37,5% for passenger cars and by 31% for trucks in relation to 2021. It is supposed to happen gradually so that the said reduction over the years 205-2029 would not be lower than 15%. The quoted values refer to the average size vehicle park by a given manufacturer.

Early 2021 was set as the moment of changes. Then the maximum CO_2 emission norm is supposed to be implemented on the level of 95 gr/km. Before this happens, the 1st January 2020 marks the implementation of the obligatory limit CO_2 95gr/km. It is by 35 gr more than the prospective amount in Euro 6 – 130 gr, which was deemed standard until the end of 2019. The very decisions cannot be regarded as novelty. Initial assumptions concerning the top levels were known already in 2014 (International Council on Clean Transportation, 2014).

[1] LAW on Electromobility and Alternative Fuels dated 11th January 2018, Journal 2018, item 317.

[2] F.ex. an application – EUROPEAN PARLIAMENT AND COUNCIL ORDER *altering the Order (CE) No. 715/2007 on homologation of engine cars type in relation to pollution emission from light passenger cars and vans (Euro 5 & Euro 6) and on the access to information concerning vehicle repair and maintenance,*
https://ec.europa.eu/transparency/regdoc/rep/1/2019/PL/COM-2019-208-F1-PL-MAIN-PART-1.PDF

Fig. 3 :Acceptable CO_2 emission for passenger cars and light vans

Year	gr/km
2021	95
2025	80,75
2030	59,37

Source: Author's own survey based on the EC data.

Failure to stick to the abovementioned standards is subject to financial penalties. Initially, they were of progressive nature: € 5 was paid for the first gram too much, € 15 for the next, €25 for the subsequent and finally € 95 for the further grams (European Commission). Since 2019, the latter rate has been compulsory. It refers to every registered car. In 2020, 95% cars will meet the standard: starting with 2021 - all new cars. The emission volume subject to calculation will be distributed over the entire manufacturer's fleet. This means a rise in price of many car models which for many concerns equals slump in income and lesser profit.

In practical terms, the standards planned for early 2021 will not be met by any model with the conventional combustion engine drive. This refers to both the spark ignition and compression ignition vehicles. See Fig. 1.

The reason is very prosaic. The main factor determining the CO_2 emission into the atmosphere is the burn of hydrocarbons. The volume of gas is directly proportional to the amount of consumed fuel and translates to the vehicle power (Adamski and Brzozowski, 2009).
This formula defines the situation:

$$P_s = \frac{P_t}{\vartheta \cdot \eta_m} + P_{acc}$$

Where:
P_t total power required on vehicle wheels [kW],
η_m– total efficiency of driveline,
v– engine power drop coefficient in non-specified working conditions,
P acc – power absorbed by additional accessories (i.e. air conditioning) [kW].

Fig. 4: Emission targets and average emissions for a particular manufacturer fleets in kg.

Source: Verband der Automobilindustrie (VDA).

Consumers do not seem to be interested in the purchase of significantly lower power vehicles and, what is more, it does not always solve the problem.

According to the calculations done by Intergovernmental Panel on Climate Change (IPCC) - 1 litre of combusted petrol generates 2370 g CO_2, while one litre of Diesel oil – 2650 g CO_2.

Thus (CI):

$$\frac{2370\ gr}{100\ km} \times Xl = 95\ {}^{gr}/_{km},$$

which means:

$$23{,}7\ {}^{gr}/_{km} \times Xl = 95\ {}^{gr}/_{km}$$

Hence:

$$X = \frac{95}{23{,}7}\ {}^{gr}/_{km} = 4{,}008\ l$$ – combustion is not likely to be in excess of 4 litres in the mixed cycle per 100 km,

the limit is supposed to be lower by 15% in 2025 against the 2021 level, which is in line with the 80,75 gr/km value:

$$X = \frac{80{,}75}{23{,}7}\ {}^{gr}/_{km} = 3{,}40$$, thus, combustion is not supposed to be in excess of 4 litres in the mixed cycle per 100 km,

and in 2030 is supposed to decrease by 37,5% in relation to 2021 i.e. down to about 59,37 gr/km:

$$X = \frac{59{,}37}{23{,}7}\ {}^{gr}/_{km} = 2{,}50$$

for compression ignition (CI) engines operated by diesel oil,

thus, in the CI case

$$\frac{2650\ gr}{100\ km} \times Xl = 95\ {}^{gr}/_{km},$$

which means:

$$26{,}5\ {}^{gr}/_{km} \times Xl = 95\ {}^{gr}/_{km}$$

Then:

$$X = \frac{95}{26{,}5}\ {}^{gr}/_{km} = 3{,}58\ l$$ – combustion uses 3,58 litres in the mixed cycle per 100 km,

in 2025 this value is going to drip down by 15%, i.e. 95 × 15% = 80,75 gr/km:

$$X = \frac{80{,}75}{26{,}5}\ {}^{gr}/_{km} = 3{,}04,$$

and in 2030 this value will decrease by 37,5%, i.e. 95 × 37,5% = 59,37:

$$X = \frac{59{,}37}{26{,}7}\ {}^{gr}/_{km} = 2{,}22$$

Technical data:
Engine: 1-cylindrer, fluid-cooled in thermosiphon system
Cylinder capacity: 500 cm^3
Power: 10 KM
Gearbox: 3-gear
Rear-wheel brakes
No Differential
Maximum speed: 80 km/h

Given today's technology and engineering opportunities, no exclusively hydrocarbon fuel operated vehicle is able to meet the said standards. Much sought by the customers car power and weight are the major obstacle. There exist vehicle prototypes powered by petrol which are able to meet the emission requirements. However, owing to the functionality issue, they were never implemented into mass production or hit the market. An example of such a car is the German Hanomag Komissbrot manufactured in 1920s, over 15 000 items of which appeared on the roads.

Fig. 5: Hanomag Komissbrot (Germany) – 1920s, CO_2 emission below 20 gr/km – 15 000 cars were manufactured

Source: autoexpert.pl.

Fig. 6: Possible motor industry development trends changes triggered by the CO_2 emission levels restrictions

New legislation getting the car manufacturers to offer car models subjected to downsizing or the plug-in and electric vehicles builds up one of the possible scenarios of the situation development in the market. Its coming true is equal to the reduction, and on a longer run, even to total elimination of new combustion engine cars.

Fuel Alternative to Electromobility

Electromobility involving electric and plug-in hybrid vehicles seems to be the only predictable development path of the motor market.

Nevertheless, the principles of a scientific study have it that other potential solutions must be indicated. An alternative to the reduction of the drive units capacity might be new constructions. However, it does not seem possible that there are such ones present and waiting to be implemented for it is difficult to imagine that any concern having such a vehicle in place would waive the opportunity to present it to win the advantage over the competition and dominate the market. Information on designs and prototypes of vehicles featuring the well-known standards and consuming less than 4 litres of petrol or 3.5 litre of diesel have systematically been appearing for years. The procedure path from the Concept Car to the production onset is long and the scepticism concerning the final effects of such enterprises is well-grounded. It results from the so far experienced implementation cases and is reflected in lack of such vehicles on the market. If the restrictions concerning the construction of new type drive units seem to have negative forecast, then the possibility of changes to liquid fuel composition used for combustion engines must be seriously taken into consideration.

The definitions of fuels that have appeared so far and based on the legislative instruments[3] and tax regulations[4] contain gaps connecting the product with the system used for its production[5]. This, however, does not seem a solution for a longer perspective. This is the situation where a substance never before used for that purpose has not yet become a problem but is the matter of time. Given the popularity of the solutions applied in South America, adaptation of the more and more successful

ethanol-based technologies, even in the USA, should be taken into consideration. CO_2 emission into the atmosphere in case of C_2H_5OH power is balanced by CO_2 absorbed by the plants used for alcohol production (Żółty and Stępień, 2016). It is also lower than the mined hydrocarbons derived engine petrol (Patyk and Kułakowska, 2013).

Fig. 7: Test results of lead-free petrol against petrol and ethanol blends

3000 rot/min	vol. 14,3 %	3000 rot.min	13,4 % vol.

Source: study by Patyk and Kułakowska (2013).

The difference is minor because lower combustion value triggers higher fuel consumption (Ambrozik and Łagrowski, 2014). As a result, the difference reaches about 2%. Nevertheless, which is worth repeated emphasising, owing to its biological origin, ethanol is treated as emission-free medium (Stelmasiak, 2014).

As fuel, it also has many other advantages, such as high culture work and strong independence of external temperature conditions which allows for operation in extreme cold external surrounding. A higher octane than in petrol is in favour of ethanol because it means resistance to uncontrolled spontaneous fuel combustion. It also has broader flammability limits and bigger flame velocity. It is characterised by greater evaporation heat which has some impact on the engine performance powered by it. As to the drawbacks, it features a greater ability to mix with water which is detriment to the device's durability. A more serious fault in this fuel is its lower vapour pressure than in engine petrol, and so the very combustion process. The high failure rate, shorter life and excess fuel consumption are drawbacks of all spark ignited engines. The list of potential difficulties the application of ethanol as energy medium poses must be expanded by the limited storage opportunities and flammability.

Service and Related Infrastructure Development Problems

The present stage of the electromobility development in Poland can be tagged as initial. It is due to the general regulations included in the abovementioned *Law on Electromobility and Alternative Fuels,* which makes the legislative basis for all activities within this area of the motor market[6]. The executive laws help here as the important completion and supplement, such as the Order by Minister of Energy on the technical requirements for charging stations[7] or the charging stations records[8]. The inherent feature of the creation period of the broadly meant mobility-related market is the relatively small number of RV and PHEV vehicles that hit the roads. On 12th December 2019 there were only 6672 such vehicles. The EV were in the majority - 4178, while PHEV – 2494 (PSPA, 2019). The public charging stations alike - 888, of which 624 – AC and 264 – DC (PSPA, 2019).

Fig. 23 : EV and PHEV registered in Poland on 12th December 2019

Source: Author's own survey on the basis of pspa.com.pl

The relatively small number of the entities is not here a problem, as they are going to appear, and taking into account the said dynamics of the motor market in Poland on the basis of the passenger car segment, the process will keep unfolding at a fast pace. The main challenge is not the very idea but its transfer into the planning sphere. One of the fundamental issues is the energy security.

Power Protection

According to the data concerning the preferences of electric car drivers, in the USA and Western Europe countries the absolute majority of such car owners charge their vehicles at home or at work; rarely at shopping centres (Muzi, 2018). It would be practical to assume having a standard in place which states in big city satellite towns, at 10:00 p.m. in nearly every household additional 3,7 kWh to 22 kWh power supply will be provided. This means multiplication of previous consumption by a few or a dozen times. In case of shopping centres those values are still bigger.

A small village of Chomęcice near Komorniki, 15 km away from Poznań city centre in central-west Poland was taken as an example. It is one of the wealthiest, most modern with most developed transport infrastructure regions in Poland. In nearly 400 houses there live 1234 residents[9]. Owing to its specific type and the wealth of the citizens, the number of cars registered in this area oscillates around 800 and the figure is significantly higher than average in Poland, i.e. 600 cars per 1000 (Eurostat, 2019). Had they been electric, half of the number would be charged at night with the use of minimum power of 3,7 kWh, energy consumption would have been 1,5 MW. The local transformers are able to secure one third of this figure. Their possible extension would not help much given the inadequate electric energy network systems.

The above described example may be applied to any locality in Poland. Contrasted to other places in terms of electric power infrastructure, it shows successful which is due to the region prosperity among others. In the national dimension, the existing condition can be considered as totally useless for any progress in terms of electromobility and the presence of this type of vehicles bigger number.

[9] Data by Urząd Gminy Komorniki

Conclusions

The electromobility programme in Poland finds its place in the area of political declarations. Its concept is based on the assumption this king of suggestion or proposition will convince the society to back up the government. The idea exposes its innovative elements and will give airs of the governing party contradicting the stereotypes of right-wing populists unable to think innovative.

From the marketing point of view, the programme was successful. The critical approach imposed on the opposition merely lack of objectiveness. The criticism traditionally used for this purpose putting forth the argument of limitations as the historic conditions' heritage did not work here. The electromobility area is a global challenge of the future. All the states are at more or less the same stage and the differences in implementation are acceptable.

The concept of electromobility development as the economy flywheel for the nearest future is perfectly composed with the characteristics of the Polish fuel sector. Featuring no downstream, doomed to import hydrocarbon-based fuels, it owes its economic existence only to the privileged legal position that ensures the advantage over the foreign competition. What is important and wroth pointing out, the greatest oil concern of Poland, the PKN Orlen has spotted niche businesses for them and started diversifying the income sources focusing on electric power production and marketing. Given the fuel stations network, correlating this activity with electromobility is only the matter of time.

In Polish circumstances, the electromobility development plan is greatly aided by the Polish motor market size and dynamics. The passenger car segment only, displays over 20 million vehicles, and there is a clear trend for upgrading and implementation of innovative solutions. Following this analysis, the only possible direction of changes is the alternate way of car powering, i.e. the introduction of electromobility.

The distribution infrastructure across the country still remains the prohibitive barrier to be overcome. Its characteristics prevent the electromobility programme to be implemented. It is due to the unsatisfactory electric power supply in terms of medium voltage line and transformers density. It is the electric power distributors who are responsible for the infrastructure improvement. They are companies with National Treasury share. They are among the richest economic entities in Poland and also play a significant political role. The scale of the investment required for the electromobility development is unacceptable for them. A potential solution, which is the microgeneration expansion, is against their welfare as this would mean the end of the centred electric energy system based on concessions, which make their existence happen. This situation makes the government programme confined to a plan incapable of being implemented.

Abstract

From the perspectives of early warning and identification of risk, risk quantification and analysis, also as risk management, we propose recommendation, which include analysis of behavior citizen in panic, cooperation of the institutions in Romania. The 2019-nCoV coronavirus epidemic started in China's Wuhan city, which has spread throughout the country and subsequently, in a very short period of time, in several states, being viewed as a global contagion effect that causes great concern. As the virus gets closer to Romania, it becomes worrying and citizens are already panicking. Therefore, in this article we will analyze, according to public data, what is the current situation and how well Romania is prepared to manage the risks arising from the confirmation of COVID-19 in the country and how the behavior of citizens in a state of panic is influenced.

Keywords: Coronavirus, 2019-Ncov, Risk Management, Viable System Model, Romania;

Introduction

Mankind is nowadays situated at one of its thousands of key points which have left their footprint within history (either pandemics or wars, among other events resulting in mass deaths). This time, every grain of power on a global scale is focused on the occurrence of the novel coronavirus in Wuhan. Time and time again, there have been performed tests on the hypotheses assuming an influenza-related virus (even the 1918 Spanish flu), SARS coronavirus (Severe Acute Respiratory Syndrome) or MERS (Middle East Respiratory Syndrome) and the avian flu. Within one month from the occurrence of the first infection, the structure of the new strain has been discovered and named Wuhan or Coronavirus 2019-nCoV, after the city where it first made its mark. According to experts, respiratory disease in Wuhan is caused by a new type of coronavirus remotely related to SARS coronavirus (SARS-CoV). Aggressive human-to-human transmission has led to a large number of coronavirus infections leading to the deaths of over 1000 people in several countries. According to official World Health Organizations figures, there were 2,918 deaths out of a total of 81,109 confirmed cases worldwide. The majority were registered in China (2,718 out of 78,191). These figures indicate a mortality rate slightly above 3%.

In this paper we set out to analyze the first economic and social effects of the risk arising from the SARS-CoV- 2 viruses in Romania. We consider that the greatest impact on society in Romania is public panic, lack of medical
supplies, insufficient hospital beds and lack of medical staff. Through this research, we believe that we will contribute to the Romanian literature on the topic of risk management in the context of Coronavirus.

The work is structured on 3 important sections. The first section presents the most important problems that may arise in Romania after the pandemic has been confirmed. The second section presents the medical system in Romania and addresses the emergency department within a hospital from a cyber perspective. We propose a new approach to the viable system model **[1]** within the emergency department to build a clear picture of potential issues regarding the management of patients arriving at the emergency room. The main problem is how to manage waiting time when selecting patients according to the severity of the case. In addition, we also conducted a brief analysis on the situation of beds in hospitals in Romania compared to Italy, a country strongly affected by this pandemic. In the last section we discuss the risks generated by the pandemic in Romania and propose some solutions to reduce their impact throughout the society.

The specialized literature in this field was not very extensive. In view of the situation and urgency of this pandemic, the international academic community is looking for different possibilities to accelerate the development of the disease detection and the identification of an appropriate treatment. More and more academic and research organizations and institutions propose different solutions to help the above objective. For example, the Wellcome Trust collected over 100 signatures to provide access to a database of disease research findings. Thus, journals such as Springer, Taylor and Francis, Elsevier or the British Medical Journal provide important data and research in this area. **[2,3]**

The work paper deals with the incipient aspects of the appearance of Coronavirus in Romania. Due to the rapid advancement of the pandemic and research in the field will be faster, so that specialized literature will change daily.

Main Problems

The risk management of this potential occurrence of Coronavirus in Romania could poses many problems. The major potential impacts on society in Romania could be: public panic, lack of medical supplies and food, insufficient beds and medical staff. A confirmation of the coronavirus epidemic of the Romanian population could also have an impact on the functioning of economic units, such as banks.

The spread of the virus in as many countries in Europe close to Romania and confirmation of the occurrence of coronavirus in Italy has already caused panic among the population. Access to the Internet, to social networks such as Facebook and inter-national news, makes it easy to increase panic and the appearance of chaos in the behavior of citizens. With panic, the economic issues will become even larger in the short term. On an emotional basis, consumption may also rise, but only artificially. This could also lead to a penury in goods, which relies on popular perception of a certain danger. Among the causes, there could be miscommunication, media hype and individual subject knowledge. For example, because of the fear that this form of virus will be confirmed in Romania, people have started to buy as much food as flour, pasta, water, oil, gourd and canned food to prepare with supplies. Thus, a chaos has already been created that does nothing more than amplify the panic even more.

Figure 1: Photography of a supermarket in Romania
Source:https://www.mediafax.ro/social/cozi-in-supermarketurile-din-tara-romanii-si-au-facut-provizii-de-teama-coronavirusului-foto-si-video-18890921

Fear of a coronavirus epidemic in Romania has made it difficult for citizens to storm supermarkets to make food supplies and other necessary things in case isolation becomes necessary. Because of the fear of the coronavirus, and the locals from Borşa, Maramures County, they emptied the shelves of supermarkets. Some of them think about what's worse and make supplies for a few weeks. Others send packages for relatives established in Italy or another affected country. The panic created is self-stimulated by many news stories, some documented and others less documented. Another event that contributes to this behavior of Romanian citizens is also due to the fact that Italy is part of countries infected with coronavirus. A 71-year-old Italian citizen was in Romania on February 18-22, and now, having returned to the Italian town of Cattolica, he has been confirmed to be infected with this virus. This event together with the entry of Italy on the list of infected countries, generated another shock of fear in the population of Romania. **[4,5]**

The head of the Supervisory Board of the National Bank of Romania said that the situation may become worrying for the Romanian banks if they do not provide a working scenario in case of unforeseen events, such as coronavirus, regarding the continuity of the business. From an economic point of view, in the context of investors fearing that the epidemic with the new coronavirus will slow down the economy, European and Asian stock markets have been on a downward trend. The panic created among the citizens leads to as many purchases regarding non-perishable foods, hygiene and protection materials. People need to be aware that this exaggerated fear can lead to a lack of food and hygiene materials, and this is a potential danger to life, health and basic survival. The population must be rational at these times regarding the choices and decisions they make.

The Medical System in Romania

A difficult question, but relevant as it may be, is whether the medical system in Romania is ready for a possible coronavirus pandemic. Do the medical units in Romania have enough beds for an emergency patient boom? Do they have enough medical staff? Do the hospitals in Romania have an emergency system within a hospital that is ready to make an appropriate and timely triage on a large volume of patients coming to the emergency for fear of a possible coronavirus infection?

In the following, we will describe from the perspective of a viable system how an emergency room is organized within a hospital in Romania and how the triage is performed. In addition, we will analyze the situation of available beds in Romania compared to Italy. In addition, we will analyze the situation of available beds in Romania compared to Italy. According to some researchers that this virus has the

characteristics of a pneumonia, we will analyze how many deaths were in Romania due to this disease compared to Italy before the possible occurrence of this virus.

Figure 2: Hospital available beds in Romania compared to Italy

Source: Authors computation based on data available at 26.02.2020
https://ec.europa.eu/eurostat/tgm/table.do?tab=table&plugin=1&language=en&pcode=tps00046

According to the Eurostat, hospital beds provide information on health care capacities, i.e. on the maximum number of patients who can be treated by hospitals. Total hospital beds are all hospital beds which are regularly maintained and staffed and immediately available for the care of admitted patients; both occupied and unoccupied beds are covered. Hospitals are defined according to the classification of health care providers of the System of Health Accounts (SHA).

Table 1: The data of available beds

Year	2006	2007	2008	2009	2010	2011	2012	2013	2014	2015	2016	2017

Table 2 : The data of the death due to pneumonia

Year	2011	2012	2013	2014	2015	2016
Romania	30.75	34.75	31.8	32.56	38.45	36.45
Italy	13.01	13.91	13.24	12.89	15.98	14.35

Source: Authors computation based on data available at 26.02.2020
https://ec.europa.eu/eurostat/tgm/table.do?tab=table&init=1&language=en&pcode=tps00128&plugin=1

According to the Eurostat, death rate of a population adjusted to a standard age distribution. As most causes of death vary significantly with people's age and sex, the use of standardized death rates improves comparability over time and between countries, as they aim at measuring death rates independently of different age structures of populations. The standardized death rates used here are calculated on the basis of a standard European population (defined by the World Health Organization). **[6,7]**

Although there are more beds in Romania than in Italy, the lack of beds and medical staff in the number of patients is already a known problem in Romania. In addition, as shown in Table 2, in Romania there is a higher death rate from pneumonia than in Italy, so from this point of view we can say that there is a possibility that the human body is not prepared for coronavirus. In addition, many Romanian citizens

rush to the hospital after experiencing cold symptoms or fever because of the fear of viral infection. The lack of beds and medical staff could be an important risk factor. According to the data updated so far, there are 380 confirmed cases and 12 people dead in the European Union (plus Great Britain, Iceland, Norway and Liechtenstein, Switzerland). The map presented by European Center of Disease Prevention and Control (ECDC) is updated in real time.

From the ECDC's point of view, things are as follows: At this point, the best way to reduce the spread of the virus is to quickly identify and test suspicious cases and to identify and monitor the people they came in contact with. In the past, systematic implementation of infection prevention and control measures has been effective, both for SARS-CoV (severe acute respiratory syndrome) and MERS-CoV ("Middle East respiratory syndrome", published in 2013 in Saudi Arabia).

An approach to the Viable System Model in the Emergency Medical System

The association between the mathematic and cybernetic models in order to modelling behaviour of subsystems. Associating mathematical and cybernetic systems, modelling the behaviour on subsystems can lead to the apparition of discrepancies between decision results adopted according with the delivered solutions and the existing expectations between the members of human society. Even though differences are present, the obtained results can be used in order to improve regulatory processes in order for the medical system to use an optimal allocation combination of resources and guarantee the satisfaction of all agents of human society. **[1,8]**

National protocol for the triage of patients in emergency hospitals structures from 25.03.2019 is based on ESI (Emergency Severity Index) triage scale, from 1 to 5, in order to facilitate the priority based on state of emergency. The second goal of this type of triage, by asking who should be seen first, beside taking into consideration what resources are required for the patients, but also sending them to the right place at the right time. Triage is done in a specially arranged area, having specific lay outs depending on the available space. Two parameters are taken into account, the moment when the patient entered in the facility and is seen by triage assistant and the moment when the patient is receiving the first medial consultation in the treatment areas.

The character of the limited resources regarding the emergency medical personnel requires the diagnosis of the emergency system for an optimal allocation of these resources. Thus, an approach to the Viable System Model (VSM) may highlight certain factors that would influence the viability of the entire emergency system.

Starting from the cybernetic conception of Norbert Winer, McCulloch and Ross Ashsby, Stafford Beer created the viable system model as a systemic tool for observing collective behavior at large systems. VSM allows a qualitative evaluation of the strategies used to operate with the complexity inherent in cybernetic systems, so that useful tools can be made in the organizational diagnosis but also in establishing optimal decisions. VSM is a means of observing the structural context in which different people engaged in an organization, enterprise or economic system evolve, showing how they interact and how to solve certain problems. Viable systems are capable of having a separate, autonomous existence, compared to other components of the enterprise. Stafford Beer, the parent of managerial cybernetics, laid the fundamental foundations of the viable system model starting from the way the human system works, considering it structured into different relatively autonomous systems, but capable of coordinating and working together to ensure the well-being of the whole organism. Thus, he defined 5 systems that form the basic structure of VSM. Starting from these theories, I will describe the viable system of the emergency admissions department within the Hospital of Bucharest.

Moreover, I will consider the 5 triage rooms to be the 5 basic systems of a viable system at this medical institution. The 5 codes associated with the triage are described in section 4 and represented in the diagram below.

System 1: includes everything intended to ensure the functioning of the entire system. In the case of my study, system 1 associates it with level 1 of the triage, the red code, in which the medical

intervention on the patient is immediate and does not allow waiting queues. A very large number of patients at this level, in a very short period of time, leads to a large allocation of existing staff.

System 2: In some situations, patients may arrive in the emergency room with a major risk of intervention. Thus, from the number of resources allocated to system 1, they can also be allocated here for medical interventions in case of need. Therefore, a conflict of resources is created. Resolving these conflicts is the task of system 2, providing stability to the model. At the level of this system, there must be already assigned personnel to do the correct sorting and to place them in yellow code corresponding to the level 2 of the sorting, and only if it is the major emergency in which the resuscitation is required to be allocated to system 1.

In case of following the investigations at system level 2 or if the patient associated with code 1 does not die and it is found that multiple personnel will be needed and that vital functions are affected, the emergency room associated with level 3 is allocated, green code. Thus, system 3 has the role of supervisor for system 1, optimizing the interactions, seeking to make an efficient allocation of personnel. This increase of efficiency in the functioning of a system is called synergy. This is a process by which the result of the functioning of the elements of system 1 (medical resources) together leads to greater results.

The patient who has stable vital functions and needs a single medical resource is included in the triage code 4, the blue code. Thus, in system 4 we will place the patients in this level of triage, after they have become stable, but still have to be monitored. System 4 will evaluate threats, opportunities and elaborate different reports on changes in vital signs. So, this system produces plans to ensure long-term viability.

The system 5 associated with the level 5 triage, white code, has the role to ensure that all patients included here improve their health quickly, without going to other interventions and worsening the health condition. System 5 must maintain its balance and function in a certain context without losing its cohesion.

Risk Management, Discussion and Recommendations

Most EU Member States have developed risk assessment methodologies, adopted in national law and already operational. These developments are taking place in the context where, starting with 2010, in order to improve the capacity of the Member States to respond through measures of prevention, preparation and intervention to the identified risks, the European Commission has initiated a process of creating a unique methodological framework for risk assessment. to enable the development of common European strategies and policies, based on comparable results at EU level. A common European framework aims at better management and distribution of resources, with the aim of preventing and managing effectively and efficiently the negative effects of disasters and other risks at European Union level. Several epidemics and pandemics that have emerged in recent centuries have their origin in China. In 1781-1782, a flu virus killed many people in China and other countries. The Asian crisis that broke out in 1957 killed over 1 million people. Then followed SARS, in 2002, and bird flu, in 2013. **[9,10,11]**

An important measurement for the prevention and control of the epidemic could be the analysis of the possible risks and their monitoring. Risk monitoring combined with knowledge based on the analysis of larger amounts of data and certain information, combined with artificial intelligence and data science could be a factor that would contribute to improving the reason and behavior of citizens. Due to the high rate of spread of an epidemic, a small amount of data is used and little research is needed to make quick decisions so that the spread of the contagion is prevented. From the point of view of risk management, several parties must be involved, as follows: medical resource, political departments, emergency departments, patient, coronavirus suspected patient, research institutions, citizen, media and inter-national community. They must create a complex network of interactions so that the best decisions are made. When it comes to a contagious disease, many people face panic. We recommend the use of medical personnel specialized in psychology and not only to intervene to promote an optimistic psychology.

Another important player that could help increase citizens' optimism is the government itself, or even the president. For example, it is to be appreciated that the president of Romania discusses with the citizens through press conferences and transmits that the level of mobilization remains high but calls for calm and correct information. All citizens must understand that it is the responsibility of each individual, not just the institutions, to cooperate, to fully respect the directions and advice of the authorities, in order to have a successful strategy in preventing and combating coronavirus infections.

Another recommendation is to continue to publish in a transparent and correct way the reports on citizens who were suspected of the virus but the test came out negative. The media should focus on such news, not on hyperbolizing fake and unrealistic news. To avoid limiting existing resources, authorities should impose in the case of a coronavirus infection, but perhaps before that, a department that will determine for each household the optimal consumption and their needs to accurately provide information regarding medicines, protective masks and food. Another recommendation is to equip several hospitals with the necessary equipment for testing people regarding the transmission and occurrence of this virus because at present there are only a few units throughout the country and every minute is precious in these conditions**.[12,13]**

In Romania, there was a great debate about how the authorities prepared to take security measures at airports in the case of passengers, Romanians and foreigners, who came from Italy, the European country most affected by coronavirus and where many live. Romanian. The question is what specific measures should the Romanian authorities take at airports in order to avoid contact between suspected / infected persons coming from Italy (for example) and other persons? It is up to the Member States to decide what measures to take and ECDC has no power over their decisions. Member States have different approaches to quarantine and the measures to be taken to prevent the spread of the virus, including for returnees or returning from an epicenter of infection. The control measures to be taken to minimize the subsequent transmission of the virus are based on the available information regarding the magnitude of this outbreak and the rate at which it spreads.

Unfortunately, just at the moment of designing this article, the first case of a citizen infected with COVID-19 was confirmed on the Romanian territory **[5]**. The Secretary of State and the Minister of Health officially declared the first case of a patient infected with coronavirus. The Secretary of State stated that the patient was in good condition, had no fever, cough, had no symptoms. Because he is positive, he will be transferred to the hospital and hospitalized. A crew from ISU Dolj, with a special insulated truck, are already departing from Craiova to take the person from their home and transport them to "Matei Balș" Hospital, from Bucharest. Under these conditions, the first and most critical step is restoring people's confidence because many people are and will be psychologically affected. So far, Romania has proven that it still has the situation under control, the state institutions act quickly and preventively every potential and existing case.

Funding: This research received no external funding.

Conflict of Interest: The authors declare no conflict of interest.

Conclusions

In the next research, we will analyze how the behavior of citizens will change considering that the existence of this virus in a patient has been confirmed right now. We will see how the press and state institutions will react to this topic. In addition, we will analyze what will be the impact on industry, companies, banks and, implicitly, in the country's economy.

In this paper we analyzed how the installation of the Coronavirus pandemic would affect Romania from an economic, social and risk management point of view. It is clear that the deficiencies of the medical system together with the panic created by the media creates a negative effect on the way people react to the situation. The key points of such an event is calm and rational thinking. From an economic point of view, we expect the impact to be a negative one, because the pandemic is set up globally. Stock markets will be affected, industries will cease activity and lay off employees.

The economic behavior will be influenced by the behavior of all citizens, organizations and businesses and the decisions taken by each actor involved in the economic system. **[14]**

All of these will create an ideal framework, unfortunately, for the installation of a possible economic crisis. It all depends on how the pandemic will worsen or improve. Installing it in a country and its longer life span will have devastating effects both on the economic level and on human lives.

Taking preventive measures before confirming the coronavirus to a citizen of Romania, we can say that the institutions were prepared for this occurrence. We will see how things will evolve in the next paper. The state will evolve in a positive sense only by making rational decisions, increasing the optimism of the citizens and respecting the strict rules regarding the treatment of this pandemic.

Abstract

The rapid pace of growth of data quantities and the need to make sense of the information chaos have made it possible to introduce a new concept that encompasses these two aspects. Living in a world where we can identify a wealth of data and information, the data mining technique is a useful tool for analyzing a large data set. In this article we have analyzed a data set in order to allow the observation of how innovation has different causal factors in the private sector. The analysis was carried out in several countries in Europe. The first step of the analysis was data processing and descriptive statistics. The next step was to analyze the main components to reduce the dimensionality of the analyzed data set. The third step of the analysis is the cluster technique in order to classify the variables into classes so as to ensure a minimum variability within the class and a maximum variability between classes. The last part of the analysis proposed in this article was the use of classification trees to see what characteristics influence an individual's decision to become an entrepreneur.

Keywords: Data Mining, Private Sector, R Studio, Opinion Influence, Big Data

Introduction

The present work was elaborated to apply the reduction of the dimensionality of a certain data set in order to allow the observation of the way in which the innovation in the private sector, at the level of Europe (by country), has different causal factors (direct or indirect) that allow it to grow and develop, or otherwise, to decrease. These can be: the share of the population with higher education, the share of foreign doctoral students, the share of companies that have high-speed internet access, public or private expenses with research, the share of companies offering training or innovating, the number of publications resulting from public sector collaboration and private, private sector investments in research and higher education.

The rapid pace of growth of data quantities and the need to make sense of the information chaos have made it possible to introduce a new concept that encompasses these two aspects. This is Big Data, the concept that refers to the exponential growth of structured and unstructured data.

Methodology

Big Data is any collection of datasets that are so big and complex that can no longer be processed using traditional means. Forrester analysts described the Big Data phenomenon as "the ability of a company to store, process and analyze all the data needed to function efficiently, make informed decisions, reduce risks and serve the needs of customers."

In 2001, analyst Doug Laney gave a definition of the concept of Big Data that included the three V's:

- volume (if in 2000, a regular computer would have 10 GB of storage space, now Facebook generates 500 terabytes of new data daily, a Boeing 737 generates 240 terabytes during a secure flight over the United States, etc.)
- velocity (user behavior can be reflected by accessing advertisements, various sites, and this happens quickly; online game systems host millions of competing users, each producing a lot of data every second);
- variety (Big Data does not only refer to numbers, character strings, login data, but also includes audio and video data, unstructured data from social media sites, 3D data, the latter making databases and traditional analytics tools to be unprepared; traditional databases were designed to operate on a single server, thus being expensive and finite as capacity in the Big Data context).

SAS specialists added two other dimensions, namely variability and complexity. The first term refers to the inconsistency of the data, and the second refers to the existence of multiple sources of data that make their correlation necessary. Thus, Big Data refers to any complex set of unstructured data, which can no longer be managed with the help of traditional databases, the difficulties of storing, analyzing, manipulating data, viewing and sharing.

The term Big Data is first mentioned in August 1999, when Steve Bryson at al. published the article "Visually exploring gigabyte data sets in real time" in "Communications of the ACM". One of the chapters of the paper is called "Big Data for scientific visualization"[**Error! Reference source not found.**].

In October 2003, Peter Lyman at al. of the Berkeley University publish the paper "How much information?". It tries to quantify the total of new and original information created annually in the world and kept in physical format (books, magazines, etc.), on DVDs and CDs or on magnetic disks. It is found that in 1999 around 1.5 exabytes of unique information were produced worldwide, that is to say about 250 megabytes produced by one person. [7]

R is software that works on the basis of a programming language, providing a variety of statistical analysis and data mining techniques. The popularity of this software has increased lately, due to the variety of facilities it offers in terms of analysis techniques. Thus, R encompasses linear and nonlinear models, classical statistical tests, time series analysis techniques, classification methods, clustering and so on. Through the packages that add functions to the program, the facilities are constantly increased.

Results and Discussions

The study of dimensionality reduction is based on a sample from 2017 consisting of indicators from 28 countries:

Figure 1: The table of the indicators from 28 countries

In the figure below, you can see, in detail, the name of each indicator considered in the paper:

	A	B
1	Indicator	Name
2	I112	Share of population with higher education (group 25 -34 years)
3	I123	The share of foreign doctoral students
4	I131	The share of companies that have high speed internet access
5	I211	Public expenditure on Research % GDP
6	I221	Private expenditure on research development
7	I223	Share of companies offering trainig (IT Competencies)
8	I312	Share of companies that have innovated (non-technological innovation)
9	I322	Number of publications resulting from public-private collaboration
10	I323	Private sector investments in research and higher education
11	I333	The number of designs (aesthetic appearance of a product) registered

Figure 2: Descriptions of the name of each indicator

In order to perform the analysis of the chosen data set, by applying the dimensionality reduction, the R Studio software was used. The first step in the analysis represented the creation of descriptive statistics. Thus, in the figure below, you can see the correlations between the data presented. As the blue increases in intensity, the stronger the correlation between the indicators. The empty squares in the figure

represent that the probability is greater than 0.05, that is there is a statistically insignificant coefficient between certain indicators. For example, the indicator I112 (weight of the population with higher education) has very strong correlations with all the indicators in the data set:

Figure 3: The correlation matrix between the indicators

In the correlation matrix of the figure below, we can say that there is a strong direct (positive) correlation between I211 (Public expenditure on Research% GDP) and I221 (Private expenditure on research development) of 0.80 and a strong correlation in the sense directly (positive) between I223 (Share of training companies) and I312 (Share of innovating companies) of 0.81. Further in the analysis, the correlation matrix was created using the chart. Correlation () function in the Performance Analytics package that allows the correlation chart type to be made.

The values above the main diagonal, in the figure below, represent the values of the correlation coefficients, and the stars represent the significance levels (three stars → significant correlation coefficient, with an associated probability of 0%, two stars → less significant correlation coefficient, a star → very low correlation coefficient). In the figure below, you can see the histograms related to the analyzed indicators, those inclined to the left (related to I123, I131, I211, I221, I322, I323, I333) have the most extreme values to the right, and the indicator I312 has a distribution inclined to the right, with several extreme values to the left. Last but not least, indicator I112 has a distribution close to the normal one.

The graphs below the main diagonal, in the figure below, represent scatter plots detailing the relationship between two quantitative variables. For example, the first scatter plot represents the relationship between indicator I112 (weight of population with higher education) and indicator I123 (weight of foreign doctoral students). Analyzing each scatter plot, we observe a general tendency of growth, more precisely the association between variables is positive. Also, you can see that there are countries (represented by circles) that are positioned above the average or very low, below the average. These countries represent the tools of the dataset.

The Correlation Matrix Chart graph also shows the intensity of the connections between the analyzed variables, so we can see in the 6th scatter plot a very strong connection (the dependency line is drawn

at a distance of about 45 degrees) between the indicator I131 (the share of companies that have high-speed Internet access) and I211 (public spending with% GDP research).

Figure 4: The correlation matrix chart

The second step in the analysis was represented by the analysis of the main components, because following the analysis of the correlation above, it was found that there is informational overlap. We will use the princomp () function to reduce dimensionality by approaching spectral decomposition.

Next, the eigenvalues of the correlation matrix were determined:

Figure 5: Output of the eigenvalues of the correlation matrix

Then, we calculated the number of the main components that will have lambda greater than 1, complying with Kaiser's Criterion and observed the presence of three main components in the chosen data set, following the analysis of the variances representing the square elevation of the standard deviations of each main component.

```
> comp_principale
Call:
princomp(x = c2, cor = TRUE, scores = TRUE)

Standard deviations:
   Comp.1    Comp.2    Comp.3    Comp.4    Comp.5    Comp.6    Comp.7    Comp.8    Comp.9   Comp.10
2.1371229 1.3773048 1.0348787 0.9487691 0.7655302 0.5747423 0.4986770 0.4035662 0.3533782 0.3343873

 10  variables and  28 observations.
```

Figure 6: Output of the princomp () function

In the figure above, following the application of the princomp () function, the standard deviations of the main components were displayed, which shows the percentages of information taken by each new component created. It is also observed that the first three main components take the highest percentage of information from the data set.

Using the summary () function, the simple proportions and cumulative variance ratios of the main components resulted in R. This confirms that we will keep in the analysis, only the first three main components, the standard deviation of the first component is 2.1371229, of the second 1.3773048, and of the third 1.0348787, exceeding the value 1, according to the criterion. to Kaiser. It is also found that the first main component retained in the analysis accounts for 45.6% of the total information, the second holds only 18.9% of the total information, and the third holds only 10.7% of the total information.

Figure 7: The variances of the main component

In the figure above, we can see graphically the three main components (Comp1., Comp.4 and Comp.7) that we will keep in the analysis, results based on the calculated values.

Figure 8: The screeplot of the main component

In order to determine the optimal number of main components that we should keep in the analysis, a line-type screeplot was developed. In the figure above, it is observed how the eigenvalues decrease, thus, the first variance passes to the value 4 (variance = 4.5672943), the second variance decreases to the value of approximately 2 (variance = 1.8969684), and the third component decreases to about 1 (variance = 1.0709738). Then, the slope changes and the values reach below 1, becoming insignificant in the analysis. Therefore, we will only analyze the first three main components in the analysis.

Figure 12: Output from R software

In the two figures above, we observe the correlation matrix between the main components and each indicator chosen in the analysis. Thus, Comp.3 presents a strong correlation of 0.81 with the indicator I112 (weight of the population with higher education), but in general the informational redundancy has decreased, as a very weak correlation

Figure 13: The three dimensional graph

In the three-dimensional graph resulting in R Studio, using the Scatterplot3d () command, you can see the 3 main components and the countries considered in the analysis. Thus, countries such as Finland, Belgium, Denmark, the Netherlands are grouped, more precisely, they are similar in information from the perspective of the 3 main components represented. Germany and Malta represent the outliers, and the majority of countries are grouped above the average of the third main component, with positive values predominating, with Germany, Austria, Romania and Italy below average.

The third step of the study was to perform a cluster analysis. First, the distances between countries were calculated using the Euclidean distance as a calculation method.

Figure 14: The Euclidian methods

It can be seen from the graph of Euclidean distances above that the distance between Germany (6) and Belgium (2) is 4.51. The Euclidean distance was calculated by taking into account the main scores.

Figure 15: Ward method

In the figure above, the WARD distance was calculated, which is based on minimizing the increase in the sum of the squares of errors, after the groups are merged into one. By making a cut in the figure above, at the level of about 6, 3 clusters are obtained. The first cluster is made up of countries such as the Czech Republic, Hungary, Slovakia, Estonia, Croatia, Romania, Bulgaria, Poland, Cyprus, Lithuania.

Figure 16: Centroid method

Using the centroid method, the Euclidean distances between the arithmetic averages of the components of the elements in the three groups were calculated, using the centroid of the clusters. After plotting a cut in the dendrogram, the distribution of the analyzed countries is observed in three clusters. Luxembourg and Malta are part of the first cluster, while the second cluster is made up of countries such as Germany, Denmark, Austria, Norway, the Netherlands, Finland, Belgium and Switzerland.

Figure 17: Silhouette plot for the Ward method

Analyzing the figure above, realized by the function silhouette (), for the Ward method, it can be observed that the highest average is in the case of the division of the countries into 3 classes. Most countries correctly distributed (the value of the silhouette coefficient approaching more than 1) are also in the case of the division into 3 classes, but two countries will remain correctly distributed, with the coefficient of silhouette less than 0.

Figure 18: Silhouette plot for the Centroid method

Analyzing the figure above, realized by the function silhouette (), for the Centroid method, it can be observed that with the increase of the number of clusters, the coefficient of silhouette decreases, but it still remains positive, therefore, the countries are distributed correctly. Therefore, the division of countries into 3 clusters is recommended.

Figure 19: Cluster plot

From the figure above, realized in R Studio, it is observed even more clearly, the 3 clusters and the countries that form them, represented by numbers. Also, the border countries, such as: 12 (Italy), 7 (Estonia), 5 (Denmark), have small silhouette coefficients.

The use of classification trees in the analysis of the decision to become an entrepreneur

The purpose of the analysis is to see what are the characteristics that influence a person's decision to become an entrepreneur. The data set used has been downloaded from www.gemconsoltum.com and is presented as follows:

Figure 20: The table of the data set

From the total of 230 countries we chose for analysis the country of Germany because it has a higher number of records (3842), which will help us to obtain a greater accuracy of the results. For the analysis I will consider the following variables:

• bstart - represents the variable y by which an individual wants or does not want to open a business; depending on the following features;
• suskill - represents a variable by which the individual thinks he or she has competencies entrepreneurs to open the business;
• fearfail - represents the variable that registers the fear of failure, which prevents it individual to open a business;
• gender - represents the gender variable;
• gemwork3 - represents the occupational status and already has three levels;
• gemhhinc - represents the income category;
• knowent - binary variable - which indicates that the individual has acquaintances friends who have opened a business;
• gemeduc - a variable that represents the level of education of the individual;

From the total of 3842, following the data cleaning process, the following division was obtained:

```
> germany<-na.omit(germany)
> table(germany$bstart)

  No   Yes
2647   192
```

Figure 21: Output of R

Thus, at present we have a total of 2839 registrations, of which 2647 consider that they do not want to open a business, while 192 individuals want to open a business.

Figure 22: The classification tree

On each branch we see the variable used and the level it takes ("Yes" / "No"). Only the leaf nodes are labeled, and for "type" = 3 on each branch of the tree we see the variable used and the level it takes. For the numerical information it is observed that we used "extra" = 106 and the probability of class 2 ie the class "yes", that is the weight of the observations from the total sample from the initial node to the root node. It started from 0.11 as a probability of the "no" class, meaning a proportion of 23% of the respondents said they were not afraid of failure. The first variable used was "suskill" whereby the individual believes about having entrepreneurial skills to open the business. It is noticeable that on the left branch we have "No", ie only those who have the answer no have been selected, and the no tag is associated. The tree in the previous figure shows a pale pink leaf which shows us that we have a fairly low probability of 0.64, ie 6% as a risk of misclassification. For respondents who do not know close persons who have a business, it is found that those between 35 and 45 years old do not consider that they can open a business, whereas a percentage of 6% people consider that they can be entrepreneurs in the near future. I applied the "plum" function on the initial tree, using the minimum accepted value of the complexity parameter and obtained a new tree with the variable "suskill" in the first place in importance. Even if the "root" variable is not found on the tree, it appears in the tree with a probability of 60.4%.

The tree below was made using the training set. It is noticeable that we have a probability of 0.98 for individuals who consider that they do not have entrepreneurial skills to open a business.

Figure 23: Training set method of the tree

Conclusions

This article demonstrates the usefulness of the analysis and analysis tools applied to the large datasets generated in the process of observing innovation in the private sector in Europe.

In the first part of the analysis I observed that there is a strong correlation between public spending on research and private spending on research and development. A strong positive correlation was also observed between the share of companies offering training and the share of companies that innovated.

From this first analysis, we observe that the more training offered by companies, the more performance of a company increases. An important correlation was also observed between the share of companies that have access to high-speed Internet and public spending on research. For a clearer analysis, the principal components analysis technique and the clustered technique were used to correctly group the countries considered in the analysis from the variable point of view taken into account.

The last part of the analysis was the evaluation of the characteristics that influence a person's decision to become an entrepreneur. The tree classification technique was used. Germany having the most records in the dataset, was the country for which we analyzed the proposed objective.

Future analyzes of this article are aimed at implementing data mining techniques by applying an online questionnaire to several countries in Europe to determine information about the behavior of individuals who want to be entrepreneurs and how to change this behavior at certain changes. For this purpose, correspondent analysis and conjoint analysis will be used.

Abstract

The implementation of a new investment is subject to uncertainty in many aspects. Therefore, not only should it be preceded by the analysis of internal and external factors that may affect it but also be based on the principles of risk management. The implementation of a product innovation is one of the undertakings, which are burdened with high risk. It mainly stems from the fact that making the decision about broadening the product portfolio most often aims at increasing the organization's profits. The present paper identifies and assesses risk factors related to the implementation of a new product based on a waste raw material on the food market. At the first stage of the research risk factors were identified through brainstorming within the areas of the organization's context, experience, market observations and professional literature. Next, each risk factor was assessed by the research participants according to the likelihood of occurrence and its potential effects of occurrence. The risk value was obtained through multiplying the abovementioned characteristics by each other. On the basis of the obtained results critical (unacceptable) risks were determined. Consequently, mitigation actions were proposed in reference to the unacceptable risks. These actions should contribute to reducing the importance of the threats to an acceptable level, and, thus, boost the project's chances to succeed.

Keywords: Risk, Risk Assessment, Product Innovation, Risk Assessment in The Food Industry, Oil Production Industry

Introduction

The process of diversifying production should be properly planned and realized in a controllable way. It is important to find an appropriate business reason and develop a strategy for actions, which should precede and shape the planning of operational activities. Success on new markets is accompanied by a high risk of failure; therefore, it is extremely significant to carry out a detailed analysis of all factors of varying impact on actions and to properly manage all major threats (Chauhan et al., 2018). The aim of the present research was to identify and assess the risk of implementing a product innovation in an enterprise from the oil production industry, as well as to plan actions related to unacceptable risks.

Risk Management

It is commonly believed that most actions are taken in the uncertain circumstances of changeability and unpredictability of the organization's context (Korombel, 2017). Moreover, it is also assumed that uncertainty is a type of a concrete risk (DSDM Consortium, 2010). The ISO 31000 standard defines risk as the effect of uncertainty on objectives and emphasizes the role of managing diverse risks (ISO 31000). On the other hand, within agile management risk is understood as an occurrence or a set of uncertain occurrences, which, if materialized, have a negative impact on achieving the planned

objectives. It is also important that risk related to the actions taken by the organization does not only generate threats, but also creates opportunities (Hopkin, 2018). Thus, not only does risk assessment support managerial decisions within mitigating risks but also helps to identify the strengths of the project. It is commonly assumed that risk is a combination of the likelihood of an expected event's occurrence (both negative and positive) and the scale of the potential impact on objectives (Hillson, 2009).

The conception of risk management was initiated by the insurance industry at the turn of 1940s and 1950s and was gradually adapted in other areas of management, which is confirmed by numerous publications from this period (Beck da Silva Etges and Cortimigila, 2019; Cagliano, Grimaldi and Rafele, 2014; Cole,Gine and Vickery, 2017; Hoseini, Hertogh and Bosch-Rekveldt, 2019; Shah, Etienne, Siadat and Vernadat, 2017). The core of risk management is the systematic, punctual and structured decision-making in uncertain circumstances, which consists in the identification of possible threats, as well as taking preventive and corrective actions. Therefore, risk management requires the elasticity of realized actions, adapting to the ongoing changes of structures, processes and knowledge level.

All these measures aim at minimizing negative effects of threats related to the actions taken by the organization (Aven, 2016). Managing risk in a project is commonly divided into six basic stages, including (1) risk management planning, (2) risk identification, (3) quality risk analysis, and (4) quantity risk analysis, (5) planning risk mitigation actions, (6) risk monitoring and controls (Hopkin, 2018; Hoseini, Hertogh and Bosch-Rekveldt, 2019). It is also reflected in the risk management model described in the ISO 31000 standard, which states that risk management should embrace determining the context, risk assessment (risk identification, analysis and evaluation) and risk treatment (ISO 31000). The risk assessment process should result in selecting a specific strategy for risk treatment mainly from the following options:

- avoidance – changing the conception of operation,
- transfer – delegating the realization of certain actions to external entities,
- mitigation – taking proper actions, which aim at reducing negative effects of the materialized risk,
- acceptance – accepting the existing risk and acting in uncertain circumstances (Crispim, Silva and Rego, 2019).

The complex and correct risk management in a project or an organization brings many tangible benefits. The most obvious of them include increasing the likelihood of achieving business objectives, improving the decision-making process, and boosting the efficiency of resource allocation. Consequently, risk management should be reflected in cost reduction, shorter time of implementing changes, bigger sense of control over subsequent stages of the project, and preparedness for the occurrence of potential threats (Aven, 2016; Hillson, 2009).

Risk Management in The Food Industry

The food product market undergoes constant evolutionary changes. Even the best-prepared and realized expense and price strategy stops bringing the expected results due to the decreasing role of price as a determinant of consumers' purchasing decision. Consumers' awareness and knowledge are incessantly growing, which is accompanied by the rising expectations towards food products reflected best in the cyclical consumption trends (GlobalFoodForums®, 2019; Giampietr et al., 2018). The crucial condition of gaining competitive advantage is innovativeness. However, it is mostly evolutionary (and not revolutionary), which means that the food market is full of similar products, differing in flavor, form of sales and packaging. The analysis of specific segments of the food industry seems to indicate that the oil production industry is an area resistant to revolutionary changes. The biggest changes within the production technology and new products in this industry could be witnessed in 1990s and now the room for changes within raw material usage is very limited (Boczor and Błażejczyk-Majka, 2018; Chauhan et al., 2018).

The domestic market of edible oils, especially the cold pressed ones, has shown a growing tendency for the last decade, which has triggered considerable interest of researchers. Relevant studies include the quality evaluation of raw materials and final products, as well as increasingly often of byproducts (OECD/FAO, 2016). During the process of cold pressing a significant amount of pomace, i.e. the remaining part of oily raw materials from which the proper oil has been extracted by means of mechanical methods, is created. Numerous studies indicate that oil production waste is a rich source of nutrients and can be successfully used in other branches of the food industry, e.g. in bakery and confectionary, without any threat to health (Coelho & Salas-Mellado, 2015).

