Abstract

The main goal of the paper is to determine in what way the coherence of the advancement levels of HRM subfunctions may influence on the performance financial results of MNCs. The research problem covered the identification and analysis of the relationships between the advancement levels of HRM subfunctions (independent variables) and the financial performance results of local subsidiaries of MNCs (dependent variable). The HRM subfunctions considered in the research were: employee resourcing, employee retention, engagement & satisfaction, performance appraisal, career development, talent management, competency management, development of leadership, employer branding. The research sample covered 200 headquarters (HQs) of MNCs and their local subsidiaries. The empirical research results show that there are some identifiable and statistically significant correlations between dependent and independent variables. Excluding employer branding, what has been found is that the higher the advancements level of HRM subfunctions and the stronger the associations between the advancement levels of these HRM subfunctions - the better the financial performance results of foreign subsidiaries of MNCs. Our study, therefore, represents an original effort at examining all these relationships.

Keywords: HRM, Subfunctions, Advancement Level, Coherence, Performance Results, Multinational Company, Central Europe

Introduction

This section should follow keywords. This section should provide background of the study and highlight research motivation. We are living in times, as presumably all organizations and their managers are aware, in which maintaining a profitable business becomes more and more complicated task. This is mostly because they have to operate in a highly competitive and rapidly changing environment. The companies understand that it is essential to identify effective ways to manage their employees and they build more or less advanced human resources management (HRM) systems to support their business performance.

There are numerous publications in which the authors present empirical research findings on the relationship between the HRM advancement level and organizational performance results. Some of them focus on the overall human resources management (HRM) advancement level or significance to the company's results, whereas others consider individual contribution of particular HRM subfunctions to the organizational performance results (Ginevičius *et al.* 2010). However

there are also those who study internal coherence of HRM subfunctions and their synergistic impact on company's success (Ridder et al, 2012). Anyway, the problem is much more complicated in multinational companies (MNCs) than in those operating on a single home market.

So far only a few studies have focused on some of the above mentioned phenomena from the perspective nested in economies such as Central and Eastern Europe (Farndale et al., 2017:1630). In most cases the research on MNCs has covered the companies deriving from developed countries (usually from the West Europe and the USA) whose foreign direct investment (FDI) was located in less developed countries (e.g. Brewster, 2007; Morley et al., 2009; Wilkinson and Wood, 2017). No specific research of this scope has been performed in MNCs headquartered in economies in transition or just after-the-transition, like those in Central and Eastern Europe (Festing, Sahakiants, 2013; Haromszeki 2014; Stor and Kupczyk 2017). Then, the more complex and interrelated ties between the HRM advancement level and organizational performance in such organizations stay rather unknown what makes a clear research gap. In this context the main goal of the paper is to determine in what way the coherence of the advancement levels of HRM subfunctions may influence on the performance financial results of MNCs headquartered in Central Europe.

In consequence, the paper is structured as follows. After this short introduction the authors discuss the theoretical background of the study based on a literature review. This results in formulation of two research hypotheses. Furthermore, the focus is on the research methodology, sample and measures. The empirical research findings and discussion over them come next. The article ends with a research summary and final conclusions.

The theoretical background of the study

The advancement level of HRM and company's performance results

Over the past few decades there has been a considerable scientific interest in investigating the relationship between HRM and different indicators of organizational performance (*c.f.* Kazlauskaite, Buciuniene, 2010) as well as in the impact strength of the HRM practices and systems themselves on the overall organizational performance (Kapondoro et al., 2015). Different perspectives (*c.f.* Stor, 2018) and different paradigms (*c.f.* Kaufman, 2015) have been taken to determine such associations.

In the literature there are various classification of company's performance results which the researchers have proved to be correlated with HRM practices. In most cases they refer to such four general categories of performance results as: organizational, behavioral, financial, and managerial. In this paper we are interested in the two last categories. In short, the financial results cover financial liquidity, profits, market share, sales, company's goodwill, share price, and firm value (Richey, Wally, 1998; Pfeffer, Veiga 1999; Arthur 1994; MacDuffie 1995; Huselid 1995; Becker, Gerhart 1996; Combs et al., 2006). The managerial results refer to research on interrelations and levels of coherence between business strategies and particular subfunctions of HRM with company's performance results (Beer et al., 1984; Schuler, Jackson 1987; Wright and Snell 1991; 1995; Guest, 1997; Chanda and Shen, 2009; Guest et al., 2011; Stor, Suchodolski 2016; Stor, Haromszeki 2019).

All in all, there is a vast array of various approaches to the relationships between the HRM advancement level and organizational performance results. Anyhow, being interested in both managerial and financial results, all this leads us to our first research hypothesis:

H_1: The higher the advancement level of HRM subfunctions the better the financial performance results of foreign subsidiaries of MNCs.

The internal coherence of HRM and company's performance results

Theorists adopting the configurational approach posit that internal coherence among individual HRM subfunctions is a key of success (Huff, Schüssler, 2016), and that – assuming that these subfunctions are internally consistent – combinations of HRM subfunctions are likely to have larger effects on organizational outcomes than the sum of the component effects due to individual practices (Bamberger et al., 2014). That is, the contribution of HRM to performance is explained through "the synergic integration of the elements that build it" (Martin-Alcazar et al., 2005, p. 637).

Crucial to the configurational perspective, is the argument that the impact of HRM on organizational performance is dependent on the adoption of an effective combination of HRM practices (Villajos et al., 2019), often referred to as HRM bundles (Gooderham, et al., 2008; Pocztowski, 2018). Thus the configurational approach has as its basis that maximizing firm performance is dependent not on the HRM subfunctions implemented in isolation but on the bundling together of interrelated elements of HRM practices in an internally consistent manner (Urlich, Brockbank, 2005:171-172; Ridder et al, 2012). Configurational theories propose that the relationship between HRM and company's performance involves complex interactions between bundles of HRM activities and outcomes (Arthur 1994; MacDuffie 1995). Such bundles of complementary and congruent practices are held to produce substantially greater performance effects than individual HRM practices or subfunctions (MacDuffie 1995;; Ichniowski, et al., 1997; Perry-Smith, Blum, 2000; Vergurg et al., 2007). Configurations represent recurring patterns of how key organizational variables fit together to form an identifiable whole (Walker, et al., 2015, p. 41). When applied in the research conducted in MNCs, the configurational perspective with its equifinality effect has revealed that such an approach captures more aspects of the complexity surrounding MNCs' examination and evaluation of their foreign subsidiaries (Dikova et al., 2017:406). In some more advanced studies on strategic management, the researchers have even developed special models of hierarchical relationships among different HRM strategies and substrategies in MNCs (e.g. Stor, 2007).

On the whole, research results suggest significant organizational benefits from effective and efficient management of coherent HRM subfunctions. Accordingly, our second hypothesis is formulated in the following way:

H_2: The stronger the internal associations between the advancement levels of HRM subfunctions the better the financial performance results of foreign subsidiaries of MNCs.

The Empirical Research Methodology

Our research problem covered the identification and analysis of the relationships between the advancement levels of HRM subfunctions and the financial performance results of local subsidiaries of MNCs. In a result of theoretical studies, we have formulated two hypotheses which were presented in the previous section.

The company's financial performance results make a dependent variable. HRM and its subfunctions are treated as an independent variables. Their advancement level was measured with comparison to the general worldwide trends based on the best practices. Basing on the literature review the authors have selected 9 subfunctions of HRM that are the most popular or valuable in business organizations. The subfunctions, measures and scales used to the particular variables incorporated in the tested hypotheses are presented in Table 1.

The research data has been gathered in two ways: CAWI (computer aided Web interview) and CATI (computer aided telephone interview). All the questions were asked in the context of the last

two fiscal years and this time framework was reminded by the interviewer several times during the interview survey. This procedure was to assert that the respondents were considering a specific period of time in which they were able to logically assess the interconnections between HRM and business phenomena under study. The survey was conducted in January 2018. The collected data were analyzed both within descriptive and correlational statistics. All calculations were performed by means of Statistica v. 12.5 - an advanced analytics software package with the level of significance set to alpha = 0.05. Kolmogorov–Smirnow test was performed to determine the normality of data distribution. To assess the questionnaire reliability Cronbach's alpha as a measure was used. The relationships between the quantitative variables were examined by the means of Pearson correlation coefficient (referred to as Pearson's r).

The research sample covered 200 headquarters of MNCs deriving from a Central European country (Poland). They were nonfinancial economic entities, existing on the market no less than two years, with a dominant share of the Polish capital, which possessed at least one foreign subsidiary, and this subsidiary was an effect of a foreign direct investment (FDI). The reference base for the number of business entities was the last report drawn by the Polish Central Statistical Office. The report indicated that there were 1760 Polish economic entities which confirmed possessing 4086 subsidiaries in 150 countries in 2015 (*Activities of Enterprises...,* 2017). Hence, we assumed that the size of a sample composed of 200 entities is sufficient to conduct the research because when the confidence coefficient stays at the level of 0.95 the maximum measurement error amounts to 0.065.

The sampling was of the purposive type to fulfill the requirements specified above. The structure of the research sample was diverse in terms of the companies' business profiles - according to the European Classification of Business Activity (ECBA) - although not all of the sectors of the economy were represented; length of operation in years; size of organizations (as measured by number of employees); type of FDI investment; and the ownership share of the HQs in their foreign subsidiaries. Furthermore, the MNCs under research differed in the number of total and foreign entities they controlled, number of host countries in which their subsidiaries were located, and level of country's development in which their most representative subsidiary operated. An average MNC operated on the market longer than 11 years, was rather a large organization, had about 13 entities, about 8 of them were foreign subsidiaries, located in 4 countries, established as greenfield investment with a majority ownership share belonging to the Polish HQ.

We assumed that some specific parameters, for example, an industrial area, size of the company, its legal form or country's economic development could influence the performance of businesses in the sample. However, the results of statistical testing did not demonstrate the impact of these parameters on business performance.

The Empirical Research Findings

Descriptive statistics and internal consistency

The basic descriptive statistics for the variables connected with the main research problem are presented in Table 1. On average, the financial performance results of MNCs, when compared to their main competitors, are somewhere between "similar to others" and "above average" ($\bar{x} = 3{,}74$). So, their financial standing on average is good. The advancement levels of particular HRM subfunction are relatively high. The means calculated for each of them ranges from $\bar{x}\,min = 3{,}70$ to $\bar{x}\,max = 3{,}81$. The *min scale value* is reached by employee resourcing ($min = 1{,}71$) and the highest by employer branding ($max = 4{,}93$).

Table 1: Basic descriptive statistics for the main variables under study: HRM subfunctions and MNCs'performance financial results

VARIABLES		Valid N	Mean	Median	Min	Max	SD
Financial performance results		200,00	3,74	4,00	2,00	5,00	0,51
The advancement level of HRM subfunctions	**Employee resourcing**	200,00	3,76	3,86	1,71	4,71	0,48
	Employee retention	200,00	3,70	3,80	2,40	4,80	0,38
	Engagement & satisfaction	200,00	3,70	3,73	2,91	4,64	0,30
	Performance appraisal	200,00	3,76	3,75	2,25	4,50	0,34
	Career development	200,00	3,81	3,83	2,50	4,50	0,36
	Talent management	200,00	3,70	3,83	2,00	4,50	0,46
	Competency management	200,00	3,71	3,75	2,50	4,63	0,37
	Development of leadership	200,00	3,70	3,75	2,00	4,38	0,39
	Employer branding	200,00	3,74	3,71	2,36	4,93	0,36

Scales:
- Performance results: comparison to the main competitors: 1 - poor, 2 – below average, 3 – similar to others, 4 – above average, 5 – very good;
- Advancement level: comparison to the general trends based on the best worldwide practices: 1 - very low, 2— low, 3— average, 4—high, 5—very high;

Source: own research data

The research findings show that among 9 HRM subfunctions being analyzed the highest advancement level belongs to career development ($\bar{x} = 3{,}81$). The second position is occupied *ex aequo* by performance appraisal and employee resourcing ($\bar{x} = 3{,}76$). The full ranking list is depicted in Graph 1.

Graph 1: The ranking of the mean values of the advancement level of HRM subfunctions
Source: own research data

Before proceeding further in the analysis, Cronbach's alpha coefficient was computed to check for the internal consistency within the questionnaire (see table 2). The reliability analysis covered 9

five-point scale items (HRM subfunctions). Cronbach's alpha showed the questionnaire to reach high reliability, α = 0.906. All items appeared to be worthy of retention, resulting in a decrease in the alpha if deleted.

Table 2: Reliability and item-total statistics

Variable	Summary for scale: Mean=33,5794; Std. Dv.=2,62692; Valid N:200 Cronbach alpha: ,**906023;** Standardized alfa: ,908333 Average inter-item corr.: ,531908

Correlation Analysis

The results of the correlation tests (at $p<.05$) for the main research variables are presented in Table 3. Apart from the advancement level of employer branding, all the other advancement levels of HRM subfunctions are positively correlated with the financial performance results of MNCs. The range of values for the correlation coefficient of these variables is in the interval between $r=.15$ and $r=.35$, where the lowest value is gained by employee retention and the highest by talent management.

All this means that our hypothesis **H_1** can be partially accepted because - with the exception of the advancement level of employer branding - the other 8 advancement levels of HRM subfunctions are positively correlated with the financial performance results of MNCs.

Table 3: The results of a correlation test for the advancement levels of HRM subfunctions and the financial performance results of MNCs

VARIABLES	1.	2.	3.	4.	5.	6.	7.	8.	9.	10.	$\overline{xHRM(1-9)}$

* Pearson's r significant at p < ,05000;											

Source: own research data

In our analysis we have also calculated the means of internal correlations between 9 HRM subfunctions ($\overline{xHRM(1:9)}$). Three variables, i.e. career development, competency management, and development of leadership are *ex aequo* on the first place because they take the highest mean ($\overline{x(r)} - .50$). Three other variables are *ex aequo* on the second position (with $\overline{x(r)} - .46$). They are: talent management, performance appraisal, and engagement & satisfaction. The remaining HRM subfunctions in a descending order are: employee resourcing ($\overline{x(r)} = .43$), employee retention ($x(r) = .42$), and employer branding ($x(r) = .37$). Then we have juxtaposed all these means with the values of correlations between each of HRM subfunctions and the performance financial results of foreign subsidiaries of MNCs. The curves representing these two sets of values are depicted in Graph 2. They provide visible relationship between the sets under study.

Graph. 2: The coherence of HRM subfunctions and company's performance financial results

Source: own research data

Finally, the correlation test conducted for the mean of internal relationships between advancement levels of HRM subfunctions and the financial performance results of foreign subsidiaries of MNCs reveals statistically significant and strong correlation *r*=.71. Hence, our last analysis leads us to the confirmation of hypothesis **H₂**. As shown in Table 4, the stronger the internal associations between the advancement levels of HRM subfunctions the better the financial performance results of foreign subsidiaries of MNCs.

Table 4: The results of a correlation test for the mean of internal associations between advancement levels of HRM subfunctions and the financial performance results of MNCs

Research summary

In our research we were particularly interested in the identification and analysis of the relationships between the advancement levels of HRM subfunctions and the financial performance results of local subsidiaries of MNCs. Successfully, we have identified some regularities within the scope of the selected variables and the analysis of the empirical research findings leads to the conclusion that the higher the advancements level of HRM subfunctions and the stronger the associations between the advancement levels of these HRM subfunctions - the better the financial performance results of foreign subsidiaries of MNCs. This does not include employer branding which makes an exception. Namely, no statistically significant correlation has been found in this scope. The possible reason is that it's difficult or even impossible to identify a straightforward relationship between the advancement level of employer branding and the financial performance results of company because there may be a mediating variable that intermediates the casual relationship between the dependent and independent variables. In our study we have applied some simplified statistical correlational analysis which is not dedicated to such type of investigation. Hence, as about the future research we would recommend to look for some mediating variable(s) that may explain in details or discover new ties between the variables under study.

Final Conclusions

Our final conclusion based on the analysis of the empirical research findings suggests that there is a clear, identifiable impact that the coherence of the advancement levels of HRM subfunctions may exert on the financial performance results of MNCs. It means that by manipulation of the HRM advancement level we may influence on the company's financial results in such a manner that raising the HRM advancement level we can expect an increase in company's financial outcomes. However, it is important to emphasize that individual HRM subfunctions show much weaker correlations with the financial outcomes than the internally coherent HRM. We believe that this final conclusion authorizes us to state that the goal of our paper has been achieved. We have successfully determined in what way the coherence of the advancement levels of HRM subfunctions may influence on the performance financial results of MNCs.

Notwithstanding this accomplishment, there are some limitations of our research. For example, the final conclusions can't be extended on the whole population of MNCs worldwide because the research sample, even though deliberatively selected, was composed only of those MNCs that were headquartered in one Central European country. Additionally, although it was diverse in terms of the companies' business profiles, not all sectors of economy were represented. Some other flaws are also noticeable in the measurement scales or the calculations based exclusively on

the mean values. Yet the other reservations may concern asking the informants the general questions about the company's financial performance results instead of using hard performance indicators. This practice is not at odd within this type of research, however it may undermine the subjectivity of evaluation.

Despite all these constraints, our study contributes to the scientific discipline of management. On one side, as said above, MNCs headquartered only in Central Europe make a limit to the research, but on the other side they provide a unique perspective. To our best knowledge, it's been the first research of this type. We have confirmed the phenomena - identified also by other researchers as mentioned in the introductory part of the paper - referring to the positive relations between HRM and organizational performance results, and in our case in MNCs. Our study has also some novelty value which consists in the identification of a statistically significant associations between the internal coherence of the advancement levels of HRM subfunctions and the financial performance results of MNCs.

In the above context it's worth noticing that the relationships between the advancement levels of HRM subfunctions and the financial performance results of MNCs headquartered in Central Europe seem to be similar within their strength to those identified in the companies in Western Europe (*cf.* Stavrou, Brewster, 2005). They only seem to be similar because when the particular researchers use different measures and classifications of HRM subfunctions (also called bundles) in their studies (*cf.* Verburg et al., 2007) their research results are hardly comparable (Boon et al., 2019). Anyway, to the best knowledge of the authors of this article none of the published papers so far has addressed to the impact of the internal coherence of HRM on MNC's financial outcomes in such a comprehensive way as it has been done in this work.

As for the practical implications of the research results, they mostly rely on indicating that if there is so strong positive relationship between the associations among the advancement levels of HRM subfunctions and the financial performance results, then there is huge potential and opportunity in using HRM subfunctions in more effective and efficient way that will lead to higher financial outcomes. Of course, it's necessary to remember that HRM is only one of the factors that determine such outcomes. There many others, as to mention economic growth, production technology, market competition, prices for components, service or product demand etc. Anyway, the presented research findings may help the managers of MNCs uncover some hidden opportunities existing in the management practices of their regional businesses and inspire them to create such ties between HRM subfunctions which can successfully impact their business performance.

Abstract

The main goal of the paper is to determine in what way the degree of HRM contribution to the MNC's performance results influences on the perceived value of human factor as a competitive differentiator on the market. The research problem covered the identification and analysis of the relationships between the degree of HRM and its subfunctions' contributions to the MNC's performance results (independent variables) and the perceived value of human factor as a competitive factor (dependent variable). The research sample covered 200 headquarters (HQs) of MNCs and their local subsidiaries. The empirical research findings show that there is a clear, identifiable relationship between the degree of HRM contribution to the MNC's performance results and the perceived value of human factor as a competitive differentiator on the market. This relationship is true when considered from the global perspective, when the MNCs evaluate their worldwide HRM practices and the impact of these practices on the worldwide competitive value of their human factor. There are some exceptions and differences when the overall HRM contribution or its particular HRM subfunctions' contribution are juxtaposed with the overall human factor or its two subfactors at the local subsidiaries level.

Keywords: HRM, subfunctions, contribution, performance results, multinational company, synergy effect

Introduction

The role of human resources management (HRM) in competition on human factor is not a new topic in management literature and practice. It may even sound as a *cliché* to say that to maintain a profitable business and gain competitive advantage it is essential to identify the effective ways to manage employees and build such HRM systems that contribute to business performance.

There are numerous publications in which the authors present theoretical conceptions and empirical research findings on the relationship between HRM and organizational performance results. Some of them focus on the overall HRM significance (or contribution) to the company's performance results (Ginevičius *et al.* 2010), whereas others consider individual contributions of particular HRM subfunctions (Ridder et al, 2012). Similarly, the role of associations between HRM practices and human factor in organizational performance has been studied in many ways and in different geographical regions. On the whole, the research results suggest the positive role both of the quality of human factor (Chen 2014) and HRM outcomes towards organizational performance results (Katou, Budhwar 2010). It becomes obvious that knowledge assets and employee competencies are becoming significantly important for a firm's performance and competitiveness. And because the entirety of human capital is held by employees it is the aim of management is to pass human capital in the form of employees' special skills on to a network of many people, where it is fertilized and transferred to the ownership of the company (Gomezelj, Antončič 2015). What is more, the

knowledge and experience of senior managers and the workforce are seen as valuable assets which are costly to replace or to rebuild (Brauer 2013).

However, the contribution to company's performance results through such HRM practices that make human factor a competitive differentiator on the market is much more complicated in multinational companies (MNCs) than in home organizations (Arora et al., 2018). The geographical spread of their foreign subsidiaries, their internationalization index, different local environment (economic, legal, political, technological, social etc.) (Bartelsman et al., 2019) with comparison the environment of the headquarter (HQ) are only a few examples showing the complexity in which MNCs have to operate (Kiselakova *et al.*2019; Díez-Esteban, 2019). For the MNCs understanding local environmental demands is of crucial importance in order to properly evaluate which kind of organizational practices their subsidiaries need to develop into high-performance entities. That is why they can find some of their human factor features and HRM practices remarkably important to their local performance success and in consequence impose some different policies (Berchtold 2010).

So far only a few studies have focused on the above mentioned phenomena in the MNCs headquartered in economies in transition or just after-the-transition, like those in Central and Eastern Europe (Festing, Sahakiants, 2013; Haromszeki 2014; Stor and Kupczyk 2015; Farndale et al., 2017). In most cases the research on MNCs has covered the companies deriving from developed countries (Albulescu et al., 2018; Cieślik, 2019) whose foreign direct investment (FDI) was located in less developed countries (e.g. Brewster, 2007; Morley et al., 2009; Wilkinson and Wood, 2017). In our research we are interested in such MNCs and in this context the main goal of the paper is to determine in what way the degree of HRM contribution to the MNC's performance results influences on the perceived value of human factor as a competitive differentiator on the market.

In consequence the paper is structured as follows. After this short introduction the authors discuss the theoretical background of the study based on a literature review. This results in building an empirical research model and formulation of the research hypotheses. Furthermore, the focus is on the research methodology, sample and measures. The empirical research findings and discussion over them come next. The article ends with a research summary and final conclusions.

The theoretical background of the study

The human factor as a competitive differentiator on the market

The companies may compete on different factors, as to mention quality of design or manufacturing, features and quality of service, price for each sale, profit margin, technology, reputation and of course human resources (Nasab et al. 2013; Karaszewski, 2013). However, it is human resources that are of the fundamental importance to business success and its ability to gain competitive advantage (Katou, Budhwar, 2010; Kearns, 2010) and which can be perceived as an extraordinary competitive factor of a company. This view has been developed within the resource-based theory for nearly 30 years (Barney, 1991; Dyer, 1993; Wright et al., 1993; Becker et al., 2001, Ingham, 2007; Huselid, Becker, 2011; Mayo, 2012; Juchnowicz, 2014).

Human resources can be grouped into various categories and usually this categorization refers to their owners, meaning employees (Kazlauskaitė et al, 2010) who possess different abilities, skills, knowledge, needs, professional backgrounds, etc. and thus may have varying responses to HRM practices. In the research and business practice human resources as a human competitive factor are usually disaggregated into two subfactors: non-managerial employees and managerial staff (Patel, Hamlin, 2012; Yoon, 2016) because of the different qualifications and competencies required from them (Sienkiewicz, 2014; Stor, 2014; Kupczyk, Stor, 2017; Doornich, 2018), a different range of responsibilities formulated toward these two groups and a different scale of consequences that their behaviors and decisions may bring to a company (Karaszewski, 2013; Haromszeki, 2014; Stor, Suchodolski, 2016; Anzengruber, 2017; Stor, Haromszeki 2019). So, it leads to a conclusion, which is taken for granted in the HRM literature, that the value of the human factor as a competitive factor is a resultant of the HRM practices they have experienced in the organizations. But the relationship can be reciprocal. A company may invest in HRM depending on how it perceives its contribution to

the company's success. And as the research on the MNCs' practice shows this may look differently depending which organizational level is considered. So far, we know that some significant differences within this scope have been identified between the HQs of MNCs and their foreign subsidiaries (Andersen, 1993; Stor, 2011; Latusek-Jurczak D. 2014; Żarnik-Żuławska, 2016; Delery, Roumpi, 2017).

The contribution of HRM to company's performance results

Empirical studies on the relationship between the HRM contributive practices and the company's performance results usually fall into one of the following categories: financial, organizational, managerial, and behavioral. The researchers use a vast array of various measures within each of them. The financial results can be presented, for example, as profits, sales, market share, financial liquidity, company's goodwill, share price, and firm value (Richey, Wally, 1998; Pfeffer, Veiga 1999; Arthur 1994; MacDuffie 1995; Huselid 1995; Becker, Gerhart 1996; Beatty et al., 2003; Combs et al., 2006). The organizational results may cover productivity, quality of products/services, efficiency, innovativeness, competitive advantage (Arthur, 1994; Huselid, 1995; Becker, Gerhart 1996; Huselid et al., 1997; Pfeffer, Veiga 1999; Birdi et al., 2008; Ferguson, Reio 2010; Sparrow et al., 2016; Paawe, Ferndale, 2017). The managerial results mostly refer to the interrelations and levels of coherence between business strategies and particular subfunctions of HRM with company's performance results (Beer et al., 1984; Schuler, Jackson 1987; Wright, Snell 1991; Guest, 1997; Chanda, Shen, 2009; Guest et al., 2011; Stor, Suchodolski 2016). The behavioral results include employee attitudes, employee engagement and satisfaction, employee and/ or managerial interpersonal relations, employee competency development, leadership (Nagy, 2002; Rich et al., 2010; Ferguson, Reio, 2010; Juchnowicz, 2014; Sparrow et al., 2016; Stor, Haromszeki 2019).

Furthermore, as it was mentioned in the introduction, some of authors focus on the overall HRM contribution to the company's performance results (Ginevičius *et al.* 2010), whereas others consider individual contributions of particular HRM subfunctions (Ridder et al, 2012). Additionally, some researchers are interested in the overall HRM practices directed to the overall human factor, while others consider only managerial staff. It is because managerial competencies differ from the competencies of other employees in a significant way (Haromszeki, 2013; Raziq, et al., 2020) and the companies dedicate some of their HRM subfunctions exclusively to their current or potential managers. It's worth emphasizing that the research has revealed that priority given to managers significantly affects organizational performance (Mabey, Thomson, 2000; Garavan, Heraty, 2001). Moreover, due to the linear association between managerial competencies and firm performance (Hughes & Rog, 2008), investment in managerial competencies is desirable, especially as their role in company's strategy creation and implementation is invaluable (Zakrzewska-Bielawska, 2019).

The assumption taken in the research model

The literature review and accompanying theoretical considerations have resulted in the empirical research model presented in Figure 1.

Fig.1: The empirical research model of relationships between contributive HRM and competitive human factor

Source: own concept

Accordingly, seven research hypotheses, that describe the relationships between the variables in the model, have been developed. They are as follows:

H_1: The higher the degree of the overall HRM contribution to the MNC's performance results, the higher the value of the overall human factor as a competitive factor.

H_2: The higher the degree of the overall HRM contribution to the MNC's performance results, the higher the evaluation value of non-managerial employees as a competitive factor.

H_3: The higher the degree of the overall HRM contribution to the MNC's performance results, the higher the evaluation value of managerial staff as a competitive factor.

H_4: The higher the degree of the individual HRM subfunctions' contributions to the MNC's performance results, the higher the value of the overall human factor as a competitive factor.

H_5: The higher the degree of the individual HRM subfunctions' contributions to the MNC's performance results, the higher the evaluation value of non-managerial employees as a competitive factor.

H_6: The higher the degree of the individual HRM subfunctions' contributions to the MNC's performance results, the higher the evaluation value of managerial staff as a competitive factor.

H_7: The higher the degree of the individual HRM subfunctions' contributions to the MNC's performance, the higher the degree of the overall HRM contribution to the MNC's performance results.

The Empirical Research Methodology

The research problem covered the identification and analysis of the relationships between the degree of HRM and its subfunctions' contributions to the MNC's performance results (independent variables) and the perceived value of human factor as a competitive factor (dependent variable). In the result of theoretical studies, we have built the empirical research model and formulated seven research hypotheses to be verified in the empirical research - presented in the previous section.

Dependent and independent variables have been considered in the context of the companies' financial performance results. Basing on the literature review 9 subfunctions of HRM have been selected as the most popular or valuable in business organizations. The appraisal of human factor as a company's competitive factor was split into two other subfactors: (1) non-managerial employees' skills and knowledge and (2) managerial staff's competencies. In the research we took a twofold perspective: 1) the global HQ's perspective in which the MNCs evaluate their worldwide (overall) HRM practices and overall human factor and 2) the perspective of their foreign subsidiaries in which they evaluate the particular HRM subfunctions and particular subfactors of human factor. The subfunctions, subfactors, measures and scales used to the particular variables incorporated in the tested hypotheses are presented in Table 1.

We have used two methods to collect the research data: CATI (computer aided telephone interview) and CAWI (computer aided Web interview). The questions were resided in the context of the last two fiscal years and the interviewer reminded the respondents of this context several times during the interview survey. The goal of this procedure was to ensure that the respondents were referring to a precisely outlined period of time in which they were able to logically assess the interconnections between HRM and business phenomena under study. The survey was conducted in January 2018. All calculations were made with the aid of Statistica v. 12.5 - an advanced analytics software package with the level of significance set to alpha = 0.05. To determine the normality of data distribution we used Kolmogorov–Smirnow test. To analyze the collected data both descriptive and correlational statistical methods were used. The relationships between the quantitative variables were tested by the means of Pearson correlation coefficient (referred i.e. Pearson's r).

The research sample was comprised of 200 headquarters of MNCs originating from a Central European country (Poland). They were nonfinancial economic entities, existing on the market no less than two years, with a dominant share of the Polish capital, which possessed at least one foreign subsidiary, and this subsidiary was an effect of a foreign direct investment (FDI). The reference base for the number of such organizations was the last report elaborated by the Polish Central Statistical Office. The report said that there were 1760 Polish companies which registered 4086 business entities in 150 countries in 2015 (*Activities of Enterprises...,* 2017). In consequence it was assumed that the size of a sample mentioned above is sufficient to conduct the research because when the confidence coefficient stays at the level of 0.95 the maximum measurement error amounts to 0.065.

The sampling was of the purposive type to meet the specified requirements. The structure of the research sample was diverse in terms of the companies' business profiles - according to the European Classification of Business Activity (ECBA) - although not all of the sectors of the economy were represented; length of operation in years; size of organizations (as measured by number of employees); type of FDI investment; and the ownership share of the HQs in their foreign subsidiaries. Furthermore, the MNCs under research differed in the number of total and foreign entities they controlled, number of host countries in which their subsidiaries were located, and level of country's development in which their most representative subsidiary operated. An average MNC operated on the market longer than 11 years, was rather a large organization, had about 13 entities, about 8 of them were foreign subsidiaries, located in 4 countries, established as greenfield investment with a majority ownership share belonging to the Polish HQ.

We assumed that some specific parameters, for example, an industrial area, size of the company, its legal form or country's economic development could influence the performance of businesses in the sample. However, the results of statistical testing did not demonstrate the impact of these parameters on business performance.

The Empirical Research Findings

Descriptive Statistics

The basic descriptive statistics for the variables connected with the main research problem are presented in Table 1. On average, the financial performance results of MNCs, when compared to their main competitors, are somewhere between "similar to others" and "above average" ($\bar{x} = 3{,}74$). So, their financial standing on average is good. The mean value of the overall human factor as a competitive factor is between "similar to an average" and "rather high" ($\bar{x} = 3{,}56$) with a $\bar{x}\,min = 2{,}74$ and $\bar{x}\,max = 4{,}44$. When this factor is analyzed by its two components their mean values are lower. The evaluation value of non-managerial employees is $\bar{x} = 3{,}38$ and of managerial staff is $\bar{x} = 3{,}39$. It's necessary to remind that the value of the overall human factor is not calculated as a mean of its two subfactors but with regard to the assumed perspective: global vs local subsidiaries. Anyway, the means calculated for each of them ranges from $\bar{x}\,min = 2{,}00$ to $\bar{x}\,max = 5{,}00$.

Table 1: Basic descriptive statistics for the main variables under study: contribution of HRM subfunctions to companies' performance results and human factor

VARIABLES		Valid N	Mean	Median	Min	Max	SD
Financial performance results		200,00	3,74	4,00	2,00	5,00	0,51
The overall human factor		200,00	3,56	3,61	2,78	4,44	0,35
Competitive factors	**1. Non-managerial employees**	200,00	3,38	3,00	2,00	5,00	0,67
	2. Managerial staff	200,00	3,39	3,00	2,00	5,00	0,62
The overall HRM contribution		200,00	3,56	3,56	2,78	4,78	0,36
The significance of HRM subfunctions	**1. Employee resourcing**	200,00	3,90	4,00	2,00	5,00	0,52
	2. Employee retention	200,00	3,53	3,00	3,00	5,00	0,67
	3. Engagement & satisfaction	200,00	3,32	3,00	2,00	5,00	0,61
	4. Performance appraisal	200,00	3,43	3,00	2,00	5,00	0,61
	5. Career development	200,00	3,55	4,00	2,00	5,00	0,57
	6. Talent management	200,00	3,53	4,00	1,00	5,00	0,62
	7. Competency management	200,00	3,57	4,00	2,00	5,00	0,61
	8. Development of leadership	200,00	3,45	3,00	1,00	5,00	0,61
	9. Employer branding	200,00	3,80	4,00	2,00	5,00	0,67

Scales:
- Performance results: comparison to the main competitors: 1 - poor, 2 – below average, 3 – similar to others, 4 – above average, 5 – very good;
- Competitive factor: with comparison to the main competitors: 1 - strongly lower, 2—rather lower, 3—similar to an average, 4—rather higher, 5—strongly higher;
- Significance (contribution) of HRM to performance results: 1 - not important, 2 – slightly important, 3 – moderately important, 4 – important, and 5 – very important;

Source: own research data

The degree of the overall HRM contribution to the company's performance results reaches the mean of $\bar{x}\,min = 3{,}56$. It means it's closer to "important" than to "moderately important". The means calculated for each of the individual HRM subfunctions' contributions range from $\bar{x}\,min = 3{,}32$ to $\bar{x}\,max = 3{,}90$. The *max scale value* is reached by all of them ($max = 5{,}00$), whereas the lowest by two, i.e. talent management and development of leadership ($min = 1{,}00$).

The research findings show that among 9 HRM subfunctions being analyzed the highest degree of contribution is ascribed to employee resourcing ($\bar{x} = 3{,}90$). The second position is occupied by employer branding ($\bar{x} = 3{,}80$) and third by competency management ($\bar{x} = 3{,}55$).The full ranking list is depicted in Graph 1.

Fig.1: The ranking of the mean values of the contribution of HRM subfunctions to companies' performance results

Source: own research data

Correlation Analysis

The results of the correlation tests (at $p<.05$) for the main research variables are presented in Table 2 and 3 respectively. The analysis proves that the degree of the overall HRM contribution is positively correlated with the value of the overall human factor as a competitive factor (r=.71), and with the evaluation values both of non-managerial employees (r=.22) and managerial staff (r=.35) as competitive factors. All this confirms three of our hypotheses, i.e. $\mathbf{H_1}$, $\mathbf{H_2}$ and $\mathbf{H_3}$.

As far as the degrees of the individual HRM subfunctions' contributions to the MNC's performance results are considered, apart from employee resourcing, all the other degrees of particular HRM subfunctions are positively correlated with the value of the overall human factor as a competitive factor. The range of values for the correlation coefficient of these variables is in the interval between r=.24 and r=.50, where the lowest value is gained by employee retention and the highest by development of leadership. So, our hypothesis $\mathbf{H_4}$ can be partially accepted.

In the case of the degrees of the individual HRM subfunctions' contributions to the MNC's performance results and their associations with the evaluation value of non-managerial employees as a competitive factor, five subfunctions reveal such statistically significant correlations, whereas four don't. Those correlated are: employee retention (r=.15), engagement & satisfaction (r=.24), performance appraisal (r=.22), career development (r=.14), and employer branding (r=.29). Interestingly, within those uncorrelated, there is employee resourcing again. Hence, our $\mathbf{H_5}$ can't be fully accepted. The range of its confirmation is even smaller than in the hypothesis $\mathbf{H_4}$.

Analyzing the relationships within the hypothesis $\mathbf{H_6}$ we observe that similarly to the relationships within the hypothesis $\mathbf{H_4}$, apart from employee resourcing, all the other degrees of particular HRM subfunctions are positively correlated with the evaluation values of managerial staff as a competitive factor. Here the range of values for the correlation coefficient of these variables is in the interval between r=.18 and r=.37, where the lowest value belongs to development of leadership and the highest to employer branding. Then, our hypothesis $\mathbf{H_6}$ can be accepted only to some extent as well.

Table 2: The results of a correlation test for the contribution of HRM subfunctions to companies' performance results and human factor

VARIABLES		The overall human factor	Competitive factors	
			1. Non-managerial employees	2. Managerial staff
The overall HRM contribution		**0,71***	**0,22***	**0,35***
The significance of HRM subfunctions	**1. Employee resourcing**	0,09	-0,05	-0,07
	2. Employee retention	**0,24***	**0,15***	**0,26***
	3. Engagement & satisfaction	**0,37***	**0,24***	**0,31***
	4. Performance appraisal	**0,48***	**0,22***	**0,15***
	5. Career development	**0,47***	**0,14***	**0,20***
	6. Talent management	**0,46***	0,14	**0,25***
	7. Competency management	**0,40***	0,07	**0,18***
	8. Development of leadership	**0,50***	0,06	**0,18***
	9. Employer branding	**0,47***	**0,29***	**0,37***
* Pearson's r significant at p < ,05000;				

Source: own research data

Finally, the correlation test conducted for the degree of the individual HRM subfunctions' contributions to the MNC's performance and the degree of such contributions of particular HRM subfunctions (see Table 3) shows all correlations being statistically significant. The weakest association at r=.24 concerns employee resourcing and the range of values for the correlation coefficient of the other subfunctions is in the interval between r=.51 and r=.64, where the lowest value is gained by employee retention and the highest by performance appraisal. Hence, our last analysis leads us to the confirmation of hypothesis $\mathbf{H_7}$.

Research Summary

In our research problem we were particularly interested in the identification and analysis of the relationships between the degree of HRM and its subfunctions' contributions to the MNC's performance results (independent variables) and the perceived value of human factor as a competitive factor (dependent variable). The visual juxtaposition of these two variable is depicted in graph 2.

Graph 2: The juxtaposition of human factor with relation to HRM and its subfunctions' contributions to company's performance result

Source: own research data

In summary it can be said that we have successfully identified some regularities within the scope of the selected variables and the analysis of the empirical research findings leads to the conclusion that the higher the degree of the overall HRM contribution to the MNC's performance results, the higher the value of the overall human factor as a competitive factor and the higher the evaluation values of its both subfactors, i.e. non-managerial employees and managerial staff. Additionally, what we've found is that the higher the degree of the individual HRM subfunctions' contributions to the MNC's performance, the higher the degree of the overall HRM contribution to the MNC's performance results. These relationships are true when considered from the global perspective, i.e. when the MNCs evaluate their worldwide HRM practices and the impact of these practices on the worldwide competitive value of their human factor as differentiator on the market.

However, when the associations are considered from the perspective of particular local subsidiaries and when HRM is disaggregated into its individual subfunctions, some different phenomena are observable. Firstly, employee resourcing is a subfunction that has no statistically significant correlations either with the overall human factor or with its two subfactors: non-managerial and managerial. The probable reason is that it is such a subfunction toward which it is difficult to indicate simple direct relationships between its contributive role in the company's performance results and then with its impact on the competitiveness of human factor. Even though the best people with the best qualifications and competencies are employed through a highly advanced selection process, it takes time to evaluate if their exhibit competitive attributes in business practice. Moreover, the value of their competitive attributes, if any at all, may be the resultant of other HRM subfunctions, not selection itself. This raises a question if employee selection should be evaluated for its contribution to company's performance at all, and if so, it seems to be questionable to evaluate it in the same way as other HRM subfunctions.

Excluding employee resourcing from the analysis, the other interesting phenomena appears in the juxtaposition of the correlations between the particular HRM subfunctions' contributions and two subfactors of human factor. The positive relationships between the degree of the subfunctions' contributions and both the value of the overall human factor as well as the evaluation values of managerial staff are visible, whereas in the case of non-managerial employees not all of their evaluation values correspond with HRM subfunctions. Because this refers to talent management, competency management and development of leadership, the possible reason may come from the fact that in business reality these three subfunctions may be dedicated rather to the managerial staff than

to other employees. Although in their nature and assumptions they should cover not only current but also potential managers, meaning ordinary employees, they may be not adjusted enough to the real employees' needs. It means that at the intentional level, which is formulated at the HQ of MNC, it looks much better than when it is considered at the implementative and resultative level of local subsidiaries. Hence, the effectiveness of these three HRM subfunctions in competition on non-managerial employees on the market is doubtful. It seems that intentions deviate from the practice. But it also suggests that there may be a mediating variable or even a few variables that intermediate the casual relationship between the dependent and independent variables. In our study we have applied some simplified statistical correlational analysis which is not dedicated to such type of investigation. Hence, as about the future research we would recommend to look for some mediating variable(s) that may explain in details or discover new ties between the variables under study.

Final Conclusions

Our final conclusion based on the analysis of the empirical research findings suggests that there is a clear, identifiable relationship between the degree of HRM contribution to the MNC's performance results and the perceived value of human factor as a competitive differentiator on the market. Of course, there are some exceptions or differences when the overall HRM contribution or its particular HRM subfunctions' contributions are juxtaposed with the overall human factor or its two subfactors, but it leads to another important conclusion. Namely, the organizational level of measurement, whether it is the HQ's or local subsidiary's – changes both the degree of HRM and its subfunctions' contributions as well as the perception of the value of human factor and its two main components. We believe that all this authorizes us to state that the goal of our paper has been achieved. We have successfully determined in what way the degree of HRM contribution to the MNC's performance results influences on the perceived value of human factor as a competitive differentiator on the market.

We think our research results are a kind of accomplishment but it is not devoid of some limits. Primarily, the final conclusions can't be extended on the whole population of MNCs worldwide because the research sample, even though deliberatively selected, was composed only of those MNCs that were headquartered in one Central European country. Furthermore, although the sample was diverse in terms of the companies' business profiles, not all sectors of economy were represented. Some other imperfections are also noticeable in the measurement scales or the calculations based exclusively on the mean values. Yet the other reservations may concern asking the informants the general questions about the HRM contribution to the company's performance results or about the competitive value of human factor instead of using hard performance indicators. This practice is not at odd within this type of research, however it may undermine the subjectivity of evaluation.

However, all in all our study contributes to the scientific discipline of management. On one side, as said above, MNCs headquartered only in Central Europe make a limit to the generalizations, but on the other side they provide a unique perspective. To our best knowledge, it's been the first research of this type. We have also confirmed the phenomena - identified by other researchers as mentioned in the introductory part of the paper - that there is a positive relationship between the dependent and independent variables under study.

As for the practical implications of the research results, they mostly rely on indicating that if there is a strong positive relationship between the HRM contribution (including its subfunctions) to company's performance and the value ascribed to the human factor (including both managerial and non-managerial employees), then we can expect that the effectiveness of HRM practices is high and they bring desired results. Then, there is a huge potential and opportunity in using HRM subfunctions in more effective and efficient way that will lead to better company's outcomes, having of course in mind that that HRM is only one of the factors that determine such outcomes. Anyway, the presented research findings may help the managers of MNCs and their local subsidiaries uncover some hidden opportunities existing in the management practices at different organizational levels and inspire them to create such subfunctional ties between HRM and company's performance which can successfully impact their managerial and non-managerial employees' competitive advantage.

Changes in The Length of Financial Statements Prepared According to The International Accounting Standards By the Largest Capital Groups in Poland

Piotr PREWYSZ-KWINTO

WSB University, Torun, Poland
piotr.kwinto@wsb.torun.pl

Abstract

In recent years, a significant increase in the length of financial statements has been observed. It is caused by numerous changes in accounting standards regarding the disclosure of information that occurs as a result of dynamic changes taking place in the global economy. The aim of this paper is to present the results of the own study on changes in the length of financial statements prepared according to the International Accounting Standards and by the largest capital groups listed on the Warsaw Stock Exchange in the period 2012-2018. In the quantitative analysis, techniques of descriptive statistics and statistical tests of significance were used. The obtained results allowed for positive verification of research hypotheses posed in the study concerning the increase in the number of pages of financial statements in the period 2012-2018 and the dependence of the length of the financial statements on the size of the entity preparing it.

Keywords: Financial Statement, Accounting Regulations, IAS/IFRS.

Introduction

Financial statements constitute a basic form of communication between an entity and its environment, and they are the main source of information about an entity's operations. Those statements become more and more extensive as a result of dynamic changes observed currently in today's economic reality and leading to among others the emergence of particularly complex forms of conducting activity or concluding more and more complex transactions by entities. It is also a consequence of the changes in the financial reporting standards regulating the rules of their preparation. The standards adapting to the changes in the economic reality require presenting and disclosing a bigger amount of information.

The aim of this paper is to present the results of a study concerned with the changes in the length of financial statements of the biggest capital groups listed on the Warsaw Stock Exchange (WSE) prepared in accordance with the solutions found in the International Accounting Standards (IAS) and International Financial Reporting Standards (IFRS). For the purpose of the conducted study, the two following study hypotheses were formulated:

H1: The length of the financial statements of the biggest capital groups listed on the WSE increased in the years 2012-2018.
H2: The length of the financial statements depends on the size of a capital group which prepares it.

The set goal was achieved by analysing the available source literature and the results of international studies conducted in this field. The verification of the formulated study hypotheses was based on a quantitative analysis of the information included in the financial statements of the biggest capital groups listed on the Warsaw Stock Exchange, i.e. of its two main indices: WIG20 and mWIG40. In the quantitative analysis of the achieved information, the methods of descriptive statistics and statistical tests of significance were used.

The study consists of two parts. The first presents the most significant aspects concerning the increased extensiveness of financial statements prepared in line with the international financial

reporting standards. In the second part, the results of the conducted study concerning the change in the number of pages of financial statements and verifying the formulated study hypotheses are presented

The extensiveness of financial reports – the theoretical and practical background

The rules of preparing and presenting financial information were regulated in detail in the IAS 1 *Presentation of Financial Statements*, which was adopted in August 1997 for the first time and replaced three other standards, i.e. the previous IAS 1, IAS 5 and IAS 13 (Lis 2014). In accordance with paragraph 10 of IAS 1, a complete set of an entity's financial statement consists of two parts. The first one includes basic components, i.e. a statement of the financial position, a statement of profit or loss and other comprehensive income, a statement of changes in equity, and a statement of cash flows, which synthetically present information concerning an entity's assets and the sources of their financing, income and costs or proceeds and expenses. Understanding of the figures included in the basic components requires their more detailed presentation and discussion. They can be found in the additional information, which constitutes the second, particularly important and also the most extensive part of each financial statement, which results from the fact that the additional information is supposed to provide information necessary for the understanding of the statement. Therefore, they are not only explanatory notes for the entries included in the basic components, but also a detailed presentation of the rules of preparing a financial statement used by an entity defined as an accounting policy.

The fact that the additional information constitutes the longest part of a financial statement arises from the detailedness and extensiveness of the information that needs to be disclosed. It is also the factor determining the number of pages of the whole document. The reports prepared regularly by the international consulting company Deloitte (2013-2019) and concerning business reports of British listed companies show that from 2012 to 2016, an average number of pages of a financial statement increased by 13%, i.e. from 56 to 61 pages, and to 2018 it increased by as much as 22.2%, i.e. from 54 to 66 pages. An average number of pages of an annual report, which apart from a financial statement included additional, also non-financial information, increased by as much as 60.7%, from 107 to 172 pages. The results obtained by Deloitte are confirmed by a study conducted by another international network of audit and advisory company – KPMG (2014,2016). In 2016, an average number of pages of a financial statement determined on the basis of data from 270 entities from all over the world increased when compared with 2014 by 16.2%, i.e. from 74 to 82 pages. An average length of an annual report increased in the same period by 23.6% (from 165 to 204 pages). A steady increase in the extensiveness of financial reports is also confirmed by international scientific studies. It was demonstrated by among others M. Lang and L. Stice-Lawrence (2015) when analysing the number of words in 15,000 financial statements of companies from 42 countries from all over the world for the period from 1998 to 2011. The median of the number of words increased in the studied period by 114%, i.e. from 11,611 in 1998 to 24,860 in 2011. T. Dyer, M. Lang and L. Stice-Lawrence (2017) received very similar results analysing the text of annual reports required by the US Securities and Exchange Commission (SEC) for the period from 1996 to 2013. The analysis indicated an increase in the number of words in the median of the studied companies by 113%, i.e. from about 23,000 in 1996 to almost 50,000 in 2013.

Increased requirements as regards the disclosure of information are considered to be the main reason for the increase. It results from a constant introduction of new or a modification of existing international accounting standards owing to the changing and more and more complex economic reality. This is confirmed by the results of international studies. The impact of using international accounting standards on the increase of the length of financial statements was indicated by among others M. Morunga and M. E. Bradbury (2013) and M. Lang and L. Stice-Lawrence (2015).

It should be emphasised, however, that the increased length of financial statements following the necessity to disclose the information in connection with all the financial reporting standards does not have to lead to the increase of its usefulness. Such an opinion was given by among others H.

Hoogevorst, who, in June 2013 at a conference in Amsterdam, said the following: *Financial statements swell up like balloons; however, the amount of useful information does not grow just as fast* (Turulska, Wambier, Żyliński 2017). Users find it more difficult to locate appropriate information in a longer and longer financial statement, and the less important information can distort the important information. What is more, as A. Jurewicz (2011) emphasized, the disadvantage of too detailed disclosures is extensive additional information, which requires a knowledge of finance and accounting, also time to draw conclusions regarding the evaluation of an entity's financial situation from a user.

The abovementioned problems concerning the increase in the length of financial statements became a stimulus for conducting a study verifying whether they also referred to the capital groups listed on the Warsaw Stock Exchange. The methodology of the study and the obtained results are presented further in the study.

The study methodology and characteristics of studied group

The study covered 60 biggest capital groups listed on the Warsaw Stock Exchange, i.e. those that on 1st July 2019 comprised the two main indices: WIG20 and mWIG40. The analysis, however, covered only those entities which prepared financial statements in accordance with the IAS/IFRS during the whole examined period of time, i.e. from 2012 to 2018. 55 met this condition. The other five (all comprising mWIG40) in 2012 were not listed on the Warsaw Stock Exchange yet or did not prepare financial statements in line with IAS/IFRS, but in accordance with the national financial reporting standards, i.e. the Accounting Law. The comparative analysis took into account only the consolidated statements prepared for operations in 2018 financial year or a financial year finished in 2018, and consolidated statements for year 2012 or finished in 2012 if the balance-sheet date was other than 31st December. The capital groups included in the study represented different sectors, which is presented in detail in table 1.

In the studied group, the entities representing the financial sector (banks and insurance companies) constituted the biggest part – 22%, those from the chemical industry (including the fuel sector) and the Information Technology industry – 9% each. The "Others" category includes capital groups representing the hotel, media, transport and other service industries.

Table 1: Studied capital groups by the type of conducted activity

Sector	Number of companies	Share
Automotive	2	3.6%
Chemical and Fuel	5	9.1%
Construction	4	7.3%
Electromechanical	3	5.5%
Energy	4	7.3%
Financial services	12	21.8%
Food	2	3.6%
Information Technology	5	9.1%
Metal	3	5.5%
Mining	3	5.5%
Retail and wholesale	4	7.3%
Telecommunication	2	3.6%
Other	6	10.9%
Total	**55**	**100.0%**

Source: own work.

The Results of The Conducted Study

The study started with establishing whether the number of pages of financial statements prepared by the studied capital groups grew following the trend presented above[1]. The obtained results show that an average number of pages of a financial statement prepared for the year 2018 amounted to 104.8 with a standard deviation of 43.8. It was increased by 13.4 pages (14.7%) when compared with the year 2012, when it amounted to 91.3 with a standard deviation of 32.8 Therefore, the obtained results confirm the hypothesis formulated in the introduction concerning the number of pages of financial statements. For the statistical verification of the formulated hypothesis one-tailed test of significance of two means for dependent variables was conducted – the same studied group but the data come from two different periods of time. When constructing assumptions for the test, H_0 hypothesis was formulated and it proposed an equal average number of pages in the year 2018 (m_1) and 2012 (m_2) ($m_1 = m_2$), and H_1 hypothesis was formulated proposing that the mean from the year 2018 was bigger ($m_1 > m_2$). The verification of the formulated hypothesis was conducted with the use of Student's *t*-test. The calculated value of the t-statistic amounting to 3.175 led to rejecting H_0 hypothesis in favour of H_1 with the level of significance of $p<0.002$. It means that an average number of pages of financial statements prepared in 2018 is significantly statistically higher than in the year 2012.

The number of pages of financial statements was also analysed taking into account the size of the studied capital groups measured with regard to which index they belong to – to WIG20 (the biggest capital groups) or to mWIG40 (the smaller ones). In the year 2018, an average number of pages of the capital groups of WIG20 amounted to 121.7 and was increased by almost 17 pages when compared with the year 2012, when it amounted to 104.8. For the smaller groups, it increased from 83.6 in the year 2012 to 95.1 in 2018, that is by 11.5 pages. An average number of pages of financial statements of the big groups increased by 16.5%, and the smaller ones by 13.5%. The increase appeared to be statistically important, which was confirmed by the one-tailed tests of significance of two means constructed similarly to the test conducted earlier for the whole studied group. The value of the Student's *t*-statistic amounted to 1.77 for the entities from the WIG20 index and 2.83 for those from the mWIG40 index. The statistical significance was therefore confirmed with the level $p<0.05$ for the groups from the WIG20 index and $p<0.004$ for those from the mWIG40 index. The conducted tests of significance for the whole studied group and for the bigger and smaller groups separately confirmed that an average number of pages of financial statements prepared in the year 2018 was significantly statistically bigger, which allowed a positive verification of H1 hypothesis formulated in the introduction of the study.

When analysing the number of pages of financial statements of the studied groups, it should be underlined that the difference between them was significant. In the year 2018, the most extensive statement was prepared by the PKO BP bank and it consisted of as many as 225 pages. The least extensive was, however, a statement of the Livechat Group, and it had only 34 pages. For comparison, in 2012 the most extensive financial statement was presented by ING BŚ (188 pages), and the shortest of only 30 pages, was prepared by the Sanok Group. Therefore, the difference between the longest and the shortest financial statement in 2018 amounted to as many as 191 pages, and in the year 2012 – 152 pages. The existence of significant differences in the length of financial statements of the studied entities confirms the high standard deviation calculated earlier for the data from the two periods of time.

The conducted analysis also included comparing an average number of pages calculated for the big groups from the WIG20 index and the smaller ones from the mWIG40 index separately. In the year 2018, an average number of pages of financial statements of the big groups amounted to 121.7 and therefore it was by 26.6 pages higher than those from the mWIG40 index. It means that the financial statements of the big capital groups were longer by 28% on average. In the year 2012, the difference was slightly smaller. It amounted to 21.2 pages, that is the financial statements of the big groups were longer by a quarter (25.4%). For the statistical verification of the obtained results, two one-tailed tests of significance of two means for independent variables were conducted for the year 2018 and 2012 separately. When constructing the test statistical test confirming the difference in the number of pages of the statements of the capital groups from WIG20 and mWIG40, hypothesis H_0 was formulated

proposing equal means ($m_1 = m_2$), and H_1 hypothesis proposing a higher mean for the WIG20 groups ($m_1 > m_2$). The verification of the formulated hypothesis was conducted with the use of Z-test, and additionally, for the purpose of comparing the results, also with Student's *t*-test. The obtained results of the relevant statistics and their statistical significance are presented in table 2.

Table 2: The results of the tests of significance concerning the differences of an average number of pages of financial statements between the capital groups from the WIG20 and mWIG40 indices

Value of	2018	2012
Z-statistic	2.068	2.470
p <	0.019	0.007
t-student statistic	2.032	2.451
p <	0.024	0.009

Source: own work.

The results presented in table 2 allowed rejecting H_0 hypothesis in favour of H_1 in both studied periods of time, which confirms that a statistically significant difference can be observed between the number of pages of financial statements of the groups of the WIG20 and mWIG40 indices. The presented results, therefore, confirmed the H2 hypothesis formulated in the introduction of the study proposing the influence of the size of an entity on the length of a prepared financial statement.

The observed changes in an average number of pages of financial statements taking into account the size of an entity encouraged a more detailed analysis. Its objective was to verify whether all the studied entities lengthened their financial statements in the analysed period, or whether there were those whose financial statements shortened. The obtained results presented in graph 1 demonstrate that the length of the financial statements of all the entities changed but an increase was not seen in all the cases.

Figure 1: The change in the number of pages of financial statements of the studied capital groups.

Source: own work.

Figure 1 demonstrates that in the financial statements of the two thirds of the studied groups (67.3%),the number of pages increased and 32.7% it decreased. The increase in the number of pages concerned 65% of the big groups of WIG20, the decrease concerned 45%. In the case of the smaller groups, for those from the mWIG40 index it was 68.6% (an increase) and 31.4% (a decrease) respectively. The most significant absolute increase in the number of pages was observed in the financial statement of the PKO BP Capital Group – as many as by 100 pages (from 125 to 225), and the biggest decrease concerned the PKP Cargo Capital Group, whose consolidated financial statement shortened by 39 pages (from 105 to 66). As far as relative changes are concerned, the most significant increase in the number of pages was seen in the financial statement of the Bogdanka Capital Group –

by as much as 177.4% (from 46 to 100 pages), and the biggest relative decrease concerned also the PKP Cargo Capital Group – by 37.1%.

Due to the fact that the change in the number of pages of particular financial statements was different, the studied entities were divided into four groups. The first group included those whose financial statements changed (lengthened or shortened) insignificantly, i.e. by up to 10%, in the studied period. The second group comprised the entities whose statements changed in the number of pages by from 10 to 25%, the third one included those for which the change amounted from 25 to 50%. The entities for which the change in the number of pages was the most significant, i.e. over 50%, belonged to the last group. Then the quantities established for the individual groups were changed into proportions and the obtained results are presented in table 3.

Table 3: The proportions of the studied capital groups taking into account the change in the number of pages of their financial statements

change of number of pages	groups from WIG20		groups from WIG40		Total	
	N	%	N	%	N	%
up to 10.0%	4	20.0%	5	14.3%	9	16.4%
10.01% - 25.0%	5	25.0%	11	31.4%	16	29.1%
25.01% - 50.0%	7	35.0%	15	42.9%	22	40.00%
above 50.0%	4	20.0%	4	11.4%	8	14.5%
Total	**20**	**100.0%**	**35**	**100.0%**	**55**	**100.0%**

Source: own work.

The obtained results indicate a significant variability of the changeability in the number of pages of financial statements both for the whole group and taking into account the big and smaller entities separately. The obtained results are confirmed by the high standard deviation presented earlier. In the studied period of time, the number of pages of financial statements changed the most often, i.e. in 40.0% of the cases from 25 to 50%. The share of the capital groups with a small change – by up to 10% and with a big change – by over 50% was similar and amounted to about 15%. Attention should be drawn to the fact that in the case of the big groups of the WIG20 index, the changes in the number of pages were similar to those of the mWIG40 index. For about 55% of the entities in each of the groups, financial statements changed their length by about a quarter, and in the case of the other 45%, the change was not higher than 25%. It is worth pointing out that the changes in the number of pages spread more evenly among the groups from the WIG20 index than among those from the mWIG40 index. The presented results show that although an average number of pages of financial statements increased in the studied period by 14.7%, the length of individual statements changed much more dynamically. It can indicate that an average number is not the best reflexion of the changes in the length of financial statements.

An analysis was also conducted taking into account the groups whose statements were shortened or lengthened separately. In the first group (a decreased number of pages), a decrease in the number of pages of a financial statement was noted in the range between 25 and 50% the most often (44.4% of the cases), and it was 57.1% of those from WIG20 and 36.4% from mWIG40 respectively. No case with a decrease in the number of pages of over 50% was noted.

In the other group (an increase in the number of pages), an increased number of pages in the range between 25 and 50% was also observed the most often (37.9%). The financial statements which increased their length by up to 10% constituted only 10.8%, but as much as 21.6% of the studied entities lengthened their financial statements by over 50%. Such a situation concerned 30.8% of those from WIG20 and 16.7% of those from mWIG40.

Conclusion

The results of the quantitative analysis of the length of financial statements of the biggest capital groups listed on the Warsaw Stock Exchange in the period of time from 2012 to 2018 presented in the study led to a positive verification of the two study hypotheses formulated in the introduction. An average number of pages of financial statements prepared for the year 2018 was significantly statistically higher than that of the same groups prepared for the year 2012. Identical results were obtained taking into consideration all the studied capital groups and conducting a separate analysis taking into account their size measured by their belonging to the WIG20 index or mWIG40 index. Therefore, the obtained results confirmed the results of the international studies conducted in this field. Similarly, the financial statements of the bigger groups (from the WIG20 index) proved to be significantly statistically longer than those of the smaller groups (from the mWIG40 index) in both of the studied periods. In the year 2018 the difference in an average number of pages between the studied groups amounted to as much as 28%, and in 2012 – 25%.

It is also worth emphasising that although an average number of the pages of financial statements increased, the increase did not concern all the analysed capital groups. In the case of one third of them, the number of pages was decreased. It can indicate that an average number is not the best reflexion of the changes in the length of financial statements. Moreover, the length of individual financial statements changed quite dynamically, which is confirmed by the high standard deviation. The changes were observed in the range from 25 to 50% the most often.

Due to the fact that the study covered only the biggest capital groups listed on the Warsaw Stock Exchange, which represented different sectors, an analysis of the changes in the length of financial statements taking into account the conducted activity was not possible. However, answering the question whether a correlation between the number of pages of financial statements and the type of activity exists would be an important aspect from the point of view of a complete assessment of changes in the length of financial statements. Such an analysis shall be conducted in a separate study.

Footnotes

[1] The analysis was conducted on the basis of the actual number of pages of a financial statement without taking into consideration the typesetting, i.e. the font size, the type space between lines or the number of lines.

Evaluation of the military Integrated Multi-level Information System supporting the management of logistics in the Polish Armed Forces as the determinant of the country's military security

Slawomir BYLEN

Military University of Technology, Warsaw, Poland
slawomir.bylen@wat.edu.pl

Abstract

According to experts in the field of military security, effective management and leadership of a large organisation, which is undoubtedly the Ministry of National Defence (MND), is not possible today without a well-functioning information system, especially a logistical one, which includes IT tools supporting the management of military resources. The recognition that the state of computerisation of MND in the area of logistics, human resources and finance is archaic and the growing need to ensure military security in the new geopolitical conditions contributed to the development, implementation and exploitation of the Integrated Multi-level Information System (IMLIS) of the Polish Armed Forces. The paper presents the genesis of implementation, the current state of work on IMLIS and prospects for development of this system. The article describes, among other things, the organization of the implementation process, basic functionalities of the system, as well as the prospects of development of new functionalities as of 2019. According to the author, a particularly important value of the article are the results of research related to the evaluation of the IMLIS information system in terms of the impact on the quality of the military logistics system management and related to the evaluation of its functionality from the point of view of employees (users) operating the system.

Keywords: Military Security, Management of The Military Logistics System, Logistic Information Systems.

Introduction

The progress in the field of computerisation of contemporary economic processes in the 21st century forced the necessity to implement significant changes in the field of information technology support for the logistic system in organizational units of the Ministry of National Defence. The IT systems used in the 20th century to support the management of personal and material resources have become inefficient and their adaptation to contemporary realities became physically and economically unjustified and often even impossible. Efficient management of the possessed potential and resources, which was managed and was at the disposal of MBUs (Military Budget Units) required modern support solutions by implementing a unified IT system.

At that time, the freedom to implement specific IT solutions led to the occurrence of various material resources management systems (IT SYSTEM MAG-MAT, IT SYSTEM “LOGIS”) or human resources management systems (IT SYSTEM “ETAT”, IT SYSTEM “WAKAT”, IT SYSTEM “SPIRALA”), which often were duplicating the same activities and processes, and at the same time were mutually exclusive (Byłeń, 2016). These software applications (named the domain software applications) were not integrated with each other, which often resulted in the presentation of disparate data, particularly in terms of establishing the true states of resources and means, and led to the duplication of functions of the systems themselves, through various interpretations of the data entered. As a result, instead of providing IT support to the processes for effective logistics and financial management by the managerial staff, including above all the commanders and administrators of these resources, disinformation and unreliability in the interpretation of the presented states in registers of personnel and material resources, especially inconsistencies in the field of appropriate systematization in terms of classification and availability, was occurring. The registers kept this way resulted in

unreliable accounting and reporting, which resulted in incorrect material and financial planning at various levels and inefficient management of resources.

Genesis of implementation and general characteristics of the Integrated Multi-level Information System

In order to meet the needs of computerization in the Polish Armed Forces, a decision was made to build and implement a centralized, integrated and unified IT system supporting the management of logistics, finances and human resources. The objective defined within the works was primarily to provide a tool supporting the entire process of managing the resources of the Ministry of National Defence, regardless of the level of execution of individual tasks. The specific objectives of implementation are to:

- provide reliable and up-to-date information on the resources of the Polish Armed Forces;
- provide IT support for the processes of management and logistics management of the Polish Armed Forces;
- replace old systems in order to improve logistics, human resources and financial processes (new technologies, integration);
- ensure confidentiality and security when accessing data.

The following assumptions of the IMLIS system should be considered crucial:

- standardization of processes within the whole ministry,
- one integrated register of resources.
- integration of resource management processes (economic events are registered by the persons performing them, one-time data entry).
- on-line reporting.
- reduction of the number of reports, data transferred between cells and units.
- simplification of activities performed in resource management processes.

The target solution was also to ensure data exchange between IMLIS and C4ISR systems used in the Polish Armed Forces and within NATO and EU. In addition, the system should ensure communication with national systems (e.g. with the systems of Tax Offices, Social Insurance Institution, etc.). The role of the integrated logistics system in the Polish Armed Forces and the possibilities of cooperation with IT systems of the non-military system of the state and IT systems of NATO and the European Union are presented in Figure 1.

Fig. 1: Role of the system and scope of collaboration of IMLIS system with other IT systems of the Polish Armed Forces

Source: (MND 2017).

Whereas, within the framework of cooperation with domain IT systems in logistics, finance and human resources, the IMLIS system currently cooperates with IT systems exploited in the Polish Armed Forces, which are presented in Figure 2.

Fig. 2 :Environment and cooperation of the IMLIS system with the domain systems of the Polish Armed Forces

Source: Materials of the IT Inspectorate, (MND, 2017).

The IMLIS system is built on the basis of solutions offered by SAP (Auksztol, Balwierz, Chomuszko 2012), namely SAP ERP (Enterprise Resource Planning) version 6.0, which, as part of its basic functionality, includes a comprehensive package of IT solutions for management in business enterprises (Fig. 3).

Fig. 3: Integrated Multi-level Information System implementation technology

Source: (MND, 2017).

Legend: Logistyka (Logistics), Rachunkowość (Finances), Zarządzanie kadrami (Human Resources Management), Funkcje międzyaplikacyjne (Inter-aplication functions).

SAP ERP is a software package that contains a full spectrum of IT solutions, i.e. both the transaction system (SAP R/3 or SAP ECC), in which all operations are carried out, as well as the data warehouse, portal, mobile devices support (palmtops, radio terminals) and integration and programming tools (ABAP, JAVA) (Bogusz, Ślęzak, 2015, p. 49). The architecture of the system allows for a flexible modification and the incorporation of new modules depending on the requirements - its creation for specific MBUs needs.

The SAP R/3 system has a modular structure. Each module provides support in a specific area of the organization's activity. The implementation of the SAP R/3 system can take place in stages, during which the functionalities concerning individual modules are activated. There is a strong emphasis on

inter-module integration, which provides an integrated and comprehensive approach to the functioning of large economic organisations. Among all the modules, the key modules implemented in the first place should be distinguished, such as FI "Financial Accountancy", MM "Materials Management" and HR "Human Resources Management". For the purposes of implementations requiring modification or extension of the standard software, the ABAP Workbench application development environment is prepared (Fig. 4).

Fig. 4:Functional architecture of the Integrated Multi-level Information System
Source: (Ścięgosz, 2017.

The basic functionality of the IMLIS system includes processes supported by the following modules: FI (Financial Accounting), FIFM (Budgetary Accounting), FI-AA (Fixed Assets), CO (Controlling), MM (Materials Management) (FM 2014). Subsequent modules will be used as the IMLIS MND System develops and do not have to be incorporated simultaneously at all locations where the system operates (MND 2018).

In addition to process analysis, the modules of IMLIS MND System are based on previously identified basic data (MND 2007a and 2007b):

- Uniform Material Index, i.e. an ordered way to describe products used in the Ministry of National Defence;
- Single Company Account Plan, containing a list of synthetic accounts common for the entire MND and the accounting schemes of economic operations;
- dictionary data on human resources management (by military specialities).

Inspection, verification and evaluation of the Integrated Multi-level Information System based on survey results

The objective of the research was to determine the degree of influence of the military logistics IT system on the quality of logistics management on the scale of the Polish Armed Forces and its impact on the integration of logistics processes with financial and human resources. The practical objective was:

- to study the impact of IMLIS MND System on the efficiency of the work of the system users;
- to identify the strengths and weaknesses of the IMLIS MND System (assessment of the functionalities);
- to verify the assessment of the training system of system operators (examination and assessment of the quality of training of system users (persons operating the system) and meeting their expectations regarding the organization of trainings of system operators;
- to find directions for the development of the system, so that the occurring information flows can support the processes of managing the army's logistics system as effectively as possible.

Due to the issues raised and the methodology adopted in the study, it was decided to obtain data by means of a diagnostic survey carried out by means of a survey technique. The research covered users of the IMLIS MND System with the 2RBLog and 3 RBLog systems. The survey was attended by 565 respondents, of which 74% were women (420 persons) and 26% men (145 persons). Fig. 5 shows the division of respondents by gender.

Fig. 5: Division of respondents by gender

Source: own analyses.

The way the research was conducted was important from the point of view how to select the right test sample. The sampling methodology for empirical research indicates which methods are most effective and how to calculate the minimal sample size so that the research can be representative. To calculate the necessary sample size (nb), the following data are needed: the size of the population that is of interest to the researcher (N), a statistically calculated indicator (Z), which is taken as a default value of 1.96 for significance level p = 0.05 and an error rate of maximum 4%. In the author's opinion, the adopted sample size seems to be even oversized. Table 1 shows the number of active accounts of IMLIS MND System by location of workstations together with the number of surveyed account users.

Table 1: Number of active user accounts of the Integrated Multi-level Information System

No.	User of IMLIS MND IT system	Number of active accounts	
		RLB X	RLB Y

11.	Telecommunications Section	3	5
12.	Upbringing Section	2	3
Total	Military Base Command	165	201
Total	Depots and workshops	527	422

No.	User of IMLIS MND IT system	Number of active accounts	
		RLB X	RLB Y
Active accounts in total		692	623
Respondents [persons] in total		127	438
Respondents [%] in total		18.3	70.3

The in-house elaboration.
Legend: RLB – Regional Logistics Base.

The summary presented in Table 1 shows that out of 1315 active accounts in Regional Logistics Base X and Regional Logistics Base Y of the IMLIS MND system, almost 43% of users (565 people) were surveyed. According to the division into workplaces of the respondents, most people work in military economic entities (air bases or war port commands) 425 (75.0%), followed by soldiers and employees of regional logistics bases 105 (19.0%). Division of respondents by place of work (Figure 6).

Fig. 6: Division of respondents by place of work

Source: own analyses.

Legend: PMC (Port Military Command), AB (Air Base), GSU (Garrison Support Unit), RLBase (Regional Logictics Base), LogBde (Logistic Brigade).

Among the users expressing their opinions, 206 people (36%) are IMLIS MND users over 6 years, 108 people (19%) 4-6 years, 182 people (32%) work with the system for 1-3 years, 70 people (13%) work under one year. Division of respondents by the duration of using IMLIS MND system (Fig. 7).

Fig. 7: Division of respondents by length of service

Source: own analyses.

The most numerous group among the participants of the survey were 205 people working over 6 years (36%), followed by 182 people working from one to three years (32%), 108 people working 4-6 years (19%) and 70 respondents working under one year (13%). From the above list, there is a high degree of stability in the positions held, and consequently high competence and great skills in handling IMLIS MND. The next question concerned the division of respondents by their position in the military unit (Fig. 8).

Fig. 8: Division of respondents by their position in the Polish Armed Forces
Source: own analyses.

Another criterion for the selection of respondents concerns the division of respondents into personnel groups (Fig. 9).

Fig. 9: Division of respondents by their membership in the military and labour force group
Source: own analyses.

From the diagram presented in Figure 9 it follows that the basic group of people serving the IMLIS IT system are civilian employees of the army (the official name is the employees of Ministry of National Defence).

Apart from the 7 metric questions, related to getting to know basic information about the research group, the survey defined primarily 10 substantive questions. They are presented in Table 2.

Table 2: The list of subject matter questions concerning the evaluation of the Multi-level Information System

Question No.	Question	Expanded question
1.	Please assess the impact of IMLIS on the quality of logistics information management in the army.	Will it positively influence the quality of accounting and planning of army resources?
2.	Please evaluate IMLIS capability to ensure data security in the system.	It is concerned with database protection, availability of system resources, availability of network, shared information, certificates, etc.).
3.	Please evaluate the user-friendliness of data entry into the IMLIS.	Does the IMLIS have sufficient and clear instructions and manuals for operating and entering data into the system?
4.	Please evaluate the technical support of the IMLIS.	How does the IMLIS "Helpdesk" support system work?
5.	Please evaluate the process of indexation of tangible products in favour of implementing the IMLIS.	Has the assignment of the Uniform Material Index to defence products in the MND had a positive impact on the implementation of the IMLIS MND?
6.	Please evaluate the overall suitability of IMLIS.	Refers to the degree of suitability of IMLIS for electronic accounting and military resources.
7.	Please evaluate the reliability of IMLIS.	Is the System characterized by high failure rate? Does the system allow for assistance with regard to reported errors?
8.	Please evaluate the performance of the IMLIS.	Refers to the response time of the system to an entered command, data transfer, labour consumption of data entry and validation).
9.	Please evaluate the usefulness of the IMLIS.	It refers to ease of use, ease of navigation in the system, speed of switching to other options, comprehensibility of entered data, etc.
10.	Please evaluate the functionality of the IMLIS.	Are all real subsystems and functional areas of military logistics represented in the system?

The in-house elaboration.

The survey form was developed using closed and semi-open questions. The first type is characterized by the fact that the respondent made the right choice from specified answers. The questions are aimed at answering the questions concerning the main research issues. In addition, some of them have been supplemented with an option of own response of the respondent. Such questions have had an option of presenting own evaluations, due to no possibility to list all possible solutions. It was decided to develop design survey form in such way owing to the complexity of the surveyed issues. It was not possible to create an easy to understand form containing all possible options at once. Thanks to such design, the survey is universal by nature and each respondent could be treated individually. The intention of such design of survey form was to obtain information on the evaluation of the implementation and exploitation of the IMLIS MND System used by the Polish Armed Forces. In the article, due to its scope, the results of the research are limited to answering mainly questions 1 and 10 and to assessing the quality of training of the IMLIS system users.

The research shows that the majority of respondents positively assess the impact of implementing the IMLIS system (answers to questions 1, 3, 4, 5) on the quality of management and directing the logistics system (Fig. 10).

Fig. 10: Evaluation of the impact of the implementation of the IMLIS system on the management of logistics information in the Polish Armed Forces
Source: own analyses.

The answers presented in the figure (Fig. 10) show that the respondents evaluate positively the implementation of the system and its impact on the management of logistic information in the armed forces, 76% positive answers (40% YES, 36% RATHER YES). At the same time, a large percentage of people (18%), who do not have an opinion on the impact of the implementation of the system on the quality of management (directing) of the logistics system, seems to be wondering.

The second area covered by the survey was the evaluation of functionality of Integrated Multi-level Information System (Fig. 11).