Among the main advantages of the further use of pomace as byproducts we may point out the reduction of post-production waste treatment costs and the potential profit from selling press cakes as pomace flour. Sales of this product relates to entering new segments of the market and attracting new consumer groups. Such projects amount to an opportunity (and sometimes even a necessity) for small, family oil mills balancing on the verge of profitability (Bińczak, 2019).

Adapting production to the needs of the new undertaking does not have to be costly, yet, as any new project, entails some risk of failure. Therefore, it calls for the cluster analysis of all relevant factors and taking account of its results in the process of making managerial decisions.

Market risk in the food industry is mostly analyzed in the context of the assessment of the product's impact on consumers' mood and health. It is common to carry out the analysis of exposure to a given nutrient, its biological, chemical and physical safety, as well as to manage risk in the supply chain, i.e. from harvest to the final consumer's purchase (Wrzosek et al., 2017). The approach to risk in the food industry is regulated by law, including the Regulation (EC) no. 178/2002 of the European Parliament and Council of 28 January 2002, which establishes general principles and requirements of the food law, as well as creates the European Food Safety Authority (EFSA). The regulation also contains food safety procedures related to risk analysis that guarantees the minimization of chemical, physical and biological threats of products (Rozporządzenie 178/2002). However, it should be noted that complex risk management of introducing a new product onto the market has been conspicuously absent in research.

Proper Research

The analysis was focused on a family enterprise from the oil production industry, which operates in the Kujawy-Pomerania Voivodeship and specializes in natural edible oils (a statistical oil company in Poland). The company described is J.A.W Łącz Przetwórstwo Roślin Oleistych-Nasiennictwo Ltd. It is a family company in the oil industry producing natural vegetable oils since 1992. The organization has full control over the production process, from sowing plants to harvesting raw material, oil pressing and distribution. The company specializes in cold pressing of edible oils from flax, hemp, sunflower and rapeseed. In addition, it produces oil cake, deoiled meal and firewood briquettes. It is a member of various organizations for organic, traditional and regional food producers. The amount of oil production is: rapeseed oil about 100,000 l, linseed oil about 20,000 l, sunflower 12,000 l, hemp oil about 2,000 l. Production structure: approx. 34% oil and 66% oil cake (data for 2017). Its offer includes both pressed oils – linseed oil, sunflower oil, hemp oil – and refined rape oil. The oils are sold in containers from 250 ml in the case of pressed oils to 5 l in the case of refined rape and sunflower oils. The average annual production volume reaches 20.000 l of linseed oil, 12.000 l of sunflower oil, and approx. 2.000-4.000 l of hemp seed. The efficiency of production is 30%. So far pomace has been sold to local farmers for approx. 4,70-10,70 PLN (1,10-2,50 EUR), while the price of raw materials was approx. 7,00-25,60 PLN (1,65-6,00 EUR). The average price of the enterprise's products was approx. 34,10 PLN (8,00 EUR) for sunflower oil, approx. 64,00 PLN (15 EUR) for linseed oil, and approx. 170,00 PLN (40 EUR) for hemp oil. The oil mill is not dependent on suppliers – raw materials are mostly obtained from farms belonging to the owners of the mill. Retail sales prevail and are realized through phone orders and the Internet service. The enterprise cooperates with several shops located in the same voivodeship in addition to its own shop.

In light of the growing competition and limited technological capacity not allowing to enlarge the present production volume, the enterprise looks for new forms of activity, including the ones involving the rational use of treating byproducts that cannot be transferred to local farmers and breeders. The enterprise has already made the decision about broadening its product portfolio with pomace flours created in the process of milling press cakes, which are obtained in pressing oils. Moreover, the enterprise plans to continue the strategy of selling products in its online shop.

The aim of the present research was to identify and assess the risk of implementing a product innovation in an enterprise from the oil production industry, as well as to plan actions related to unacceptable risks.

Research Method

The research was carried out in two stages (Table 1). The first stage consisted in brainstorming in the group of 10 persons (top management, relevant employees and the present paper's authors). In this way the risk factors of commercializing a new product based on the oil production industry byproducts were identified. The process was founded on the determined context of the organization, its experience, market observations and relevant professional literature. Next (stage 2), the risks attached to each of the identified factors was estimated with the use of our own methodology prepared in accordance with the ISO 31000 standard. This stage aimed at determining risk gradation, indicating priorities in relation to mitigation actions and opportunities.

Table1: Research characteristics

	Stage I	Stage II
Objective	Risk factor identification	Risk estimation and assessment
Method	Brainstorming	Own methodology of risk estimation based on the ISO 31000:2018 standard
Tool	Survey	Survey

Source: own research

In the present study we calculated risk by multiplying the likelihood of a detected event's occurrence and the size of its impact on realizing the planned objectives (effect) by each other. Due to the fact that the ISO 31000 standard does not define a specific methodology of attaching value to risks, i.e. guidelines for risk criteria and their values, in the present study we used the matrix method for risk estimation with the use of the scale ranging from 1 to 4 (Table 2.).

Table 2: Risk estimation measures

Scale	Likelihood	Effect
1	low (0-30%)	insignificant
2	medium (31-60%)	medium
3	high (61-80%)	significant
4	very high (81-100%)	very significant

Source: own research

Risk levels for specific factors were calculated by multiplying Likelihood and Effect of the occurrence by each other (Table 3).

Table 3: Risk estimation matrix

EFFECT	very significant	4	8	12	16
	significant	3	6	9	12
	medium	2	4	6	8
	insignificant	1	2	3	4
		low	medium	high	very high
		likelihood			

Source: own research

Next, on the basis of the obtained value the risks were classified into one of the four groups – insignificant, acceptable, conditionally acceptable, and unacceptable (Table 4.).

Table 4: Classification of risks according to importance

Range	Risk level
1 - 4	low (insignificant)
5 - 8	medium (acceptable)
9 - 12	high (conditionally acceptable)
13 - 16	very high (unacceptable)

Source: own research

The statistical analysis of the results was carried out with the use of IBM SPPS Statistica. Basic statistical measures, including the average and standard deviation, were calculated.

Research Results

Risk Factor Identification

The basis for identifying main risk factors of expanding production and entering a new market segment was the SWOT analysis, which was used to determine and classify all internal and external factors with impact on the current and future situation of the organization taking account of the organization's market position and its micro- and macrocontext. While defining internal factors the following aspects were considered: groups of resources, i.e. personnel, financial resources, knowledge and infrastructure, sales, customer service, logistics, the applied technology, capacity for development, and business process realization tools.

The first stage resulted in the list of 20 risk factors referring to the market situation, the product's specificity and the enterprise's experience (Table 5).

Risk Estimation

The risk factors defined at the first stage of the research were then subjected to assessment in the context of the likelihood of occurrence and the impact scale. The estimation was carried out within the same team of 10 persons, who identified the factors. The discussed results amount to the average of values given by each research participant (Table 5).

Table 5: Risk factors for the process of implementing a product innovation

No.	Risk factor	Value of risk	Description of risk
Internal			
1.	Lack of experience in production not related to fats	6.0±1.4	acceptable
2.	Lack of technological facilities and expertise	6.0±1.2	acceptable
3.	Lack of financial resources for purchasing new equipment	6.0±1.2	acceptable
4.	Shortage of employees	6.0±1.2	acceptable
5.	Lack of room and proper conditions to store the raw material	6.0±1.3	acceptable
6.	Lack of room and proper conditions to store final products	6.0±1.4	acceptable
7.	Lack of financial resources to carry out the marketing campaign	16.0±0.0	unacceptable
8.	Insufficient profit in relation to the spending	12.0±1.5	conditionally acceptable
External			
9.	Poor recognizability of the brand	4.0±0.1	insignificant
10.	Lack of knowledge of the nutritional value of the raw material	16.0±0.0	unacceptable
11.	Lack of knowledge of the energy value of the raw material	16.0±0.0	unacceptable
12.	Lack of knowledge of the chemical and biological processes occurring in the raw material	16.0±0.0	unacceptable
13.	Lack of knowledge of the product's suitability for consumption	16.0±0.0	unacceptable
14.	Limited access to the raw material (seasonal access)	9.0±1.3	conditionally acceptable
15.	Limited number of consumers	16.0±0.0	unacceptable
16.	Limited demand for the product	9.0±1.9	conditionally acceptable
17.	Consumers' reluctance to waste raw materials	16.0±0.0	unacceptable
18.	Difficulty in selecting the price strategy	6.0±1.3	acceptable
19.	Lack of outlets	6.0±1.2	acceptable
20.	Growing competition	6.0±1.3	acceptable

Source: own research

Respondents displayed large consistency of estimation despite the fact that the assessment was carried out individually. Seven risks were identified as unacceptable, 3 – as conditionally acceptable, 9 – as acceptable, and 1 – as insignificant. The low level of consumers' and food producers' awareness of the nutritional values of pomace flours was considered the most important and dangerous factor for the project's success. The expected effect of it is reluctance to the designed product and the fear of lack of demand that would assure the return of the incurred costs and obtaining income at the assumed level. The factors related to the lack of the enterprise's knowledge and experience were considered important. For example, they included difficulty with estimating the expiry date of the product, the necessity to adjust production and employ new workers, which can be problematic when balancing on the verge of the existing production's profitability. The factors linked with the internal adaption of the enterprise to the new production technology were considered less significant due to the fact that it is relatively simple and the enterprise has some resources, as it sells press meal for fodder.

Mitigation Actions

In professional literature it is hard to find any information on the complex risk estimation in the food industry in the context of commercializing new products. It can stem from the interdisciplinary character of our research and the focus on the product itself (and not the accompanying factors). However, the necessity to carry out risk assessment in relation to product quality, including its safety and availability, is strongly emphasized in relevant papers. In order to minimize risk and increase the probability of the project's success the enterprise should launch cooperation with a research unit, which is able to conduct a complex research in the nutritional and energy value of press cakes as well as to assess their suitability for consumption and the dynamics of chemical and biological processes occurring during storage. This knowledge may become a major asset in advertising campaigns and will allow to reduce costs related to conducting research with the use of own resources, including employing new personnel. In addition to nutritional aspects the advertising campaigns should stress the environment-friendliness of using press cakes, as consumers increasingly often take it into account. Not only does the cooperation with a research unit boost credibility but also allows for presenting the product at conferences and finding its new applications.

The factors, which were considered crucial in the context of the project's success, mainly stem from the demand for the product at the insufficient level and, consequently, the relevant low income from sales. It seems that at initial stages the enterprise should focus on intensified marketing and advertising activity targeted on its existing clients. Making better use of the enterprise's website and social media accounts appears to be a highly efficient and cost-free tool in such a situation. These communication channels allow for the direct contact with the consumer, personalized messages and publications. In order to strengthen the message and credibility it is useful to invite a person, who is involved in research in nutrition, and an expert, whose studies focus on the use of waste in the food production, to join the advertising campaign. Once the product is established in the consumers' awareness and the number of rival products is bigger, the enterprise should reconsider the expense and price strategy based on the in-depth analysis.

It should be noted that the general risk related to the production and implementation of pomace flours can be automatically reduced by the changes on the food market and in the consumers' awareness. For the last several years we have observed a shift from the highly-processed food to natural products of high nutritional value. The demand for new gluten-free raw materials (as well as interest in them) has also been growing (GlobalFoodForums®, 2019). Moreover, the need to implement eco-friendly actions, e.g. rational waste treatment (in compliance with the zero-waste policy) and minimization of food waste, has been increasingly emphasized.

The abovementioned questions of designing and implementing innovation on the food market should not be discussed only in the context of maintaining the nutritional and health safety of the new product, as it is recommended to take into account all factors that have impact on the whole project from planning to commercializing and selling the product. The analysis of professional literature within the scope risk management in the food industry indicates two main trends. The first one relates directly to the risk of maintaining the food product's safety, including allergens, durability, vulnerability to microbiological, physical and chemical contamination, as well as the risk in the supply chain (Prakash et al., 2017; Kassie et al., 2014). The other trend is centered on the last phase of the project, i.e. the risk assessment of consumers' reluctance to accept the product, failing against the strong competition of substitute products, and the insufficiently long (in comparison with expectations) product life cycle (Białoskurski, 2018; Fuller, 2016). In addition, some papers touch upon the questions of risk management in projects linked with the implementation of new technologies and machinery, which engages the enterprise's resources and requires large spending (Arrenvalagan and Mohamed, 2016, Rezaee et al., .2018). In spite of different aims of applying risk assessment in the food industry projects they share the common (and analogical to the results obtained in the present study) notion that efficient risk management in new projects is necessary to achieve goals in an efficient and effective way. Moreover, it allows for taking actions in controlled circumstances throughout the whole period of realizing the new project, as well as for taking immediate corrective actions or timely preventive actions (Beck da Silva Etges and Cortimiglia, 2019).

Summary

The process of commercializing a product innovation in an organization is always burdened with a high risk of failure, which calls for in-depth assessment, analysis and management. In the case of the discussed enterprise the biggest threat seems to be the origin of the raw material, which can discourage consumers, the uncertainty of outlets, or the limited human and financial resources, which significantly hinder efficient and memorable advertising campaigns on the national scale. Broadening the product portfolio preceded by risk assessment allows for taking account of all potential difficulties at the stage of planning. It enables the enterprise to properly prepare and increases its chances to succeed. The research also depicts that risk assessment does not have to engage a team of interdisciplinary experts, as it can be founded on the knowledge and experience of employees and careful observations of the macro- and microcontext of the organization.

Resumen

La creación de empresas de alto contenido tecnológico por los propios emprendedores es uno de los principales mecanismos de transferencia tecnológica desde la universidad y los centros de investigación públicos a la industria. Es por ello, que está recibiendo un fuerte impulso con ayudas públicas y la eliminación de ciertas barreras legales en la nueva ley de universidades. Este trabajo tiene como objetivo analizar los determinantes de éxito y fracaso de empresas Spin Off en territorios de baja capacidad de I+D, mediante la evaluación de un instrumento de política pública de intervención, que permiten apoyar la supervivencia de estas unidades empresariales. Se presenta una revisión bibliográfica de los ejes temáticos de empresas de base tecnológica Spin off y los determinantes de éxito y fracaso de estas Spin off. El tipo de investigación que se empleará para desarrollar la investigación será Explicativa-Correlacional, teniendo en cuenta que la investigación va más allá de la descripción de las variables o del establecimiento de relaciones entre estas variables. Además, se espera conocer la relación o grado de asociación que exista entre entre tres, cuatro o más variables en el contexto particular a estudiar. Actualmente se da a conocer cómo será la estructura del desarrollo de la investigación asociadas al planteamiento del problema a resolver, objetivos, ejes temáticos de la investigación, diseño, método y técnicas a utilizar.

Palabras clave: Factores determinantes; Emprendimiento, Spin Off, transferencia de tecnología.

Abstract

The creation of companies with a high technological content by the entrepreneurs themselves is one of the main mechanisms for transferring technology from the university and public research centers to industry. For this reason, it is receiving a strong boost with public aid and the elimination of certain legal barriers in the new university law. This work aims to analyze the determinants of success and failure of Spin Off companies in territories with low R&D capacity, by evaluating a public policy instrument for intervention, which will help support the survival of these business units. . A bibliographic review of the thematic axes of spin-off technology-based companies and the determinants of success and failure of these spin-offs is presented.

The type of research that will be used to develop the research will be Explanatory-Correlational, bearing in mind that the research goes beyond the description of the variables or the establishment of relationships between these variables. Furthermore, it is expected to know the relationship or degree of association that exists between three, four or more variables in the particular context to be studied. Currently, the structure of the research development associated with the approach to the problem to be solved, objectives, thematic axes of the research, design, method and techniques to be used will be disclosed.

Introducción

Durante las últimas décadas, cada vez más investigaciones se han centrado en el emprendimiento como facilitador de la creación de valor social, especialmente en el contexto de las economías emergentes (Londres y Hart, 2004, 2010; Sinkovics et al., 2014). Los problemas relacionados con la creación de valor son evidentes en el contexto de las economías emergentes debido a la baja capacidad del estado para resolver los problemas socioeconómicos. Además, estas economías sufren debido a los desafíos relacionados con la escala, la coordinación y la sostenibilidad de la creación de valor socioeconómicol. En tal contexto, el papel del emprendimiento social para abordar estos problemas múltiples e interdependientes se vuelve vital para estimular el cambio social a través de la innovación (Peredo y McLean, 2006; Sinkovics et al., 2014; Weerawardena y Mort, 2006; Zahra et al., 2009). Debido a este potencial, el emprendimiento social se ha denominado como una nueva norma (Corbett, 2016), por lo que se considera que toda actividad empresarial tiene una dimensión social. Su enfoque disruptivo y no tradicional de la innovación social es un aspecto importante del emprendimiento social, según Nicholls & Pharoah (2008).

Para Fuster, Padilla-Meléndez, Lockett, & del-Águila-Obra (2019), la Teoría del Emprendimiento del Conocimiento es un trabajo que se ha utilizado ampliamente para estudiar la ubicación de la empresa, el emprendimiento estratégico, las tasas de inicio a nivel regional y la cooperación con universidades. En particular, Hellerstedt et al. (2014) demostraron cómo las características del entorno económico y político dentro de cada región influyen en la proporción de spin off consolidadadas, encontrando que el desbordamiento de conocimiento de las universidades y la I+D basadas en la empresa afectan considerablemente los indicadores de creación tanto para las empresas de alta tecnología como de conocimiento. Acs, Braunerhjelm, Audretsch, & Carlsson (2009) mencionan que la Teoría del Emprendimiento del Conocimiento se centran en el nivel de los individuos y su papel en la transferencia de conocimientos. El conocimiento no se relaciona "automáticamente" con otras organizaciones, sino que está sujeto a restricciones institucionales, geográficas y de costos (Almeida y Kogut, 1999; Feldman, 2003) conocido como filtro de conocimiento según Acs et al. (2009) . Esto se define como la brecha entre la inversión en nuevos conocimientos y su comercialización (Audretsch et al., 2014: 316), que conduce a una actividad innovadora y al crecimiento económico.

De nuevo Acs et al. (2009), menciona que las teorías contemporáneas del emprendimiento generalmente se centran en el reconocimiento de oportunidades y la decisión de explotarlas. Aunque la literatura sobre emprendimiento trata las oportunidades como exógenas, la teoría predominante del crecimiento económico sugiere que son endógenas y que el conocimiento creado de forma endógena da como resultado la difusión de conocimientos, lo que permite a los empresarios identificar y aprovechar oportunidades. En este sentido, y como resultado, los modelos de crecimiento endógeno no incorporan un elemento crucial en el proceso de crecimiento económico: la transmisión de “spillovers” de conocimiento a través del espíritu empresarial (Audretsch, 1995). Esto implica que el conocimiento en sí mismo es solo una condición necesaria para el ejercicio de una empresa exitosa en un modelo de crecimiento. Un enfoque interesante recientemente se centra en la asignación de recursos sociales gastados en I + D y espíritu empresarial.

Los países de América Latina y el Caribe (ALC) deben seguir en busca de los medios adecuados para atender a las necesidades básicas de sus poblaciones, con programas de nutrición y saneamiento, reducción de la pobreza, educación de calidad universal y modernización económica. Al mismo tiempo, deben aportar la contribución que les corresponda para hacer frente a los actuales desafíos mundiales. En este contexto, aún en el informe realizado por el Banco Interamericano de Desarrollo (2010), se establece la necesidad de aprovechar las oportunidades que ofrece el cambio tecnológico en una economía globalizada como condición imprescindible para cualquier economía emergente. El incremento en el volumen de recursos canalizados hacia la investigación y el desarrollo (I&D) y la innovación, proveniente de fuentes tanto públicas como privadas, denota que los formuladores de políticas públicas y los dirigentes del sector privado están tomando cada vez mayor conciencia de la importancia del conocimiento para el crecimiento de la productividad.

Incluso con desarrollos positivos como los que se han logrado, la situación general de la región, está caracterizada por una baja intensidad tecnológica y déficits severos en aspectos tales como capital humano, inversión en I&D tanto pública como privada, infraestructura tecnológica, coordinación entre instituciones y eficacia institucional, según Navarro, Crespi, & Zuñiga (2010); esta baja intensidad tecnológica de los sistemas económicos latinoamericanos es consecuencia directa de una estructura económica que depende, en su mayoría, de sectores en los cuales la intensidad tecnológica es también baja, como los relacionados con la extracción de recursos naturales. Allí se llega, sin embargo, a la conclusión de que la región registra más bien un "déficit de innovación", es decir, está caracterizada por una subinversión en tecnología, independientemente de cuál sea la estructura económica prevaleciente en cualquier país en particular. Dicha conclusión apunta a que las inversiones en innovación e I&D resultan decisivas para superar la brecha de productividad entre los países de América Latina y el Caribe y el resto del mundo.

Como lo manifiesta Merino Moreno & Villar Mártil (2007), se resalta el interés del análisis sobre el potencial innovador que se viene identificando en los procesos que posibilitan la transferencia de conocimiento a la sociedad a través de diferentes sistemas y canales cuya disposición y tratamiento varían según sus propósitos. Dentro de este argumento inicial toma cuerpo, como ejercicio tanto de transferencia de conocimiento como de indicador de innovación, la creación de nuevas empresas de base tecnológica, sobre todo de aquéllas que generan mayores expectativas de contribución al estado del bienestar, a saber, las que suponen y aportan un reto innovador basado en la aplicación de conocimiento tecnocientífico y en desarrollos tecnológicos, tanto desde la óptica de ser recurso y capacidad para la creación de valor económico, como desde su consideración para explicar la empresa actual a modo de organización basada en conocimiento para, en definitiva, crear innovación.

Es por ello, que surge la necesidad de esta investigación en conocer los determinantes del proceso de éxito y fracaso de las empresas de base tecnológica, siendo éstas un mecanismo de innovación, que contribuyen así a generar ecosistemas empresariales. La literatura reciente apunta a esto como un área de investigación emergente y prometedora en la que se están invirtiendo cada vez más en las universidades para facilitar el crecimiento económico. Esto se basa, parcialmente, en la idea de que un ecosistema universitario empresarial bien establecido o exitoso conduce automáticamente a la aparición de ecosistemas empresariales con beneficios subsiguientes para la región, según lo define Fuster et al.(2019).

Este artículo está estructurado de la siguiente manera, primero una introducción del problema que se pretende analizar a través de la revisión bibliográfica sobre las empresas de base tecnológica-EBT y sus determinantes de éxito y fracaso, nuestra contribución a través del desarrollo de los objetivos de la investigación y finalmente la metodología que se utilizará para alcanzar los resultados previstos.

Planteamiento del Problema

Para estudiar los factores de éxito y fracaso de las spin off de base tecnológica, City, Amara, City, Rherrad, & Laciak, n.d.), identifican, que existen dos conjuntos de factores que probablemente influyen en la decisión del emprendedores sobre su spin off: los factores de "nivel micro" y "nivel macro". El primer conjunto de estos factores está relacionado con los atributos de los investigadores y las características de sus proyectos de investigación y hallazgos tecnológicos. En cuanto a los determinantes del "nivel macro", la investigación ha demostrado que factores determinantes como los sistemas tecnológicos y las políticas universitarias influyen en la creación de spin-off universitarios.

Cualquiera que sea el nivel de análisis adoptado, se requieren dos condiciones para asegurar el éxito de la creación de spin-off: i) la capacidad empresarial, así como las habilidades técnicas para evaluar el potencial industrial de la tecnología (Roberts y Malone, 1996; Clarysse y Moray, 2004), y ii) el grado de apoyo que reciben los beneficios de sus organizaciones matrices según Roberts y Malone (1996); Steffensen et al. (1999).

Esta necesidad de estudiar estos factores se ve medida por la relevancia de la innovación para la competitividad empresarial y territorial, donde la regeneración de la oferta supone mejoras para el

usuario y, por tanto, genera exigencias sociales que se derivan hacia otros productos y servicios movilizando los esquemas de comercialización y atención al ciudadano. Es más, este enfoque innovador por su soporte en las tecnologías plantea decididamente un esquema de competencia territorial tanto a nivel internacional, donde las balanzas comerciales de tecnología se imponen como referencia de competitividad global, como intranacional, entre regiones, basados en el enfoque de los planes regionales de innovación (Myro y Fernández, 1996) citado por Merino Moreno & Villar Mártil (2007).

Bueno (2005) define que las empresas de base tecnológica y del conocimiento tecnocientífico juegan un papel clave como activo crítico y recurso valioso en la Sociedad y Economía del Conocimiento, requiere ser gobernado adecuadamente tanto desde la óptica de su creación, como de su desarrollo y posterior gestión. En este caso, cabe hacer referencia a las competencias asociadas a este gobierno del conocimiento organizativo basadas en dinámicas de vigilancia tecnológica, redes, comunidades de práctica, comunicación, capital intelectual, gestión de la información, retención del conocimiento, calidad, etc.

Por lo tanto, y para alcanzar los objetivos propuestos en la investigación se identifica que para el planteamiento del problema, la investigación se oriente a dar solución al enunciado ¿ Cuáles son los determinantes de éxito y fracaso de las empresas de base tecnológica Spin Off cuando operan en territorios de baja capacidad de I+D?, y que a su vez estaría apoyadas por unas preguntas secundarias: ¿Cuáles son los elementos determinantes presentes en las empresas de base tecnológica Spin Off asociadas al éxito o fracaso de su operación?, ¿Qué efectos están presentes entre los determinantes de éxito y fracaso de las Spin Off que redundan en su supervivencia?, ¿Cómo es la influencia del ecosistema de innovación sobre los determinantes de éxito y fracaso de las Spin Off? y ¿Cuál sería el comportamiento de las Spin Off durante un proceso de intervención?.

Objetivos

Objetivo General

Analizar los determinantes de éxito y fracaso de empresas Spin Off en territorios de baja capacidad de I+D, mediante la evaluación de un instrumento de política pública de intervención.

Objetivos especificos

Caracterizar los determinantes de éxito y fracaso de las Spin Off, que permiten definir el potencial de crecimiento y sostenibilidad en el mercado de la comercialización de conocimiento.
Determinar los efectos presentes entre los determinantes de éxito y fracaso de las Spin Off que definen su superviviencia.
Analizar la influencia del ecosistema de innovación en los determinantes de éxito y fracaso de las Spin Off.
Evaluar el instrumento de política pública de intervención de las Spin off.

Revisión de Literatura

Empresas de Base Tecnológica-EBT: spin off

Según lo que define Cocorullo (2017) las universidades ahora se consideran actores vitales en el proceso de transferencia de conocimiento, innovación y tecnología del sector académico al sector comercial / productivo. Si en el pasado las universidades cubrieron este rol otorgando patentes a personas externas, la situación ha cambiado fuertemente. En la actualidad, las instituciones académicas también están dedicadas a la creación y promoción de spin-offs y nuevas empresas, como instrumentos para responder a la presión social sobre la rendición de cuentas y el diálogo con la economía mediante el intercambio de resultados de investigación científica (Geiger 2006; Laredo 2007).

Un problema preliminar es la diferencia entre los términos "spin-offs" y "start-ups". En particular, la etiqueta "puesta en marcha" se puede aplicar a cualquier nueva forma de empresa innovadora en su etapa embrionaria. Una vez que el proyecto se lanzó y se separó de la universidad, se convirtió en una

entidad propia, por lo que se puede describir como "spin-off de investigación universitaria". Ser un spin-off podría considerarse como una condición genética que continúa a lo largo de la vida en el mercado empresarial y que podría mitigarse si el spin-off se hace más grande que la institución original.

En consecuencia, el término "spin off" se adoptó para describir una nueva forma de iniciativa empresarial que resulta de una fase previa de investigación académica y que ahora está separada de la institución original y se ha convertido en una entidad independiente en el negocio. El mundo, como instrumento de explotación de la investigación académica. (Lazzeri y Piccaluga 2012).

Para Cocorullo (2017) las empresas Spin Off derivadas de la investigación se definen como nuevas empresas creadas por una institución científica, instituto nacional de investigación, universidad, escuela técnica, institución o laboratorio de I + D público o privado para transferir y comercializar las invenciones resultantes de los esfuerzos de I + D de sus investigadores. La literatura divide entre diferentes tipos de empresas basadas en la investigación, diferenciándose de acuerdo a:

- El tipo de institución matriz de la que se derivan;
- La motivación del investigador;
- Los vínculos entre la institución matriz y el investigador;
- Los medios y fuentes de su financiación.
- Los modelos aplicados institucionalmente para su creación.

En lo que respecta al primero de los criterios de diferenciación de las spin off antes mencionadas, son dos tipos principales de empresas derivadas, es decir, derivaciones corporativas y spin-offs científicas. Las empresas spin-off corporativas son creadas por la empresa matriz con miras a comercializar ideas, tecnologías, productos o soluciones de proceso que no están dentro del área principal de su actividad, pero aún están consideradas comercializable y rentables. Se establecen las spin-offs científicas que comercializan las innovaciones provenientes de instituciones de investigación matriz.

Dependiendo del tipo de organización de investigación, las derivaciones científicas pueden dividirse en spin-offs académicas, las establecidas por investigadores universitarios,y las derivadas no académicos basados en la investigación, establecidos por el personal científico de organizaciones públicas de investigación, es decir, institutos de investigación o laboratorios públicos.

La definición introducida por Klofsten & Jones (2000) enfatiza cómo los spin off académicos se pueden identificar a través de cuatro aspectos que se describen a continuación: un nuevo negocio (entidad autónoma de la universidad, con su propia identidad legal); creado por la universidad (excluyendo así a todas las demás entidades o instituciones de investigación); para el uso de los resultados derivados de académicos (no solo todos los resultados patentables, sino también todos los conocimientos técnicos y científicos adquiridos durante la actividad académica); cuyo propósito es obtener una ganancia (para luego excluir todas las actividades sin fines de lucro).

Por su parte según Merino Moreno & Villar Mártil (2007), la denominación «Empresas de Base Tecnológica» es un término que se refiere a un nuevo tipo de empresas que refleja la transición al nuevo ciclo del sistema capitalista a nivel mundial. El contexto actual establece una serie de criterios que según el profesor Veciana favorecen la creación de nuevas empresas, a saber, «el cambio tecnológico, la sociedad del conocimiento, el sector servicios, el poder tractor de la gran empresa, el problema ecológico, la privatización de servicios públicos, el cambio de estructura demográfica, el cambio de valores de la sociedad, los movimientos migratorios y las políticas de fomento y ayuda a la creación de empresas y empleo».

El interés por esta tipología empresarial, según Camacho et al (1999), radica generalmente en los siguientes factores:

1.Potenciar el I+D regional como motor de la economía regional.
2.Mejorar las relaciones interinstitucionales en el sistema de I+D, especialmente en lo referente al marco de interacción universidad-empresa.

3.Promover la transferencia de tecnología como eje de competitividad y bienestar social, donde las PYMEs, aparte de las grandes empresas, ostentan un lugar clave en la estructura del tejido empresarial y, por tanto, requieren un lugar protagonista en la estrategia regional de innovación (Asheim y Isaksen, 2001).
4.Impulsar el autoempleo como alternativa atractiva de desarrollo profesional.

En definitiva, para Merino Moreno & Villar Mártil (2007), todo este planteamiento del perfil de la EBT se aglutina en la tabla 1, ante la carencia de una definición única, se define Empresa de Base Tecnológica - EBT (Spin Off) como aquella organización productora de bienes y servicios, basados en tecnología nueva o innovadora, comprometida con el diseño, desarrollo y producción de nuevos productos y/o procesos de fabricación innovadores, a través de la aplicación sistemática de conocimientos técnicos y científicos.

Tabla 1: Carácterísticas y consecuencias de Empresas de Base Tecnológica

Características	Consecuencias
Rápido crecimiento	Altas necesidades de capital
Muy enfocadas en innovación	Necesidad de apoyos comerciales
Gestionados por tecnólogos	Necesidad de ayuda gestora
Propiedad intelectual	Posibilidades de elevados márgenes

Fuente: Merino Moreno & Villar Mártil (2007). Pág.150.

Las EBTs se consideran proyectos empresariales donde su principal característica es «el I+D es el negocio» y no una partida presupuestaria. Su proliferación impacta decisivamente en aspectos socioeconómicos como son el empleo, la labor de transferencia tecnológica, el desarrollo regional, etc., haciendo llegar al mercado el conocimiento tecnocientífico.

No obstante, Merino Moreno & Villar Mártil (2007) al margen de estas características cabe hacer referencia a la consideración sobre la reflexión semántica del concepto de «éxito» evidenciando la entrada en un terreno complejo condicionado por el carácter subjetivo del individuo a la hora de considerar si ha logrado el éxito en su proceso de creación de empresa o por el contrario ha fracasado. Este enfoque trascendente podría delimitarse a través de ciertos aspectos básicos que, en su conjunto, enmarcarían de alguna forma el éxito, y por derivada negativa, el fracaso, a saber:

1.La supervivencia del proyecto empresarial. Es decir, se asocia el éxito con la sostenibilidad en el mercado deduciendo la presencia de un grado competitivo suficiente.
2. El crecimiento de la empresa. En este caso, el incremento de la dimensión empresarial mostraría la competitividad y potencial organizativo.
3. El aumento de cuota de mercado. Así, se podría vislumbrar el potencial de la oferta de valor de la empresa.
4. El cumplimiento de las expectativas. De esta forma, se ajustarían sobremanera los criterios de éxito dado que se incluye la percepción del individuo.

Determinantes de éxito y fracaso de spin off

Según City et al. (n.d.), estudios previos sobre cómo las universidades promueven la creación de spin-offs (Radosevich, 1995; Roberts y Malone, 1996; Carrayannis y otros, 1998; Steffensen y otros, 2000) intentan comprender y distinguir los principales problemas planteados por la creación de tales empresas en universidades. En su intento de abordar el fenómeno, esta revisión se ha centrado en las organizaciones matrices (Roberts, 1991a; Rogers, 1986; Steffensen et al., 1999; Smilor et al., 1990), y

en un conjunto complejo de factores como el capital de riesgo, el entorno económico, los activos complementarios y las redes sociales (Chiesa y Piccaluga, 2000; Segal, 1986; Steffensen et al., 1999). Estudios anteriores han prestado poca atención a los determinantes que influyen en la decisión del investigador de una spin off sobre sus resultados académicos y hallazgos.

En su tipología, Di Gregorio & Shane (2003) identifican dos conjuntos de factores que pueden influir en la decisión del investigador de crear una spin off sobre su investigación: factores de "nivel micro" y "nivel macro". El primer conjunto de estos factores está relacionado con los atributos de los investigadores (Levin y Stephen, 1991; Shane y Khurana, 2000; Roberts, 1991; Zuckeret al., 1998) y con las características de sus proyectos de investigación y hallazgos tecnológicos (Shane , 2001a). En cuanto a los determinantes del "nivel macro", la investigación ha demostrado que los determinantes como los sistemas tecnológicos (Shane, 2001b) y las políticas universitarias (Kenney, 1986; Goldfarb et al., 2001) influyen en la creación de spin-offs universitarias.

Cualquiera sea el nivel de análisis adoptado, se necesitan dos condiciones para asegurar el éxito de la creación de spin-offs: i) la capacidad empresarial y las habilidades técnicas para evaluar el potencial industrial de la tecnología (Roberts y Malone, 1996; Clarysse y Moray, 2004), y ii) el grado de apoyo que las empresas derivadas reciben de sus organizaciones matrices (Roberts & Malone, 1996).

En Colombia, como lo describe Vesga (n.d.) y con una mirada a los niveles macro, de las empresas y de los individuos permite identificar fortalezas y debilidades críticas para el desarrollo del capitalismo del emprendimiento y la innovación en nuestro país.

Para este autor en los tres niveles, Colombia presenta una situación destacada en términos de fuerza empresarial y potencial de desarrollo. Una acción decidida sobre puntos críticos en los niveles de las empresas y los individuos podría tener un impacto grande desde este punto de vista. Podría convertirse en el elemento que resolviera el cuello de botella del problema.

A la luz de lo anterior, algunos puntos relevantes para avanzar en el desarrollo del capitalismo emprendedor en el país serían los siguientes:

1. Capital de riesgo. Uno de los puntos centrales que bloquean el desarrollo de empresas nuevas es la ausencia de capital de riesgo. Un cuello de botella básico está en la ausencia de mecanismos de salida para los inversionistas y en la escasa cultura de evaluación de proyectos y valoración de empresas que tienen altos niveles de riesgo.

2. Redes. La construcción deliberada de redes de emprendedores es un paso necesario para el desarrollo de estos proyectos. Las capacidades competitivas de las empresas de innovación dependen en forma crítica de los activos intangibles relacionados con el conocimiento, los cuales requieren de la existencia de redes efectivas para poder desarrollarse.

3. Infraestructura. El desbloqueo de los sistemas de puertos y carreteras del país es esencial para el emprendimiento innovador. En términos de telecomunicaciones y tecnologías de información se ha avanzado en esta década, pero se requiere acelerar el paso.

4. Actores. Existe en Colombia una amplia gama de iniciativas y actores que están trabajando para que el país desarrolle una cultura empresarial más emprendedora y más innovadora.

5. Investigación. Es indispensable multiplicar los esfuerzos de investigación sobre los determinantes de las fuerzas que afectan el emprendimiento y la innovación en los tres diferentes niveles. Hay una concentración de esfuerzos en el tema macro y en las consideraciones de política pública, pero sabemos poco sobre los determinantes en los niveles de la empresa y el individuo.

En términos generales, los hallazgos de la investigación se han centrado en la revisión bibliográfica asociadas a spin off de orígen universitarios y se han aceptado como determinantes de las spin off.

Tipo De Investigación

El tipo de investigación a emplearse en la investigación es Explicativa-Correlacional, teniendo en cuenta que la investigación va más allá de la descripción de las variables o del establecimiento de relaciones entre estas variables; es decir, están dirigidos a responder por el comportamiento de esos determinantes en la supervivencia de estas empresas intensivas de conocimiento, es decir, en qué condiciones se manifiestan estas dos o más variables. Además, se espera conocer la relación o grado de asociación que exista entre entre tres, cuatro o más variables en el contexto en particular a estudiar.

En la primera etapa, asociado al cumplimiento del primer objetivo donde el estadío es Descriptivo, donde lo que se busca será una descripción completa de los determinantes de la innovación de éxito y fracaso que están presentes en las Spin off, teniendo en cuenta que se debe estudiar estas características que no se manifiestan tan evidentes en la realidad. Esta etapa se realizará la validación del instrumento de medición.

Para la segunda etapa, siendo el estadío Explicativo, se perseguirá explicar la relación de los efectos asociados a la acción de los determinantes de innovación en la supervivencia de las Spin off. En esta etapa se utilizará la herramienta de modelo de regresión logística multinivel para definir las relaciones.

Para la etapa tres, teniendo en cuenta que el estadío es Correlacional, se definirá establecer la relación de influencia de los ecosistemas de innovación que se encuentran alrededor de estas empresas spin off y su relación con los determinantes de innovación de éxito y fracaso.

Y finalmente para la etapa cuarta y definitiva, el estadío es Evaluativo, en el que se evaluarán los resultados del proceso de intervención de las spin off que permitan verificar los determinantes de innovación de éxito y fracaso presentes.

Método

El método a utilizarse en la investigación será el método Hipotético-Deductivo, donde el procedimiento permitirá hacer de la actividad una práctica científica. El método hipotético-deductivo tiene varios pasos esenciales: observación del fenómeno a estudiar, creación de una hipótesis para explicar dicho fenómeno, deducción de consecuencias o proposiciones más elementales que la propia hipótesis, y verificación o comprobación de la verdad de los enunciados deducidos comparándolos con la experiencia.

Diseño de Investigación

Con relación al diseño de la investigación y cómo se recogeran los datos, los objetivos especificos están enmarcados en un diseño de campo, transeccional, de evolución de grupo, univariable para cada uno de los objetivos del proyecto.

Hipótesis

Para la presente investigación y teniendo en cuenta que el diseño de la investigación es transeccional, las hipótesis son de investigación y se fundamentan en diferencia de grupos, correlacionales y causales, donde se recolectarán datos sobre categorías, contextos, variables y sus relaciones en los dos momentos desarrollados por el programa Probeta del Distrito de Barranquilla-Colombia para evaluar el cambio en éstas.

Las hipótesis se encuentran estrechamente relacionadas con algunos factores de éxito y fracaso de la innovación: el modelo de negocio, el tipo de producto o servicio que proporcionan a sus clientes, capacidad empresarial, habilidades técnicas para evaluar el potencial industrial de la tecnología, el

grado de apoyo que reciben de sus organizaciones matrices y su capacidad de adaptarse a los cambios continuos y mantener su capacidad de innovación. A continuación se relacionan:

H1: El éxito o fracaso de las Spin Off está relacionado con un ecosistema de innovación con alta intensidad de I+D.
H2: El efecto de las variables de innovación de éxito y fracaso en Spin Off es igual en las unidades de negocio en un tiempo inicial con aquellas participantes en el tiempo final.
H3: El modelo de negocio y las habilidades técnicas para evaluar el potencial industrial de la tecnología son los determinantes que definen el éxito o fracaso de las Spin Off en el entorno de innovación.
H4: El instrumento de política pública de intervención de las Spin off impacta en el comportamiento de los determinantes de innovación en la vida de estas empresas a lo largo del proceso.

Unidades de Estudio

Las unidades de estudio de esta investigación hacen parte del programa PROBETA, convocatoria en la que se invita a científicos, grupos de investigación y empresas de tecnología de la ciudad, pertenecientes a los sectores: salud, energía y medio ambiente, a presentar sus iniciativas. Esta población cuenta con 33 empresas dispuestas para ser el objeto de estudio de esta investigación.

Técnicas e Instrumentos de recolección de datos

Tabla 2: Técnicas de recolección de datos por objetivo específico

Objetivo específico	Evento	Técnica de recolección de datos	Instrumento
Caracterizar los determinantes de éxito y fracaso de innovación de las Spin Off.	Determinantes de éxito y fracaso de innovación Spin Off	Encuesta	Cuestionario
Determinar los efectos presentes entre los determinantes de de éxito y fracaso de las Spin Off que definen su superviviencia.	Determinantes de éxito y fracaso de innovación	Entrevistas estructuradas	Guía de entrevista Modelo de regresión logística multinivel
Analizar la influencia del ecosistema de innovación en los determinantes de éxito y fracaso de las Spin Off.	Ecosistema de innovación Determinantes de éxito y fracaso de innovación	Se trabaja con datos recogidos Revisión documental	Matriz de análisis Modelo de regresión logística binaria
Evaluar un instrumento de política pública de intervención de las Spin Off.	Determinantes de éxito y fracaso de innovación Spin Off	Técnica Sociométrica Entrevista estructurada	Guía de entrevista Evaluación Socioeconómica

Abstract

Since globalization became a worldwide phenomenon, a relationship between trade and foreign direct investments (FDI) has attracted economists' and policy-makers' attention. In the aftermath of the last financial crisis, this interest increased as both trade and foreign capital played a pivotal role in the rebalancing of countries' external positions. Despite widespread post-crisis deleveraging and adjustment processes, some euro area countries, including Ireland and Portugal, continue to have large negative net international investment positions, which are well below prudential thresholds. This paper explores, using ARDL models, the influence of the FDI liabilities on demand for exports and imports of goods and services for Ireland and Portugal. The results point to substitute relationships between trade and FDI in both of these countries.

Keywords: Trade Openness, Financial Openness, Foreign Direct Investments

Introduction

Traditionally, international trade and foreign direct investments are the main drivers of economic integration, which interact with each other. Membership in the European common market, adoption of a common currency the euro, and the EU policy aimed at liberalization of trade and capital flows with non-EU countries, enhanced the attractiveness of European countries as trade partners and recipients of foreign investments. Due to these institutional arrangements, as well as technological improvements in communication, information processing, and transportation, the European countries have significantly enlarged their economic openness. According to the UNCTAD data, the average of the EU trade openness, gauged as a sum of exports and imports to GDP, augmented from 50% in 1980 to 87% in 2018. A substantial growth was registered also in capital flows. The average stock of inward foreign direct investments accumulated in the EU economies increased from 5% do 54% of GDP (UNCTAD database).

Rich empirical evidence confirms the widespread benefits of higher economic openness, both in terms of trade and financial factor mobility, which contribute to higher competitiveness, productivity, and consumer's satisfaction (Grossman and Helpman 1991, De Mello 1999, Borenstein et al. 1998, Kose et al. 2006). Although positive effects of capital and trade flows are well documented, there is also rich literature proving that the extended exposition to foreign demand and external financing raises a concern about too much dependence on outward factors. The main drawback of high economic openness is, that it causes higher vulnerability of a domestic economy to international shocks (Rodrik 1997, Stiglitz 2002, Prasad et al. 2003, Shiller 2000). The last financial crisis revealed that countries which accumulated huge external imbalances suffered more from the global turmoil (Lane 2013, Kalantzis et al. 2014). Following a widespread post-crisis deleveraging and adjustment processes, a

number of current account imbalances have been corrected. However, some euro area countries, including Ireland and Portugal, continue to have large negative net international investment positions, below -100% of GDP**,** which is well below prudential thresholds set at -35% of GDP (Eurostat 2018, European Commission, 2018). As both trade and financial flows affect external balance, their role in restoring external equilibrium is essential. Taking into account that these two types of flows may interact with each other, it is worth examining the character of their interlinkages. The identification of the nature of the FDI-trade nexus may not only help to understand the rebalancing process of excessively indebted economies but also evaluate the effects of globalization.

In this paper, we provide the empirical research of the long-run relationship for export and import demand. Besides traditional determinants of the demand for exports, i.e. a foreign income and a relative price level, proxied by a real effective exchange, we add the stock of inward FDI as an explanatory variable. Similarly, the demand for imports is determined by conventional explanatory variables, i.e. domestic income, a real exchange rate, and FDI stock. The study is for two euro-zone economies, Ireland and Portugal, which were severely hit by the last financial crisis and still experience macroeconomic imbalances, in particular involving vulnerabilities from large stocks of net external liabilities.

The paper is organized as follows. In section 2, we review the theoretical issues relating to trade and its determinants, including more specifically, the role of FDI. In section 3, we describe the methodology and present the models for two countries. In section 4, we presents and discuss the empirical results. Conclusions are made in Section 5.

Trade and Foreign Direct Investments: Theoretical considerations and empirical evidence

The classical theory of trade is not useful in explaining the trade-FDI nexus, as it assumes that production factors are immobile between countries. According to the traditional models of trade, exports is determined by the opportunity costs of production and production possibilities frontier in each country. This, implies that country's pattern of comparative advantages is based on the domestic resources, which differ between countries, however, are not mobile internationally. Such approach constraints country's export capacity to domestic factor endowments. Also, a typical function for aggregate imports is based on the Marshallian demand function, where the volume of imports demanded by the domestic residents depends on the domestic income and the ratio of import price to domestic substitute price adjusted for the exchange rate (Feenstra and Taylor, 2014; Lichteinstein 2016).

The increasing openness of economies, as a result of regional integration and globalization processes, gave rise to examine the trade effects of international mobility of production factors. In a seminal paper published in 1957, Mundell showed that trade in goods and production factors movement are substitutes. According to Mundell (1957), the extent to which factor mobility would substitute for goods mobility depends on many factors, such as the relative size of the trading countries, the technologies employed, and restrictions on commodity and capital flows. For example, if barriers on production factors, like capital or labour, are imposed, their effects would be offset by an equivalent increase in imports of capital-intensive or labour-intensive goods, exposing those domestic producers to even more foreign competition. In other words, if capital or labour cannot enter the country, the commodities will. In a similar vein, if domestic policy-makers attempt to protect their market by placing a tariff on capital-intensive or labour-intensive imports, the effect would be higher prices and higher return rate of capital, that attract more foreign investors and more labour. Mundell's reasoning pointed that trade and production factors flows are substitutes, thus it is pointless to restrict the flows of goods, labour or capital.

In the 1980s. the New Trade Theories influenced by monopolistic competition, industrial organization and liberalization of goods and capital flows, shed new light on the relationship between trade and capital flows. Markusen (1984) and Helpman (1984) distinguished between horizontal and vertical foreign investments. The former focuses on the improvement of market access or market growth

prospects, which create a substitutional relationship with the trade. The latter is mainly based on the differences in factor endowments between countries and produces complementarity linkages with trade (Camarero and Tamarit, 2004). Thus, if the foreign investors' interest is generated by a market-seeking strategy, the FDI inflows substitute with the international trade (Anderson et al. 2019). In turn, if foreign investor aims at cost reduction and efficiency improvement, the FDI contribute to complementarity, rather than substitutability with trade. The vertical type of the FDI is often associated with international fragmentation of production and activities of multinational corporations. Countries increasingly involved in international production networks trade within industries, as well as within firms, i.e. they export and import different varieties or qualities of products of the same industry, as well as sell abroad semi-finished commodities, which undergo further processing (Borga and Caliandro, 2018).

Models and Methodology

To explore how foreign direct investments affect trade we analyze the long-run relationship using the following model for exports:

$$ln\, EX_t = \alpha_0 + \alpha_1\, ln\, FDI_t + \alpha_2\, ln\, GDP_t + \alpha_3\, ln\, RR_t + \varepsilon_t \qquad (1)$$

where EX denotes exports of goods and services, FDI is the stock of inward foreign direct investments, GDP is the world's gross domestic product, which stands for the foreign income, and RR is the real effective exchange rate. For all the variables given in constant US dollars, i.e. EX , FDI , and GDP, the base year is 2010. The real effective exchange rate is a nominal effective exchange rate index adjusted for relative movements in national price indicators. The index of the RR for the year 2010 equals 100.

Similarly, the model for imports is specified as follows:

$$ln\, IM_t = \alpha_0 + \alpha_1\, ln\, FDI_t + \alpha_2\, ln\, GDP_t + \alpha_3\, ln\, RR_t + \varepsilon_t \qquad (2)$$

where IM denotes imports of goods and services, GDP stands for the gross domestic product of the importing country. Both of these variables are measured in 2010 constant US dollars. The FDI and RR variables are defined as above. All the data, except the stock of the foreign direct investments, are collected from the World Bank WDI database. The FDI data derived from the UNCTAD database. The dataset covers yearly data over the period 1980-2018.

According to the theory, the signs of the FDI coefficients in equations (1) and (2) depend on the substitutability or complementarity existing between trade and FDI. A positive sign of α_1 is expected when the stock of FDI inflows and exports or imports are complements, whereas a negative sign appears when FDI and trade flows are substitutes. With respect to the GDP variable in the export model, the signs of α_2 should be positive, as the GDP stands for the world income which represents foreigners' demand for domestically exported goods. Considering the sign of the GDP variable in the model for imports, the theory also predicts a positive link between trade (real imports) and the real production, which stands for of the domestic income. The sign of the coefficients α_3 which relate real effective exchange rates to exports (in the export model) and imports (in the import model) should be, respectively, negative and positive. The negative α_3 in the model for exports implies that real exchange rate appreciation deteriorates country's price competitiveness, which results in lower exports. With respect to the model for import, appreciation of real exchange rate makes foreign commodities cheaper for domestic consumers, which should be reflected in higher imports.

In empirical economics considerable attention has been paid to testing for the existence of relationships in levels between variables. In the last years, two approaches have been mainly used: the two-step residual-based procedure (Engle and Granger, 1987) and the system-based reduced rank regression approach due to Johansen (1995). Recently, a new approach called "ARDL bounds testing approach to cointegration" has gained considerably in popularity among researchers. Philips (2018) has clearly

shown that for short time series the rate of type I error using the bounds test is very often far closer to the nominal level than that of the other two cointegration tests. Also Narayan (2005) found evidence that the small sample properties of the bounds testing approach are far superior to that of the other cointegration procedures.

To implement the bounds testing procedure (Pesaran et al., 2001), the long-run relations given in equations (1), (2) have been reformulated as an autoregressive distributed lag (ARDL) model that incorporates the short-run dynamic adjustment process as follows:

$$\Delta \ln Z_t = \beta_0 + \sum_{k=1}^{p_1} \beta_{1,k} \Delta \ln Z_{t-k} + \sum_{k=0}^{p_2} \beta_{2,k} \Delta \ln FDI_{t-k} + \sum_{k=0}^{p_3} \beta_{3,k} \Delta \ln GDP_{t-k} + \sum_{k=0}^{p_4} \beta_{4,k} \Delta \ln RR_{t-k} + \gamma_0 \ln Z_{t-1} + \gamma_1 \ln FDI_{t-1} + \gamma_2 \ln GDP_{t-1} + \gamma_3 \ln RR_{t-1} + \xi_t, \quad (3)$$

where Z denotes EX or IM, respectively.

In the first step, one has to ensure that none of the variables is above $I(1)$. In the presence of $I(2)$, the critical values computed by Pesaran et al. (2001) are not valid. To test unit roots in the time series Phillips–Perron (1988) test was used.