Fig. 11: Assessment of the functionality of the Integrated Multi-level Information System
Source: own analyses.

The functionality of the system was considered in terms of its simplicity, ease of use, consistency, flexibility, ability to interact with other systems and expanding the ability to connect subsequent modules. The results of the research presented in the graph show a positive evaluation of the IMLIS System by the respondents (49%), including a very good evaluation by 9% of the respondents and a good evaluation by 40% of the respondents. This is all the more important as only 5% of the users among them have a negative opinion of its functionality.

However, comparing the answers to questions 1 and 10, concerning the assessment of the impact of the implementation of the IMLIS MND on the quality of management of the military logistics system with the assessment of the functionality of the IMLIS system, one can notice significant differences in the answers (Fig. 12). Logically, it seems difficult to explain. However, after an in-depth analysis, significant differences in terms of questions can be identified. The first question concerns a group of general questions, not directly related to the evaluation of the system, and the second question belongs to the group of specific questions, directly related to the experience of operating the system and the existing deficiencies during its operation.

Fig. 12: General assessment of the suitability of IMLIS MND for the evaluation of two basic qualitative and functional characteristics

Source: own analyses.

From the above list it follows that there is a particularly large difference in the answers "very good" (31%) for the impact of the system implementation on the quality of management in relation to the system functionality. The total difference between "very good" and "good" answers was 27%. Negative answers ("sufficient" and "unsufficient") make 20% of the answers as regards the functional assessment and 10% of the answers concerning the management quality assessment. This demonstrates the need to intensify efforts to implement further functional modules into the IMLIS MND, which are currently not present in the system, or the IMLIS MND does not have the capacity to interact with other IT systems implemented in the MND.

Another area of research was the evaluation of the scope and manner of conducting trainings as regard exploatation of the IMLIS (Fig. 13).

Fig. 13: Evaluation of the quality of the system operation trainings of Integrated Multi-level Information System users

Source: own analyses.

The results of the survey conducted among 70 employees of the Administrative Department of the Ministry of National Defence (Supreme Audit Office 2016) presented in Figure 13 show that users of IMLIS MND System have a particularly negative opinion of the complex operation of the system (67% of responses) and point out that the training courses do not meet the expectations of improving their operation skills (53%). Next among the training negatives is the evaluation of the level of training 58% (sufficient) and 22% (inadequate) of the training programme, due to the fact that the training programme was not adapted to the needs of the position held. A significant percentage of negative evaluations relate to the scope of trainings. In the opinion of 46% of the respondents, the scope is too narrow and in the opinion of 21% of responders the scope is too wide. The other area of research was the assessment of the organization of trainings on exploitation of the IMLIS MND (Fig. 14).

Fig. 14: Evaluation of the quality of the system operation trainings of IMLIS MND users
Source: own analyses.

On the basis of the answers received, the respondents postulate to include, when organizing future trainings for the IMLIS system users, such aspects as: adapting training programs to the needs of users at a given position 62% of the answers, extending the training time 21%, the need to direct people having similar skills in the program operation to a given training - also 21%. In addition, 10% of the respondents pointed the need to increase the number of training hours (practical training) and 21% mentioned the need for training providers to stop rushing. After training in the operation of the system and a year's work in the IMLIS system, 54% of the respondents indicated that they were able to efficiently navigate in the System. In turn, 24% of the respondents stated that they had mastered the system on a poor level.

Benefits and directions of development of the Integrated Multi-level Information System

For the first time in the Polish Armed Forces the solution, which is fully integrated, was implemented. The implementation of the IMLIS system has brought many benefits, which should be considered not only in terms of technological advancement. Undoubtedly, the replacement of technology, which has not been developed for many years, with modern solutions is a quantum leap forward in the field of computerization of the ministry. However, this implementation should not only be seen as a change of tool, but also as a stage of optimisation of management processes at all levels of management and command.

The benefits of the system implementation are (MND 2013a and 2013b):

- having one central database of resources;
- unified resource management processes;
- having logistical information available on line and on demand;
- a single data entry into the system (avoiding duplication of economic events);łe
- universal access to information on resources;
- the main source of knowledge (data) about the resources held by the ministry;
- consistency of the technology platform;
- integration of functional divisions of the Ministry of National Defence.

However, an unsolved problem remains the insufficient number of analysts, designers and programmers of IT systems. This problem exists because specialists in this field are required to have interdisciplinary knowledge: knowledge of technology, knowledge of the implementation of integrated solutions, knowledge of the so-called business, i.e. the way the ministry functions and knowledge of the course of processes at all levels in a computerised environment (Cirulis, Ginters 2013; Kisielnicki, Sroka 2005; Klimek 2005).

The experience gained during several years of implementation of IMLIS system is an invaluable guide for many cells responsible for functioning of the computerization system not only for military logistics, but for the entire ministry. Among the most frequently mentioned problems that have been encountered so far, one should mention:

- lack of standardisation of processes within the whole ministry;
- unordered data in the "old" logistics register systems;
- significant delays in preparing data to be migrated;
- the lengthy process of comparing data on resources possessed;
- lack of sufficient reliability of the registers kept;
- lack of effective and efficient supervision over the course of system implementation.

Discussions and Conclusions

The implementation of IMLIS system in logistics provides real-time information management, automation of processes in the areas of planning, acquisition, recording, operation and monitoring of logistics resources and enables the exchange of information for the needs of the logistics management subsystem in the Polish Armed Forces (MND 2014).

Once fully operational, the IMLIS system will undoubtedly be the irreplaceable tool for a professional army, especially the tool supporting the processes of military logistics management and logistical information management. In the future, once the IMLIS system has reached its full potential, military commanders will be provided with a powerful tool that will enhance the process of making key decisions. Military commanders will be equipped with knowledge of capabilities they have at their disposal, soldiers, their weaponry and their ability to act. Moreover, military commanders will also be able to accurately estimate the costs of the planned operation. This is the purpose of the integrated multi-level IT system of the Ministry of National Defence IMLIS system, which has been being built in the army over the last decade.

Conclusion and recommendations to improve the functionality of the system IMLIS, resulting from the study:

1. The modules in the sphere of financial and budgetary accounting, i.e. in the chief accountant's division, are fully functional.
2. The new modules in the logistics division are at the final phase of implementation.
3. The biggest backlog is in the implementation of human resources modules, which in the future are intended to cover the whole issue of the human resources division.

4. The challenge in achieving full system capacity is undoubtedly the aspect of connecting (cooperating) various IT systems being currently outside the IMLIS system, which were created in the past, but their ability to have compatibility was not taken into account.
5. The process of training system operators should be improved by including in the organization of future training of system users such aspects as:

   - adaptation of training programs to the needs of users in a given position;
   - extension of training time;
   - referring to training people with similar skills in operating the program;
   - increasing the number of training hours (practical training);
   - not hurrying by trainers.

Now all the units, which perform the functions of economic entities, work in this system (Wróbel 2017). Currently, according to the data presented by the IT Inspectorate, every day between 2,000 and 2,500 users work with the logistics modules of the system and they input new business events to IMLIS system.

According to military security experts, it is important to look at the future of IT systems supporting the management of military logistics and logistical information in MND not through the prism of technological solutions but by ensuring the security of data and information about the resources held by limiting access to the system to outsiders and unauthorised persons.

Abstract

In paper, we consider the development results of educational technologies at university level for wildfire risk management while climate change as part of environmental economics. While studies, we used methods of data bases constructing within digital educational platforms, web-technologies and virtual reality tools. Now, we see digital transformation of university education, due to new concepts of obtaining and presenting educational materials. We use digital educational platforms, which integrate heterogeneous hardware and software resources with the use of web-technologies in distributed networks and wide application of cloud services. As digital educational platforms, we propose to use Google Classroom. Widely, we use remote sensing databases for educational purposes within wildfire risk management. We consider the issues of digital content creation within university education, essentially in practical training. We present the enlarged groups of practical works in this area. For data exchange and preliminary discussion while research, we used platform https://www.researchgate.net/profile/Valery_Abramov2/.

Keywords: educational technologies, wildfire, risk management, environmental economics

Introduction

Last time, a digital transformation, named Industry 4.0, extends in the global economy, during which a lot of enterprises plan and implement wide spectrum of information technologies (Baikov, 2019), (Bidenko, 2019), (Drabenko, 2019), (Frolova, 2019), (Lukyanov, 2019). This leads to serious technological changes in natural risk management (Berboushi, 2014), (Ershova, 2018), (Garcia, 2018), (Isaev, 2015), (Istomin, 2018), (Shilin, 2019), including wildfire (Targino, 2019), which requires the development of new educational technologies, especially for university level (Popov, 2019).

In the article, the authors describe the development results of digital transformation technologies for university practical learning (UPL) in geo-information management area (Burlov, 2018), (Fokicheva, 2016), (Fokicheva, 2015), (Istomin, 2015), (Lednova, 2014), (Malakhova, 2014), in large environmental projects (Mandryka, 2019), (Popov, 2014), (Popova, 2019), (Rumyantseva, 2017), (Zhigulsky, 2018) within environmental economics (Chusov, 2019), (Golosovskaya, 2014), (Karlin, 2014), (Karlin, 2009), (Popov, 2016). Significant attention in the implementation of such industrial projects should be paid to geo-information support of natural risk management in the context of climate change (Mikheev, 2019), (Bournashov, 2014), (Gogoberidze, 2014), including the issues of information collection and processing (Fokicheva, 2019), (Khaimina, 2014), (Popova, 2019), (Tatarnikova, 2019), (Ya, 2019). The educational technologies, discussed in this article, take these factors into account.

Methods and data

In research, we used: methods of data bases (DB) constructing in case of digital educational platforms (DEP), web-technologies (WT), big data technologies (Novikov, 2019), (Sokolov, 2019), geo-information technologies (Veretennikov, 2019), (Yaily, 2019) and virtual reality (VR) tools. Also, we used Foresight technologies, theory of decision making under uncertainties (Palkin, 2019), risk management approach. From the point of view of geo-information management, we structured geo-space to allocate the interconnected components of the solution space (Istomin, 2015). While study, we used data bases and tools of digital online platform EOS (DOP EOS) eos.com, which contains space images from the Landsat-8 and Sentinel-2 satellite systems.

Results

While our research, we developed digital educational technologies (DET) for implementing university practical learning (UPL) in the field of wildfire risk management. We gave preference to the use of digital educational platforms (DEP) that integrate heterogeneous hardware and software resources with the use of web-technologies in distributed networks and wide application of cloud services (Popov, 2019). As DEP in our work, we used Google Classroom. Its main advantages are ease of use, universal access, flexible feedback system and its free of charge. This DEP usage eliminates a system administrator because of Google servers implementing, and also a content Manager because each teacher is responsible for the content of his course (Popov, 2019).

While development of digital content within UPL in the field of wildfire risk management while climate changes we used the decomposition as a technique in the preparation of the methodological basis. On Fig. 1, we present the enlarged groups of practical works in the field of wildfire risk management:

1) problem statement in wildfire management;
2) field works on data collection for wildfire risk management;
3) processing and analysis of the data for wildfire risk management;
4) preparation of geographical information system (GIS) layers and creating digital maps within wildfire management;
5) decision-making in the framework of geo-information support of wildfire risk management.

Figure 1: Enlarged groups of practical works within UPL in the field of wildfire risk management while climate changes

While our work, we developed digital content of practical works within UPL in the field of wildfire risk management while climate changes for all above-mentioned groups (fig.1), using freely distributed recording program CamStudio, a microphone and a camera to record the lecturer's explaining the individual sections.

As essential DEP in the field of wildfire risk management while climate changes, we propose to use DOP EOS eos.com, that provides efficient tools for searching, processing, and analyzing large amounts of satellite data from the Landsat-8 and Sentinel-2 satellite systems. Usage of DOP EOS allows to find and use satellite images of forest areas with wildfires zones for training purposes, to determine the location of these fires and to assess their main spatial characteristics (linear and area dimensions), which are the main initial parameters for conducting wildfire struggle measures within wildfire management while contemporary climate change era. Let's go to example. In figures 2-4, we show the sequential training operations performed for the largest wildfires in Australia in the fall of 2019 with using of DOP EOS. Date of space images is 3rd September 2019, region Australia. For Australia's wildfire period in 2019, we analyzed images of Landsat 8 and Sentinel-2 satellite systems, using DOP IOS. We obtained the pictures in the figures 2-4, using DOP EOS's data bases and tools, and combining on one image the first and second mid-infrared (1566-1651 nm and 2107-2294 nm, respectively) and red (636-673 nm) channels, which allowed to identify the wildfires zones on combined space image as reddish colored areas on greening plane.

Figure 2: Combine space image with wildfire zones (reddish colored areas), general view by DOP EOS (Australia region, 3rd September 2019)

Figure 3: Enlarge image of wildfire area and measuring its characteristics

Figure 4: Enlarge image of other wildfire area and measuring its characteristics

As essential result, we propose the usage of DOP EOS tools to estimate the linear size of wildfires zones and their areas for training purposes.

Discussion

The essential task of university practical learning (UPL) in the field of wildfire risk management is to teach students the practical aspects of work with DOP EOS tools, which requires a developed learning base in special geo-information systems (GIS) laboratory. In some cases, real practical work in special GIS laboratory can be undergoes with virtual reality (VR) technologies (Popov, 2019), that can reduce total cost of learning process.

Results of study can be useful for goals of geo-information management to large space-distributed projects, including forestry and emergency management, within the environmental economy while climate change.

Conclusion

In the article, we present the results of digital transformation technologies development for We present the results of digital transformation technologies development for UPL in the field of wildfire management with using the DOP EOS eos.com. We paid the main attention to the UPL, which are useful for goals of geo-information management to large space distributed projects, including forestry emergency management, within the environmental economy while climate change. When choosing a digital educational platform (DEP), we prefer Google Classroom. Widely, we use remote sensing databases for educational purposes within wildfire risk management. We consider the issues of digital content creation within university education, essentially in practical training. We present the enlarged groups of practical works in this area. We point out that the application of the developed UPL technologies will significantly reduce the cost of training of technical specialists, partially replacing the expensive stages of training with virtual reality simulation. The right combination of virtual reality simulation and usual practical training activities will improve the teaching quality and the training level for university students. Results of study can be used for learning purposes in forestry and emergency management within the environmental economy while climate change.

Acknowledgment

While study, associate professor Nikolay Popov, head of geo-information systems laboratory in Arctic and Subarctic Institute at the Russian State Hydrometeorological University, gave us very useful consulting. The platform https://www.researchgate.net/profile/Valery_Abramov2/ gave us excellent opportunities for preliminary discussion and data exchange while this research.

Abstract

The article is devoted to the analysis of types of innovations created by modern enterprises. The first part of the article includes selected theoretical aspects relating to the concept of innovation and types of innovation defined in the literature. Around the various definitions and concepts of innovation, the most common definitions of innovation appearing in the literature are indicated. Although the issue of innovations and types of innovations are areas of research interest for both scientists and practitioners, a research gap in identifying types of innovations created by modern enterprises has been noticed. This area became the leading theme of the empirical study presented in the second part of the article. The aim of the study was to identify the types of innovations created by the selected enterprises. For this purpose, innovations were divided, according to their typology, adopted in the literature into: product, technology, market and organizational. The field of research interest was not only social innovations related to changes in motivational techniques. To achieve this goal, we ask the following research questions: What types of innovations do the selected enterprises most often implement? What is the scope of implemented innovations in the selected enterprises? Key results from the study are presented in the second part of the article.

Keywords: Innovation, Businesses, Types Of Innovation

Introduction

Contemporary enterprises that strive to be competitive show "the ability to efficiently achieve goals on the market arena of competition" (Stankiewicz, 2002). Only enterprises that can create and distribute innovations have such ability (Haffer, 2008). The level of enterprise innovation determines the level of its competitiveness. It can be concluded that in the modern global economy one of the main driving forces of competitive enterprises and developing countries is innovation.

The essence of Innovation - A General Theoretical Framework

Literature on innovation is both extensive and diverse. Zalewski (2007) emphasizes that it includes the work of authors who present different approaches and have different professional experience, thus shaping the wealth of definitions. However, it is worth quoting the approach of J. A. Schumpeter (1912), whose work had a significant impact on the theory of innovation. On the basis of economic sciences, he formulated 5 cases in which new combinations of various natural elements and human productive power, i.e. innovation, appear. He distinguished types of innovations such as (Schumpeter, 1960):

- creating a new product or placing on the market goods with new properties, i.e. one with which customers are not yet familiar, or a new type of good;

- the introduction of a new production method, i.e. a method that has practically not yet been tried in a given branch of industry, and this method may not rely on a new scientific invention, e.g. a new sales method of dealing with a given good;
- the opening of a new outlet, i.e. a market in which a given branch of industry from a given country has not been introduced before, regardless of whether the given market previously existed or not;
- acquiring a new source of raw materials or semi-finished products, regardless of whether the source previously existed or was just created;
- carrying out a new organization for some industry, e.g. the creation or liquidation of a monopoly.

Innovation in J. A. Schumptere's reasoning is treated very widely. It covers not only technical activities but also economic undertakings, e.g. gaining new markets, changing organization. It is worth noting, however, that J. A. Schumpeter's theory arose at the beginning of the 20th century and referred to the capitalist economy typical of that period. At that time, elements such as land, capital and production were of fundamental importance. Information and knowledge were less significant in the functioning of companies. The end of the 20th century, in turn, introduced changes in this approach. Factors such as intellectual work, knowledge and information have gained more importance. Even now they decide on the development of a given organization, its competitive position. Nowadays, innovations are the practical implementation of ideas, knowledge or discoveries that are based on both business abilities and ingenuity.

Similar views to J. A. Schumpeter are shared, among others, by I.A. Allena, E.M. Rogers and P.R. Whitfield (2003, 1979). According to I.A. Allen (1996) is an innovation that introduces new products, processes or practices to widespread use. Everett M. Rogers (2003) recognizes that innovation is an idea, practice or object that is perceived as new by the person or other host entity. In addition, Rogers emphasizes that it does not matter when it comes to human behavior, whether the idea is objectively new, measured by the passage of time from the first use or discovery. The cognitive novelty of the individual's idea determines the response to it. If the idea seems new to the individual, it is an innovation. Percy R. Whitfield (1979) defines innovation as a series of complicated solutions to solve problems, resulting in a comprehensive, completely developed novelty.

Currently, the development of knowledge, science and technology tends to increase complexity. It results in the fact that the introduced innovations are more and more complex and thus more difficult to define. According to the approach of P. Drucker (1992) and A. Pomykalski (2001), they are a multi-dimensional and complex process in which various fields of science and technology are involved. T. Sierotowicz (2007) claims that on the one hand, a single innovation affects various branches of the economy, and on the other, the use of many fields of knowledge and techniques in one innovation increases.

Contemporary enterprises strive to become or remain innovative in an increasingly complex market environment (Crossan, Apaydin, 2010). To this end, they are developing new approaches and tools that combine many aspects of the innovation ecosystem. New business models indicate that modern organizations should create, integrate and develop knowledge in the innovation process not only in internal structures, but also in cooperation with the external environment (Ritala, Hurmelinna-Laukkanen, 2013). Nowadays, knowledge as a source of competitive advantage has become dispersed and available in new forms of information and communication technologies (ICT).

Typology of innovation in the OECD methodology

There are many typologies of innovation in literature, but the most frequently cited is the classification according to the Oslo Manual developed by the OECD and Eurostat (2005). Innovations are seen as an evolving process in which new or significantly improved products or processes replace existing ones. Therefore, this theoretical approach distinguishes four types of innovation, they are:

- product innovation,

- process innovations,
- organizational innovations,
- marketing innovations.

Product innovations refer to changes in products and services. We are talking here not only about creating a completely new product or service, but also about introducing significant improvements in existing products or services. Product innovation is considered to be "the development of a new application for a product with only minor changes in its technical specification" (OECD, 2005). Therefore, changes within product innovations concern functions that a product or service provides to customers. These include the creation of completely new products but also the improvement of those currently used. In the literature, the terms product innovation and product innovation are used interchangeably, hence these two terms are also used in this paper.

There are several definitions in the literature related to product innovations. The first is that product innovation is the implementation of a product or service that is new or significantly improved in relation to its features and applications. We are talking about significant improvements in technical terms, materials and components, as well as ease of use, embedded software, or other functional features. All these changes lead to the company being able to better meet the clients' needs. Therefore, product innovations refer to changes in the way a given product or service affects the customer (Bogdanienko, 2004). An example of product innovation is the introduction of "breathable fabrics". In this case, the changes consisted in the use of new materials that improved the performance of the existing product (i.e. clothing).

A comprehensive approach to defining **process innovations** is presented in the OECD Handbook (2005). Accordingly, process innovations also known as process innovations relate to the introduction of a new or significantly improved production or delivery method. These include changes that affect technology, software or devices. By introducing process innovations, companies can reduce unit costs of production, increase production, quality or provide new or significantly improved products. It is emphasized that process innovations relate to changes in methods and the production process in such a way as to achieve greater efficiency, faster processing, higher throughput, while reducing costs.

Innovations within processes can also include:

- changes in delivery methods (relating to the company's logistics and covering devices, techniques and software that is used to obtain production means, deliver finished goods or allocate resources);
- new or significantly improved methods of creating and providing services (consisting of changes in the scope of software and hardware that is used in service companies, or changes in the techniques and / or procedures used to provide services);
- new or significantly improved techniques, software, and organization of ancillary activities of an enterprise such as accounting or IT**.**

The use of a new, organizational method, which has not been used in the organization so far and which is the result of strategic actions taken by management, is referred to as **organizational innovation**. The implementation of the new organizational method can refer to both the principles of operation adopted by the company, to the company's relations with the environment, and to the organization of the workplace (OECD, 2005). From this definition it follows that there are three basic categories of organizational innovations, they are:

1) organizational innovations regarding the general organization of the company (in the scope of operating principles adopted by the company),
2) organizational innovations regarding the organization of the workplace,
3) organizational innovations regarding relations with the external environment.

Marketing innovations are "the introduction of a new marketing method involving significant changes in product design / construction or in packaging, distribution, promotion or price strategy" (OECD,

2005). A change in the design / construction means any change in the appearance and form of the product that does not affect its functional or usable features. Also includes product packaging changes. In turn, new marketing methods for product distribution are mainly based on the implementation of new sales channels in the company. With the exception of logistics methods, such as storage, transport or handling. Marketing innovations in product distribution also include the introduction of new ways of displaying products. On the other hand, changes in product promotion include the use of new ways to promote products or services.

Innovations Created By Modern Companies – Selected Results Of Empirical Research

Methodology

The study of the types of innovations created by enterprises began literature studies, which allowed to isolate the main types of innovations created in enterprises. The results of this stage of work allowed the development of a research tool, which was a questionnaire. The survey among 150 companies was preceded by a pilot study carried out in order to justify the choice of proposed research methods and control of designed research tools.

The survey of enterprises was started in early August 2018 and covered 1000 enterprises. The sampling procedure combined elements of simple random selection with elements of targeted selection. The questionnaire was posted on the website. Access to the questionnaire was sent by email to representatives of the companies surveyed. The final maneuverability of the questionnaires after the study was completed was 15%, in the number of 150 correctly completed questionnaires. The analysis of enterprise research results was made using the Microsoft Excel 2016 spreadsheet. In turn, special computer software (CATI Support) was used to draw individual units selected for the study.

Bearing in mind the need to adapt to editorial requirements, selected empirical material illustrating the activity of enterprises in individual areas of innovation covered by the research was presented in various configurations.

Key Test Results

Product Innovations

The product innovations implemented in the last five years concerned products previously manufactured, completely new products and products that are patented inventions or contain them. The structure of innovative activity in this respect in the studied time period is shown by the data summarized in Table 1.

Table 1: Business product innovations in the last five years

Variable	n	%
Introduction of absolutely (absolutely) new products	54	36
Modernization of products previously manufactured	64	42,7
Technological modification of previously manufactured products	36	24
Introduction of new products imitating competitors' products	15	10
Patenting inventions	3	2

Source: own study based on the study.

Declarations of enterprises that their product innovations concerned products previously offered by them definitely prevailed. Significantly more often, these products were modernized (42.7% of indications) than technologically modernized (24.0%). In this case, we can talk about a certain conservatism in the innovation policy of the surveyed companies, in which a greater emphasis on discounting already proven solutions, but given in a "new package" rather than on the search for new challenges brought by technological changes.

Significantly less frequently studied enterprises have introduced new products to the market in the past five years. This group of product innovations includes the activities of introducing absolutely new products (36.0%) and introducing new products that are imitations of products manufactured by competitors (10.0%).

The structure of product innovations of the surveyed enterprises in the last five years was also analyzed, as signaled earlier, also due to their industry membership is presented in Table 2.

Table 2: The business industry of the company, and the introduction of innovation over the last 5 years

Variable	Enterprise business											
	Other service activities		Industrial processing		Accommodation activities		Professional and scientific activities		Wholesale and retail trade		Information and communication	
	n	%	n	%	n	%	n	%	n	%	n	%
Introduction of absolutely (absolutely) new products	18	38,3	15	38,5	5	29,4	5	31,3	5	55,6	3	37,5
Modernization of products previously manufactured	13	27,7	24	61,5	7	41,2	9	56,3	2	22,2	4	50
Technological modification of previously manufactured products	7	14,9	11	28,2	4	23,5	7	43,8	1	11,1	2	25
Introduction of new products imitating competitors' products	2	4,3	7	17,9	0	0	2	12,5	2	22,2	1	12,5
Patenting inventions	2	4,3	0	0	0	0	0	0	0	0	1	12,5

Source: own study based on the study.

In terms of product innovations, the surveyed companies prefer improved versions of previously manufactured products, it can be seen that this regularity applies to the greatest extent to the industrial processing industry: modernization of previously manufactured products - 61.5%, but only 28.2% of innovations consisting in their technological modification).

Innovations consisting in the modernization of existing products concerned 50.0% of product innovations declared by enterprises in this industry, while those involving technological modifications - 25.0%. The average of both indicators amounted to 37.5% and was significantly lower than for the industries discussed above.

The least innovative in terms of product innovations consisting in the improvement of existing products turned out to be enterprises conducting other service activities as well as wholesale and retail trade enterprises.

The highest rate of implementation of absolutely new products was recorded in the wholesale and retail trade - 55.6% of the total declared innovations of this type in this industry. Implementations of products imitating competitive products were twice lower in this industry, and their indicators amounted to 22.1%.

Technological Innovations

Technological innovations have been conceptualized just like product ones. Hence, similarly to the latter, innovations related to the implementation of new technologies (own or imitation used by competitors), related to the modernization of previously used technologies and related to obtaining patents for them can be distinguished. Empirical data on product innovations are summarized in Table 3.

The surveyed enterprises, regardless of belonging to a criterion group and the frequency of choosing a given option, most often pointed to innovations related to the modernization of previously used technologies.

The technological innovation most preferred by the surveyed enterprises in the last five years was the modernization of previously used technologies. Technological innovations consisting in obtaining patents for own technologies played a marginal role in this respect.

Table 3: Technological innovations introduced by the company over the last 5 years

Variable	n	%
Introduction of absolutely (absolutely) new technologies	36	24
Modernising previously used technologies	100	66,7
Introduction of new technologies imitating technologies used by competitors	19	12,7
Patenting technology	6	4

Source: own study based on the study.

Empirical material related to product innovations ordered according to the industry criterion of the surveyed enterprises is presented in Table 4.

The surveyed enterprises, regardless of the industry, preferred technological innovations in the past five years, consisting in improving previously used technologies. To the greatest extent this concerned enterprises from the information and communication industry - 87.5%. The activity rate for enterprises conducting professional and scientific activity was not much lower - 81.3%.

In the past five years, the surveyed enterprises were showing significantly less activity in implementing technological innovations consisting in introducing new technologies imitating competition solutions.

On the other hand, enterprises operating in the field of accommodation - 11.8% and the information and communication industry - 11.1%.

Table 4: The company's business industry and the introduction of technological innovations over the last 5 years

Variable	Enterprise business											
	Other service activities		**Industrial processing**		**Accommodation activities**		**Professional and scientific activities**		**Wholesale and retail trade**		**Information and communication**	
	n	**%**	**n**	**%**	**n**	**%**	**n**	**%**	**n**	**%**	**n**	**%**
Introduction of absolutely (absolutely) new products	17	36,2	6	15,4	5	29,4	1	6,3	3	33,3	1	12,5
Modernising previously used technologies	31	66	28	71,8	9	52,9	13	81,3	4	44,4	7	87,5
Introduction of new technologies imitating technologies used by competitors	2	4,3	7	17,9	1	5,9	4	25	2	22,2	0	0
Patenting technology	2	4,3	1	2,6	2	11,8	0	0	1	11,1	0	0

Source: own study based on the study.

The surveyed enterprises, regardless of the industry, preferred technological innovations in the past five years, consisting in improving previously used technologies. To the greatest extent this concerned enterprises from the information and communication industry - 87.5%. The activity rate for enterprises conducting professional and scientific activity was not much lower - 81.3%.

In the past five years, the surveyed enterprises were showing significantly less activity in implementing technological innovations consisting in introducing new technologies imitating competition solutions.

On the other hand, enterprises operating in the field of accommodation - 11.8% and the information and communication industry - 11.1% showed the most active in implementing patented technologies.

The empirical material obtained during the research regarding technological innovations was also analyzed due to the territorial scope of the surveyed enterprises. Data related to this issue are summarized in Table 5.

Table 5: Territorial scope of the company's activities and the introduction of technological innovations over the last 5 years

Variable	Territorial scope of the company's activities							
	European market		**Domestic market**		**Local market**		**Global market**	
	n	**%**	**n**	**%**	**n**	**%**	**n**	**%**
Introduction of absolutely (absolutely) new technologies	6	40	12	15,1	15	33,3	2	50
Modernising previously used technologies	12	80	62	72,1	23	51,1	3	75

Introduction of new technologies imitating technologies used by competitors	2	13,3	10	11,6	7	15,6	0	0
Patenting technology	0	0	2	2,3	4	8,9	0	0

Source: own study based on the study.

Enterprises operating on the Global (50%) and European (40%) markets are more often implementing absolutely new technologies than those operating on the Local markets (33.3%) and Domestic (15.1%). Less frequently studied enterprises have implemented innovations in the past five years consisting in the introduction of new technologies, but imitating competitive technologies.

However, the most preferred technological innovations in the past five years were, as in the previous case, innovations consisting in the modernization of previously used technologies. To the greatest extent this concerned enterprises operating on the European market (80%), and in slightly smaller enterprises operating on the Global (75,)% and Domestic (72.1%) markets. Significantly less often such innovations were used by enterprises operating on the Local market (51.1%).

Market Innovations

Market innovations, generally speaking, are related to the enterprise's activity directed at the target market, the one where it is already present and new, including new segments of the current market on which it intends to enter. Empirical material illustrating the material scope and scale of activity of the surveyed enterprises related to given innovations is presented in Table 6.

Table 6: Market innovations introduced by the company over the last 5 years

No.	Variable	n	%
1	Creation of new product brands	29	19,3
2	Creation of new after-sales services	33	22
3	Development of new price policy instruments	35	23,3
4	Creating new distribution channels	24	16
5	Entering new market segments	44	29,3
6	Entering new markets geographically	12	8
7	Development of new forms of promotion	58	38,7
8	Creating new packaging	14	9,3
9	Creating new market needs	25	16,7
10	Gaining access to new raw materials, components, cooperative elements, etc.	6	4

Source: own study based on the study.

In the past five years, the most frequently surveyed enterprises reached for innovations consisting in the implementation of new forms of promotion - 38.7%, and significantly less - 29.3% - for innovations aimed at entering the new market segments on which they were already present.

The surveyed enterprises showed by far the least activity in the area of market innovation in the last five years in activities aimed at gaining access to new production components, raw materials or components - 4%.

Table 7: The industry branch of the enterprise and the introduction of market innovations in the last 5 years

Variable	The branch of business activity											
	Other service activities		**Industrial processing**		**Accommodation activities**		**Professional and scientific activities**		**Wholesale and retail trade**		**Information and communication**

Source: own study based on the study.

The above data allow to speak about a kind of specialization of the surveyed enterprises in the area of market innovations depending on the industry. The surveyed companies belonging to various industries introduced market innovations consisting in the creation of new after-sales services. The professional and scientific industry has not created after-sales services in the past five years. None of the industries, except for other service and manufacturing activities, implemented innovations aimed at increasing the geographical scope of their activities. New packaging was introduced only by industrial enterprises - 30.8%, information and communication - 12.5% and to a significantly smaller extent - enterprises whose activity is related to accommodation - 5.9%. Innovations consisting in gaining access to new production components were not undertaken at all by enterprises conducting professional and scientific activities as well as the information and communication industry. Others showed little activity in this respect, the largest wholesale and retail enterprises - 11.1%.

To sum up, it can be stated that in the past five years, the surveyed enterprises introduced various market innovations, but they were not preferred to an equal degree. Innovations aimed at increasing the range of market presence were not focused on gaining new geographic markets.

Organizational Innovations

Organizational innovations declared by the surveyed enterprises were quite few and consisted primarily of changes in the organizational structure. Significantly less often innovations concerned other aspects of business organization. Data related to this issue is provided in Table 8.

Table 8: Organisational innovations introduced by the company over the last 5 years

Variable	n	%
Making changes in the organizational structure	83	55,3
Transfer of the performed function to other enterprises	10	6,7
Retreat of unprofitable activities	19	12,7
Implementation of a quality system	24	16

Table 9: Territorial coverage of the company's activities and the introduction of organisational innovations over the last 5 years

Variable	Territorial scope of the company's activities							
	European market		**Domestic market**		**Local market**		**Global market**	
	n	**%**	**n**	**%**	**n**	**%**	**n**	**%**
Make changes to the organizational structure	6	40	46	53,5	29	64,4	2	50
Transfer of the function to other companies	3	20	7	8,1	0	0	0	0
Withdrawal of unprofitable fields of activity	3	20	10	11,6	6	13,3	0	0
Implementation of the quality system	2	13,3	18	20,9	2	4,4	2	50
Wdrożenie systemu informatycznego	4	26,7	18	20,9	9	20	0	0
Deploy a resource planning system	1	6,7	6	7	1	2,2	0	0

Implementation of the logistics system	5	33,3	7	8,1	2	4,4	1	25
Implementation of a modern cost accounting system	1	6,7	19	22,1	13	28,9	0	0
Implementation of a performance measurement system	1	6,7	4	4,7	0	0	0	0
Change your business location	0	0	7	8,1	0	0	1	25
The alliance's strategic	3	20	5	5,8	1	2,2	0	0
Merger or acquisition of a competitor, internationalisation of activities	1	6,7	1	1,2	1	2,2	0	0
Acquiring a national strategic investor	2	13,3	12	14	0	0	0	0
Acquisition of a foreign strategic investor	2	13,3	2	2,3	0	0	0	0

Source: own study based on the study.

Analyzing empirical data (Table 9), the most preferred organizational innovation consisting in changing the organizational structure most often in the past five years was most often used by enterprises operating on the Local market - 64.4%, significantly less frequently enterprises operating on the Domestic market - 53.5%, with a similar frequency like the last companies operating on the Global market - 50%, and the least frequently operating on the European market - 40%.

Conclusions

The surveyed enterprises in the past five years have expressed a high degree of activity in implementing product, technological, market and organizational innovations, although the diversity of these innovations should be considered quite limited. Product innovations of the surveyed enterprises were based to a small extent on patents and inventions. This means that the new products were not innovative, but were the result of a new look at products previously manufactured by companies.

In the case of technological innovations, the situation was slightly different than in the case of product innovations: a slight, though visible advantage of innovations consisting in modernizing previously used technologies, own technologies or competition. The most active in this respect turned out to be, usually associated with innovation, enterprises in the professional and scientific industry as well as information and communication.

The market innovations of the surveyed enterprises in the past five years were focused primarily on increasing the attractiveness of the products offered and increasing the range of their sales, but without determined efforts to reach new markets in geographical terms. The most active in implementing market innovations were companies operating on the European market and operating in the professional and scientific activities as well as information and communication industries.

The catalog of organizational innovations declared by the surveyed enterprises was, compared to the previously discussed groups, quite long, but above all they implemented those consisting in introducing changes in the organizational structure (over half of the indications), while others were significantly less frequent. Most often, innovations were used by enterprises operating on the European market, and internalized by industry: conducting professional and scientific activities. Organizational innovations requiring the use of modern ICT and modern methods and management techniques were also characteristic of the latter.

Summary

Modern enterprises face many new challenges that relate to various areas of their activity. Growing technological progress, social changes and constantly changing market trends mean that modern market

models should constitute an integrated system combining all these changes. The solution for companies is to implement innovation as a response to changes in the market environment. Innovations are the driving force for those enterprises that want to build new management standards, and focus their activities on generating ideas that affect further development (Białoń, 2010). Such organizations gain the name of modern and competitive, finding recognition among customers, which in turn translates into building a competitive advantage. J. Schumpeter emphasized this by claiming that entrepreneurs will strive for innovation in order to gain a strategic advantage (Schumpeter, 1995).

Marketing Strategy vs Implementation of Innovative Solutions in an Enterprise – Case Study of a Company in the Construction Sector

Małgorzata ŁĘGOWIK-MAŁOLEPSZA

Częstochowa University of Technology, Poland
m.legowik-malolepsza@pcz.pl

Abstract

This paper discusses the issue of executing a marketing strategy within the context of implementation of innovative solutions. All presented considerations are divided into two principal parts – theoretical and empirical. The first part of this paper presents the essence of formation of the company's marketing strategy taking into account the role of innovation as an instrument of executing the strategy. The second part of the paper presents the results of empirical studies conducted on the basis of a case study. This publication allows better understanding of the attributes of the adopted marketing strategy in the context of assessing the level of engagement of sales in generating profit in the analysed company. This article contributes to the discussion on the identification of opportunities and threats related with the execution of marketing strategies of companies. The issue of executing a marketing strategy is important and valid due to its influence on the decision-making processes in terms of effectiveness of sales, in particular if this goal is achieved via implementation of innovative solutions.

Keywords: Marketing Strategy, Innovative Solutions.