Table 1a: Unit root result (Ireland)

Variables	p-value for levels	p-value for differences
EX	0.8346	0.0004***
IM	0.6836	0.0318**
FDI_	0.5483	0.0000***
GDP_IM	0.6209	0.0022***
GDP_EX	0.2360	0.0001***
RR	0.4992	0.0000***

*Note: For level variables tests include a constant and a trend. The differenced variables tests include only a constant. Rejection of a unit root hypothesis is indicated with asterisks. *, ** and *** indicate, 0.1, 0.05 and 0.01 significance levels, respectively.*

Table 1b: Unit root result (Portugal)

Variables	p-value for levels	p-value for differences
EX	0.7988	0.0000***
FDI	0.9595	0.0000***
GDP_EX	0.2360	0.0001***
REER	0.8791	0.0002***

*Note: For level variables tests include a constant and a trend. The differenced variables tests include only a constant. Rejection of a unit root hypothesis is indicated with asterisks. *, ** and *** indicate, 0.1, 0.05 and 0.01 significance levels, respectively.*

Tables 1a, 1b show that none of the variables included in the models are beyond $I(1)$. Consequently, the results warrant performing the second step of the Pesaran procedure which is the F-test to identify the existence of the long-run (cointegration) relationships among the variables. For this, the null hypotheses of no cointegration, $H_0: \gamma_0 = \gamma_1 = \gamma_2 = \gamma_3 = 0$ in equation (3) - is tested vs. H_1: that at least one of coefficients differs from 0. The optimal lag structures are determined by the Akaike Information Criterion (AIC) using a maximum of 4 lags. The significance of the error-correction term

(EC) is then used as another criterion to determine the existence of the long-run relationship among the variables. For this, the t bounds test is performed. The long-run effects of the explanatory variables on the dependent variable are obtained by the estimates of γ that are normalized on γ_0. We check residual autocorrelation, heteroscedasticity and normality. We also investigate the stability of coefficients in the models using CUSUM tests. The results for Ireland and Portugal are displayed in tables 2a-2b and 3a-3b, respectively.

Table 2a: ARDL cointegration summary results with long-run regression coefficients for FDI, GDP and RR (Ireland)

Dependent variable		**EX**	**IM**
Order of ARDL		ARDL(1,1,0,3)	ARDL(3,3,0,0)
Bounds Test	**F - statistic p-value I(1)**	13.280*** p = 0.000	11.092*** p = 0.001
	t - statistic p-value I(1)	-5.651*** p = 0.001	-5.556*** p = 0.002
EC		-0.287*** (SE=0.051)	-0.531*** (SE= 0.096)
Independent variable	**FDI** **GDP** **RR**	-0.333***(p=0.000) 4.043*** (p = 0.000) -3.533*** (p = 0.000)	-0.120*** (p=0.009) 1.792*** (p = 0.000) -0.066 (p = 0.824)

*Note: AIC is used to select the order of ARDL lags for first-differenced variables. For example, (2, 1, 1, 3) indicates that 2 lags are selected for EX, or respectively, for IM, 1 lag for FDI, 1 lag for GDP, and 3 lags for RR. *, ** and *** indicate, 0.1, 0.05 and 0.01 significance levels, respectively.*

Table 2b: ARDL cointegration summary results with long-run regression coefficients for FDI, GDP and RR (Portugal)

Dependent variable		**EX**
Order of ARDL		ARDL(1,2,1,2)
Bounds Test	**F - statistic p-value I(1)**	12.219*** p = 0.000
	t - statistic p-value I(1)	-4.782*** p = 0.008
EC		-0.345*** (SE=0.072)
Independent variable	**FDI** **GDP** **REER**	-0.407***(p=0.001) 2.547*** (p = 0.000) 1.406*** (p = 0.000)

Note: AIC is used to select the order of ARDL lags for first-differenced variables. For example, (2, 1, 1, 3) indicates that 2 lags are selected for EX, 1 lag for FDI, 1 lag for GDP, and 3 lags for RR.
, ** and * indicate, 0.1, 0.05 and 0.01 significance levels, respectively.*

Table 3a: ARDL model diagnostics. Dependent variable: EX and IM, independent variables: FDI, GDP and RR (Ireland)

Dependent variable	EX	IM
$adj.R^2$	77.60%	77.18%
B-G test	F = 1.763 (p = 0.1724)	F = 1.474 (p = 0.2457)
Durbin's alternative test	F = 1.339 (p = 0.2868)	F = 1.028 (p = 0.4159)
B-P test	χ^2 = 1.28 (p = 0.2570)	χ^2 = 0.50 (p = 0.4814)
White test	χ^2 = 36.00 (p = 0.463)	χ^2 = 36.00 (p = 0.4215)
SK test residual normality	χ^2 = 3.54 (p = 0.4215)	χ^2 = 1.36 (p = 0.506)
RCM	ST (p > 0.1)	ST (p > 0.1)
OCM	ST (p > 0.1)	ST (p > 0.1)

*Note: *, ** and *** indicate, 0.1, 0.05 and 0.01 significance levels, respectively. The B-G test denotes Breusch-Godfrey LM test for higher-order serial correlation in the disturbance. Durbin's alternative test was used to test for serial correlation in the residuals (minimal p-value across 4 lags with the corresponding value of the test statistic is reported in the table). B-P test (Breusch-Pagan test) and White test were used to test residual heteroscedasticity. SK test denotes skewness and kurtosis test used to test residual normality. RCM and OCM stand for stability test of the coefficients in a time-series regression over time. The test statistic is constructed from the cumulative sum of either the recursive residuals (RCM) or the ordinary least-squares residuals (OCM). ST indicates that the estimated model parameters are stable, whereas NST suggests otherwise.*

Table 3b: ARDL model diagnostics. Dependent variable: EX, independent variables: FDI, GDP and RR (Portugal)

Dependent variable	EX
$adj.R^2$	80.61%
B-G test	F = 2.644 (p = 0.1165)

B-P test	χ^2 = 0.30 (p = 0.5814)
White test	χ^2 = 37.00 (p = 0.4226)
SK test residual normality	χ^2 = 0.86 (p = 0.6506)
RCM	ST (p > 0.1)
OCM	ST (p > 0.1)

Note: as stated before in table 3a.

Findings and Discussion

Our results reveals that the stock of the FDI inflows significantly affects exports in both countries under the study. As concerns imports, the FDI turned out to be a statistically significant determinant of Irish imports, whereas for Portugal the import model provided unexpected results. The signs for the FDI in the estimated models are negative, which point to the substitutability between the stock of the FDI inflows and trade.

For Ireland, the coefficient on the FDI stock -0.333 in the export model suggests that a 1% increase in the stock of the inward FDI reduces exports by 0,33%. Similarly to the export case, the FDI coefficient in the model of Irish imports is also negative (-0.12), which implies that the stock of FDI inflows is a substitute to imports. Our outcomes also confirmed statistically significant long-run dependence of Irish exports on the foreign income and the real exchange rate. The estimated regression coefficients have the expected signs and magnitude. The estimated coefficient on income is 4.043, which suggests

that a 1% increase in the world income leads to more than 4% rise in the Irish exports. The elasticity of exports with respect to the real exchange rate, -3.533, indicates that a 1% increase in the exchange rate (appreciation) will result in export decline by 3.5%. This result inclines to consider so-called Dutch disease as an explanation of the substitutability between FDI inflows and exports. Dutch disease is a well-known economic phenomenon that refers to a loss of competitiveness when domestic currency appreciates as a result of capital inflows. In fact, the FDI capital which during the last two decades has been heavily invested in Ireland contributed to strengthening the domestic currency, which deteriorated Irish export competitiveness. As the real exchange rate is identified as a significant determinant of exports, we infer that the inward FDI may affect exports not only directly, but also indirectly, i.e. through the exchange rate channel. As concerns the import model, the results show that Ireland's GDP is a significant determinant of imports, whereas the coefficient on the real exchange rate turned out statistically insignificant.

In the case of Portugal the elasticities obtained from the estimated export model provide statistically significant results indicating the dependence of Portuguese exports on the inward FDI, the real exchange rate and income. The coefficient on the FDI -0.407 suggests that a 1% increase in the stock of the inward FDI reduces exports by 0,4%. This result, similarly to Ireland, indicates that the inward FDI substitutes exports. As concerns the income elasticity of exports, the obtained coefficient is of the expected sign. Its value 2.547 suggests that 1% increase in the world's GDP enhances Portuguese exports by more than 2.5%. The estimated coefficient on real exchange rate (1.406) is highly significant, however its positive sign is not in line with the theory. The interpretation of such estimate should take into account the fact of the euro adoption and prevailing trade relations with the EU countries, which may be determined to large extent by non-price factors, including quality and consumer's preferences of the product brand.

The obtained results also indicate that when the variables are out of long-run equilibrium, the economic forces, captured by the adjustment coefficients EC, push the model back to long-run equilibrium. For Ireland, in the model of exports the speed-of-adjustment coefficient EC -0.287 implies that nearly 29% of the disequilibrium error is corrected after each year. In the case of Portugal, the speed-of-adjustment coefficient EC is -0.345, that implies correction of more than 34.5% disequilibrium errors within a year. Concerning the EC coefficient estimated in the model of Ireland's import, it is negative and statistically significant. Its value of -0.531 indicates that change from the equilibrium level is corrected by 53% each year.

Comparing the results for the two economies under the study, we found that the world's GDP has stronger impact on exports in Ireland rather than in Portugal's economy. This finding is a natural consequence of the fact, that Ireland is much more oriented towards trade with the non-EU economies. The share of the extra-EU exports constitutes around 50% of total Ireland's exports, whereas for Portugal it is less than 25%. It is worth noting, that shortly after the introduction of the euro, the share of the EU as a trade partner in total Portuguese exports reached 81.4%, and the share in imports was 80% (Data: UNCTAD database).

The estimates for export models for both economies identified significant substitutability between the stock of the FDI inflows and exports, however the coefficient on the FDI revealed higher for Portugal. This relationship appeared to explain a much worse position of Portugal in the trade balance. For most of the period considered, Portugal registered high trade deficits, which significantly deteriorated its net international investment position. In contrast, Ireland performed foreign trade surpluses throughout most of the period considered. However, similarly to Portugal, its excessive deficits, registered on the financial account, resulted from the net incurrence of liabilities, both of debt and equity ones.

Conclusions

Our research sheds some light on the ongoing debate over the economic openness and the factors behind trade performance. The evidence presented in this paper focuses on two aspects of the economic openness: trade and capital flows in the form of foreign direct investments. Each of them affects country's external balance. Although trade, according to the balance of payment classification, is

included in the current account, and the FDI is a financial account's item, these two variables should not be treated separately, since they interact. Thus, we investigated the nature of the long-run relationship between exports, imports and the stock of the FDI inflows. Our research is carried for two euro-zone economies: Ireland and Portugal. Both of them have accumulated excessive negative net international investment positions, respectively, -165% and -106% of the GDP, that is much below the prudential thresholds set at -35% of the GDP. Thereby, Ireland, as well as Portugal, faces the challenge of external rebalancing. The identification of the nature of the trade-FDI relationship may help to understand the effects of their globalization.

The main conclusions that can be derived from our findings pointed to a substitutability between stocks of the FDI inflows and trade. The fact that the inward FDI is a substitute for exports reduces the attractiveness of this form of capital flows, that is commonly regarded as relatively stable and export-promoting. We are aware, that the relevant relationship between trade and FDI is not limited to the strict issue of whether they are substitutes or complements. In-depth analysis should cover other aspects of economic openness, including the presence of externalities and technology transfers, that are associated with trade and capital flows. Further research may also consider sectoral interlinkages between FDI flows and trade. Bearing in mind a dynamic nature of this relationship, related to bidirectional flows of trade and capital, as well as the increasing role of services in international transactions, it can be concluded that the empirical study in this area should be continued.

Abstract

After a sharp collapse in 2009, the world trade rebounded in 2010, reaching its pre-crisis volume. Although the v-shaped recovery occurred relatively fast, in the subsequent years, trade growth has been sluggish. An analysis of the pre- and post-crisis evolution of trade-income elasticities sheds some light on the structural factors behind the recent trade slowdown. The aim of this study is to explore whether import demand elasticity has changed in Poland's economy in the wake of the last financial crisis. The findings show that the income elasticity of import demand in the period 1995q1-2008q3 is nearly double that of the post-crisis era (2008q4-2019q3). This induces a structural break in the import response to income changes and gives rise to an in-depth analysis of the supply-side factors behind the recent trade slowdown.

Keywords: trade slowdown, long-term import elasticity, import-income relationship, foreign trade

Introduction

Rich empirical literature confirms a key role of trade and financial integration in driving economic prosperity (e.g. Krugman, 1979; Grossman and Helpman, 1991; Frankel and Romer, 1999; Melitz and Ottaviano, 2008; Busse and Kröniger, 2012). It is also well evidenced, that a lot of growth, especially in emerging market economies, took place through the creation of export-oriented industries, import-intensive investments and participation in the global value chains (Escaith and Inomata, 2013; Goh, 2013). Besides emerging markets in Asia, Central and Eastern European economies intensively liberalized their economies and benefited from higher trade and capital openness. Their increasing economic openness resulted from the transition from a planned to a free-market economy in the 1990s, as well as a progressive integration with the Western European countries in the 2000s. Yet, a convergence process, with the European Union high-income countries, has not been fully accomplished, the new member states faced "a global trade plateaus" problem (Evenett and Fritz, 2016). In the post-crisis era, which characteristic features are weak economic growth and trade slowdown, keeping at catching-up requires new-thinking, especially if growth strategies relied on international relationships.

While the global trade slowdown is a recent phenomenon, the analysis of a long time period can shed light on structural changes that may have occurred in the trade-income relationship. Various studies, including Escaith et al. (2010), Ollivaud and Schwellnus (2015), Timmer et al. (2016), Constantinescu et al. (2020), identified that a long-term elasticity of the world trade to GDP tended to be higher before the Global Crisis of 2008 than in the recent times. A structural break in the relationship between international trade and income was found, for example, by Ito and Wakasugi (2015), Constantinescu et al. (2020), and in the ECB studies (2016). Despite a consensus on the weaker trade response to income changes in the post-crisis era, economists differ in terms of the value and the time of the exact breakdown of the import demand elasticity.

The aim of this study is to explore whether import demand elasticity has changed in Poland's economy in the wake of the last financial crisis. By applying the ARDL model, we compute long-term response

of imports to the GDP changes over the period 1995q1-2008q3, and 2008q4-2019q3, i.e. the period preceding and following the outbreak of global financial crisis. The identification of the structural breaks in the long-term relationship between Poland's imports and income not only helps to explain trade slowdown in Central Europe but also permits to rethink about growth strategy and adapts it to the new post-crisis environment.

The paper is organized as follows. In section 2, we present a definition of the trade elasticity and briefly discuss its theoretical framework. In section 3, we review the relevant empirical studies of import elasticities and summarize the estimates published in the recent literature. Section 4 describes the methodology and presents the models estimating a long-run income elasticity of imports for Poland's economy. In section 5, we interpret the results of the study and outline the directions for further research on the nature of contemporary international trade. Conclusions are in Section 6.

The Elasticity of Imports - Definition and Theoretical Framework

Trade elasticities are crucial components of import and export demand equations. They show how international trade, both its volume and direction, is affected by income and relative prices. The former is generally gauged by gross domestic product (GDP), and the latter is frequently measured by real exchange rates. The trade effects of income changes are reflected in income elasticity of exports (or imports), whereas the influence of price adjustments on trade is explained by price elasticities of exports (or imports). As our study concerns the income-import relationship, this section focuses on the theoretical background of the causality running from income to imports.

A typical model of imports includes domestic income as a key determinant of the domestic residents' demand for foreign goods. The expected sign of this interlinkage is positive, as imports are a part of the general domestic consumers' and producers' demand for both final and intermediate goods. As the vast majority of consumers and producers' needs are satisfied with domestic trade, simple use of the general consumption theory to explain international trade would lead to a mismatched interpretation of the economic performance. Thus, trade theory helps to consider the role of international frontiers in domestic agents' behaviors.

Three approaches can be used to explain the relationship between income and import demand. They refer to the classical trade theories, the Keynesian theory, and the new trade theory. According to the classical trade theories, import demand is derived from the optimal consumer behavior, and depends mainly on the relative prices of domestic and foreign goods (Feenstra and Taylor, 2014). In this approach, a fundamental feature of import demand is price elasticity, which results from a production factor endowment, its productivity, and comparative advantages established in a particular country. In the Keynesian framework, the relationship between trade and income is analyzed on the aggregate level, with the assumption that relative prices are rigid. Thus, import changes result from short-term income fluctuations and the average propensity to import. Keynesian approach is useful in explaining the role of international trade in cyclical fluctuations (Lichtenstein 2016). However, neither classical nor Keynesian models of trade account for imperfect competition and intra-industry trade. On the contrary, the new trade theory adopts these relevant, to the contemporary economies, factors. The assumptions of monopolistic competition and increasing returns to scale shed new light on the linkages between imports and income. Such an approach points to the additional reasons, for example, market structure, exchange-rate pass-through, international fragmentation of production processes, or consumer tastes and preferences, which influence trade elasticities.

Empirical Framework of Import Elasticities: A Recent Literature Review

Most recent empirical studies of trade elasticities point that the long-term income elasticity of imports declined in the wake of the last financial crisis. For example, Constantinescu et al. (2020) use an error correction model to assess whether the global trade slowdown is structural or cyclical. The authors estimate a relationship between trade and income in the past four decades. Statistical tests confirm that the income elasticities of trade in the 1990s. were significantly different from the estimates for the

1980s and the 2000s. The long-term trade elasticity of the 1990s nearly doubled that of the period 1970-1985 and 2001-2015. This finding suggests a structural break in the trade-income relationship.

Ito and Wakasugi (2015) estimated short and long-term import elasticities of the world trade and the Japanese economy. The authors distinguished two periods: 1988-2000 and 2001-2012. Their findings showed that in both periods, the long-term elasticity exceeded 1, however in the second period import response to income changes fell twice below the level of the first period. For the Japanese economy, the import elasticity revealed greater in the 2000s. than in the 1990s., however this difference was not so big, as for the world economy (table 1). According to the authors, the results for Japan suggest that structural changes in trade occurred after the 2000s. The findings published by Ollivaud and Schwellnus (2015) confirmed an inverted-U shape relationship between imports and income over the period 1970-2015. In the years 1986-2001, when the global trade was exceptionally high, the income import elasticity was estimated at 2.3, whereas in the years preceding and following this period, trade elasticity fell to 1.3 and 1.8, respectively. Escaith and Miroudot (2015) confirmed a steep increase in trade elasticity about the year 2000, and a steep fall thereafter. Nevertheless, when Ollivaud and Schwellnus (2015) computed global income elasticities excluding intra-eurozone trade, their results suggested that the decline in import response to income changes after the year 2000 was only slightly lower than in the 1990s. This suggests that trade slowdown resulted from cyclical, rather than structural factors.

Reviewing the recent empirical studies on trade elasticities, it should be noted, that some of them prove that the trade-income relationship depends on the level of countries' development. For instance, Bernhardt (2016) analyzed the income elasticities of imports for bilateral trade relationships among developing Asian and South American countries and two key Northern markets, i.e. the US and the eurozone. He received mixed results in terms of whether South-South trade presents higher income elasticities than South-North trade, however, his findings showed that South-South trade can be an alternative source of growth for developing countries, especially if an economic and trade slowdown persists in developed economies.

Table 1 summarizes the estimates of income elasticities of imports demand published in the recent relevant literature.

Table 1: Income elasticities of imports: a review of the recent studies

Model and Methodology

To examine the relationship between trade and income, we follow the standard literature methodology and use the Error Correction Model (ECM) representation of the first-order autoregressive distributed-lag model or ARDL (1,1) as presented in (Constantinescu et al., 2020). This specification is generally sufficient to ensure a white noise error term (see Irwin (2002); Escaith, Lindenberg, and Miroudot (2010)). In particular, we are interested in estimating the long-run income elasticity of trade (in short, the trade elasticity), which measures the long-run relationship between imports and income. We also estimate the speed of adjustment to the long-run equilibrium. Specifically, we run a regression of the form:

$$\Delta lnIM_t = \alpha + \beta \cdot \Delta lnX_t + \gamma \cdot lnIM_{t-1} + \delta \cdot lnX_{t-1} + \varepsilon_t \quad (1)$$

where Δ denotes first differences, IM_t is the import volume, and X_t is real GDP at time t, α is a constant, and ε_t is the error term (Phillips-Perron unit root tests indicate that both import volume and real GDP are I(1)). In this framework, the short-run trade elasticity is β, while the speed of adjustment to the long-run equilibrium is $-\gamma$. The long-run trade elasticity is given by $-\delta/\gamma$.

Residuals were found to be stationary by the bounds test (Pesaran et al., 2001). Moreover, the Breusch-Godfrey LM test accepts the null hypothesis that there is no serial correlation in the residuals of the linear regression. These results further justify the use of the ECM specification. We check also residual homoscedasticity and normality. The results are displayed in table 2.

Table 2: Results of Estimation Using Quarterly Data

The data we used in our research comes from the Eurostat database. Import volume covers imports of goods and services, and is measured in euros deflated with the GDP deflator. Real aggregate income is given as chain-linked volumes (2010 index = 100) of Gross Value Added. All the data are seasonally and calendar adjusted.

Empirical Results

The elasticities obtained from the estimated import demand model for Poland are statistically significant. They show that in the period 1995q1-2008q3, long-term elasticity of imports was 2.66, and then, in the post-crisis period (2008q4 to 2019q3), it declined to 1.40. This finding is in line with the estimates of other authors who indicate that the world trade elasticity was above 2 in the 1990s., then decreased, but remained above 1 (see table 1). It must be taken into account that the studies differ in terms of the periods of analysis, thus they are not consistent in determining the date of the breakdown

in the trade-income relationship. Our results suggest that in Poland's economy a structural break in the import elasticity might occur in the wake of the last financial crisis.

Figure 1 illustrates the growth rates of Poland's GDP and imports in five sub-periods over the years 1992-2017. It is easily seen, that prior the crisis, the GDP growth in Poland was well below the growth rates of imports. This difference was particularly striking in the years 2005-2008, when the average growth of imports reached 23.7%, whereas the GDP was growing at the rate of around 5.2%. The data presented in figure 1 also shows, that after the global crisis of 2008, Poland's imports were raising less slowly than GDP. The slowdown in import demand was a natural consequence of the overall weakness in the aggregate output, however, as the difference between the growth rates of these two variables was much smaller than in the pre-crisis era, it suggests that cyclical factors may not fully explain why trade has become less responsive to GDP. This evidence implies that structural factors might play a role in the recent trade slowdown.

Our study also provides estimates of the speed of adjustment to the long-run equilibrium. The speed-of-adjustment coefficients EC -0.197 (for the period 1995-2008) and -0.302 (for the period following the crisis) imply that 19.7%, and respectively, 30.3% of the disequilibrium errors are corrected after each quarter.

Fig. 1: Poland's GDP and imports – average yearly growth rates

Source: Data from UNCTAD database.

A high import elasticity identified for Poland in the pre-crisis era results, to a large extent, from trade creation effects that emerged from the integration with the EU economies. However, in the long term, the incentives from functioning in a common market fade, so does the dynamics of trade growth. The additional reason for a lower trade elasticity in the post-crisis era was a slower pace of trade liberalization registered on a global scale. As a lot of countries, including the advanced European Union economies, resorted to protectionism after 2009, the changes in trade regime influenced both the volume and the composition of the foreign trade. The evidence of the global value chains confirms that a recourse to protectionism, especially so-called "behind-the-border restrictions", was associated with a decline in Poland's activity in the international network, both as a recipient and a supplier of intermediaries. As many firms seeking cost-cuts developed their supply chains and outsourced parts of their production to low-cost countries, e.g. the Eastern and Central European economies, their trade intensified. The OECD data on trade in value-added shows that share of foreign value-added embodied

in Poland's exports increased from 16.1% in 1996 to 32.4% in 2011, and declined to 26.6% in 2015 (OECD, TiVA). The slower pace of expansion of international production measured by a share of foreign value added in parts and accessories to total exports, implies weaker import's response to changes in GDP.

It is worth noting, that low income elasticity of imports may have implications for the growth prospects. As import elasticity is often related to the development of investments and international supply chains, a slower expansion of these trade drivers reduces the scope for productivity and technology spillover. On the other hand, if income growth exceeds the rate of import development, it helps to rebalance a current account. Moreover, less import-intensive production may result from gaining new comparative advantages and specialization of domestic producers in import substitutes. This does not imply the end of globalization, but rather moving to the up-stream levels of the global production chains.

Conclusions

Most of the recent empirical studies of import performance, by using state-of-the art econometric tools, e.g. cointegration techniques and error correction modeling, identify a substantial decline in income elasticity of trade. The weakness in the foreign trade relative to economic activity is observed on the global scale, and seems to be a syndrome of the post-crisis era. While economists agree on the decline in in the trade-to-GDP ratio, they differ as to the exact time of this breakdown.

This study examined whether income elasticity of imports has changed in Poland's economy in the aftermath of the last financial crisis. Our findings revealed a considerable difference in imports response to income changes in the years preceding (1995q1-2008q3), and following the crisis (2008q4-2019q3). The evidence of the reduced income elasticity of imports in the post-crisis era is in line with the estimates of other authors and suggests that trade slowdown might result from structural changes. As structural adjustments, on the contrary to cyclical factors, have a more lasting impact, their final effects will occur in the future. This opens an area for further research on the nature of the trade-income relationship and its influence on countries' macroeconomic performance.

A Reality Check of Machine Learning Algorithms on Daily Bitcoin Prices

Dan Gabriel ANGHEL

Department of Money and Banking, The Bucharest University of Economic Studies, Bucharest, Romania, dan.anghel@fin.ase.ro

Abstract

In this paper, we test the superior predictive ability of Machine Learning models in the Bitcoin market, while adjusting the results for data snooping. Our findings show that Machine Learning models inspired from five different types of classifiers are capable of generating above-random predictions for future price changes and, consequently, positive excess returns over the naïve buy and hold benchmark. However, when accounting for data snooping, the returns turn out to not be statistically and economically significant. Moreover, Machine Learning models underperform more simple and popular models derived from Technical Analysis, such as moving average cross-over rules. Even though the scope of the paper is limited, the evidence provided may be considered troublesome for investors considering applying ML-inspired trading models in cryptocurrency markets.

Keywords: Reality Check, Machine Learning, Artificial Intelligence, Bitcoin

Introduction

Analyzing the superior predictive ability of Machine Learning (ML) algorithms in financial markets is not a new research topic. Early evidence reported some success of ML-inspired models for predicting price movements on the stock and foreign exchange markets (Park and Irwin, 2007, review several relevant examples), but these were quickly criticized due to methodological limitations related to how the estimated performance measure was adjusted to trading costs, liquidity, risk, and data snooping. Because of this, ML algorithms were largely dismissed in applications related to forecasting financial asset prices, at least in the financial economics literature. However, the literature has regained its momentum due to the recent surge of new, alternative asset markets, such as cryptocurrencies, coupled with the recent advances in ML programming techniques that recorded great successes when applied to other important practical topics, such as speech and handwriting recognition (Hinton, Osindero and Teh, 2006), autonomous driving, or gameplay learning (Chen, 2016).

Many recently published papers discuss the predictability of cryptocurrency returns using ML-inspired models. For example, McNally, Roche and Caton (2018) implement Recurrent Neural Networks (RNN) and a Long Short Term Memory Network (LSTM) to achieve a classification accuracy of 52.78% for one-day-ahead price changes. Using intraday (hourly) data, Fischer, Krauss and Deinert (2019) employ the Logistic Regression and Random Forest approaches to construct statistical arbitrage portfolios that earn annualized out-of-sample returns of up to 29% (Sharpe Ratio 2.54), which is significantly higher compared to the -71% (Sharpe Ratio -1.46) obtained by an equal-weighted portfolio of 40 cryptocurrencies in the same time period. Chen, Li, Sun (2020) combine various ML learning techniques with different data structures and dimensional features to achieve price prediction accuracies of 66% and 67.2% on daily and 5-minute data, respectively. Other related papers also find that ML-inspired forecasting models consistently obtain above-random prediction accuracies and significantly positive excess returns in the cryptocurrency market.

This renewed interests for ML applications in financial markets and the positive evidence reported in the recent literature reignites an older question: do such algorithms really have superior predictive ability over financial asset prices (albeit in the cryptocurrency market), after adjusting the results to known methodological issues? Put differently, given alternative forecasting models that are easier to learn and cheaper to implement, is the significant investment into learning, developing and implementing ML-inspired prediction models worth the effort? Although recent papers try to control

for some of the known limitations, data snooping remains a problem that has not been properly addressed. This paper tries to fill in this gap by evaluating several prediction models inspired from ML using the Reality Check test of White (2000), on the specific case of the Bitcoin-US dollar market. Moreover, we test if ML models are capable to outperform classical prediction models, such as the ones inspired from Technical Analysis (TA), which have a long history and have been widely used in other financial markets (Park and Irwin, 2007).

The contribution that this paper makes is important from both practical and theoretical perspectives. From a practical perspective, we basically test if investing into learning, developing and implementing ML trading strategies in cryptocurrency markets is worth it; if not, investors would be better off with using much cheaper and easier-to-learn methods for forecasting cryptocurrency prices. From a theoretical perspective, our paper is related to the long-standing debate of market efficiency (Fama, 1970) and to the recent discussion on data snooping (see, e.g., Harvey, 2017). Our results evaluate if the overperformance recorded by ML forecasting models remains significant after controlling for data snooping, while also shedding some new light on the weak-form efficiency of the most popular cryptocurrency market, namely Bitcoin.

The remainder of the paper is organized as follows. Section 2 presents the data sample, defines the set of ML forecasting models, and presents the statistical tests used to evaluate them. Section 3 shows and comments on the results. Section 4 concludes.

Methodology

Data Sample

The data sample is collected from the Gemini Exchange via https://www.cryptodatadownload.com/ and consists of daily prices (Open, High, Low, and Close) and trading volumes for Bitcoin (BTC/USD) in the period April 28, 2013 – December 31, 2019. In total, 2439 observations are used. OHLCV data is needed in order to compute some of the selected technical Analysis indicators (discussed in Section 2.3) used as benchmarks in the statistical tests. It is also useful for tweaking the methodology in order to incorporate trading costs and market frictions associated with liquidity. However, for initializing the features needed by ML models at the beginning of this main sample, closing price data as far back as July 18, 2010 is additionally collected from Coin Metrics (https://coinmetrics.io/).

Machine Learning Models

The main goal of the paper is to test if ML models have superior predictive ability on the Bitcoin market. First, because of the general nature of ML algorithms, we frame the problem as a classification task. Specifically, we construct models that try to predict the future direction of price movements, up or down, and not the exact expected return. This is also useful from a practical perspective, because the predictions made by the various models can be associated to "signals", i.e. the suggested trading positions that investors should take in the market. An expected rise in prices would signal investors to buy the asset (a long position), while an expected decline would signal investors to sell (stay out of the market). In this latter case, short positions would also be possible, but would be conditioned by investor risk preferences and market limitations; we do not consider them in the current analysis.

Second, because we are not focusing on a particular type of ML algorithm, we select and define several alternatives, based on both classical and recently introduces concepts. The classifiers that we select are Support Vector Machines – SVM (Cortes and Vapnik, 1995), Logistic Regression, Random Forest (Ho, 1998), Wide and Deep Neural Networks – WDNN (Cheng et al., 2016), and Recurrent Neural Networks – RNN (Rumelhart, Hinton and Williams, 1986). The models are constructed and implemented in Python, with the help of the packages *Scikit-Learn*, *Keras*, and *TensorFlow*. For brevity, short descriptions for each model are listed in Table 1, while the reader is referred to Géron (2019) for further details regarding their overall characteristics and the specific ways they are implemented in Python.

Note that the risk of data snooping is considered when constructing the models (for example, we add several Dropout layers to the WDNN classifier) or implementing them. The actual implementation goes as follows. First, we use the daily closing prices (C_t) to compute the log-return series, $r_t = \ln(C_t/C_{t-1})$. Second, we construct a binary variable used in the ML classification tasks, this taking 1 if the next day's return is positive and 0 otherwise. The ML algorithms use this as the TARGET variable in the training phase, and tries to predict it in the testing phase. Third, we construct the set of features used by the ML classifiers to make predictions. Following similar approaches in the literature (e.g., Fischer, Krauss and Deinert, 2019), each day we compute the total return over the past m days, $R_{t-m,t} = \sum_{k=1}^{m} r_{t-m+1}$, in our case selecting m from $\{1,2,3,4,5,6,7,10,14,21,28,35,42,49,56,63\}$. Essentially, this choice implies that we try to predict future returns by using the price action in roughly the last 2 months. The resulting series are added to the FEATURES list.

Table 1: List of ML classification models

Classifier	Package	Implementation
SVM	sklearn	SGDClassifier(alpha=0.0001, average=False, class_weight=None, early_stopping=False, epsilon=0.1, eta0=0.0, fit_intercept=True, l1_ratio=0.15, learning_rate='optimal', loss='hinge', max_iter=1000, n_iter_no_change=5, n_jobs=None, penalty='l2', power_t=0.5, random_state=7, shuffle=True, tol=0.001, validation_fraction=0.1, verbose=0, warm_start=False)
Logistic Regression	sklearn	LogisticRegression(C=1.0, class_weight=None, dual=False, fit_intercept=True, intercept_scaling=1, l1_ratio=None, max_iter=1000, multi_class='auto', n_jobs=None, penalty='l2', random_state=None, solver='lbfgs', tol=0.0001, verbose=0, warm_start=False)
Random Forest	sklearn	RandomForestClassifier(bootstrap=True, ccp_alpha=0.0, class_weight=None, criterion='gini', max_depth=None, max_features='auto', max_leaf_nodes=None, max_samples=None, min_impurity_decrease=0.0, min_impurity_split=None, min_samples_leaf=1, min_samples_split=2, min_weight_fraction_leaf=0.0, n_estimators=5000, n_jobs=None, oob_score=False, random_state=7, verbose=0, warm_start=False)
WDNN	keras	Layer (type) Output Shape Param # Connected to input_1 (InputLayer) [(None, 34)] 0 dropout (Dropout) (None, 34) 0 input_1[0][0] dense (Dense) (None, 32) 1120 dropout[0][0] dropout_1 (Dropout) (None, 32) 0 dense[0][0] dense_1 (Dense) (None, 32) 1056 dropout_1[0][0] dropout_2 (Dropout) (None, 32) 0 dense_1[0][0] dense_2 (Dense) (None, 32) 1056 dropout_2[0][0] dropout_3 (Dropout) (None, 32) 0 dense_2[0][0] dense_3 (Dense) (None, 32) 1056 dropout_3[0][0] concatenate (Concatenate) (None, 66) 0 input_1[0][0] dense_3[0][0] dense_4 (Dense) (None, 1) 67 concatenate[0][0] Total params: 4,355 Trainable params: 4,355 Non-trainable params: 0
RNN	keras	Layer (type) Output Shape Param # simple_rnn (SimpleRNN) (None, None, 4) 36 simple_rnn_1 (SimpleRNN) (None, 4) 36 dense_5 (Dense) (None, 1) 5 Total params: 77 Trainable params: 77 Non-trainable params: 0

However, we consider that the return series are not enough to accurately forecast future price movements and other variables may also be important. We explicitly consider volatility, which we also incorporate using the standard deviation of returns over the past n days, selecting n from $\{7,14,21,28,35,42,49,56,63\}$. As a way to further incorporate the possible effect of higher

moments in the distribution of returns, such as asymmetries and thick tails, we also add the observed skewness of the return series over the same historical windows as for volatility. We end up with a set of 33 features, which we use to train the SVM, Logistic Regression, Random Forest and WDNN classifiers. Because the RNN classifier was developed to explicitly handle time-series data, we use a different set of only 4 features when training it, this consisting of the daily return, the squared return, the cubed return and the biquadrate return.

Finally, we implement the following procedure to fit our models and make predictions. Starting with April 21, 2013, we constitute a training set using all available observations in the extended sample prior to that day (July 18, 2010 – April 20, 2013). We train each model on the first 70% of days and then select the best one by measuring prediction errors on the remaining 30% of days. This cross-validation implementation tries to avoid the problem of fitting to the noise in the data. Early Stopping is also implemented; this stops training when the prediction error on the validation set starts to diverge from the one on the training set, implying that the models start to overfit the data. The resulting models are used to make one-day-ahead predictions using the feature set observed in the current day and the following 27 days. After 4 weeks, the models are retrained and the process is repeated until we reach the end of the sample. Note that this procedure assures that we conduct a true out-of-sample test. To test if the models are capable to predict returns several days ahead, we also record and evaluate the lagged predictions up to one week.

Evaluating the Performance of ML Forecasting Models

First, we are interested to test if the ML models are capable of providing non-random predictions above the naïve 50% threshold. For this, we analyze the prediction accuracy of each model using simple t-tests, both on the entire sample and on subsample of 1 year of data.

Second, we evaluate the superior predictive ability of ML models by using their predictions to simulate trading and compute, evaluate their empirical performance. In order to avoid look-ahead bias, we perform all trades on the Open price of the day following each prediction. Also, for simplicity, we do not consider trading fees. Further, in order to control for data snooping, we test the results using the Reality Check (RC) methodology proposed by White (2000). The RC evaluates the null hypothesis that the best performing prediction model in the set ("universe") is not capable to outperform a benchmark model. Here, we use the buy and hold strategy as the naïve benchmark and the simple average excess return over the benchmark as the performance measure for each model. The RC effectively evaluates the data-snooping-free statistical significance of the average excess return obtained by the best ML model, using the empirical distribution of excess returns constructed via bootstrap simulation. In our implementation of the RC, we use the stationary bootstrap of Politis and Romano (1994) with $B = 10{,}000$ iterations.

Third, we also evaluate if ML models are capable to outperform simpler alternatives, namely prediction models ("*technical trading rules*") derived from Technical Analysis (TA). For this test, we select three classes of TA models that are very popular among investors and have also been widely used in the relevant literature (see, e.g., Sullivan, Timmermann and White, 1999). Specifically, we employ moving average crossover rules and their extension, the MACD indicator; the RSI indicator; and the Stochastic Oscillator (%k). Colby (2002) provides a detailed description of each indicator, while our implementation is based on the work of Anghel (2015), which constructs prediction models by successively setting values to their various parameters, such as the lookback window (for which we also use a maximum of 143 days). The resulting universe of TA prediction models has 17,365 individual entities, out of which only 12,312 make trades and are considered. We use this together with the ML-inspired models in a second RC test to essentially evaluate which are better. The number of alternative TA models used may seem excessive, but is motivated by the need to reinforce the point on the dangers of data snooping. However, we also consider alternative universes. Overall, we run several robustness tests using smaller universes but the conclusions do not materially change, even though specific results do. For example, we report the results from a small set of 196 models based on the simple moving average cross-over rule.

Results

Predictive ability of ML models

The results of the predictive accuracy tests are reported in Table 2. We find that most ML models make non-random predictions, as shown by the statistical significant full-sample prediction accuracies. Even though the estimated accuracies vary for the different prediction models–the most successful is the Random Trees 4-d.a. model, with an overall accuracy of 54.49% (t=4.87), while the less successful is the SVM 6-d.a. models with an accuracy of 50.65% (t=0.70)–most models tend to obtain above-random results on the entire sample.

*Note: t-statistics are reported in square parenthesis for full sample (year) prediction accuracies in excess of the random 0.5 threshold. ***, **, and * denote statistical significance at the 1%, 5%, and 10% levels, respectively.*

On the other hand, the estimated accuracies do significantly change from one year to another. The multi-model one year average is highest in 2017 at 57.60% (t=4.34), while being lowest in 2014 at 48.19% (t=-1.25). Also, the various prediction models obtain widely different results on a year-by-year basis. The best yearly performance in our sample is obtain by the RNN 6-d.a. classifier in 2016 (61.56%), while the worst is obtain by the SVM 5-d.a. classifier in 2014 (44.38%).

Overall, the results support previous findings regarding the overall prediction accuracy of ML-inspired models, which range from 52% (McNally, Roche and Caton, 2018) to 66% (Chen, Li, Sun, 2020) on daily Bitcoin data, but also show that the this significantly varies in time and that ML-inspired prediction models can significantly underperform in some particular periods.

ML Performance When Adjusting for Data Snooping

The results of the RC tests conducted for the universe of ML models (Panel A), ML and moving average (MA) models (Panel B) and ML and TA models (Panel C) are reported in Table 3. For the entire sample and for each individual year in the sample, we report the prediction model that obtained the best performance, its average excess return compared to the buy and hold benchmark and the RC p-value that evaluates its significance while accounting for data snooping. Also, Figure 1 provides a visual representation of the location of the full-sample performance (excess return) obtained by the best ML model within the empirical distribution estimated via bootstrap simulation in two of the three RC tests.

Table 3: RC test results

Panel A. 35 ML Models				
Year	**Best Model**	**Average Daily Return**	**Annualized Return**	**RC p-value**
2013	ML classifier [13]	0.2589%	63.94%	0.8308
2014	ML classifier [23]	0.3598%	131.34%	0.1712
2015	ML classifier [26]	0.3179%	116.02%	0.1519

*Note: ***, **, and * denote statistical significance at the 1%, 5%, and 10% levels, respectively.*

Several interesting results are worth noting. First, the best ML model (no. [13], representing the Logistic Regression 6-d.a. model, as recorded in Table 2) obtained an average annualized excess return of only 21.76% over the full sample. As can be seen in Figure 1, this almost falls within the left tail of the empirical distribution of excess returns. As a result, the RC p-value is 0.8527, implying that the results is not statistically and economically significantly. Similarly, we observe that the significant predictive ability of ML forecasting models enable them to earn positive excess returns each year in

our sample, but none of the estimated results are statistically and economically significant, as can be inferred from the RC p-value. The Random Forest 2-d.a. models comes closest to achieving superior performance, but even a 177.5% return in excess of the buy and hold in 2018 does not qualify as being significant at the 10% level after adjusting for data snooping. Overall, these results lead to the conclusion that ML-inspired trading models are not able to generate statistically and economically significance performance in the Bitcoin market. We note that the reported performance is actually overestimated by not accounting for fixed trading costs, which further reinforces this conclusion.

Second, the tests of the 35 ML vs. the 12,312 TA models (Panel C, Table 3) show that TA models outperform the ML models in every year, and also on the entire sample. In this latter case, the simple cross-over rule that buys Bitcoins when the 11-day moving average is above the 20-day moving average outperforms the best ML model in terms of average excess return by a factor of 2.1 to 1. Similar results are obtained for each year in the sample, culminating in 2018 with a version of the Stochastic Oscillator (%K) model earning 286.13% above the buy and hold benchmark, this being statistically and economically significant at the 5% level. Moreover, the results reported in Panel B show that simple moving average cross-over rules outperform ML models in 3 of the 7 investigated years. Overall, the findings show that ML forecasting models underperform even some basic and popular prediction models derived from technical analysis, which are much easier to learn, develop and apply by investors.

Figure 1: Empirical Distribution used to evaluate RC null hypothesis (full sample test)

Third, the statistical significant excess performance obtained by the TA prediction model in 2018 even after adjusting for data snooping may indicate that the Bitcoin market is not weak-form efficient. However, given that this is the only RC null rejection in our tests, and that the results were estimated without adjusting for trading costs, we restrain from drawing a definite conclusion in this regard solely based on the reported results. Further research is necessary to elaborate on this issue.

Conclusions

There is currently a significant expansion of the literature focusing on forecasting financial asset prices using Machine Learning algorithms, such as Artificial Neural Networks (ANNs), Genetic Programming, or other Machine Learning (Artificial Intelligence) algorithms. Although the recent literature more thoroughly controls for possible methodological issues, the important problem of data snooping remains significant. This paper evaluates the superior predictive ability of Machine Learning models on the Bitcoin market, while specifically adjusting the results for data snooping. Five types of Machine Learning classifiers are considered, namely Support Vector Machines, Logistic Regression, Random Forest, Wide and Deep Neural Networks, and Recurrent Neural Networks. The prediction results are then tested using the Reality Check proposed by White (2000).

Overall, we find that Machine Learning models are capable to generate above-random predictions for future price changes, this echoing similar results in the literature (e.g., McNally, Roche and Caton, 2018). However, the predictions do not generate statistically significant excess returns over the naïve buy and hold strategy, when accounting for data snooping. Moreover, Machine Learning models underperform more simple and popular models derived from Technical Analysis. The results imply that, at least when using daily price series, investing into learning, developing and implementing ML models is not worth the effort on the Bitcoin market, especially when other cheaper and better-performing alternatives exist.

The paper does however present some limitations that do not enable the generalization of this result. First, the hyper-parameters related to learning rates, optimization methods, number of layers (for neural networks) or other important ML setups were not optimized. Thus, there might still be a margin for developing ML models that would generate better results. As a counterpoint, other simple and popular Technical Analysis methods, such as Filters, Support and Resistance levels, and many more, were also excluded from the tests. Second, only daily trading data was considered, while intraday data may be important for this discussion. Similarly, besides historical trading data, other information regarding Bitcoin trading and the cryptocurrency market were not included. Finally, only Bitcoin prices were investigated. While this is the oldest and most recognized cryptocurrency, many other price series from this continuingly growing market remain to be investigated. All of these limitations can be addressed in future studies.

Luis GOUVEIA
University Fernando Pessoa, Porto, Portugal, lmbg@ufp.edu.pt

Abstract

This paper aims at analyzing and evaluating the consumption of energy of Android power saving applications however, the study has been done in a qualitative manner. The secondary analysis has been done by evaluating the past research papers and surveys that has been done to assess the perception of the users regarding the phone power from their battery. In addition, the study highlights an issue that the notifications regarding the power saving shown on the screen seems to exploit a lot of battery. Therefore, the study has been done to reflect the ways that could help the users to save the phone battery without using any power from the same battery in an efficient manner. The goal of the study was also to provide a simple insight into four main research questions. As to the research question about energy saving features that could aid in energy resistance includes the flight mode, do not interrupt, power off Wi-Fi and data connections. Furthermore, with regard to the research questions about the fact that power saving application consumes a lot of electricity, past studies clearly indicate that there is a lot of battery depletion due to several factors and these problems have become a major problem for smartphone users and manufacturers. The study offers a good insight into many ways that could be used to more effectively conserve smartphone energy.

Keywords: Android smartphones, Android applications, Power-saving, Battery.

Introduction and Background

Power management has been considered as one of the basic feature in the mobile phones however, mobile companies have been urged in introducing advanced power management features and different power interface and advanced configuration (Datta, Bonnet and Nikaein, 2012). Not only the computer engineers but the mobile phone application developers have been seen to show their interest in encouraging power saving features that must be advanced and must not incur power of the phone. Android version of phone holds the Linux Kernel and has put forward its power management systems including Google I/O (Zhuang, Kim and Singh, 2010). Moreover, it has been reported in the research that there are around 400,000 devices of Android who has activated the power management systems but for some of the individuals, these applications have become an issue. The developers of power management systems and applications have been seen to be very sophisticated thus the hardware components available in the applications have been seen to and consume a lot of battery power and also the storage of the mobile phones. High drain of power from the energy saving applications has become a major issue for the users thus they are having really bad experience. Moreover, there are some of the important components such as GPS, Wi-Fi and OLED which is consuming high energy level and power (Paek, Kim and Govindan, 2010). As per to another study and research, in the power saving applications there is a role of third party advertisements that aims at consuming around 30% of the total power consumed by application (Ravi et al., 2008). This is the reason that the persistent usage of the applications could increase the advertisements and automatically decrease the uprightness of the battery. Android aims at developing an aggressive policy and application for the power saving that includes wake locks and helps in conserving the battery life but this is not enough and sufficient for saving the battery. In addition, there are several

applications in the Google play store that provides the users to get facilitated with the power saving applications. In order to understand its consistency and power saving modes without wasting the power of phone, the researcher has done an in-depth analysis to check its operating principle. It has been explored that most of current power-saving-applications tends to control the features of a smartphone including Wi-Fi, 2G and 3G, brightness level, GPS as they have a significant impact in making the battery life prolong. In addition, the deep analysis also revealed that the use of power-saving modes is statically significant which also controls the features of smartphone. There are several mobile phones who have a pre-define control on saving the battery life. With the changing patterns of smartphone usage, the idea of dissipation of power has been seen to be varied (Ravi et al., 2008). In order to deal with the threats regarding the investigation of the research, it is clear that there are various aspects of android battery saving development which have identified major semantic bugs and syntactical errors. These errors play a major role in destroying the capability of the power saving applications in showing up their capability (Payet and Spoto, 2012).

In this contemporary world, the increase in the application developers have also showed an increase in uncovering various vulnerabilities. This is the reason that several developers have urged in developing the criteria to save the power. For this, the researchers and developers have done a research by performing every step statically and ensured that there could be an android application code that might help the users in ensuring high scalability and save the power of the mobile phones (Moran et al., 2015)(Arzt et al., 2013). At that time, the study remained incomplete because of severe obstructions in the specific Android features and the biggest hindrance in the completeness of analysis made the researcher dissatisfied in proposing a mode of power saving (Li et al., 2015)(Lu et al., 2012). One of the common barriers that have been confronted by Android is the lack of the main point of entry or the construction of call graph. these issues regarding the introduction of saving modes without compromising the battery of the mobile devices might be controlled if the handlers of Android and other mobile phones work more efficiently.

Not only is this there several other challenges carried by the mobile application that includes the support of Java programs. Java reflection statements helps in dealing with the dynamic code loading however, major support of Java application would be helpful in obtaining a hype on power saving solution (Moran et al., 2015). According to the recent survey and analysis, securing the mobile phone from viruses is the only way to use it for long term however, responses from multiple smartphone users indicated that downloading and using power saving applications caused an negative impact on their phones thus it is exploiting their battery usage adversely (Lu et al., 2012) (Payet and Spoto, 2012). The fact about using smartphone is that it is energy constrained and its life relies on limited use of battery supply (Li and Halfond, 2014). The researchers have been playing very well in showing up advanced battery technology that could help in saving the consumption of battery and helps in alleviating the limitations in using the phone. It is important to improve the capability of the developers to construct an energy saving methodology which could be used as an essential source of reducing effect of energy constraints (Hao et al., 2013).

Research Aim and Questions

The primary aim of this study is to give a unique idea regarding the battery saving without the consumption of any power from the battery. The study looks into following questions:

- Does power saving applications also consume a lot of power?
- What are the issues regarding current power management applications?
- What are some of the proposed ways that could help in saving power of the phone?
- What are some of the battery saving features that could help in improving battery resistance?

Related Work

In the present era, smartphone devices are taking the first place among other technology platforms as users now prefer them for different life purposes. In the past few years this trend has increased, and there has been a significant increase in the number of smartphone users. Smartphones are known to intake an unusual amount of electricity budget of the world due to the repeated charging of battery (Ahmad et al., 2016). Besides that, a report provided by Barry Flscher (Fischer, n.d.) the volume of energy it takes in charging iPhone 5 smartphones globally is equal to the accumulated power utilized by 54000 United States households for each year. Following this report, the power demanded by iPhone 5 each year is ranging from 3.5 to 4.9 kWh. Furthermore, the financial expense for charging an iPhone 5 per year is $0.41. Another approach through which the electricity budget can be minimized globally is through energy estimation.

Power models for mobile devices

The task of modeling consumption of power could be divided along two aspects (Kjærgaard and Blunck, 2012). Initial aspect is related to the approach through which measurements are collected for designing the framework. These calculations can be gathered through utilizing an internal battery interface or through external equipment. The second aspect is the sort of data through which the framework was built. Such a power framework can be planned from: computation of system usage, for instance processer data accessible from OS level, consumptions of power computation for each system call construct to OS and consumption of power computations each application program interface call constructed in a particular language of programming. Numerous research attempts have been managed on the gathering of power models for various hardware building elements of a cell phone device for assisting application developers for estimating energy needs of the mobile application.

Power Tutor (Zhang et al., 2010) utilizes data taken from voltage drop for determining the battery discharge rate to approximate the consumption of power. These frameworks are assembled and approved for single-core mobile processors. The calculations identified that application of the identical model for contemporary high-performance multi-core mobile devices would be somewhat incorrect. Moreover, the Wi-Fi model is unable to discriminate among the energy consumed while sending and receiving states producing not so precise results. Shye et al. (Shye, Scholbrock and Memik, 2009) provided a solution in which he used a background logger which was monitoring the resource usage by emphasizing various hardware elements of the cell phone device periodically. A linear regression framework was planned through accumulating present calculations with an external device, with, OS described statistics of battery operating voltage and logger information. Even though, the framework is developed for a sole core Central processing unit, and lower Central processing unit frequencies are not considered while planning the model of power whereas it is rather imprecise for the offloading utilize case. Powerprof (Kantardzie, 2005) also uses a smart battery to calculate the consumption of power at the length of time they take to run through a particular Application Program Interface (API) and such data is utilized for measuring the energy operation of application API calls. Utilizing genetic algorithms (Yoon, 2012), an energy usage profile is identified for every method call. This method is implacable solely when a smart battery applying that particular Application Program Interface is accessible, and it supposes that every time a way is called the similar quantity of power will be utilized, which is usually over-elaborated. AppScope (Jung et al., 2012) is an energy based on an Android mentoring system that utilizes power frameworks and usage facts or data for every hardware element. Linear regression power frameworks are built utilizing DevScope (Kim, Kong and Chung, 2012), and equipment resource utilization examining is taken by loading extra modules into the Linux kernel. For estimating the utilization data of each traces, application, and inter-process communication are examined, showing a significant overhead. Moreover, this equipment is not managing the multi-core processors. Figure.1 clearly illustrates that there are certain categories of applications which are more towards the consumption of battery in smart phones. However, those categories include Entertainment, lifestyle and productivity, travel and transportation, music and media applications, camera, utilities and other tools.

Fig. 1: Applications and consumption of battery in Smart phones (Kim, Kong and Chung, 2012)

Figure.2 points out the list of non-idle energy and their percentage of consumption of battery. Non-Idle energy refers to the power that is active or in-use however, the most common and active energy includes the power of Internet, UI and Camera that seems to consume a lot of battery.

Fig. 1: Percentage of non-idle energy (%) (Kim, Kong and Chung, 2012)

Besides that, the method described in Kim et al. (Ali et al., 2016) provided an expanded online power approximation method for multi-core smartphones which are utilizing an external meter of power.

Present power models, as concluded in Table1 are lacking one or more than one attributes of present mobile hardware: they are outlined for single core Central Processing Units, disregarding the energy proportionality of Central Processing unit frequency scaling or it does not discriminate among the various energy states of network interface cards. Furthermore, specialized hardware and software

application program interfaces are needed for measuring the power consumption of the application of application program interface calls.

Table 1: Mobile device power models for energy efficient dynamic offloading at runtime (Ali et al., 2016).

Comparison of previous work related to power modeling.

	CPU		Display unit	Memory	Network
	Cores	Auto-scaling			Wi-Fi
CloneCloud (Chun et al., 2011)	On–Off model		x		On–Off model
MAUI (Cuervo et al., 2010)	Single-core tested				Simplified[a]
Power Tutor (Zhang et al., 2010)	Single-core	2 freq. supported	x		Simplified[a]
AppScope (Yoon et al., 2012)	Single-core	x	x		Simplified[a]
PowerProf (Kjrgaard and Blunck, 2012)	Single-core	Not mentioned			Simplified[a]
Online Estimation (Kim et al., 2012)	Dual-core	x	x		Simplified[a]
Into the Wild (Shye et al., 2009)	Single-core	2 freq. supported	x		Simplified[a]
Our work	Multi-core support	x	x	x	Detailed[b]

[a] Wi-Fi simplified model does not differentiate between Send and Receive states.
[b] Wi-Fi detailed model takes into account Send, Receive, Tail and Idle states.

This power model manages with all these restrictions. Moreover, it is proven for multi-core Central Processing Units, and all assisted frequencies are contemplated. In addition to that, Wi-Fi power framework precisely discriminates among various conditions of the wireless interface card. There is no need for specific software or hardware support, and there is no requirement of extra overhead in the analysis of various traces. This framework also observes the power consumption because of memory acquired to the application (RAM)

Previous Researches on Power Saving Modes and Applications

For extending the battery life of Android smartphones, developers have offered many applications which are accessible in the Google Play Apps store. Many such applications were analyzed at the time of the survey for understanding the power saving methods. They study how these applications increase efficiency of power saving, their principles and restrictions of operating that gather different ways in encouraging the improvements. It was identified that these energy saving applications have two different methods for managing the consumption of the energy of smartphones. The following sections are discussing the efficiency of energy consumption, operation and limitations of set Central Processing Unit for Root Users (Kang, Seo and Hong, 2011), Juice Defender (Pathak, Hu and Zhang, 2012), and Central Processing unit tuner (Pathak, Hu and Zhang, 2012). These applications are selected on the basis of their high user rating, positive feedback of the user and their popularity.

Increase in the efficiency of power saving

Many hardware elements such as GPS, Wi-Fi of tablets and smartphones take very extraordinary energy (Pathak, Hu and Zhang, 2012). Hence, energy can be saved by turning them off when they are not being utilized. Moreover, there are various characteristics like auto sync, frequency of recent notifications which uses the hardware and other connectivity. Reducing the rate at which notification occurs (mainly of Gmail, Facebook) also reduces the utilization of smartphone elements and extends the battery life. The listing is not comprehensive.

- Fastening command on Bluetooth, Wi-Fi, auto-sync, GPS, auto screen lock, airplane mode, USB, screen-always-on, mass storage, 2G, torch, 3G, 4G/Wimax (if available) and the cell phone data (APN).
- Fluctuate the brightness level of cell phone's display
- Vibration and volume management

- Screen alteration time value
- Development – night, peak, weekend.
- Timeout of setting Wi-Fi
- Getting a home screen with dark wallpaper for organic light-emitting diode (OLED) display.
- The stated three application utilizes all or a subset of these characteristic in their profiles of power saving.

Power saving Applications and its operations

It is essential to know the operating principle of the applications for investigating their restrictions. When the app is installed in a rooted smartphone and the root permissions are given then there are sliders which allow the management of the Central Processing Unit frequency done by hands (Rahmati, Qian and Zhong, 2007). After that Central Processing Unit administrator must be chosen. It manages how the frequencies of Central Processing unit are scaled among the utmost and minimum set frequencies. Mostly kernels considered as smartphones have 'performance' and 'on demand'. The moment central processing unit load gets to a threshold, on demand increases the frequency instantly and decreases the frequency when the load is on its minimum. Other present Central Processing Unit administrator is mentioned in (Rahmati, Qian and Zhong, 2007). A few of them have expert condition controlling attributes. The profiles design the application to set the Central Processing Unit frequency in certain situations. Furthermore, there is a "monitor with condition" which repeatedly monitors the situations set in profiles. If such a situation is true, then a particular profile is activated. For instance, the profile "Battery <" is place when battery level decreases below a provided level. The profile "Time" is activated for a specific time frame. Specific priority is given to all the profiles. If situations of many profiles are correct, then the priority of these profiles is inspected. The profile with the most priority is triggered. In the mobile saving applications, there are various profiles that aims at controlling over the smartphone features thus the developers must keep a deep focus on creating an application that could be able to be fully customized by the users which might be helpful in making a deep focus on saving high consumption of battery (Wood et al., 2008)

Exploring Battery Saving features

By exploring the battery saving features, it is clear that there is various ROM s that could be customized like the Lineage Operating system thus these applications help in setting the menu in a manner to optimize and conserve the consumption of battery efficiently. By toggling and pinning the options, the users could easily find and use them. For example, the best thing a user could do to save the power without compromising battery is switching off Wi-Fi and data connection when it is not needed. Moreover, there are several setups in the phone such as do not disturb option that is included for the purpose of power management. In addition, there are some of the smart applications such as IFTTT that helps the user to create their own rules to save the life of a battery efficiently (AndroidPIT, n.d.). There are several limitations regarding the previous researches such as:

- The survey done on analyzing the power saving modes have been statically gathered during the development of application and have not been customized as per the behavior of customers.
- The controlling part of the power saving application does not seem to be really intelligent thus the user must also focus on evolving around all the necessary steps.
- It is true that present mobile applications have been exploiting the battery and energy because of the display of adverts and other resources.
- This study focuses on a limited mindset of using the power saving applications or features without exploiting the mobile energy or power.
- The power consumption of the mobile for every user is different in each survey.

Conclusion and Future Work

This study has provided a review of the existing literature regarding the different solutions, techniques and tools that have been proposed by different authors in response to battery energy consumption problems of mobile applications for smart devices running on the Android OS. Based on the review of the literature, solutions presented by prior studies in relation to the approach reveal that the average estimations that the proposed tools/techniques provide tend to conflict the actual usage habits of device and the accuracy of the power consumption measurements and simulators remains an issue of debate. Therefore, while the techniques presented herein provide some potential solutions for reducing energy consumption by mobile applications on Android-based smart-devices, they are limited in their usage. This study has gone through various areas of interest in order to answer all research questions asked on the introduction section. The study also has explored the literature and related works around power saving applications, the available approaches that have either not added or added a negative effect on the area of saving energy on smartphones. The study was able to classify the different levels of power-usage among different smartphone resources. That has helped us later to sort the smartphone components in terms of their level of power consumption

Based on the findings, a significant share of power consumption in these smart devices is largely caused by applications that are installed on the devices. Depending on the applications' functionality, they entail activities such as data downloading, content display, and use of built-in-sensors such as GPS (Global Positioning System) related sensors. There are various components of mobile smart devices that facilitate the above activities including; GPS sensors, device' display, the CPU, and network interfaces among others. Consequently, activities/functions of different Android smartphone applications increase the energy consumption of any of the above-mentioned components. As a result, there has been a lot of effort in the study geared towards identifying and investigating the underlying potential for energy savings in relation to these smartphone applications at applications layer and OS layer levels.

In reference to the guidelines of the European Commission regarding energy efficiency, Huge improvements in energy efficiency are occurring across the European Union. Energy efficiency policies are delivering in terms of reducing consumption. Although much attention has been given to energy conservation, there are several issues that existing researchers need to devote more attention to. The European Union has successfully managed to decouple energy demand and economic growth. In short, this means reduction in energy use is not linked to a reduction in the economic or industrial activity (European Commission Directorate-General for Energy, 2017). The economy can now grow while energy is being saved. The primary motive for potential work is to stop following the statement that 'waste any power from the mobile battery under the premise of saving the same power from the same device. At the end, more efforts are required to recognize the core flaws in the battery savings that are being built and introduced in potential smartphones. Today we are seeing so-called 'energy intensity' 1 levels fall. This fall is due to several factors, including structural changes to the economy and advances in technology. But it is also a result of new national and European energy efficiency policies that have played a key role in reducing energy consumption across the bloc.

Resumen

La presente propuesta de investigación es producto de la participación en el Laboratorio Pedagógico realizado en el Centro para la Excelencia Docente de la Universidad del Norte -CEDU-, tiene como objetivo analizar el impacto del uso de tecnologías educativas en el desarrollo de habilidades cognitivas según la taxonomía de Bloom, en estudiantes matriculados en el periodo Julio - diciembre de 2019 en los Programas académicos de Administración de Empresas y Negocios Internacionales de la Escuela de Negocios de la Universidad del Norte en Barranquilla. A partir de la correlación de Spearman, de la aplicación de una encuesta de percepción aplicada a una muestra de 180 estudiantes y de la realización de grupos focales de validación, se obtuvo que definitivamente las herramientas tecnológicas implementadas y guiadas, desarrollan unas en mayor proporción que otras, habilidades de recordar, comprender, aplicar, analizar y evaluar en los alumnos. La habilidad de crear toca reforzarla a través de trabajos que los lleven a ser más propositivos y creativos para que puedan lograr ser estudiantes integrales. La utilización del mapa mental ayudó a sintetizar ideas y resumir la información; Quizlet permitió identificar, comprender y evaluar los conceptos; con Kahoot, recibir retroalimentación inmediata y comprender la información de manera más sencilla y con los videos priorizar y señalar aspectos importantes de un tema, mejorar la comprensión y analizar fácilmente sus componentes.

Palabras clave*:* Tecnologías Educativas, Taxonomía de Bloom.

Abstract

This research proposal is result of participation in the Pedagogical Laboratory of Center for Teaching Excellence of the Universidad del Norte (CEDU, for its acronym in Spanish). The main objective of this is to analyze the impact of the use of technological tools in the development of cognitive skills according to Bloom's taxonomy, in students enrolled in the period July - December 2019 in the Academic Programs of Business Administration and International Business of the Business School of the Universidad del Norte in Barranquilla. Based on Spearman's correlation, the application of a perception survey applied to a sample of 180 students and the realization of focus groups of validation, it was obtained that the technological tools implemented and guided definitely develop some in a greater proportion than others, abilities to remember, understand, apply, analyze and evaluate in students. The ability to create must be reinforced through assignments that make them more proactive and creative so that they can become integral students. The use of the mind map helped synthesize ideas and summarize the information; Quizlet allowed to identify, understand and evaluate the concepts; with Kahoot, the student received immediate feedback and the student was able to understand information more easily, and with videos, prioritize and point out important aspects of a topic, improve understanding and easily analyze its components.

Keywords*:* Educational Technologies, Bloom Taxonomy.

Introducción

La integración de las Tecnologías de la Información y la Comunicación en la práctica educativa constituye una de las demandas que la sociedad plantea al mundo educativo (Saez,2012) y los profesionales de la enseñanza no podemos perpetuar los modos del siglo XX: las antiguas clases magistrales dejan indiferentes a los alumnos que experimentan la vida a través de las pantallas (De la Cuadra De Colmenares, 2016). Es claro que la presencia de las TIC en la formación universitaria favorece los procesos de enseñanza y aprendizaje a profesores y estudiantes, además de mantener un aprendizaje abierto, continuo y flexible (Garcés & Alcivar, 2016).

Dado lo anterior, la necesidad de incorporar la tecnología digital en los procesos de aprendizaje, han llevado a que las Universidades cada vez más estimulan a los docentes a la aplicación de innovaciones en el aula de clase, con el propósito de facilitar el aprendizaje de los estudiantes. Pero integrar exitosamente las tecnologías en los procesos de enseñanza- aprendizaje, se produce cuando los docentes centran su atención no tanto en el recurso tecnológico en sí, sino en las experiencias de aprendizaje que se diseñan y para las que las tecnologías resultan adecuadas (Marcelo, Yot & Mayor, 2015).

Aplicar TIC en la educación, exige que el docente domine su uso en los procesos de aprendizaje y que posea los conocimientos mínimos, que sea capaz de determinar la forma y el momento para integrarlos en la práctica docente de forma creativa, de tal manera que favorezcan el aprendizaje.

Hoy día los docentes se encuentran preocupados por encontrar herramientas que faciliten los procesos de enseñanza aprendizaje de sus alumnos y continuamente están diseñando nuevas maneras de cautivar su atención. Kirkwood & Price (2014), analizaron como la tecnología había sido incorporada a la práctica de enseñanza en el contexto universitario a partir de la revisión de una gama de artículos científicos que habían sido publicados entre el 2005 a 2010 y encontraron que en, al menos, el 50% de ellos, la tecnología había sido empleada sin modificarse el método de enseñanza. El uso de herramientas tecnológicas y el aprendizaje tienen una relación estrecha porque el aprendizaje debe estar coordinado con los avances y cambios en el uso de recursos (Quesada Chaves, 2.015).

Ahora bien, cobra importancia sustancial saber hasta qué punto la utilización de dichas tecnologías impactan el desarrollo de habilidades cognitivas y el proceso de aprendizaje. Muchos autores argumentan que las habilidades cognitivas de naturaleza compleja y abstracta como pensamiento crítico, resolución de problemas y capacidad de análisis, son potenciadas por las propias características de las TIC como herramientas de manejo de información y creación de conocimiento y que son crecientemente valoradas por la sociedad del conocimiento (Claro, 2010).

Marco Conceptual Y Teorico

Taxonomia De Bloom

Fue propuesta por el psicólogo educativo de la Universidad de Chicago Benjamín Bloom en 1956. Es un modelo cognitivo compuesto por seis etapas, que se centra en las habilidades de pensamiento que una persona debería tener (Bhargav, Akalwadi y Pujari, 2016). Dichas habilidades cognitivas son las destrezas que permiten al individuo adquirir y desarrollar pensamientos y conocimientos nuevos. Contempla tres dominios el cognitivo, el afectivo y el psicomotor, siendo el primero de ellos el más desarrollado. La versión original, estaba conformada por los siguientes niveles de aprendizaje: conocimiento, comprensión, aplicación, análisis síntesis y evaluación (Favieri, 2016).

En la década de los noventas, Anderson y Krathwohl, exalumnos de Bloom, realizaron una revisión y actualización de la Taxonomía, clasificándose en dos: las básicas o Habilidades de Pensamiento de Orden Inferior (HPOI) que facilitan la adquisición del conocimiento (Recordar, Comprender, Aplicar)

y las superiores o Habilidades de Pensamiento de Orden Superior –HPOS- (Analizar, Evaluar y Crear) que facilitan la calidad y la aplicación del mismo (Eduteka, 2011).

Los niveles son los siguientes:

a. **Recordar**: hace referencia a identificar y memorizar conocimientos o información anteriormente aprendida. No involucra ningún tipo de razonamiento sobre el contenido. Allí se observa y trae a la mente, un saber previo (lugares, fechas, símbolos, etc).

b. **Comprender**: capacidad de una persona para explicar, comparar la información recibida y de representar de otra manera este tipo de información, entendiendo y construyendo, además, el significado de los mensajes orales, escritos y gráficos a través de la interpretación, ejemplificación y clasificación.

c. **Aplicar**: consiste en seleccionar y usar métodos para resolver un problema o situaciones concretas; utilizar un procedimiento mediante la ejecución o implementación.

d. **Analizar:** es descomponer un problema en sus partes, determinar cómo ellas se relacionan entre sí y con una estructura o propósito general a través de la diferenciación, organización y atribución. Distinguir y relacionar hipótesis y evidencias de la información dada.

e. **Evaluar**: se refiere a la capacidad para interpretar, justificar y hacer juicios basados en criterios o estándares mediante el control y la crítica a un determinado tema.

f. **Crear**: corresponde a la habilidad para explicar, estimar y combinar diversas ideas en una sola. Es unir elementos para formar un todo coherente o funcional, reorganizar los elementos en un nuevo patrón o estructura a través de la generación, planificación o producción.

Es una poderosa herramienta para ayudar a desarrollar objetivos de aprendizaje, ya que los explica. Es jerárquica, porque para desarrollar las habilidades de orden superior debe haberse obtenido conocimientos y habilidades de orden inferior, tal como se muestra a continuación:

Figura 1: Taxonomía de Bloom- Fuente: Elaboración Propia.

- Antes de entender un concepto, debes recordarlo
- Para aplicar un concepto, debes entenderlo
- Para evaluar un proceso, debes haberlo analizado
- Para crear una conclusión, debes haber realizado una exhaustiva evaluación.

Lo anterior implica que, si un alumno desea alcanzar un nivel superior, será necesario que primero domine los niveles inferiores que le preceden. En este sentido, al comprender este proceso de aprendizaje se le facilitará al docente el empleo de las TIC en los procesos de enseñanza – aprendizaje (Torres, Segobia & Calderón, 2020). Por tanto, Cortés (2012) citando a Churches, invita a la reflexión respecto a qué tipo de herramientas tecnológicas, posibilitaran el desarrollo de las habilidades cognitivas requeridas por los estudiantes.

En la Taxonomía de Bloom enfocada al mundo digital (Churches, 2009), los verbos que indican las habilidades cognitivas describen muchas de las actividades, procesos y objetivos que se llevan a cabo en un salón de clase, en donde las TIC exigen habilidades cognitivas "digitales". Con este punto de vista, el profesor guía el aprendizaje construyendo sobre la base de recordar conocimiento y comprenderlo para llevarlos a usar y aplicar habilidades; a analizar y evaluar procesos, resultados y consecuencias y, a elaborar, crear e innovar (Eduteka, 2011b).

Dichos verbos (Churches 2009, Cortés 2012, Favieri 2016), orientan la labor del docente en cuanto a la formulación de objetivos de aprendizaje, contenidos, tecnologías educativas a usar y mecanismos de evaluación:

Recordar: reconocer, distinguir, jerarquizar, listar, describir, identificar, recuperar, denominar, localizar, encontrar.

Comprender: Interpretar, resumir, diferenciar, parafrasear, clasificar, comparar, explicar, ejemplificar.

Aplicar: Implementar, desempeñar, usar, ejecutar, utilizar.

Analizar: comparar, organizar, combinar, distinguir, delinear, desglosar, estructurar, integrar.

Evaluar: revisar, formular hipótesis, criticar, justificar, fundamentar, probar, validar, monitorear.

Crear: diseñar, construir, planear, producir, idear, trazar, elaborar.

Herramientas Tecnológicas

La aparición de las tecnologías educativas mediadas por TIC, hicieron posible el surgimiento de los "student response systems" o sistemas de respuesta del estudiante, que permiten tener en tiempo real información sobre el progreso en el aprendizaje. Los primeros dispositivos se empezaron a utilizar en los años setentas para la enseñanza de la Biología y la Química (Judson & Sawada, 2002).

Es importante tener en cuenta que se ha venido avanzando desde los clickers y keypads a mecanismos como kahoot, socrative, google forms, question press, entre otros, que son utilizadas por internet disponibles en páginas web, en las que se formulan preguntas y se despliegan opciones de respuesta. Las diferencias entre ellas radican en su mayor o menor proximidad a las dinámicas de juegos, en el grado de complejidad técnica o en las posibilidades de obtener resultados a posteriori (Pintor Holguín, et al 2015).

Según Kay and Lesage (2009), los principales beneficios de utilizar estos mecanismos en el aula, son los siguientes:

1. Se aumenta la atención y concentración del estudiante en clase a través de la competencia con otros compañeros, ante la resolución de los problemas o preguntas.

2. Se produce una mejora notable en el aprendizaje de los alumnos, cuando interactúan en la discusión sobre soluciones adecuadas.

3. Posibilita la obtención de una retroalimentación en tiempo real tanto para el profesor como para los estudiantes, sobre la calidad de la enseñanza y el aprendizaje obtenido.

A continuación, se presenta un breve esbozo de las herramientas utilizadas en la presente propuesta investigativa:

Plataforma Kahoot

Es una plataforma de aprendizaje on line, gratuita y de acceso libre en internet basada en juegos y pruebas divertidas, que permite realizar debates, encuestas, o cuestionarios con opciones de respuesta, de verdadero y falso, para que los estudiantes respondan en un tiempo establecido; mediante dispositivos electrónicos como ordenadores portátiles, tabletas, teléfonos móviles (smartphones) con conexión a internet. Pasado el tiempo establecido, el programa muestra las respuestas correctas y arroja los resultados por estudiante y el score con la puntuación final. Hace parte del aprendizaje móvil electrónico (M-learning) y de la Gamificación. Su gran propósito es que el alumno aprenda jugando dentro del aula, para que la experiencia de aprendizaje sea más amena y motivadora.

Existen tres características en la forma de operar de kahoot: la existencia de un reto para el estudiante debido a que debe contestar de forma correcta las preguntas que se le formulan tratando de vencer a sus jugadores, el despliegue de cierto grado de fantasía debido a la competencia que se suscita por el juego y la curiosidad por las imágenes y el audio que acompaña el problema o pregunta planteada y favorecen la motivación a través de la competición entre los alumnos (Wang, 2015).

Puede ser utilizada para hacer verificación de conocimientos previos o posteriores adquiridos, comprobaciones de lecturas (Pintor Holguín, op cit) y también como mecanismo de evaluación constante estilo quiz.

Las principales ventajas de su aplicación hacen referencia a su facilidad, funciona en cualquier dispositivo con conexión a internet, rapidez para el diseño de la prueba, flexibilidad ya que puede crearse en cualquier momento y lugar, permite obtener en tiempo real información sobre el progreso en el aprendizaje para detectar problemas de comprensión o las carencias en forma rápida (Fuentes, 2016), guarda los resultados de manera automática en la plataforma y se pueden descargar sin inconveniente para llevar un registro, genera participación activa de los estudiantes y sana competencia, es entretenida y genera diversión en clase y acorta la distancia entre el docente y el alumno (Salinas, 2004).

En cuanto a los inconvenientes, es que los caracteres de las preguntas y respuestas son limitados, y se puede dar una desconexión inmediata o dificultades en el acceso a la plataforma que limita la participación de los estudiantes (De Mingo López & Vidal Meliá, 2019).

Plataforma Videos Animados

Powtoon es una herramienta tecnológica diseñada para realizar videos interactivos, es semejante a presentaciones Power Point pero se puede añadir animaciones, voces, sonido, texto e imágenes. La ventaja adicional es que se puede exportar a Youtube y las plantillas son en su mayoría gratuitos, es fácil de usar y sencilla de entender. Es importante recalcar que es necesario tener conexión a internet, y en la versión gratuita solo se puede utilizar 5 minutos, la calidad es estándar por lo que la alta resolución no aplica, se pueden utilizar 11 estilos de letra y 38 canciones (Jancsó, 2.017).

Con relación al aprendizaje, los factores que más aporta el uso del video son: asimilación más sencilla y mejor comprensión de contenidos, que sí se utilizará un método tradicional de enseñanza (Quesada Chaves, op cit), permite ser eficiente, crear interés por aprender un tema y mejorar el rendimiento académico de los estudiantes (Yenchum & Chih-Hung, 2.018). Se ha demostrado que la comprensión de los temas se optimiza con los videos por el dinamismo y el menor tiempo que este requiere para la comprensión del conocimiento, desarrolla procesos cognitivos que tienen correlación con el trabajo colaborativo y el interés por la materia, y por consecuente con los resultados académicos (Hernandez, Rodriguez, Parra, & Velázquez, 2.014).

El diseño de vídeos Powtoon ayuda al entendimiento por el componente investigativo, de innovación y de síntesis; además, logra que el alumno preste mayor atención a las materias por ser animadas (Jancsó, op cit). Es una herramienta fundamental para el mejoramiento de la comunicación, y el trabajo

en grupo, ya que disminuye la ansiedad, y ayuda a la autoconfianza y determinación, importante para el desempeño académico. (Quintela del Río, 2018).

Finalmente, los estudiantes están dispuestos y motivados en usar nuevos recursos tecnológicos al momento de tener una clase, ya que se involucran con ideas y aportes del uso de diferentes softwares usados para elaborar videos (Quintela del Río, op cit). Entre los aspectos negativos de la creación de videos, se encuentran especialmente la coordinación de los grupos de trabajo, y de las herramientas limitadas que tiene Powtoon para que los videos no se vean planos y sin innovación.

Plataforma Mapas Mentales

Los mapas mentales son estrategias didácticas que permiten al estudiante recrear una imagen sobre un determinado contenido de forma sintética, que posteriormente puede utilizar para guiar el recuerdo apoyándose en proposiciones verbales (Alvarado Peña, 2.015). Se definen como "una estrategia didáctica para favorecer el aprendizaje de conceptos, los cuales serán asociados y conectados con otras situaciones, lo que permitirá un análisis, comprensión y reflexión de lo asimilado" (Roig Zamora & Araya Ramírez, 2.013).

De esta manera, se pueden definir a los mapas mentales como organizadores gráficos creados con el fin de exponer ideas, relacionar elementos y conceptos, sintetizar y comparar diferentes opiniones. Son elementos, técnicas o estrategias para transformar la información en conocimiento (Muñoz González, Peña, & Molina, 2010).

La diferencia con el mapa conceptual radica en su estructura y componentes, el mapa mental tiene la oportunidad de insertar videos, imágenes, colores, y darle dinamismo e innovación al conocimiento que se quiere exponer.

Con respecto a lo anterior, el uso de mapas mentales para organizar, comparar y sintetizar conceptos es muy comúnmente utilizada en el desarrollo de aprendizaje. Busca aclarar ideas, ampliar información y resolver problemas, facilita el aprendizaje y los procesos de toma de decisiones; el uso de la herramienta no plantea dificultades, lo único que hay que tener en cuenta en su aplicación, es el cambio de modelos de aprendizaje. (Caballero Hernández, 2006).

Otra habilidad desarrollada por el estudiante al emplear esta herramienta es el trabajo cooperativo, lo cual es útil para aprender y crear competencias (Muñoz González, Hinojosa Pareja, & Vega Gea, 2.016).

Como recomendación (Alvarado Peña, 2.015) afirma que para desarrollar habilidades cognitivas en los estudiantes, se implemente como estrategia el trabajo con mapas mentales y otros organizadores gráficos, ya que éstos brindan posibilidades tanto al estudiante como al docente, al facilitar la identificación de la manera como representan sus modelos mentales, permiten definir las ideas relevantes en un tópico o contexto planteado, y en consecuencia favorecen las capacidades de organización, de establecer prioridades, de clasificar, de categorizar la información, y en suma, mejorar sus niveles de comprensión del conocimiento.

Plataforma Quizlet

Quizlet es una herramienta diseñada para recordar conceptos, el uso es sencillo, el profesor debe tener un tema y conceptos claves claros. Utiliza dos mecanismos el primero es el aprendizaje interactivo. Una vez el docente escoge los conceptos y sus respectivas definiciones, el estudiante con un link puede acceder de manera inmediata. Este tiene diferentes formas de interactuar para aprender con la herramienta: aprender (selección de múltiple respuesta), fichas (tarjetas que muestran el concepto y luego la definición), escribir (muestra el concepto y el estudiante debe definirlo), ortografía (es una actividad de escritura) y probar (herramienta evaluativa).

El segundo mecanismo es el juego. Este tipo de juegos se divide en individual; combinar que es en parejas y el grupal que es live. El profesor abre esta opción y entrega un código de ingreso en

quizlet.live , luego el sistema agrupa a los estudiantes en equipos con nombres llamativos y empiezan las preguntas.

El juego de quizlet incluye el cooperativismo y la colaboración, debido a que solo a un alumno de todo el equipo, le llega la respuesta. Por tanto, todos deben estar atentos, en la pantalla se ven los resultados, si pierdes vuelves a comenzar. Es un excelente mecanismo para interactuar y aprender.

Metodología De La Investigación

La metodología de la investigación planteada es de tipo cuantitativo. Debido a que este tipo de investigación, presenta un orden rigoroso y su objetivo se centra en medir para comprobar hipótesis. Así mismo, se determinan unas variables de estudio y se plantea un proceso para probarlas y someterlas a mediciones por lo general de carácter estadísticas tal como lo sugieren Hernández, Fernández y Baptista, (2014). De acuerdo con sus postulados, también se puede establecer que el alcance de la investigación es correlacional, porque tiene como fin conocer el grado de asociación que puede existir entre dos o más variables teniendo en cuenta un contexto en particular, tal como se presenta en el estudio propuesto.

El proceso metodológico fue el siguiente: durante el primer semestre del 2019 se realizó una prueba piloto con el fin de identificar cuáles fueron las herramientas tecnológicas que mayor impacto tuvieron en el aprendizaje de acuerdo con la percepción de los alumnos, lo que sirvió de parámetro para continuar con la propuesta en el segundo semestre de 2019.

Posteriormente se determinaron las materias objeto de intervención, las cuales fueron Gestión del Talento Humano en el programa de Administración de Empresas y Negocios y Culturas Globales en el programa de Negocios Internacionales de la Escuela de Negocios. Se realizó la programación de las asignaturas mencionadas contemplando los temas, las herramientas tecnológicas utilizadas y los objetivos de aprendizaje por cada herramienta. Estos objetivos se plantearon de tal manera que se relacionarán con las habilidades cognitivas que se deseaban reforzar o desarrollar.

En tercer lugar, se diseñaron las guías de trabajo, los tutoriales del uso de las herramientas, se escogió el material de revisión y se crearon los mecanismos de evaluación que fueron parciales y rúbricas. Luego, se rediseñaron las encuestas y los test por herramienta con el fin de medir la percepción que los estudiantes tenían frente a cada tecnología educativa utilizada (Mapas mentales, Kahoot, quizlet y video animado) y su impacto en el desarrollo de sus habilidades cognitivas de acuerdo con la Taxonomía de Bloom.

El desarrollo de la propuesta consistió en aplicar el pretest por medio de la herramienta tecnológica quizlet, el cual pretendía verificar los conocimientos previos que el estudiante tenía del tema abordado durante las clases. Posteriormente, las docentes introdujeron los respectivos conceptos y subtemas y luego se aplicó nuevamente el quizlet como postest con el fin de verificar si hubo mejora frente a la primera aplicación. Por último, los estudiantes desarrollaron las guías de trabajo para asegurar su comprensión de la temática y pudieran elaborar los mapas mentales donde sintetizaron la información aprendida. Una vez realizadas las actividades descritas se procedió a la realización del parcial, en el cual se verificó los conceptos aprendidos por los estudiantes y que tanto ayudaron las herramientas tecnológicas aplicadas en su proceso de aprendizaje, alineadas con la taxonomía de Bloom. Una segunda medición se realizó con Kahoot como pretest y postest, y, por último, se solicitó la elaboración de un video animado que incorporó los conceptos aprendidos y su validación se efectuó con el segundo parcial.

Una vez aplicadas las tecnologías educativas escogidas por las docentes, se procedió a la aplicación de la encuesta diseñada por cada una de las herramientas, para medir la percepción de los estudiantes sobre el impacto de ellas en el desarrollo de habilidades cognitivas. La última técnica utilizada fueron los grupos focales, para validar y conocer a fondo y de manera directa, la apreciación de los estudiantes frente al proceso y las herramientas implementadas.

Los datos recolectados a través de los Pretest y Postest mencionados, los parciales y las actividades realizadas a lo largo del semestre académico, fueron digitalizados, organizados y analizados por medio de matrices y se incorporaron en la herramienta estadística SPSS versión 23, con el fin de establecer si existía una correlación entre el uso de las herramientas TIC y el nivel de competencia de los estudiantes teniendo en cuenta la taxonomía de Bloom.

Se establecieron para tal efecto dos hipótesis. En términos estadísticos la H0: El uso de los mapas mentales, videos animados, Kahoot y Quizlet no impactan en el desarrollo de habilidades cognitivas de acuerdo con la taxonomía de Bloom en los estudiantes de la Escuela de Negocios de la Universidad del Norte y como H1: El uso de los mapas mentales, videos animados, Kahoot y Quizlet impactan en el desarrollo de habilidades cognitivas de acuerdo con la taxonomía de Bloom en los estudiantes de la Escuela de Negocios de la Universidad del Norte.

El estudio contó con la participación de 180 estudiantes matriculados en el periodo Julio - diciembre de 2019 en los Programas de Administración de Empresas del Departamento de Emprendimiento y Management y de Negocios Internacionales del Departamento de Mercadeo y Negocios Internacionales de la Escuela de Negocios de la Universidad del Norte de Barranquilla Colombia. Se utilizó un muestreo a conveniencia para la aplicación del cuestionario y se contó con el consentimiento informado de los participantes.

Resultados Obtenidos

Análisis Estadístico

Para analizar los datos en primer lugar se aplicó una prueba de Kolmogorov-Smirnov con el fin de comprobar si los datos se distribuían normalmente y de esta manera tomar la decisión de aplicar un test paramétrico o no paramétrico. Debido a que los datos no se comportaban normalmente, pues el nivel de significancia era menor de 0,05 confirmando la hipótesis alternativa de que los datos son diferentes a la distribución normal, se procede aplicar el test de correlación de Spearman un test no paramétrico que se utiliza para establecer relaciones de variables en datos que no se comportan tal como la distribución normal, es decir, son asimétricos.

A partir de lo anterior, se aplicó entonces el test de Spearman trabajando con un margen de error del 5% o 0,05 y un nivel de confianza del 95% o 0,95 y atendiendo a los niveles de correlación establecidos en donde se estima que la correlación más es fuerte es 1,00 y las más baja 0,00, procesando los datos obtenidos por medio del programa SPSS.

Los resultados arrojaron que, para el caso de la asignatura Gestión del Talento Humano, del programa de Administración de Empresas, si hay correlación entre los niveles de la taxonomía de Bloom "Comprender, aplicar y analizar" evaluadas en el primer parcial y la herramienta "quizlet", denotando como esta herramienta permitió a los estudiantes alcanzar los tres niveles mencionados y por ende teniendo mejores resultados en su calificación del parcial 1, de la misma manera, se puede afirmar que hay correlación entre el nivel de la taxonomía de Bloom "Comprender" y el video animado, denotando como la creación de videos y procesar la información en una forma distinta a la convencional, permite a los estudiantes comprender mejor la información ayudando a su proceso académico. Lo anterior se sustenta en que su nivel de significancia fue menor a 0,05 como se observa en la tabla 1 en los datos resaltados.

En el caso de la asignatura de Culturas Globales, del programa de Mercadeo y Negocios Internacionales, si hay correlación entre el nivel de la taxonomía "Aplicar" evaluado en el primer parcial con el video interactivo y el nivel de la taxonomía de Bloom "Analizar" y la herramienta de kahoot, denotando como estas herramientas permitieron a los estudiantes alcanzar los niveles mencionados respectivamente y por ende permitiendo tener mejores resultados en su parcial 1. Así mismo, se evidencia una correlación entre el nivel de la taxonomía "Comprender" evaluado en el segundo parcial con la herramienta de "Quizlet y Kahoot", dando a conocer como el uso de ambas herramientas ayudaron a los estudiantes a la obtención de resultados positivos en su parcial 2. Lo anterior se sustenta en que su nivel de significancia fue menor a 0,05 como se observa en la tabla 2 en los datos presentados.

Análisis Encuesta De Percepción

Con el propósito de medir las percepciones de los estudiantes frente al uso de las herramientas tecnológicas utilizadas en la clase, se procedió a realizar una encuesta en google forms, obteniendo los siguientes resultados:

Tabla 3: Resultados porcentuales de la implementación tecnológica según herramientas y beneficios

HERRAMIENTAS /BENEFICIOS	MAPA MENTAL	QUIZLET	KAHOOT	VIDEO
Organizar el conocimiento para un mejor aprendizaje	79%	79%	73%	72%
Sintetizar ideas, resumir la información y conocimiento	83%	82%	72%	77%
Priorizar y señalar aspectos importantes de un tema	82%	82%	77%	78%
Comprender la información de manera sencilla	74%	83%	79%	76%
Facilitar el aprendizaje al poner en práctica la temática	76%	83%	77%	75%
Estudiar de manera más práctica	77%	83%	76%	74%

Mejorar el entendimiento del tema	80%	83%	77%	78%
Identificar fácilmente los conceptos	79%	83%	77%	75%
Relacionar las temáticas con mayor facilidad	77%	80%	76%	76%
Analizar fácilmente la temática	79%	81%	76%	78%
Desarrollar trabajo colaborativo	68%	74%	74%	72%
Retroalimentar aprendizaje	70%	77%	78%	71%
Incrementar y estimular la creatividad	74%	70%	70%	74%
Comparar aprendizaje	72%	73%	76%	72%
Diseñar una forma de presentar el aprendizaje	79%	81%	81%	76%

Fuente. Elaboración propia.

Como se puede observar en la anterior tabla, la percepción de aprendizaje de los estudiantes con la utilización de las cuatro herramientas tecnológicas fue alto. Este porcentaje unió las categorías totalmente de acuerdo y de acuerdo. Es importante destacar que todas ellas, apuntan al desarrollo de habilidades cognitivas de la taxonomía de Bloom: Recordar, Comprender, Aplicar, Analizar, Evaluar y Crear.

Sin embargo, resaltaremos algunos porcentajes especiales: en el **mapa mental** sobresale el aporte de la herramienta para sintetizar ideas, resumir la información y el conocimiento; en **quizlet** se valora la comprensión de los temas, el entendimiento de los mismos, el identificar fácilmente los conceptos y estudiar de manera más práctica; con **Kahoot**, se distingue aprender por medio del juego, recibir retroalimentación inmediata y comprender la información de manera más sencilla y con **los videos** priorizar y señalar aspectos importantes de un tema, mejorar la comprensión del mismo y analizar fácilmente los temas.

A continuación, se analizan los resultados de la percepción del estudiante sobre el uso de herramientas para mejorar su aprendizaje.

Figura 2: Las herramientas tecnológicas como mecanismo de aprendizaje

Fuente. Elaboración propia

La herramienta que más facilitó el aprendizaje fue quizlet por que de acuerdo con lo manifestado en los grupos focales, ayudó a recordar, comprender y evaluar conceptos, fue la herramienta más valorada por los alumnos por que aprenden de los errores que van cometiendo al resolver las preguntas; mientras que el video fue considerada una herramienta que no facilitó el aprendizaje.

Figura 3: Las herramientas que facilitan y dificultan el aprendizaje del estudiante

Fuente. Elaboración propia

Las herramientas que menos presentan dificultades en su uso son kahoot (15%) y quizlet (19%) respectivamente y las de mayor dificultad son los mapas (23%) y los videos (31%). La explicación para estos resultados es que, las dos primeras plataformas ponen al estudiante en un contexto determinado con un test previamente definido por el docente. Mientras que los mapas y videos deben ser desarrollados por los estudiantes con base en una guía previamente diseñada, pero donde ellos pueden poner su creatividad al servicio del trabajo solicitado.

Continúa ratificándose que la herramienta que más ayudó al estudiante a desarrollar estrategias y habilidades de estudio fue quizlet con un 83%, seguido por los mapas mentales (76%), kahoot (72%) y videos (67%).

Figura 4: El aporte del uso de las herramientas tecnológicas en el desarrollo de estrategias y habilidades de estudio

Fuente. Elaboración propia

Para culminar, los estudiantes percibieron que han obtenido un aprendizaje significativo a través del uso de quizlet (82%), kahoot (78%), mapas mentales (73%) y los videos (71%).

La experiencia más agradable con el uso de las herramientas fue kahoot con un 87%, seguido de los videos animados (86%), mapas mentales (72%) y quizlet (65%).

Con respecto a la edad, podemos encontrar que entre las edades de 16 a 19 años se percibe un aprendizaje mejor con Quizlet, mientras que las edades entre 20 a 22 años el mapa mental es mejor percibido. Todas las edades presentaron dificultades en el uso de videos animados y en el rango de 20 a 21 años de edad no se percibe aprendizaje con Kahoot ni Quizlet.

Finalmente, por semestre se evidenció que a los alumnos de segundo semestre, se les facilitó quizlet mientras que se les dificulta el uso de videos animados, kahoot y mapa mental. Mientras que a los estudiantes de los semestres V y VII se les facilita el aprendizaje con el uso de mapa mentales y el quizlet, aunque también hay un porcentaje del séptimo semestre, que indica que con el uso de mapa mentales se les dificulto el aprendizaje.

Análisis Grupos Focales

Con base al análisis de contenido cualitativo realizado al grupo focal con 25 estudiantes de la asignatura Gestión del Talento Humano, se pudo concluir con respecto a la proporción o frecuencia de los datos obtenidos de los alumnos, que el uso de las tecnologías educativas favorece el aprendizaje haciendo que la clase sea distinta al tener una nueva forma de enseñanza y que no se debería cambiar nada de ella.

Con respecto a las herramientas y materiales usados a lo largo de la materia, manifiestan que las guías son útiles para el estudio, que los mapas mentales y quizlet al ser concisos ayudan al aprendizaje, en quizlet agregan que les ayuda a aprender de los errores, pero que al ser de memoria no ayuda a llevar el concepto a la práctica. En cuanto a la guía y el video cuentan que les ayudó para su aprendizaje y análisis de la información.

Sin embargo, de las herramientas utilizadas cambiarían quizlet, debido a los inconvenientes al momento de escribir el concepto por errores en tildes o formas de escribirlo. Con la herramienta de Kahoot dijeron que ayuda al aprendizaje y que el vídeo desarrolla la creatividad.

Con base al análisis de contenido cualitativo realizado al grupo focal de la asignatura de Culturas Globales, se concluyó de la información obtenida de los alumnos que las herramientas facilitaron el aprendizaje de esta.

Por otra parte, dicen que las herramientas fueron útiles, que quizlet (mayormente usada) y los videos les sirvieron bastante, que las herramientas son dinámicas, sintetizan los contenidos, les ayudan a recordar la información y tener un mejor desempeño en el parcial. Además, agregan que los mapas mentales, kahoot (usado una vez), los videos también fueron útiles y que quizlet fue la herramienta que mayor facilitó su aprendizaje, es decir, fue útil.

En conclusión, para recordar, comprender y evaluar les sirvió quizlet; para analizar y crear fueron de utilidad los videos en powtoon; y los mapas y las lecturas, les permitieron aplicar los conceptos aprendidos en clase.

Discusión

Esta investigación da cuenta del impacto que tiene el uso de las tecnologías educativas en el desarrollo de habilidades cognitivas de acuerdo con la propuesta de Bloom, validando la H1. Los resultados de los diferentes análisis (estadístico, encuesta de percepción y grupos focales) determinaron como el uso del mapa mental promovió la habilidad de recordar al hacer posible que los estudiantes pudieran identificar conceptos, resumir y sintetizar ideas; quizlet activó las habilidades de comprender, aplicar y analizar, que llevaron a los alumnos al entendimiento de la información, facilitar el aprendizaje, y priorizar los aspectos más importantes de un tema. Kahoot fue percibida como la herramienta que brinda retroalimentación en tiempo real sobre el aprendizaje y el video como mecanismo para incrementar y estimular la creatividad, ayudar a la comprensión, aplicación y análisis de la información.

Los anteriores hallazgos nos permiten validar que, para desarrollar habilidades cognitivas en los estudiantes a través de las tecnologías educativas implementadas en el aula, hay que alinearlos con el diseño de objetivos de aprendizaje, contenidos, temas y actividades coherentes y pertinentes de la

asignatura y con esquemas de evaluación, que permitan a los docentes determinar si dichas habilidades están siendo efectivamente desarrolladas. Según Churches (2009) la taxonomía para la era digital, no se enfoca en las herramientas y en las TIC, pues éstas son apenas los medios. Se enfoca en el uso de todas ellas para recordar, comprender, aplicar, analizar, evaluar y crear. Como lo expresa Cortés (2012) que, a partir del contenido temático y las habilidades involucradas en el aprendizaje, se debe seleccionar el recurso TIC para lograr un aprendizaje significativo.

Por último, se pudo evidenciar la necesidad que el estudiante tenga un rol activo en el uso de herramientas para que estas puedan generar un efecto en el aprendizaje; la tecnología demanda de autorregulación y autonomía que muchas veces el estudiante de primeros semestres puede tenerlo en menor medida por su pequeño lapso de tiempo en la universidad. Por lo tanto, el uso de estas herramientas debe ser dado con retroalimentación y tutoriales de uso en estos semestres.

Conclusiones

Sin lugar a dudas, la incorporación de tecnología al aula de por sí establece un cambio en la forma cotidiana de dar las clases. En este sentido, haremos alusión a cada herramienta utilizada por ejemplo **quizlet,** además de que concentró la atención de los estudiantes y fue la más valorada, incorporó a través de diversos juegos una manera diferente de aprender conceptos básicos y necesarios para el desarrollo posterior de la materia.

Con **kahoot,** mecanismo de respuesta rápida, se incentivó al estudiante en una sana competición por el resultado, es una forma de aprender jugando. Allí al estudiante se le clarificó también los conceptos y preparó para posteriores pruebas de medición de conocimientos adquiridos.

La elaboración de **mapas mentales y videos**, llevó a los estudiantes a revisar los textos para desarrollar las guías de trabajo y con este insumo proponer una forma de organización del conocimiento adquirido, de manera creativa, novedosa y útil para su proceso de aprendizaje.

En el grupo focal realizado con los estudiantes de Gestión del talento Humano y Negocios y Culturas Globales quedó manifiesto lo anterior: “que el uso de las herramientas tecnológicas favorece el aprendizaje haciendo que la clase sea distinta al tener una nueva forma de enseñanza y que fueron útiles. Los estudiantes consideran que no se debería cambiar nada de la clase”, lo que significa que realmente las herramientas tecnológicas utilizadas lograron su cometido.

Los principales cambios asociados en la utilización de las herramientas fueron primero la incorporación de las rúbricas con el propósito de medir de manera clara, efectiva y equitativa los resultados de los mapas mentales y videos animados e interactivos desarrollados por los estudiantes. Este sistema brindó transparencia a la calificación ya que permitió que los estudiantes supieran de antemano los items tenidos en cuenta y el resultado final de su esfuerzo y dedicación.

El segundo cambio y más importante fue poder incorporar en la elaboración de los parciales, las preguntas alineadas con las habilidades cognitivas de la taxonomía de Bloom que se pretendían reforzar en los estudiantes. Este aspecto es el más relevante de la experiencia, porque realmente nos permitió determinar qué herramientas les sirvieron para desarrollar dichas habilidades y consecuentemente qué resultados en el desempeño académico pudieron obtener de su uso.

La transformación de metodologías docentes aplicando la teoría constructivista, puede crear impacto en el estudiante que está acostumbrado a clases convencionales, donde el profesor entrega la información y el estudiante no se encarga de practicar o investigar en clase. En la medida en que el docente tenga un pleno conocimiento y dominio de su materia, puede derivar estrategias pedagógicas que faciliten el proceso de aprendizaje de sus alumnos, combinándolos con las habilidades necesarias para que el proceso de enseñanza se logre de una manera óptima.

Los docentes deben apropiarse de las tecnologías de educación o herramientas digitales, atendiendo a las exigencias del mundo contemporáneo enfocando sus esfuerzos en el desarrollo de habilidades de orden superior como analizar, evaluar y crear en sus alumnos. Por tanto, es necesario fomentar la creatividad e innovación desde el inicio de la carrera, para que el desarrollo de mapas mentales, videos y demás tecnologías sean vistas como herramientas más amigables con su proceso de aprendizaje.

Recomendaciones

Los mapas mentales como organizador gráfico son una herramienta eficiente para el aprendizaje, al igual que los videos, pero deben ser guiados por preguntas y enseñar de manera práctica su uso para lograr los resultados esperados con su implementación.

Para integrar exitosamente las tecnologías en los procesos de enseñanza- aprendizaje, se requiere que los docentes centren la atención no tanto en el recurso tecnológico en sí, sino en las experiencias de aprendizaje que se diseñan y determinar la forma y el momento para integrarlos en la práctica de forma creativa e innovadora, de tal manera que favorezcan el proceso de aprendizaje.

Para finalizar, se recomienda realizar investigaciones que correlacionen tecnología usada, con habilidades cognitivas y desempeño académico de los estudiantes.

Agradecimentos

La investigación fue posible gracias al acompañamiento, asesoría y apoyo constante del equipo del Centro para la Excelencia Docente (CEDU) de la Universidad del Norte, en el marco del Programa Laboratorios Pedagógicos durante el segundo semestre del año 2019.

Abstract

The article reveals the results of a study of the role and place of universities in the formation of "Industry 4.0", based on the rapid development of industries and fields of activity that form a new technological structure. The basis of technological development is the generation of intellectual property. A detailed analysis of the processes of university participation in the creation of a new technological structure is considered on the example of nanotechnology. The study showed a significant lag in the contribution of universities to the creation of intellectual property products to be commercialized. It is proved that this situation is connected, first of all, with the absence of new models of universities in the conditions of radical changes in the external environment. Changes in the activities of universities are of a point-like nature: a significant part of higher education institutions in Russia carry out passive changes, focusing more on factors of influence from the state. Therefore, most universities in terms of their development dynamics are not real leaders in their subject areas. Moreover, many universities still do not pose such tasks, mainly engaged in the reorganization of current activities in the traditional format. The authors recommend accelerating the development and implementation of university development

strategies, which should be aimed at enhancing their participation in the transition of the economy to "Industry 4.0". In addition, a transition to a new model of the university's activity is required using the drivers of changes within universities, based on the development of their scientific potentials.

Keywords: Industry 4.0; digital economy; Virtual Factories of the Future; innovation; digital supply chains; intellectual property; nanotechnology; new technological way.

Introduction.

Significant changes in the activities of universities are point-like in nature: a significant part of higher education institutions in Russia make passive changes, focusing more on external factors of influence from the state, and therefore most of them are not real leaders in their subject areas of activity. Moreover, many universities still do not pose such tasks, mainly engaged in the reorganization of current activities in the traditional format. Universities can make a difference by recognizing the needs of society, reflecting the irreversibility of change processes in «Industry 4.0». The fundamental moment in the formation of the new role of universities in society, which determines the development of an innovative strategy for managing the development of universities, is the concept of "Industry 4.0".

As part of the formation of a new management paradigm in the context of the transition of the economy to "Industry 4.0" using digital technologies, it is necessary to identify and substantiate the transformation processes in the development of modern universities. The concept of "Industry 4.0" is used in scientific research as an analogue of the concepts of "wave of innovation", "technical and economic paradigm", "technological structure", etc. Previously, the emergence of the industry took a relatively long time, since the speed of dissemination of innovations that determine the emergence of technological mode was slow. Currently, there is a tendency to reduce the duration of cycles. It should be noted that a study of the literature on changes in the education system for "Industry 4.0" allows us to conclude that the problem zones are updated and there are no ready-made solutions.

1. Relevance of the research

A review of the literature shows studies formulating the direction of changes of various types of universities under the changes of technological revolutions. Authors [2] define Industry 4.0 technologies as "disruptive," such as Internet of Things, Data Science, Deep Learning, Augmented Reality, Edge Computing, and Digital Twins. This is due to the fact that, despite new opportunities for many areas, educational methods for teaching these technologies are not yet available. In this connection, the authors talk about the need to form a common structure to support education in the context of Industry 4.0. Industry 4.0 has different requirements for technological education, which should be fully gamified, because it is precisely this approach that they believe contributes to the development of innovation [8].

However, the previous training paradigm [5] today does not close the gap between training and changes in the industry, regardless of the profile of the university. Thus, the university itself should become such a factory that quickly responds to changes in the external environment. Within the framework of the "training factory" paradigm, the introduction of cyberphysical systems will be required [6].

The vision of Industry 4.0 means new approaches and technologies, but also a methodology for working in a company, which requires high financial costs and a staff shortage [1], namely other competencies from managers. For example, an important problem, according to the authors in the implementation of Industry 4.0, is the formation of new job roles and the construction of new employee management systems in companies. The Fourth Industrial Revolution and its underlying digital transformation, known as Industry 4.0, are progressing exponentially. The digital revolution is fundamentally changing the way people live and work. The fundamental design principles and technological trends of Industry 4.0 also require the architectural design of Industry 4.0, but we must not forget about the dependence of the sustainability of changes in Industry 4.0 from management [3]. For example, researchers claim that there are no proven systems for managing sustainable supply chains, which is a problem for management [12].