Introduction

Implementation of innovation in a company, which functions in conditions of hyper-competition forces competitors to undertake immediate decisions to maintain or obtain advantage on the market (Kotler, Caslione, 2009). A substantial component of the structure of the company's innovative and competitive potential is a strategy, which should serve to achieve set goals (Prahalad, Krishnan, 2010). This means that innovation becomes a strategic imperative of the development of modern enterprises (Chan Kim, Mauborgne, 2007), which allows creating a proposal of value based on innovation. Thus, innovation should take into account product, service, market, marketing as well as technical and technological areas, executed in micro and macro scales (De Wit, Meyer, 2007). Implementation of innovation may become the stimulus that triggers development (Itami, Nishino, 2010).
The uncertainty about the conditions of conducting business activity hinders creating effective marketing strategies. Therefore, companies, in particular those functioning on developing markets, expect innovative model solutions in the area of exemplification of business ideas (Brzóska, 2009), in comparison to companies functioning in highly developed economies. Although the theme of innovation is more frequently discussed in source literature, still a gap was noticed in the area of assessing the level of realization of marketing strategies in the context of implementation of innovative execution solutions (Stępień, 2019). Therefore, a study question was defined: is the application of innovative solutions in the process of executing a marketing strategy reflected in the increased engagement of sales to generate profit? In consequence of this question, the aim of this paper is to recognize the attributes of the adopted marketing strategy, assess the level of engagement of sales in generating profit in the analysed company, as well as identify opportunities and risks in the execution of the marketing strategy in the analysed company. Research methods applied to achieve this goal included literature studies, a case study, a descriptive analysis as well as an analysis of the trend related with the sales profitability coefficient. Empirical studies were conducted on the basis of data provided by a company in the construction sector, which conducts business on the global market.

Formation of a marketing strategy in enterprises

Contemporary markets are generally characterized by a high level of competition, which means that maintaining the market position in these conditions becomes an extremely difficult task for the management. Therefore, to maintain and increase competitive advantage, companies should develop a long-term concept of efficient operation on the market, which will allow to effectively use the company's attributes and opportunities created in the environment.

The preparation of a long-term concept of efficient operation on the market consists in formulating a marketing strategy, which defines the steps that should be taken to effectively satisfy identified needs of the market. This means that the formation of a marketing strategy is a decision-making process, which consists of formulating the main problems and selecting optimum solutions from the perspective of selected goals and conditions of their execution (Morris, Kuratko, 2002). In the source literature, a marketing strategy is defined as a long-term action plan relating to product planning and development, selection of product range, positioning the product on the market, selecting the target market, price and distribution policy, communicating with the market as well as building a positive company image – organized to satisfy clients and ensure profit for the company (Urbanowska-Sojkin, 2011). Assumptions of a marketing strategy as a market-oriented strategy concentrate on three principal stages. The first stage is the identification of the market and the consumer (buyer) on this market, along with their current and future needs, which become the starting point for activities undertaken within the scope of this marketing strategy (Liebl, Schwarz, 2010). The second stage is preparation of activities, and it is based on extended research. The third stage consists in using a wide range of instruments and tasks, which influence buyers in the process of executing the adopted marketing strategy (Bratnicka, Dyduch, 2014). The process of formulating the company's marketing strategy is presented in diagram 1.

Diagram 1: Process of formulating the company's marketing strategy

Source: I. Penc-Pietrzak, 2015, p. 54.

A marketing strategy consists in several instrumental strategies, meaning product strategy, price, promotion and distribution, and simultaneously constitutes one of the many functional strategies (Drucker, 2010). Therefore, the selection of instruments for the execution of the marketing strategy should be adjusted to individual attributes and conditions of functioning of the given company. In selecting various combinations of elements of a marketing strategy the management should take into account the criterion of the internal cohesion of instruments and subordination to executed goals (Chen, 2008). The set of instruments to execute a marketing strategy may be related with the product, its equipment and price, product distribution as well as support for product sales processes (Garbarski, I. Rutkowski , 2001).

It should be underlined that a marketing strategy cannot be agreed without accounting for company goals in the following functional areas: production, finance, research and development, HR policy (Ansoff, 1991). It must interact with other strategies implemented in the company, to ensure cohesion in all areas of operation. What's more, the process of formulating marketing strategies should be consistent with the rules of formulating the company's global strategy; this is most noticeable in the structure of the company's goals and the manners of achieving these goals (Holm, Kumar, Rohde, 2012). Hence, the company's goals determine the borders of formulating the goals of marketing activity as well as alternative manners of achieving these goals.

An important element of a marketing strategy is taking into account the goals and needs in regard to the measures used by individual Strategic Business Units. They constitute an intentionally formed area of the company's interests - a relatively uniform area from the perspective of conducting effective strategic management (Kumar, Rahman, Kazmi, 2013). Strategic Business Unitsmay operate on completely different markets, which require the application of various mix-marketing instruments (Penc-Pietrzak, 2015). This means that the formation of a marketing strategy occurs on two levels: the company as a whole, and Strategic Business Units (Ansoff, 1987; Ansoff, Sullivan, 1993). It is worth noting that the form of the marketing strategy is indirectly affected by the company's mission and vision, which ensure consistent development and building a competitive advantage (Dutton, Duncan, 1987), thanks to directing activities and outlining the future position in the environment. The process of shaping a marketing strategy comprises an analysis of the market surroundings as well as an analysis of the company's resources. A specification of the results of the surroundings and company resources analyses allows formulating strategic alternatives covering specification of marketing goals, selection of target markets, as well as selection of proper marketing-mix instruments, which are subject to evaluation and allow the selection of the best variant (Holopainen, Toivonen, 2012).

Summing up, it is worth noting that formulating a marketing strategy, meaning a strategy of operating on the market constitutes an essential element of marketing management in every enterprise. A properly developed marketing strategy allows for an optimum use of the company's strengths and measures in accordance with the market situation; therefore it enables to satisfy needs of clients in the best possible manner.

Innovation as a tool for execution of the marketing strategy

In general terms, a strategy reflects a holistic approach to company management. It means that marketing strategies should take into account an integration of the selected sources of innovation opportunities with the company's potential and resources (Inauen, Schenker-Wicki, 2011) as well as seek various instruments and tools to develop identified development opportunities (West, Gallagher, 2006). Therefore, marketing innovation is an effect of decisions made in the area of selecting the company's operation policy, selecting assets used by the company, as well as selecting the model of corporate governance, which defines the manner in which the company will use these resources (Casadesus-Masanell, Ricart, 2011). Thus, these elements become a guarantor of generating the value spiral, and allow creating the feedback loop.

Marketing innovation in companies may be introduced in the new value proposal area, new operational activities, and in the area of value capture. Defining the new value proposal may be

conducted through expanding the product offer by complimentary services and maintenance, engagement of external partners in the process of outsourcing a part of sales, or through creating unique product purchase experiences. An example of an innovative solution is supporting the value proposal with new operational activities such as: development of a cooperation platform to ensure complex services for clients, redefining interactions with customers through conducting training for employees to revive their engagement in customer service, or reorganizational of internal processes. A marketing innovation in the area of a change in the value capture would be making the offer more attractive and reducing the prices of products in order to win new customers, provide gratuitous services, and obtaining benefits from advertisements, as well as separating strategic parts of activity based on a new costs and work model (Lindgardt, Hendren, 2017).

Marketing innovations should take into account the types of the company's activity, which determine the selection of customers, the scope of operation, the ability to capture value, and strategic control (Slywotzky, Morrison, Andelman, 2000). Innovations in these areas allow adjusting the scope of marketing activities to the customer's priorities, thanks to which enterprises ensure profitability through entering the so-called profit zone (Reeves, Love, Tillmanns, 2012). This means that marketing innovations should be based on both strategic knowledge of the customer's needs and priorities, and knowledge of the market on which the enterprise functions.

Summarizing the above analysis, it may indicate that marketing innovations should relate not only to the product, because currently it is not the main source of value for the customer. An important area of initiating marketing innovations is creating unique purchasing experiences for customers, because these experiences may be directly translated to an increase in sales. Therefore, applying traditional marketing instruments is not a sufficient value generator for the customer, and they should be supplemented by a completely new set of tools exercised in the company's operational activity. When new competition appears on the market, companies should modify not only sales processes, but also identify factors that ensure the company's entry and maintenance on the market as well as long-term profitability.

Methodology of Research

The research procedure applied to achieve the goal in the area of identifying the attributes of the adopted marketing strategy is a case study. The application of a case study to achieve the planned goal allows presenting a detailed picture of studied circumstances (Yin, 1984). However, a case study is a method with a probabilistic possibility of scientific cognition. This means that a case study has certain limitations (Gibbert, Ruigrok, Wicki, 2008). These limitations included intuitiveness and subjectivity of judgment and small representativeness of results. However, a substantial advance of a case study is presentation of an in-depth picture of analysed relations. A research tool applied in the assessment of the level of engagement of sales to generate profit is the net sales profitability ratio. The analysis of the trend of this ratio enables obtaining information about a change in the sales effectiveness in the analysed company. Empirical studies were conducted on the basis of data from financial statements of the analyse company. Additionally, opportunities and risks of executing the marketing strategy in the analysed company based on macroeconomic data were identified.

Recognizing the attributes of the adopted marketing strategy in the analysed company

The analysed company is a global organization dealing with production and sales of cement, concrete and aggregate. Global challenges require executing the company mission, which consists of meeting global needs of customers and creating added value for partners; this will allow the company to become an enterprise offering most efficient and profitable construction solutions in the world.

The marketing strategy of the analysed company is based on an assumption pursuant to which production and sales of offered products is a solution that may result in an increased standard of living and allows overcoming barriers, linking societies and creating the basis for development in the

country. The analysed company is distinguished amongst competition by the need of continuous development and innovation. The attribute, which differentiates the analysed company, is the need for change and for modern solutions, which enables meeting customer expectations and providing customers with innovative construction solutions.

Executing the adopted assumptions, the company focuses on expectations of customers. Therefore, it treats all customers with priority. Since quality and availability of products, as well as small distance are very important for customers, the company organized its commercial network in a manner that ensures meeting the needs of customers in the best way possible.

Satisfying the needs of customers takes account of the implementation of newest technological solutions. The company uses modern technological solutions not only to satisfy the needs of customers, but also to raise knowledge and qualifications of its employees, and to effectively operate in various market segments. For this purpose, the company introduced an IT platform and normalization of processes, which contribute to easy and consistent identification of best solutions and their subsequent implementation in the global network of the company's facilities. Thanks to introducing innovative solutions, the company increased the level of customer service and the level of safety of information flow, which contributed to an increase in productivity and performance of the analysed company, and to strengthening the brand in the global scale.

An important attribute of a marketing strategy of the analysed company is engagement in social responsibility. The realization of the assumptions of social responsibility is reflected not only in the economic context consisting in reduction of costs. The analysed company reduces the energy consumption by implementing environment-friendly solutions through developing a new fuel structure, within the scope of which almost 80% of the total cost of fuel is based on sources with low price variability; additionally, the enterprise uses alternative fuels. The philosophy of social responsibility sets the strategy of a balanced development of the analysed company, which consists in conducting efficient and profitable activity simultaneously caring for the needs of the environment and the society.

One of the attributes of the marketing strategy are the employees, who constitute an important element of the social responsibility philosophy of the analysed company. Firstly, the human resources policy consists in improving the safety of employees. Preventing accidents at work is deemed to constitute the foundation of the social responsibility philosophy of the analysed company, because high safety standards improve the performance of executed tasks.

To build a universal organization, the analysed company expects from employees both highest qualifications and high mobility. Employees in the analysed company are able to work in any location on the globe. To execute the employees' mobility policy, the company implemented well developed personnel planning and development tools, which include: succession planning, development, or evaluation of potential. Therefore, the company provides its employees with training, international exchanges, and work, which may the fulfilment of expectations for professionals.

The Level of Engagement of Sales in Generating Profit in The Analysed Company

The effectiveness of marketing innovations is reflected in the results generated by the company. Therefore, empirical studies in the area of evaluation of the level of engagement of sales in generating profit were conducted on the basis of a case study regarding financial data of the analysed company. The company was selected for the analysis (due to availability of data essential to conduct empirical studies). The scope of empirical studies covers the period 2016-2019. The applied research tool, which enabled conducting an evaluation of the engagement of sales in generating profit, is the sales profitability ratio. This ratio reflects the level of engagement of sales in generating profit in the analysed company. Conducting the research process with the use of the case study enabled presenting a precise and in-depth image of analysed circumstances and relations.

The sales profitability ratio allows obtaining information serving for the analysis of decision-making processes in the area of the sales return rate; this also enables assessing the effectiveness of marketing activities. The analysis of setting the sales profitability ratio also provides information about decision aiming at ensuring the effectiveness of operations in the analysed company. The share of net profit in sales in the years 2016-2019 in the analysed company demonstrated an increasing tendency (Diagram 2).

Diagram 2: Setting the net sales profitability level in the analysed company

Source: Own elaboration.

The upward trend of the net sales profitability ratio demonstrates the effective sales policy and appropriate decisions in terms of price and marketing policy. In the assessment of the setting of the net sales profitability ratio in the analysed company from the perspective of the execution of the marketing strategy information was obtained on the relation of net value to the net sales value. However, it should be noted that the decision-making process in the sales area in the analysed company depends, amongst others, on the structure of the product range, costs of production, and the price and marketing policy of the entire group of companies, not only companies with their seat in individual countries. Therefore, global decisions are sometimes inconsistent with decisions made in the given country. This results from the fact the process of execution of a global marketing strategy of a group of companies often does not take account of the economic situation and the scale of transfers between subsidiaries, or the tax policy, which directly affect the setting of the net sales profitability ratio in individual branches of a company operating on the global market.

Identification of opportunities and risks of the execution of a marketing strategy in the analysed company

The conducted studies with the use of the net sales profitability ratio enable assessing the level of engagement of sales in generating profit in the analysed company. However, the presented ratio is related with limited fields of perception, therefore it is justified to obtain a complete evaluation by examining opportunities and risks in the execution of a marketing strategy of the analysed company in the coming years.

Based on the analysis of the macroeconomic situation on markets, on which the analysed company is operating, opportunities and risks were identified with regard to the execution of the adopted marketing strategy for the years 2020 – 2025. Identified opportunities include the upward trend of economic indicators in the construction industry, although the assessment of their setting requires the application of the rule of prudence. The improvement of the condition of the construction sector in the conditions of a moderate downturn contributes to the stabilization of the prices of materials, services, and salaries on the construction market. Opportunities include an improvement of the financial situation of construction-related companies, which may be translated to timeliness in execution of liabilities. Important areas in the process of seeking opportunities to execute the adopted marketing strategy are the high qualifications of employees and the trend of continuous development of professional qualifications.

Analysing the risks in the execution of the adopted marketing strategy, the decrease in the number of self-government investments should be emphasized; in connection with the downturn in the segment of transport infrastructure and the decrease in the dynamics of government investments, this constitutes an important element, which may prevent achieving intended goals. In addition, weak results of road contractors and high price competition between contractors may become the factors, which reduce the level of planned revenue.

Discussion

Attempting to assess the effectiveness of the applied marketing strategy in the analysed company, which operates on the global market, it may be concluded that the implementation of marketing innovations is reflected in the increase of sales during the analysed period. The setting of the line of the sales profitability ratio line is the basis to assume that the priority for the analysed company is building the position of the leader in the analysed market segment. The analysis of development opportunities of the analysed company suggests opportunities to execute the adopted marketing strategy. Initiating new methods of external and internal communication, implementation of modern technologies and expanding cooperation in the area of using the Internet as an internal communications carrier should allow maintaining high operational effectiveness of sales. However, the identified risks and the variability of economic circumstances in the surroundings of the analysed company require skills to select appropriate modern marketing tools in order to execute the adopted marketing strategy. Therefore, maintaining the competitive advantage should be carried out in account of solutions aimed at activities focused on creating special value for the customer, which may be obtained through the value of offered products and foreseeing market trends.

Summary

Making the decision about the form of execution of a marketing strategy in the operation of a company is individual for every enterprise. The effectiveness of the marketing strategy depends on factors such as: the market, on which the company operates, the number and quality of activities undertaken by the competition or demand for produced goods. Therefore, enterprises must adjust the scope of the applied marketing strategy to the conditions of the endogenous and exogenous environment.

In response to the question – will the application of innovative solutions in the execution of a marketing strategy be reflected in an increase of engagement of sales in generating profit? It should be concluded that companies operating on global markets should implement innovative solutions in the execution of their marketing strategy because, on the one hand, it allows achieving a growth of sales profitability, and on the other hand it enables conducting business on various markets. The purpose of this paper was to recognize the attributes of the adopted marketing strategy, assess the level of engagement of sales in generating profit in the analysed company, and identify opportunities and risks to the execution of the marketing strategy in the analysed company.

The conducted empirical studies suggest that implementation of modern technological solutions, mainly in the IT area, constitutes an important attribute of the adopted marketing strategy in the

analysed company. Coherent and comprehensive information to assess sales effectiveness was obtained through an assessment of the level of engagement of sales to generated profit using the net sales profitability ratio in the analyzed company. The conducted identification of opportunities and risks in the execution of the marketing strategy in the analyzed company constitutes the basis for forecasting the future directions of the company's development. This research approach allowed achieving the set goal.

The main contribution of this article is in-depth knowledge of the relations between a marketing strategy and implementing innovative solutions to execute this strategy, as well as the possible influence of the marketing strategy on the increased sales profitability. What's more, enterprises operating on global markets, characterized by a high pace of changes must skillfully select the instruments to execute the adopted marketing strategy. The application of marketing innovations should consist of implementing pioneering solutions in the area of influence on the target market.

Therefore, it may be recommended for the analyzed company to expand the structure of its offer of products and services, introduce an electronic channel and applications allowing to use mobile devices, apply expanded reality solutions in the area of warehouse management and in processes of sales and communication with customers, as well as brand positioning. To achieve the goal of this article, the author mainly conducted literature studies and a case study, an analysis of the trend of the net sales profitability ratio, and a descriptive analysis. The multispectral nature of the execution of a marketing strategy and implementation of innovative solutions meant that certain considerations in this article were presented in a general manner; on the one hand, this allowed presenting the complexity of the discussed issue, and on the other hand it inspires to further research.

Division and Options of Rational Substitution of Foodstuffs Within Basic Groups as A Guarantee of The Safety of Soldiers of The Land Forces During the Execution of Official Tasks

PhD. Paweł KLER

Institute of Logistics, Faculty of Security, Logistics and Management, Military University of Technology in Warsaw, ul. gen. S. Kaliskiego 2, 00-908 Warsaw, Poland,
pawel.kler@wat.edu.pl

Abstract

The overriding theme of the paper is to secure for the soldiers of the Land Forces the conditions for the safe performance of their duties by indicating the optimal conditions for their nutrition. Foodstuffs were grouped and characterised. The groups are for use in individual nutrition of soldiers of the Polish Armed Forces serving in peacetime, in situations when they do not have the right to free mass catering. The principles and opportunities for product substitution have been identified where more expensive products need to be substituted by cheaper ones, due to their hampered availability or seasonality. The principles of rational human nutrition were also presented. The considerations allowed us to conclude that a social group with an increased energy expenditure, performing a specific job to which the soldiers of the Land Forces were assigned, should apply the principles of proper nutrition, taking into account an option of foodstuff substitution. Otherwise, soldier's physical capacity, may be reduced, his concentration span may decline, responsiveness may be reduced and an option of intense physical effort during the performance of official tasks.

Keywords: Foodstuffs, Nutrition, Product Categories, Soldiers' Nutrition

Introduction

One of the prerequisites for the soldiers to carry out their tasks effectively is a proper diet , with an energy balance in equilibrium. Rational nutrition can guarantee not only the effective implementation of the assigned mission, but also its safe accomplishment. Each nutrient has its own range in the food ration supply. Consumption of too much or too little food ration may cause upset health condition. The optimal scope of nutrient absorption is individual for each human being. It depends on age, nature of work, gender and health condition. The food ration used in soldiers' nutrition must meet their energy requirement for the training process and provide all the nutrients in appropriate quantities and proportions.

General Principles of Proper Nutrition of Soldiers

One of the conditions for ensuring good health condition and a healthy body is the proper frequency of meal consumption in land forces nutrition. The percentage breakdown of energy according to the standard into specific meals served during the entire day is shown in Appendix No. 1. A soldier should have meals 3-5 times a day with breaks every 3-4 hours in order to perform the tasks set before him in order to perform the tasks set before him. Too long breaks between meals result in a drop of glucose level in blood, causing a feeling of hunger. Hunger and dehydration make the soldier feel worse and reduce the well-being of the soldier, reduces his concentration, alertness, psychophysical activity and increase his irritability. This may adversely affect the daily functioning of the body and result in standstills in the performance of official tasks.

It should be noted that the energy value of meals consumed during the daily cycle should be equal to 100% of the energy standard, e.g. for breakfast 30%, for lunch 40% and for dinner 30% of energy when eating 3 meals a day.

Referring to the *Recommended Dietary Allowance for the Polish population*, it is recommended for an adult to consume not less than 45 - 65% energy from carbohydrates, 20 - 35% energy from fats and 10 - 20% energy from protein (Jarosz, M. 2017).

The specific nature of the job performed determines the diet of adults, including soldiers. The work performed can be divided in terms of gravity into light sitting, moderate, heavy and very heavy physical jobs. If a soldier does most of the work being seated (seating jobs in the armed forced represent marginal percentage), he should consume low energy foodstuffs. His diet should be easily digestible. The basis should represent foodstuffs with a lower fat content (cheese, milk, lean meat) and products rich in fibre (dark bread), fruits and vegetables. The diet of people dealing with hard physical labour, which applies to the majority of the soldier population, should be enriched with high-energy foodstuffs such as: fish, meat, groats, legume seeds, pasta (Army Doctrine Publication. 2017) . With growing consumption of carbohydrates, the need to supplement B vitamins increases.

Since 2010, since the introduction of the Polish army's professionalisation, soldiers in peacetime feed themselves on their own. Under exceptional circumstances, soldiers may be entitled to free meals, e.g. during training on the training grounds, attending various courses, on Navy ships, during flights performed by the Air Force flying personnel and in other situations specified in applicable legislation. The candidates for professional soldiers in the training period as well as those on duty are also fed free of charge. The rules of organizing nutrition and standards of feeding the soldiers of the Polish Armed Forces are regulated by the secondary legislation and decisions of the Minister of National Defence. Currently, the soldiers serving in Polish Armed Forces units at the time when they should be fed following the principles of mass catering, pursuant to the Food Service Activity Regulations DD/4.21.1.(A) of 2016, implemented by virtue of the Decision No. 399/MON, and the Regulation of the Minister of National Defence of 27 April 2018 on free catering for professional soldiers and soldiers serving as candidates.

Through continuous research on energy expenditure and nutritional patterns of different social groups, at different ages, and with different severity of work performed, the knowledge about foodstuffs and individual human nutrition continues to be updated. In order to facilitate the illustration of the hierarchy of individual food categories, a pyramid of proper nutrition was created, which corresponds to the modern model of proper human nutrition. It presents the idea of nutrition, which is intended to give a chance for healthy life, maintaining physical and mental fitness into old age. It shows the proportions of essential food categories in the daily diet. The higher the pyramid level, the lower the frequency and amount of food consumed from the selected food category.

It should be emphasized that this pyramid is mainly used for feeding a healthy person. Depending on age, religion, susceptibility to allergies, applied diet, work performed and physical effort taken, it needs to be modified. The pyramid is developed and updated by the experts from the Food and Nutrition Institute. The pyramid shown in Figure 2 below is designed for a healthy adult.

Fig. 1 : Adult healthy eating and physical activity pyramid

Breakdown of Primary Food Products into Categories and Their Characteristics

Foodstuffs may be categorized by their origin, ingredients or characteristics, depending on their nutritional value and composition. Taking into account the needs or the purpose of the social group covered by the survey, foodstuffs may be broken down into different basic categories. When assessing the quality of food, it is important to first pay attention to the requirements that foodstuffs have to meet and the control of compliance with such requirements. These are basic components of the recommended dietary allowance that aim to protect consumers.

In order to plan the daily ration in connection with the rational nutrition principles, fewer categories are used, with as much variety as possible when selecting foodstuffs within the category. Meanwhile it is advisable to divide the ration, i.e. the recommended dietary allowance, into a larger number of categories. For the purposes of the conditions assumed in the publication, foodstuffs were divided into 9 categories. They are categorized by similar nutritional values and chemical composition (Kunachowicz, 2007).

Fruits and vegetables

Foodstuffs from this category are characterized by high nutritional value and low energy value. They represent a potential source of vitamins, organic acids, fiber, antioxidants, minerals and essential oils. They contain a certain amount of protein, simple carbohydrates, and have protective and regulating functions for the human body. Fruits and vegetables, thanks to their smell, taste, colour and consistency, are a pleasure to eat by humans. They show an alkaline effect. Their protective role against tumours should be emphasized. The correct consumption should reach 800g/person/day. In many countries, especially highly developed ones, the statistical consumption of fruits and vegetables per capita is relatively higher than in Poland.

It is advisable to increase the consumption of fruits and vegetables. When developing a diet, it is necessary to plan the consumption of fruits and vegetables in the form of juices, frozen and canned fruits and vegetables, certainly if we do not have access to fresh produce, so that their daily consumption is not lower than 600 grams. Care should be taken to ensure that each meal contains fruits or vegetables, boiled or raw. People who take care of their body structure should largely base their diet on them.

Potatoes are a special vegetable, due to their starch content (approx. 18%) and protein content (1.5 - 2.5%), which are of high biological value. They are a source of certain amounts of dietary fiber. Iron, potassium, phosphorus, sodium, magnesium are the main minerals in potatoes. Thanks to the high concentration of potassium, the potatoes have alkaline properties and contain numerous B and C vitamins. The content of vitamin C is determined from 10 to 40 mg/100g (Kunachowicz et al., 2007, pp. 138-139). An important aspect is the storage of potatoes and their culinary treatment. Improper use of potatoes may reduce the value of the vitamins they contain. Therefore, the healthiest thing to do is to eat boiled potatoes. In Poland, some people treat potatoes as a separate group of foodstuffs, mainly because of their high consumption volume.

Vitamin C is the most widely recognized antioxidant. It aims at strengthening of the immune system and blood vessels. The category characterized by a large amount of vitamin C includes the following vegetables: tomatoes, parsley, kale, pepper, brassicas: savoy cabbages, red cabbages, Brussels sprouts, white cabbages, cauliflower. The fruit category, which is the most valuable in terms of vitamin C content, comprises: strawberries, wild strawberries, raspberries, rosehip, elderberry, red, black and white currants, gooseberry, blueberries, and citrus fruits: oranges, grapefruits, lemons.

Beta-carotene, in addition to assisting in the process of vision, is responsible for the immune system, cell and tissue formation, and for skin appearance. It shows anti-cancer properties due to its antioxidant properties. The fruits and vegetables and fruits belonging to this category include: carrots, tomatoes, Chinese cabbage, lettuce, chicory, red pepper, pumpkin, kale, dill, broccoli, asparagus, parsley, beans, spinach, chives and sorrel, as well as fruits such as melons, papayas, peaches, nectarines, oranges, apricots or mangoes.

Vegetables recommended for consumption: fresh, frozen and appertized, vegetableslightly salted soups with little fat; baked or cooked potatoes, deep-fried vegetables, vegetable juices, pickled vegetables;

from fruits: fresh, frozen, compotes, jams, juices and other preserves.

Cereal Products

This product category is mainly represented by rice, flours, groats, flakes, etc., as well as products made from them (including but not limited to noodles, bread, pasta). Nutritional values depend mainly on the technological processing applied and on the type of grain used. These products are rich in complex carbohydrates, mostly starch, minerals such as magnesium, iron, B vitamins and dietary fiber. Meanwhile they contain a negligible amount of fats and calcium. The most valuable nutrients are found on the outer part of the grain, so products that are poorly “purified" are richer in nutrients. Flour-based dishes are applied in nutrition universally, because they are cheap and have a relatively high nutritional value. Cereal products are the basis of nutrition and should be consumed at every meal, but in moderation specific to individual needs.

The products recommended for use are: whole-grain bread and cereals, rusks, pancakes, doughnuts, biscuits, buns, tortillas, pasta, rice, groats or noodles. As a supplement - processed crackers, sweetened cereals.

Dry Legume Seeds

The products belonging to this category are to a certain extent similar to the categories of cereal products and vegetables. However, they are distinguished in a separate category due to their specific nutritional properties. This category comprises soya beans, broad beans, lentils, beans and peas. Their protein content has a high biological value, especially soybean - 35-40%, while in beans, peas and lentils it is over 20%. Legume seeds are also rich in B and C vitamins, carotene and carbohydrates, as well as being a source of fat with a significant content of EFAs (soybean). Dry and fresh legume seeds spread the necessary minerals such as copper, fibre, potassium, iron, sulphur, calcium and magnesium throughout the body.

Before consumption, it is recommended to boil and soak the seeds, since this has a positive effect on process of their digestion and minimizes flatulence and other hardship in the digestive process. They exhibit an alkaline effect. In order to enrich the diet with vegetable protein, increased amounts of legume seeds should be consumed. Their energy value is significantly high and a variety of dishes can be composed using beans, soya or lentils. On the Polish market you can find ready-made dishes with these seeds.

Products recommended for use are as follows: cooked seeds in any form, soups, canned seeds.

Meat and Fish

This category is a particular source of protein, vitamins A and B, iron and copper. Depending on the size, age and species of the animal, the percentage of fat (2 - 30%) and protein (15 - 20%) is determined. Meat from animals for slaughter is otherwise known as 'red' meat, as opposed to poultry meat, referred to as 'white' meat. Poultry meat has a lower fat content than red meat. It is therefore advisable from a nutritional perspective to consume more poultry meat in parallel to the reduction of red meat consumption. The recommended weekly dose of meat per adult is 0.5 kg.

Fish contains more minerals than meat. They are a good source of iodine and fluorine. Fish meat is characterized by such nutrients as: protein, magnesium, Omega-3 acids, potassium, phosphorus, iodine, vitamins A and D. Fish consumed with the bones are a source of calcium. Especially marine fish are recommended because of the high content of omega-3 polyunsaturated fatty acids.

The products that should dominate the diet of this group of people include: lean processed meat, lean cured meat, fish in any form 2 - 3 times a week, crustaceans, skinless poultry, liver at least once a month. Rarely fried or fatty meat, fried poultry or poultry with skin, etc.

Milk and Dairy Products

Milk is used to make numerous products such as kefirs, buttermilk, yoghurt and many varieties of cheese. Dairy products and milk are the most valuable food products. Their ingredients are necessary for the proper functioning of the body. From this product category we obtain such nutrients as calcium, protein, fats, milk sugars (lactose), fat-soluble vitamins A, B, D. They contain only a trace amount of iron. Meanwhile milk and dairy products do not contain vitamin C or fibre. Protein is a building block component of the human body, so dairy products play an important role in every phase of human life, especially for children and pregnant women. It is impossible to replace milk with another food product (Gawęcki, 2010, pp. 342-343). Dairy products have alkalising properties and should therefore be used in the best possible manner, as ingredients in a variety of dishes in order to enrich their nutritional value.

Milk, kefirs, yoghurt are recommended for use from this category.

Butter and cream

Butter is a relatively easily digestible fat with significant organoleptic properties. It should contain 82-84% fat. Due to the high cholesterol content, its consumption should be restricted. Butter is also characterized by a large quantity of short-chain saturated acids. It is crucial that the butter contains vitamins A and D, so it is best to eat them raw as they do not lose their nutritional value. High temperature causes the formation of harmful compounds (carcinogenic, e.g. acrolein), resulting from the thermal depreciation of butter. For people having problems with high cholesterol level, mixed products containing butter and margarine or oils are suitable.

The source of fat, but also vitamin A, soluble in fats, similarly to butter, is cream. Enriched with small amounts of minerals and protein, it plays an important role in bringing variety to everyday diet, but is easily replaced by other products with lower fat content, e.g. natural yoghurt (Kunachowicz et al., 2007, p.133).

The products recommended for use are butter with a fat content of more than 82% and cream soups with a dash of cream added.

Eggs

The basic product of this category are hen eggs. They are the safest for human health, and their sales is most common in the marketplace. Hen's egg white is considered to be of the highest nutritional value and is fully absorbable by the human body. Egg yolk contains iron, vitamins A and D and fatty compounds (about 250 mg cholesterol in 1 egg yolk). Because of these compounds, too much yolk should not be consumed. Eggs are acid-forming products. Nevertheless, they are a valuable product not only because they contain significant nutritional values, but also have valuable organoleptic values and special physical and chemical properties. Eggs have thickening, emulsifying, binding and raising properties. Their small amount gives the food its proper consistence (Gawęcki, 2010, pp. 349-350). There are few products that would have such a wide array of culinary applications. Eggs are the basic ingredient of many dishes. Eggs are subject to heat treatment, and eating them raw can cause food-borne poisoning.

The recommended intake is 3 to 5 eggs per week.

Fats

In this product category, fats can be divided into fats of animal and vegetable origin. Back fat and lard are the main representatives of animal fats. They mainly provide energy (630 - 900 kcal/100 g), cholesterol and saturated fatty acids, as well as vitamins A and D. The atherosclerotic effect of animal fats causes cardiovascular diseases, obesity and cancers when their intake exceeds the recommended dietary intake. Therefore, their intake from the daily diet should be reduced in favour of vegetable fats, which contain polyunsaturated fatty acids, beta-carotene, tocopherols and, above all, are cholesterol-free. Vegetable fats have an antiatherosclerotic activity proven by epidemiological studies. In the Mediterranean countries, olive oil is mainly consumed, resulting in a rare occurrence of atherosclerosis and ischaemic heart disease. In the domestic market, available vegetable fats with the highest content of essential unsaturated fatty acids (EFA – essential fatty acid) (Bojarowicz, Woźniak, 2008, p. 471) is vegetable butter, sunflower oil, soybean oil and enriched margarines. They should be eaten raw (as a salad dressing, directly on bread) because unsaturated fatty acids are sensitive to high temperatures. Rapeseed oil and olive oil are used in a variety of dishes, and also for frying. Oils that are cold-pressed are not refined, which results in their specific organoleptic characteristics. Their colour is slightly green because of the chlorophyll they contain. In combination with refined oils they contain more vitamins.

It is recommended to use the following items from the Fats category: rapeseed oil, mayonnaise or salad dressing (made with oil), avocado, olives. In addition: margarine made from hydrogenated or saturated fats, coconut or palm oil. Hydrogenated vegetable fat, bacon, lard, grease added to dishes, sauces.

Sugar and Confectionery

This category comprises confectionery, jams, cakes, chocolate and marmalades. This group is characterised by a high sucrose content of up to 99% and energy properties (300 - 600 kcal/ They mainly supply the energy, which is commonly dubbed "empty calories". Their sugar content ranges from 40-99%. Depending on the product composition, they provide partial values for fat, minerals, protein and organic acids. It should be noted that this category comprises bee honey, whose main ingredients include monosaccharides and substances preventing microbial development.

Excessive consumption of confectionery products and sugar promotes obesity and tooth decay, but also has a beneficial effect on the functioning of neurotransmitters in the brain. Unfortunately, confectionery products and sugars have an acidifying effect on the body, so they should be consumed occasionally.

From this product category bee honey is recommended.

One of the components influencing human welfare according to the World Health Organization (WHO) is proper and healthy nutrition, which is sometimes, due to lack of time or covetousness, satisfied incorrectly. As a result of the presented description of product categories, it can be concluded that there is no food product that can contain all the necessary nutrients for humans, especially in quantities that ensure proper functioning of the body. That is why it is so important to consume products from different food groups, taking care to diversify your meals.

Substitution of Foodstuffs - Principles and Opportunities

When planning a menu, more than often food rations have to be modified. This may be driven by necessity to substitute more expensive products with cheaper ones, because of the constrained availability of certain foodstuffs or seasonality.

Foodstuffs from the presented 9 categories may be substituted as follows:

Fruits and vegetables

Basic product - 100 g fresh fruits and vegetables.

Substitute products: With vitamin C: 100 g peppers, Savoy cabbages, tomatoes, Brussels sprouts, broccoli, 90 g fruits and vegetables from the category providing vitamin C, 60 g drinking juices.
With carotene: 90 g vegetables and fruits from the group providing carotene, 20 g tomato concentrate 20% / 30%,
Other: 100 g Savoy cabbages, broccoli, chives, Brussels sprouts and other products providing vitamin C and carotene, 90 g frozen vegetables and fruits, 60 g drinking juices, 20 g dried fruits

Cereal Products

Basic product – 100g flour.
Substitute products: 135 g rolls or bread and semi-confectionery products, 100 g beans, pasta, peas.

Dry Legume Seeds

Main product - 100 g dry legume seeds.
Substitute products: 135 g bread and rolls, 100 g groats, flour and pasta.

Meat and fish

Main products - 100 g bone-in meat and gutted fish.
Substitute products: 400g liquid milk, 200g homogenised cheese, 200g ungutted fish and herring, 120g eviscerated poultry, 100g offals, fish fillets, eggs, cottage cheese, 70g ham, sirloin, sausage, gammon, 60g melted cheese.

Milk and Dairy Products

Main product - 100 ml milk.
Substitute products: 100 ml kefir or yoghurt, 10 g cheese spreads, 15 g cottage cheese, 30 g homogenised cheese, 50 g concentrated milk

Butter and Cream

Main product - 100 g butter.

Substitute products: 280 g 30% whipping cream, 450 g 18% cream, 700 g 12% cream

Eggs

Main product - 100 g eggs (2 pcs.).
Substitute products: 400 g of liquid milk, 200 g of homogenised cheese, 100 g of cottage cheese, canned fish, offals, fish fillets, 80 g of de-boned meat, 60 g of ham, tenderloin, 50 g of powdered milk.

Fats

Main product - 100 g of lard.
Substitute products: 120 g margarines, lard, 100 g hydrogenated fats.

Sugars and confectionery products

Main product - 100 g of sugar.
Substitute products: 125 g of natural or artificial honey, 150 g of jam, fruit syrups, 200 g of jam and marmalade.

Knowing the values and composition of individual foodstuffs, one product can be substituted for another, but the principle of substitution within the same product category should be mainly followed. If not possible, products from other categories may be used, but the content of the main nutrients should be taken into account. When substituting e.g. poultry meat, we take into account the similar protein content that products from other categories contain. Poultry meat substitution options are shown in Figure 1.

Fig. 1: Substitution of 100 g of poultry meat with other foodstuffs.
Source: Own elaboration

Summary

Foodstuffs contain essential nutrients in various quantities and proportions. Food ration of soldiers of the Land Forces should supplement the loss of energy, provide the building blocks for the reconstruction of the tissues that are being used up, and contain the necessary number of components that regulate the metabolism (Kler, Bertrandt, 2017, pp. 397-402). It should be born in mind that

there is no food product that contains all the nutrients in quantities that are optimal for the human body. Therefore, it is recommended to diversify the food ration as much as possible.