Another example of the study of the "Industry 4.0" phenomenon from the point of view of management is the value chain of a business, and therefore it is increasingly analyzed by management scientists [8]. However, there

are no studies that define new rules for university participation in the creation of Industry 4.0 values. All the above determines the relevance of research on the participation of universities in the implementation of Industry 4.0.

2. Contents of the study

It should be noted that at present Russia, having passed the stage of the birth of Industry 4.0, is at its ascending stage. The transition to Industry 4.0 is based on the development of nanotechnology, cellular technology, genetic engineering methods, as well as the emergence of alternative energy (hydrogen energy, the use of wind and solar energy), taking into account the acceptability of their economic parameters). Modern society not only translates innovations into innovations, but first of all creates the conditions for the accelerated development of those industries and fields of activity that are leading in the formation of Industry 4.0.

Changes in industries consist in the fact that they are transitioning to fundamentally new processes of creating value for consumers. These processes are a sequence of stages of creating a product (product, service) with new functional properties for the end user. Thus, the manufacturing activity that characterizes Industry 4.0 and creates unique products / services for the consumer is a long-term competitive advantage of economic entities. It should be noted that an important role in the development of technologies belongs primarily to technical universities, which are directly involved in the creation of new basic technologies.

Confirmation of entry into the phase of Industry 4.0 is the development of the economy of a new technological generation - Digital Economy. In Russia, this transition is carried out as part of the National Technology Initiative through the implementation of the nationwide TechNet project. TechNet is a cross-market and cross-industry sector that provides technological support for market development by the National Technology Initiative and high-tech industries through the formation of Digital, Smart, Virtual Factories of the Future.

Understanding the essence of “factories of the future” is based on the principles of combining material and digital / virtual activities, which sets up fundamentally new business processes at all levels in a single value chain. The organization of production must comply with the requirements for creating products “best in class”, that is, a fundamentally new, customized / personalized new generation of products. “Factories of the future” use value chains of the type “technology - competencies - TestBeds - product” for each task to achieve this goal.

Important tasks are also set during the development of fundamentally new - digital - control systems for production systems within the framework of the Industry 4.0 concept. The inefficiency of the "factories of the future" may arise due to the abandonment of company management from the technology of production of new products inevitably can result.

Modern universities not only preserve, but also objectively expand their role in the transition of the economy to Industry 4.0, as they are one of the few institutional structures of society that are able in the process of their educational, scientific, innovative activity to form the competencies of specialists for the future technological structure.

Currently, the role of universities in the formation of Industry 4.0 in Russia is generally small. So, according to the Agency for Strategic Initiatives, the market for educational services for factories of the future is 0.9%, which, unlike all other areas of development, is the last position. Thus, at present, the technologies of Industry 4.0 have gone much ahead compared with the positions of universities in this process, which indicates that universities, as a scientific organization, are not in full compliance with the modern challenges of the economy. This means that universities have to transform their activities in accordance with the requirements of the sixth technological order.

Analysis of the use of intellectual property and developments for the period 2012–2018 shows the lag of university participation in the use of intellectual property compared with other types of economic activity, despite the tendency to insignificant stable growth, which clearly does not correspond to the required pace for a change in technological structure. A similar situation is observed when analyzing the use of the resources of intellectual activity in education, where even with insignificant positive dynamics, a decrease in the share of growth in the use of intellectual property in education by an average of 20% over years is visible (Figure 1).

The absence of significant changes in the use of the results of intellectual activity in universities indicates minimal changes in their educational and scientific processes. As a result, there is no increase in the introduction of unique educational technologies in universities, which is explained by the weak orientation of the management system towards the growth of integration of educational and scientific activities.

The statistics on Russia allow us to conclude that the total number of organizations performing research and development in 2018 decreased by 1.6% compared to 2012 [11, p. 8, 23-24]. The reduction in the number of research organizations is associated with the policy pursued by federal ministries and departments to optimize the subordinate network of scientific organizations. The reform was carried out through the enlargement or liquidation of those organizations that practically stopped scientific activity [11, p. 23-24]. At the same time, the share of organizations performing research and development in the total volume of economic activity in 2018 amounted to 53% and decreased, compared with 2005 (73.7%), by almost 20 percentage points [ibid, from. 23-24], which

indicates a certain lag in this sphere from serving the needs of the nascent way of life.

Figure 1 – The share of intellectual property in research and development and education
Source: calculated by the author according to statistics [7, 9, 10 and 11].

At the same time, the share of organizations performing research and development in the "Education" section, in the total number of organizations performing research and development, in 2018 amounted to 26.9% and increased, compared to 2005, by 14.9 percentage points. n. This dynamics testifies to the positive dynamics and the involvement of educational organizations in conducting research. At the same time, statistics on the number of organizations cannot reflect qualitative changes in the field of development of science.

For a qualitative analysis, we consider the results of scientific research and research for the period 2012–2018 using the example of the “Use of Intellectual Property” indicator (Figure 2), using the data for 2007 as the basis for a comparative analysis of changes.

Figure 2 - Use of intellectual property, 2007–2018.
Source: calculated by the author according to statistics [7, 9, 10 and 11].

The total number of uses of intellectual property has a tendency to stable slight growth without significant changes. The share of the use of intellectual property in research and development remains almost unchanged over the years. In education, there is a similar trend in the use of intellectual property.

An analysis of data over recent years does not indicate a change in the policy of using intellectual property in the field of scientific development and education, but rather characterizes positive dynamics without breakthrough changes reflecting the transition to a new technological structure. This contradicts the forecast expectations of a trend towards a peak increase in the use of intellectual property in the field of scientific research and education in accordance with a change in technological structure.

The education sector does not make a significant contribution to the use of intellectual property, even having a slight positive trend over the years: the share of using intellectual property in education is on average 20% less (Figure 3).

It should also be noted that there are no significant changes in educational activities based on the widespread use of the resources of intellectual activity. This means minimal changes in the educational and scientific processes associated with an increase in the introduction of unique educational technologies.

Figure 3 - Share of the use of intellectual property in research and development and education.
Source: calculated by the author according to statistics [7, 9, 10 and 11].

The share of the use of intellectual property in scientific research is slightly higher than in the educational sphere. However, there is no need to talk about an increase trend either. In scientific developments, to the same extent as before, the results of intellectual property are used, each time focused on the search for new solutions, without developing or commercializing the results of intellectual activity. This indicates the implementation of short-life innovations, ending in limited use. Since the sixth Industry 4.0 is characterized, among other things, by the active development of nanotechnology, we consider the scale and dynamics of growth in the creation and use of nanotechnology in general by type of economic activity, as well as in relation to scientific development and education.

The number of nanotechnologies developed (Figure 4) tends to increase, but it is extremely small in all types of economic activity, as well as in the research and educational sectors.

The dynamics of the number of nanotechnologies used is close to this trend (Figure 5): it reaches its peak in 2018 and amounts to 1166 units. However, these increases in use are so insignificant that we cannot talk about the trend: 2015 and 2018 indicators, comparable in values, respectively 1,152 and 1,166. If we consider the use of nanotechnology in scientific research, we can see that their share is decreasing. A similar picture regarding education.

Figure 4 - The number of developed nanotechnologies in 2014–2018.
Source: calculated by the author according to statistics [7, 9, 10 and 11].

Figure 5 - The number of nanotechnologies used in 2010–2018.
Source: calculated by the author according to statistics [7, 9, 10 and 11].

Analysis of the developed nanotechnologies from the position of their specific weight among all types of economic activity: the share of nanotechnologies in the field of scientific research shows a decrease from 2013 to 2015, and in 2018 there was a slight increase of 4%. At the same time, nanotechnological developments in the field of education in 2015 amounted to 26%, and in 2018 - 23%, which corresponds to a decrease of 3%.

Thus, an analysis of the development and use of intellectual property and nanotechnology suggests that in the development of "Industry 4.0" there is no clear evidence of the active role of the field of science and education. So, for example, the state allocates significant resources to the nanotechnology sphere, including in the organization of the educational sphere, but the effectiveness of these organizations not only does not remain the same, but also decreases (Figure 6).

The analysis of statistical data allows us to conclude that universities and scientific organizations do not

meet the modern requirements of the economy; at the moment, Industry 4.0 has gone much further compared to the positions of universities in this process.

The lack of efficient use of state resources allocated for the formation of a new technological structure is largely due to the mismatch between the activities of organizations in the field of science and education, including due to insufficient compliance of the management system with available resources and performance requirements.

To change the current situation, a fundamentally new innovative university strategy is needed that can ensure the active participation of universities in the new technological structure on a regular, sustainable basis and thereby realize the new role of universities in society.

Figure 6 - The proportion of developed nanotechnology in science and education in 2010–2018.
Source: calculated by the author according to statistics [7, 9, 10 and 11].

3. Conclusion

At the same time, the adaptation of universities to changes in Industry 4.0 does not have a single theoretical scheme, which leads to the implementation of various transitional options for constructing organizational and economic mechanisms for universities serving various technological structures that coexist in society. This fact reflects a certain spontaneity of the process of changing Industry 4.0, which is characteristic of the previous stages, and at the same time right now it is possible to pass this period in a controlled manner.

It should be noted that the university's product management system is many times more complicated and allows independent implementation of several value chains, however, with a further increase in value chains, a crisis will inevitably occur, since there is no automation of management. As a result, the organization of product integration processes while maintaining the old management system leads to duplication of functions. It should be noted that in the organization of universities, elements of a self-organizing system are emerging.

The aspect of the influence of the new technological structure requires additional research on the new capabilities of the university, since this phenomenon determines the development factor. Previous models of university activities have exhausted themselves, do not meet the requirements of the external environment. At the same time, the external and internal components of the forces that influence the university's organization model should not be opposed; they do not contradict, but complement each other: the university must ensure its rapid development in the context of the formation of a new technological structure, while ensuring the current effectiveness and efficiency of its activities.

Universities, as well as the entire sphere of education, are inevitably integrated into Industry 4.0 and must support transitional changes, which requires a certain amount of activity of organizations in the field of science and education among other types of economic activity. This means that universities will have to transform their activities

to meet the requirements of the sixth technological order. The development of modern universities can be achieved not only in the competition for consumers and in finding answers to market challenges by improving the quality of current activities, but also primarily by understanding the role and place of universities in the development of products that create value for consumers in movement towards a new technological mode.

В этой связи существенно возрастает значение научного потенциала университета, который не только обеспечивает развитие продуктов, но и требует от менеджмента соответствующего ресурсного обеспечения. Формирование и реализация научного потенциала вузов возможны за счет принципиально новой инновационной стратегии университета, способной обеспечить активное участие университетов в новом технологическом укладе на регулярной, устойчивой основе и тем самым реализовать новую роль университетов в обществе.

In this regard, the scientific potential of the university is significantly increasing, which not only ensures the development of products, but also requires appropriate resource support from the management. The formation and realization of the scientific potential of universities is possible due to a fundamentally new innovative strategy of the university, capable of ensuring the active participation of universities in the new technological structure on a regular, sustainable basis and thereby realizing the new role of universities in society.

Abstract

Evolving economy and the development of robotization refers to many areas of economic life. Accounting and reporting is no different here, yet the manner in which the process is progressing and the areas it concerns attracts great interest among employees of finance and accounting departments and is becoming a subject of studies which will allow for getting the answer- is accounting nothing but a set of repetitive evidencing operations, which could be entirely handled by automatization of work? To present the areas of accounting in which economic entities are introducing or will introduce robotization and automatization of work and to describe those areas related to presenting data in annual reports which are not covered by information technologies. As a result of the conducted research, four fields were distinguished, in which the robotization processes will be implemented and human labor significantly limited, as well as those areas in which implementing robotization is currently impossible. Directions of further works on that topic have been presented for the perspective of next 5 years. In addition, the essence of narration in accounting and reporting was pointed to.

Keywords Accounting, Reporting, Robotization And Automatization

Introduction

Economic entities which aim to stay on the market must base their operations on a number of right decisions, including financial ones. Undoubtedly, the decision-making process is to large extent dependent on access to reliable information concerning the economy. Thanks to such data, it is possible to make not only strategic decisions, but tactical and operational ones as well. With their help, it is possible to eliminate deviations from the established patterns, make amendments in the operation plans, or modify the range of operations. The information one uses in the course of decision-making process may have a synthetic or analytical form. Synthetic data is processed with the available computational and analytical tools. Analytical data, on the other hand, are essential for explaining the reasons, and consequently the results of the ongoing changes and determining the factors which impact the shape of a company's financial outcome. However, a crucial role in the decision-making process is played by both financial and non-financial data.

It is worth emphasizing that in the period of such sharp competition the need for access to financial information is constantly growing. Annual reports play an important role in the evaluation of the outcomes of the activity performed by the entity, with the data allowing for an analysis of cause and effect relationships. Managers of organizations need analytical information, as it helps them to study future trends, and on their basis to forecast future conditions of functioning for the company, as well as the outcomes achieved by it.

Having a well-functioning system of financial reporting helps to prepare in advance to the changes taking place in the business environment, and diagnose the risk factors to protect oneself from their

effects. In order to prepare reliable financial information, an entity is obliged to keep record of its business operations, whose effects have an impact on individual values of assets, sources of financing, operation outcomes and the amount of fiscal liabilities (both the income tax and the VAT liabilities/overcharge). Making annual reports is regulated by individual legal solutions of a given country or is based on international solutions included in international standards of financial reporting. Regardless of the legal conditions, the execution of financial and accounting processes requires the use of modern technological solutions, especially in terms of digital reporting. However, not all elements of an annual report can be prepared with the use of specialized financial and accounting software.

Materials and Method

The aim of the study is to point to the financial and accounting fields which have undergone automatization and robotization of processes, as well as those where the processes have not been implemented.

Critical analysis of literature was used as the research method. For the purpose of identifying the financial and accounting areas which have undergone automatization and robotization of processes, the results of own study conducted between November 2019 and February 2020 among accountants employed in two large economic entities operating in two regions of Poland. The above findings were compared with the data coming from the report entitled Robotic Process Automation – Robots conquer processes in back office prepared in 2016 by Capgemini Consulting and Capgemini Business Services (Capgermini Consulting, 2016). The report contains the processed findings of the research on the possible implementation, and the areas in which an entity had already implemented RPA processes, and which areas were still to undergo the process.

Using IT in accounting and Financial Reporting

In recent years, in increasing number of publications and amount of researchers' interest has been focused on specialized financial and accounting programs. Computer software was a guarantee of quality of the performer recording and accounting operations, processes and data storage. Using integrated IT systems (ERP class) provides the opportunity to import/export data, limits the time and costs related to recording, allows for generating comparisons and reports, with the interference of systems effectively shortening the time of data generation in different cross-sections and areas, at the same time supporting organization management systems.

Currently, the range of information technologies is becoming wider and includes, among others, digital recording, e-declarations, remote accounting, cloud accounting. Other solutions used in accounting practice are international financial centers, sharepoint platforms and digital documentation related to them. The presented solutions allow for full access to digital financial and accounting data, reduce costs related to creating backup, and contribute to increased efficiency and speed of transactions. In terms of financial and accounting services for companies, an increasing role is played by the progressing automatization and robotization, which requires next generations of technological solutions. Automatization of business processes is widely discussed and described in papers on management (Attaran & Woods, 2018), financial accounting (Toth, 2012) and management accounting (Tessier & Otley, 2012), which is evidenced, among others, by an increase in the number of publications on that matter in ScienceDirect database (36 in 2017, and 41 publications in 2018). The analyzed publications point to increased interest in automation and robotics in terms of handling logistic processes, sales, finances and accounting- which are referred to as Robotic Process Automation – RPA. In a traditional approach of the RPA language– a computer software license is considered a robot (Willcocks, Lacity & Cragi, 2015). A different view is presented by ForProgress, which defines a robot as a tool functioning in such a manner as if a human being was physically operating a given software. For other authors, however, automatization of business processes involves replacing human labor, leading to the realization of tasks and processes in a manner which is faster, less costly and more dynamic (Fersht & Slaby, 2012). It should be remembered that automatization of financial and accounting processes is not merely a result of works aimed at replacing human labor by robots. The implemented changes are meant to combine the labor of humans and robots- referred to as virtual workers. Such complex work

allows a robot to perform simple, repetitive tasks, leaving creative tasks, which require subjective evaluation, individual, homogenous solutions, as well as devising and implementing modifications in technological systems to the accountants. Among the major benefits resulting from automation of business processes there are (Delotitte, 2017):

- increased level of compliance with process realization procedures,
- improved quality,
- higher effectiveness,
- reduced costs of operation,
- increased productivity,
- better and wider access to management information,
- automatization of some round-the-clock
- flexibility of scaling and configurations of comparisons and their areas,
- availability of process history,
- monitoring and supervision of process,
- reduced service time,
- adjusting solutions to the requirements of business users.

In contemporary literature on accounting, the authors emphasize the important role of the processes of automatization and robotization in the fields of: recording business events, writing reports and analyses, synchronizing account balances, processing transactions, generating year-end closings (Chew & Robinson, 2012; Brazina & Urgas, 2018). It should be noticed that modern technological solutions provide business managers with fast access to financial information relevant to the process of making management decisions (Percells, 2016).

The use of RPA in financial and accounting processes

The fields of robotization of processes presented in literature are reflected by research. On the basis of conducted and presented research included in the report entitled Robotic Process Automation – Robots conquer processes in back office, published in 2016 by Capgemini Consulting and Capgemini Business Services, it appears that 53% of respondents use RPA solutions in the field of finances and accounting. The results of the research conducted are presented on Graph 1

Graph 1: Financial and accounting processes in which RPA solutions were implemented

Source: Capgeminin Consluting. (2016). Robotic process Automation – Robots Conquer Business Processes in Back Office.

The presented findings indicate that the process of robotization and automatization was most commonly employed during recording liabilities (21% of respondents pointed to that field), with the next position being held by recording debt and reporting to stakeholders (13% of respondents pointed to those areas). The lowest percentage, merely 2%, was recorded in the cases of payments, running the general ledger, or financial reporting.

Similar studies were con ducted among accountants employed in large business entities operating in Pomeranian and Kuyavian-Pomeranian regions. The study involved 90 accountants from various business entities, representing different sectors. The survey was conducted between November 2019 and 10 February 2020. The respondents were asked, among others, about the manner in which the processes of robotization and automatization were progressing in their organizations in terms of financial and accounting services, and which of the proposed fields are most frequently subject to such processes. The survey results are presented on Graph 2. The robotization processes progress gradually, as the implementation processes require both financial investments and time necessary for a proper development of the automatized processes.

Graph 2: Financial and accounting processes in which RPA solutions were implemented according to accountants in Polish business entities.

Source: Own study based on an own survey

Based on the survey findings presented, it appears that the processes of robotization most frequently involve the fields related to recording liabilities, evidencing employee delegations, external reporting and taxes.

While making a comparison of the results, it is worth noting that, according to accountants, one field which is often pointed to as one undergoing the process of robotization is taxes. According to 12% of the respondents, the process of automatization is being implemented, which may be the result of introducing e-declarations, uniform controlling files related to the tax on goods and services (VAT) and the possibility of them being controlled by organs of fiscal administration.

RPA processes have already been implemented in some units, but as the report indicates, respondents were asked to point to the fields in which the studied entities were planning to introduce automatization and robotization within the next 3-5 years. As shown on Graph 3, the number of planned implementations is impressive.

Graph 3 : Financial and accounting processes in which implementation of RPA solutions is planned

Source: Capgeminin Consluting. (2016). Robotic process Automation – Robots Conquer Business Processes in Back Office.

The respondents most frequently pointed to robotization in terms of dealing with liabilities to contractors (79%), running the general ledger (68%) and dealing with payments from customers (64%). On that basis, Polish respondents were also asked about the planned changes in terms of accounting and implementation of robotization processes in finance and accounting departments. However, the respondents were rather moderate in pointing to further robotization processes, which was demonstrated on Graph 4.

Graph 4 : Financial and accounting processes in which implementation of RPA solutions is planned according to accountants in Polish business entities

Source: Own study based on an own survey

As shown on the graph above, among the Polish business entities the processes of robotization will most commonly concern handling liabilities and debts (dealing with contractors) and doing the taxes. According to the respondents, it had been caused by the introduction of changes in the Polish fiscal regulations related to Uniform Controlling Files (so-called JPK, which are related to paying the tax on goods and services- VAT), and the introduction of shared payment mechanism.

However, for some of the respondents, the introduction of processes of robotization and automatization of payments is dependent upon high costs being involved in software implementation.

The respondents were also asked about the fields of finances and accounting in which the RPA process would not be implemented. Almost 90% of the studied accountants pointed to changes in yearly reports, resulting from the changes included in the Accountancy Act (Polish legal regulations) concerning non-financial information in reports.

Non-Financial Information in Annual Reports

The cautious approach of respondents to the prospects of development of the automatization process in accounting, mentioned in the previous part of the article, may have a number of causes. However, one of the limitations to the expansion of robotization in accounting which is hard to negate is the recent rapid increase in the importance and the practical usage of non-financial information in reporting. Financial information reflect ex post data, whereas contemporary economy is oriented towards providing ex ante information, which is why more and more frequently the financial data presented in reports are supplemented with non-financial information in a descriptive form. Narrative accounting has become a verbal description used both in theory, policies and practice of accounting. Such a description is commonly used in annual reports of economic entities. The descriptive form is becoming more and more complex in the reports generated by accounting systems, and supplemented with graphic elements, in the form of charts, diagrams or drawings. Such a presentation of data greatly limits, or even eliminates the possibility to robotize labor. Using narration in reporting results from economic changes and technological progress, but first of all belongs to the practices which are more and more commonly used by business entities. Using past (historical) and previously used solutions is becoming impossible, as the process of perfecting financial reporting plays and important role in the information system and the manner in which an entity communicates with its environment. Preservation of the status quo in this respect, according to G. Mueller, will be a certain recipe for disaster in the field of financial information. However, development of the narration in accounting is predominantly the strengthening of the communication process, which is greatly impacted by the complexity of economic phenomena, growing needs of users, changes and development of accounting standards. Such an approach allows for creating the image of accounting in financial reports addressed at external recipients, and is related to creative accounting, making it possible to present the economic situation according to the expectations and carry out an organization's projected goals. Creating an organization's image may be analyzed from two perspectives: positive (improving the usability and suitability of information and increasing the transparency of the company's presented image) and negative (manipulating with information, providing a false image, fraud). Apart from the widely recognized creative accounting, a new solution in the field of accounting is narration.

Narrative accounting and its impact on the growing importance of non-financial information

Narrative accounting attracts significant interest and has become a subject of scientific research. V. Beattie, B. McInnes and S. Fearnley (2004) have devised the methodology of conducting an analysis and evaluating narration in accounting. They have also presented the concept of qualitative analysis based on coding any disclosures in annual reports, distinguishing four areas:

- the past and the future,
- financial and non-financial data,
- quantitative and non-quantitative information (description of a fact or an opinion),
- disclosures related to finances, strategies, management analysis and goal completion.

A different approach to analysis and the research conducted in 2011 and 2013 was adopted by N.M. Brennan and D.M. Merkl-Davies (Brennan & Merkl-Davies, 2011; Brennan, Merkl-Davies & Doris, 2013), who based the possibility to use narration in accounting on the feasibility of creating a desired image of an entity by managing the recipient's impression. According to the authors, it may lead to a decrease in the quality of reporting, as well as erroneous allocation of capital by users who are susceptible to suggestions. In addition, they concluded that the areas of managing the impression in reporting include:

- building an entity's reputation by its stable evaluation over time (comparing to selected years in comparison to which the current data demonstrate tendencies for growth).
- creating market and/or financial image.

As a part of communication with a user in narrative accounting, areas have been distinguished, allowing for:

- manipulating the clarity and comprehension of information by using complex language, which makes it possible to provide a company's blurred image in the periods of poor performance,
- rhetorical manipulation, which allows for raising the level of trust and improving an organization's reliability,
- thematic manipulation, thanks to which it is possible to highlight positive information and hide negative one,
- visual manipulation, making use of graphic elements aimed at diverting the user's attention from the remaining information,
- presenting comparisons on the basis of properly selected periods in order to accomplish an entity's projected goal,
- crediting oneself with accomplishments, positive results are the outcome of an organization's actions, whereas negative ones have appeared as a result of external factors, which can be described as independent by an organization.

Narrative reporting has not been unambiguously defined, as it includes all types of information which supplement annual reports, which constitute a set of financial and non-financial information necessary for presentation, understanding the context and diagnosing and evaluating the results of the whole of a company's operations and resources, as well as its current and future financial and market situation (Samelak, 2013). The Federation of European Accountants defines non-financial reports as all information other than financial (FEE, 2015), which is revealed by a company, but cannot be presented by means of concrete amounts of money, despite the fact that they may involve financial consequences (FEE, 2015a, p. 46). Up till the present, no single and commonly accepted definition of non-financial reports has been adopted (Sniezek, Krasodomska & Szadziewska, 2018, p. 68). Narrative reporting allows for presenting a wide range of information concerning an organization's results and accomplishments, and at the same time it may be overly complex and present information in such a manner that it enables the creation of an organization's outcomes and image in accordance with the management's expectations, but in the form it is currently taking, it seems unlikely that it will be subject to robotization of labor due to its individual nature, wide variety and lack of repetitive elements.

The problem of standardizing non-financial reporting and automatization of processes in accounting

Achieving homogeneity in terms of structure and range of information in non-financial reporting is extremely difficult due to lack of appropriate standards, which would compel all entities to write reports in a manner which is transparent, clear for stakeholders and, most of all, comparable. EU Directive 95 on disclosure non-financial information and information on diversity leaves entities with the possibility to choose the form and range of disclosure and publication of information, pointing only to the necessity to preserve the minimum of information required by the directive. Business entities make use of various norms and directives available on the market published by international organization, which facilitates diversity in terms of disclosures. However, non-financial reporting is gaining importance year by year, and a growing number of companies is deciding to disclose their data on customer relations, ethics and preventing corruption, responsibility for the product, employees, natural environment, dialogue with their environment or social responsibility. Such an approach provides companies with the opportunity

to take a holistic and strategic look at their organizations and estimate their impact on the business, social and natural environment. In addition, it allows to notice new business opportunities. Such a transparent presentation of information makes a company appear more trustworthy in the eyes of both external and internal stakeholders. Directive 4 by GRI (*Global Reporting Initiative*) is the best-known and most commonly used document which provides assistance in writing non-financial reports, both in Poland and worldwide. It contains rules concerning a good report, writing it, or the set of indicators which allow companies to write a report which would be a valuable management tool for them, as well as a relevant source of information about a company and its approach to building up value for stakeholders(Deloitte, 2016). Non-financial information in a report should be presented in an organized manner and concern the following groups of information concerning (Deloitte, 2016a):

- strategy and analysis – including the presentation of the company's vision and mission, as well as projected goals in economic, environment and social terms, as well as the values an organization creates,
- organizational profile – information about the company and its basic products and areas of activity, the property structure and legal form, as well as the markets of operation and the scale of organization,
- identification of relevant aspects and limitations- the key areas of activity which influence the stakeholders' evaluation and decisions, description of changes in terms of disclosure and their outcomes, pointing to the ways to verify a report, as well as presenting the reasons for not disclosing some information,
- stakeholders' involvement – information on the key stakeholders and their participation in the processes of revealing the organization's results,
- corporate order – information about the managers and management in terms of effectiveness of management, organizational structure and responsibilities of individual units, as well as reference to the realization of projected goals and motivational system,
- ethics and honesty– disclosures concerning the rules, norms and standards of ethics used within the company,
- indicators and results – presentation of the calculated indicators related to economic, environmental and social results, whose choice should take into account the needs of particular groups of stakeholders in the decision-making process,
- report's profile– information concerning the period described in the report, as well as the attitude towards external verification.

It is not difficult to notice that a vast majority of the abovementioned groups of non-financial information cannot be subjected to a far-reaching and detailed standardization. It is due to not only to the specific nature of information itself, but also to its varying role from the point of view of providers and recipients. Even if the groups include figures, the crucial aspect for both parties is to interpret the data in the context of the issue they demonstrate. It is a message which allows for operating with such elaborate nuances that automatization of those actions would be impossible.

Regulative Framework of Presenting Non-Financial Information

When presenting a non-financial report, it should be assumed that, according to GRI 4 directive, there are two types of indicators: profile and detailed. Profile indicators concern:

- strategy and analysis,
- organization's profile,
- identification of the relevant aspects and their limitations,
- stakeholders' involvement,
- report profile,
- corporate order,
- ethics.

Detailed indicators describe the information related to the approach to management and refer to the economic, environmental and social categories.

In terms of ethics, the most important indicators concern:

- values, rules, standards and norms used by the organization,

- functioning of internal and external mechanisms of consulting within the organization in terms of ethical and law-abiding behavior,
- functioning of internal and external mechanisms of reporting cases of unethical or lawless behavior within the organization,

It is worth noting that as part of GRI4 directive, an entity should describe internal and external mechanisms in the field of breaching ethical standards or law, as well as issues related to an organization's honesty, providing an example of reporting cases of unethical behavior to direct superiors, describing the rules of whistleblowing or ethics helplines.

Despite various, often differing approaches to accounting and narrative reporting in Poland, the lawmakers have introduced the legal rules in terms of presenting financial and non-financial information. They are undergoing constant changes, which are driven by the need to tailor them to the expectations of external users and the remaining stakeholders. According to the legal act on accounting, the extent of presented non-financial information is dependent upon the size of a business entity and includes statements which contain the information on (Legal act from 29 September 1994 on accountig):

1) a brief description of the entity's business model,
2) the key non-financial indicators of effectiveness related to the organization's operations,
3) a description of policies used by the entity in relations to social, employee, environmental, human rights and anti-corruption issues, along with a description of the results of using them,
4) a description of due care procedures- if the entity makes use of them among the policies mentioned in point 3,
5) a description of relevant risks related to the entity's operations which may have detrimental effect on the issues mentioned in point 3, including the risks related to its products or relations with the external environment, including contractors, along with a description of managing those risks.

Regardless of the law-maker's intentions, in order to force the reporting entities to be brief and concrete in terms of the information they disclose, the nature of the issues to which reporting entities are meant to refer to facilitates their use of vast amounts of non-financial information. The motivation behind the selection and range of non-financial information by those entities may be influenced by the factors described above in relations to the issues of narrative accounting.

Conclusions

Robotic Process Automation (RPA) – automatization of complicated processes which replace humans thanks to the implementation of advanced software – changes the future of back office processes. Companies all over the world are starting to realize that RPA is another digital transformation which will allow employees to stop working on repetitive tasks.

The comparison of Capgemini Consulting research results and the authors' own research shows that the concentration on financial and accounting processes in the area of automation and robotization already accomplished is very convergent. This is particularly visible in receivables and payables, and among processes of heterogeneous nature, in reporting to stakeholders. However, studies in the Pomeranian and Kuyavian-Pomeranian regions show clearly reduced expectations for further automation and robotization compared to the results of Capgemini Consulting, except for financial reporting processes. Compared to Capgemini's research, the noticeably greater importance of taxes processes in relation to other processes, both already subjected to automation and robotization, as well as planned ones, is also characteristic. In both cases, the low importance of intragroup settlements for respondents from the Pomeranian and Kuyavian-Pomeranian regions results from simpler organizational structures of enterprises, usually operating in this area as one unit (dominance of small and medium enterprises).

The presented findings indicate that the repetitiveness of work mainly concerns dealing with suppliers and recipients, but also other areas, for example writing reports. Robotic Process Automation allows

employees to concentrate on initiatives which provide more value added, essential for the company's bottom line. Undoubtedly, accounting and narrative reporting constitutes the area which so far has not been subjected to the robotization process, due to its unique nature, but also because of the lack of standardized rules of presenting non-financial information.

Abstract

This article is theoretical and empirical in nature. Its main purpose is to determine the significance of trust shown by final purchasers in their openness in jointly creating a marketing offer with the offerors. A cognitive-critical analysis of the literature on marketing, marketing management and relationship management was used to prepare the theoretical section. The results of the analysis indicate a cognitive and research gap regarding the trust in a product felt by final purchasers in the context of their active participation in the process of creating a marketing offer. In order to reduce the gap, four research hypotheses were formulated, and empirical studies were conducted in which a questionnaire was used to gather primary data. The data were subjected to statistical analysis using Pearson chi-square test and V-Cramer coefficient analysis. The results indicated that there were statistically significant dependencies between trust in products and the following aspects: (a) respondents' willingness to cooperate with offerors, (b) respondents' opinions concerning producers listening to purchasers' suggestions, and (c) the way respondents interpret cooperation with producers. There were no statistically significant dependencies between trust in products and respondents' opinions on the effectiveness of producers as initiators of final purchasers' marketing activity.

Keywords: Trust, Final Purchaser, Product, Offeror, Marketing Offer, Commitment of Final Purchasers

Introduction

Trust is the basis of any long-term relationship between at least two entities, both private and professional. This results from the definition of the verb 'to trust' defined as 'to believe that someone is good and honest and will not harm you, or that something is safe and reliable' (https://dictionary.cambridge.org/dictionary/english/trust). Given the definition, trust is part of key market values that determine the competitive strength of contemporary companies operating in the consumer market. Offerors having trust in themselves and their products is a prerequisite for final purchasers to undertake purchase and extra-purchase activities. This has special significance when deciding on repeat-buying of a particular product or products from a particular offeror. Therefore, it determines the creation and strengthening of behavioural and emotional loyalty to a reliable, credible and honest offeror. It is also vital to have even stronger involvement by the final purchasers in relationships with offerors when creating a marketing offer with them. Accordingly, it is extremely important to undertake theoretical and empirical research on the significance of trust relating to the scope of market behaviours exhibited by contemporary final purchasers.

The results of the cognitive-critical analysis of the literature on the subject, presented further in this article, indicate that the role of trust has not yet been analysed, especially when it comes to the willingness of final purchasers to participate in the creation of a marketing offer and their perception as initiators and recipients of this activity. The purpose of this study is therefore to determine the significance of trust shown by final purchasers in their openness in jointly creating a marketing offer with the offerors.

Literature Review

Trust is a multi-dimensional category (see Fang, Guo, and Zhang, 2015). It can be considered from various perspectives, including sociological, psychological and ethical (see Bauman, and Bachmann, 2017). Virtually all perspectives are used to analyse trust in management (see Guillén Parra, et al., 2011), including marketing management and marketing, or macromarketing (see Pirson, Martin, and Parmar, 2016), which analyses interactions between offerors and purchasers as large groups of entities.

Similar to trust, which is the basis for marketing relationships, especially long-term ones, (see Bauman, and Bachmann, 2017; Kim, Ferrin, and Rao, 2009), interactions are multi-dimensional, beginning with the initiation of a particular relationship until its effects appear. The most important dimensions of marketing relationships are sociological (social), psychological and ethical. Obviously, this also concerns relationships between final purchasers and offerors, including producers, traders and service providers. On the one hand, a given purchaser decides to establish a relationship with a particular offeror based on his/ her subjective feelings (see Dietz, 2011) which result from, among other things for example, the hierarchy of values they share, which is a psychological dimension. On the other hand, in the decision-making process the purchaser considers the behaviour and opinions of other people, especially those visible in social media (see Hanaysha, 2018) and current consumer trends, which is a sociological dimension. For both perspectives, ethical issues are of great importance as they reflect an offeror's previous behaviour towards purchasers and other groups of market entities, the natural environment and an individual purchaser, provided that the purchaser already has some experience of previous relationships with the offeror. Ethical issues are particularly important in online transactions (see Elbeltagi, and Agag, 2016) which result from the specificity of the virtual environment which does not involve personal contact between a final purchaser and an offeror.

Taking into consideration the perspective of time, trust can be considered as a category relating to the past or the future. In the first approach, trust is based on the experience of the individual and/or other people reflecting the conduct of a particular offeror. In the second approach trust refers to assumptions about the actions that may be taken in future by a particular offeror and whether those actions comply with the expectations of the individual. An example of connecting trust with the past is the definition presented in the introduction to this article, and referring to trust in the future is exemplified in a definition proposed by P. Sztompka (2007), according to which trust is a kind of bet taken on uncertain future actions of other people. However, it seems that in market relationships it is the right approach to analyse trust as a category that reflects past experience, as it allows the risk of choosing the wrong partner to be reduced, while increasing the likelihood of establishing a relationship that brings the expected benefits to both parties. From the point of view of offerors, one of the key benefits is purchasers' loyalty to them, their offer and brand (see Bakator, et al., 2019).

As can be seen, trust is a very complex category that forms the basis of virtually any market relationship (see Maia, et al., 2018). It is of key image-forming importance, determining the perception of a particular offeror, which affects the perception of products and other elements of a marketing offer. A high level of trust helps create positive attitudes towards a given company and its offer (see Chen, and Dibb, 2010) and consequently its positive image, whereas distrust in a particular entity leads to building a negative image, as well as a negative image of its offer.

The feeling of trust in an offeror, or its lack thereof, is reflected in specific forms of activity undertaken both of a purchase and non-purchase nature. Purchasers are definitely more eager to buy products from companies that they trust, showing greater openness to various forms of contact with such offerors, even when they require much more involvement than typical shopping activities. These include two basic forms of behaviour: communication and creation (see Baruk, 2019). Considering the paradigm shift in contemporary marketing from creating an offer for a purchaser to jointly creating the offer (see Dellaert, 2019), it is extremely important that offerors skilfully initiate such involvement and use its effects appropriately.

However, it should be emphasised that the lack of trust on the part of final purchasers also results in behavioural and emotional consequences felt by offerors (see Fang, Guo, and Zhang, 2015). People do not willingly buy the products of unreliable companies, and this generates a negative emotion of the perception of these companies. In addition, purchasers share their unflattering opinions with others (see Chen, and Yuan, 2020), contributing to the creation of an unfavourable image of an offeror and their offer; they effectively discourage other purchasers from buying.

It is worth noting that so far in the literature on the subject trust has been analysed primarily in relation to shopping and communication behaviours. In recent years, trust in products in the context of shopping behaviour has been most often analysed in relation to online shopping (see Kooli, Ben Mansour, and Utama, 2014; Thi Mai Anh, and Huong, 2019), especially the intention to repeat it (see, inter alia, Sullivan, and Kim, 2018; Kim, et al., 2012; Shiau, and Luo, 2012). In turn, for communication behaviour trust is increasingly being considered in relation to online communication (see Huete-Alcocer, 2017; Abubakar, and Ilkan, 2016; Lee, Park, and Han, 2011; Awad, and Ragowsky, 2008), i.e. electronic word of mouth (eWOM) (see Hussain, et al., 2017).

The theory and research consideration has not yet been applied to trust in the context of creative behaviours involving active cooperation between final purchasers and a company in creating a marketing offer. One can therefore speak of a cognitive and research gap in this respect. The pursuit to reduce the gap was the main premise for choosing the scope of this study. An attempt was made to solve the following research problem: how significant for final purchasers is their trust in products that they adopt an open attitude to creating a marketing offer jointly with a company?

In order to solve the research problem, the following goal was pursued: to determine the significance of trust shown by final purchasers in their openness to create a marketing offer jointly with offerors. An attempt was also made to achieve the following specific research goals:

G1: to identify the share of respondents who are willing to engage in the preparation of products, advertisements and other elements of a marketing offer.
G2: to identify respondents' opinions on the effectiveness of offerors in encouraging purchasers to cooperate in the process of preparing an offer.
G3: to identify respondents' opinions on whether offerors listen to purchasers' opinions and use their spontaneous willingness to cooperate.
G4: to define respondents' trust in products according to the extent of final purchasers' commitment in their preparation.
G5: to check whether there is dependence between trust in products and respondents' willingness to cooperate with offerors.
G6: to check whether there is dependence between trust in products and respondents' opinions on the effectiveness of offerors in encouraging purchasers to cooperate.
G7: to check whether there is dependence between trust in products and respondents' opinions on offerors' listening to purchasers' suggestions.
G8: to check whether there is dependence between trust in products and the way respondents interpret cooperation with producers.

Four research hypotheses have also been verified:

H1: there is dependence between trust in products and respondents' willingness to cooperate with producers.
H2: there is dependence between trust in products and the perception of producers as initiators of final purchasers' participation in marketing activity.
H3: there is dependence between trust in products and the perception of producers as recipients of final purchasers' spontaneous activity.
H4: there is dependence between trust in products and the way of interpreting the cooperation between final purchasers and producers.

General Characteristics of The Research

In order to achieve the research goals and verify the hypotheses, primary research was conducted. The research was implemented as part of research project 11/B/HS4/00430 financed by the National Science Centre. The research was conducted in the third quarter of 2018 among 1,200 people representing Polish adult final purchasers from all over Poland. A total of 1,012 completed questionnaires qualified for statistical analysis. The survey population was 61% female, which corresponded to the structure of the general adult population of Poland (see http://www.polskawliczbach.pl/#ixzz4F3Nogl1N). Non-random selection of a quota-type sample was applied. It must be underlined that according to M. Szreder (2010), it is not always necessary to apply random selection, and more and more often non-random selection can even be treated as an opportunity for a researcher. The research was direct in nature, requiring the interviewer's personal contact with respondents. This made it possible to obtain a high return rate of completed questionnaires.

The present study represents only a small fragment of research covering a much broader scope. The scope of the research presented in this article includes the following: (a) respondents' opinions reflecting their trust in products based on purchasers' involvement in the preparation of the products, (b) respondents' opinions on the cooperation with producers reflecting their willingness to jointly create a marketing offer, (c) the perception of producers as initiators of purchasers' marketing activity and as recipients of the effects of purchasers' spontaneous activity, and (d) the interpretation of cooperation between final purchasers and producers.

The primary data collected during the research were used in further stages of the research process, namely statistical analysis using the following methods and tests: cross-table analysis, Pearson chi-square independence test, and V-Cramer contingency coefficient. The chi^2 test was used to determine if there were statistically significant dependencies between the analysed variables, and the V-Cramer coefficient was used to determine the strength of relationships between the analysed variables. The V-Cramer coefficient is used when at least one variable has more than two values (see King, Rosopa, and Minium, 2018), i.e. if the contingency table has dimensions of at least 2×3.

Research Results

The results of the research indicate that almost 41% of respondents showed an open attitude to the creation of a marketing offer with the producers of a product (Table 1). Such cooperation may be the result of its stimulation by producers or it may result from spontaneous attempts of involvement by final purchasers in joint activities. However, nearly one third of respondents positively assessed producers as the initiators of purchaser marketing activity. It is true that a slightly larger percentage of respondents positively assessed offerors as beneficiaries of purchasers' spontaneous activity, but in both cases the majority of respondents perceived producers unfavourably. Perhaps this was one of the reasons for more than half of respondents declaring their unwillingness to participate in marketing activities.

Table 1: Respondents' attitudes towards cooperation with producers (%)

Variable	Ratings (%)	
	yes	no
Willingness to engage in the preparation of products, advertisements and other elements of an offer	40.8	59.2
Respondents' opinions on the effectiveness of producers in encouraging purchasers to cooperate in the process of preparing an offer	31.1	68.9
Respondents' opinions on whether producers listen to purchasers' opinions and use their spontaneous willingness to cooperate	39.2	60.8

Source: own study based on research results.

As clearly seen in Table 2, the largest percentage of respondents trusted products prepared by manufacturers in accordance with the principles of the classic marketing approach most, i.e. based on the results of research into purchaser expectations. However, it is worth noting that almost every third respondent felt the greatest trust in the products jointly prepared by producers and purchasers, i.e. in accordance with the assumptions of the prosumer marketing approach. By far the smallest portion of respondents most trusted products prepared by purchasers only with the support of the offeror. An analogous structure of indications reflecting trust in products is observed for respondents expressing their willingness to participate with producers in the preparation of an offer together, although for this group a clearly different percentage of indications for individual types of products can be seen. This applies especially to products jointly prepared by manufacturers and purchasers, and products prepared by producers based on purchasers' own ideas. For respondents showing openness to cooperation with producers, the share of respondents who mainly trust products created jointly was almost 12% higher than for all respondents, whereas the percentage of respondents who mainly trusted products prepared by producers without the participation of purchasers was almost two times lower than it was for all respondents.

Table 2: Products that generate the greatest level of trust in respondents and their willingness to engage in the preparation of products, advertisements and other elements of a marketing offer (%)

Products that generate the greatest level of trust in respondents	Respondents' willingness to engage in the preparation of products, advertisements and other elements of a marketing offer (%)		
	yes	no	total
prepared by producers based on their own ideas	10.6	28.0	20.9
prepared by producers based on the results of research on purchaser expectations	44.7	44.3	44.4
jointly prepared by producers and purchasers	41.3	21.5	29.6
prepared by purchasers only with the technical assistance of producers	3.4	6.2	5.1
total	100,0	100.0	100.0

Source: own study based on research results.

However, a different structure of trust in products was identified for respondents showing a closed attitude towards cooperation with producers. It is true that in this group the largest proportion of respondents trusted products prepared within the framework of the classic marketing approach the most, but the second position in terms of the percentage of indications was taken by products prepared by producers themselves, i.e. not in line with the marketing approach. The percentage of respondents who felt the greatest confidence in products prepared by producers themselves was clearly higher than among all respondents and almost 2.5 times higher than among those ready to cooperate with producers. It can therefore be assumed that there is dependence between trust in products resulting from the way they are prepared and the attitude towards joint creation of the offer. This issue is analysed later in this study.

Taking into account respondents' opinions on the effectiveness of producers in encouraging purchasers to jointly create a marketing offer, it turns out that the structure of trust in the four product types considered is the same for all respondents and for those who perceive producers positively and negatively (Table 3). The differences are only visible in the case of the percentage of indications concerning particular types of products. The largest proportion of respondents who most trust products prepared by producers based on the results of research on purchaser expectations (i.e. according to the assumptions of the classic marketing approach) occurred among respondents who positively perceive the effectiveness of producers. For the same group of people, the smallest percentage of respondents showing the greatest trust in products prepared in accordance with the principles of a prosumer marketing approach was identified at the same time, which may cause some surprise. However, it should be remembered that joint actions may also be a result of spontaneous

activity by final purchasers. Therefore, unfavourable opinions about the role of producers as initiators of purchaser involvement do not prejudge the scope and level of this involvement, as it may also be autonomous.

Table 3: Products that generate the greatest level of trust in respondents and their opinions on the effectiveness of producers in encouraging purchasers to cooperate in the process of preparing an offer (%)

Products that generate the greatest level of trust in respondents	Respondents' opinions on the effectiveness of producers in encouraging purchasers to cooperate in the process of preparing an offer (%)		
	yes	no	total
prepared by producers based on their own ideas	20.3	21.2	20.9
prepared by producers based on the results of research on purchaser expectations	48.3	42.7	44.4
jointly prepared by producers and purchasers	25.4	31.5	29.6
prepared by purchasers only with the technical assistance of producers	6.0	4.6	5.1
total	100.0	100.0	100.0

Source: own study based on research results.

An identical structure reflecting trust in products was also identified for both all respondents and for those who positively assess producers as recipients of purchasers' spontaneous activity, and those with a different opinion about manufacturers (Table 4). However, unlike the context discussed earlier, the largest percentage of respondents who most trust products prepared jointly by producers and purchasers was identified for those who perceive manufacturers positively. It amounted to almost 32%, although it was clearly lower than for respondents who were willing to cooperate with producers (where it exceeded 41%) (see Table 2). It can therefore be assumed that there is dependence between trust in products and the perception of producers as beneficiaries of the spontaneous activity of final purchasers.

Table 4: Products that generate the greatest level of trust and highest opinions of respondents and whether producers listen to purchasers' suggestions and use their spontaneous willingness to cooperate (%)

Products that generate the greatest level of trust in respondents	Respondents' opinions on whether producers listen to purchasers' suggestions and use their spontaneous willingness to cooperate (%)		
	yes	no	total
prepared by producers based on their own ideas	19.1	22.1	20.9
prepared by producers based on the results of research on purchaser expectations	42.1	45.9	44.4
jointly prepared by producers and purchasers	31.7	28.2	29.6
prepared by purchasers only with the technical assistance of producers	7.1	3.7	5.1
total	100.0	100.0	100.0

Source: own study based on research results.

The trust in products was also analysed from the perspective of cooperation between purchasers and offerors. As seen in Table 5, both for all respondents and for those who mostly trust products prepared as part of the classic marketing approach, and for those who mainly trust products prepared as part of the prosumer marketing approach, the largest proportion of respondents identified

cooperation with producers with the possibility of preparing an offer that would better meet purchasers' expectations. It is worth noting that for respondents primarily trusting products prepared without any participation by recipients, the largest percentage considered cooperation with producers as a waste of time, whereas for all respondents the number was over two times lower. Cooperation with manufacturers was identified as a waste of time by the smallest proportion of respondents in the group of people who mostly trust products prepared with offerors. It can therefore be assumed that there is dependence between trust in products and the way of interpreting interaction between final purchasers and producers.

Table 5: Products that generate the greatest level of trust in respondents and the way respondents interpret their cooperation with producers (%)

The way respondents interpret their cooperation with producers	Products that generate the greatest level of trust in respondents (%)				Total
	P1	P2	P3	P4	
Waste of time	35.8	12.7	8.0	43.1	17.7
Possibility of preparing an offer that better meets purchaser expectations	34.0	47.2	44.7	35.3	43.0
Producers pretending that they consider the opinion of purchasers	10.8	15.3	7.7	2.0	11.5
Producers' possibility of saving money by using purchasers' ideas	7.1	7.6	11.3	7.8	8.6

Producers' build good relationships with purchasers	3.3	6.4	3.3	2.0	4.6
Total	100.0	100.0	100.0	100.0	100.0

where: P1 – products prepared by producers based on their own ideas; P2 – products prepared by producers based on the results of research on purchaser expectations; P3 – products jointly prepared by producers and purchasers; P4 – products prepared by purchasers only with the technical assistance of producers

Source: own study based on research results.

Table 6: Analysis of dependencies between respondents' trust in products based on the extent of purchasers' involvement in their preparation and variables reflecting respondents' attitudes towards cooperation with producers

Dependence	Pearson chi-square test value	V-Cramer coefficient value	Level of significance 'p'
Trust in products and willingness to cooperate	71.605	0.266	**0.000**
Trust in products and opinions on producers' effectiveness in encouraging purchasers to cooperate	5.242	0.072	0.155
Trust in products and opinions on producers' listening to purchasers' suggestions	8.086	0.089	**0.044**
Trust in products and the interpretation of cooperation with producers	152.789	0.224	**0.000**

Source: own study based on research results.

In order to check whether there are statistically significant dependencies between the analysed variables, statistical testing was conducted. It was concluded that such dependencies exist in the case of trust in products and openness towards cooperation with producers, trust in products and the perception of producers as the recipients of final purchasers spontaneous activity, and trust in products and the interpretation of cooperation with producers (Table 6). Preliminary conclusions about the occurrence of these dependencies proved to be correct. However, the dependencies identified are weak. The values of the V-Cramer coefficient in each case are less than 0.3, i.e. the boundary value between the weak and medium strength of dependence between the analysed variables (King, Rosop, and Minium, 2018). Therefore, hypotheses H1, H3 and H4 for respondents can be considered valid. However, hypothesis H2 is not valid. There was no statistically significant dependence between trust in products and the perception of producers as initiators of marketing activity by final purchasers, as evidenced by a significance value greater than the limit value of 0.05.

Conclusions

Based on the considerations presented above, the majority of respondents did not show their willingness to engage in joint preparation of a marketing offer with the offerors. This may result from the fact that offerors were unfavourably perceived by over half of respondents. It was visible especially in the case of assessing producers as initiators of initiators of final purchasers' marketing activity. Considering the scope of purchasers' engagement in the preparation of products as key elements of a marketing offer, the majority of respondents trusted products prepared by manufacturers based on the results of research into purchaser expectations the most, i.e. in accordance with the principles of the classic marketing approach. Products prepared jointly by producers and final purchasers generated a lower level of trust by respondents.

Statistically significant dependencies were identified between trust in products resulting from the scope of purchasers' engagement in their preparation and the following three variables: (a) respondents' willingness to cooperate with offerors, (b) respondents' opinions concerning producers listening to purchasers' suggestions, and (c) the way respondents interpret cooperation with producers. The first dependence was relatively the strongest, although none of them was characterised by high strength. Thus, hypotheses H1, H2 and H3 were considered valid for respondents. However, hypothesis H2 for respondents was not valid. There was no statistically significant dependence between trust in products and the perception of producers as initiators of marketing activity by final purchasers. The results obtained from the research have a cognitive and applicability value. They allow the gap identified when analysing the literature on the subject to be reduced and make it easier for managers to take more effective actions aimed at including final purchasers in the process of joint creation of a marketing offer by creating their trust in products and in the offerors.

Obviously, the conducted research has some limitations including its subjective scope (the research comprised only adult final purchasers), objective scope (the research comprised only selected aspects of trust in products in the context of final purchasers' cooperation with offerors), and geographical scope (the research was conducted only in Poland). The pursuit to overcome the limitations will guide future stages of the research process, and the degree of detail of the analysis will be deepened.

Analysis of Stated Consumer Preferences Using Multinomial Logit Models and Discretechoice R Package

Andrzej BAK
Wroclaw University of Economics and Business, Poland, andrzej.bak@ue.wroc.pl

Tomasz BARTLOMOWICZ
Wroclaw University of Economics and Business, Poland, tomasz.bartlomowicz@ue.wroc.pl

Abstract

The purpose of the article is to analyze consumer preferences using the selected multinomial logit models consisting of unordered categories. These models are included in the area of microeconometrics and are applied to analyze stated consumer preferences following the approach based on choices and random utility theory. The conducted empirical research was based on the authors' DiscreteChoice package developed for CRAN R project. The package implements a multinomial, conditional and mixed logit models as well as the functions which can be applied in the discrete choice method for the construction of an experiment, e.g., for a fractional factorial design development, option set coding and model parameter estimation.

Keywords: consumer preferences, discrete choices, microeconometrics, multinomial logit models, R program.

Introduction

One of the key elements of marketing research is measuring and analyzing consumer preferences. If this measurement is based on the data collected using surveys, allowing the registration of consumers' intentions at the time of the survey, the measurement is focused on stated preferences corresponding to the hypothetical (declared) consumer preferences.

Various methods and models are applied in the study of stated preferences, which are generally classified into three groups: composition, decomposition and mixed methods.

Decomposition methods, including conjoint analysis methods and discrete choice methods [Walesiak and Bąk, 2000], [Bąk, 2004], represent the most commonly used methods, which allow both measurement and analysis of stated preferences.

The analysis of stated consumer preferences, in terms of products and services, using decomposition methods consists in the distribution (decomposition) of empirical preferences (stated, e.g., in a survey) into partial utilities of attribute levels describing the analyzed profiles of products or services. A statistical model (e.g., linear regression model or logit probability model) represents the basic decomposition tool.

Probabilistic models, which describe the probabilities of choosing profiles from the offered set of different product or service variants are used within the group of discrete choice methods. The choice of individual profiles is influenced by both their attributes and the characteristics of respondents. These variables are usually of a discrete nature (representing categorical variables and nominal variables). The purpose of estimating discrete choice models is to analyze the probabilities of choosing individual options (profiles) and parameters, which indicate the importance of attributes.
The theory of random utility constitutes the theoretical basis for the discrete choice models [Coombs, Dawes and Tversky 1977, p. 214]. It allows quantifying utilities and, as a consequence, identifying the

factors followed by the consumers when choosing the specific products or services. These factors can be related to both consumer characteristics and product or service attributes. It means that the unordered category models are applied in the survey of consumer preferences, among which the most commonly used models are: multinomial logit model, conditional logit model and mixed logit model [Winkelmann and Boes 2006]. The distinction between these models is not clearly interpreted in the subject literature.

The purpose of the article is to discuss the basic differences between the aforementioned logit models [So and Kuhfeld 1995], [Long 1997], [Agresti 2002], [Cameron and Trivedi 2009], [Jackman 2007], [Powers and Xie 2008], [Gruszczyński 2010], [Bąk 2012], [Bąk 2013] and to present the Discrete-Choice package [Bąk and Bartłomowicz 2020] developed for R program, the functions of which allow the implementation of the research procedure based on choices using multinomial models. The package functions were illustrated by the example of using stated consumer preferences in empirical research.

Multinomial Unordered Logit Models in Stated Preference Measurement

The application of variables in microeconometric models results, most frequently, from performing measurements on weak (non-metric) scales. The collected observations usually take the form of discrete numerical values.

In the area of microeconometric research, the following types of response variables (referred to as qualitative variables) are most often used [Gatnar and Walesiak 2011, p. 113], [Gruszczyński 2012], [Bąk 2013]:

a) dichotomous variables (binomial, bi-category, e.g. binary),
b) polytomous variables (multinomial, multi-category), among which the variables representing ordered and unordered categories are included,
c) limited variables, among which censored and truncated variables are distinguished,

The listed below types of models are most frequently used in microeconometrics to apply in the analysis of stated consumer preferences [Gatnar and Walesiak 2011 p. 113], [Gruszczyński 2012], [Bąk 2013]:

a) binomial models:
- linear probability models,
- logit and probit models,
- complementary log-log models,
- log-linear models,

b) multinomial models:
- unordered category models,
- ordered category models,

c) latent class models,
d) survival (duration) models,
e) limited variable models.

The unordered category models are applied in the marketing research conducted using discrete choices, taking the form of MultiNomial Logit Model (MNL) and Conditional Logit Model (CLM) and also the Mixed Logit Model (MLM) representing the combination of the aforementioned models[So and Kuhfeld 1995], [Long 1997], [Agresti 2002], [Cameron i Trivedi 2009], [Jackman 2007], [Powers and Xie 2008], [Gruszczyński 2010], [Bąk 2012], [Bąk 2013].

The multinomial logit model is a generalization of a logit model for binary data and can be applied when the response variable, in a discrete way, takes values from the set consisting of more than two categories (multinomial variable). The model derives from the random utility theory and the so-called Luce's choice axiom (constant utility model) [Coombs, Dawes and Tversky 1977, p. 217], [Bierlaire 1997]. The multinomial logit model can be presented in the following form [So and Kuhfeld 1995],

[Long 1997, p. 151], [Agresti 2002], [Powers and Xie 2008, p. 243], [Cameron and Trivedi 2009, p. 500], [Gruszczyński 2010, p. 161]:

$$P_{ki} = \frac{\exp\left(x_k^T \beta_i\right)}{\sum_{l=1}^{n} \exp\left(x_k^T \beta_l\right)} \tag{1}$$

where: P_{ki} – probability of choosing *i*-th category with *k*-th status of predictor variables describing consumers; x_k^T – vector describing *k*-th row of **X** matrix (values of predictor variables for *k*-th consumer); β_i – parameter vector related to *i*-th category of a response variable.

In the case of conditional logit model proposed by McFadden [McFadden 1974, pp. 105-142] the probability of choosing *i*-th profile from the set consisting of *n* elements is estimated based on the following correlation [So and Kuhfeld 1995, p. 7], [Long 1997, p. 178], [Powers, Xie 2008, p. 256], [Cameron and Trivedi 2009, p. 500], [Gruszczyński 2010, pp. 172-173]:

$$P_{ki} = \frac{\exp\left(z_{ki}^T \alpha\right)}{\sum_{l=1}^{n} \exp\left(z_{kl}^T \alpha\right)} \tag{2}$$

where: P_{ki} – probability of choosing *i*-th category with *k*-th status of predictor variables; z_{kl}^T – *k*-th vector of **Z** matrix (predictor variables describing the *i*-th option chosen by *k*-th consumer); α – parameter vector.

Both multinomial and conditional logit models are used to analyze individual choices from the set of available alternatives (categories, options, profiles), and while in the multinomial model (1) the probability of choosing the *i*-th option is estimated taking into account the predictor variables which characterize consumers, in the conditional model (2) it is the probability of choosing the *i*-th option regarding the values of predictor variables characterizing this option. It results from the assumption – constituting also the main distinctive feature of the discussed models – that the multinomial logit model analyzes the characteristics of consumers and their impact on the choices of specific options, whereas the conditional logit model the characteristics of products or services (choice options) and their impact on the choices made by consumers.

In terms of the mixed logit model (3), the probability of choosing *i*-th category with *k*-th status of predictor variables can be described using the following correlation [Hoffman and Duncan, 1988], [So and Kuhfeld 1995], [Powers, Xie 2008, p. 258 et seq.], [Cameron and Trivedi 2009, p. 500]:

$$P_{ki} = \frac{\exp\left(x_k^T \beta_i + z_{ki}^T \alpha\right)}{\sum_{l=1}^{n} \exp\left(x_k^T \beta_l + z_{kl}^T \alpha\right)} \tag{3}$$

In the mixed logit model both consumer characteristics and the attributes describing the choice options are considered. It means that the predictor variable matrices take into account both the individual characteristics of consumers and also the attributes of products or services.

To estimate the binomial and multinomial models the concept of Generalized Linear Models (GLM) is used. A regression model is formulated in which the expected value of the predictor variable distribution (consumer preferences) depends on the linear combination of the predictor variables:

$$E(\boldsymbol{y}) = \mu = \boldsymbol{x\beta} \tag{4}$$

The distribution of $\boldsymbol{y}$ observation vector is characterized by μ expecred value. If the observations are independent and present $N(\mu, \sigma^2)$ distribution, then $\boldsymbol{\beta}$ parameters are estimated using a classical Ordinary Least Squares (OLS) method. As a result a systematic component of GLM model is obtained:

$$\eta = \boldsymbol{x\beta} \tag{5}$$

referred to as η linear predictor.

The distribution of $\boldsymbol{y}$ observation vector depends, e.g., on the measurement scale and often such distribution is a non-normal one, e.g., a binomial or Poisson in the case of non-metric scales. The representation of various distributions of $\boldsymbol{y}$ observation vector (in particular from the exponential family of distributions) in the generalized linear model is allowed by g link function, which links μ expected value with η linear predictor:

$$g(\mu) = \eta = \boldsymbol{x\beta} \tag{6}$$

Inverse link function:

$$g^{-1}(\eta) = \mu \tag{7}$$

is called a mean function.

The basic advantages of generalized linear models include the following features:

- discrete and continuous variables can be present in the model,
- many predictor variables can be included in the model,
- linear transformations of variables with non-linear distributions can be used,
- non-normal distributions may be included, in particular the discrete distributions,
- a model can be estimated in the case of collinearity of variables (when the inverse matrix to $\boldsymbol{X}^T\boldsymbol{X}$ matrix does not exist, the so-called generalized inverse matrix is specified).

The subject literature also points to the limitations in the application of generalized linear models, which include: the assumption about the independence of observations, inadequacy of the adopted observation distribution, a limited number of nonlinear models which can be re-represented in the model using the link function [Halekoh, Højsgaard 2008].

The characteristics of DiscreteChoice R package

DiscreteChoice statistical software package represents the authors' [Bąk and Bartłomowicz 2020] extension (module) of R program, including the implementation of selected multinomial logit models, applied in measuring consumer preferences using the discrete choice methods. The package correct functioning requires installing the latest base version of R program (3.6.2) [R Development Core Team 2011] and some additional packages, the most important of which are AlgDesign [Wheeler 2012], rms [Harrell 2019] and ggplot2 [Wickham et al. 2019]. The package can be downloaded and installed from the package homepage – the website of the Department of Econometrics and Computer Science of Wrocław University of Economics (http://keii.ue.wroc.pl/DiscreteChoice). DiscreteChoice package is written in R programing language and available under the GNU license (free of charge and provides access to the source code). The package, in addition to R program, is also compatible with the software dedicated to R environment such as: RStudio and Microsoft R Application Network.

The total of 16 functions are offered in the current version of the package (1.07) (see Tab. 1), among which 9 functions allow: converting the data about individual consumer choices into the data sets for logit models (functions: MNLdata, CLMdata, MLMdata), the estimation of model parameters and determining the intercept values for the individual consumer characteristics (functions: MNLmodel, CLMmodel, MLMmodel) and also the probability estimation of the profile choice (functions:

MNLprob, CLMprob, MLMprob) for each of the three logit models (multinomial, conditional and mixed). The special purpose functions include the functions which allow generating the set of non-collinear variables (the possibility of removing collinearity between artificial variables based on the Variance Inflation Factor (VIF) value [Maddala 2006; Greene 2008]) – CLMattrsel function) and the hazard ratio graph (CLMgraph function) for the conditional logit model.

In addition, the package provides a tool supporting the survey design, i.e. the construction of the appropriate factor systems characteristic for the analysis of consumer preferences in accordance with the discrete choice methods. For this purpose, the DiscreteChoice package uses the AlgDesign package functions [Wheeler 2012]. Its implementation in the DiscreteChoice package is carried out in the form of a function which allows generating partial factor systems with the suggested number of blocks and profiles in each block, including "none of the above" profile for given vectors covering the number of levels and the names of variables (MNMdesign function). This means the possibility of designing an experiment followed by obtaining the preference measurement results using the DiscreteChoice package function of R program.

The detailed characteristics of all available functions, data sets and the selected examples of the package application in measuring stated preferences are available in the documentation of the DiscreteChoice R package.

Table 1: Functions of the DiscreteChoice R package

Functions of the package	
MNMdesign (vars, names, blocks=3, profiles=6) – function makes sectional, fractional factorial design with suggested number of profiles and alternatives in each block of profiles using vectors of variables' number and variables' names	
MNLdata(y, x, z) – function returns data set for multinomial logit model	
CLMdata(y, x) – function returns data set for conditional logit model	
MLMdata(y, x, z) – function returns data set for mixed logit model	
MNLmodel(y, x, z) – function returns intercept coefficients and slope coefficients (parameters estimates) for individual specific variables using multinomial logit model. Intercepts and variables' coefficients corresponds to the effects on the probability of choosing options (profiles) over reference option (profile)	
CLMmodel(y, x) – function returns slope coefficients (parameters estimates) for characteristics of alternatives using conditional logit model	
MLMmodel(y, x, z) – function returns slope coefficients (parameters estimates) for individual specific variables and characteristics of alternatives using mixed logit model	
MNLprob(y, x, z) – function returns probability of profiles choice using multinomial logit model	
CLMprob(x, y) – function returns probability of profiles choice using conditional logit model	
MLMprob(y, x, z) – function returns probability of profiles choice using mixed logit model	
CLMattrsel(x, y) – function returns set of attributes (without duplicated attributes) for conditional logit model	
CLMgraph(x, y, type=1) – function returns graph of hazard ratio using conditional logit model	
Functions' arguments	
vars	vector of empirical preferences
names	vector of variables' names
blocks	number of blocks (optional), default value: blocks=3
profiles	number of profiles in every block (optional), default value: profiles=6
x	matrix of choice-specific attributes (profiles, alternatives)
y	vector or matrix of individuals choices (dependent variable)
z	matrix of individual-specific characteristics
type	type of ratio hazard graph (optional, 1 – vertical bars, 2 – horizontal bars), default value: type=1

The application of DiscreteChoice package in measuring stated preferences

In the example illustrating the application of selected multinomial logit models, the identification and analysis of respondents' preferences referred to gastronomic services. 4 attributes were selected in the study (along with their corresponding levels): a price (up to 10 PLN, 10-20 PLN, above 20 PLN), a place of consumption (restaurant, gastronomic facility, canteen, bar), a kind of consumption (meal, dessert, drink) and an hour of consumption (morning, afternoon, evening). The study was conducted using 136 correctly completed survey questionnaires (Marta Więcław is the author of the survey).

The number of variables along with the number of their implementation levels means that a maximum of 108 different gastronomy service profiles could be used in the example. Finally, as results from the applied discrete choice method, for the purposes of the study 3 data sets were selected, 6 profiles in each set, with the reference profile in the last position. The used in the study sets of profiles assessed by the respondents are presented in Tab. 2-4.

Table 2: The first block of profiles ("none of the above" profile)

Price	Place	Kind	Time	Choice
10-20 PLN	bar	dessert	morning	1
to 10 PLN	restaurant	drink	morning	2
to 10 PLN	canteen	dessert	afternoon	3
above 20 PLN	canteen	drink	afternoon	4

All the applied factor systems and data are included in the DiscreteChoice catering data set.

The Multinomial Logit Model

In the case of a multinomial logit model, the analysis used a single set of profiles to choose from, which means that the final number of observations corresponded to 136 respondents (136 · 1), whereas the number of rows in the data set was 816 (136 · 6 · 1), the fragment of which is presented below:

```
> z1<-as.data.frame(Z[, 7])
> n<-names(Z)
```

```
> colnames(z1)<-n[7]
> data=MNLdata(Y3, X3, z1)
> head(data)
  subject option choice int1 int2 int3 int4 int5 age1 age2 age3 age4
age5

6       1      6      0    0    0    0    0    0    0    0    0    0
0
```

In the structure of the above data, each row presents 1 choice option, while the full set from which the respondent was choosing one option (profile) corresponds to 6 rows. The choice options are represented by a zero-one variable in the set; in each case the option 6 is the reference profile. The respondents were choosing 1 out of 6 profiles each time. The respondent-specific variable was age, the chosen option was determined by the price and the selected profile was represented by the choice variable.

As a result of applying the DiscreteChoice package of R program for the above data in the multinomial logit model, the parameter estimates are obtained for the age-specific variable characteristic for the respondents:

```
> MNLmodel(Y3, X3, z1)
$estimate
                 coef        se           t  Pr(>|t|) exp(coef)

```

The obtained set of results (5 intercepts and 5 parameters for the age-specific variable) represents the effect affecting the probability of choosing an option (profile) 1–5 in relation to the reference profile marked as number 6. The profile No. 1 is more often chosen by younger respondents.

As a result of applying the MNLprob function, the estimates of the probability of choosing individual profiles by the respondents are obtained (at an individual level and in the cross-section of all respondents).

```
> pmnl=MNLprob(Y3, X3, z1)
> apply(pmnl, 2, "mean")
        p1         p2         p3         p4         p5         p6
0.02205912 0.41911326 0.10293990 0.08088135 0.21323584 0.16177054
```

Out of the six selection profiles p1-p6, the probability of choosing the profile number 2 is the highest (price –10-20 PLN, place – restaurant, kind – meal, hour of consumption – afternoon). The probability of choosing the profile number 1 is the lowest (price – above 20 PLN, place – canteen, kind – drink, hour of consumption – morning).

The Conditional Logit Model

In the case of a conditional logit model, the analysis used all 3 sets of profiles to choose from, which means that the number of observations corresponded to the number of the respondents multiplied by 3 (136 · 3), i.e. 408 observations, whereas the number of rows in the data set amounted to 2448 rows (136 · 6 · 3).

As a result of applying the DiscreteChoice package of R program for the above data in the conditional logit model, the parameter estimates are obtained for the selected variable specific variants characteristic for the choice option, i.e. price, place, kind and hour:

```
> CLMmodel(X, Y)
$estimate
              coef        se           t  Pr(>|t|) exp(coef)

```

The results' interpretation using hazard ratios is presented in Figure 1. The values of hazard ratios greater than 1 indicate the stimulating effect of variables on the choice of profiles. From among the variables included in the study, the stimulating effect is achieved by the variable price up to 10 PLN (price1) and 10-20 PLN (price2), and also a restaurant as a place of consumption (place1) and a kind of a meal in the form of a meal (kind1). The other variables have a negative impact on the choice

of profiles. It means that the respondents prefer a low or medium price, a restaurant as a place of consumption and meals (as well as an afternoon hour of consumption).

Based on the model parameter values, the probability of choosing the particular profiles was calculated and the obtained values indicate that the profile No. 14 (price – 10-20 PLN, place – restaurant, type – meal, hour of consumption – afternoon) is the most preferred one, to be followed by the profiles No. 11, 7, etc. The profile No. 13 is characterized by the smallest choice probability (price – 10-20 PLN, place – canteen, type – drink, hour of consumption – morning).

The Mixed Logit Model

In the case of a mixed logit model, 1 set of profiles to choose from was used in the analysis, which means that the number of observations corresponds to 136 respondents (136 · 1), whereas the number of rows in the data set is 816 (136 · 1 · 3). The model uses one variable characterizing the set of alternatives (choice options), i.e. the hour of consumption and one variable characterizing the unit of analysis (a respondent) in the form of age. As a result of using the DiscreteChoice package of R program for the above data, the parameter estimates of the selected specific variables are obtained.

```

The estimated parameters of the mixed logit model should be interpreted in terms of probability [Gruszczyński 2002]. With regard to the variable characterizing the set of alternatives, i.e. the time of consumption, the most probable choice is the evening (time3), the least probable choice is the morning (time1), which results from a negative parameter value for this variable. Regarding the variable characterizing the unit of analysis (a respondent) – age, the option No. 1 (age1) is the most probable choice, while the option No. 4 (age4) is the least probable choice.

Despite using a smaller number of data in the case of a mixed logit model, the obtained probabilities of profile choices correspond to the results obtained using the CLMprob function – the least preferred profile is the profile No. 1.