Diseases of civilisation such as obesity, etc., which in the 21st century inevitably accompany the majority of social groups, are the result of widespread eating habits of adult consumers, which unfortunately deviate from the health-oriented nutrition model. The soldiers of the Land Forces are not the only exception here. As research shows (Kler, Bertrandt, 2018), soldiers often make fundamental mistakes when they feed themselves, drawing knowledge about the principles of proper nutrition from friends or from the Internet.. Incorrect application of dietary guidelines may bring them to the situation where they feed themselves using unbalanced diets, which may reduce their physical performance, reduce their concentration span, responsiveness and an option of intense physical effort while performing official tasks. Insufficient nutritional awareness can affect the quality and safety of performed official duties. It can be curtailed through the application of the following principles:

- To add to the daily menu the products from all categories: cereal products, fruits and vegetables, milk and dairy products, products providing complete protein. The principle of bringing variety should apply to all meals.
- To reduce the intake of fats, particularly of animal origin, and to replace them with fats of vegetable origin.
- To increase significantly the consumption of fruits and vegetables and fruit as well as dry legume seeds.
- To reduce the consumption of red meat and its processed products in favour of white meat, fish, legumes, quark.
- To increase significantly the consumption of fish and fish products.
- To increase the consumption of milk and dairy products with reduced fat content.
- To reduce the consumption of table salt.
- To enhance physical activity level continuously.
- To reduce continuously sugar and confectionery products consumption.
- To increase moderately the consumption of cereals and potatoes.
- To reduce egg consumption to 2–3 eggs per week.
- To eliminate products not recommended for the body - spirits and all kinds of stimulants.

When substituting products we should mainly follow the following dietary recommendations:

- the substitution should be the best applied within the same product category - e.g. substitution of animal fats with vegetable fats,
- within other categories, products may be substituted, however, making calculation following the principle that the amounts of basic nutrients and energy values are similar
- the substitution as a whole must not affect the nutritional value of the prepared meals, butter can to some extent be exchanged for cream, because both products contain vitamin A and fat,
- in certain cases, combined substitutions may be applied, e.g. meat dishes may be substituted by dishes made from dry legume seeds supplemented with small quantities of meat, sausage, poultry or grated hard cheese.
- fruits and vegetables rich in vitamin and carotene should not be substituted in the long term with other fruits and vegetables in small quantities.
- the product being substituted should have a similar composition - e.g. a product that is a source of vitamin C should be substituted by a product with similar properties.

When eliminating a food product for health reasons, it is important to remember that the products to be substituted should be of similar nutritional value and that the proportions of substitution should be maintained.

Abstract

Waste management must be able to serve all waste generation. This is needed to avoid the potential environmental impact of residual waste that is not transported. However, in the 2017 Sukmajaya District, Depok City has a level of waste collection and transport rates only 47% are served. Sukmajaya District had 4 types of waste transportation services, physical legal landfill, non-physical legal landfill, door to door services, and trade in services. This research aims to identify the pattern of illegal landfills for the improvement of waste management. Data collection in this study was carried out using secondary data from government agencies, interviews, and field surveys. This research was conducted using one of the spatial analysis tool namely distance analysis tools such as buffer analysis and Euclidean distance analysis. The results showed that the Sukmajaya district had 4 legal landfill sites and 123 illegal landfill sites. Illegal landfills found to exist near secondary and tertiary, near river and shrub class of land use, and area with a low-density population.

Keywords: GIS, Spatial Analysis, Waste Management, Waste Collection Transport

Background

Waste management is one of the big problems faced by many countries in the world (Chaudhary, Nidhi, & Rawal, 2019). Especially in a developing country that always had their priority on the development and economic growth then put less priority on waste management even waste generation positively associated with economic growth (Wilson et al., 2015). There are two of the five stages in urban solid waste management that need to be focused, namely the collection and transportation stage (Chaudhary et al., 2019; Kaza, Yao, Bhada-Tata, & Woerden, 2018). This stage of urban solid waste management is a major concern because it used 60-80% of the total urban solid waste management budget (Chaudhary et al., 2019). In low-income countries, urban solid waste that is not collected will be disposed of in the open, burned, or some will be composted (Kaza et al., 2018). The direct combustion process (Kaza et al., 2018) and emissions from transport carriers used can increase greenhouse gases in the atmosphere (Chaudhary et al., 2019).

Management of municipal solid waste that is not optimal can directly or indirectly affect the environment (Wilson et al., 2015). Indirect influence on the environment one of which arises when urban solid waste is dumped in the open or the edge as a result of the lack of available facilities (Tadesse et al., 2008). Illegal disposal of municipal solid waste will directly pollute surface water, seawater also groundwater can be polluted in the long run. (Wilson et al., 2015). In addition to illegal disposal, the process of burning urban solid waste that is not done with the right technology can be a pollutant for a local air and accelerate the phenomenon of climate change (Kaza et al., 2018; Wilson et al., 2015).

Urban solid waste management has a direct impact when it comes to the stage of collection, transportation, and removal of urban solid waste. poor transportation and collection of rubbish have an impact on vehicle gas emissions. On the other hand, good urban solid waste management can contribute to reducing greenhouse gas emissions by 15-20% (Wilson et al., 2015).

Depok City with increasing waste generation has a transportation rate of rubbish far below 100%. Waste transported in Depok City is only 21-56% of the total solid waste generation (Kristanto, Gusniani & Ratna, 2015; Paramita, Murtilaksono, & Manuwato, 2018; Sukarmawati, 2012). This value is not yet proportional to the costs allocated for the waste collection and transportation stage, which is 72% of the total budget for waste management which in 2008 was Rp. 9,588,734,350 (Sukarmawati, 2012). Waste management consists of three stages, namely collection, transportation, and waste management. Currently, most research focuses on the initial stages of generation or the final stage of waste management in the landfill. The second stage, namely transportation, is the stage that consumes the biggest budget cost of the three stages, so optimization at the transportation stage that is supported by the intervention at the collection stage needs to be done. The more important role is owned by the waste collection stage because it is directly related to the sustainable use of resources, saving on the waste management system, and reducing the negative impact on nature (Pires et al., 2018). Illegal landfills do not arise randomly (Glanville and Chang, 2015; Jakiel et al., 2018), bad solid waste management is one of many factors that could trigger the emerging of Illegal landfills. The emergence of illegal landfill locations is affected complexly by economic, environmental, and social factors (Glanville and Chang, 2015). In detail, the factors that influence the distribution of illegal landfills (Glanville and Chang, 2015) are demographics (for example population density, unemployment rate, per capita income), availability of waste facilities or services, ability to service facilities or solid waste services, the effectiveness of law enforcement, access location (distance to the road), acceptance of community culture towards illegal landfills.

The correlation between illegal landfill locations and distance to settlements shows a negative relationship in Lucendo-monedero, Jordá-borrell, & Ruiz-Rodríguez's (2015) research. However, research that had been conducted in Japan showing positive results between illegal landfill locations and distance to settlements (Ichinose and Yamamoto, 2011). Garbage that is placed illegally can have risks to the economy, environment, and social (Glanville and Chang, 2015). The quality of the environment can decrease due to special concentrations of waste such as iron, hydrocarbons, nitrogen, and gasoline (Glanville and Chang, 2015). Besides, the illegal landfills environment has an impact on public health, statistically, the existence of illegal landfills contributes significantly to the number of kidney and lung sufferers in the same area (Glanville and Chang, 2015). The area's topography features determine the dangerous level of the distribution of existing illegal landfills. The results of research by Jakiel et al. (2018) shows that illegal landfills have arisen in many valley areas adjacent to water bodies. In addition to the research location, Jakiel et al. (2018) is an area with karst rock types, so pollutants from the illegal landfills can be easily infiltrated to groundwater. The category that a location is said to be illegal landfills is if the existing rubbish heap is greater than 1 m^2 (Jakiel et al., 2018). The variables used to analyze the distribution of illegal landfills are the size of the illegal landfill location, solid waste composition, regional topographic features, and age (Jakiel et al., 2018). The size of this illegal landfill location in the research of Jakiel et al. (2018) is measured in m^2.

Methods

Survey

This research using secondary data owned by the government and taking primary data from field surveys. Spatial data such as rivers and population density are secondary data obtained from the government, for road networks in this research using OpenStreetMap Indonesia data. Waste management facilities both transport routes and legal landfill locations are obtained from interviews and interviews with the government. Primary data such as illegal landfill locations were obtained by tracking all roads in the study area. The primary survey is carried out with the help of a mobile application to provide location coordinates, record images, and survey forms.

Methodology

The field survey that was conducted focused on mapping the distribution of illegal landfill locations by crossing the entire road network in the study area. The survey form is prepared digitally to obtain detailed information regarding the illegal location of the landfills encountered. Detailed information on illegal landfills regarding the type of land cover at that point, the extent and volume of illegal landfills, and documentation. Regional physical data, waste management services, and illegal landfill locations are analyzed using spatial buffer analysis, euclidean distance and simple statistics to determine the relationship between variables.

Results And Discussions

General Figures

Based on the field survey, 123 illegal landfills were found in Sukmajaya District, Depok City. In Tirtajaya subdistrict with the lowest population density at 6,171 people / km^2 has the highest number of illegal landfills was found, 41 locations (33%). Cisalak subdistrict has a population density that is not much different from Tirtajaya Subdistrict, which is 6,731 people / km^2 but the number of illegal landfills is at least 7 location points. Sukmajaya Subdistrict with the third-lowest density found 20 locations (16%) illegal landfills. Slightly different from Sukmajaya Subdistrict, Baktijaya Subdistrict found 19 illegal landfill locations (15%) with a much higher population density than Sukmajaya Subdistrict which was 19,939 person/km^2. Abadijaya Subdistrict, which is the most populated found 23 illegal landfills (19%), then Mekarjaya Subdistrict has 13 illegal landfills locations (11%).

Sukmajaya Subdistrict has 3 population density categories namely less than10,000 person/km^2 in 3 Subdistrict namely Sukmajaya, Tirtajaya, and Cisalak. In the Mekarjaya and Baktijaya Subdistrict are in the population density of 10,000-20,000 people / km^2. Abadijaya Subdistrict has the highest population density with 22,738 people / km^2 and belongs to the population density of more than 20,000 people / m3.

The lowest population density category has the highest number of illegal polling stations with 68 location points. In areas, with a population density of 10,000-20,000 person/km^2 32 illegal landfill locations were found, with at least 23 illegal landfills found in the densest areas with a category more than 20,000 person/km^2. The survey results show that the number of illegal landfills with population density has an inversely related relationship, the higher the population density, the less the number of illegal landfills found.

Relation Illegal Landfills and Geophysics

Geophysical elements used in this research are based on the type of land cover, distance from the road and distance from the river. The type of land cover surveyed consists of seven types, namely settlement, roadside, vacant land, riverside, park, paddy field/field/garden and drainage side. The survey results show that illegal landfills locations are spread over 4 types of land cover, namely vacant land, riverside, roadside, and settlement. The distribution of illegal landfills is mostly found on the type of vacant land, namely 68 locations, while the least is on the riverside with 2 locations.

In the type of roadside, there are 22 illegal landfill locations and 31 illegal landfill locations in settlement types. The survey results show that illegal landfills are more commonly found in built areas such as settlements or vacant land. Based on previous research, the allegation of garbage disposal in this type is nearby residents. In contrast to illegal landfills that are on the roadside or riverside, the alleged garbage dumpers in this type are private vehicle drivers.

On the main road, 116 illegal landfill locations are found that are more than 20 meters from the main road, while very few are found at closer distances. Two illegal landfill location points are less than 5m, there are 3 illegal landfills location points between 5 m-10 m. In the range of 10 m-15 m and 15 m-20 m, each found only 1 illegal landfill location. This shows that the existence of the main road has a negative relationship or is inversely related to the location of the illegal landfill location, further away from the main road the more illegal locations are found.

The relationship between the location of illegal landfills and local roads is divided into 5 categories starting from the closest distance less than 5 m, 5 m-10 m, 10 m-15 m, 15 m-20 m, and more than 20 m. The pattern of distribution of illegal landfill locations found on the main road is different from the distribution pattern on local roads which shows the opposite. At most local roads there were 59 illegal landfill locations at 0 m-5 m category. The second most is at 5 m-10 m category, with a total of 26 illegal landfill points. But in the next range of 10 m-15 m, there were found at least illegal landfill

points, 9 locations. Increased again at 15 m-20 m category with 14 points illegal landfills and 15 points illegal landfills at more than 20 m categories. Findings from the results of this survey show that distance to local roads has a positive relationship with the presence of illegal landfills points. The closer a location is to a local road, the higher the possibility of the emergence of illegal landfills at that location.

The relationship between the location of illegal landfills and the river is divided into 5 categories, starting from the closest distance of less than 100 m, 100 m-200 m, 200 m-300 m, 300 m-400 m, and more than 400 m. Illegal landfills distribution pattern with the distance to the river evenly from the closest to the farthest.

The survey results show that the most illegal landfill locations were found at more than 400 m category by 33 location points. However, the second most is at less than 100 m category by 26 points. The third-largest is at 300 m-400 m category from the river by 25 points. Categories 200 m-300 m from the river found 20 illegal landfill locations and at least 18 illegal landfill locations found in the distance of 100 m-200 m from the river. The survey results show that the location of illegal landfills has a negative relationship with the distance to the river, the further from the river, the more points found illegal landfills location. This shows that the people of Sukmajaya Subdistrict already have an awareness not to throw garbage in the river.

Relation of Illegal Landfills and Waste Management Service

In this research, investigate the relationship between the distribution of illegal landfills with waste management services that already exist in the Sukmajaya District. The waste management service consists of the service area which is seen from the distance to the existing legal landfills, both constructed or not. Waste management services apart from the service area are also seen from the service route.

The relationship between illegal landfills location and waste management service route is categorized into 2, namely the area inside the collection route and the area outside the collection route. The survey results show that the number of illegal landfills outside the route is more than the illegal landfills inside the collection route. The number of illegal landfills inside the collection route is 59 locations while the number of illegal landfills outside the collection route is 64 locations.

The relationship between the location of illegal landfills and the official landfills is divided into 5 categories, starting from the closest distance of less than 100 m, 100 m-200 m, 200 m-300 m, 300 m-400 m, and more than 400 m. The survey results show that illegal landfills were found in 90% or 111 locations in the category of distances of more than 400 m from the official landfills. This result shows that one of the reasons for the emergence of illegal landfills is because there are still many areas that have not been served by official waste management facilities.

The relationship between the location of illegal landfills and the official non-constructed landfills is divided into 5 categories, starting from the closest distance less than 100 m, 100 m-200 m, 200 m-300 m, 300 m-400 m and more than 400 m. Survey results show that illegal landfills were found at 87% or 107 locations in the category of distances of more than 400 m from the official non-constructed landfills. This result shows that one of the reasons for the emergence of illegal landfills is because there are still many areas that have not been served by official waste management facilities.

Discussion

Using statistic and spatial analysis as described in the result section, the most influential factor is population density and availability of a waste management facility. According to the result shows that illegal landfills are more commonly found in built areas such as settlements or vacant land. This result agrees with the research that had been conducted in Japan by Ichinose and Yamamoto (2011), but at the same time disagree with Lucendo-monedero, Jordá-borrell, & Ruiz-Rodríguez (2015). This result could be affected by the culture of the country because Indonesia and Japan are Asian countries. Another finding shows that the location of illegal landfills has a negative relationship with the distance to the river, the further from the river, the more points found illegal landfills location. These findings were different from the results of research by Jakiel et al. (2018). That research shows that illegal landfills have arisen in many valley areas adjacent to water bodies.

Conclusion

This research aims to identify the pattern of illegal landfills for the improvement of waste management. The result shows that illegal landfills have a positive relation with population density and distance to the local road. Illegal landfills also have a negative relation with distance to the primary road, distance to the river, and distance to waste management facility. Sukmajaya District had the most influential factor is population density and availability of waste management facility.

Abstract

Nowadays, cancer remains a serious disease, associated with heavy treatment costs and long-term sequelae that represent high costs of care. However, earlier diagnosis means better chances of cure and less extensive treatment. This work highlights the socio-demographic and medical factors of patients with breast cancer admitted into the 'reproductive health referral center' RHRC of Tetouan, and their impact on the various waiting-times, from onset of symptoms to access to histological diagnosis.
This is a retrospective descriptive study conducted on the breast cancer in the RHRC of Tetouan. We used accessible data from 81 women with breast cancer on registers, ranging from 46 women in 2017 to 35 women in the first half of 2018. In this study, the average consultation time is 260±345 days. As for the patients, 21% were between 18 and 39 years old, almost half 46.9% had a very low socioeconomic level and almost 33.3% were illiterate. Delay attributable to the patient or the health system delays diagnosis. Patient socioeconomic level was significantly (p=0.004) associated with health system delay, and education was significantly associated with consultation delay (p=0.020) and total time to diagnosis (p=0.026). To improve the quality of access to breast cancer care, it is necessary to make more efforts by adopting a policy whose main actions tend to minimize the factors which accentuate the length of these delays and instill health education in the Moroccan teaching curriculum in order to increase the level of literacy among Moroccan citizens.

Keywords: Breast Cancer, Consultation Delay, Diagnosis Delay, Waiting-Times, Literacy, Morocco

Introduction

Nowadays, breast cancer remains a serious disease, associated with heavy treatments and long-term consequences that represent high management costs (Delaloge *et al.*, 2016; Maghous *et al.*, 2016).

As a result, systematic screening and improved treatment and management have been required to reduce breast cancer mortality over the past 20 years (Park, Anderson and Gail, 2015; Basu *et al.*, 2018). However, the role of screening is currently controversial in terms of improving treatment (Gøtzsche and Jørgensen, 2013).

The prognosis of breast cancer is strongly linked to biology (hormonal receptors, Her2, proliferation, immune infiltrate...), but also to its stage at diagnosis.

An earlier diagnosis is synonymous with a better chance of cure, but also with less burdensome treatments (Mandelblatt *et al.*, 2016).

While early diagnosis improves the prognosis and is a decisive step in the process of breast cancer management, the current state of breast cancer care in Morocco is marred by a number of observations that may constitute obstacles to improving the quality of its management (Mimouni *et al.*, 2018).

Indeed, several studies have shown that delay in diagnosis and access to treatment remains a major problem (Rutqvist, 2006; Chintamani *et al.*, 2011; Hansen *et al.*, 2011), which has led to an awareness of the lengthy delays in access to care (Maghous *et al.*, 2016).

These waiting times depend both on the patient himself and on the health system in general. They may vary by country, region, patient characteristics, type of cancer and management strategy (Pourcel *et al.*, 2013). As a result, timeliness of care and access to care services has become a priority in public health policy at the international (Revaux *et al.*, 2014) and national (Basu *et al.*, 2018) levels, and is an important component of quality and continuity of care. It is also an indicator of healthcare system performance and a tracer of inequalities in access to healthcare (Molinié *et al.*, 2013). Some countries have committed themselves to the evaluation and quantified reduction of the time taken to treat cancers and have made this an objective of their cancer plans (Pourcel *et al.*, 2013).

As for Morocco, to date there is very little data available on the various consultation, diagnosis and treatment access times (Mimouni *et al.*, 2018).

Hence the objective of this retrospective epidemiological study spread over one and a half years (starting in 2017) was to determine the consultation, referral and histological diagnosis times of women with breast cancer admitted to the Reference and Reproductive Health center of Tetouan (RRHT) and to analyze the factors likely to influence duration.

The present study targeted a Moroccan sample of women with breast cancer at Tetouan reference center. The aims of this study were to

1) Analyze the most common causes of delays
2) Determine the delay time in the diagnosis of breast cancer in a sample of Moroccan women

Subjects and Methods

Study Population

The study is a retrospective study where the sample was based on the medical files of admitted patients for breast cancer at a reference center in Tetouan during the period from January 2017 until the first semester of 2018. Reference and reproductive health center of Tetouan (RRHT) is a Basic Health Care Facility (BHCF). The center is composed of two physicians, a head nurse, an administrator and two midwives.

The inclusion criteria's included all patients diagnosed with breast cancer and admitted to the Tetouan reference center during this period.

Data Collection

Different documents (e.g. patient records, reference center daily records, quarterly activity reports, breast cancer registry, mammographic examination reports, and pathology and extension examinations) were used in order to collect sociodemographic and clinical variables of included patients. We have received prior authorization for the collection of data, so we would like to thank the managers and the entire team of the reference centre for their cooperation.

Sociodemographic variables were analyzed including age, socioeconomic status, place of residency, and education. Other variables, related to the patient or the health system, were selected to assess their relationship to the different time frames described above. They have been categorized based on data from the literature (Benbakhta *et al.*, 2015; Mimouni *et al.*, 2018). The socio-economic level was

defined on the basis of the monthly income per household published by the High Commissioner's Office for Planning with moderation:

-Very low economic level: with a monthly income below 2000DH/household
-Low economic level: to monthly income between 2000DH and 3000 DH/household.
-Medium economic level: Monthly income between 3000 and 10 000 DH/household. While clinical variables included the referee (person who referred the patient to the reference center), history of tumor in the family, tumor characteristics (tumor size, size as measured at X-ray examination, lymph nodes involvement, Bi-RADS "Breast Imaging Reporting and Data System" mammographic classification of ACR (American College Radiology)), and diagnosis motif of reference (nodule, nipple discharge, other motifs included swarming and extreme fatigue). Moreover, the criterion for different delays were analyzed including patients delay, reference delay, histological diagnosis delay, and total diagnostic delay. Patients delay refers to the time elapsed from the first symptoms to the first medical consultation; reference delay refers to the apse of time from the first medical consultation to when patients access the reference center, while histological diagnosis delay refers to interval of time from the first medical consultation until the diagnosis based on the histopathology exams. Finally, total diagnostic delay included interval of time between the apparition of first symptoms and the date of histologic diagnosis.

Statistical Analysis

Basic characteristics were calculated by use of descriptive statistics including means, medians, standard deviation, effectives, and percentage. Violation of the normality assumption was revealed by Shapiro-Wilk test in the delays data. Consequently non-parametric test were performed. The comparison of the different delays according to socio-demographic and clinical variables was ensured using Kruskal-Wallis H and Mann-Whitney U tests. The delays were presented in the form of means and medians. All statistical analysis were conducted by use of SPSS V 21 with significance set at 5%.

Results

After the notification of the first symptoms within the breast area, 8.6% of women were able to see a doctor within 7 days. Another 19.8% of patients visited a doctor within the period of 8 to 30 days. 23.5% had a medical visit between 1 to 3 months. While 16% had an appointment between 3 to 6 months. 32.1% of the patients had medical appointment not before 6 months (Table 1).

Table 1: Distribution of patients on different delay times for the diagnosis of breast cancer

Patients delay						
Time	7 days and less	From 8 to 30 days	Over 1 to 3 months	Over 3 to 6 months	Over 6 months	Total
N	7	16	19	13	26	81
%	8.6	19.8	23.5	16	32.1	100
Reference delay						
Time	7 days and less	From 8 to 30 days	Over 1 to 3 months	Over 3 to 6 months	Over 6 months	Total
N	50	19	6	6	-	81
%	61.7	23.5	7.4	7.4	-	100
Histological diagnosis delay						
Time	7 days and less	From 8 to 30 days	Over 1 to 3 months	Over 3 to 6 months	Over 6 months	Total
N	36	31	13	1	-	81
%	44.4	38.3	16.0	1.2	-	100
Total diagnostic delay						
Time	7 days and less	From 8 to 30 days	Over 1 to 3 months	Over 3 to 6 months	Over 6 months	Total
N	-	10	17	16	38	81
%	-	12.3	21	19.8	46.9	100

After visiting a specialist physician, women were asked to perform medical tests. The results revealed that the mean time for a patient to visit a doctor after the apparition of first symptoms that could indicate breast cancer to the first medical visit was 260.8 days. However, the average time from the first medical consultation to patient access to reference center was only 22.5 days; while the average time from the first medical visit until histological test completion counted for 21.6 days. Finally, the time from the first symptom that could indicate breast cancer to histological test completion was 305 days (Table 2).

Table 2: The mean waiting time of women during breast cancer diagnosis

	Mean ± SD	Min	Max	Median	N
Patients delay	260.8 ± 345	3	1440	90	81
Reference delay	22.5 ± 40.5	0	180	3	81
histological diagnosis delay	21.6 ± 26.6	0	150	10	81
Total diagnostic delay	305 ± 349.7	10	1777	157	81

Table 3: Different delay times with regard age, place of residency and socioeconomic status

	Age range				Place of residency			Socioeconomic status			
	18-39	40-69	≥ 70	Sig	Village	Town	Sig	Very low	Low	Medium	Sig
Patients delay	**316.47**	**219.57**	**501.67**	**.05**	**287.42**	**237.28**	**.23**	**226.21**	**255.75**	**321.52**	**.172**
Reference delay	**11.18**	**25.28**	**28.17**	**.587**	**12.08**	**31.77**	**.115**	**29.79**	**12.15**	**19.57**	**.463**
histological diagnosis delay	**11.76**	**24.19**	**25**	**.054**	**14.92**	**27.58**	**.607**	**26.5[a]**	**10.25[a]**	**23.52**	**.004**
Total diagnostic delay	**339.41**	**269.03**	**554.83**	**.153**	**314.42**	**296.63**	**.784**	**283.00**	**278.15**	**364.61**	**.520**

[a] *Mann–Whitney U Test (N= 58, U= 181.500, p = .001).*

Table 3 displays the comparison between the different delays and sociodemographic variables assured by Kruskal Wallis and Mann–Whitney U Tests. The comparisons revealed a significant difference in terms of socioeconomic status of patients with breast cancer for the health system delay. The mean time for the very low socioeconomic status group 26.4 days; this was significantly ($p < .01$) higher than the patients with a low socioeconomic status (N= 58, U= 181.500, $p = .001$).

Table 4: Different delay times with respect to level of education and the referent

	Level of education					Referent				
	No qualification	Primary school	Secondary school	Higher education	Sig	The patient	Hospital	Health staff	Association	Sig
Patients delay	**390.74[a]**	**168.16[a,b]**	**217.29**	**300[b]**	**.020**	**291**	**259.82**	**292.04**	**224.42**	**.669**
Reference delay	**22.52**	**19.25**	**31.35**	**13.6**	**.867**	**16.2**	**22.39**	**19.75**	**26.79**	**.998**
Histological diagnosis delay	**19.41**	**25.47**	**21.76**	**8.8**	**.343**	**0[e,f,g]**	**19[e]**	**27.04[f]**	**23.83[g]**	**.014**
Total diagnostic delay	**432.67[c]**	**212.88[c,d]**	**270.41**	**322.4[d]**	**.026**	**307.20**	**301.21**	**338.83**	**275.04**	**.907**

[a] Mann–Whitney U Test *(N= 59, U= 267.500, p = .012).*
[b] Mann–Whitney U Test *(N= 37, U= 28.000, p = .019).*
[c] Mann–Whitney U Test *(N= 58, U= 260.500, p = .009).*
[d] Mann–Whitney U Test *(N= 37, U= 32.000, p = .032).*
[e] Mann–Whitney U Test *(N= 33, U= 17.500, p = .006).*
[f] Mann–Whitney U Test *(N= 29, U= 5.000, p= .001).*
[g] Mann–Whitney U Test *(N= 29, U= 10.000, p= .003).*

The comparison in terms of patients delay time and total diagnostic delay with education level revealed a significant difference between the four groups (*e.g.* no qualification, primary school, secondary school, higher education) ($p < .05$). Mann–Whitney U Test revealed significant higher average time for the group with absence of any qualifications (390.74 days) when compared to those who reported primary school level (168.16 days) *(N= 59, U= 267.500, p = .012)*. Similarly, total diagnostic delay for those with no qualifications (432.67 days) was higher when compared to the other education level groups and significantly higher than those who reported primary school level (212.88 days) (N= 58, U= 260.500, $p = .009$). With respect to the person who referred the patient, health system delay was significantly lower (0 days) when the patient refers oneself compared to the hospital (19 days), health staff (27.04 days), or an association (23.83 days) (Table 4).

Table 5: Different delay times with respect to the motif of reference and tumor size

	Motif of reference				**Tumor size**		
	Nodule	**Nipple discharge**	**Other motifs**	**Sig**	**Less than 3 cm**	**More than 3 cm**	**Sig**
Patients delay	362	313.6	68	.174	198.69	252.55	.160
Reference delay	26.7	50.4	23.9	611	19.77[c]	30.39c	.022
Histological diagnosis delay	18.95	24.8	21.5	.972	31.85	23.42	.584
Total diagnostic delay	407.65[a]	388.80[b]	113.40[a,b]	.047	250.31	306.36	.222

[a] *Mann–Whitney U Test (N= 30, U= 53.500, p = .041).*
[b] *Mann–Whitney U Test (N= 15, U= 6.000, p = .020).*
[c] *Mann–Whitney U Test (N= 59, U= 282.000, p = .022).*

The group who had nodule and nipple discharge as a motif of reference displayed the significant highest time average (407.65 and 388.8 days; *(N= 30, U= 53.500, p = .041 & N= 15, U= 6.000, p = .020;* respectively) for the total diagnostic delay when compared to other motifs (such as swarming, intense fatigue...). While those who had a tumor size of more than 3cm had significantly higher reference delay (30.39 days) when compared to those with lower tumor size (19.77 days) *(N= 59, U= 282.000, p = .022)* (Table 5).

Discussion

This work has several scientific and methodological advantages, since it allowed us to draw up an inventory of the delays in breast cancer management at the Reference and Reproductive Health center of Tetouan (RRHT) and it is the first study of this type in our region.

It highlights the medical, educational and socioeconomic factors of admitted breast cancer patients (RPHT) and their impact on the various delays, from the onset of symptoms to access to histological diagnosis by these subjects.

We were interested in the measurement of delays in access to diagnosis since they are part of the different care times, which appear as performance indicators of the health care system (Maghous *et al*., 2016). A quality healthcare system must continually measure and evaluate its delays in order to minimize them, because the longer the delay, the more the patient loses confidence in the healthcare system, and the illness may worsen and may go from an early stage of cancer to a high, even incurable, stage (Li, 2013).

In the present study, the average consultation time was 260±345 days with a median time of 90 days, which is higher than that of a national study (Benbakhta *et al*., 2015), which was 65 days. This is higher than the one reported in some European countries. Such as Italy (Montella, Crispo and Aiuto, 2001), France (Latrache *et al*., 2004), Great Britain and Germany (Nosarti *et al*., 2000), which had median delays of 31, 28, 13 and 21 days respectively, but this delay remains lower than that recorded in Tunisia (Landolsi *et al*., 2010), Libya (Eramah *et al*., 2012) and Iran (Montazeri, Ebrahimi and Mehrdad, 2003).

With regard to the reference time (time taken from the local health Centre to the Reference and Reproductive Health Centre), the average was 22.5±40.5 days, with a median of 3 days, with a maximum of 180 days and a minimum of 0 days. In our research, we decided to study it because of its importance in order to evaluate the quality of the reference circuit in this region and to compare it with other research at a national and international level.

For the time of histological diagnosis, the mean was 21.6±26.6 days, with a median of 10 days, which is lower than those found in two national studies (Benbakhta *et al*., 2015; Mimouni *et al*., 2018); which were respectively 20 days and 29.5 days, inferior to that in Tunisia (Limam, 2015) which was 15 days and that of a study in France (INCA, 2013) which was 13 days. As for the total time to diagnosis, the mean is 305±349.7 days, with a median of 157 days, which is higher than that of a national study, which was 20 days (Benbakhta *et al*., 2015).

With regard to socio-demographic factors, the time to visit (time a patient takes from the onset of symptoms to the day she visits), shows a significant association with age groups; where the young age group [18-39] shows a significantly shorter delay compared with the old age group +70. This was confirmed by other studies, where age was considered a risk factor for both cancer development and long delay [15-49]. Therefore, any education and intervention program should target older women in particular (Grunfeld *et al.*, 2002).

The socioeconomic level of patients was significantly (p=0.004) associated with the time to histological diagnosis, with women with very low economic status being diagnosed late, a result similar to other studies (Benbakhta *et al*., 2015).

Education level is significantly associated with the time to consultation and with the total time to diagnosis. In fact, the time to consultation of patients with primary school education is lower than that of illiterate patients, similar to other research where education influenced the time to diagnosis (Khan *et al*., 2018). However, in our study, women with higher levels of education lagged behind those with only one level of education, which may be because their higher education level did not positively influence their literacy or because their education system lacked specialized education about breast cancer prevention and early detection.

Time to referral was significantly associated with tumor size greater than 3cm (p=0.02), a result similar to other studies (Benbakhta *et al*., 2015). We find that the longer patients wait, the worse their disease gets.

Mammographic classification did not show significant differences in the different time frames.

Patients who present nodules as a reason for referral have a significantly higher total time to diagnosis than those with other symptoms (intense fatigue, tingling, etc.); the lack of knowledge about breast cancer symptoms probably explains this. However, women need to be educated about the different types of breast cancer symptoms.

Finally, in order to better understand the factors influencing the delay of diagnosis and treatment of breast cancer patients, studies are needed to investigate these associations, particularly in Morocco.

Limitations

The duration of the study was only 1.5 year, which gives it an aspect of exemplarity and not representativeness. We focused only on the time taken for consultations, referrals and diagnoses since they are the only time periods accessible in the documents. We did not deal with the time taken to access treatment since it is not one of the missions of the reference Centre, but there is still a significant time period and we suggest that other studies look at this time period; this could make the work more comparative at the national and international level.

Despite these limitations, we have made significant efforts to highlight those findings that could be useful and serve as a basis for further research and the development of recommendations to promote quality management of breast cancer patients in this country.

Conclusion

Through this work, although it was only exemplary, we demonstrated that both patient-attributable and health system delays play a role in delaying access to diagnosis and later access to treatment for breast cancer patients in our region.

We have highlighted some factors that impede their referral pathway such as the academic and socioeconomic level of the subjects.

In fact, these patients most often consult late after the onset of symptoms. It is important to bring these patients to consult at an early stage and this, by several complementary measures: by sensitizing them, by reinforcing the patient's circuit, by providing the oncology health structures with sufficient human and material resources.

Earlier diagnosis means a better chance of cure, but also less burdensome treatment. Therefore, we suggest making greater efforts to improve the quality of access to breast cancer care by adopting a policy whose main actions tend to minimize the factors that increase the length of these delays and to inculcate health education in the Moroccan educational curriculum in order to increase the level of literacy among Moroccan citizens.

As for the tests currently used for the diagnosis of breast cancer in Morocco: mammography, biopsy and MRI; they remain important, but we recommend developing research on epigenetic biomarkers and the detection of tumor-induced mutations in circulating DNA in order to carry out tests that diagnose cancer very early or even predict it (pre-cancer).

Abstract

The purpose of the article was to show the issues of leadership in sports teams on the example of ice hockey. The undertaken research focused attention on the issues of current and desired leadership style in ice hockey team's management. The OCAI Cameron and Quinn questionnaire was used. In the light of the research results obtained, it can be stated that the ice hockey coaching staff, centered at OSHL, perceives the current features of the work environment, which are characterized by hierarchical culture. The formalization of interpersonal relationships dominates, in which hierarchy applies and strict procedures apply. Leaders are coordinators focused on efficiency, which in the case of sport is expressed by the result of the game. Efficiency is ensured by formal rules and regulations. On the other hand, they believe that the organizational culture of the coaching work environment should undergo a metamorphosis. Clan culture creates a friendly workplace in which people willingly interact with each other. Reminiscent of a big family. Bosses and supervisors assume the role of advisors, teachers and even parents. The organization continues thanks to employee loyalty and commitment to tradition. A high degree of involvement is observed. The organization emphasizes the long-term benefits of personal development and attaches great importance to consistency and morale. The measure of success is the development of human resources and concern for employees. The organization highly values teamwork, participation and consensus.

Keywords: Organizational Culture, Sport Leadership, Ice Hockey

Introduction

Ice hockey as a discipline of team sports game bases its functioning on the organizational and legal principles of the Polish Ice Hockey Association (PIHA, org. PZHL). In terms of training and functionality (training, sports games, HR processes, etc.), it is based on the functioning of Ice Hockey Training Centers (IHTC, org. OSHL) and the work of managing managers (trainers) who manage the players' activities. The relationship between managing managers, ice hockey trainers, and executive employees (ice hockey players) is a case study, by analogy with other work environments, types of organizations and sectors of the economy. As an organization, it creates a specific organizational culture in the ideal (goals, values, strategy), normative (norms, rules, regulations, statutes and regulations) and physical and material (physical, communication and behavioral artifacts).

This specific sports environment (ethos, physical structure, dress code, proxemics of the rules of the game, etc.) has a specific vision of methods and techniques of managing people, ice hockey players, which in their operational work is expressed and applied by managing managers, ice hockey trainers. An environment of very hard and permanent competition can become a case study and an example for other sports organizations and disciplines, as well as other sectors of the economy in which fierce struggle and competition take place. One of the most important aspects of organizational culture is the dominant management style and it has just been analyzed as part of this research process. The middle level of management, line managers, implement the strategic arrangements of the highest

level of management, therefore, organizational culture managers, trainers and managers were subjected to research in organizational culture.

The issue of leadership is currently of great interest to both scientists and management practitioners participating in various sectors of the economy. One of the most popular and arousing public interest is sport, although in general it is not directly associated with management and science. This sector of the national economy has enormous image, investment and economic potential, which puts it at the forefront of other economic sectors.

Apart from the indisputable social values of sport, it also has its economic value and constitutes a significant part of the national economy. Information on employment and the share of the sports sector in both state revenues as well as in public and private sector expenditure are necessary to create strategies in the field of sport and to plan future activities that are part of the implementation of the state's economic policy. Macroeconomic values related to sporting activities can also be used to plan tasks with a broader regional or EU scope (GUS, 2010:6).

The impact of sport on the economy is almost PLN 10 billion. In 2018, the sport industry generated a total of PLN 9.63 billion in value added. This amount would al-low each Polish citizen to finance two tickets for the qualifying matches of the European Championships. At the same time, it generated a total of nearly PLN 3 billion in remuneration. This amount is equivalent to the sum that each year the newly-weds receive as wedding gifts. In 2018, the sport industry also contributed to maintaining a total of nearly 109 thousand. jobs. Such a number of jobs would make it possible to find employment for every eighth unemployed person in Poland (Polish Economic Institute, 2019:4).

Sport, which is primarily associated with active leisure, or sports competition, is also an important branch of industry. It is part of the national economy and generates revenues for the state budget. On the other hand, sport is related to the expenses of the state budget, budgets of local governments, private enterprises and house-holds (GUS, 2010:7).

Therefore, it seems justified that issues related to leadership, so important for the economy, both on a microeconomic and macroeconomic scale, should be the subject of scientific analysis in relation to the sports sector. However, the article is not devoted to the issues of sport economics, but to one of the factors that contribute to the formation of the mentioned multiplier, namely the culture of leadership.