```
> pmlm=MLMprob(Y3, x1, z1)
> apply(pmlm, 2, "mean")
        p1         p2         p3         p4         p5         p6

```

The full version of the following example illustrating the application of discrete choice method in the analysis of stated preferences is available in the documentation of the DiscreteChoice R package [Bąk and Bartłomowicz 2020].

Conclusions

The article addresses the differences between the selected models of unordered categories: multinomial, conditional and mixed logit models. These models can be regarded as complementary in the applications aimed at measuring latent preferences in the microdata. The examples of using multinomial logit models presented in the article confirm the above conclusions.

The estimation of different types of multinomial logit models requires different empirical data structure. The DiscreteChoice package includes functions that transform empirical data into the required structures and also the functions estimating the parameters of all three types of multinomial logit discrete choice models, which in further analysis means the possibility of conducting more detailed analyses of consumer behavior based on the carried out empirical studies, taking into account both the unit of analysis – consumers (identified by its characteristics), and the objects of analysis – products or services (described by means of their attributes).

The article presents an example of using the most important functions of the DiscreteChoice package in analyzing the stated consumer preferences based on the example of gastronomic services.

Abstract

Nowdays, online platforms are one of the channels used by retailers to trade their products. In this sense, measuring customer satisfaction online is essential to assess the quality of the service provided, the existing physical infrastructures and to identify the causes of dissatisfaction and organizational inefficiencies. Thus, the objective of this paper is to analyze the satisfaction and loyalty of the online customer of the Auchan commercial brand through the evaluation of the dimensions of the quality of the electronic service. The findings obtained show that customers are satisfied with the online services of Auchan of the Famalicão (Portugal), showing greater preference and satisfaction with the Drive service. The dimensions of the e-service with the highest levels of satisfaction correspond to Guarantee, Fulfillment and Security, and the levels with the lowest level of satisfaction refer to reliability. Furthermore, customers expressed strong loyalty to Auchan of the Famalicão's e-commerce. In this sense, it is recommended that Auchan should be established priorities and intervene in the dimensions with the worst assessment to increase customer satisfaction and loyalty and, therefore, boost the performance, profitability and sustainability of the Auchan Famalicão online channel.

Keywords: E-Service Quality, Customer Loyalty, E-commerce, Online Retail Industry.

Introduction

Electronic commerce is a distribution channel that is undergoing great expansion, being considered as the future of retail. Undoubtedly, e-commerce is an area of great importance and has a competitive advantage for organizations that have this distribution channel. Nevertheless, this channel is very competitive and presents some difficulties in retaining customers. According to several studies in the field of marketing (Abd-El-Salam, Shawky & El-Nahas, 2013; Disfani et al., 2017; Durvasula & Lysonski, 2010; Khare, Parveen & Rai, 2010; Martinelli & Balboni, 2012; Tang et al., 2015; Yu & Ramanathan, 2012; Yuen & Chan, 2010) to retain customers it is crucial to keep them satisfied, through the service provided, providing a pleasant and excellent shopping experience, and for that it is essential to guarantee a effective logistical support, which ensures that the product reaches the customer at the location, time and quantity required by the customer.

The transactions of goods or products, through online means, have seen a considerable increase in recent years, being increasingly one of the methods chosen by customers for the purchase of goods or services. Online services show a gradual and fleeting increase in the share of sales volume, thus representing a channel to which retail companies should pay attention, importance and investment, given that it is a future trend for retail. Several companies that operate through traditional commerce (physical stores) complement their services, with online means, creating synergies between the two marketing methods, thus achieving greater market penetration, as well as satisfying a greater number of customers in a way more practical and more comprehensive. Organizations try to offer customers several advantages in order for them to opt for online services, but they have certain characteristics such as their intangible dimension, the impossibility of immediate possession of the products and contact with them. To this extent, despite certain impossibilities, e-retailers must present their customers with advantages that overcome these aspects, such as the convenience and convenience of the process, the reduction of time with the purchase act, as well as the fact that the process is simple and less stressful.

According to several studies (Galego, 2014; Hofacker et al., 2007; Rao et al., 2011; Wolfinbarger & Gilly, 2003) customer satisfaction in online media is related to the maximization of the various logistical components inherent throughout the process: the place, the time and the availability of the products at the specified time and without great efforts for the customer. According to Zeithaml, Parasuraman and Malhotra (2002) the quality of the e-service is central to the success of online sales in any organization, being the main means of creating value and the main factors of customer retention.

There is a difficulty in determining the satisfaction factors, as well as the failures that customers perceive, that is, obtaining feedback from them. This fact makes it difficult and postpones the improvement of less satisfactory processes for customers, and organizations must find ways to analyze their customers' satisfaction with the various services they have available. To this extent, this study emerged to help the Auchan supermarket in Famalicão to assess customer satisfaction and loyalty in its electronic channels, with the central objective of determining which attributes of the e-service have the greatest influence on online customer satisfaction, as well as, factors that do not please customers and therefore should be improved in order to increase their satisfaction and, consequently, foster their loyalty. The paper is organized into three sections, in addition to this introduction and the main conclusions, as follows. On section two, a short review of the main literature on quality e-service, customer satisfaction and customer loyalty. After, on section three (methodology), the instrument to collect data is presented. That is, in this section, we describe the questionnaire used and along with the formulation of the research hypotheses. Then, on section four, the data analysis and findings are presented. The paper finalizes with the discussion of findings and main conclusions of the research. This study is of particular interest for modern Portuguese distribution, given that most retail insignia are still taking their first steps on the online channel. Knowing in this study the dimensions of quality e-service that the Auchan customer is most satisfied with, as well as the dimensions that are determinants of customer satisfaction and loyalty online. It is also relevant for the development of the literature in the Portuguese traditional retail industry.

Literature Review

E-Service Quality

The e-service is defined as an action that brings value and benefits to the consumer through online platforms (Hofacker et al., 2007). The e-service encompasses the procedures on the website, allowing access to the consumer's purchase decision process, as well as order fulfillment. E-service involves different levels of service from research to obtaining the product (Rabinovich, 2007). Zeithaml, Parasuraman and Malhotra (2002) developed e-servqual to measure the quality of the online service. According to them, e-servqual consists of seven dimensions, which are divided into a main service scale and a customer recovery service scale. The first four dimensions (efficiency, reliability, fulfillment, privacy and security) form the main e-servqual scale, being the means of evaluating customers' perceptions of the quality of service offered by online retailers. These dimensions include the criteria that customers use to evaluate the online service:

- Efficiency refers to the ability of customers to access the website, find the product and the information they want easily, as well as check out with minimum effort;
- Fulfillment incorporates the accuracy of service promises, having products in stock and selling the products in the promised time;
- Reliability is associated with the technical functioning of the website, mainly in relation to its activity and availability;
- The Privacy and Security dimension includes ensuring that shopping behavior data is not shared and that personal information is secure.

The e-service is characterized as an information system made available to customers in order to facilitate transactions through online means, which can create a competitive advantage if it occurs in an efficient way (Herington & Weaven, 2009). For Parasuraman et al. (1988), service quality can be defined as the organization's ability to meet or exceed customer expectations and the difference between customer expectations and perceived service. When expectations are not met, the customer is dissatisfied with the quality of the service, and when these are exceeded, the customer is delighted. Briefly, the quality of the e-service results from the difference between expectations and consumer assessment (Parasuraman et al., 1988).

The quality of the e-service results from the processes made available to customers in order for them to purchase and receive the items in an effective and efficient manner, which is constantly being evaluated by consumers (Zeithaml et al., 2002). According to Wolfinbarger and Gilly (2003), the quality of the e-service is centered on the fulfillment process, in which the dimensions of stock availability, punctuality and reliability are inserted. Therefore, for e-fulfillment to have quality, it needs to be effective from the information process and transport of the stock to its delivery. According to Rao et al., (2011), there are three determining factors in the quality of the e-service, namely:

- Operational factors include parameters of the service that contribute to quality, productivity and efficiency, these can be characteristics of the service such as the location, time, availability and conditions of the product and fit into the fulfillment.
- Relational factors are parameters such as proximity and understanding of the consumer, such as communication and responsibility.
- Logistic costs are parameters of the logistics service that allow the perception of consumer satisfaction regarding the price they pay and the cost that the logistics service requires, being able to establish standards of service quality levels.

Customer Satisfaction

Customer satisfaction should be the main concern of companies, as satisfied customers are loyal, being a primary step for the success of any organization (Mansano & Gorni, 2014). Customer satisfaction with services occurs in the process of purchasing or providing a service and is influenced by individual emotional factors, the context and the cost-benefit ratio (Moura, 2006). Satisfaction represents an appreciation on the part of customers in relation to a product or service and is influenced by the specific qualities of the products and / or services and their perception of quality (Zeithaml, Parasuraman & Berry, 1994). The concept of satisfaction is formed by two distinct components, the structural part related to the tangible components and emotional satisfaction, which refers to the intangible components, such as the company's image. The emotional component of customer satisfaction is related to the subtraction of expectations with the perceived perception. Perception is a value judgment based on the senses, but with a lot of emotional content (Huete, 1998). There is a strong link between customer satisfaction and service quality, a factor that makes it possible to determine higher prices. Service quality consists of responding to customers' needs and expectations (Vavra, 1996). Customer satisfaction results from a comparison between perceived performance and their expectations, and when expectations are not exceeded, the customer is discontented and may not use the services again. On the other hand, a satisfied customer, that is, if he reaches his expectations, he will probably resort to the service again, and when the expectations are exceeded, the customer is delighted (Kotler & Keller, 2006). Consumer satisfaction is the primary factor in creating the company's competitive advantage, when the activity or service exceeds customer expectations (Woodside, Frey & Daly, 1989). According to investigations carried out, satisfaction is the primary factor for customer loyalty (Shankar,

Smith, & Rangaswamy, 2003). Accordingly, retaining and expanding the number of loyal customers, as well as creating actions in order to increase that same satisfaction are factors of high importance for companies that operate online. According to Folstad et al. (2010), ease of use and utility of the process are factors with an impact on customer satisfaction and consequent on customer loyalty in the context of e-commerce.

Customer Loyalty

Customer loyalty is a term with relevant relevance in terms of literature, given the belief that it contributes to the creation of sustainable competitive advantage and consequent profitability for companies, through the act of buying or communicating with a recommendation about it before others (Zau, 2010). Customer satisfaction is the result of the quality of the service and guaranteeing it increases the probability of the customer becoming loyal. This term has been commonly defined as the action of repeatedly buying goods or services in the same organization (Veloso, Magueta, Fernandes & Ribeiro, 2017). The positive perception of service quality increases the possibility for customers to be dedicated to supporting, developing and strengthening loyalty behavior (Yuen & Chan, 2010). The truly loyal customers are those who feel that the company is able to meet their needs much better than other companies, thus excluding the possibility of change (Shoemaker and Lewis, 1999).

Bothe (1996) stated some methods that make it possible to maintain the achievement of loyalty towards its customers, namely: knowing the customer's needs; evaluate competition in relation to the ability of others to satisfy and retain customers as well as measure the degree of customer satisfaction and loyalty.

The emergence and expansion of the Internet, such as electronic commerce, allowed the supply of products or services in an agile and individual way. This new way of doing business has led marketing to reinvent itself, being a more relational marketing, that is, there is a focus on managing customer relationships through a personalized and impersonal relationship, a fact that allows you to respond more easily to the needs of customers and create a lasting relationship and mutual benefits, which can lead to customer loyalty (Brexendorf et al., 2010).

According to several studies, the main factors that lead to customer loyalty online are: price, product quality and performance of fulfillment. The quality of the product is related to third parties, which makes it difficult to change, leaving only the price factor and fulfillment as factors of competitive differentiation (Galego, 2014).

Methodology

This study aims to assess the satisfaction of Auchan Famalicão's online customers, identifying the attributes and dimensions related to the quality of the e-service and its performance in order to determine which attributes reveal an impact on customer satisfaction and also, obtain a view of this store's ability to attract and retain its customers online. In other words, it is intended to: 1) Assess the degree of satisfaction of Auchan Famalicão's online customers with online services ?; 2) Assess the degree of satisfaction with the quality of e-service and its sub-dimensions, as well as perceive the degree of loyalty to the online services of this supermarket; and 3) Analyze whether the quality of e-service (placing and delivery of the order) are determinants of customer satisfaction and whether the quality of e-service and satisfaction are antecedents of the loyalty of Auchan / Auchan Famalicão online customers.

In order to be able to respond to the proposed objectives, a quantitative exploratory research was carried out through the application of questionnaire surveys in which the target population was Drive customers looking for Auchan Famalicão online services. In this sequence, a questionnaire adapted from Galego (2014) was applied to answer the following questions: 1) Are the online consumers of Auchan Famalicão satisfied with the different online services ?; 2) Which e-service variables allow the perception of quality (order and delivery) to perform better ?, 3) Which e-service items (quality of order placement and quality of delivery receipt) with better and worst performance/consumer evaluation)?; 4) What is the consumer preferred product delivery method ?; 5) What is the online service most used by Auchan Famalicão customers ?; and 6) Which product categories are most frequently purchased online at Auchan Famalicão? The Questionnaire was applied directly to customers of Drive Famalicão, during the first half of 2019. In this study, respondents were required to fill out three sections. The first

section consisted of a standard demographic profile of respondents. The second section contained the characterization of purchase process. The last section includes the statements of dimensions e-service, customer satisfaction and loyalty. Respondents were asked to use a five-point Likert-type scale (between 1 = 'strongly disagree' and 5 = 'strongly agree') to record their perceptions. Construct reliability was assessed by using the Cronbach's alpha coefficient. Reliabilities ranged from 0.7 to 0.88, suggesting that the construct could be used with confidence. In line with the study objectives and the literature review, five study hypotheses were outlined:

H_1: There are differences in customer satisfaction regarding the attributes of the e-service related to placing the order (availability of stock; delivery time, quality of information, ease of use, website design, privacy and security and guarantee and accountability).
H_2: There are differences in customer satisfaction regarding the attributes of e-service quality (fulfillment, efficiency, reliability, privacy, guarantee and accountability).
H_3: There are differences in customer satisfaction regarding the attributes inherent to receiving the order (location, time, product quality, stock availability, ease and communication and price.
H_4: There are differences in the degree of customer satisfaction regarding the three factors (operational, relational and cost) of the e-service.
H_5: The dimensions of the quality of the e-service (placing and receiving the order) have a direct and positive influence on online customer satisfaction.
H_6: The dimensions of the quality of the e-service (placing and receiving the order) have a direct and positive influence on customer loyalty online.
H_7: Customer satisfaction has a direct and positive influence on their loyalty to the online service.

In order to respond to the objective of the study and the research hypotheses, exploratory / descriptive analysis techniques were used with the presentation of graphs and tables of absolute and relative frequency. To measure the intensity of the linear correlation between variables, Spearman's correlation coefficient was used. Additionally, linear regression was used to estimate models that allow identifying the determinants of the behavior of the variables under analysis and the influence between them. In all analysis was considered a significance level of 5%.

Data Analysis and findings

Demographic Profile

About ninety (89) individuals participated in the investigation, of which 70.8% (63) were female. Most individuals who buy online, 69.7% (62), were aged between 30 and 49 years. As for the distance from the residence to the store, it is verified that in 52.8% (47) of the cases it is less than 6 km and that 23.6% (21) was greater than 10 km. Most individuals, 74.2% (66) had an income of up to € 1400. The level of education is essentially secondary and higher. As for technological capacity, respondents classified it in most cases as good and / or very good.

Characterization of the online process

It was found that 50.6% (45) of the respondents used Auchan's online services exclusively. As for online shopping, the majority, 59.6% (53), do it once a week and 31.5% (28) monthly. Regarding the amount spent, it is observed that 65.2% (58) said they spent between 50 and 100 € and 20.2% (18) between 100 and 150 €. It was found that the majority of consumers surveyed have a preference for the DRIVE service (collection in the car park) offered by Auchan over other services (Average = 4.25; Median = 5).

Correlation and Regression Analyses

The Table 1 shows the results obtained for the degree of satisfaction with the online shopping experience of Auchan by the surveyed consumers. In general, it can be said that consumers are satisfied in all the items evaluated, since all the average values obtained are higher than three (theoretical expected value) and the median varies between four and five, which means that at least 50% of the respondents are satisfied or very satisfied. However, the items that stand out are: contacts by employees (Ave = 4.71); compliance with the deadline (Ave = 4.70) and comfort and convenience of the service (Ave = 4.69) with the highest levels of satisfaction. On the other hand, the items with the lowest average

levels of satisfaction stand out: website design (Ave = 3.69); quality of product information available on the website (Ave = 3.70) and ease of use on the website (Ave = 3.75). It should be noted that the dispersion values are relatively low, which reveals an agreement in response among the respondents. Regarding the way these items that constitute the delivery of the order correlate with customer satisfaction, it is observed through Spearman's coefficients that not all are statistically significant and those that are have direct correlations and of low intensity.

Table 1: Characterization of the degree of satisfaction with the online shopping experience of Auchan

Item	Online purchase frequency					Average	DS	Median	Correlacion
	MI	IS	IN	S	MS				
Convenience	0,0%	0,0%	5,6%	20,2%	74,2%	4,69	0,58	5	0,101
Service time	0,0%	0,0%	5,6%	21,3%	73,0%	4,67	0,58	5	-0,134
Contacts by employees	0,0%	0,0%	5,6%	18,0%	76,4%	4,71	0,57	5	0,241*
Immediate availability	2,2%	4,5%	18,0%	31,5%	43,8%	4,10	1,00	4	0,181
Compliance with the deadline	1,1%	0,0%	3,4%	20,2%	75,3%	4,70	0,59	5	0,212*
Ease of use website	3,4%	15,7%	16,9%	30,3%	33,7%	3,75	1,18	4	0,101
Website design	3,4%	16,9%	15,7%	36,0%	28,1%	3,69	1,15	4	0,002
Quality of product information	2,2%	15,7%	21,3%	31,5%	29,2%	3,70	1,12	4	0,176
Monetary savings	0,0%	0,0%	21,3%	34,8%	43,8%	4,22	0,78	4	0,188
Privacy and security	0,0%	0,0%	18,0%	22,5%	59,6%	4,42	0,78	5	0,216*
Warranties and accountability	0,0%	0,0%	16,9%	20,2%	62,9%	4,46	0,77	5	0,165

Figure 1 shows the results obtained for the degree of satisfaction of the sub-dimensions of the quality of the e-service, the Guarantees (Ave = 4.63), followed by Fulfillment (Ave = 4, 40) and Security (Ave = 4.15). The lowest values are shown by Efficiency (Ave = 3.69) and Reliability (Ave = 3.72)

Fig. 1: Degree of satisfaction by sub-dimension of e-service quality

Table 2 shows the results obtained for the degree of satisfaction with Auchan's online delivery processes. In general, it can be said that consumers are satisfied with all the items evaluated, since all the average values obtained are higher than three (theoretical expected value) and the median varies between four and five, which means that at least 50% of the respondents are satisfied or very satisfied. However, the items that stand out are: delivery time (Ave = 4.82); right product and in good condition (Ave = 4.67) and ease of communication (Ave = 4.62) with the highest levels of satisfaction. On the other hand, the items with the lowest average levels of satisfaction stand out: place of delivery (Ave = 3.72); service price (Ave = 4.28) and products offered (Ave = 4.42). It should be noted that the dispersion values are relatively low, which reveals an agreement in response among the respondents. Regarding the way these items that constitute the delivery of the order correlate with customer satisfaction, it is observed through Spearman's coefficients that not all are statistically significant and those that are have direct correlations and of low intensity.

Table 2: Characterization of the degree of satisfaction with Auchan's online delivery processes and Spearman's correlation with Satisfaction

Item	Online purchase frequency					Average	SD	Median	Correlacion
	MI	IS	IN	S	MS				
Delivery place	2,2%	20,2%	15,7%	27,0%	34,8%	3,72	1,21	4	0,212*
Delivery time	0,0%	0,0%	2,2%	13,5%	84,3%	4,82	0,44	5	0,361**
Right product and in good condition	0,0%	0,0%	3,4%	25,8%	70,8%	4,67	0,54	5	0,079
Replacement of products	0,0%	0,0%	6,7%	28,1%	65,2%	4,58	0,62	5	0,260*
Products offered	1,1%	0,0%	10,1%	34,8%	53,9%	4,42	0,72	5	0,256*
Ease of communication	2,2%	2,2%	0,0%	24,7%	70,8%	4,62	0,75	5	0,137
Service price	0,05	0,0%	7,9%	56,2%	36,0%	4,28	0,60	4	0,278**

Figure 2 shows the results of the degree of satisfaction of the delivery of the order distributed by the factors of the quality of the e-service, with the highest value of satisfaction related to relational factors

(Ave = 4.62), followed by operational ones (Ave = 4.44) and finally the logistical cost factors (Ave = 4.28).

Fig. 2: Degree of satisfaction by sub-dimension of e-service

The results obtained for the place of delivery of the purchases preferred by consumers and what is actually used most. It is observed that 93.26% use the drive, but 60.67% responded that they prefer this place. In reality, 33.71% of the respondents stated that their preferred place of delivery is the home, but later they end up using the drive. Therefore, it was observed that the delivery location coincided with the preferred location in 64.0% (57) of the cases. It was found that the satisfaction results were statistically identical between the individuals who received the order at the preferred location (Ave = 4.59; SD = 0.50) and the individuals who received the order at another location other than the preferred one (Ave = 4.55; SD = 0.57).

As to the reason for using this service, 71.9% (64) of the respondents referred to the convenience and convenience of the delivery point; 22.5% (20) responded that it was the fact that the service charge was lower and 5.6% (5) stated that other delivery points were unavailable.

Regarding the degree of satisfaction with the online services provided by Auchan, table 3, it is observed that the DRIVE service was used by all respondents and that they are very satisfied (Ave = 4.71; Ave = 5). The other services were used by few consumers, but they also registered high levels of satisfaction.

Table 3: Characterization of the degree of satisfaction with the online services provided by Auchan

Item	Online purchase frequency					Average	DS	Median
	NS	PS	S	MS	TS			
Delivery of home (n=18)	0,0%	0,0%	27,8%	50,0%	22,2%	3,94	0,73	4
In-store pickup (n=3)	0,0%	0,0%	0,0%	66,7%	33,3%	4,33	0,58	4
DRIVE (n=89)	0,0%	0,0%	2,2%	24,7%	73,0%	4,71	0,51	5
App Auchan (n=26)	3,8%	0,0%	11,5%	50,0%	34,6%	4,15	0,78	4

As for the loyalty of Auchan's services, Table 4 concluded that the surveyed consumers revealed high levels of loyalty, intend to continue using the services, have positive aspects to mention about the services and intend to recommend the same to others.

Table 4: Characterization of the loyalty of Auchan online services

Item	Online purchase frequency					Average	DS	Median
	I	PP	NINP	MP	C			
Intention to return	0,0%	0,0%	4,5%	5,6%	89,9%	4,85	0,47	5
I would say positive aspects about services	0,0%	0,0%	4,5%	14,6%	80,9%	4,76	0,52	5
Would recommend Auchan online services	0,0%	0,0%	4,5%	28,1%	67,4%	4,63	0,57	5

The majority, 98.9% (88) of the respondents believe that the service fee pays for the entire purchase process. Table 5 shows the internal consistency of the dimensions of the scale used. Values above acceptable are verified, even being considered good. The placement of the order has a reasonable consistency, the reception of the same shows a low correlation and the issues inherent to the customer's loyalty present a good consistency of the values.

Table 5: Scale dimensions composition and internal consistency

Dimension	Indicators of scale	Cronbach Alpha dimension
1 – Placement of order	6.1 a 6.11	0,775
2 – Reception of order	7.1 a 7.7	0,671
4 – Customer Loyalty	12.1 a 12.3	0,882

By analyzing Table 6, it was concluded that the correlations between the dimensions under study are of low intensity, with the exception of the coefficient obtained between placing and receiving the order that has moderate intensity. All coefficients are positive, which indicates direct correlations between variables. Between loyalty and satisfaction, the coefficient obtained is not statistically significant.

Table 6: Spearman correlation coefficients between dimensions

	Placement of order	Reception of order	Customer Loyalty	Customer Satisfaction
Placement of order	1	0,593**	0,363**	0,218*
Reception of order		1	0,250*	0,342**
Customer Loyalty			1	0,122
Customer Satisfaction				1

**-significative to 5%; ** - significative to 1%.*

In general, it can be said that the users of the service were satisfied. Looking at Table 7, it can be seen that in the ordering, placing and receiving processes, the average values obtained are higher than 4 points, which indicates satisfaction with these services. These results certainly influence the overall satisfaction of the customer with the service point, whose average obtained was 4.57 points, a value very close to the maximum possible (5 points). It should be noted that the average level of customer loyalty in this service is also very high, 4.75 points.

Table 7: Characterization of dimensions

	Minimum	Maximum	Average	Standard deviation
Placement of order	3,27	5,00	4,28	0,48
Reception of order	3,14	5,00	4,44	0,43
Customer Loyalty	3,00	5,00	4,75	0,47
Customer Satisfaction	3,00	5,00	4,57	0,52

The application of the multiple linear regression model, Table 8 allowed to obtain a parsimonious model that makes it possible to predict the dependent variable from a set of independent variables. The first regression model presented tests the influence of placing and receiving orders on the variation in customer satisfaction. The model obtained has a significance level of 1% statistical significance, that is, the variation in customer satisfaction is explained significantly by the estimated model. By applying the t test, it is concluded that the receipt of the order ($\beta = 0.412$; p values <0.01) significantly determines the behavior of customer satisfaction. The order placement variable has no significant influence on the variation in customer satisfaction. The estimated model explains, on average, about 14.5% of the variation in customer satisfaction. The estimated model 2 relates customer loyalty to the variables: order placement, order receipt and customer satisfaction, it is at a significance level of 5% statistically significant. The determinant of the model that significantly influences the variation in customer loyalty was by the t test: placing the order with a coefficient $\beta = 0.377$ and p-value <0.01. The estimated model explains, on average, about 12.5% of the variation in customer loyalty.

Table 8: A summary of Regression Models

Dependent variable	Independent variables	Adjusted R^2	*F* value (p value)	Standardized coefficients	*t* value (p value)
Customer Satisfaction	Constant	0,145	8,451 (0,000)	2,384***	4,176(<0,001)
	Placement of order			-0,011	-0,094(0,925)
	Reception of order			0,412***	3,423(0,001)
Customer Loyalty	Constant	0,125	4,051 (0,010)	3,383***	5,824(<0,001)
	Placement of order			0,377***	3,044(0,003)
	Reception of order			-0,042	-0,319(0,750)
	Customer satisfacion			-0,004	-0,033(0,974)

Conclusion

Currently, the measurement of online customer satisfaction by retailers participating in online commerce is essential to assess the qualification of the service provided, the existing physical infrastructures and the quality of the service, and also to identify causes of dissatisfaction and organizational inefficiencies (Costa & Ruiz, 2011). Therefore, this investigation aimed to assess Auchan Famalicão's online customer satisfaction and loyalty. The results obtained show that the customers of the Drive service at this store are globally satisfied with the services provided by this retailer. This can be justified, given the lack of competition, in the city under study regarding the DRIVE service. However, the attributes: employee contacts, meeting the delivery deadline, comfort and convenience of the service stand out for the high satisfaction they present. On the contrary, the design of the website, the ease of use of the website and the quality of the information available on the website are the items with the lowest rating by customers. Regarding the sub-dimensions of the quality of the electronic service, there is greater satisfaction in the response capacity and guarantees, followed by compliance, on the other hand, reliability is the sub-dimension that needs to be improved. This study is in line with the results presented by the study by Galego (2014) and by Wolfinbarger and Gilly (2003), who stated that compliance was one of the sub-dimensions of the quality of the electronic service, which brings satisfaction. Regarding the attributes of receiving the

order, there are also values in all items, higher than the theoretical value expected, however, the delivery time, the right products and in good condition and the ease of communication present greater associated satisfaction and place of delivery. delivery stands out by the negative. Regarding the performance factors of the e-service, all present high values, highlighting the relational factors. Operational factors that, according to the literature, are the most important carriers, have high value (4.44).

Through this research it was noticed that, in general, customers are satisfied and loyal with the service under study. However, it was concluded that the attribute of the electronic service with the highest degree of satisfaction is the responsiveness and guarantees, and compliance also has a high degree of satisfaction. On the contrary, the attributes of the electronic service: efficiency and reliability showed substantially lower values. The items, ease of use of the website, website design and quality of information about the products showed the least appreciation by the customer. In this sequence, it is observed that the items with less satisfaction are associated with the site, being able to affirm that it needs to undergo some changes, namely, to become more appealing, intuitive and highlight the information about the products that customers really want. These measures would improve customer satisfaction and loyalty and, therefore, the profitability and sustainability of this service. In addition, in the items inherent to the size of the order placement, the delivery location is notable, due to its small size and space with little coverage, which is inconvenient, both for customers and for employees, on days of greater precipitation. , checking a customer's discontent and even failure. Thus, suggesting the increase in the size of the space allocated to the service, as well as the implementation of a cover from the entrance of the gallery to the place destined for the service.

It is possible to affirm that studies of this nature are of immeasurable importance, since they allow determining the degree of customer satisfaction in relation to the various associated attributes, as well as the causes responsible for the impact on customer satisfaction, loyalty and involvement in the online service and the redefinition of organizational strategies to fill these gaps. To this extent, the present investigation made it possible to identify the level of satisfaction of Auchan Famalicão's DRIVE service online customers, as well as to identify the dimensions related to their satisfaction and loyalty. This work also contributed to the identification of factors that influence customer satisfaction and loyalty and which require intervention by management bodies. It should also be noted that the priorities must be defined and intervened in terms of the quality of the electronic service provided to customers, in order to increase their satisfaction and loyalty to this commercial store in Famalicão and, consequently, achieve better performance while strengthening their competitiveness and sustainability.

This work was financially supported by the research unit on Governance, Competitiveness and Public Policy (UIDB/04058/2020), funded by national funds through FCT - Fundação para a Ciência e a Tecnologia.

Abstract

The article considers the possibility of applying the methodology of functional-cost analysis to the study of the processes of production of railway sleepers from modified wood. It has been established that coniferous wood is currently in short supply. Therefore, it is proposed to produce railway sleepers from soft hardwood, a lack of which in Russia does not exist. Sleepers made from innovative hardwood modified according to innovative technology are not inferior in performance to sleepers from natural coniferous wood. However, the production of railway sleepers from modified hardwood is expensive. Functional-cost analysis allowed optimization of costs for the production of innovative products. Functional-cost analysis allowed us to determine the contribution to the production of railway sleepers from modified wood of each function. It is proved that the greatest contribution to the formation of production costs is made by the costs of monitoring the parameters of the installation during the warm-up cycle. The use of functional-cost analysis made it possible to study the process of creating the value of innovative products, make operational management decisions to optimize production, and set prices for railway sleepers from modified hardwood.

Keywords: Innovative Products, Railway Sleepers From Modified Wood, Functional-Cost Analysis, Costs.

Introduction

In modern Russia, the development of innovations in the industrial sector is a state priority, and industrial policy is considered inextricably linked with innovation. Innovation is the main tool for modernizing national industry and enhancing its competitiveness.

Russian railway transport is one of the largest railway networks in the world. According to the Federal State Statistics Service, the operational length of general-purpose railways in the Russian Federation in 2018 is 86,613.4 kilometers.

Sleepers are elements of the upper structure of the railway track and are designed to ensure a constant gauge, transfer loads from the rails to the ballast cushion, and secure the track on the roadway. When choosing a material for the manufacture of sleepers proceed from such basic factors as cost per life cycle and operational characteristics. Currently, the following types of sleepers are used on the world's railways: wooden; reinforced concrete; metal; polymer (plastic) (Kuryanova, 2017).

The characteristics of various types of sleepers are also considered by foreign scientists. Thus, E. Ferro, J. Harkness, L. Le Pen (2020) study composite sleepers and load-bearing elements made of polymers, and sometimes steel or fiber reinforcement, which are an alternative to traditionally used analogues of wood or prestressed concrete. S. Laryea, M. Safari Baghsorkhi, J-F. Ferellec, G. R. McDowell, C. Chen (2014) compare the characteristics of concrete and steel sleepers using experimental and discrete elements.

The main barrier when choosing wooden sleepers is a short service life, the quality of impregnation and a depleted raw material base. Coniferous species, mainly pine, are the raw materials for the production of wooden sleepers. But with a shortage of these species, sleepers can be made from soft hardwoods, a lack of which is not observed in Russia (Shamaev, 2013).

Sleepers made of modified hardwood are impregnated with high-quality impregnation in terms of their physical and mechanical properties and are not inferior to sleepers made of natural softwood. The predicted service life of modified wood sleepers can be significantly higher than that of wooden sleepers made from natural coniferous wood (Shamaev, 2013). The planned sleepers made of modified wood should be identical to the sleepers made of natural wood for the purpose, shape, size, method of processing tolerances of defects, but with improved performance.

The innovative production of modified wood sleepers is costly. Therefore, it is necessary to establish the possibility of optimizing costs for the production of innovative products.

In modern conditions, various methods of making managerial decisions are applied in terms of determining the costs of the production processes of innovative technologies. One of these techniques is the functional-cost analysis.

Functional-cost analysis as a system of economic and analytical work in close coordination with design work was developed in 1947 by an American engineer Lawrence D. Miles. A feature of this technique is the application of a functional approach, which is implemented through the organization of collective discussions of rationalizing proposals in an analytical working group (team). An important place in this process is given to the application of various methods of technical creativity, activating the search for non-standard technical solutions, due to the implementation of which the object undergoes serious reconstruction, becomes competitive and highly profitable (Sheremet, 2017). Thus, the initial functional-cost analysis was conceived as a tool for improving the construction of material objects. Currently, the objects of functional-cost analysis in Russian practice are both material objects and technological processes, production, organizational and information structures, as well as their individual elements or groups of elements.

Functional-cost analysis is a systematic study of the functions of the studied object in order to optimize the ratio of the claimed quality of the functioning of the studied object and the cost of implementing its functions in the life cycle of this object (Kuzmina, 2015). Functional-cost analysis refers to the methods of systematic research of all the functions of any object. It is aimed at minimizing costs at all stages of the design, production and operation of the facility, at least while maintaining (improving) its quality and usefulness (Misakov, 2016).

Thus, the use of functional cost analysis can increase the competitiveness of enterprises by solving specific problems of cost management (Morkovina, 2018). The object of the study of functional-cost analysis in this work is the process (technology) of manufacturing railway sleepers from modified wood.

In the study, the functional-cost analysis allows us to assess the real value of the sleepers from modified wood.

Methods

During the study, the methods of questioning, comparison, comparison and observation were used in part:

- surveys of employees of enterprises producing wooden sleepers;
- identifying and establishing the significance of factors affecting the organization of the production of sleepers from modified wood, coordination of expert opinions was carried out based on the calculation of the dispersion coefficient of Kendall concordance;
- desk study, including an assessment of the results. In the course of desk research, experience and forms of innovation support in the Russian forest sector were studied.

The cost of functions was determined on the basis of the developed technology for the production of railway sleepers from modified wood. When determining the time for the operation of the technology, methods of photographing working time and rationing were used. The production technology of sleepers from modified wood differs from traditional solutions by the combination of three operations in time: impregnation, drying, pressing of wood. To process the information received, the generalization method was used by summarizing and grouping the data. When conducting a functional-cost analysis of the process of obtaining railway sleepers from modified wood, we adhered to the corrective form, which identifies unnecessary costs, saving reserves, reducing costs, increasing the competitiveness of innovative products.

The use of functional-cost analysis in various fields was also considered by foreign scientists. So, Takeo Yoshikawa, John Innes, Falconer Mitchell (1994) studied the application of functional cost analysis in a production environment. Shannon L. Charles, Don R. Hansen (2008) carried out cost estimates based on activity and functional costs.

Results and Discussion

For enterprises engaged in innovative developments, special preferential conditions are provided, the state stimulates the innovative activity of economic entities (Kuznetsov, 2017).

However, despite numerous reforms of the state forestry management system of the Russian Federation, the production of wooden sleepers in Russia is currently in a state of depression. This is confirmed by a survey of managers of railway sleepers (Figure 1).

Figure 1: Factors holding back the development of innovative technologies in the Russian forest sector

In order to ensure the use of innovative technologies as the basis for reducing production costs, we studied the transition to an innovative method for the production of sleepers from modified hardwood (table 1).

Table 1: a description of the process for producing modified wood sleepers

Process name	Name of works
1. Preparatory work before starting the operation for the impregnation of blanks	Transportation of birch timber to the wood modification workshop
	Installation Inspection
	The inclusion of heating elements for heating an antiseptic in a bath with a hot antiseptic
2. Impregnation of sleeper blanks	Lifting the pressure plate
	Installation of thermocouples in sleepers
	Loading sleeper blanks into cassettes
	Loading cassettes with blanks in the impregnation bath
	Closing the lid of the working bath clamp
	Lowering the pressure plate to contact the workpieces
	The inclusion of a pumping unit that provides the injection of hot antiseptic into the working bath
	Turning on the pumping unit, which ensures the pumping out of a hot antiseptic from the working bath, setting the level of antiseptic in the working bath
	Monitoring the parameters of the installation during the warm-up cycle
3. Pressing sleeper blanks	Draining a hot antiseptic from a working bath and simultaneously pouring a cold antiseptic into it with the addition of a stabilizer
	Setting the level of cold antiseptic in the working bath, turning off the pump units
	Temperature control of workpieces and antiseptics
	Monitoring the parameters of the installation
	The inclusion of a hydraulic station for pressing sleeper blanks to a given degree
	Pumping cold antiseptics from the working bath
	Lifting the pressure plate
	Trolley rolling out
	Unloading a package of cassettes with sleeper blanks to a workshop site

The working procedures carried out during the functional-cost analysis with the aim of systematic analysis of the functions of the object are carried out in a certain logical sequence [1]:

- construction of a structurally elementary model of an object;
- the formulation of the functions of the object;
- a group of functions of the object;
- checking the correct distribution of the functions of the object;
- description of functional relationships;
- graphic representation of functional relationships;
- assessment of the significance of the functions of the object;
- assessment of the functional reserve of the object.

Based on the algorithm of the system analysis of functions, we compiled a structurally elementary model, determined the functions of the process for producing railway sleepers from modified wood (table 2), and presented a combined functional-structural model for producing innovative sleepers.

Table 2: functions for the production of railway sleepers from modified wood

Item name	Functions	The code
Production of railway sleepers from modified wood	home	F0
Preparatory work before starting the operation for the impregnation of blanks	Main	F1
Transportation of birch timber to the wood modification workshop	Subsidiary	F1.1
Installation Inspection	Subsidiary	F1.2
The inclusion of heating elements for heating an antiseptic in a bath with a hot antiseptic	Subsidiary	F1.3
Impregnation of sleeper blanks	Main	F2
Lifting the pressure plate	Subsidiary	F2.1
Installation of thermocouples in sleepers	Subsidiary	F2.2
Loading sleeper blanks into cassettes	Subsidiary	F2.3
Loading cassettes with blanks in the impregnation bath	Subsidiary	F2.4
Closing the lid of the working bath clamp	Subsidiary	F2.5
Lowering the pressure plate to contact the workpieces	Subsidiary	F2.6
The inclusion of a pumping unit that provides the injection of hot antiseptic into the working bath	Subsidiary	F2.7
Turning on the pumping unit, which ensures the pumping out of a hot antiseptic from the working bath, setting the level of antiseptic in the working bath	Subsidiary	F2.8
Monitoring the parameters of the installation during the warm-up cycle	Subsidiary	F2.9
Pressing sleeper blanks	Main	F3
Draining a hot antiseptic from a working bath and simultaneously pouring a cold antiseptic into it with the addition of a stabilizer	Subsidiary	F3.1
Setting the level of cold antiseptic in the working bath, turning off the pump units	Subsidiary	F3.2
Temperature control of workpieces and antiseptics	Subsidiary	F3.3
Monitoring the parameters of the installation	Subsidiary	F3.4
The inclusion of a hydraulic station for pressing sleeper blanks to a given degree	Subsidiary	F3.5
Pumping cold antiseptics from the working bath	Subsidiary	F3.6
Lifting the pressure plate	Subsidiary	F3.7
Trolley rolling out	Subsidiary	F3.8
Unloading a package of cassettes with sleeper blanks to a workshop site	Subsidiary	F3.9

In accordance with the combined model, using data on the costs of the production of innovative sleepers, we determined the costs of producing sleepers from modified softwood species.
Production costs for the production of modified timber sleepers for one cycle are presented in table 3.

Table 3: production costs for the production of sleepers from modified wood per cycle (16 sleepers), Euro

Type of work	Payroll Fund, Euro	Depreciation, Euro	The cost of acquiring materials, Euro	Electricity costs, Euro	Costs of fuels and lubricants, Euro	Costs of repair and maintenance of premises and equipment, Euro	Production cost, Euro
Preparatory work before starting the operation for the impregnation of blanks	2.47	3.72	130.15	2.68	7.12	2.24	148.38
Impregnation of sleeper blanks	110.55	49.93	0	13.18	0	6.06	179.72
Pressing sleeper blanks	13.64	14.23	24.10	17.66	0	6.34	75.97
Всего	126.66	67.88	154.25	33.52	7.12	14.64	404.07

The cost of functions and the importance of the technological processes for the production of sleepers from modified wood are shown in table 4.

Table 4: costs of functions and their significance for the production of modified timber sleepers in one cycle

Items	Function code	Costs, Euro	Cost ratio,%	Significance, %
Production of railway sleepers from modified wood	F0	404.07	100	100
Preparatory work before starting the operation for the impregnation of blanks	F1	148.38	36.7	33.2
Impregnation of sleeper blanks	F2	179.72	44.5	37.5
Pressing sleeper blanks	F3	75.97	18.8	29.3

The ranking of the costs of the functions for the production of sleepers from modified wood is presented in Figure 2.

Figure 2. The ranking of the costs of the functions for the production of sleepers from modified wood

The ranking by significance is shown in Figure 3.

Figure 3: Ranking by importance of the functions for the production of sleepers from modified wood

Thus, the most expensive and significant function in the production of railway sleepers from modified wood is the main function of “Impregnation of sleeper blanks”.

In order to ensure the competitiveness of innovative products, it is necessary to optimize the most costly processes identified using the functional-cost analysis. The most expensive function is the F2

function “Impregnation of sleeper blanks” due to the high cost of the auxiliary function “Monitoring the parameters of the installation during the warm-up cycle”, which provides for two operations - direct control of the parameters and passive rest between the control points.

The duration of passive control for one cycle of impregnation of sleeper blanks is 44.68 hours. The work to improve the structure of working time costs in the operational work of manufacturing sleepers with improved operational performance may consist mainly in eliminating passive monitoring and increasing active work time due to this, which can be achieved by developing multi-unit service, expanding service areas, combining professions and functions.

Under these conditions, a reduction of passive surveillance by 50% will significantly reduce the production cost of railway sleepers. So, while saving time at 22.34 hours with the operator’s pay for the installation operator 2.08 euros per hour, the total savings for the “Impregnation of sleeper blanks” function will be 46.47 euros. The optimization results are presented in table 5.

Table 5: cost comparison of existing and design options for the production of railway sleepers from modified wood

Items	Function code	Production costs, Euro		
		Existing option	Design option	Change
Production of railway sleepers from modified wood	F0	404.07	357.6	46.47
Preparatory work before starting the operation for the impregnation of blanks	F1	148.38	148.38	0
Impregnation of sleeper blanks	F2	179.72	133.25	46.47
Pressing sleeper blanks	F3	75.97	75.97	0

The analysis shows that the optimization of production costs for the most costly functions made it possible to increase the competitiveness of railway sleepers from modified wood with improved performance indicators (Figure 4).

Figure 4: Production cost of the modified-wood sleepers of the existing and design (after cost optimization) options, Euro

According to Figure 4, the production cost of one sleepers from modified wood of the existing version is 25.25 euros, the production cost of one sleepers from modified wood of the design (after cost optimization) option is 22.35 euros.

Thus, the functional-cost analysis apparatus turned out to be effective and allowed to achieve cost optimization by the functions of the production process for manufacturing railway sleepers from modified wood - the production cost per unit of production will be reduced by 2.9 euros.

Conclusions and Recommendations

Thus, the functional-cost analysis is a means of cost management, which shows the specific relationships of all the functions of the system with respect to each other, reveals the need and importance of functions, and also helps to identify unnecessary, duplicate and problematic (costly) functions.

The performed work on the functional-cost analysis of the innovative technology for the production of sleepers from modified wood revealed that the technology does not require significant changes, it does not have unnecessary and duplicate functions.

The main function "Impregnation of workpieces" takes first place in terms of importance and the amount of costs due to the high cost of the auxiliary function "Monitoring the parameters of the installation during the warm-up cycle".

It is necessary to modernize the identified cost function in the technology under study by eliminating passive monitoring and increasing the time of active work (with an increase in production volumes this can be facilitated by multi-unit service, expansion of service areas, combination of professions and functions).

According to the results of the functional-cost analysis in the existing version (according to the current technology), the production cost of one sleepers made of modified wood is 25.25 euros.

According to the results of the functional-cost analysis in the project version (results of cost optimization planning), the production cost of one sleepers made of modified wood will be 22.35 euros.

After cost optimization based on cost-based analysis, railroad ties made of modified wood will become more competitive in the market for relevant products. The introduction of innovative technologies in the woodworking industry will reduce the cost of manufacturing products and increase their useful lives.

Abstract

The article presents selected methods of multidimensional comparative analysis called taxonomic methods that enable the classification, grouping and ordering of economic objects according to selected diagnostic features. The dairy sector companies were selected by revenue in 2017 in the Visegrad Group countries and 20 companies were included in the analysis. The business entities were subjected to comparative financial analysis using parameters of descriptive statistics based on 10 most popular indicators representing profitability, operational efficiency, financial liquidity and debt of dairy sector entities in 2015-2018. Then, the companies were ordered according to Hellwig's synthetic measure of development, using the average values of these indicators in the examined years and normalizing them earlier. The article shows that multidimensional comparative analysis allows to determine the most attractive entities using the synthetic measures and taking into account the values of financial indicators. It also makes it possible to show a graphic presentation in the form of two- and three-dimensional charts. In its classic form, however, it has its drawbacks and limitations that are pointed out.

Keywords: multidimensional financial analysis, Hellwig's synthetic measure of development, Wroclaw taxonomy

JEL codes: G3, D63

Introduction

Rankings and analyses of attractiveness of the best companies are conducted all the time and they are always popular among, for example, future investors. Frequently, rankings are based on financial data.
The aim of the article is to carry out a multidimensional comparative financial analysis of the best companies in the dairy sector of the Visegrad Group countries, on the one hand using financial analysis indicators and on the other, selected methods of multidimensional comparative analysis (the so-called MCA methods). These are also called taxonomic methods and can be used as tools to describe economic and natural phenomena that allow to define the relations between the objects studied, at the same time reducing the excess of information, ordering and synthesizing study results (Kolenda M.,

2006). When measuring the financial efficiency of economic entities (companies, branches, sectors) characterised by financial indicators, these methods allow to classify, group and order the entities by creating rankings according to selected features (financial indicators). If a comparative analysis refers to the value of financial indicators in a given moment of time (e.g. at the end of a period: month, quarter, year), one deals with statistical methods. On the other hand, if multidimensional comparative analysis is used to evaluate the financial situation of selected business entities at the end of reporting periods in a given time range, one deals with a dynamic comparative analysis. The selected MCA methods presented in the article were implemented on the financial data of 20 companies in the dairy sector that represent the Visegrad Group countries, gathered in the Emerging Markets Information Service (EMIS) database. From each country, i.e. Poland, Hungary, the Czech Republic and Slovakia, five best companies with the highest income in 2017 were qualified to the study.

Theoretical background: characteristics of selected methods

The template method that is certainly commonly known and most frequently used in practice is the measure proposed by Z. Hellwig, where a template object of the following coordinates is set based on matrixes of standardized input variables (Panek T., 2009):

$$O_0 = [z_{oj}]$$

Hellwig's measure allows to order selected objects according to the level of phenomena that cannot be measured with one measure, e.g. technological progress, social and economic development, life conditions, social and technological infrastructure. Hellwig's measure of development synthesizes information from a sequence of diagnostics variables and assigns one aggregated measure to the phenomenon analysed (Krakowiak-Bal A., 2005).
In this type of multidimensional comparative analysis, the vector of variables (financial indicators) is analysed:

$$X = [X_1 , X_2 , \dots ,X_m]$$

where: m – number of variables (financial measures)

After analysing economic entities, variables (financial indicators) are often expressed in heterogeneous units of measurements. Also, their values are presented with the use of units of different orders of magnitude. In order to use the methods of Multidimensional Comparative Analysis (MCA), it is necessary to carry out the process of normalization according to the following general formula:

$$z_{ij} = \left(\frac{x_{ij} - a_j}{b_j}\right)^{c_j}, \ (i = 1,2, \dots, n; j = 1, 2, \dots , m)$$

Z_{ij} – value of the X_j variable for i-th object after normalization

a_j ,b_j ,c_j – different values depending on the method of normalization.

One of the most popular methods of normalization is standardisation according to the formula:

$$z_{ij} = \frac{x_{ij} - \overline{x_j}}{s_j},$$

$\overline{x_j}$ - arithmetic mean of the X_j variable (financial measure),

s_j – standard deviation of the X_j variable.

Applying the above solution is useful for standardising diagnostic characteristics adopted for the study and classified as stimulants and destimulants (Świardyńska N., 2018 s. 74). After normalization, financial indicators (variables) become dimensionless quantities, i.e. quantities without a unit, whereas the variables are unified according to their location and variability. Unitisation is another method of variable normalization. It is carried out according to the following formula:

$$z_{ij} = \frac{x_{ij} - min_i x_{ij}}{O_j},$$

z_{ij} – unitised value of the X_j variable for the i-th object,

$min_i x_{ij}$ – minimum value of the X_j variable for the i-th object,

O_j – range of the X_j variable.

The aim is to order the objects from the best to the worst, and the ordering criterion is the level of the complex phenomenon. Variables should be normalized. Variables can be stimulants, destimulants, nominants or of neutral character. In case of stimulants, the increase in their value reflects an increase in the level of the complex phenomenon. In case of destimulants, the increase in their value reflects a decrease in the level of the complex phenomenon. In case of nominants, variables have a specific, most beneficial value called the nominal value. The increase in its value to the nominal value causes the increase of the level of the complex phenomenon, whereas the increase over the nominal value causes the decrease in the level of the complex phenomenon. Such a variable is undesired in the set of variables that describe the phenomenon.

After normalization, some variables (financial indicators) that describe a given object have to be transformed to stimulants. And so, the indicators that are destimulants are transformed to stimulants by deducting the value of the destimulant from the unity (for unitized data) and multiplying the value by (-1) (for standardized data).

Changing a dominant into a stimulant is carried out based on the formulas below:

$$\left\{ \begin{array}{ll} 1, & dla\ x_{ij} = N_j \\ \dfrac{-1}{x_{ij} - N_j - 1} & dla\ \ x_{ij} < N_j \\ \dfrac{-1}{x_{ij} - N_j + 1} & dla\ x_{ij} > N_j \end{array} \right\}$$

where:

Nj – nominal value for the j-th variable.

The values of the stimulant are within the range of (0,1].

Similarity is the feature that makes it possible to compare objects (leaders), i.e. the closer the values of variables (financial indicators), the more related two objects are. In multidimensional comparative analysis, similarity is defined by the distance between the objects which is expressed according to the following formula:

$$d_{il} - \sqrt[p]{\sum_{j=1}^{m} |z_{ij} - z_{lj}|^p},$$

where:
d_{il} – distance between the i-th and l-th objects,

z_{ij}, z_{lj} – normalised values of the i-th and l-th objects for the X_j variable,

p – constant.

If p=1, then the result is the New York distance, also called city-block, Hamming's or Manhattan, which is defined by the formula:

$$d_{il} = \sum_{j=1}^{m} |z_{ij} - z_{lj}|.$$

When p=2, however, then the most frequently used formula for Euclidean distance is created:

$$d_{il} = \sqrt{\sum_{j=1}^{m} (z_{ij} - z_{lj})^2}.$$

Using the distance method and Hellwig's method of development pattern requires variables to be normalised and converted to the form of stimulants or destimulants.

Afterwards, a pattern, i.e. an abstract object of the best values for each feature (indicator) is defined, as well as an anti-pattern consisting of the "weakest" values for each variable (each indicator). In practice, the most convenient method is the one where, assuming that all diagnostic variables are reduced to stimulants, the coordinates of the model object (Grabiński T. i inni, 1989), also known as the pattern, can be expressed in the following way:

$$Z_0 = [z_{01}, z_{02}, \dots, z_{0j}, \dots, \dots \; z_{0m}]$$

$$z_{oj} = \begin{Bmatrix} max_i z_{ij} & for\ z_j\ that\ is\ a\ stimulant \\ min_i z_{ij} & for\ z_j\ that\ is\ a\ destimulant \end{Bmatrix}.$$

The anti-pattern is expressed as follows:

$$Z_{-0} = [z_{-01}, z_{-02}, \dots, z_{-0j}, \dots, z_{-0m}]$$

$$z_{-oj} = \begin{Bmatrix} min_i z_{ij} & for\ z_j\ that\ is\ stimulant \\ max_i z_{ij} & for\ z_j\ that\ is\ a\ destimulant \end{Bmatrix}$$

This assumption is often useful, e.g. in research into economic development, when there is no fear that the selection of maximum values is not "too good" (Strahl D., 1978). The interpretation of this method is as follows. As it is assumed that all variables are stimulants, the higher the value of m_i, the higher the level of the complex phenomenon studied characteristic of the object. Thus, already based on the sum values, it is possible to order objects, e.g. from the best to the worst, according to the level of the complex phenomenon (Dziechciarz J., 2003).

On the other hand, the synthetic measure in the distance method is based on the formula of unitising transformation, i.e. a method of variable normalization, and is as follows:

$$z_i = \left(\frac{d_{i0} - min_i\{d_{i0}\}}{max_i\{d_{i0}\} - min_i\{d_{i0}\}} \right)^p.$$

In the next step, the similarity of each object to the pattern created is measured with Euclidean distance. The smaller the distance between the object and the pattern, the closer (more similar) the object is to the pattern, thus representing a high level of the financial situation analysed of entity (a dairy company). Euclidean distance between the i-th object and pattern (d_{i0}) is as follows:

$$d_{i0} = \sqrt{\sum_{j=1}^{m} (z_{ij} - z_{0j})^2}, (i, l = 1, 2, \dots, n)$$

The last stage in both methods is about setting a synthetic measure that makes linear ordering of objects possible. In Hellwig's method of development pattern, this (m_i) measure is expressed with the following formula:

$$m_i = 1 - \frac{d_{i0}}{d_o}, (i = 1, 2, \dots, n).$$

The (m_i) measure usually takes values from the range of [0; 1]. The less distant the object is from the pattern, the higher the values. The fraction denominator (d_0) is the distance between the pattern set (the exemplary company) and the anti-pattern, and it is calculated based on the formula:

$$d_{i0} = \overline{d_0} + 2\, S_d$$

where,

$\overline{d_o}$ – *mean*

S_d – *standard deviation*

Multidimensional comparative analysis is based on the construction of the synthetic measure of development (SMD). One has to remember that many SMD constructs were designed with reference to the topic of linear ordering. In 1990, M. Walesiak took up one of the first attempts at completing the gap in the subject of discussing various SMD constructs (Walesiak M., 1996). An interesting modification was also presented by A. Młodak in his paper where he used a set of positional measures to normalise input variables when constructing Hellwig's measure (Młodak A., 2006). Following Hellwig's pioneering proposal made in 1968, there has been a number of its developments, as well as novel ideas. It is worth mentioning the following papers (in chronological order): Cieślak (1974), Dittmann, Pisz (1975), Bartosiewicz (1976), Pluta (1976), Nowak (1977), Strahl (1978), Panek (1984), Jajuga (1986), Lira i inni (2002), Strahl (2006), Strahl, Markowska (2008), Młodak (2009), Walesiak (2011), Wydymus (2013), Pietrzak (2014) (Muller-Frączek I., 2017). The modifications listed above are just a few examples of a whole set of proposals for the improvement of the synthetic measure of development.

Although the method is commonly known and used, it has many variants and modifications. This is particularly influenced by various methods of standardization and unification of variables, and adopting a pattern and an anti-pattern. What is also important is the denominator that defines the space where the objects studied are located and the distance between them set by the distance from the pattern. In this paper, the solutions described and considered to be the most classic were applied.

Data sources and Research Methodology

In the research conducted, data from dairy companies published in the Emerging Markets Information Service (EMIS) database were used. Based on statements for twenty best dairy companies in the Visegrad Group countries, ten selected and most popular financial analysis indicators were calculated.

The highest values of profitability indicators were scored by the Olma a.s. (ROE – 19.76%, ROA – 11.40%) company, and the lowest by SOLE-MIZo Zrt, (ROE – minus 34.79%). The highest values of CR and QR financial liquidity indicators were scored by the Tolnatej Zrt. (CR – 3.25, QR – 2.69) and Syraren Bel Slovensko a.s. (CR – 3.23, QR – 2.76) companies, and the lowest by the Danone sp. z

o.o. (0.32, 0.26) company. The highest cash financial liquidity was that of Savencja Fromage&Dairy (0.78), and SM in Piątnica (0.60) came second. The highest debts are those of the SOLE-MIZo (DR – 91.06%) and Agro Tami a.s. (DR – 80.49%) companies, and the least indebted companies are Olma a.s. (DR – 1.50%) and Tolnatej Zrt. (DR – 20.86%). As far as operational efficiency is concerned, the fastest receivables rotation is that of FrieslandCampina (2.7 days) and Korostej Kft (3.24 days), whereas the slowest receivables rotation is that of Milk Agro (26.14 days). The best inventory rotation is that of Korostej Kft (11.76 days), and the worst that of OSM in Piątnica (43.98 days). The highest liabilities rotation is that of Danone (168.8 days) and SOLE-MIZo (162.68 days). Liabilities are settled fastest by OSM in Łowicz (41.72 days) and SM Mlekovita (43.92 days).

Results and graphic presentation of the research

The algorithm presented in point 2 was applied, and the results of the multidimensional comparative analysis gathered are shown in Table 2. The best dairy companies were ordered according to the highest aggregate score of Hellwig's method, i.e. synthetic measure of development.

Table 2: Results of the multidimensional comparative analysis of the best dairy companies.

Hellwig	Dairy company	ROE	ROA	Income
0.992	FrieslandCampina Hungaria Zrt.	15.12%	10.90%	97,379.54 EUR
0.982	Tolnatej Zrt.	12.11%	9.59%	99,797.65 EUR

Source: Own study based on financial statements from the EMIS database.

Using Hellwig's algorithm, the synthetic measure of development was calculated for 10 indicators of each of the best dairy companies that participated in the study. The highest value of the indicator close to 1 was scored by the FrieslandCampina Hungaria Zrt. company, which was characterised by high profitability of own capital in all the years analysed in the study (min. 13.8%, max. 16.11%). The Tolnatej Zrt. Company's score was similar; however, its results were lower (min. 10.63%, max. 13.22%). The results in Table 2 can have various interesting graphical presentations, as shown in the following picture. It often gives a better perspective of the ranking.

Fig. 1: Results of the multidimensional comparative analysis of the best dairy companies.
Source: Own study based on financial statements from the EMIS database.

The company with the lowest evaluation is SOLE-MiZo Zrt. It has considerable fluctuations due to over 7 million EUR net loss that affects its negative -178% profitability of own capital. Due to the weak last year, even over 20% of own capital profitability in 2016 does not allow SOLE-MiZo Zrt to hold a higher position according to Hellwig's algorithm.

Continuing the analysis based on Picture 1 and Table 2, the second lowest position is held by Okręgowa Spółdzielnia Mleczarska in Łowicz whose profitability is min. -22.26 % in 2018 and 0.11% in 2015, as shown in Picture 1. Data in Table 2 were also used to make a three-dimensional bubble plot (a bubble plot is a scatterplot where a third dimension is added), where the results of multidimensional comparative analysis were ordered according to the Y axis. The X and Z axes show achievements of dairy companies with respect to ROE and ROA indicators, whereas the size of the object, the so-called bubble, is created by income. The largest objects with respect to income are Spółdzielnia Mleczarska Mlekovita and Bidfood Czech Republic s.r.o.

Fig. 2: A three-dimensional bubble chart of multidimensional comparative analysis of the best dairy companies against their profitability and income.

Source: Own study based on financial statements from the EMIS database.

The three-dimensional version can be simplified to a flat two-dimensional form which is also attractive as it singles out larger entities with respect to income.

Fig. 3: A two-dimensional bubble chart of multidimensional comparative analysis of the best dairy companies against their profitability and income.

Source: Own study based on financial statements from the EMIS database.

Based on the above charts, one can state that companies which have highest income, i.e. the Polish Mlekovita and Czech BidFood do not score high according to Hellwig's algorithm. Although the Czech leader improved profitability from -4.37% in 2015 to 13.26% in 2018, it was listed next to the Polish leader whose situation was reverse: its profitability of own capital in 2015 was 7.27% and fell to 1.40% in 2018.

Conclusion

The article presents Hellwig's algorithm and calculates 10 most popular financial analysis indicators for 20 best dairy companies in the Visegrad Group. One has to remember that there may be some distortions due to the legal form of conducting business activity or secondary activity, e.g. the sale of frozen food or ice cream, as is the case for a few companies. These are, however, the best companies that the EMIS database qualifies as companies with predominantly dairy activity. These companies also compete with one another on local markets and use products that are not only their leading ones for that. According to the assumptions made in the article, the algorithm made it possible to order companies from the best to the worst by the level of synthetic measure of development based on selected indicators. The algorithm presented should be modified as it treats all the indicators as stimulants only. When improving the algorithm, indicators should be divided into destimulants, nominants and stimulants. Each of them should have an arbitrary best pattern defined, which does not always and for each indicator means the maximum.

Review of Selected Conventional and Unconventional Marketing Strategies

PhD Katarzyna ŁUKASIK

Czestochowa University of Technology, Faculty of Management, Poland,
katarzyna.lukasik@wz.pcz.pl

Abstract

The purpose of the article is to characterize selected conventional and unconventional marketing strategies and to determine their role in generally understood marketing. The analysis is a literature review of various sources related to the studied subject. The article is an introduction to conducting own research in the above research area. The characteristic of both marketing techniques shows that unconventional marketing is more effective in attracting customers 'attention, but is also a time-consuming and demanding task for marketers' creativity, taking into account the amount of research and work they need to put into preparing this strategy, the final effect of this strategy is shocking or intriguing consumers, which can actually be profitable.

Keywords: Marketing, Strategy, Conventional Marketing, Unconventional Marketing

Introduction

Nowadays, many companies, organizations and business activities look for a way to attract new groups of consumers. Present-day market is saturated by numerous services and products by companies that promise to potential customers flawless, high-end products using different, sometimes untrue, techniques of marketing. As most people think, marketing is not only focused on advertising, even though it is an important aspect of this study. The idea of marketing is much more complexed and can be defined in various ways. It is a crucial aspect of any company in the present, ruthless, business society and economic profit is contingent on the marketing skills of a given enterprise. Business aspects such as accounting, management, administration and finances will not have estimated impact if the management of the company does not know the market demands and won't identify properly the consumers' needs. Many types of companies such as banks, restaurants, factories etc., use marketing to meet the objectives of their customers. It helps them to develop their companies, make greater profit and strengthen the position on the market. The biggest companies in the world are aware of that they cannot allow to lose their guard when their management has been confronted not only by rapid change in consumer needs but also ruthless competitors. It is not a secret that the modern world is quickly changing and it won't wait for big, now successful, companies to follow (Kotler, et al., 2009).

Marketing is undoubtedly one of the most important elements, the core of the good prospering company and organization. Good advertisement helps the company to develop on the market by gaining the needed attention to prosper within the next years. Nowadays, when the technology develops rapidly, many entrepreneurs have more ways to promote their services and commodities, since with the well-developed market, gaining customers' attention became harder than ever and they have to try to use less conventional techniques. Entrepreneurs try different types of media in order to differentiate from their competitors but it is hard to predict if their marketing strategy will work the way as it was predicted. It is clear that the task of promotion the company is not easy thing to do but with the right means and vision of the brand presented within those advertisements, it becomes possible.

Definitions and Marketing Theories

In the modern society, it seems that marketing is not purely focused on the products but also, appraisal of the customers, is something that truly matters. Many people think that marketing is an essential discipline of the economy and business studies, and also the very first quality of collective culture is known as the "customer orientation". Although, the theoretical definitions of marketing vary and it is based on point of view and research made by given person.

According to the American Marketing Association: "Marketing is the activity, set of institutions, and processes for creating, communicating, delivering, and exchanging offerings that have value for customers, clients, partners, and society at large." This definition clearly shows that "communicating" is not a sufficient term of the marketing process and services. It is clear that it is much more than this; marketing is forming those services, from the beginning and gives it to their allies and partners. It is not a whim based on having enough resources but the necessary part of the well developed and managed enterprise, next to the financial management, strategic planning, estimating person's influence in enforcing given task, etc. (Miller, 2010).

Moreover, the term "exchanging offerings that have value" from definition above, means that one person gives something worthwhile to another person and in the end the product or service is returned to the first person in shape of something equally valuable. In other words: customer gives their resources (money) and receives from company service or product. Before those goods are distributed to stores, the sector which is responsible for marketing actions, decides about the looks and the main characteristics of the given product (taste, smell, texture etc.) based on the customers' needs and priorities. People responsible for marketing are aware of how much potential customers are willing to give to buy desired products, not by using the data about the costs of production. It is crucial for them to decide in which stores their products will be placed, what kind of advertising campaign they will use, etc. (Miller, 2010).

Another definition is provided by the Chartered Institute of Marketing who says that this study is accountable for recognizing, predicting and meeting consumers' expectations. This point of view can be comparable to value-based marketing, which described role of marketing as an aspect increasing shareholder's contribution. Based on this definition, marketing may be perceived as the process of management which purpose is to boost the returns to shareholders by building up relations with important customers and making the "competitive advantage" (Paliwoda, Ryans, 2008).

According to Business Dictionary, marketing is a process by which products and services leave the production or concept stage to the consumers, waiting to purchase it. It is closely connected with four, vital marketing elements which are called "4 P's" (http://www.businessdictionary.com/definition/marketing.html):

- product – identifying, selecting and developing service or product;
- price – establishing the price of given service or product;
- place – choosing which way of distribution is the best to deliver it to customer;
- promotional Strategy – the stage of establishing and enforcing.

This management process is used as a tool which helps the companies to determine customers' expectations and, in the end, satisfying their needs. It is different than just selling products or services. Professor Theodore C. Levitt claimed that sale is only focused on the way of luring potential customers to give their money in exchange of given product and it does not matter how this is happening. Selling does not concern about the whole process, identifying, building and satisfying customer's objectives. To put it in another way, marketing is not entirely focused on making consumers pay for services but on creating perfect product which will live up to customer's expectations (Pizam, 2008).

Other theory says that, marketing used to be once perceived as a "creative industry" which included such science branches like advertising or selling but now, thanks to studies such as psychology, sociology, economics etc. marketing is perceived as science, which is supported by various universities

by Master-of-Science program (Zhou, 2012). Marketing process launches the product to the market by using such techniques like market research, segmentation, targeting, strategies of promotion etc. Many of involved studies, such as i.e. product design, involve the usage of the creative arts.

Marketing, besides being the creative art, might be also seen as "societal process" because people create, offer and sell their services and products to other people. The general term for this phenomenon is known as "social marketing", which shows how this study is able to not only inspire the positive behaviors, but also contains the green marketing. Today, exist two roles of modern marketing and have following impact on society. Firstly, inspires marketers to use their abilities in order to develop social good. Secondly, it embraces the idea of the controlling and regulating the traditional market by using specific ways. This type of marketing is often used to share publicly the techniques in changing the human behavior such as gambling, smoking and other addictions (Kotler, et al., 2009).

Meeting the organizational objectives in Marketing Concept, might be risky if given company is oblivious to the customers' needs. It is important for the company to be better than their competitors, in order to gain new groups of consumers. Marketing concept is one of the ways which focuses on profits and selling but at the same time, it is not their only one concern. This study tries to focus less on production and sales and instead, it is focused on customer service, trying to figure out what consumer need, etc. "The job is not to find the right customers for your product but to find the right products for your customers". Selling concept focuses on maximizing sales, manufacturing products, while marketing concept has more personalized approach towards business by using the data and information about personal preferences of consumers. More concerned about customers companies, try, besides enforcing marketing concepts, search for the most accurate studies about consumers' desires towards given products or services. This type of company policy works out well, when the customers' needs are specified clearly but there are cases when customers are not aware of their requirements for company's products or services, which is caused by fast development of the market and technology. Many years ago, people didn't know they needed such things as computers, television or cellphones, so it is important for companies to know the consumer's needs better than them in order to excel the competition (Kotler, Armstrong, 2010).

In order to present exactly what opportunities marketing has today and what tools it uses, first they will be placed in the table below (tab. 1).

Table 1: Described selected conventional and unconventional Marketing Techniques

Conventional Marketing Techniques	Unconventional Marketing Techniques
Public relations	Viral marketing
Storytelling	Street marketing
Branding	Guerilla marketing
Email marketing	Ambush marketing
Visual marketing	Astroturf marketing
	Buzz marketing
	Advergaming
	Cause marketing

Conventional Marketing Techniques

One of the best-known strategies in marketing is the *public relations,* which role is to describe the issues, manage the research and at the same time be a channel of communication with the customers. In other words, public relations might be defined as the "strategic conversation", which could be also interpreted in various ways since the term of public relations is hard to definitely characterize because some people it is an interpretation or the way of stating facts. This phenomenon is often used in the various fields, not only in business, like in charity organizations and also government. What is more, there are different types of conducting the public relations – corporate or agency. In corporate public

relations, the organizations use their employees for managing, while in case of the agency the company is using the people from the outside of their own enterprise like professional consultants.

One of the most citied definitions of this term is by J. Grunig, who said that public relations is "the management of communication between an organization and its publics" which popularity might be reasoned by the amount of information which this definition contains in this short sentence. What is more, it presents the basics of the career among the board, in contrast to the marketing and journalism (Bowen, 2010). In contrast to promotion, which is often characterized as the financed media recognition, the Public Relations works on the relations with media in order to send the given information which tends to be more credible and informative than the standard marketing techniques (Lamb, Hair, McDaniel, 2012). One of the main aim of Public Relations is to improve the organization's image, since the people responsible for this field in the industry are obliged to communicate with the media in order to secure the company from the bad press, which transfers directly to improving the organization's image. What is more, people responsible for the PR may play the role of be the proxy of given enterprise by appearing on the proper events and help with the bad publicity and give the management a hand in the general marketing during the rolling-out the new commodities (Wetfeet, 2008).