Leadership as an interpersonal process between a leader and a team is particularly expressive and specific in relations of a military, rescue and sport nature. In sport, however, the relationship between the leader - trainer and player - student is interesting. Coaching activity in team sports becomes particularly important.

As a consequence of the above justification, the author of the presented article set himself the goal of presenting the results of leadership tests in the environment of ice hockey coaches. As a niche discipline, he does not enjoy equal interest in foot-ball, but due to the fact that ice hockey is a highly contact discipline and it causes strong emotions, leadership plays a particularly important role in it. Together with the competitive environment, sports and functional and functional infrastructure, rules of the sport discipline and the procedures of its training and playing, it creates an ice hockey culture, i.e. a specific type of organizational culture.

Despite some differences in the definition of culture, their authors generally do not show a significant polarization of views. They see it as a general term, which includes social behavior and standards in force in human communities, as well as knowledge, beliefs, art, law, customs, habits, habits and all forms of communication as well as motivational and cognitive processes that characterize their members. Leadership is an important element of culture and together with it creates a basis for the existence of various types of human communities, including socio-professional groups such as sports team coaches.

Culture in The Interpersonal and Organizational Dimension

Culture theorists seeking to systematize this concept have developed a typology for its definition, reflecting various aspects of cultural phenomena: descriptive and enumerating, historical, normative, psychological, structural, genetic and general description (Czaja, 2013:63).

Normative definitions of culture explain the basics of people's behavior in moral and cultural categories, emphasizing the importance of values and norms in shaping social structures and interpersonal processes. Stoner, Freeman and Gilbert write about it, defining culture as a set of important concepts, such as norms, values, attitudes and beliefs common to members of the organization (Stoner, Freeman, Gilbert, 2011:20).

Psychological definitions refer to psychic mechanisms that are the source of human cognition, including the process of learning, motivation, attitudes, creating habits, abilities and processes of interpersonal communication. Sikorski defined culture as: „a system of thinking patterns and actions that are well-established in the social environment of the organization and are relevant to the implementation of its for-mal goals" (Sikorski, 2002:4).

Structural definitions focus on the holistic nature of individual cultures and their internal specificity. Definitions of this type are attempts to define subject cultures, e.g. classes and social groups, professional groups etc. Piwowar-Sulej writes that culture: „is a model of basic assumptions that a given group discovered, invented or developed during confrontation with internal problems of this group or environ-mental problems. These assumptions have proved themselves, so they were considered binding and are passed on to new members of the group as an appropriate way of perception"(Piwowar-Sulej, 2014:143).

General descriptions are formulated for practical purposes, for the needs of institutions dealing with culture, as well as for teaching purposes. They contain a compendial set of cultural features, describe the methodology of its creation and development. The encyclopedic definition defines it as: the whole of the material and spiritual achievements of humanity, accumulated, preserved and enriched throughout its history, passed down from generation to generation. The culture understood in this way includes not only material products and social institutions, but also the principles of social coexistence, procedures, patterns, criteria of aesthetic and moral assessments adopted in a given community and determining applicable behavior.

The social and professional environment in which a particular professional group operates operates based on an organizational and legal structure, which is a type of formal organization, e.g. institutions, enterprises, associations, associations, etc. It generates various social and economic phenomena and processes that include the above-mentioned aspects of culture definition relating to a relatively specific organizational entity. It has a relatively mature, coherent and expressive organizational culture, in other words, the culture of a given socio-technical system.

Organizational culture is a practical methodology for the perception, identification and evaluation of an organization and its environment in the light of their mutual interactions and the context of these feedback, it is the result of laboriously acquired in-depth knowledge, as well as systematically achieved rich experience, acquired through social processes through an optimally configured personality decision-maker (...) on which they build groups, teams and organizations formed on the basis of developed standards " (Mrozowicz, 2010:13-29).

The presented article uses the theory and methodology for assessing the type of organizational culture by K. Cameron and R. Quinn, who define it as: „all the fundamental assumptions that a given group came up with, discovered or created, learning to adapt to the environment and internal integration. Unwritten, often sub-consciously followed rules that bridge the gap between what is written and what

is actually happening. Culture is about shared views, ideologies, values, beliefs, expectations and norms" (Cameron, Quinn, 2015:28-59).

Leadership in organizational culture

In the literature on the subject, there are many attempts to define the leadership process, which is one of the leading elements constituting culture, including organizational culture.

R. W. Griffin defines them as: using non-compulsory influence to shape the goals of the group or organization, motivating behaviors focused on achieving those goals and helping to determine the culture of the group or organization (Griffin, 2004:544). The author of the definition draws attention to the use of motivational influence to shape the group's goal in such a way that the group itself feels the desire to follow the leader, regardless of his formal position in the structure of the organization. The formal position of a leader strengthens the influence of leadership, the synergy of both types of power, formal and informal, acts as a catalyst, reinforcing the effect of leadership influence.

A. Kożuch believes that „leadership can be defined as a process of managing and influencing task-related group activities" (Kożuch, 2008:73). As in the previous definition, the lea-der influences the activities of the group, but omits the cause of the influence of in-formal power. Some leadership influences are discreet, camouflaged, unofficial and sometimes even confidential.

Coaching-oriented definition is cited by J. Stoner, who defines leadership as a process of managing and influencing the activities of group members related to its tasks (Stoner, 1997:453). In this approach, the formal authority of the leader is very strongly emphasized, while his optics of his actions focuses on goals rather than people. This kind of approach may prove useful during technique and motor skills training, where repetitions of activities and actions play the most important role until the complete automation of optimally effective behavior (eupraxia).

J. Deja and Z. Śliwa refer the concept of leadership to authority. „The leader is a human-age who refers mainly to his own substantive and moral authority. His actions are aimed at expanding and strengthening these types of authority. This does not mean disregarding formal authority. An effective leader bases his leadership on all his types and, depending on the situation, he emphasizes the one who meets the requirements of a given situation" (Deja, Śliwa, 2002:7) . An important role in leadership is played by, for example, one's own and authority, which, if they are based on their knowledge and skills, form the basis of trust, commitment and loyalty among subordinates. In the case of athletes, it is an absolute condition, because didactics and coaching practice should be based on authentic own resources. This does not mean that every good trainer should have masterful sports achievements, but should have the skills and knowledge to manage individual and team work.

The original vision of leadership is formulated by J. Woroniecki, writing: „no social cell can be included in its regulations in such strict notches that it functions like an automaton at the push of a button. It would be far from the ideal of human society, composed of rational and free individuals, whose spontaneous activities con-tribute to the common good. This superordinate activity of the subordinates is to be directed by the superior by means of orders and reminders, and it is now necessary to consider how he should do it" (Woroniecki, 2016:12). The originality of the above approach is based on the fact that its author placed the main emphasis on the ethical aspect of exerting managerial influence. Unfortunately, the whole of the thought cannot be considered an appropriate and universal leadership imperative. While conscious emission of leadership actions, leading to the achievement of some social good by a person, a team or organization, is a desirable phenomenon, the choice of management style based on formal instruments of power can be an ineffective means of influence which is to lead to this goal. In the repertoire of a good leader, apart from commands and reprimands, incentives, praise and rewards should take an important place.

The cited opinion of a well-known theologian and religious may be surprising given the nature of the social role he plays. It turns out that also in such a specific social environment, the issue of leadership is very important.

In summary, it should be emphasized that: ,,management is a continuous transfer of multidimensional interpersonal relations between the supervisor and subordinates, the leader and subordinates. Managing people enables the progression of work efficiency by shaping the individual and interpersonal competences of team members. Coordination activities belong to endogenous determinants, but their formation is conditioned by the influence of exogenous and situational factors" (Nagody-Mrozowicz, 2015:450). Issue of management actions in the form of exerting formal influence, delegation of decision-making powers, various forms of vertical communication, legal use of motivational reinforcements in the form of prizes and penalties, as well as shaping strategies and operational activities in creating and implementing the vision of organizational culture is a legalistic complement to power.

Sports team as a social system

A team is a set of people who have a common, specific goal and complementary skills (Kmiotek, Pecuch, 2012:150-170) . The team is treated as a specific, coherent group of people with clearly defined roles, norms and group responsibilities (Rutka, Wróbel, 2012:74-81). There is a sense of mutual responsibility in the team, a willingness to take actions and belonging together. The team, as an element of the organization, has both formal and informal connections, strives to perform specific tasks in order to achieve material and non-material gratification (Kożusznik, 2002:103-109). It is assumed that the team achieves better results than employees ac-ting individually, due to the synergy mechanism, based on resource transactions be-tween team members based on communication channels and interpersonal relations (Ćwik, 2013:2-10).

A sports group, like any group, creates a system - a set of interrelated ,,elements" that interact and are more than just a simple sum of their parts. The system has its structure, it is characterized by diversity, dynamism and ability to develop. Regardless of whether we consider a group of young athletes or older, the development stages of such a group are similar (Grzesik, 2020).

In today's sports reality, we are dealing with transfers almost virtually all the time and very rarely there are situations when a team at the senior level in the same statement plays for more than one season. There are smaller or larger rotations in the composition, both in terms of players and coaches. Bands are created from scratch. Every season, therefore, a group of strangers or only partially known to each other meets during the preparatory period. These units are to form a real team and achieve their goals. For some teams it will be the medal of the Polish champions-hips, for others it will be promoted to the higher class, while others will aim to stay in the league (Grzesik, 2020).

Polish Hockey League

The professional sports game of ice hockey teams is based on league games. On April 26, 2013, the Polish Ice Hockey Association (PZHL) set up a limited company, which aims to organize and manage the highest-level league games in Poland (thus becoming a professional league), while PZHL became the sole shareholder of the company. Up to and including the 2012/2013 season, the highest competition class in Poland operated under the name Polish Hockey League (PLH), and earlier as the first league. In June 2013, the HC GKS Katowice, Zagłębie Sosnowiec and Polonia Bytom clubs signed the contract with the Polish Hockey League (PHL). On July 15, 2013, the "Wild cards" declared 1928 KTH and MMKS Podhale Nowy Targ, entitling to play in the league provided that the licensing requirements are met. On July 25, 2013, three clubs were licensed: Polonia Bytom, JKH GKS Jastrzębie and MMKS Podhale Nowy Targ.

The essence of ice hockey tactics

Ice hockey is a very dynamic team sport game full of temperament and emotions, played on the ice pane with the use of specific sports equipment. Its characteristic feature is the constant, full of bustle and psychophysical advancement fight of two teams, interspersed with an alternating attack and defense (Gabryś, Rutkowski, 2002:12). The antagonized goals of stakeholders of both organizations - rival teams - cause permanent emotional tensions, dynamics and speed of offensive or defensive play, fast physical exhaustion with a properly selected system of changes, conditions of potential collisions and resulting injuries of the motor apparatus. During the offensive game, the main task of the competitor is to lead the puck, free himself from the defense player, assume the optimal shooting position and shoot at the opponent's goal (Mruk, 2000a). In a defensive game, the defender's task is to attack and block the opponent's body, try to take the puck and block shots (Mruk, 2000b). Ice hockey is a game in full physical contact, where the rules of the game tolerate violation of personal space to the limits of al-most physical aggression. A visual assessment of the hockey teams' struggle implies the unique confrontationality of ice hockey compared to other team sports. In basketball and handball, for example, there is also full body contact between players of opposing teams, but the technique and tactics of the game direct the player's attention to the elimination, reduction or minimization of contact (Grage, 2002; Neumann, 2003).

T. Gabryś and T. Rutkowski distinguish several so-called Hockey schools (Gabryś, Rutkowski, 2002:13), which, regardless of their type, require fast and perfect skating:

- Canadian, in which individual and brutal duels in full contact are a characteristic feature. The essence of the game is an individualized attack full of personal virtuosity, the whole team is involved in the defense, the goal of the game is its demonstration;

- Russian, in which the emphasis is on excellent physical preparation and high pace of the whole team. The emphasis is on the individual technique of driving and playing with a stick, as well as subordinating all competitors to the goal of the whole team. Collectivism is supported by a very large number of applications;

- Czech, which is based on a perfectly organized defense game of the whole team, which is the starting point for a fast and coordinated attack. In the defense game specific tactical tasks are carried out, in the offensive game individual predispositions and skills are used.

Ice hockey theorists and trainers point out the characteristic characterological and psychomotor features of players in this sport discipline (Kostka, Bukac, Safrik, 1986). The subjectification of pre-selection and recruitment assessments during recruitment for the first stage and in subsequent training cycles and phases is emphasized (Kostka, McDonald, 2002).

According to the trainers, the characteristics of an optimal ice hockey player are: motor speed, character hardness, resistance to brutal physical contact, creativity, the ability to soberly assess the situation, the ability to maintain emotional balance under the influence of intense sports competition. Playing technique and motor preparation are a sine qua non condition and only a starting point in shaping the result of a sports team (Gabryś, Rutkowski, 2002:15).

Characteristics of organizational cultures according to Cameron & Quinn

Culture programs the mind of its participant. It is a learning methodology that in a non-invasive and imperceptible way shapes the mind of an individual almost irretrievably (Mrozowicz, 2010:13-19). From now on, from the moment of initiation, that is, the first moments of learning, she becomes a member of the community and begins to count as much as it is worth the place she fell in the evolutionary flow of phylogeny. Mystically oriented fatigues will call this process karma, and statisticians will see in it the rules of normal distribution, the man of science should perceive it as a

result of the social orientation of human existence, based primarily on multiple forms of inter-personal communication.

G. Hofstede & G. J. Hofstede write: „culture is always a social phenomenon, because it is to some extent common to people living in a given social environment. Particularly noteworthy is the authors' digression that: Culture is an unwritten set of social game rules. It is a collective mind programming that distinguishes members of one group or category of people from another" (Hofstede G., Hofstede, 2007:17). Probabilistic features of culture are emphasized by comparing it to a game in which the account of probability rules, and the final states are merely equivalent. Culture is potential because it is created by libertarian oriented people who go beyond geometrically constructed patterns.

P. Bordieu perceived the collective programming of the mind on the basis of the statement that: „specific living conditions form a" habitus ", i.e. a system of constant and transmitted tendencies. Habitus is the basis of practice and ideas that interact without external control" (Bordieu, 1980:88-89). So the impact of the cybernetic super-system is not necessary for the internal organization of the part, which confirms the thesis about self-organization of the system and relative autonomy, according to L. von Bertalanffy (Bertalanffy, 1984).

According to the concept of organizational culture understood in this way, its theorists K. Cameron & R. Quinn created a typology of cultures and specified their axial features (Cameron, Quinn, 2015).

Clan culture is a friendly workplace in which people willingly cooperate with each other. Reminiscent of a big family. Bosses and supervisors assume the role of advisors, teachers and even parents. The organization continues thanks to employee loyalty and commitment to tradition. A high degree of involvement is observed. The organization emphasizes the long-term benefits of personal development and attaches great importance to consistency and morale. The measure of success is the development of human resources and care for employees. The organization highly values teamwork, participation and consensus.

Dynamics, entrepreneurship and creativity reign in the organization of adhocratic culture. People are not afraid of risk. Leaders are considered innovators and visionaries. What ensures organization consistency is the desire to experiment and intro-duce new products. It is important to lead the way in your field. In the long run, the organization puts emphasis on growth, taking challenges and acquiring new resources. Success is identified with offering unique products or services. The organization is seeking a leadership position in the field of products or services. The organization encourages freedom and initiative.

The hierarchical culture is dominated by formalization of the workplace in which strict hierarchy applies. Everything people do is governed by procedures. Leaders pride themselves on being good coordinators and organizers focused on efficiency. The most important is the efficient functioning of the organization. Its formal rules and regulations ensure consistency. The strategic perspective is about stability, per-formance and smooth operation. The measures of success are: reliability of deliveries, adherence to schedules and low costs. Employee management focuses on job security, ensuring stability and predictability.

In the market culture, the organization is primarily about results, the main concern is the implementation of tasks. People are very ambitious and focused on achieving goals. The leader is a supervisor focused on competitiveness and production. He is ruthless and demanding. Coherence of the organization ensures its expansiveness and willingness to win. Reputation and success are the main concerns. In the long run, what counts is competitiveness and achieving measurable goals. The measure of success is market share and continuous expansion of the market and gaining new ones. Competitive prices and market leadership are important goals. The style of management is based on the promotion of fierce competition.

Methodology of own research

In the methodological dimension of the presented research results, their interpretation and application aspects, the following issues will be discussed: research goals and questions, characteristics of the study group and description of the research tool.

Research goals and questions

In terms of research objectives, the following were distinguished:

- theoretical goal: presentation of organizational culture issues and ice hockey features, which due to the rules, strategy and features of this team game discipline, has a specific organizational culture;

- research goal: empirical identification of the dominant management style in ice hockey in the current (operational - "how is?") And future (strategic - "how should it be?") In the opinion of the management (hockey trainers / trainers on boats);

- application purpose: showing the relationship between the characteristics of a sport discipline and the management style preferred by managers as a case study for other sport disciplines and task teams of another type of organization.

The objectives of the research were achieved by verifying the answers to the following research questions:

- What type of organizational culture currently exists in the ice hockey coaching environment?

- What type of management style is currently used in the ice hockey coaching environment?

- What are the perceptions of organizational culture and leadership in the future (e.g. in the strategic dimension of 5 years)?

- What is the reason for the dissonance between the real and the potential situation, in other words between the perception of the current state and the anticipation of the future state?

Study Group

Ice hockey as a discipline of team sports game bases its functioning on the organizational and legal principles of the Polish Ice Hockey Association (PZHL). In terms of training and functionality (training, sports games, HR processes, etc.), it is based on the functioning of Ice Hockey Training Centers (OSHL) and the work of managing managers (trainers) who manage the activities of the players.

The sample was taken from the general population (GP) of OSHL trainers (GP = 53). The study group (GB) finally included 40 randomly selected ice hockey coaches from four Polish cities: Katowice, Oświęcim, Nowy Targ and Toruń. The sample has high representativeness in terms of quantity (75% GP) and distribution of respondents (all OSHL sets).

Research Tool

The purpose of the OCAI questionnaire for assessing the culture of the organization is to identify six basic dimensions of culture. The completed questionnaire is information on how the organization works and what values characterize it.

OCAI consists of 6 aspects, which are expressed in the form of question sentences:

1. What is the general characteristics of the organization? 2. What is the leadership style of the organization? 3. What is the style of employee management? 4. What ensures the consistency of the organization? 5. What is the most emphasized? 6. What are the criteria for the success of the organization? (Table 1).

The undertaken research focused attention on the issues of the current and desired leadership style in ice hockey teams management.

Each question has four answers, between which 100 points should be distributed in a way that reflects the situation of the organization. The closest answer to the truth will be the more assigned points. The current status is a type of culture in the pre-sent situation, while the desirable status is one that in the respondents' opinion should present the functioning of the organization in five years.

The results are obtained by adding up the points obtained, which have been allocated to the answer A in the current state column, after which this sum of points should be divided by six. The arithmetic mean of the points is obtained. Similarly, the remaining answers B, C, D. are followed. In the next step, answers about the de-sired state are calculated in an identical manner (Cameron, Quinn, 2015:15). All results are obtained in the form of arithmetic means that add up to 100 points. The highest point result is the dominant aspect of organizational culture and the dominant desired state.

These four aspects, which were expressed in the questionnaire by upper case letters: A, B, C and D, represent the types of organizational cultures that Cameron & Quinn described in their classification, presented earlier in this article. The letter A refers to clan culture, the letter B corresponds to adhocultural culture, the letter C is related to the market culture, and the letter D expresses the hierarchical culture

Tabel 1: ***Aspect of organizational culture: "What is the style of leadership in an organization?" based on the theory of K. Cameron and R. Quinn. Source: Cameron K., Quinn R. Organizational culture - diagnosis and change: a model of competing values. Wolters Kluwer. Warsaw 2015***

What is the leadership style in the organization?		**Current status**	**Desired status**
A.	Leadership in an organization is commonly identified with providing advice and help as well as providing care		
B.	Organizational leadership is commonly identified with entrepreneurship, innovation and risk-taking		
C.	Leadership in the organization is commonly identified with firmness, expansiveness and result orientation		
D.	Leadership in organization is commonly identified with coordination, efficient organization, and creation of harmonious conditions for achieving good results		
Total (in points)		100 points	100 points

Research results

As a result of the tests, it was found that:

 leadership in the study group is commonly identified with coordination, efficient organization, and creation of harmonious conditions for achieving good results - that is, with autocratic management style common in hierarchical cultures (28 points, Table 2);

 the study group would like to change the current style of leadership, based on hierarchical relations to a style that characterizes clan cultures, which is identified with providing advice and help and providing care for subordinates (29.6 points, Table 2).

Tabel 2: ***Aspect of organizational culture: "What is the style of leadership in an organization?" based on the theory of K. Cameron and R. Quinn. Source: Cameron K., Quinn R. Organizational culture - diagnosis and change: a model of competing values. Wolters Kluwer. Warsaw 2015***

What is the leadership style in the organization?		Current status	Desired status
A.	Leadership in an organization is commonly identified with providing advice and help as well as providing care	24,9	29,6
B.	Organizational leadership is commonly identified with entrepreneurship, innovation and risk-taking	21,0	24,3
C.	Leadership in the organization is commonly identified with firmness, expansiveness and result orientation	26,1	23,0
D.	Leadership in organization is commonly identified with coordination, efficient organization, and creation of harmonious conditions for achieving good results	28,0	23,1
Total (in points)		100 points	100 points

Conclusions

In the light of the obtained research results, it can be stated that the ice hockey coaching staff, concentrated in OSHL, perceives the current features of the work environment, which are characterized by hierarchical culture. The formalization of interpersonal relationships dominates, in which hierarchy applies and strict procedures apply. Leaders are coordinators focused on efficiency, which in the case of sport is expressed by the result of the game. Efficiency is ensured by formal rules and regulations.

On the other hand, they believe that the organizational culture of the coaching work environment should undergo a metamorphosis.

Clan culture creates a friendly workplace in which people willingly interact with each other. Reminiscent of a big family. Bosses and supervisors assume the role of advisors, teachers and even parents. The organization continues thanks to employee loyalty and commitment to tradition. A high degree of involvement is observed. The organization emphasizes the long-term benefits of personal development and attaches great importance to consistency and morale. The measure of success is the development of human resources and concern for employees. The organization highly values teamwork, participation and consensus.

It follows that ice hockey trainers in Poland appreciate the benefits of a style of managing people that corresponds to clan culture, but currently the culture that prevails in this work environment is interpersonal relationships based on hierarchy and autocratic style of management.

The conclusion can be concluded on the basis of the above research results and arguments that there is no process of conscious and committed leadership among the studied professional group, and the players must adapt to the influence of trainers.

National Culture in Quality Management Research

Abstract

Ever since Geert Hofstede first introduced the value dimensions model, national culture has been one of the most important research topics in business research altogether, and the same goes for quality management research. Implementation of quality management systems and principles in an organization is dependent on the environmental context and dominant cultural values. However, changes in international markets and trends, such as globalization, have acted as drivers of both organizational and national isomorphism. This has led to questions being asked about the relevance of national culture in contemporary quality management research. In order to answer these questions this paper provides a review of literature on national culture in quality management research. The aim of the paper is to analyze different models of national culture and key research topics in the field of quality management and national culture. To provide a more meaningful insight the paper also discusses critiques of national culture construct and offers new directions for future research of the role national culture plays in quality management research.

Keywords: National Culture, Quality Management, Value Dimension Models.

Introduction

Peter Drucker defined culture as a master variable that has an effect on all aspects of an organization. The same can be said about culture in societies as well. National culture can be seen as an invisible link between individuals coming from the same societies that influences everything that they do and the way they do it. Importance of national culture has been recognized in business research quite some time ago. Kirkman et al. (2017) state that early national culture scholars such as Kroeber & Kluckholn (1952) have already shown that cultural values have a significant influence on workplace behavior and attitudes and thus indirectly influence other organizational outcomes as well. Differences in national culture also dictate the way multinational corporations enter foreign markets as well as their business strategies altogether.

National culture refers to how members of a culture generally behave, regardless of the environment in which they are. On the other hand, it is clear that it will have a significant impact on the behavior of individuals in organizations, and indirectly on the results of organizational processes and their acceptance or rejection by individuals. Gerhart (2009) explains how two conflicting management theories, institutional theory and resource theory, give completely different conclusions about the potential impact of national culture on organizational outcomes. According to institutional theory, organizations will adapt to the environment, while according to resource theory, the key to sustaining an organization's viability and survival is "looking inside" and differentiating from others by possessing an idiosyncratic combination of resources which competitors cannot copy, regardless of the environment. Oliver (1991) integrates these two views, explaining that an organization will have a number of different strategic responses to institutional pressures and adapt its behavior to the context and situation in such a way that it will resist depending on the economic gain from adaptation or resisting. The impact of national culture on the implementation of quality management in organizations should also be analyzed in this context.

The widespread attention national culture received over the years has resulted in an impressive body of literature. However, as it often happens the literature streams have become somewhat entangled and the literature itself disparate. Therefore, the aim of this paper is to bring together different parts of the literature and help establish connections between different research streams. In order to do so we will explain the construct of national culture and the national culture value dimensions models as well as more recent approaches to national culture. The paper will also offer a comprehensive review of the field and give recommendations for future research as well as an overview of critiques of dominant national culture research in the context of quality management.

Literature Review

National culture was first mentioned in the theories of cultural anthropology. According to the anthropologists, culture is learned and absorbed through behaviors that are transferred through generations and strengthened through various socializing agents such as family, parents or social leaders. Taras et al. (2009) claim more that socializing agents and experiences individuals within a particular collective share, the greater the chance they will share a similar cultural lens through which they view the world and from which they derive values and attitudes toward particular behaviors. National culture can be viewed as a key informal institution of a country (Berry et al., 2010). At its core, national culture contains the responses of individuals within a society to certain problems they encounter on a daily basis. Inkeles and Levison (1969) were among the first to hypothesize that national culture can be seen as a set of values that explain how people cope with authority, gender roles in society, and ways to resolve conflict. Given the great interest of scholars from almost all parts of the social sciences, a large number of different definitions of national culture can be found in the literature. All definitions at least partly define national culture as a shared characteristic of a particular group of people, and state values are the basis of national culture. In this paper, we define national culture as “a complex, multi-level construct with values in its core, and outwardly manifested through practices, symbols and artifacts. It is shared by individuals who belong to a group or society. It forms over a long time and is relatively stable over time” (Schein, 1983; Hofstede et al., 2010).

National culture was often treated as an exogenous variable in business research. Impact of national culture was recognized but not quantified. This changed in the mid-1980s when Dutch scientist Geert Hofstede (1983) introduced his national culture value dimensions model. The model measured four dimensions of national culture: power distance, individualism vs. collectivism, uncertainty avoidance and masculinity vs. femininity. The dimensions were a reflection of four anthropological problem areas that were handled in different ways in different societies. Two more dimensions were added in the model later (long term vs. short term orientation and indulgence vs. restraint). Following Hofstede, a number of scientists developed their own models of national culture value dimensions. Schwartz (1994) analyzed differences and similarities of culture at national and individual level and defined three types of problems that people in all societies had to deal with: relationship between an individual and the group, ensuring socially responsible behavior and the relationship between society and nature. Another value dimensions model was introduced in the GLOBE study (House et al., 2002). This model analyzes social practices as well as social values. Practices are defined as "the way something is really done" in a society, and values are defined as "the way we think something should be done." In the GLOBE study, authors measured culture at the level of society, industry and organization, concluding that there are more dimensions of culture than those identified by Hofstede. Schwartz's model of dimensions of national culture as well as the GLOBE model of practices and values of national culture are widespread and used in quality management literature. However, all of the models in question can be observed as a conceptual breakdown of existing national culture value dimensions first found in the Hofstede model, and not really as brand-new models that are better at describing national culture (Taras et al., 2009).

A number of critiques of the Hofstede’s model can be found in the literature. Taras et al. (2016) believe there is a lot of cultural variation within a single national culture and that geographical division of national culture does not take into account what really affects differences within the

country's culture. They also state there are far fewer cultural groups than there are countries, and that demographic and environmental characteristics are far more important than political boundaries for defining the dimensions of national culture. Tellis et al. (2009) argue that various modernization agents such as the increase in international exchange, disappearance of national borders and internationalization of higher education have led to the distinction between countries with their specific cultures being blurred, making national culture no longer a relevant construct. Some authors have also suggested alternative ways of measuring national culture. Gelfand et al. (2006) measure the characteristics of national culture by how strict they are in the form of the existence of strict norms and hierarchies in society, or loose in the form of greater tolerance of deviant behavior and heterogeneous norms. Gelfand et al. (2006) take the view that norms form a visible part of the national culture and significantly influence the behavior of individuals, and therefore their behavior in organizations, which would mean that norms will have a much greater impact on a society. Swidler (1986) takes a similar view and argues that culture does not so much shape an individual's behavior on the basis of values but above all through social norms. Alternative models of observing national culture can also be found in the works of Inglehart & Baker (2000) and Myers & Tan (2002) who believe societies can be divided into traditional and secularly rational ones, oriented towards survival or expression of oneself. In doing so, societies with traditional values emphasize the importance of religion, the connection between parents and children, and respect for authority and family values, and such societies generally record higher levels of national pride. The secular - rational set of values is the opposite of the traditional one. Survival-oriented societies emphasize economic and physical security and have relatively low levels of trust and tolerance for diversity, while societies inclined to express themselves attach great importance to environmental protection, diversity tolerance, and participation in economic and political life. Ronen & Shenkar (2013), however, believe that it is not necessary to speak of national culture at the level of nation-states, but of national cultural clusters. Kostova (1997) came to a similar conclusion in her work on institutional profiles of countries, explaining that there are only a few dominant institutional profiles of states, although many more states exist. We can conclude that national culture is a complex and multidimensional construct which is difficult to quantify. The Hofstede model serves as an approximation of the aggregated value dimensions that exist in all social groups in the world, and the values that are assigned to different dimensions make this model easy to use for quantitative analysis which can explain its wide use.

The use of national culture in quality management research is interesting since quality management principles and values are usually seen as “universal remedies” that should be applicable in all organizations and lead to improved organizational performance. However, Newman & Nollen (1996) argue that viewing quality management as an “universal remedy” is not necessarily good since values, attitudes and behaviors vary across national cultures, which will also lead to variations in the results of applying "universal remedies" in an organization. Following this argument, Sousa & Voss (2008) explain that quality management models and systems, as well as the way they are implemented in organizations, are generally prescribed and universal, but their success will largely depend on the local context. Prasad & Tata (2003) state quality management implementation will be influenced by cultural, political, legal, economic and educational factors. The cultural dimension is shaped by attitudes towards management, perceptions of authority, inter-organizational cooperation, attitudes towards business, wealth and material things in general, beliefs about foreigners and the scope of nationalism. These factors are very similar to descriptions of Hofstede's dimensions of national culture. Zhang & Wu (2014) state that differences in cultural factors will influence differences in the performance of quality management practices in an organization while Wang et al. (2012) conclude that cultural environment acts as a moderator between quality management practices and firm performance. Therefore, we can conclude that there is a widespread consensus in the literature regarding the influence of national culture on different quality management initiatives in organizations.

Nakata & Sivakumar (1996) were among the first to explain that different national cultures often mean different outcomes for individual quality initiatives in organizations. They take the introduction of the "quality function deployment" in American companies as an example. The method has been very successful in Japan, while it never came to life in US companies due to the overwhelming

resistance of workers who did not accept this new form of organizing daily practices and routines within their organizations. There are a number of authors which analyzed the influence of national culture value dimensions on quality management in an organization. According to Lin (2009), the impact of national culture on quality management is highest when there is a high level of uncertainty avoidance and low power distance in a country. Naor et al. (2010) state that power distance, future orientation, and performance orientation within organizations themselves differ greatly between Western and Asian countries. They explain this by the fact that these dimensions will be significantly influenced by organizational structure and strategic policy. Power distance will depend largely on the hierarchy and bureaucracy in the organization. Moreover, management initiatives and rewards will affect the performance orientation of the organization, while technological capabilities and executive planning will affect the differences in future orientation. Kull & Wacker (2010) analyzed the impact of GLOBE cultural dimensions on the effectiveness of quality management practices in Asian countries. The analysis was conducted using secondary data, and the authors concluded that national culture influences the acceptance of quality management values and indirectly the effectiveness of quality management practices as well. In this paper, the authors conclude that uncertainty avoidance and masculinity, have the most significant influence on quality management practices, while other cultural dimensions have had a minor impact. Noronha (2003) analyzed the impact of Chinese national culture on total quality management practices in organizations. In doing so, he used Parsons's (1956) sociological perspective according to which the values of the subordinate value system would be defined by the superior value system. In this case, organizational culture should be defined by the influence of national culture in which it is embedded. Noronha (2003) defined four dimensions of quality: quality climate in the organization, quality processes, quality methods and quality results, and concluded that quality climate serves as a mediator of the impact of national culture values on the application of quality practices in the organization. Wiengarten et al. (2015) analyzed the impact of collectivism at the national and organizational levels on the relationship between LEAN management practices and organizational operational performance, concluding that higher level of collectivism at both the national and organizational levels have a positive effect on operational performance and LEAN management practices. In their earlier paper, Wiengarten et al. (2011) similarly analyzed how dimensions of national culture moderate the relationship between investment in quality practices and production performance, and concluded that dimensions of individualism-collectivism, masculinity, and uncertainty avoidance significantly moderate this relationship.

Discussion

The majority of papers analyzing national culture in the context of quality management are using Hofstede's value dimensions model. It is important to state that Hofestede's model can serve solely for the comparison of social groups, not for the analysis of individual differences. Thus, despite all criticisms of the model, it can be concluded that it remains a valid and good instrument for assessing the value dimensions that prevail in a particular national culture. In doing so, these values will not be equally valid for each individual within the society, nor can they be assessed at the individual level, but they allow comparisons to be made between different countries without distorting the conditions necessary to carry out quality scientific analysis. In carrying out the analysis, it is important to take into account the strenght of the effect of national culture, since the question is not whether national culture influences different processes within a country or organization, but to what extent that influence is significant and how it can be measured and analyzed (Kirkman et al., 2017). The question remains as to was this done in the existing research.

As stated earlier, quality management practices are defined as "universal remedies" that should not be too dependent on the organizational environment. This has led to two different approaches in the literature. According to the convergence theory, organizations can avoid the influence of national culture on their practices and organizational values through organizational practices (Tellis et al., 2009). The emergence of these organizational practices will then be defined by different technological, institutional and economic motives and not dependent on dominant national culture values. On the other hand, Ralston et al. (1997), according to the divergence theory, consider that national culture will have a dominant influence on organizational values and practices in any case,

and that its influence will vary depending on national specificities, but will not be overcome by other factors. The divergence theory is closer to the arguments that can be found in institutional, population-environmental and contingency theories of management. These three theories state that organizations must adapt to their environment due to environmental pressures, and these pressures are largely manifested through the practices and values of the environment, that is, the society within which an organization operates. Reconciling the two conflicting views, Nelson & Gopalan (2003) claim some organizations within countries follow the contours of national culture quite consistently, while others systematically reject national values. An explanation for organizations that reject national values can be partially found in the work of Taras et al. (2016), who find that technological and economic forces increase homogeneity in the practices of organizations from different countries and reduce cultural differences between countries over time. In this context, quality management can be seen as one of the factors that should reduce differences in practices across organizations in different countries. On the other hand, it is to be expected that businesses, which for various reasons are more woven into the local context, will continue to follow the contours of their national culture, no matter what requirements are put in front of them and what adjustments they have to make.

In this context, it is important to note that papers that view quality management principles as universally applicable were usually conducted in multinational companies competing in dynamic international markets and often operating in high-tech sectors. As a rule, these companies retain their competitive advantage due to the ability to use economies of scale, which require highly uniform and detailed business processes that all employees are familiar with. In addition, these organizations are not woven into the local context and bring with them certain behavioral patterns and organizational processes, and most often have a diverse human resources structure that does not necessarily have to be made up exclusively of the native population. In order to shed more light on these understudied issues, a number of authors indicate that more cross-cultural research on the specifics of practices and the value of quality management in different countries is needed in order to provide a clear answer to the question under which conditions is quality management universally applicable and to what extent (Prasad & Babbar, 2000; Metters, 2008; Naor et al., 2010).

Conclusion

Based on the above, a few conclusions can be drawn. The first is that certain dimensions of national culture show a significant influence on the relationship between quality management practices and different organizational outcomes. Among them are the dimensions of individualism-collectivism and power distance. The way these dimensions work is manifested primarily through an organizational climate that partly reflects the values of national culture (Naranho, 2003). It is also apparent that a relatively small number of papers have analyzed this relationship solely in the context of SMEs. It can be expected that these organizations are more embedded into the local cultural context, and for this reason the influence of national culture on them could be more manifested. The investigation of the relationship between national culture and quality management in SME's could be an interesting avenue for future research.

Most studies that have analyzed the impact of the environment on the implementation of quality management practices have shown that there is some influence of national factors on quality management practices and their outcomes in organizations. However, these studies have focused on organizational outcomes in the form of operational or financial performance of the company. Very few studies have considered other organizational variables. Future studies should try to investigate other organizational outcomes that could be influenced by the differences in national culture.

Regarding national culture itself, future research of national culture and quality management should also try to broaden the view on national culture past Hofstede's value dimensions model. Gelfand et al.'s (2006) framework of strict and loose societies could be an interesting avenue of future research since previous work has already shown that collectivism has an influence on the way quality management is implemented in an organization, and strict and loose societies are somewhat correlated to levels of individualism vs. collectivism in a society. Leung et al. (2005) propose that

qualitative and experimental research could also provide new insight into the role national culture plays in different organizational processes, and this could be investigated in the context of quality management as well.

It is very important to note that national culture is only one of the factors that will influence the application of quality management in an organization. Formal institutions, customer pressure and the macroeconomic environment also have significant impact on an organization. Therefore, while it can be argued that differences in the way quality management is implemented in an organization will be somewhat culture dependent it cannot be said that these differences will depend solely on cultural factors. Therefore, more research on the influence of other external factors that act in alignment with national culture and influence quality management in an organization should be conducted.

Corporate Social Responsibility Strategy and Costs of Its Implementation - Case Study

Marcin Stepien

Czestochowa University of Technology, Faculty of Management, Poland
marcin.stepien@wz.pcz.pl

Abstract

The problem of identification and evaluation of costs incurred for the implementation of the corporate social responsibility strategy was addressed in the study. The study was divided into two main parts, theoretical and empirical. The theoretical part of the study presents a strategic perspective on the idea of corporate social responsibility based on literature studies. The considerations presented in the empirical part include the results of research conducted in a production company operating in Poland. The aim of the study was to identify the costs incurred for the implementation of the corporate social responsibility strategy and to assess the possibility of optimising these costs. The research methods used to achieve the goal are: a method of literature analysis and criticism, a method of descriptive analysis and a case study. The issue of identification and assessment of costs incurred in the implementation of the corporate social responsibility strategy is important and current due to its impact on maintaining the competitive position of the enterprise on the market.

Keywords: Social Responsibility Strategy, Costs Of Social Responsibility Strategy Implementation.

Introduction

The changes in the environment and growing competition are leading companies to seek new ways to gain market advantage (Dess and Beard, 1984). At the same time, the needs reported by external and internal stakeholders, as well as the increase of environmental awareness of the society, have contributed to the fact that managers of enterprises have started to focus on the social and environmental aspect of their activities (Hamel and Valikangas, 2003). It is now believed that by protecting the environment and gaining the trust of their stakeholders, companies can achieve a competitive advantage and thus maximise profits (McGahan and Porter, 1989). This assumption has shaped the concept of corporate social responsibility, which is now the basis for developing the strategy of many enterprises.

The enterprise and the strategy it implements, considered from the perspective of the idea of corporate social responsibility, is the result of establishing inter-organizational relations in order to meet the needs reported by the stakeholders (Pearce and Robinson, 1989). Understanding the essence of these relationships, the ways in which they become special and how effective companies choose and manage their resources leads to better organization management (Kay, 1996; Łobejko and Pierścionek, 2011).

Therefore, the main source of competitive advantage of enterprises implementing corporate social responsibility solutions becomes a way to provide customers with the expected value, which is the awareness that the enterprise combines environmental, social and economic solutions.

The strategy identifies areas where the company has specific competencies that give it an advantage over its competitors. An area of outstanding competence is what an organization does particularly well (Griffin, 1999). This distinction from the competition gives the right strategic advantage. The basis for building an effective business strategy is a business approach that generates favourable

economic results and simultaneously achieves environmental and social objectives (Macharzina and Wolf, 2008; Gabler et al., 2006). This corporate approach combines CSR-oriented management and the achievement of economic objectives. In this context, the aim of the study was to identify the costs incurred for the implementation of the corporate social responsibility strategy and to assess the possibility of optimising these costs in accordance with current Polish balance sheet regulations.

A strategic perspective on the idea of corporate social responsibility

The growing interest in the idea of corporate social responsibility has become the main element of the strategy of modern enterprises. The basic assumption of the concept of Corporate Social Responsibility is that companies not only strive to maximize profits, but also fulfil a number of obligations towards their stakeholders (Kotler and Lee, 2005). This assumption has shaped the approach of enterprises to the implementation of the concept of corporate social responsibility, which currently plays an important role in the management processes of enterprises, both local and global.
The idea of corporate social responsibility encourages the active assumption of responsibility for society and the environment by engaging in activities that benefit both the company and society or the environment (Dyllick and Hockerts, 2002). These circumstances improve the company's reputation, which translates into its financial results as customers have a positive perception of its social activities (Gustafson, 2007).

The concept of Corporate Social Responsibility is derived from American corporate business. According to the definition proposed by the European Commission, Corporate Social Responsibility is a concept whereby companies help create a better society and a cleaner environment (Green Paper, 2001). This means that, in line with the concept of Corporate Social Responsibility, enterprises voluntarily include social and environmental aspects in the costs of their activities and contacts with stakeholders (Lindgreen and Swaen, 2009). The provisions of the Green Paper indicate that the activities of companies should be carried out in two dimensions: internal and external (Guthey and Lange, 2016). The first covers socially responsible practices in human resource management, health and safety at work and adaptability to change. The external dimension relates to the local community, business partners, suppliers, customers and human rights issues.

Both internally and externally, the document indicates socially responsible activities in the area of broadly understood environmental protection (Crane and Matten, 2004). These actions aim both to systematically reduce the negative environmental impact of the company (L'Etang, 1994) and to draw attention to global environmental problems. Therefore it can be said that social responsibility is the mutual cooperation between the external and internal dimensions (Porter and Kramer, 2006). What is more, the concept of corporate social responsibility includes many activities in the field of human capital, shaping appropriate relations between employees, taking care of business cooperation (Łęgoik-Świącik, 2019) with local government organizations, local community and non-governmental organizations, as well as protection of the natural environment (Łęgoik-Małolepsza, 2019), which in turn contributes to increase the competitiveness of the company and shaping the conditions for sustainable social and economic development.

Research Methodology

The research methods used to achieve the set research goal are: the method of analysis and criticism of literature, the method of descriptive analysis and the method of case study. In the first part of the study the method of analysis and criticism of literature was used. The method of analysis and criticism of the literature is used to identify the new approach and to justify the purpose of the study. Therefore, the application of this research method makes it possible to present the achievements of science in a given field and to point to a research presentation existing in the studied area. The applied research method allows to indicate the topicality and innovativeness of the studied problem in relation to the current state of knowledge in the studied area (Coombs et al., 2009). Moreover, the analysis and criticism of the literature allows us to signal differences and existing dependencies and important features of previous scientific research.

In the second part of the study, the research method used is descriptive analysis. It is applied to the description of the research methodology used in the conducted research. The descriptive analysis method was used to characterise the identified generic costs and activities undertaken to implement the corporate social responsibility strategy in the surveyed company, which allowed to formulate conclusions. Conclusions were formulated on the basis of observations, abstractions and generalisations of the observed compounds. This research method made it possible to identify the relationships observed and the gap in perception of the problem under investigation.

In the third part, empirical, the broadcasting method used is a case study. It allows to present an accurate and deepened picture of the studied phenomena and relations (Gibbert et al., 2008). However, it should be noted that case study is a method with probabilistic possibility of scientific cognition (Eisenhardt and Graebner, 2007) resulting from intuitive and subjective judgements, low representativeness of results, high time and cost effectiveness of conducted research. Nevertheless, the main advantage of conducting the research process with the use of case studies is the desire to develop the concept of the studied phenomenon and to interpret it in depth.

The characteristics of the surveyed company

Empirical research was conducted based on a case study. The company investigated was selected on the basis of a targeted selection. The basic selection criterion was the availability of separate financial statements on an annual basis, in accordance with the assumption that the company is separated on the basis of the organizational and legal criterion, is economically independent and remains in competitive relations. Additionally, as a selection criterion, the unit management implementation was used, taking into account corporate social responsibility.

The surveyed entity is a manufacturing company, its head office is located in Poland and it is classified as a medium-sized enterprise sector. Conducting the research process with the use of a case study allows to present an accurate and in-depth picture of the examined phenomena and relations. However, one should remember about the probabilistic possibility of scientific cognition using the case study method (Czakon, 2015).

The company produces a wide range of accessories for window decoration, such as curtain rods, blinds, pleats. It sells its products in Poland, Germany, the Czech Republic, Romania, Lithuania, Latvia, Russia and Hungary. The investigated company mainly supplies network customers. It also cooperates with many smaller businesses that sell finishing materials and provide interior design services. The research period is 2015-2019. It is worth mentioning that the company is ISO 9001: 2001 certified and the quality of its products has been awarded by consumers with the "Customer Laurel".

Research Results

The aim of the study is to identify the costs incurred in the implementation of the corporate social responsibility strategy and to assess the possibility of optimising these costs in accordance with the current regulations of balance sheet law in Poland. In the first stage of the research procedure in the surveyed company, costs were distinguished, guided by the criterion of their identification in order to implement the assumptions of the corporate social responsibility strategy and improve the management of key areas of the company's operations. Shaping the trend of costs incurred for the implementation of the assumptions of the corporate social responsibility strategy in the surveyed company is presented in Fig. 1

Fig. 1: Share of % of costs incurred for corporate social responsibility (CSR)
Source: Own calculations

They analyse the level of costs incurred for the implementation of the corporate social responsibility strategy in the surveyed company. It should be noted that they constitute an element of costs by type. On the basis of the conducted research, it is noted that in the surveyed company a significant part of costs incurred in the implementation of the corporate social responsibility strategy is an important cost management instrument. The level of these costs is being reduced from 11. 93% of costs in 2015 to 9. 30% of costs in 2018. In 2019, an increase in the level of the analysed costs is observed, which was influenced by, on the one hand, an increase in the level of production and sales, on the other hand, this increase was caused by inflation factors in Poland.

In the second stage of the examination procedure in the investigated company, overheads were distinguished, which were divided analytically into types characterizing the costs incurred. In the company covered by the survey, costs by type were grouped, guided by the criterion of their identification to improve the management of strategic areas of the company's operations, taking into account the principles of social responsibility. The criterion adopted resulted in the analytical separation of costs by type due to their incurrence and calculation costs reflecting the places where costs arise in the company. With regard to the costs incurred in the implementation of the corporate social responsibility strategy in the surveyed company, six types of costs were specified, which characterize the actions taken (Fig. 2): car depreciation, electric energy usage, fuel consumption, costs of used packaging, waste management costs, training costs for employees.

Fig. 2: Costs by type incurred for the implementation of the corporate social responsibility strategy

Source: Own calculations

Considering the results of the research carried out in the field of identification of generic costs incurred for the implementation of the corporate social responsibility strategy in the surveyed company, it is noted that in the field of car depreciation there is a reduction in the costs incurred. This is an effect of actions taken to replace the car fleet with vehicles with significantly reduced emissions, which was reflected not only in the environmental but also economic benefits obtained.

During the research period, energy consumption was reduced by replacing lighting with led lighting, which resulted in a significant decrease in the level of discussed costs in 2016. In addition, air-conditioning equipment and ducts have been upgraded to reduce energy consumption while increasing efficiency. The increase in production in the following years caused fluctuations in the level of costs related to energy consumption, however, the efficiency of led lighting makes it bring economic and environmental benefits in the long term.

When examining the level of fuel consumption costs, it was noted that a significant reduction in expenditure related to the purchase of fuels resulted in a decrease in the level of the costs in question. However, the increase in fuel prices in Poland caused an increase in fuel consumption costs in subsequent years.

When analysing the level of costs incurred for packaging, it should be noted that in the investigated company, packaging management was rationalised by organizing the selection of packaging for cardboard packaging and foil, which are then resold to recycling companies. This has led to a decrease in packaging costs between 2015 and 2018. The increase in costs for packaging in 2019 was caused by both price increases and production increases.

As far as third-party services are concerned, the effectiveness of cooperation with waste disposal service providers has been improved. A very important activity undertaken in the scope of implementation of the corporate social responsibility strategy in the examined company is the education of employees. They analyze the costs incurred for the education of employees. It was noted that the training was provided to employees responsible for organizing pro-ecological activities. This is due to the fact that the key assumption of the adopted corporate social responsibility strategy in the surveyed company is the implementation of the concept of sustainable development, and this results in costs in the surveyed area.

Discussion and Conclusions

While making an attempt to assess the possibility of optimizing the costs incurred for the implementation of the corporate social responsibility strategy in the surveyed enterprise, it should be pointed out that the costs identified as costs of the implementation of the corporate social responsibility strategy are an element of the enterprise's typical costs. The company in question shows a significant share of the costs of benefits incurred for the implementation of the corporate social responsibility strategy, which means that their identification, recording and observation is an important instrument for managing and optimizing the company's costs.

The research shows that the surveyed company bears the burden of waste management and fulfils information obligations related to the implementation of the concept of sustainable development. However, it is noted that there is a lack of recording solutions for homogenous identification of costs incurred for solutions implementing the corporate social responsibility strategy in the surveyed company. Therefore, the recommendation for the surveyed enterprise is to implement solutions in the area of research of costs not incurred, which are related to expenses occurring in the sphere of implementation of the corporate social responsibility strategy.

Summary and Conclusions

The aim of the study was to identify the costs incurred for the implementation of the corporate social responsibility strategy and to assess the possibility of optimising these costs in accordance with the current Polish regulations of the balance sheet law. The conducted research shows that in the surveyed company there is a need for more and more detailed separation of analytical items of costs concerning activities related to the implementation of corporate social responsibility strategy. A clear implication of the theoretical and empirical assumptions of the conducted case study is that companies expect up-to-date information about the diversity, structure and level of costs incurred for the implementation of the corporate social responsibility strategy, especially in the field of pro-ecological solutions.

The main contribution of the article is an in-depth understanding of the coexistence of the corporate social responsibility strategy and the accompanying costs incurred in its implementation. The study supports the current view that companies operating in a competitive environment are forced to seek new market advantages. One of the important areas of creating a competitive advantage may be the costs incurred for the implementation of the corporate social responsibility strategy, and their optimization and effective management may have a positive impact on the operating environment of the enterprise, contributing to the creation of competitive market advantages.

Abstract

One of the most used means of communication by tourist destinations today is social networks. Regardless of the part of the world you are in, the information provided is monitored in real time and by anyone. In a moment of public health crisis (e.g. pandemic), a communication plan is created and these same resources are used and disseminated quickly. At the same time, the development of a country's tourist activity is globally recognized as a generator of revenue and provides more employment and a greater contribution to the economy. However, tourism is a sector of activity quite sensitive to market changes, economic crises, climatic effects, epidemics / pandemics, which cause many fluctuations. Therefore, it is relevant to mention the negative impacts that tourism is suffering in the face of the Covid-19 pandemic. Thus, in order to combat the negative effects of Covid-19 on tourism, some destinations started to use motivational communication strategies / campaigns, presenting their beauty, encouraging the visitation of tourists / travelers after the crisis. The general objective of this study is to present the communication strategies used to combat the negative effects of Covid-19 on tourism, presenting good practices of advertising campaigns (in Portugal and Brazil) available on social networks. It is asked, what are the communication strategies used to combat the negative effects of covid-19 on tourism? In this sense, a descriptive research and a preliminary study with analysis of social networks were carried out. Future studies should make it possible to deepen this problem, using in-depth interviews and elaborating a focus group with tourists and residents (in Portugal and Brazil).

Keywords: Communication strategies, Covid-19, tourism, epidemics, crisis

Introduction

Tourism is an activity that encompasses several areas and services, so it can be considered a sector that is very sensitive to changes in consumer income; the constant economic, political, social and environmental crises; epidemics and pandemics, among others; which can have serious long-term impacts on local communities, threatening the image of destinations, the inflow of foreign exchange, tourism resources and employability. The advancement of technology has changed consumer behavior. In an era marked by information and knowledge, it is imperative to create value and differentiate (Ferreira & Sousa, 2020) Thus, it is necessary to think about communication plans that are effective and capable of taking information to the tourist / traveler in times of crisis, regardless of the continent they are on. Therefore, social networks are used as excellent resources in this context.

The COVID-19 name given by the World Health Organization, to the disease caused by the new coronavirus SARS-COV-2, which can cause severe respiratory infection such as pneumonia, first identified in humans, in late 2019 in the Chinese city of Wuhan, Hubei province, has spread to several countries / continents being considered one of the pandemics that has most killed people and disrupted world markets. In view of this reality, many destinations that lived off the provision of services for tourist activity, had to close their borders to not receive tourists / travelers, further compromising local economies. In order to communicate assertively with tourists / travelers, the destinations launched campaigns, which encourage people to stay at home at this time, but to plan themselves in the future for visits when the destinations are free of the risk of spreading the disease.

The general objective of this article is to present the communication strategies used to combat the negative effects of Covid-19 in tourism, presenting 04 advertising campaigns, 02 in Brazil and 02 in Portugal, available on social networks. The research problem involves asking, what are the communication strategies used to combat the negative effects of covid-19 on tourism? The methodology of this study is exploratory in nature, an analysis of social networks and good communication management practices in crisis scenarios. Future studies should, however, deepen the results obtained in the first phase of the investigation. The theoretical framework was divided into 5 sections, the first being the introduction, the second describing the communication strategies adopted for times of crisis; in the third chapter, the relevant data on tourist activity in Brazil and Portugal were covered; in the fourth chapter, it dealt with epidemics / pandemics and the impacts on tourist activity; and finally, in the fifth chapter, the Communication strategies used by the tourist destinations Portugal and Brazil were pointed out, to combat the negative effects Covid-19 by reading the advertising campaigns in these countries.

Communication Strategies in Tourism Crisis Contexts

Communicating is the human being's ability to interact with others through signals (verbal or non-verbal), and involves exchanging information between two or more interlocutors. Derived from the word "communicare", it refers to the act of "sharing, participating in something, making it common" (Deetz, 2010; Moderno, 2017; Neiva, 2019; Kunsch, 2018; Silva, Sousa & Fernandes, 2019) Facing the transformations that have been occurring continuously and the great global uncertainties present in the contemporary world, there is no more space for a merely instrumental, technical and tactical communication (Kunsch, 2018). In view of this, the development of the means of communication caused human communication to change profoundly and restructured relations between people in a spontaneous way, moving from face-to-face communication to computer-mediated communication (Corazza, 2015).

Assuming that crisis communication is one of the prime areas of public relations management, it was interesting to deepen theories on the subject. It begins by defining a crisis “understood as a situation or event that requires immediate action to prevent a potential negative impact on an organization or its interlocutors” (Norsa, 2003, p. 20; Diegues, 2011) To better analyze the concept crisis, crises were divided into unpredictable and predictable situations, respectively. The first are those that can cause the most damage to an organization's image due to its unpredictability, for example, natural disasters, accidents, sabotage, epidemics / pandemics. Predictable crises result from actions that the organization is aware of and, therefore, can prepare itself to face them and manage them in the most appropriate way. This is the case, for example, with physiological changes, pregnancy, retirement, dismissals, death (Caetano, Vasconcelos & Vasconcelos, 2006; Lampreia, 2007; Diegues, 2011). It is about unforeseen situations, the focus of this research.

Within the communication area, managing a crisis is the biggest challenge that the professional can face. The company must be prepared to react by communicating to any emergency: either through a preventive communication plan to deal with foreseeable crises, or through a combative communication plan to extinguish the unpredictable crises. (Neiva, 2019).

Proposing a strategy, therefore, means following a method to carry out business communication and disseminating it to the public of interest, whether formed by the employees themselves or by customers and other stakeholders (all parties directly or indirectly interested in the business) (Neilpatel , 2020).

Within the communication strategy, social networks have been used more frequently to initiate relationships with potential customers and to approach partners in the market; e-mail marketing since most people have an e-mail, indoor media broadcast in closed and busy spaces of stores and subway stations and SMS marketing is a sure idea to be able to inform and at the same time increase engagement and relate to the target audience (Alves, Sousa & Machado, 2020).

In strategic communication, in a time of crisis, it must be based on two perspectives: "first, the alignment of communication with the organization's objectives and its contribution to the achievement of results" and second, "the role of social actors in what concerns respect to organizational decisions" (Oliveira & Paula, 2007). As stated earlier, communication must always be planned in order for the organization to achieve its objectives. The information transmitted must be weighed from a functionalist and striking perspective, assertiveness in outlining objectives and the way in which they are proposed to be achieved. The message must contain information that is part of the company's context and that, in some way, makes sense to its audiences (Neiva, 2019). In tourism, communication should be assertive to seek potential customers for tourist destinations.

Tourism: Relevant Data

Tourism is one of the most important and current engines of growth for an economy, marked by dynamism, diversity of supply and constant growth (Sousa & Rodrigues, 2019). As tourism is one of the sectors whose degree of involvement is necessary for its success, the diversification of tourism products and services becomes a requirement capable of leading to increased demand for new types of tourism needs (Macedo & Sousa, 2019). The management of a tourist destination requires its positioning, given that the image transmitted is an influential and determinant aspect in the purchase decision (Sousa & Simões, 2012).

In 2016, Portugal reached record numbers in tourism, with special emphasis on expanding the activity to less traditional months, with two thirds of the growth occurring in the so-called low season; decrease in the seasonality index from 37 to 35%; 14.2% increase in employment in tourism; 1.5 million increase in air capacity; diversification of markets, with significant growth in the American, Polish and Brazilian markets; 5% growth in the domestic market; 1,500 new companies linked to tourist entertainment (ET, 2017). According to the World Travel & Tourism Council (WTTC) report, tourism grew 8.1% in 2018, achieving the highest rate among the countries of the European Union (EU) and also one of the highest among all European countries (Observer, 2019). These results demonstrated the capacity of tourism to generate more income, more jobs and to expand more and more the activity throughout the year and the territory. (ET, 2017)

In Brazil, the direct participation of tourism in the economy was US $ 56.8 billion in 2016, equivalent to 3.2% of GDP. The total contribution of the sector was US $ 152.2 billion, 8.5% of the National GDP. (Brazil, 2018). According to data from the Ministry of Tourism of Brazil, for the year 2017, 6.6 million tourists from the world entered the country, generating foreign exchange revenue of 6 billion US dollars, according to data from the World Tourism Organization (OMT). In all, more than ten million international landings were made at Brazilian airports in 2017. Tourism injected US $ 163 billion into Brazil in 2017. According to the World Travel and Tourism Council (WTTC), Tourism's contribution to national GDP was 7.9% of the national GDP and is responsible for 6.59 million jobs. These figures demonstrate that tourism can contribute to economic, social, cultural and environmental development. (Oliveira, 2019)

Contemporary tourism comes in the most varied forms and for the most diverse audiences, aiming to meet all types of demand and satisfy the desires and needs of tourists / visitors by offering a variety of tourist products and services (Pinto da Silva et al., 2019). The world is increasingly interdependent and interconnected, so that small-scale crises in one part of the world could have a significant impact on the other side of the world (Gonçalves, 2012). Thus, one can understand the complexity of this phenomenon, since it is an activity that proposes to work and move various types of services present in the world market, being considered a sector very sensitive to the impacts of some phenomena such as variations in consumer income, negative climatic effects, political and social instability, price

fluctuations in the market, inflation, exchange rates, economic crises, epidemics and pandemics (Sousa & Alves, 2019). On the phenomena called epidemics and pandemics, we have the focus of this article.

Epidemics / Pandemics and The Impacts on Tourist Activity

Major epidemics have shaped the history of mankind, even with the improvement of the population's socioeconomic conditions and the advent of vaccines and antimicrobials throughout the 20th century, infectious diseases are responsible annually for around 10 million deaths worldwide and are among the main causes of lost years of life (WHO, 2008; Moura & Rocha, 2012).

Epidemics represent the occurrence of an injury above the historical average (or median) of its occurrence. The disease that causes an epidemic generally appears suddenly and spreads for a certain period of time in a specific geographic area, often affecting a high number of people (Moura & Rocha, 2012). It is no longer possible to understand epidemics without covering the speed of population displacements, which must be taken into account in the speed of the control measures implemented, that is, in the surveillance of communicable diseases. Leaving this reality open when emphasizing the spread and geographical mobility of epidemics through infected individuals: local epidemics become pandemics, geographically generalized (Ujvari, 2011; Magalhães & Machado, 2014).

The modern concept of a pandemic is that of an epidemic of major proportions, with the aggravation of having rapid circulation, over more than one continent. An example is the "Spanish flu", which followed from World War I, in the years 1918-1919, and caused the death of about 20 million people worldwide (Chien, 1983; Rezende, 1998).

Influenza or influenza is considered to be an infection is an acute disease of the respiratory system, caused by the Influenza virus, having a high capacity for transmission and global distribution. (Costa & Merchan-Hamann, 2016). Among the various pandemics that occurred in the 20th and 21st century, which caused crises in the world, we can mention: Spanish Flu, between 1918 and 1920; the Asian Flu, between 1957 and 1960; Hong Kong Flu, between 1968 and 1969, Between the years 2003 and 2004, highly pathogenic avian influenza - A (H5N1), Pandemic Influenza A in 2009 (Xu et al, 2004; Ellis et al, 2003; Brazil, 2010; Costa & Merchan-Hamann, 2016).

In 2020, the World Health Organization declares that the "COVID-19 epidemic" is a "pandemic". The announcement comes when there are more than 120 countries with reported cases of infection (RTP, 2020). The world balance of deaths, due to the pandemic of the new coronavirus, surpassed on March 25, 2020, the 20 thousand victims. Worldwide, the number also broke another barrier: 460 thousand confirmed cases (Martim, 2020). The Wellcome Trust called the coronavirus “a significant and urgent threat to global health” 1 and called on “researchers, journals and funders to ensure that research results and data relevant to this outbreak were shared quickly and openly to inform the response to public health and help save lives (Larivière, Shu & Sugimoto, 2020; Carr, 2020).

Inside or outside the Earth's orbit, tourism generates business opportunities for both large conglomerates (airlines, hotel chains, cruise lines) as well as small businesses, whether local travel agencies, inns, restaurants or tour guides who work in their communities (Masson, 2020). With regard to global tourist activity, the coronavirus pandemic has been analyzed for offering great negative economic impact, greater than the influenza A pandemic in 2009 (Opção, 2020). Thus, when analyzing the sector, it is observed that it loses one million jobs in the world daily due to the effects of the new coronavirus pandemic, according to data revealed by the World Travel and Tourism Council (WTTC). According to the Council's latest investigation, the sector generates 10.4% of the world's Gross Domestic Product (GDP) and one in 10 of the world's jobs. The sheer volume of hotel closures, the suspension of most flights, the interruption of cruise lines and the increase in global travel bans are having a catastrophic 'domino effect' affecting a large number of service providers across the world. world (Check it out, 2020).

Trade fairs, congresses and business conventions concentrate the largest budgets of business tourism. Serial cancellations generate losses much more significant than those caused by individual dropouts from leisure travelers. The problem gets worse when both types of tourists give up traveling. IATA,

the International Air Transport Association, which represents the 290 largest companies in the sector, projects a loss of revenue of nearly $ 29.3 billion this year. Also according to the organization, some companies claim that up to 50% of passengers have stopped flying - and most want to be compensated for the cancellation (Masson, 2020). In the midst of the pandemic, deaths, economic crises, social isolation, the destinations still need to think about communication strategies with their tourists / travelers, taking the message visit them later, stimulating post-pandemic tourism.

Communication strategies for tourist destinations in Portugal and Brazil (covid-19)

The emergence of the Internet has introduced profound changes in society. With this new means of communication, it unfolds in a symbolic environment of interfaces, of multiple images and sounds that make virtuality a reality. In this way, the information that is made available through the internet, represents the main element for the social organization of humanity (Castells, 1999). With the Internet, geographic distance has lost its power of separation as people from different and remote parts of the planet can communicate instantly, and it becomes more valuable instruments of diffusion and information exchange, due to its capacity to establish fast communications, regardless of the geographic location of their users (Borges, 2001, Marujo, 2008)

In the minds of potential tourists, the image of the “tourist destination” may be susceptible to changes over time. One way to establish this image is to use the communication channels and the internet comes to help (Prata, 2014). Crisis communication plays a very important role. It aims to reduce potential damage, protect the value of the organization and minimize impacts on its reputation (Ipdt, 2020)

Tourism is experiencing a moment of crisis, which was initiated by the spread of the Covid-19 virus. In the midst of this pandemic, tourist destinations needed to organize themselves, in order to take information about the closings of cities, airports to receive tourists / travelers. A serious decision that has not only negatively impacted the economy of destinations, but has also put employability at risk, as well as their image. The decision was to protect people, reducing contacts and consequently the proliferation of the virus. In this pandemic moment of the new coronavirus, many tourist promotion campaigns have adopted an exceptional tone: they remember that the doors of destinations are open to travelers, but only after the crisis of the covid-19 has passed. Until then, they encourage everyone to stay in their homes (Maia, 2020).

Given this fact, (02) two campaigns created in Portugal and (02) two in Brazil will be presented, where the objective of both is to show the natural beauty of their destinations, but to encourage visits by tourists / visitors after Coronavirus. The campaigns were made available by official bodies, on various social media, but this is the reading of Facebook, Instagran and YouTube. On Facebook, the number of likes in the post (video) is positive and negative, the number of people who viewed the video and the number of comments. YouTube sees the number of views, the number of positive and negative likes. On Instagram, you can see the number of followers, the number of views and the number of comments below the post (video). All data were extracted on 29/03/2020 at 2: 20h.

Portugal Campaigns

The Madeira Promotion Association launches a social media campaign to appeal to stay at home in this moment of greatest world fragility. Stay home now. Dream online. Visit us later 'is the campaign launched by the Madeira Promotion Association. This is the motto of the most recent awareness campaign launched on social networks in Portuguese, Spanish, French and German on @visitmadeira and www.madeiraallyear.com. The campaign's main platforms are video and images on social networks (Radio, 2020). In addition, the campaign also stresses that, even with the physical borders closed, the digital ones remain open and ready to make passengers experience, through online tools, the attractions of the Madeira Archipelago, such as levadas, cliffs, belvederes , among other options (Portal, 2020).

As for the reactions of people on social networks, there is: Facebook, the campaign had 1,900 likes and the reactions were diverse: 1,600 people said ok, 255 people a love, 1 a scare, 5 cries , 1 person angry,

in addition 57 people commented and 573 people shared the video. On YouTube, the video had 11,689 views, 116 positive and 4 negative likes and on Instagram with 192 thousand followers, with 19,652 views, you can see 91 comments.

Turismo Centro de Portugal launched the “Haverá Tempo!” Campaign, in which it points out ways for the near future, post-pandemic COVID-19. The campaign calls on the Portuguese to stay at home, noting that "there will be time" to get to know or return to the Center of Portugal, which will be waiting for you when the disease is resolved. The campaign has as main platforms a video and images on social networks, accompanied by the hashtag # haveratempo # turismocentrodeportugal (Publituris, 2020)

As for the reactions of people on social networks, there is: Facebook, the campaign had 1.8 thousand likes and the reactions were diverse: 1.4 thousand people said ok, 420 people a love, 5 cries, 1 person angry , in addition 155 people commented and 3114 people shared the video. On YouTube, the video had 14,628 views, 196 positive likes and 1 negative, and on Instagram with 10,900 followers, 3,069 views, you can see 48 comments.

Brazilian Campaigns

In Brazil, one of the main tourist destinations, Salvador launched the campaign with the hashtag #visitedepois to encourage travelers to keep alive the desire to go up and down the slopes of Pelourinho, eat acarajés in Rio Vermelho and watch the sunset at Farol da Barra when the routine returns to normal. The campaign aired over the weekend, with a video on Youtube, with versions in English and Spanish. The text recalls that "the city that has always had its doors open needs to retreat" and that "we want you to come, but not now". (Maia, 2020)

As for the reactions of people on social networks, there is: Facebook, the campaign had 7,400 likes and the reactions were diverse: 6,800 people said ok, 611 people a love, 44 cries, 1 scared person , in addition 688 people commented and 2,877 people shared the video. On YouTube, the video had 871 views, 30 positive likes and 1 negative, and on Instagram with 272 thousand followers, 72,514 views, 1710 comments can be seen.

CVC Operadora Brasil launched a campaign that encourages people to postpone their travels. The video brings images of some of the main destinations in the country and highlights the campaign's motto: Stay at Home, Travel Later. The objective is to encourage customers to remain in quarantine, but taking advantage of this time to plan their next trip after the coronavirus crisis, which is damaging the tourism sector globally (Hotelnews, 2020).

As for the reactions of people on social networks, there is: Facebook, the campaign had 444 likes and the reactions were diverse: 336 people said ok, 104 people love, 4 people angry, in addition 207 people commented on something and 317 people shared the video. On YouTube, the video had 30,416 views, 1.1 positive likes and 17 negative likes and on Instagram with 2,100 followers, 53,316 views, you can see 532 comments.

Final Considerations and Future Research

Although tourism was the lever for economic and social development in many countries, since 2019, some fluctuations in the generation of foreign exchange have been perceived, given the economic pressures that have been experienced in many countries and their interdependence, where small-scale crises in one part of the world dramatically impact the pattern of travel to other parts. It was observed in this article the economic dependence of Brazil and Portugal regarding the dividends that the tourist activity brings. In view of the volatility of tourism activity vis-à-vis foreign markets, the impact that a crisis situation can have on these destinations is worrying. Nowadays, specifically in the first half of 2020, with the WHO decree on the Covid-19 pandemide, a disease caused by the new coronavirus, it affected the economic structure of all countries. With or without registered cases, the blockages and restrictions on the fleets of tourist destinations imposed to contain the advances of the disease are directly reflecting on the economy.

Therefore, several tourist destinations reacted with their communication plans to decree a state of emergency, for all those people (tourists / travelers). They created motivational campaigns that deny tourism at this time, and encourage tourist flows after the Covid-19 pandemic outbreak. We identified 04 advertising campaigns, 02 of which were carried out in Brazil and 02 in Portugal, made available on social networks (Facebook, YouTube and Instagram) that:

In Portugal, people do not use social networks as often, since the greatest impact of viewing in the Stay at Home / Madeira video was 19,652 people on Instagram; The video "Haverá Tempo / Portugal", on the other hand, had the largest viewing impact of 14,628 people on YouTube. There is little access to facebook in both campaigns.

In Brazil, on the other hand, people use social networks very often, since the greatest impact of viewing in the video "Visite Depois - Salvador" was through Instagram, totaling 72,514 people. In the CVC video Stay at home, Travel later, had the greatest viewing impact of 53,316 people. Which means that people have been using Instagram a lot, leaving aside other social networks.

It is concluded that in view of the existing communication strategies, social networks were chosen to viralize the advertising campaigns described above, in order to combat the negative effects of Covid-19 on tourism. We have the vision that the tourist destinations Portugal and Brazil, will need to reinvent themselves, with creative ideas for the reuse of tourist spaces after the Covid-19 outbreak, since they are highly affected when the economy and employability in the service provision sectors. In this sense, a descriptive research and a preliminary study with analysis of social networks were carried out. Future studies should make it possible to deepen this problem, using in-depth interviews and elaborating a focus group with tourists and residents (in Portugal and Brazil).

Abstract

This research aimed to analyze the strategy of political marketing in affecting the factors which become electors' decision in Governor Election of East Java Province in 2018. This research used a quantitative survey approach using factor analysis techniques using SPSS. The research site was in Madura, East Java Province of Indonesia. The number of respondents was 101 people who were selected purposively. The theoretical basis used was the political marketing product theory which included 3 (three) products as follows; the credibility of the candidate, the candidate's work program, and the identity of political parties. In addition to the three political marketing products, in this research, the researcher included elements of pesantren politics as a form of local politics derived from local wisdom politics. This was a marketing strategy in the region. These four political marketing products were reduced to several indicators according to their respective operational definitions. The results of data processing in factor analysis using SPSS showed that there were 7 (seven) factors which affect voter decisions in the 2018 East Java Governor Election, which were, pesantren politics, the identity of political parties, support of various parties, the candidate's work program, the credibility of the candidate, communication style, and attractiveness. This research contributed to reformulating the winning strategy in the election of regional heads to provide input in the formulation of the winning strategy for the Election of the Governor of East Java Province in 2023.

Keywords: Political Marketing, Governor Election, Pesantren Politics

Background

Pesantren (Islamic Boarding School) and politics are usually considered as two opposing entities. This dichotomy can't be separated from the assumption that politics is dirty and pesantren are the opposite. In fact, in the theory of the relation between religion and state (politics), Din Syamsuddin (1993) explains that one of the patterns of religious and state relations is in the form of a symbiotic, this is reciprocal and interdependent. In the context of Indonesia which implements a democratic system, the relation between religion and the state is mutually complementary and influential, as evidenced by the first principle of Pancasila which places the Godhead as an inseparable element. It means that political voluntarily in Indonesia gives the widest possible space for religious groups, religious institutions, including pesantren to get involved in politics. The emergence of Abdurrahman Wahid or Gus Dur as the 4th President of RI is a clear proof that the involvement of political actors from pesantren can't be ignored.

In Pierre Bourdieu's modality theory (1986), the position of pesantren is considered to have complete capital to be used as a goal in gaining significant votes in elections, either in economic, cultural, social, and political capital. In economic calculations, pesantren has capital in the form of several students and alumni resources Culturally, the culture in pesantren is still very patronage, in which the direction and *fatwa* of the Kiai/scholar is an obligation that must be obeyed. Michael Rush and Althof (1990) states this patronage relationship to be a fairly effective and well-established method of influencing the exercise of political power through various levels of supervision.

Also, socially, the existence of pesantren in a region usually has a very strong influence in society. Politically, the *Kiai* is still an important actor who has an electrical effect in political contestation because it can't be separated from his figure and also his extensive political network with many parties. In carrying out his political leadership, *Kiai* uses his authority based on his charismatic authority, which according to Max Weber is a special ability which is in a person and a gift from God (Turner, 1982:36).

At the local political level, the political influence of pesantren was very clear in the East Java (East Java) Governor Election (Pilgub) in 2018, in which both the Saifullah-Puti and the Khofifah-Emil received direct support from the pesantren leaders. The leadership of the pesantren or Kiai is the key to maximizing the mobilization of Nahdlatul Ulama (NU) residents who are 'barn' of the votes in East Java. The final results of the vote recapitulation released by the East Java Provincial KPU resulted in the Khofifah-Emil winning, with details of Khofifah-Emil receiving 53.55% with 10,465,218 votes, while Saifullah-Puti gained 46.45% with 9,076 .014 votes (See figure 1). From 38 districts/cities in East Java, Khofifah-Emil was superior in 27 districts/cities, while the Saifullah-Puti pair is only superior in 11 districts/cities (*www.kpujatim.go.id*).

The winning of Khofifah-Emil was very visible in Madura. Based on data from the East Java Provincial KPU (General Election Commissions), the Khofifah-Emil was superior in 3 (three) districts which were Pamekasan, Sumenep, and Sampang. Whereas the Saifullah-Puti only excelled in the Bangkalan district. Madura has always been a battle for votes for politicians during elections. This is reasonable Madura Madura has a strong pesantren mass base, including for the two candidates at the 2018 East Java Governor election. The four districts in Madura are known as the city of students/santri, that have hundreds of Pesantren.

Based on the background above, this research aims to analyze the strategy of political marketing in affecting the factors which became the voter's decision in the East Java Province Election (Pilgub) in 2018.

Literature Reviews

The previous researches about pesantren politics have been conducted, such as research by Sansan Hasanudin (2017) titled Religio-Political Mechanism of Pesantren: Mobilization of Hamida Network in Electoral Politics in Tasikmalaya. The results of this research indicated that political power can originate from informal networks that are integrated with formal networks manifested in the political power of the pesantren social network called the Miftahul Huda Alumni Association (Hamida). Secondly, a research conducted by Kun Wazis (2015) with the title Political Strategy Gaining Mass Support for Pesantren: A Case Study of the Form of Political Communication of Candidates for Legislative Candidates of the Republic of Indonesia in Jember and Lumajang Elections in the 2014 Legislative Elections. from the research, it can be concluded that political strategies used by the candidates to obtain support for the mass vote of Pesantren in different ways, including using forms of political communication in the form of political rhetoric, political public relations, political campaigns, political lobbying, and political action, both in Jember and Lumajang by characteristics and political attitudes of the respective Islamic boarding schools. The third study conducted by Merlia Indah Prastiwi (2015) entitled Politicization of Pesantren and Shifting Functions of Pesantren in Madura. The result of the research concludes that in general, the response of the Madurese people supports the involvement of the Kiai in politics because the Madurese people still position the Kiai as the main figure and role model. Therefore, the involvement of the Kiai in politics is expected to change the political bad image.