Next conventional marketing strategy is *storytelling*. By using this tool in the marketing, management creates the picture of their enterprise by establishing its values, culture and other crucial aspects used in creating a successful brand. Each company has its own story and the marketing team is responsible to be certain it's a positive one (Tybout, Calkins, 2005). Even though, storytelling seems to be a good solution for the company's marketing strategy, its history was very rocky since it seems marketing management mixed feelings towards this method. It comes back from time to time because it seems to be timeless in contrast to other strategies considering the fact that storytelling has greater impact on the audience because it is influencing audience's emotions. As technology developed, people who are in charge of marketing realized that they have more chances to use this form of strategy in order to achieve their goals. Since the development of social media and many other channels used in viral marketing, dissemination of information they wanted to share became much easier than in the past, before the digital era. The important aspect of storytelling is the fact that the company shouldn't tell any story, it needs to be interesting, memorable and generally, valuable to make the audience feel the desired emotions (Snow, Lazauskas, 2018).

Another strategy used by various companies is *branding*, which seems to have the great power in influencing the way of perceiving given commodities and services. It is believed that consumers first see the name of the company and then the product, they are considering to buy, which means that the opinion they have about given enterprise is the same as about the product itself. As the opinion varies between the two individuals, it is not quite truthful towards the product which doesn't really matter since the main problem in marketing is how people actually perceive given product and as long as it meets the customers' needs, it is fine. The way the audience perceive given commodity is connected with how the product's brand is popular between other brands and if they will notice that the thing has the logo of the known brand (for example Apple or Samsung) they will instantly assume the product has the best looks, quality and won't question its price, since it is the brand they admire. However, if customers will see that something is on sale, they will instantly assume there is something wrong with given product and they will think longer about purchasing the item. This phenomenon is called prism (fig. 1) which it generally means that if people have a positive opinion about the brand, they will automatically assume that the product they launch is also as good as the company behind it. The quality is strictly connected with the name of the enterprise because for example customers who wear skirt from Gucci or Zara feel better than those who wear identical skirt from local supermarket.

Fig. 1: Brand Prism

Source: own research

The vast majority of people think that branding revolved around captivating slogans, nice looking logo and the name of the company which sounds good but in reality, the idea of branding is more complex. It is considered to be one of the "greatest challenges" the marketing team is struggling with. Behind every successful brand there are hundreds of other companies which failed during the time they were launched on the market alongside today's top enterprises and their successful products. The biggest challenges those companies had to face was dealing with finances, image, price and the quality of their products during those years.

Another type of the marketing strategy is *using an email* as the mean of promoting the product. Although it might have different meaning, some people believe it's the ultimate communication link between the clients and the company of their choice, others just see it as another advertisement, like other, more traditional ones. Nowadays, almost every person has personal email which is used to communicate in business dealings and personal messages and it's rapidly pushing away the traditional letters which used to be sent for centuries. The main advantage of this strategy is the low costs of the marketing which is the direct cause of the sent amount of email advertisements to many people. Once the ad is created it might be sent to the millions of people, the only cost the company has it's the cost of designing and writing the advertisement – which usually looks, more or less, the same as the traditional one, used in TV commercials or newspaper advertisements. Emails can be also applied to send the notifications about the company's discounts, special offers and new products, which makes it the fastest way to catch the customers attention towards the company's offers. It's believed that the electronical mail is the ultimate tool which provides more accurate data for the marketing research since the customer's data about shopping habits and preferences might be sold outside of the company. Email, in contrast to traditional advertising, offers such advantages as for example: less time for creating the advertising campaign, reduced expenditures, quicker response. What is more, it might be used for registering the complete consumer's shopping cycle beginning from the selection of a given product to the purchase (Chaffey, 2007). Before creating the strategy of the email marketing, the marketing team should come up with the interesting content of the emails and it is important to influence people by the personalized messages which will create the emotional bond with the customer, and in the end, it will result in loyal customers who won't even think about choosing the competitors' products. By creating the email strategy which varies from the typical advertisements, the company guarantees themselves that after the purchase the given person will come back to buy more offers presented by the company (Ellis, 2013).

The last strategy used by the companies is *the visual marketing* which is considered to be one of the most popular marketing techniques among all. Potential customers are surrounded by the numerous ads in everyday life, not only commercials, banners, billboards, and others. Going through the local store, one can see various product packages, which are also a form of advertising. The integral elements of visual marketing are flyers, displays, road signs, gadgets, clothes, parts of cars and parts of food supplies packaging. It is common to see in the enterprise those communicational features and methods of organization which are seen in the coherent way. What is more, those elements are also an important asset in the marketing protection, companies use this type of strategy to increase the effectiveness in selling products after recognizing the taste of potential consumers and it all comes to the visual concept of given advertisement. Main features of this type of design are such things like texture, shape, color, size and the general look. Although the background of presented commodities is also important in the customers vision of given product. All of those elements are the integral part of the strategy called

visual marketing which it generally means the studied use by the companies the visual elements such as symbols and signs, which sent beneficial information for potential customers. What audience sees is the important aspect of enlarging predicted financial gain and nowadays management team tends to hire special companies for such areas as package design, logo, advertising, website and other visual elements which are important for the audience (Wedel, Pieters, 2008).

Unconventional Marketing Techniques

Unconventional marketing is perceived as one of the most innovating marketing techniques which provides new perspectives not only for the companies but also for its consumers. It is one of up to date marketing trends which helps to highlight the advantages of company's image or the environment in business, since one of the greatest challenges met by businesses is competing against bigger and known brands in the world of marketing. Since those big businesses spend huge amounts of money on marketing, their less financed and known competitors still have an opportunity to run against them. Unconventional marketing is one of the most effective methods to make the company more visible, attractive and interesting for potential consumers without spending fortune on the marketing. What is more, this strategy allows smaller companies to have an impact on the international, national or regional market.

As it is observed in everyday life, making the information surprising or scandalous is the fastest way to reach out to people and the message, given by word of mouth, is the most popular one. Customers trust more their family and friends than the stranger who passes the message. Nowadays, the information is usually not only send through emails and phones, but also through social media, forums and blogs. The purpose of *viral marketing* is to pass on information about the enterprise, services and products by using mass means of communication to reach greater number of potential customers. It is a great and relatively cheap way to promote company's offerings because the information is not perceived as the advertisement or commercial because Internet users chose themselves if they are keen to read it or not. This kind of information is usually send by the friend or family member, which makes it more believable source than the company's (Fong, Yazdanifard, 2014). Well-designed viral advertising should contain elements of surprise (Southgate et al., 2010) and elicit emotional responses with high arousal, positive or negative (Berger and Milkman, 2012; Brown et al., 2010; Eckler and Bolls, 2011; Henke, 2013).

Fig. 2: Visualization of the Viral Marketing

Source: own research

The environment of marketing is very amenable to fashion in their area. Viral marketing (fig.2) is an up-to-date expression and the term describes the phenomenon which have been around since the 90's. It focuses on delivering the message in the expanded areas, which main goal is to reach the specific groups of customers. Viral marketing uses the mechanism of the vocal medium and it spreads very fast, which also might be compared to the literal virus. During the development of the phone communication, this kind of advertising also developed, which the direct cause might be that the internet is the best mean of the transmission of information. It is important, to remember that the viral marketing copies the positive approach towards the process of "infection". What is more, it could be also observed the emotional aspect of viral marketing, in the behavioral analysis of salesmen and

clients. This type of marketing uses two assumptions – first part of the consumers has a connection with newest products and the second part, usually the same customers, have an enormous impact on adaptation of the newest products by the other customers. Using this type of clients, who have an impact on the strategy, allows to use the effect in the marketing means (Wyściak, 2013).

Other types of *viral marketing*, used by the marketing teams are (Gębarowski, 2007; Henke, 2013):

- Using the mechanism of "recommend" or "send" which allows the customer to send the link to the friend or family member.
- Offering the free computer programs, crucial for Internet users.
- Sharing the valuable articles about the given product.
- Promoting product by using the interactive gadgets such like wallpapers, screensavers and e-cards.
- Sharing media files about interesting topic or content (photos, animations, videos or songs).

Enabling the option "share" on the websites, helps to inform other users about the given portal and company's scope of products. After clicking on the right link on the website, the person who recommends it has the opportunity to send their friend's email address, who will receive message sent indirectly by the website owner. What is more, the content of this email should be written more informally, like it would be written by the friend, for example: "Hi! I recommend you the XYZ website which…". The email form of this kind increases the credibility of the recommendation. The message also has to have the link to the given website and the short text written by the sender. Sometimes, the message written by the website is more developed by the creator and it contains flashy animations and pictures which will be more memorable in receival. About 57% of the interviewed internet users, admits that recommendations given by their friends, influences them to visit website. 92% of internet users send message on at least one person in their lifetime (Gębarowski, 2007).

Another type of marketing strategy is *the street marketing*, which takes place in very different locations than the advertisements usually take place. The general purpose of this marketing is that the actions take place on the streets, shopping malls, railway stations and other unique places. In contrast to regular, urban marketing which usually uses means like posters and billboards, this marketing strategy focuses on the creative way to show their product in order to gain the potential customers personal attention. One of the purposes of this marketing strategy is to create a personal bond with the customers and the main goal is to make clients to perceive a given brand in the other form than before (Saucet, 2015).

Even though the online marketing has huge impact on the marketing environment, street marketing is still an effective way to promote given products. It is based on the techniques executed by the professional marketers by using the most efficient, marketing analyses. Public places, such as streets, are not only used for everyday activities such as transporting from one place to the other but they are also locations which are used by the people to meet their family and friends, which makes it a good place for mass marketing. Because of the primary purpose of the public places, the specialists noticed that it has created marketing strategies which perceive it as a "raw material". It started explicit research on how streets became a concept, which is used in marketing strategies. It is essential to remember that the usage of the streets as the place for marketing is more than handing the brochures to the people. Usage of the streets as the advertising technique is more and the companies need to create a bond with their potential customers by presenting them fresh, inspiring and extraordinary entities. One of the best examples of presenting the given ideas is the street art, where the creators use public places as their own place to show their emotions, thoughts and opinions. It helps them to present their point of view on the given topic. By using their technique of expression, companies also can present their own services in more unconventional and personal way. Even though it is one of the newest marketing techniques, it is still treated very carefully. Companies monitor street marketing from the beginning till the end by the management who is aware of the costs of distribution and operations (Saucet, 2015). This marketing strategy does not require big investments and it can convert existing places to use as an advertisement like a bench or bus stations.

Next marketing strategy is the *guerilla marketing*, which might be executed not only by using internet means, but also companies tend to use it by the phone or personally. The main purpose of this marketing strategy is to create an environment for the customer which is not only simplified and pleasing, but also

valuable. It all starts in the moment when the company creates a product and wants to launch it for the public to buy. The guerilla used to be a very unpopular mean of marketing but nowadays it a well-known mean of promoting services and products by the smaller and bigger companies. The direct purpose for using it, it is a fact that guerilla simplifies more complicated topics and it has an impact on potential customers, when the company does it properly (Levison, Levison, 2011). The main advantages of guerilla marketing are: unique, surprising, humorous, affordable, effective (Levinson, McLaughlin, 2011; Cova, Saucet, 2014). Some authors claim that marketing activities are a battle to conquer the mind of the customer, such activities are conducted for years by the Burger War (McDonalds vs. Burger King) and the Cola War (Coca Cola vs. Pepsi) they are used as examples of battles with words and pictures (Baltes, Leibing 2008).

From the beginning, this particular strategy does not focus on the big budget spend on marketing – it focuses on the great force which is the imagination in advertising (fig. 3). It differs greatly from the conventional, traditional marketing. If a given company does not have an opportunity for big investment in their marketing strategy it is enough for them to spend their energy, time and creativity to promote their products or services. This marketing strategy gives the enterprises needed control of their marketing operations, which are much clearer than the traditional marketing since many entrepreneurs aren't quite certain what marketing is about – if it's just PR or just the company's website with all the crucial information about the given enterprise and its products. It helps the companies to maintain the size of their profits by focusing on the most important numbers, instead of bankrupting because of the strategy implemented by the given enterprise. What is more, this strategy also helps the companies to focus on their primary goals instead of losing it in the process. While the conventional marketing suggests to gain customers slowly, during the time the company grows – the guerilla marketing helps to expand the business in several ways at once by increasing numbers of business dealings and expanding the sales. What is more, standard marketing suggests which competitors the given company should be aware of, while guerilla marketing also determines the principles of those competitors, which is a help for the given company to accompany in marketing dealings, which also is an opportunity for marketing research and cutting the expense of advertising while sharing it with different company (Levison, Levison, 2007).

Fig. 3: Example of Guerilla Marketing

Source: own research

One of the form of guerilla marketing is *ambush marketing*. An *ambush marketing* is a form of associated marketing, used by an organization to derive awareness, attention, goodwill, and other benefits generated by its association with an event or property, and the organization has no official or direct connection with the event or property (Crompton, 2004)). Ambush marketing, operating in the world since the late 1980s, defines the activities of companies that, by undertaking specific actions, strive to become part of the awareness of recipients, by associating the brand with a particular sporting event. There would be nothing extraordinary about it, if not for the fact that a given company, which is identified as the sponsor of a sporting event, is not the sponsor at all. By not paying the sponsorship fee and by undertaking such activities that will allow the consumer to assign the title of sponsor to a company, large brands show considerable cleverness and creativity. Kodak was the company that

initiated the ambush marketing activities. In order to appear in the minds of the recipients and become a brand strongly associated with the Olympics without being a sponsor of the games, Kodak used other means. Namely, he became the sponsor of the United States athletics team, as well as the broadcast of the games themselves. Due to such activity and through constant presence in the media, Kodak was one of the official sponsors of the games in the opinion of the recipients. Another example of a brand that has made the most of ambush marketing is Nike. When the Olympic Games took place in Atlanta in 1996, Nike did not have the purchased rights to the name of the official sponsor of the games, but this did not prevent it from appearing among potential customers. To meet the recipients, the company Nike in Atlanta placed posters and billboards promoting the games in bulk, and created an Olympic village near the stadium. Thanks to such actions, it is Nike's view that it has strengthened itself as the official sponsor of the events (Kast, 2019).

Other option also very clever is an *Astroturf marketing*. Americans call it the laying of artificial grass. Astroturf marketing (the name comes from a synthetic turf-like flooring brand) involves running campaigns pretending to be spontaneous initiatives of individuals or groups (grassroot, which explains the association with grass) that express support or opposition to services, products, ideas, events or activities parties and politicians. Such a campaign gives the impression of an independent social response and hides the identity of its real initiators, as well as their true intentions. In fact, more and more consumers are looking for opinions about it on the Internet before buying a product. Meanwhile, a significant proportion of entries that can be found on the web are fake. Astroturf marketing, in other words, buying favorable reviews. The law allows those who pay for positive comments to be punished. The penalty can reach up to 10 percent. turnover from the year preceding the year of the decision, however, it is difficult to prove such an act. One of the world's most famous examples of this form of marketing was the activity of the Working Families for Wal-Mart group and its fake blog Wal-Marting Across America. Allegedly a grass-roots organization was supposed to support the resistance of the trade network against trade unions. In fact, it was created, as it later turned out by Wal-Mart himself and the PR agency Edelman (https://www.telix.pl../2017).

As can be seen from the above, social media play an important role in marketing today. Social media marketing is a rapidly growing form of internet marketing. Social media marketing can be included in the current Web 2.0 trend. based on a specific, two-way form of communication made through social media. Consequently, social media users are not only recipients, but also full-fledged creators of published content and active participants in marketing communication activities of enterprises. Social networks give an incredible amount of tools that can be used to promote products and services. Easy communication is the biggest advantage of social networks. The communication with the target group is extremely easy. Firm can inform its clients about the most important events, give discount coupons for products, ask for opinions and many other things. Facebook, twitter or Instagram are very useful nowadays for online marketing, so as different kind of communicators, like messenger, whatsapp and others. Company can in easy way built the relationship with customers and encourage them to buying products.

Next strategy worth mentioning is *the buzz marketing*, which is also known as word-to-mouth marketing. According to Michael R. Solomon, who explained in his book, buzz marketing is “using high-profile entertainment or news to get people to talk about your brand” (Solomon, 2013) which in other words it is simply a reaction of the customers on the given company’s products. Nowadays, potential customers are “assaulted” by the hundreds of various commercials, advertisements, banners and billboards which makes most of traditional marketing means less effective than in the past and buzz marketing helps the companies to advertise themselves using the more visible and unique way. The main problem for the companies, is the younger generations who grew up surrounded by the commercials showed on TV and other medias. Because of that they are one of the hardest target audiences among all. Young people prefer to find products and brands using the less conventional way, since regular advertising makes them more irritated than interested.

Considering the fact that *buzz marketing* is still a very new concept, the intellectuals are still doing a research on its range and influence. What is known now is that the buzz can’t be conducted by any person or blocked, its flow is natural and it is up to the customers on how big it is or if it’s positive or negative, which might be a huge drawback for some (not only small and medium) companies (Moore,

Pareek, 2009). A good example of bad buzz marketing is the one of the recent TV Commercials which was produced by the Pepsi. It supposed to be friendly and positive, but the internet users were furious when they thought the company diminished the meaning of protests, which in the commercial was solved by the drinking Pepsi's product by the opposite side of the protest.

It is important, to create buzz advertising which, ironically, will not be perceived as the "commercial message". What is more, this type of advertising is not advised to be used only for a special target audience, since its spread may migrate from target audience to another in a matter of time. The best way to create a buzz is to let the customers to build their own, subjective message about the given product, since it will have more credibility among their friends and family. Sometimes, companies themselves conduct special movement to promote their products via hired customers. One of the most known examples is when the Sony Ericsson used actors who gave the pedestrians their phones to take the photos and at the same time, those actors, admired the quality of the camera in their "new phones". Although, it is believed, that this type of strategy should never be aimed at kids, because they as customers are very gullible which makes them easy to be misled, in contrast to more mature audience (Solomon, 2013). To conclude, the enterprises should be very cautious about implementing this strategy because the risk might be too high for some of the companies, if the buzz is not created properly. It might result in the loss in the profits, losing the good name of the brand/company or even bankrupt. Companies must remember that buzz should be genuine and the way it is conducted should be as natural as possible, since modern customers are more aware than in the past years.

Next valuable asset in the marketing strategies is *the advergaming* which is conducted by the marketing team of the given company and it is considered to be a good chance for unified marketing effort. It is a game which is containing the commodity or service by a given company. Sometimes those games are created by the company only to promote given product, service or brand in general and the game is published as a marketing tool. Customers often visit companies' websites to search for information about given topic concerning the given enterprise because if the given person is interested in the product it means that he is more likely to check the information, in order to buy it. Advertising games , shows the company likeness of the given product by the data of the number of views and time spent on the website. The advergaming may also take another form and it is not necessary that a given company will make their own game by themselves. The company can also buy a place in the regular video game. Those games not only include the digital world with characters created by the game developer but also shows the company's product which makes customers more invested in the company and it simultaneously creates the positive image of the enterprise. Companies buy the place for ad on the billboards, product placements or display formats in the already existing games to promote the brand (fig. 4). The best way to do it, is the way of adding the authentic, natural elements and implementing the environment of the game. Product placement has the form of brand elements, which for example can help the gamer show the new possibilities. The last form of advergaming is buying the market spot in the user interface or during the time when the game starts and the consumer waits until the game loads. It is a good way to promote product since the video gaming industry is very developed and it possesses new consumers every day by people of all ages (Yilmaz, 2017).

Fig. 4: Example of Advergaming

Source: own research

The last presented unconventional marketing technique is *cause marketing*. It is based on the psychological aspect that people feel better among the causes which are socially close to them and they share the same perspectives and values. It engages consumers in relations between the product and the whole society and does it in a way that the part of the profits of a given product goes to the cause or problem which is important and useful for the society. If a consumer buys given product, personally contributes in solving the problem, chosen by the producer. On the list of the companies who donate part of their profit to help a cause, there are large companies like Reebok, Tesco, Cadbury or McDonald's (Straszyńska, 2013).

One can divide *cause marketing* in two terms:

- Marketing techniques is used to change the attitude of the society like promoting healthy lifestyle, prevention of pathological behaviors & charity events.
- Supporting social causes is a part of commercial marketing which direct goal is creating the good company's or brand image through sponsorship of the social activity.

From the independent studies concerning this type of marketing strategy, it is established a lot of information about perceiving cause marketing in the North America. Almost ¾ of Americans thinks that this kind of activity is the direct solution of a given social problem and 1⁄3 admits that if various brands present the same products, they will buy the one which manufacturer is conducting the cause marketing. When it comes to the Polish nation, it is known that more than the half of surveyed consumers agrees with the charity and they like to contribute` by giving the money by themselves. It is clear that this type of marketing creates a very good image about the brand or company since people like to feel invested in a noble cause. If the company says that after buying given product consumer contributes in a good cause, the given person is more likely to choose their product than the competitors' (Straszyńska, 2013).

Conclusions

In conclusion, marketing is not only the advertising aspect in a given company. It is much more – analysis, researching, studying the demography in order to gain the new groups of consumers etc. For example, marketing analyzes the characteristics appearing on the given product, the amount of money which is going to be spend by the consumer, how the commodities are going to be delivered etc. One of the most interesting abilities marketing has, is not only the ability to know the change in the consumer and needs, but also the analysis of given market sector. Marketing might have changed from its previous form in the previous era, which was mostly focused on the organization produced. Now it gives the bigger understanding of the market and customers.

It is tempting to say that, unconventional marketing is more effective in gaining the customers' attention, which might be challenging for the management of given company considering the amount of research and work they have to put in the strategy, but in the end, when the company manages to create the image which amuses, shocks or intrigues consumers it pays off. What is more, unconventional marketing strategy helps the company to grow and differentiate among their competitors in the market without spending a big budget on the marketing. Some of marketing methods are safe in the aspect on the company's image or brand but some of them must be conducted with the extra care since the incompetent and badly done strategy, may result in the opposite effect which company seems to achieve. What is more, the companies should remember to adapt their strategies to their target audience, since different people look for different products. Still some companies choose to neglect the influence of marketing strategy on the enterprises accomplishments that is why this topic is worth to analyze. Deciding on any marketing strategy, one can first conduct the market research, test ideas and approaches towards clients and staff, and check what works, which techniques give the desired results. Importantly, one should choose more than one marketing tactic to meet customer needs, reach customers market targets and improve sales results. That is why it cannot be decided clearly which marketing strategy is better, in which the company should put the most organizational possibilities and involvement of marketers.

The article is an introduction to conducting own research on the impact of conventional and unconventional marketing strategies on consumer purchasing trends.

Abstract

The most important measure of a level of economic activity is GDP. Growing GDP stimulates other economic quantities, including the research and development spending (R&D) or information communication technology (ICT) expenditure. This impact has a bilateral character - high level of spending on R&D, including the development of ICT techniques, intensifies economic activity and improves productivity. The aim of our research is to present the application of the S-curve, as well as, the modified S-curve as a tool of economic development forecasting, based on data from transition economies. According to paper's aims, we pose the following research hypotheses: (*H1): the S-curve and the modified S-curve are effective tools of economic development forecasting for transition economies; H2: the modified S-curve is more efficient than ordinary S-curve of economic development forecasting for transition economies.* We confirm both hypotheses using data from V4 countries (the Czech Republic, Hungary, Poland, Slovakia) for GDP per capita time-series (1991-2015) and R&D per capita (1995-2015). Our analysis of R&D spending per capita also suggest, that, both Poland and the Czech Republic are in the phase of fast growth, and in the relatively earlier phase of development, comparing to GDP, what implies, that the GDP growth is an important factor of the R&D spending growth. For Poland, the growth rate is the highest, which can result from the smallest level of expenditure. However, the trend analysis indicates that, within 10 years, the level of expenditure per capita should be higher than in the Czech Republic, which are the current leader of V4 countries.

Keywords: R&D, ICT, transition economies, logistic law of growth, forecasting.

JEL: C130, C220, C530, E320

Introduction

Nowadays global economy is particularly sensitive to various types of disturbance, as a result of progressive globalization (Siedlecki & Papla, 2013), (Brunnermeier, 2009), (Coffee, 2009), (Guillen, 2009), (Kolb, 2010), (Shiller, 2008). Those turbulent environment cause economic shocks, or even breaks, which interrupt economies' growth trend. Similar effects, but on a larger scale, can be observed in the case of economies, that carried out a process of economic transition. This process of transition usually follow a clear path: (1) a period of economic slowdown, which is a result of a fast and dramatic change of business environment; (2) a span of dynamic growth, which gets slower along with time.

The most important, and commonly used, measure of a level of economic activity is the Gross Domestic Product (GDP) – the rate of its growth is influenced by multiple factors, however, the level of GDP also stimulates other economic quantities, including the research and development spending (R&D) or information communication technology (ICT) expenditure. This impact has a bilateral character - high level of spending on R&D, including the development of ICT techniques, intensifies economic activity and improves productivity.

The aim of this research is to present the application of the S-curve, as well as, the modified S-curve as a tool of economic development forecasting, based on data from transition economies. According to paper's aims, we pose the following research hypotheses:

H1: the S-curve and the modified S-curve are effective tools of economic development forecasting for transition economies;

H2: the modified S-curve is more efficient than ordinary S-curve of economic development forecasting for transition economies.

The H1 hypothesis refers to the law of logistic growth. After the economic / structural transformation, the economy suffers from a dramatic breakdown, characterised by a strong decrease of economy's activity. After this phase of decline a new growth cycle opens. An initial phase of growth goes through a phase of rapid growth, which leads to a stabilization phase. We assume, that this path of development can be successfully modelled using the S-curve. The H2 hypothesis refers to the characteristic of the modified S-curve, which do not have any saturation level, in contrast to the regular S-curve. That's way the modified S-curve might better reflect the nature of business processes.

We use data coming from 4 Central and East European (CEE) countries, which, in the 1990's, went through the economic transformation: Czech Republic, Hungary, Poland and Slovakia (V4 countries). We analyse two important economic variables – GDP per capita and R&D spending. Data are obtained from OECD Database, and cover the years 1991-2015 for GDP and 1995-2015 for R&D time-series.

The paper is organised as follow: after the introduction, we shortly characterise the transformation process, which took place in V4 countries in the 1990's, (section 2), referring to the pattern of GDP growth, and R&D&I spending as GDP ratio. We want to show, that the pattern of development, which can be observed in transition economies follow the law of logistic growth. In the section 3 we present the methodology and data, first of all the mathematical form of the S-curve and the modified S-curve, which are the mathematical expression of the law of logistic growth. In the section 4 we propose the application of S-curve, and modified S-curve, in forecasting of selected time-series: GDP per capita and R&D expenditure as GDP ratio. Finally we conclude our findings in the section 5.

This paper contribute to the science in several way. First, we prove, that the S-curve, as well as the modified S-curve, can be effectively used in economic forecasting, especially in the case of transition economies. We also show, that modified S-curve better fits and explains important economic time series. Additionally we present the original method of estimation of the modified S-curve parameters.

Economic transition in CEE countries – GDP and R&D spending growth patterns

Political changes, which took place in the beginning of the 1990's, pushed CEE countries into a path of economic transformation - from a planned socialist economy into a private market economy, ergo from socialism to capitalism. For the countries of the CEE region, this meant a dramatic change of economic and social environment, which consisted of liberalization of trade and prices, as well as huge institutional reforms, involving competition policy, labour markets, privatization and enterprise restructuring (Roaf et al., 2014). Most of these changes met with significant resistance, due to severe social consequences. Part of the CEE societies couldn't find themselves in the new reality, which promoted enterprising and educated people. This transition bared, with great force, all weaknesses of socialistic economy, such as structural maladjustment or hidden unemployment. On the other hand, huge societal expectations increased pressure on decision-makers. People expected, that the fall of communism would generate rapid economic growth and fast catch up with

West European developed countries (Svejnar, 2002). It should be mentioned that, despite many similarities, resulting from implemented, for almost 50 years, the economic model of socialistic economy, initial conditions in each country were a little bit different. The situation was most advantageous in Hungary, where the economy was relatively low centralized and a degree of macroeconomic imbalance low, comparing to Czechoslovakia - much more centralized. On the other hand, Polish economy, despite of a lower level of centralization, suffered a much greater degree of internal and external macroeconomic imbalance (Fischer & Gelb, 1991), (Balcerowicz, 1994).

Regardless this different initial conditions, we can conclude, that the transformation process were characterised by the same stages in every CEE country. Tridico (2013) suggests, that the process of economic transition, which took place in CEE countries, consists of three phases: (1) chaotic, (2) macro stabilization, and (3) consolidation. At the beginning of the transition process, all CEE countries experienced the important transition recession, which consisted of dramatic decreases in GDP, high unemployment rates, and galloping inflation (Lee & Jeong, 2006), (Huw Edwards, 2006). Sicherl (1999) emphasises, that the severity of this GDP drop was as serious as during the Great Depression in developed countries after 1929. This GDP decline ranged from 13.1 percent for the Czech Republic to 25.2 percent for Slovakia (Rapacki & Próchniak, 2009). The stage of macro stabilization created stable conditions for progressive economic recovery, which could be observed after consolidation process (Tridico, 2013), (Roaf, et al., 2014). Finally, all transition economies experienced relatively high, comparing to developing countries, growth of GDP (Nur-tegin, 2007). Poland rebuilt the GDP level after 7 years, what was the best result in the region (Sicherl, 1999), (Rapacki & Próchniak, 2009) what was accompanied by important expansion of a private sector (Fischer & Sahay, 2000), (Huffman & Johnson, 2002). This privatization process, accompanied by structural reforms, was very important from the point of view of quick recovery - higher speed of reforms contributed to faster recovery (Fischer & Sahay, 2000), (Lee & Jeong, 2006), (Staehr, 2005), (Fidrmuc, 2003). The economic transition resulted in the launch of a quite new development cycle for CEE economies. We assume, that this process can be successfully modelled using the logistic law of growth, and expressed by the S-curve, or the modified S-curve.

A similar path of development can be observed in the case of R&D spending, including expenditure on ICT. As we mention above, the process of transition was accompanied by important expansion of a private sector. The massive privatisation, the opening to global economy and strong activity of international companies, allowed the transfer of technology, including ICT, and boosted R&D spending.

Globally, we can observe a long-term upward trend in the ratio of expenditures on R&D to national income (Welfens, 2008). It should be also emphasised, that the distinction between R&D and ICT spending might be a little bit tricky, because this upward trend of economy's growth usually takes the form of ICT and knowledge (R&D&I) (Nepelski & De Prato, 2014), although some research suggest, that R&D spending affect productivity much faster than ICT (Edquist & Henrekson, 2017). On the other hand, that there is complementary relationship between ICT and all others types of innovations (Arendt & Grabowski, 2018). Many research confirm the positive relationship between ICT or R&D investment and GDP growth (Niebel, 2018), (Cardona, Kretschmer & Strobel, 2013), (Sağlam, 2016), (Samoilenko, 2008), (Vu, 2011), (Jin & Cho, 2015) by higher firms productivity (Bonanno, 2016), (Piatkowski, 2003) also in the case of "old economy" industries (Piatkowski, 2006). Hong (2017) also reports the existence of bidirectional Granger-causality between investments in ICT and R&D, and the economic growth. We can conclude, that firm's productivity depends on current investments in R&D (Aw, et al., 2007), what stimulates economic growth (Wang, Yu & Liu, 2013), regardless the source of funding (private or public) (Czarnitzki & Hussinger, 2004).

Transition economies, in the beginning of transition process, suffered from the low level of R&D spending, which decreased as a result of a reduction of R&D employment in manufacturing sector. After some period of recovery, they entered a phase of catching-up process (Czarnitzki & Licht, 2006). This phase of intensive growth was a result of higher R&D efficiency of foreign enterprises which were interested in investment on newly-opened markets (Zhang, et al., 2003), (Damijan et al., 2003). From today's perspective, we can conclude, that those investments in ICT, in the case of CEE countries, played a major role in convergence process , during the 1990s (Lengyel, 2012), by generating greater productivity than in the EU-15 (Piatkowski & Bart, 2005), (Van Ark & Piatkowski, 2004), although the benefits of individual

countries varied as a result of different quality of economic and legal environment (Roztocki & Weistroffer, 2011).

Now, as members of the EU, CEE countries face the challenge of the common EU strategy Europe 2020, what means achieving the level of 3% R&D expenditure to GDP ratio by 2020 (Zawalińska, Tran & Płoszaj, 2017). Data, presented below, show clearly, that the gap between CEE countries, especially for Poland and Slovakia, and highly-developed European countries is still significant. According to that we can speculate, whether CEE countries have the potential, both in financial and human dimension, to meet the target set by EU. Forecasts, built on the basis of the S-curve, or the modified S-curve, can contribute significantly to this discussion.

Data and Methodology

The literature review, as well as the simple observation of natural and economic processes, suggests, that there are always some limits of growth, what do not automatically means that, after reaching some level, the development would stop, but we can expect the continuous decrementing of growth rates. This phenomenon can be observed both in the case of GDP (Nordhaus, Stavins & Weitzman, 1992) and R&D expenditures, and usually is caused by physically-determined upper limits (Beaudreau & Lightfoot, 2015). That characteristic implies the possibility of forecasting the time-series using the logistic growth functions.

The literature propose a lot of functions describing the logistic law, based on generalized logistic growth function (table 1). Unfortunately, in technology, finance and economy (even demography) they often don't work well, mainly due to the "unlimited growth" phenomenon - quantities such as GDP, stock market indexes, salaries in enterprises, sales or company value cannot be limited.

Table 1: Logistic growth functions

Generalized logistic growth function: $\frac{dN}{dt} = rN^{\alpha}\left[\left(1-\frac{N}{K}\right)^{\beta}\right]^{\gamma}$		
Name	Differential equation	Solution
Exponential growth	$\frac{dN}{dt} = rN$	$N(t) = N_0 e^{rt}$
Verhulst logistic equation	$\frac{dN}{dt} = rN\left(1-\frac{N}{K}\right)$	$N(t) = \frac{KN_0}{(K-N_0)e^{-rt}+N_0}$
Generic Growth Function	$\frac{dN}{dt} = rN^{1+\beta(1-\gamma)}\left[1-\left(\frac{N}{K}\right)^{\beta}\right]^{\gamma}$	$N(t) = \frac{K}{\left[1+\left[(\gamma-1)\beta rK^{\beta(1-\gamma)}t+\left[\left(\frac{K}{N_0}\right)^{\beta}-1\right]^{1-\gamma}\right]^{\frac{1}{1-\gamma}}\right]^{\frac{1}{\beta}}}$
Blumberg's equation	$\frac{dN}{dt} = rN^{\alpha}\left(1-\frac{N}{K}\right)^{\gamma}$	Not always exists
Von Bertalanffy's growth equation	$\frac{dN}{dt} = rN^{\frac{2}{3}}\left[1-\left(\frac{N}{K}\right)^{\frac{1}{3}}\right]$	$N(t) = K\left[1+\left[1-\left(\frac{N_0}{K}\right)^{\frac{1}{3}}\right]e^{-\frac{1}{3}rK^{-\frac{1}{3}}t}\right]^{3}$

Source: own study based on (Tsoularis, 2001).

The S-curve is a simple, and relatively reliable, tool which allow construction of long-term economic forecasts (Davis, 1941) of time-series which follow the rule of logistic growth. At the same time, it also enables to measure, observe and analyse, the efficiency of large scale economic systems. The S-curve is the only solution of a differential equation, called the Robertson's, Prescott's, Kuznets' law (Robertson, 1923), (Prescott, 1922), (Kuznets, 1971) (compare: (Siedlecki, 2006), (Siedlecki, et al., 2015). This function can be employed in economic growth forecasting, among all, in the case of transition, or developing economies. Despite undeniable advantages, the S-curve is characterized by several disadvantages, above all, the limited growth (an asymptote). This disadvantage can be avoided by employing the modified S-curve, which assumes the elastic and unlimited growth. The problem is, that parameters of the modified S-curve are relatively difficult to estimate.

Using the method an iterative method of estimation for functions with three or more parameters (Siedlecki, Papla, & Bem, 2017).we analyse the following time-series: (1) GDP per capita, and (2) Gross domestic spending on R&D per capita. According to OECD definition – the gross domestic spending on R&D is defined as the total expenditure (current and capital) on R&D carried out by all resident companies, research institutes, university and government laboratories, etc., in a country (OECD, 2018).

Data come from OECD Database and cover the years 1991 - 2017 for GDP time-series and 1995-2017 for R&D time-series (due to the lack of data). We analyse the process of economic development in V4 countries – the Czech Republic, Hungary, Poland and Slovakia.

Results and Discussion

Smoothing and forecasting GDP per capita

In order to present the practical application of the S-curve and the modified S-curve, in first step we use annual data for GDP per capita (PPP USD), from the period after the communism fall (1991-2015) (for Slovakia from 1992). The linear trend and the S-curve, as well as, the modified S-curve, is estimated.

Figure 1: Growth rate of GPD per capita 1991-2017 (PPP USD, 1991 = 1)
Source: own study

We calculate the GDP per capita growth rate, for all analysed countries, assuming that this ratio is the best to describe countries' development and wealth (Fig, 1, Fig, 2). This trajectory of development is quite similar to other ratios, calculated for GDP or GNI (Siedlecki & Papla, 2013), despite demographic

decrease, which can be observed in CEE countries (compare: Siedlecki & Papla, 2016). In order to illustrate obtained results we propose to use the data for Germany, for the same period.

Figure 2: GPD per capita , PPP 1995-2017

Source: own study

The analysis of the figure 1 (rates of growth of GDP per capita) and the figure 2 (GDP per capita, PPP) for V4 countries and Germany (as the example of the developed economy) suggest, that the growth rate for V4 countries is significantly higher than for Germany, what suggests, that V4 countries can be still in the phase of intensive growth (development). On the other hand, although relatively high growth rate, which can be observed during last 24 years, the level of GDP per capita in V4 group is still very low, comparing to Germany, or other developed countries. The highest growth rate are reported in the case of Poland and Slovakia, but Poland started with the lowest GDP per capita and this growth rate was too small to reach the Czech Republic or Slovakia level. This is the result of the most difficult initial conditions (compare: section 2).

In the next stage we test the hypothesis of time-series stationarity of GDP per capita, which allow us to prove, that there is some tendency (trend) in analysed process. We employ the KPSS test, for which a null hypothesis is that the time series are stationary around a deterministic trend, against the alternative of a unit root. According to the KPSS test results, we are forced to reject the null hypothesis, and adopt the alternative hypothesis, which assumes non-stationarity. For all examined countries we receive significance level under 0.01, what suggests, that there is some tendency (trend) in the GDP per capita growth (table 2).

Table 2: Results of KPSS test for GDP per capita, PPP

Country	Test statistic	Interpolated p-value
Czech_Republic	0,8590	less than 0.01***
Hungary	0,8515	less than 0.01***
Poland	0,8678	less than 0.01***
Slovak Republic	0,8570	less than 0.01***
* significance level α = 0.1, ** significance level α = 0.05 *** significance level α = 0.01		
Interpolated p-value (critical values): α = 0.1(0.355); α = 0.05(0.462); α = 0.01(0.704)		

Source: own study

Then we examine the hypothesis of stationarity of residuals for analysed time-series. Based on KPSS test, we reject the null hypothesis of stationarity for all V4 countries. That implies, that we cannot use the linear trend to smooth and forecast (table 3) - non-stationarity of linear trend residuals suggest the presence of nonlinear trend. Concluding, there is a trend in analysed process, but it doesn't have a linear form.

Table 3: Linear trend estimation for GDP per capita, PPP

Trend analysis	Czech Republic	Hungary	Poland	Slovakia
KPSS test for residuals (test statistic p-value)	0,1143 (p > 0.1)	0,2009 (0,014)	0,0976 (p>0.1)	0,1488 (0.051)

Source: own study

Those findings encourage us to use the S-curve, and the modified S-curve. We estimate the parameters of both curves (table 4 and table 5). Analogously we teste the stationarity of residuals for estimated functions, using, again, the KPSS test. Results strongly confirm, that the logistic trend exist. For all countries residuals are stationary and estimated functions are perfectly fitted (R^2 higher than 0.98 for all countries).

Table 4: S-curve estimation for GDP per capita, PPP

Analysis	Czech Republic	Hungary	Poland	Slovakia
Coefficients	K = 0,9499 b = 3,1081 r = 0,2767 intercept = 9,5286	K = 1,0900 b = 2,8575 r = 0,2813 intercept = 9,1246	K = 1,4178 b = 2,7320 r = 0,2236 intercept = 8,9527	K = 1,3073 b = 3,0404 r = 0,2831 intercept = 9,0690
R^2	**0,9837**	**0,9832**	**0,9943**	**0,9952**
KPSS test for residuals (test statistic p-value)	0,1194 (p>0.1)	0,1641 (p>0.1)	0,1238 (p>0.1)	0,0880 (p>0.1)

Source: own study

Table 5: Modified S-curve estimation for GDP per capita, PPP

Analysis	Czech Republic	Hungary	Poland	Slovakia
Coefficients	K = 0,3074 b = 2,2383 r = 0,2553 intercept = 9,5286	K = 0,3548 b = 1,8291 r = 0,2566 intercept = 9,1246	K = 0,4756 b = 1,5641 r = 0,1615 intercept = 8,9527	K = 0,4264 b = 2,0718 r = 0,2545 intercept = 9,0690
R^2	**0,9892**	**0,9940**	**0,9974**	**0,9955**
KPSS test for residuals (test statistic p-value)	0,0652 (p>0.1)	0,1203 (p>0.1)	0,0872 (p>0.1)	0,1070 (p>0.1)

Source: own study

First of all, the modified S-curve is better fitted for data (R^2 are a little bit higher) and KPSS test's parameters are lower. Secondly, as we can observe on fig. 3, the forecasts prepared using the modified S-curve are not limited by the saturation level, as in the case of the S-curve. This can be a source of better estimation's results, especially in case of developing (transition) economies. It can be concluded, that V4 countries are quite close to the slow growth rate phase, but based on the S-curve forecast, those countries will never reach the level of German's GDP per capita, or other highly developed countries. The maximum level of GDP per capita (PPP), estimated using the S-curve, based on parameters, are equal to: 35 461 USD for the Czech Republic, 27 248

USD for Hungary, 31 482 USD for Poland and 32 014 USD for Slovakia. All countries are even before the transition to the phase of stable growth (table 4, figure 3).

Figure 3: GDP per capita (PPP), estimated values of the S-curve and the modified S-curve (1991-2017) and forecasts (2018-2027)

Source: own study

Smoothing and forecasting for Gross domestic spending on R&D per capita

As the literature study suggests, the level of R&D spending (as well as the ICT spending) are related to the rate of economic growth, expressed by GDP. In the period 1995-2017 we can observe the constant growth of gross domestic expenditure per capita on R&D (fig. 4).

Figure 4: Gross domestic spending on R&D 1995-2017

Source: own study

In Poland and Slovakia, expenditure on R&D are still at a very low level, in relation to developed economies or developing Asian countries, while the Czech Republic have already achieved the level of expenditure (as % GDP) similar to the average of the developed EU countries, but the gap between the most developed countries, like Germany, is still important (fig. 4, fig. 5, fig. 6).

Figure 5: Gross domestic expenditure on R&D in selected countries in 2015

Source: own study based on OECD Database

In the case of V4 countries, there is clearly faster upward trend, both in expenditure per capita and % GDP, what is consistent with the higher GDP growth. We should expect, that other V4 countries have also a chance to close up the gap and reach the level of developed countries (fig. 4 and fig. 6).

Figure 6: Gross domestic spending on R&D per capita 1995-2017

Source: own study

As in the case of GDP, we test the hypothesis of time-series stationarity for gross domestic spending on R&D per capita, which allow us to prove, that there is some tendency (trend) in analysed process. Based on the KPSS test, we are forced to reject the null hypothesis, and adopt the alternative hypothesis, what means, that there is some tendency (trend) (tab. 6).

Table 6: Results of KPSS test for Gross domestic spending on R&D per capita, 1995-2017

Country	Test statistic	Interpolated p-value
Czech_Republic	0,8544	less than 0.01***
Hungary	0,8282	less than 0.01***
Poland	0,8062	less than 0.01***
Slovak Republic	0,5862	0,029*
* significance level α = 0.1, ** significance level α = 0.05 *** significance level α = 0.01		
Interpolated p-value (critical values): α = 0.1(0.357); α = 0.05(0.462); α = 0.01(0. 697)		

Source: own study

Unlike the analysis of GDP, in the Czech Republic we can estimate the linear trend, while for other countries, the existence of non-linear trend can be assumed (tab. 7), what encourage us, once again, to apply the S-curve and the modified S-curve.

Table 7: Linear trend estimation for Gross domestic spending on R&D per capita, 1995-2017

Trend analysis	Czech Republic	Hungary	Poland	Slovakia
KPSS test for residuals (test statistic p-value)	0,0542 (p>0.1)	0,1542 (0,047)	0,1943 (0,019)	0,2034 (0,012)

Source: own study

We estimate the parameters of both curves (tab. 8, tab. 9). Analogously, we teste the stationarity of residuals for estimated functions, using, again, the KPSS test. Results strongly confirm, that the logistic trend exist. For all examined countries residuals are stationary and estimated functions are very good fitted although the fitting measures are not as high as for GDP time-series (R^2 from 0.8684 to 0.9809, comparing to 0.9837 to 0.9974 for GDP).

Table 8: S-curve estimation for Gross domestic spending on R&D per capita, 1995-2017

Analysis	Czech Republic	Hungary	Poland	Slovakia
Coefficients	K = 1,3985 b = 2,6905 r = 0,2097 intercept = 5,1131	K = 1,1145 b = 3,0948 r = 0,3051 intercept = 4,6444	K = 2,0763 b = 3,5251 r = 0,1857 intercept = 4,2239	K = 0,7953 b = 18,8835 r = 1,0964 intercept = 4,7771
R^2	**0,9770**	**0,9484**	**0,9705**	**0,8884**
KPSS test for residuals (test statistic p-value)	0,0732 (p>0.1)	0,1540 (p>0.1)	0,1146 (p>0.1)	0,1747 (p>0.1)

Source: own study

Table 9: Modified S-curve estimation for Gross domestic spending on R&D per capita, 1995-2017

Analysis	Czech Republic	Hungary	Poland	Slovakia
Coefficients	K = 0,4803 b = 1,5394 r = 0,1429 intercept = 5,1131	K = 0,3591 b = 2,3101 r = 0,3157 intercept = 4.6444	K = 0,7680 b = 2,8191 r = 0,1387 intercept = 4.2239	K = 0,2574 b = 19,7738 r = 1,1616 intercept = 4.7771
R^2	**0,9809**	**0,9646**	**0,9653**	**0,8886**
KPSS test for residuals (test statistic p-value)	0,0476 (p>0.1)	0,1398 (p>0.1)	0,1706 (p>0.1)	0,1740 (p>0.1)

Source: own study

The forecasts estimated using the modified S-curve are not limited by saturation level, as in the case of the S-curve (fig. 7). This can be a source of better estimation's results, especially in case of developing (transition) economies. Same as before, it can be concluded, that V4 countries are quite close to the slow growth rate phase. Based on the S-curve, we can forecast, that only the Czech Republic and Poland might reach, in the future, the level of R&D spending comparable to USA or Germany. The maximum level of spending on R&D per capita, estimated using the S-curve, based on parameters, are equal to 659,57 USD for the Czech Republic, 316,68 USD for Hungary, 471,99 USD for Poland and 263,14 USD for Slovakia (table 8, figure 7). As in the case of GDP, the estimation using the modified S-curve seems to be a better solution. The modified S-curve indicates the unlimited growth along with the decreasing growth rate, what is consistent with economic theories, suggesting that a man is committed to increasing technological progress and development, what is the source of the unlimited growth, as in the case of GDP.

Poland, despite the lowest expenditure, has the highest dynamics and growth potential. The dynamic of growth, in the Czech Republic, is significantly lower, however, it should be mentioned, that the Czech Republic is already quite close to the EU average. The Czech Republic is a leader, characterised by the highest in the region GDP per capita and R&D spending per capita. Both Slovakia and Hungary have the most unfavourable situation, and the projected growth is relatively lower. In the case of Poland and the Czech Republic R&D spending grow faster than GDP, while for Slovakia and Hungary the ratio of growth is comparable to the GDP growth (fig. 7).

As in the case of GDP, we may notice, that *both* the S-curve and the modified S-curve are very good tools to estimate the non-linear trend, regardless of the fact that the value of the fitting measures are a little bit lower for R&D spending. *Those results allow us to adopt the H1 hypothesis, which assumes, that S-curve and modified S-curve are effective tools in analysing the processes of growth and phases of development cycle for transition economies*. Moreover, on the same time, we can adopt the *H2 hypothesis, assuming, that our the modified S-curve is a better tool, than the S-curve*.

Figure 7: Gross domestic spending on R&D per capita, estimated values of the S-curve and the modified S-curve (1991-2017) and forecasts (2018-2027)
Source: own study

Conclusions

In this research we successfully confirm that, in the case of V4 countries after the economic transition, the new development trajectory can be shaped using the S-curve or the modified S-curve shape. We can observe all phases of development (or business) cycle: slow, intensive and stable growth. Additionally, we present the new method of parameters' estimation, both for the S-curve and the modified S-curve. This estimation method can be successfully employed not only for the modified S-curve, but also for other functions, that cannot be presented in simpler, linear form.

Based on presented empirical findings, we can form some concluding remarks:

- in the case of transition economies the S-curve, and the modified S-curve can be successfully employed in the analysis of economic development and forecasting. A linear trend could not be employed;
- the modified S-curve is a very good tool, which allows smoothing of time series due to its monotonic and flexibility and it is slightly better fitted to the data, than the ordinary S-curve;
- the modified S-curve allows far extrapolation of economic and financial time series (especially for transition economies) because it doesn't have a saturation level;
- this findings are important for forecasting, or modelling of economic processes, which follow the rule of the logistic growth law.
- the analysis of R&D spending per capita in Poland and the Czech Republic suggests, that both countries are in the phase of fast growth, and in the relatively earlier phase of development, comparing to GDP, what implies, that the GDP growth is an important factor of the R&D spending growth
- for Poland, the growth rate is the highest, which can result from the smallest level of expenditure. However, the trend analysis indicates that, within 10 years, the level of expenditure per capita should be higher than in the Czech Republic, which are the current leader of V4 countries.

Abstract

The paper examines the role of ICT in achieving effective manpower training in Nigeria's public sector. It is a qualitative paper that relied on secondary data which were textually and descriptively analysed. The historical approach to the empirical review on manpower training in Nigeria's public bureaucracy revealed some reforms and attempts at remedying the challenges to manpower training. The application of Human Capital and Scientific Management theories illuminated the discourse. Notable impediments to manpower training in Nigeria's public sector are bureaucratic lapses in the identification of training needs; obsolete or poor strategies/approaches to manpower training; and limited appreciation of the role of ICT in achieving robust training outcomes. The paper discussed four ICT-driven learning techniques and suggested the utilisation of competent ICT professionals in manpower training (among others) as bulwark to the deficiencies identified.

Keywords: Manpower, Training, Information and Communication Technology, Public Sector.

Introduction

In today's competitive work environment, manpower training plays a significant role in organisational development (Sunday, Benjamin and Ekpe 2015). This finds expression in the fact that manpower training is a key requirement for all employees to be equipped with multiplicity of skills geared towards work improvement for future work activities and achieving organisational objectives (Attah, 2017). Similarly, the 21st century organisational environment gives another situation where machines and artificial intelligence are slowly taking over jobs, yet the essential role of human resources in realising organisational objectives cannot be overemphasised (Obisi, 2011).

Training is a significant part of human resource development which focuses on the efficiency of employees in organisations. Absence of training accounts for low manpower utilisation. Manpower training in the Nigerian public sector has been identified as a cause for concern to policy makers and researchers (Omitola, 2017; Oni-Ojo, Salau, Oludayo, and Abasilim, 2014). Furthermore, available evidence from the public sector adduces waste and lacklustre performance based on insufficient or absence of budgetary provisions, poor financing and corruption as major threats to training activities in some organisations, including Industrial Training Fund (ITF), Centre for Management Development (CMD) National Manpower Board (NMB), National Productivity Centre (NPC), to mention a few (Ofobruku and Nwakoby, 2015).

While several researchers have conducted studies on manpower training in the public sector globally, (Adiele and Ibietan, 2017; Fajoh and Faniran, 2016;; Dialoke et al, 2016; Halidu, 2015; Idoko, 2015; Aibieyi, 2014; Ibrahim and Yemen, 2014), there are limited research on the role of ICT in enhancing manpower training in Nigeria's public sector, and this constitute the focus of this paper.

Methodology

This paper employed the qualitative approach with reliance on secondary data from articles, books, conference papers and journal publications on manpower training in Nigeria. This paper is divided into subsections, beginning with the introduction, which highlights manpower training and links the concept to Nigeria's public sector. This is followed by the empirical review on manpower training; theoretical framework and its application. The nature and methods of manpower training, challenges to manpower training in Nigeria's public sector, and the extent to which ICT can enhance manpower training in the sector were sequentially discussed.

Empirical Review on Manpower Training in Nigeria's Public Sector

Manpower training in Nigeria's public sector can be traced to the 1967 Wolle's Commission which sought to identify the need for manpower training in the Federal Civil Service. The report of the commission titled- "Training Needs of the Federal Civil Service" was submitted to the Federal Government in 1968 which led to a follow-up whitepaper in 1969 titled- "Federal Government's Approach on Staff Training and Development in the Federal Public Service" (Obadan and Odushola, 2003).

Obadan and Odushola (2003) noted the following in the whitepaper:

> First, the arrangement of Department of Training Officers with duty regarding surveying staff improvement needs, getting ready and actualising projects to address these issues. Second, restructuring all Ministries to guarantee that more prominent need is given to manpower training. Third, the foundation of standing board of trustees on training. Fourth, the consolation of offices/services to build up a training unit similar with the size and capacity of the service, and ultimately, the development of Administrative Staff College of Nigeria (Obadan and Odushola, 2003, p.5).

Additionally, the 1970 Adebo Commission was set up to strategically examine the public sector issues at that time, which were compensation and wages in public enterprises and state-owned organisations, foundation of the public service commission and to suggest satisfactory courses of action for staff training (Ewoh, 2014). In 1971, the establishment of Industrial Training Fund (ITF) to advance the right skills for indigenous manpower through training received further consideration.

Okotoni (2015) documented that the Federal Government again made attempts to provide training for public sector staff through the 1972 Udoji Commission and it realised that manpower training strategies and retraining of employees would greatly impact public sector productivity. In addition, the 1985 Dotun Phillips commission/Presidential Task Force on revamping of the public sector recommended that the public sector must set aside 10% of its staff cost for training of workforce yearly, and that the professional success of public sector employees through manpower training should be seen as ideal for the development of all government employees (Adeyoriju and Fajebe, 2019, p.32).

In order to ensure faithful execution, the Ministerial Training Committee framework was presented as a significant part of the execution system (Adiele and Ibietan, 2017). During this period, the National Centre for Economic Management and Administration (NCEMA) was inaugurated in 1986 with the aim of providing training for employees. Also, in 1991, the National Manpower Board (NMB) was mandated to evaluate skill requirements for employees in the public sector.

The 1995 Allison Ayida Commission was initiated to deal with the complaints of top civil servants concerning the politicisation of the post of Permanent Secretaries. The board was saddled with the duties to review and reclassify the goals concerning the execution of programmes in government organisations, and make suggestions on modalities for improving work/efficiency in the public service (Omitola, 2012).

Under the Obasanjo presidency in the Fourth Republic, the Adegoke Adegoroye Panel was instituted with the goal of restructuring the civil service and setting up standard rules concerning the workforce. The Steve Oronsaye Committee was similarly commissioned during the Yar'adua/Jonathan administration to streamline and reposition Ministries, Departments and Agencies of government for effectiveness. The recommendations of these panels have not been faithfully implemented due (perhaps) to lack of political will and commitment by successive administrations.

Application of the Human Capital and Scientific Management Theories

Applicable to this paper is the human capital theory by Becker (1962) who saw individuals as assets that must be continuously improved through training and other considerations for higher efficiency and productivity (Eriko, 2017). This theory perceives individuals and their skills/expertise and experience alongside capacity to discharge their duties in the light of a legitimate concern for their organisations and individuals as wellspring of resources for the organisation. This theoretical approach is underscored by the essentials of manpower training, having the tendency to improve efficiency and productivity ultimately.

Also, this paper applies the scientific management theory by Frederick Taylor which takes an atomistic view of employees as economic beings to be maximised for efficiency, using manpower training for the development of organisations (Halidu, 2015). It is argued that the scientific management theory is geared towards improved profitability and efficiency through the application of effective methods targeted at maximising output and employees' training for organisational effectiveness.

The Nature and Method of Manpower Training

Manpower training deals with the information and capacities utilised in the advancement of capacity and mental power, obtained through methodical giving of guidelines for the general improvement of employees' expertise and productivity (Ofobruku and Nwakoby, 2015). Training is also a learning procedure that includes the procurement of information, abilities, ideas, and rules to improve employees' performance at work (Sabir, Akhtar, and Bukhari 2014).

Manpower training could be on the job or off the job. On one hand, the hands-on-training method is one that is given to employees within the formal setting of an organisation. This method helps in training employees in real work situations or conditions (Aibieyi, 2014). Hands-on-training strategies incorporate exhibition, work pivot, arranged work activities, entry level induction and apprenticeship (Kulkarni, 2013). In the first place, instructing is the technique for training whereby a manager helps the employee to discharge his/her duties and obligations more productively by responding to questions, directing the people in discovering answers to their concerns, setting the correct model and widening their perspectives (Banjoko, 2011). The manager should have harmonious relationship with employees and adopts appropriate remedial measures in order to accomplish organisational objectives (Fajana, 2016).

The next method is job pivot, which deals with moving employees starting with one employment position then onto the next in order to widen their experience and familarise themselves with different parts of the organisation's activities (Stoner et al., 2008). This is followed by exhibition, where the manager acquaints the employees in question with models, which is more of demonstrations than telling. This method is referred to as learning by observing. Moreover, exhibition is a deliberately created activity, displayed on practical circumstances, in which learners partake and get inputs. They are especially helpful for occupations in which the hazard and mistakes are high or in which direct perception and criticism are commonly missing.

Off the job training operates outside the real workplace. It is utilised in training both old and new employees. Off-the-work training adopts workshops, classes, contextual investigations, vestibule as strategies (Ekundayo, 2015). For example, vestibule is a type of training which includes employees

learning in a non-workplace in which conditions and hardware are for all intents and purposes not different from what will be experienced at work. Formal work situations are invigorated through this strategy so that employees are furnished with starter learning encounters preceding any real work practice. Consequently, the issue of moving the learning conditions to work is limited since the employees are engaged in what they would inevitably end up doing in real work circumstances (Adeyoriju and Fajebe, 2019).

Off-the-work training can be in form of discussions, where the study strategy is the most customary type of training. It includes the transmission of information, thoughts and verifiable data from the educator to many learners one after another along these lines having the benefit of applying minimal effort. It could also be a contextual analysis which is composed or oral portrayal and synopsis of a genuine or speculative setting or issue.

Challenges to Manpower Training in Nigeria's Public Sector

There are major obstacles to effective training outcomes in the public bureaucracy which includes poor financing and inadequate budgetary provisions for training activities. Another impediment to training is the issue of corruption which is a cankerworm that has eaten deep to the moral fabrics of the Nigerian society. It finds expression in illegal diversion of funds and conversion of public resources to private gain and advantage which circumscribe the attainment of manpower training objectives.

Other impediments are bureaucratic lapses typified by spoil system and cronyism in identifying training needs/personnel; faulty appraisal system or process that obstructs objective discovery of training beneficiaries; obsolete or poor strategies and approaches to delivering robust outcomes and improved performance in Nigeria's public sector.

Leveraging ICT for Effective Manpower Training in Nigeria's Public Sector

The role of ICT in revolutionising and achieving effective manpower training in Nigeria's public sector cannot be overemphasised. This has been established in literature as Onodugo (2016) stated that using ICT for training purposes has changed how training is conducted, and corroborated thus:

> Appropriate utilisation of ICT can change the delivery of objectives for the Nigerian public sector, in light of 21st century technological advancements and training strategies which when set up, will significantly improve the productivity levels of employees in terms of skills and expertise for the sector's development (Onodugo, 2016, p.2).

ICT, if utilised through its various processes (particularly the digital innovation, will produce employees who will perform better in carrying out their duties. ICT approaches are developed by identifying specific areas that the employees require training and will ensure that the employees go through series of activities- contextual investigations, exhibitions and other processes as contained in Onodugo (2016). The following approaches can enhance manpower training:

- **The Dynamic Learning Approach** - ICT improves learning devices for testing, counting and reviewing of information. In this manner, a motivation for training with current devices for employees to figure out how to function and adopt certifiable issues within and outside work becomes apparent (Okeh and Opone, 2014).

- **The Community Learning Approach –** This is an ICT-based learning and participation between employees and expert trainers, where the training is focused on identifying opportunities for employees to learn from successful individuals within work community, which gives the relational abilities of employees to improve on their relationship skills (being mindful/showing empathy at work) (Lopez, 2014).

- **The Innovative Learning Approach** - is ICT-based learning and application of information relevant to current realities. Training is conducted for employees based on previous information on the organisation and applying same to the attainment of organisational objectives (Onodugo, 2016).

- **The Mixed Learning Approach** - is the way to deal with training through ICT features that advances organisational coordination. This approach applies different theories to the current workings of the organisation, and explores the extent to which the theory can enhance the organisation's strategies (Okeh and Opone, 2014).

The adoption or utilisation of ICT has made significant impact on manpower training in organisations. There are electronic advances utilised for training, gathering, controlling and showing or conveying information which incorporates programming, equipment, and even the network (Anderson and Baskin, 2017). When ICTs are utilised in training correctly, they can quicken, improve, and extend essential abilities in human resources, and they can inspire employees to learn as they become increasingly autonomous and responsive to learning (Yusuf, 2015). Besides, ICTs help to link employees to their work and its impact is felt in organisational communication which has been found to energise the work environment and activates employees to become efficient in carrying out their duties (Cradler and Bridgforth, 2016).

Other advantages of leveraging ICT for manpower training are that it can help lighten the workload in the public sector through its utilisation for computerised worksheets and reports, where employees can send in weekly reports which can be verified to ensure that weekly objectives are achieved (Kulik and Cohen, 2017) in line with the strategic objectives of the sector. This is important as it will help the administrators identify areas where the employees are lacking in terms of skills and expertise, specifically with the tasks given to them and the reports they turn in (Ben and Ashang, 2017). Also, ICT can be utilised in getting essential training content for the employees, and coordinated efforts can be guaranteed through trainers comprehensively (Anderson and Baskin, 2014).

In addition, ICTs can aid the human resource department significantly towards general improvement, through e-learning expressed variously in courses, workshops, and different activities - formal and casual, where employees adopt ICTs crosswise in training programmes (Bamigboye, Aderibigbe and Buraimo, 2017). There are a few worldwide portals/on-line resources to facilitate human resources development, and if these materials are utilised properly, the efficiency level within the public sector will significantly improve (Bamigboye et al., 2015), leading to increased productivity and national development.

Conclusion and Recommendations

The paper interrogated the extent to which ICT can be leveraged upon to achieve effective manpower training in Nigeria's public sector. The empirical review on manpower training in the Nigerian public bureaucracy took a historical approach that unearth the trajectory of reforms and remedial steps/attempts at redressing the lapses and obstacles to manpower training. It identified lack of commitment and deficient political commitment as part of the factors thwarting successful execution and realisation of training objectives in the public sector. Based on these and the discussions of this paper, the following suggestions are proffered:

1. The Federal government should ensure that ICT strategy statements are clearly communicated and implemented in Ministries, Departments and Agencies.
2. The ICT component of the Federal Ministry of Communications and Digital Economy should be adequately funded and invigorated to enable the public bureaucracy take advantage of technological tools and impact the citizens maximally through improved service delivery.
3. ICT training should be mandatory for all public sector workers as part of the manpower training module by professionals/competent ICT trainers.

Abstract

Introduction: Nowadays coordination of consumer and producer interests is a mandatory element of the managing process the payback of innovative products. The coordination of interests consists in reaching a compromise between the goals of the producer and the consumer, if there are certain benefits. For this purpose, the characteristics of consumer values and product parameters must be systematically agreed between the consumer and the producer.

Materials and methods: the article is dedicated to improving the payback management of innovative products by coordination the interests of producers and consumers. This is only possible if a compromise is reached on the interests of consumers with respect to the price and quality of the products, and of producers with respect to the financial results of the sale. The purpose of the study is to develop a matrix model of ROI management of innovative products based on the introduction of criteria for assessing product innovation. Matrix-cycle management is proposed for efficient payback management. The proposed method is based on integral matrix analysis, integrated analysis, system analysis and other methods. Improvement of efficiency of management of return on innovative products on the basis of coordination of interests of interested parties can be achieved by application of the developed matrix-cyclic model of management. To eliminate the conflict between the interests of stakeholders in the methodology of management of payback of innovative products, it is necessary to introduce new quality criteria. The article presents a matrix-cyclic model. It is based on the principles of the theory of systems and the principles of management of payback of innovative products. This model allows us to justify the cyclic processes, starting with the selection of the object of payback and ending with the sale of an innovative product.

Keywords: Management, Payback, Matrix-Cyclic Model, Compromise Of Interests Of Producers And Consumers.

Introduction

The theme of effective management of payback of innovative product is relevant in modern economic conditions. This is due to the need to improve the efficiency of the processes of bringing innovative products to the Russian and international market.

The study of the problem of conflict of interests of market participants in the process of payback management is considered in the works of such authors as A.V. Dmitriev, V.P. Sheinov, T.A. Nestik, Yu.D. Krasovsky and others *(Dmitriev, 2000), (Krasovsky, 2006), (Nestik, 2001), (Scheinov, 2010)*.

It should be noted that few authors pay attention to the economic component in the conflict of interests of the parties concerned, and more attention is paid to interpersonal conflicts and their social component. The impact of product innovation on ROI management processes is not addressed.

Therefore, there is a need to introduce a matrix-cyclical model of harmonization of the interests of producers and consumers in the process of managing the payback of innovative products.

For this purpose it is necessary to include the stages of planning and coordination of the parameters of innovative products in the processes of cokability in accordance with the requirements of the consumer and the interests of the manufacturer. Therefore, it is necessary to develop ways to incorporate consumer values into the matrix-cyclic model. For this purpose in the process of interaction "consumer-producer" we will highlight direct and reverse links of agreement of interests, which affect the level of innovation of the product. Consider the fact that the balance of interests may change as a result of changes in the quality of managing the ROI of innovative products. The quality of management, in turn, depends on the completeness of the criteria taken into account. Basic management functions are the basic criteria, and additional special management functions are proposed as additional criteria.

To build a matrix-cyclic model, four types of stakeholder interaction in managing the payback of an innovative product are identified:

- conflict of interest;
- the imbalance of interests;
- consensus of interests;
- compromise of interests.

The validity of evaluation methods and the justification of their accuracy will determine the effectiveness of the development and implementation of an action plan to correct the imbalance. This determines the need to develop the methodology in the present study on the basis of the following matrix cyclic model and a set of methods for managing the payback of innovative products on the basis of basic and additional special management functions and their control indicators.

The application of a set of methods is due to the complexity of the management of payback products. It should provide conditions for harmonization of regulated characteristics of consumer value and possibilities of their provision by producers. Improvement of control quality is proposed to be implemented in formed mechanism on the basis of control procedure built into its circuit of direct and reverse links.

Materials and Methods

For the solution of the tasks set in article works of domestic and foreign scientists in the field of the theory of interested parties, managements of development, strategic management, adoption of management decisions, the economic theory, sociology, conflictology and econometrics are studied.

The main methods of a research used in work are: synthesis, analysis, comparison, system approach, induction and deduction, generalization, formal logic, analogy, classification, expert estimates, economic-mathematical methods, methods of the functional analysis.

Discussion

The realization of the idea of increasing the payback of the innovative product on indicators of reconciliation of interests consists in achieving and maintaining compromise of the goals of producers and consumers. This requires more accurate planning of the process of harmonization of consumer values and product parameters provided by the manufacturer. There is a need to develop a methodology to incorporate consumer values into the factors governing the payback management mechanism. Application of additional specialized functions of coordination of the specified goals should be carried out in the loop of direct and reverse connections of producers and consumers. This mechanism can be reflected in the matrix-cyclic model (Fig. 1).