Theoretical Framework

The theoretical basis used in this research referred to political marketing product theory in Akbiyik and Eroglu (2014), entitled *The Impact of Local Political Applications on Voter Choices.* This political marketing concept aims to influence voters by using several political marketing products, which include the candidate's credibility, the candidate's work program, and the identity of political parties. In addition to the three political marketing products, in this research, the researcher included elements of pesantren politics as a form of local politics derived from local wisdom politics. This was a marketing strategy in the region. These four political marketing products became the bargaining power of candidates who competed in the 2018 East Java Governor election in Madura.

The indicators of these variables will be developed into statement items as outlined in the questionnaire. The operational definitions of the variables and indicators are as follows:

1. The Credibility of Candidate

According to Hovland, Jannis, and Kelly (1953) in the theory of source credibility state that people are more likely to be persuaded when the source of communication shows her/himself as a credible person. It means that an individual who has expertise, trustworthiness, and attractiveness. Thus, the credibility of a candidate is the ability of a candidate leader in influencing or convincing others because it is supported by several components which are expertise, trustworthiness, and attractiveness.

2. The Work Program of Candidate

Based on Korten (1984) defines the program as a collection of related projects which have been designed to carry out harmonious and integrated activities to achieve the overall policy objectives. The requirements for the program to be implemented according to Korten (1984), it has to meet three aspects which are the suitability of the program with the issues or problems faced by the community, the suitability of the program with the target group or program beneficiaries, and the suitability of the program with the implementing organization. Therefore, a candidate's work program is a collection of work of a candidate leader to achieve targets or goals which have been determined. The target will be achieved if supported by several components which are the suitability of the issue, the suitability of the target group, and the suitability of the implementing organization.

3. The Identity of Politic Party

Based on Waterman's (1982) identity means having a clear self-image covering several goals to be achieved, values, and beliefs chosen by the individual. The political party according to Budiardjo (1998: 16) is a political party is an organized group, whose members have the same orientation, values, and ideals. So, the identity of a political party is a clear self-image of a political group that concerns party orientation, values, and ideals.

4. Pesantren Politics

According to Dhofier (1994) pesantren is a traditional Islamic educational institution to study, understand, appreciate, and practice Islamic teachings by emphasizing the importance of religious morals as guidelines for daily behavior. So, the politics of pesantren is a political activity involving pesantren actors, such as santri/student and Kiai for certain political interests. Pesantren complete capital to achieve these interests, including social capital, economic capital, and cultural capital.

Table 1: Operational Definition

Factor	Operational Definition	Indicator
The credibility of the candidate	The ability of a prospective leader in affecting or convincing others is supported by several components which are expertise, trustworthiness, and attractiveness.	1. Expertise
		2. Trustworthiness
		3. Attractiveness
Work Program of Candidate	The set of the work of a prospective leader to achieve targets or goals that have been determined. The target will be achieved if supported by several components which are the suitability of the issue, the suitability of the target group, and the suitability of the implementing organization.	1. The suitability of the issue
		2. The suitability of the target group
		3. The suitability of the implementing organization.
Identity of Political Party	A clear self-image of a political group which concerns party orientation, values, and ideals.	1. Party orientation
		2. Values of party
		3. Ideals/ goals of the party
Pesantren politics	It is Political activities involving pesantren actors, such as santri and Kiai for certain political interests. Islamic boarding schools/Pesantren has complete capital to achieve these interests, including social capital, economic capital, and cultural capital.	1. Social capital
		2. Economic capital
		3. Cultural capital

Research Method

This research used a quantitative survey approach by using research data analysis techniques using factor analysis methods. Factor analysis in this research was used to process data on the factors which affected voters in deciding the 2018 East Java Governor election in Madura. The data processing used SPSS.

The data collection method used was the questionnaire method (questionnaire). The questionnaire assessment used a Likert scale, in which the range of scores used was one to five. A score of five signified that the respondent believed strongly agree with the item statement. A score of one indicated that the respondent believed strongly disagree with the questionnaire statement.

This research was conducted in four districts in Madura, East Java province, which were Bangkalan, Pamekasan, Sumenep, and Sampang. The population in this research were all voter in Madura who had voted for the East Java Governor election in 2018. The total number of voters in Madura based on data from the East Java Provincial KPU was 3,510,637 people, with details based on each district below:

Table 2: Total of Voter in Madura for Governor Election of East Java Province in 2018

No	District	Total of Voter
1	Sampang	904.715
2	Pamekasan	869.777
3	Sumenep	868.763
4	Bangkalan	867.382
Total		**3.510.637**

Source: KPU of East Java Province, 2018

The total sample in this research was determined based on the Slovin formula. The specified margin of error was 10% or 0.1.

$$n = \frac{N}{1 + Ne^2}$$

n: total of minimum sample
N: population
e: margin of error

Thus, number of sample obtained were:
n = N / (1 + (N x e²))
n = 3.510.637 / (1 + (3.510.637 x 0,1²))
n = 3.510.637 / (1 + (3.510.637 x 0,01))
n = 3.510.637 / (1 + 35106,37)
n = 3.510.637 / 35107,37
n = 99,9971516 (rounded to 100)

Samples were taken which were based on each district was determined by the formula below:

$$nh = \frac{\text{Voter population}}{\text{Total of all population}} \times \text{Total of determined sample}$$

Thus, it was obtained a total of sample from each district as follow

Table 3: Total of sample in each district

District	Population	Sample
Sampang	904.715	26
Pamekasan	869.777	25
Sumenep	868.763	25
Bangkalan	867.382	25
Total	**3.510.637**	**101**

Source: Processed from KPU of East Java Province, 2018

To determine respondent and respondents location in each district, it is chosen in purposive. This purposive sampling method was deliberately chosen because of the consideration of the homogeneity of the Madurese people. The majority of Madurese are Muslim, pesantren culture, and formalized as NU. While the data collection method used in this research was to use a closed and open questionnaire.

Result and Analysis

East Java Pilgub 2018 was followed by two pairs of candidates, namely the first pair of Khofifah Indar Parawansa and Emil Elistianto Dardak (Khofifah-Emil) who was carried by a coalition of the parties of Partai Demokrat (PD), Partai Nasional Demokrasi (Nasdem), Partai Persatuan Pembangunan (PPP), Partai Hanura, Partai Golongan Karya (Golkar), Partai Amanat Nasonal (PAN), dan Partai Gerakan Indonesia Raya (Gerindra). Second, the pair of Saifullah Yusuf and Puti Guntur Soekarno (Gus Ipul-Puti) were carried by the Partai Kebangkitan Bangsa (PKB), Partai Demokrasi Indonesia Perjuangan (PDI P), dan Partai Keadilan Sejahtera (PKS).

The two actors not only have network and funding strength, but also support from local pesantren-based elites. This pesantren-based local elite has a high bargaining value in influencing someone in determining their political preferences. There is two great Kiai and pesantren NU in Each Java Pilgub 2018. First, the Tebuireng axis, that refers to the Jombang Tebuireng Ponpes led by KH Salahuddin Wahid (Gus Solah) and KH Asep Syaifuddin Halim (Caretakers of Amanatul Ummah Mojokerto and Surabaya Ponpes). This shaft supports the Khofifah-Emil. Second, the Lirboyo axis refers to the Pesantren Lirboyo Kediri. This axis supported the Saifullah-Puti pair (Rohim and Mahardika, 2018:60-78).

Data from the East Java Province KPU showed that the final results of the 2018 East Java Governor Election were won by the Khofifah-Emil of 10,465,218 votes or 53.55 percent. While the Saifullah-Puti won 9,076,014 votes or 46.5 percent (*www.kpujatim.go.id*). This means that there is a difference of about one million votes or nearly seven percent. The number of incoming votes was 20,323,259 total votes from 38 districts/cities in East Java. 19,541,232 were considered valid, while 782,027 were declared invalid.

In fact, the victory of the Khofifah-Emil is very clear in Madura. Based on data from the East Java Provincial KPU, the Khofifah-Emil was superior in 3 (three) districts, which were Pamekasan, Sumenep, and Sampang. Whereas the Saifullah-Puti only excelled in Bangkalan district.

Figure 1: vote acquisition of both candidate pair in Madura

The winning of the Khofifah-Emil in Madura was inseparable from the typology of the Madurese community. In general, Madura people have very religious characteristics and hold a strong patron culture, in which the position of a religious leader or Kiai is highly respected. They appreciate and respect Kiai by glorifying him.

Result of Factor Analysis

To obtain valid and reliable questions, To obtain items that are valid and reliable statements, the researcher first tested the validity and reliability of 36 statement items toward 30 respondents randomly with a margin of error of 5%. The result, out of 36 statement items, only 27 items passed the validity and reliability test. In the validity test (See Corrected Item-Total Correlation in Table 4) with a margin

of error of 5% for 30 respondents, the r value was 0.333. It means that statement items with a Corrected Item value less than <0.333 needed to be excluded or deleted. Item statements X1.1, X1.2, X1.5, X1.6, X2.8, X2.9, X3.3, X3.9 and X4.7 were less than 0.333. Thus, they must be issued in the statement list (See table 4).

Whereas the result of Cronbach's Alpha showed a reliability test value of 0.876 more than (>) 0.7 (See table 5). It showed that each item questionnaire statement was reliable, so data analysis could be continued.

Table 4: Result of Questionnaire Validity Test

Item-Total Statistics				
	Scale Mean if Item	Scale Variance if Item	Corrected Item-Total Correlation	Cronbach's Alpha if Item
X1.1	1.385.000	165.845	.152	.877

Source: Result of data processed using SPSS

Twenty items of question would be the items of the questionnaire as research material in the field. After distributing the questionnaire, the next step was to carry out a factor analysis of the results of the questionnaire distribution. Factor analysis is an analysis that aimed to find the main factor or component that best explains the variable.

Table 6: KMO and Bartlet's Test

KMO and Bartlett's Test

Kaiser-Meyer-Olkin Measure of Sampling Adequacy.		.725
Bartlett's Test of Sphericity	Approx. Chi-Square	1.359E3
	df	351
	Sig.	.000

Source: Result of data processed using SPSS

In the table of KMO and Bartlet's Test above, it is seen the KMO Measure of Sampling Adequacy (MSA) value was 0.725. since the value 0.725> 0.5, this shows the adequacy of the sample. The KMO and Barlett's test values (which appear on the Chi-Square value) were1.359E3 with a significance value of 0.000. It indicated that there was a correlation between variables and it was feasible for further processing.

Furthermore, to find out which variables can be further processed and which are issued, it can be seen in table 7 (Anti Image Correlation). MSA value of each variable> 0.5, then all variables can be processed further, except the variable X2.7 (0.425) because <0.5. Variables with MSA value <0.5 are reprocessed from the beginning by removing the variable. From27 variables, 26 variables qualified for further processing.

Table 7: Magnitude of MSA Anti Image Correlation

X1.1	X1.2	X1.3	X1.4	X1.5	X2.1	X2.2	X2.3	X2.4	X2.5	X2.6	X2.7	X3.1	X3.2
.623	.783	.593	.560	.508	.737	.749	.692	.632	.616	.671	.425	.735	.703

Source: Result of data processed using SPSS

In table 8 (*Total Variance Explained*), it shows that there are 7 (seven) factors formed from 26 variables entered. Each eigenvalue factor > 1. Factor 1 eigenvalue was 5,961 with variance (22,926), Factor 2 eigenvalue was 3,645 with variance (14,018), Factor 3 eigenvalue was 2,710 with variance (10,422), Factor 4 eigenvalue was 1,833 with variance (7,049)), Factor 5 eigenvalue was 1,584 with variance

(6,092), Factor 6 eigenvalue was 1,090 with variance (4,194), and Factor 7 eigenvalue was 1,047 with variance (4,026). The total variance of 26 variables extracted into 7 factors are as follow:

22,926 + 14,018 + 10,422 + 7,049 + 6,092 + 4,194 + 4,026 = 68,727

The amount of variance which could be explained by the new factors formed was 68.727 while the remaining 31.273 were explained by other factors that were not examined.

To find out the magnitude of the correlation between factors formed with variables, we must find the value of loading factors for each variable. For the factor loading values of each variable, see table 9. After grouping based on the highest factor loading values in each variable, 7 (seven) factors were formed, then name the seven factors. If the factor loading value of the seven factors is < 0.5, it must be excluded. The indicators that must be excluded because < 0.5 are X1.1, X1.2, X3.1, X3.3, and X3.5. While the indicators that qualify for entry into 7 (seven) factors are shown in table 10. So, the results of the factor analysis in this research indicated that there were 7 (seven) factors that influenced voter decisions in the 2018 East Java Governor Election in Madura.

Extraction Method: Principal Component Analysis.

Source: Result of data processed using SPSS

The result of processed data in factor analysis using SPSS with 26 items of statement for 101 respondents showed that Pesantren politics is the biggest factor contributing to the decision of voters in the 2018 East Java Province Governor Election in Madura. The amount of contribution was seen from the highest number of indicators and factor loading values (See table 10).

Factor Analysis of Pesantren Politics

Political factors of pesantren became the biggest contributing factor in determining voter decisions in the East Java Province Governor Election in 2018 in Madura. The magnitude of the political electoral contribution of this pesantren was because it was supported by 7 (seven) indicators and its high factor loading value.

The seven indicators were candidates supported by pesantren with many alumni (with a factor loading value of 0.884), candidates supported by boarding schools that recruited many employees (0.836), candidates supported by pesantren that are independent in the economy (0.808), candidates supported by pesantren with many students (0.802), candidates supported by pesantren whose Kiai were populist (0.731), candidates supported by Modern Pesantren (0.628), and candidates supported by Pesantren that contributes to the community (0.504) (See table 10).

From the seven indicators, for respondents the candidate factor supported by the pesantren with the most alumni was the factor with the greatest contribution in pesantren politics. It is seen from the highest loading factor. The magnitude of the electrical contribution of the alumni network was in line with research conducted by Hasanudin (2017) regarding the mobilization of the Hamida network in electoral politics in Tasikmalaya. The results of this research conclude that political power can come from informal networks that integrate with formal networks manifested in the political power of the pesantren social network called the Miftahul Huda Alumni Association (Hamida).

On the other hand, in addition to pesantren political factors, the factors affecting voter decisions in 2018 East Java Governor election in Madura were also determined by 6 (six) other factors which were the identity of political parties, support of various parties, candidate work programs, candidate credibility, communication style, and attractiveness.

Factor Analysis of The identity of the Supporting Political Party

Factor identity of supporting political party was determined by 4 (four) indicators, which were candidates who had a work program plan that fit the problem (with a loading factor value of 0.769), candidates who had a work program plan that is a solution to the problem (0.765), candidates who were supported by political parties that uphold nationalism (0.763), and candidates promoted by political parties that uphold ordinary people (0.794) (see table 10).

From four indicators, for respondents, the candidate factor promoted by the political party that upholds the common people was the biggest factor contributing to the supporting political party factor. It can be seen from the highest loading factor. Ordinary people or poor people are the main base of voters in East Java, especially Madura. So, political parties that carry a close platform or pro ordinary people will be easier to touch the psychological condition of the people of Madura. Almost all political parties

imaged themselves close to the people, even the Indonesian Democratic Party of Struggle (PDI-P) specifically carried out the jargon of the underprivileged party as the party's identity. This has become one of the party's strategies in obtaining people support.

Factor Analysis of Support from Several Parties

Factor of support from some parties was determined by 3 (three) indicators which were candidates supported by anti-corruption political parties (with a factor loading value of 0.614), candidates carried by political parties that uphold justice for all (0.592), and candidates supported by pesantren that combine *salaf* and modern traditions (0.761).

From three indicators, for respondents, the candidate factor supported by the pesantren which combined the salaf and modern traditions was the factor with the greatest contribution in the support factor of various parties. It was seen from the highest loading factor. Pesantren support always contributes a large electoral to candidates who compete in elections. Both pesantren still maintained the salaf tradition and modern pesantren. Both pesantren typologies had a large mass base.

Factor Analysis of the Candidate's Work Program

Factor of candidate's work program was determined by 4 (four) indicators which were candidates who had a work plan for millennial (with a factor loading value of 0.519), candidates who had a work plan for a low-educated people (0.841), candidates who had a work plan for a rural society (0.813), and candidates who were promoted by political parties which aims to develop Human Resources (HR) (0.522) (See table 10).

From four indicators, for respondents, the candidate factor that had a work program for people with low education was the factor with the greatest contribution in the candidate work program factor. It can be seen from the highest loading factor. Work programs aimed at people with low education are closely related to economic factors. Research conducted by Fitriyah, et al (2014) related to the determinants of candidate victory in the 2011 Batang local election concluded that economic factors, referring to the program carried by the candidate, played an important role in influencing voter choice because the people of Batang district wanted their regions to change to become more advanced and the chosen candidate is the one who is most valued to advance the area.

Factor Analysis of Candidate's Credibility

The candidate's credibility factor was determined by 1 (one) indicator, which was candidates from respected/honorable families (with a factor loading value of 0.839) (See table 10). Candidates from respected families will be more easily recognized and respected by voters. Research conducted by Purwaningsih (2015) related to kinship politics and the quality of candidates in South Sulawesi confirmed this conclusion. Network inheritance and family names will affect public support to candidates.

Factor Analysis of Communication Style

The factor of communication style was determined by 1 (one) indicator which was candidates who had a convincing communication style (with a factor loading value of 0.762) (See table 10). One candidate's success in the general election was determined by a good communication strategy. Research conducted by Jaya, et al (2015) related to the success and failure of the campaign communication strategies of the candidates in the struggle for the legislative seat of Barru regency in the 2014-2019 period, showed that the campaign strategies carried out by successful legislative candidates and failed legislative candidates were generally the same about political communication. It included the determination of campaigners, the use of campaign media, the preparation of unique messages, and the same target audience.

Factor Analysis of Attractiveness

The factor of attractiveness was determined by 2 (two) indicators which were attractive candidates (with a factor loading value of 0.504) and candidates who had work programs that could be executed by the Regional Government Work Unit (SKPD) (0.811) (See table 10).

from two indicators, for respondents, the candidate factor that had a work program that could be executed by the SKPD is the factor with the greatest contribution in the Attractiveness factor. The candidate's work program factor will always be an attraction for all voters. Candidates who had work programs that were more realistic and could be implemented by parties related to their fields will be more attractive to be chosen than candidates who only offer work programs without involving these parties, in this case related to SKPD.

From these data, it can be concluded that pesantren politics was a dominant factor in influencing voters in Madura. People in East Java, especially Madura, are a pesantren culture that still position Kiai as political teachers, the two candidates for the East Java Governor 2018 who fought together came from the largest religious organization in East Java, it was NU.

Conclusion

This research results in the findings that there are 7 (seven) factors which affect the voter decision at the 2018 East Java governor election, which are pesantren politics, identity of the supporting political parties, support of various parties, candidates' work programs, candidate credibility, communication style, and attractiveness. From the seven factors, pesantren politics is the biggest contributing factor. The amount of contribution is seen from the highest number of indicators and factor loading values. The politics of pesantren has a loading factor value of 0.844, the identity of the supporting political party of0.794, the support of various parties of 0.761, the candidate's work program of 0.841, the credibility of the candidate of 0.839, the communication style of 0.762, and the attractiveness of 0.811.

Political factors of pesantren which have the biggest contribution in influencing voter decisions in the 2018 East Java governor election in Madura are also caused by several things, which are, the majority of respondents consider pesantren to be involved in politics, although for them the involvement of pesantren in politics will shift its role as a religious institution. On the other hand, the majority of respondents do not know whether there are material benefits to be gained by pesantren who support certain regional head candidates. For them, the support given by the pesantren will have an electoral influence on the vote acquisition of regional head candidates, even though they consider that the Kiai's political choice is not necessarily followed by the santri/students or alumni. Furthermore, the support between the pesantren's Kiai for regional head candidates can be different from one another. The difference in support between Kiai pesantren is due to the diverse mass base of pesantren of each candidate, it is also because each pesantren has certain considerations in supporting one candidate.

Abstract

The purpose of this article is to determine the level of millennials' openness to innovative services offered by FinTech in Poland against the background of financial behaviours displayed in this area by the millennials in the USA. During the analysis of the level of openness to FinTech services of the examined generation, the value of FinTech adoption index for the millennials was determined and the authors developed five-step scales of openness in terms of FinTech service type (objective approach) and the number of FinTech entities (subjective approach). The authors formulated the following research hypothesis: the degree of the millennials' openness to innovative services offered by FinTech in Poland does not differ significantly from the financial behaviours displayed in this area by the millennials in USA. In order to verify the hypothesis, we used the methods of scientific description, review and critical analysis of analytical reports on the FinTech phenomenon, statistical methods and the CAWI method. The necessary empirical data of qualitative and quantitative nature were collected through a survey conducted on a representative sample of 1236 Polish millennials in December 2019. The study results have demonstrated that both in the USA and in Poland, a high level of openness of the millennial generation to FinTech services is observed. FinTech Adoption Index for US millennials was 59% in 2017, while the value of this ratio in Poland in 2019 was around 75%. The analysis of financial behaviours of the examined generation proves that in Poland, just like in the USA, payment services were the most popular.

Keywords: FinTech adoption index, millennials, scale of openness, FinTech, innovative financial services

Introduction

The FinTech issue is an important and topical issue. As J. Harasim and K. Mitręga-Niestrój (2018) indicated, 'FinTech is destroying the established setup of the financial sector and drives changes to the paradigm of financial intermediation model, which makes investigation of this phenomenon an urgent issue'. As M. Swacha-Lech (2017) emphasizes, the appearance of FinTechs constitutes a serious challenge to the competitiveness of traditional financial intermediaries, including banks. Undoubtedly, the competitiveness of modern banks is and will be affected by the emergence of FinTech companies. In the opinion of many authors, the banks' capability of fast and innovative moves is significantly limited, which may hinder their capacity for keeping pace with the trends set by FinTech companies.

At the same time, it should be emphasized that the extremely important changes in the environment of modern financial institutions are brought home by new generations:

- the Y Generation – otherwise known as the millennials, people born between 1980 and 1995;
- the Z Generation – otherwise known as the iGen, people born in the 1996-2010 period.

Regarding the world of finance, the new generations of customers show expectations and attitudes different from those of previous generations. Therefore, recognition of the characteristics of new generations and observation of the mechanisms of financial decision-making employed by these new clients of financial institutions appear to be of crucial importance for the survival and development of modern financial intermediaries.

The youngest members of the Z Generation were just nine years old at the end of 2019, while the oldest were 23 years old; hence it seems legitimate now to conduct an analysis of financial behaviours for the millennials only. Currently, for financial institutions, millennials are an extremely important group – due to both their numbers and their high demand for various financial services (they are people just entering their adult life).

The purpose of this article is to determine the level of millennials' openness to innovative services offered by FinTech in Poland against the background of financial behaviours displayed in this area by the millennials in the United States. During the analysis of the level of openness to FinTech services of the examined generation, the value of FinTech adoption index for the millennials was determined and the authors developed five-step scales of openness in terms of FinTech service type (objective approach) and the number of FinTech entities (subjective approach).

To achieve the stated objective, the authors formulated the following research points:

1) What percentages of millennials use innovative FinTech services in Poland and in the USA?
2) What types of FinTech services are most often used by millennials in Poland?
3) Which FinTech companies are the most popular among millennials in Poland (in terms of both actual use and recognition)?
4) What is the level of millennials' readiness to embrace FinTech services on a five-step scale in terms of subject and object?

Upon review of subject literature, the authors formulated the following research hypothesis: *the degree of the millennials' openness to innovative services offered by FinTech in Poland does not differ significantly from the financial behaviours displayed in this area by the millennials in USA*. In order to verify the research hypothesis thus formulated and to answer the research questions posed, we used the methods of scientific description, review and critical analysis of analytical reports on the FinTech phenomenon, statistical methods and the CAWI method. The necessary empirical data of qualitative and quantitative nature were collected through a survey conducted on a representative sample of 1236 Polish millennials in December 2019. The sample was selected in a random and quota-based manner. The sample structure was corrected with an analytical weight to match the population structure of the Polish millennials in terms of key features related to the study subject. The weight construction process took into account such socio-demographic variables as gender, age, education level, and size of the town of residence.

Use of FinTech services by millennials in the USA

The term 'millennials', already well established both in scientific literature and in colloquial language, refers to people born in the years 1980-1995, whose childhood fell at the turn of the millennium. They are also referred to as the Y Generation and are the first generation for whom wireless communication and Internet constitute their 'natural environment'. According to the GFK study (2020), Millennials constitute a significant group in the social structure of both countries: in the US they make approx. 20% of the population, in Germany - approx. 15%, and there are countries where they make up to 25%. Considering the share of millennials in the adult population, globally they constitute approx. 46%, but in regional terms these data are much more diverse, e.g. in the USA it is 36%, in Europe approx. 32%, in the Middle East - approx. 52% (Fundstrat, 2018). In accordance with Rocznik Demograficzny 2019 (GUS, 2019) in Poland, as at 31 December 2018, millennials constituted approx. 22.49% of the total population, which means 8,638,256 persons.

As estimated by Fundstrat (2018), in the United States only over the next decade (by 2030) millennials will become the richest social group, as their disposable income will increase fivefold, which with 96 million citizens (potential consumers) will constitute a significant target group for many types of enterprises - including the financial sector entities. As Sachdev (2019) claims, this trend is global, as by the beginnings of the third decade of the 21st century millennials have already become a social group that earns more than the previous generations, quickly increases their purchasing power and is the most influential consumer group in the world. As adolescents, they saw the emergence of modern technological powers – Facebook, Amazon, Google, Apple and others, which made them accustomed to all kinds of technological and digital innovations. They are also the first generation, which stays permanently online, using social media daily for both private and professional communication. Surveys conducted in 2019 by Vogels (2019) in the USA demonstrated that 93% of the millennials own and actively use smartphones, and 86% use various types of social media in everyday life (including 84% who use Facebook). Nearly 100% of this group uses the Internet, with 19% of them using only a smartphone for this purpose. As a generation open to new challenges, they easily drive the FinTech revolution (FinTech services are usually provided via the Internet), radically changing the approach to traditional financial institutions and their services.

In accordance with the Ernst&Young (2017) FinTech Adoption Index report, for the US millennials, the rate of FinTech adoption was 59%, while the global index was then 48%. The value in 2019 for 27 selected countries is presented in Table 1.

Table 1: Users of FinTech services as a percentage of the digitally active population in 27 selected countries in 2019.

Country	Percentage
China	87%
India	87%
Russia	82%
South Africa	82%
Colombia	76%
Peru	75%
Netherlands	73%
Mexico	72%
Ireland	71%
UK	71%
Argentina	67%
Hong Kong	67%
Singapore	67%
South Korea	67%
Chile	66%
Brazil	64%
Germany	64%
Sweden	64%
Switzerland	64%
Australia	58%
Spain	56%
Italy	51%
Canada	50%
USA	46%
Bel & Lux	42%
France	35%
Japan	34%
Average of 27 markets	**64%**

Source: Ernst & Young (2019).

It is extremely significant that the adoption rate of FinTech innovations increases dynamically. To compare the six largest markets (Australia, Canada, Hong Kong, Singapore, United Kingdom and the USA), it increased from 16% in 2015 to 31% in 2017 and 60% in 2019, with the largest increase taking place in the UK - 14% in 2015 against 71% in 2019.

Considering the types of services offered by FinTech companies, it should be noted that payment services are particularly popular among the millennials. In 2018, more than one in ten respondents in the US used his digital wallet with every purchase - especially paying for food, rent or Uber. According to CB Insights (2019), among the millennials, 63% of them make transactions with their smartphones, and 41% use a mobile device to finalize a transaction at a store. As Crypto Valley Journal (2019) says, among millennials whose individual or household income exceeds 100,000 USD, 25% of them own and use cryptocurrencies, and further 31% are interested in this solution. In accordance with Torpey (2019), fifty-nine per cent of millennials positively assess bitcoin as a technological innovation in the world of finance.

The US millennials also take advantage of the investment opportunities offered by FinTech companies. In 2018, 83% of millennials expressed their open attitude to alternative investment strategies using FinTech services. About 67% of the generation surveyed make use of robo-consulting and micro-investment (purchases of stocks and shares on equity crowdfunding platforms). Bitcoin investments are also popular among the millennials. According to CB Insights (2019), 20% of them own bitcoins and treat them as investments. Analyzing the US millennials' readiness to embrace such investments, Torpey emphasizes that:

- 27% of millennials prefer investing in bitcoin over stock,
- 30% prefer investing in bitcoin over government bonds,
- 24% prefer investing in bitcoin over real estate,
- 22% prefer investing in bitcoin over gold.

As many as 68% of millennials are considering alternative forms of managing their assets, including termination of traditional bank accounts and transition to an innovative technology company, such as Facebook, Google, Apple or Amazon (Fundstrat, 2018).

The millennials in USA also willingly use FinTech services to contract loans. According to CB Insights (2019), typical millennial's debt amounts to $ 42,000. Mesa (2019) emphasizes that almost 35% of millennials borrowed via FinTech platforms and companies, while only 25% borrowed from traditional financial institutions.

Insurance is another area where representatives of the surveyed generation used the services offered by FinTech companies. When analyzing the behaviour of US millennials, it should be highlighted that, in accordance with the report of Liberty Mutual Insurance/Safeco Insurance (2019), in 2019 36% of them bought car insurance online, and one in every three bought home insurance via the Internet. It is also interesting that 28% of millennials prefer to use social media for insurance.

Own Research - Description of The Research Sample

The study, based on the CAWI method, was conducted in December 2019 by a research agency called SW Research on a representative sample of 1236 millennials in Poland, aged between 25 and 40. The research sample was selected in a mixed, random and quota manner. The sample structure was corrected using an analytical weight to match the structure of millennials in Poland in terms of key features related to the study subject. The weight structure took into account socio-demographic variables such as gender, age, education and size of the municipality of residence.

By gender, the structure of research sample was as follows: 58.18% were women and 41.82% – men. A majority of respondents belonged to the 25-30 age group (see Fig. 1).

Fig. 1: Sample structure by age (in %)

Source: own study.

Taking into account the level of education, it should be emphasized that a majority (55.18%) of respondents indicated their higher education, and the smallest number (8.50%) of respondents belonged to the group with primary, lower secondary or vocational education. Those with secondary education constituted 36.32% of the sample.

Fig. 2 shows the research sample structure in terms of the size of municipality of residence. The largest number of respondents were inhabitants of rural areas (23.14%) or cities of over 500,000 residents (17.23%).

Fig. 2: Breakdown of the respondent group by population of their place of residence

Source: own study.

Taking into account the family situation, 54.94% of respondents were married or couples with dependent children, while only 0.89% were married or couples with adult/independent children. In turn, marriages or couples without children account for 14.80% of all respondents. About 15% of the surveyed population of Polish millennials were young people cohabiting with their parents, while 9.22% of them described their situation as living independently.

Another criterion taken into account in the analysis of research sample was the monthly net income achieved by the respondent (see Fig. 3).

Fig. 3: Breakdown of the respondent group by net income

Source: own study.

Most respondents indicated a monthly net income in the range of PLN 3001-5000 (389 persons). Almost a quarter of millennials surveyed (299 people) declared that they generated net income of PLN 2001-3000. Definitely the fewest respondents indicated the range below PLN 1,000 (80 people).

Own Research Results and Discussion

The study results show that a vast majority of Polish millennials surveyed (924 out of 1236 respondents) have already used FinTech services (Fig. 4).

Fig. 4: Polish millennials who have already used FinTech services

Source: own study.

Through an in-depth analysis of the responses of Polish millennials who have already used FinTech services, this article attempts to determine the level of their readiness to embrace FinTech services. To this end, the authors created two five-step scales of openness levels:

- objective approach - this approach refers to analysis of the issue examined by the types of FinTech services which millennials have used so far;
- subjective approach – this approach refers to analysis of the openness of the generation studied to FinTech services by the number of FinTech companies that millennials have used so far.

In order to determine the level of Polish millennials' openness to innovative services offered by FinTech taking an objective approach, we performed an analysis of responses to the question where respondents were asked to indicate all types of FinTech services they had used so far.

On the basis of literature review (Folwarski 2019; BCBS 2018; Szpringer 2017; Dorfleitner et al. 2017; PwC 2016), the authors distinguished five types of FinTech services:

1) payment services – e.g. money transfer, payments, mobile wallet, currencies, cryptocurrencies;

2) investment services – e.g. crowdfunding (as investors), robo-advising;
3) loans and credits – e.g. crowdfunding (as capital seekers), social lending (as borrowers), loan companies;
4) insurance services – insurtech;
5) others – e.g. companies providing cyber security and using blockchain technology.

Structure of millennials' responses to the question about the types of services offered by FinTechs that they have already used are presented in the table below 2.

Table 2: Popularity of FinTech services which millennials in Poland have used so far – objective approach (n = 924)

Type of service offered by FinTech	Response quantity	Percentage
1. Payment services	638	69.05
2. Investment services	226	24.46
3. Loans & credits	190	20.56
4. Insurance services	277	29.98
5. Others	48	5.19

Source: own study.

Similarly to the regularities observed in the USA, FinTech payment services enjoyed the greatest popularity in Poland and were used by 69.05% of millennials. It is surprising, however, that in Poland insurance services came second (in the USA, the second most popular group among FinTech services was investment). One in every four respondents declared that he had already used FinTech investment services. Just a bit fewer Polish millennials already have experience with loan and credit services provided by FinTech (20.56%). It is not surprising that other FinTech services, such as companies providing cyber security or using blockchain technology, appear to be the least popular.

By further analyzing the results obtained from the point of view of individual types of FinTech services (objective approach), the authors built a five-step scale of Polish millennials' openness in terms of FinTech service type (see Fig. 5). The first level has been assigned to people who have so far used only one type of FinTech services, and the fifth one to people who have so far used all the five distinguished types.

Fig. 5: Levels of millennials' openness to FinTech services in Poland – objective approach (n = 924 of millennials who have already used FinTech services)

Source: own study.

The highest level of such openness (fifth) was observed only in 28 examined millennials (3.93%). Persons who were classified as representing the 1st and 2nd level of openness to FinTech services, i.e. those who had already used one or two types of FinTech services, respectively, accounted for a total of 74.27% of the group. It should also be emphasized that the biggest difference was seen between the 1st and 2nd level of openness – in comparison to respondents who have already used two types of FinTech services, the group declaring that they have used just one type of service was larger by 19.41

pp. It is also interesting that in the group of 924 millennials, each of them used nearly two (1.94) types of services on average.

The subsequent part of the study was analysis of openness of the generation studied to FinTech services by the number of FinTech companies that millennials have used so far (subjective approach). To this aim, the respondents were presented with a group of 15 FinTech companies, the structure of which corresponded to the types of FinTech services identified in Table 2. The respondents' task was to indicate all FinTech companies whose services they had used so far. The popularity of 15 selected FinTech companies operating in Poland, both in the context of their brand recognition and services use, is presented in Fig. 6.

Fig. 6: Responses to the question: "Mark the companies in the list which you know and/or have dealt with" - by number of indications (N = 1236).

Source: own study.

Upon analyzing the popularity of FinTech companies presented in the chart - both in the context of their brand recognition and their services use – PayU (2020) comes to the fore. This FinTech company was established in 2006 as an online payment provider who offers the opportunity to make and receive payments via the Internet between persons identified by their e-mail address. It also provides the option of paying by credit card or bank transfer. The payment recipient does not need to have a bank account to receive money online. According to M. Solarz (2017) PayU is entity that coordinates from Poland the development of the group's payment business in the region of Central and Eastern Europe. A vast majority (92.15%) of the survey sample declared their awareness of this brand and as many as 71.12% of Polish millennials have already used PayU services.

In terms of this criterion, the Polish Payment Standard (Polski Standard Płatności, 2020) is not much behind PayU. This FinTech company was created in 2015. It allows smartphone users to make payments at stationary and online stores, withdraw and deposit cash at ATMs, as well as make instant interbank transfers and generate checks with a 9-digit code. February 2020 was the five-years' anniversary of operations of BLIK mobile payments system, established by the Polish Payment Standard. Since that time, BLIK has become widely available and massively used. Its users carried out a total of 353 million transactions worth PLN 47 billion. BLIK is the payment system most popular among the users of Polish internet, where in 2019 it overtook card payments. In 2019, BLIK had nearly 9 million users. Only 14.32% of surveyed millennials declared that they are not recognize

of this FinTech brand, and as many as 54.21% of them have already used the services of the Polish Payment Standard.

In terms of this criterion, the Polish Payment Standard (Polski Standard Płatności, 2020) is not much behind PayU. This FinTech company was created in 2015. It allows smartphone users to make payments at stationary and online stores, withdraw and deposit cash at ATMs, as well as make instant interbank transfers and generate checks with a 9-digit code. February 2020 was the five-years' anniversary of operations of BLIK mobile payments system, established by the Polish Payment Standard. Since that time, BLIK has become widely available and massively used. Its users carried out a total of 353 million transactions worth PLN 47 billion. BLIK is the payment system most popular among the users of Polish internet, where in 2019 it overtook card payments. In 2019, BLIK had nearly 9 million users. Only 14.32% of surveyed millennials declared that they are not recognize of this FinTech brand, and as many as 54.21% of them have already used the services of the Polish Payment Standard.

Cinkciarz.pl (2020) occupied the third place in terms of popularity among the respondents. It was created in 2010 as a Polish portal providing such financial services as money transfers, currency exchange, online payments, multi-currency loans and Forex transactions. The portal also offers mobile applications, the economic analysis service and access to current exchange rates and cryptocurrencies. It is worth mentioning that among the 15 companies we listed, it is the FinTech brand enjoying the highest level of millennials' brand recognition – 55.18% of respondents indicated that they know the company but do not use its services.

The least recognizable FinTech brands were, respectively: CWA, Kundi, VT Cyber and Klarna. CWA, created in 2007, is a brand of comprehensive training services provided to the customer along with supporting tools, which is the market leader of training services offered to public administration and of tailored workshops for the B2B sector. According to money.pl (2020), recently, the company has also been involved in the provision of comprehensive FinTech solutions (activities related to the platforms of SNIPAY and prostagielda.pl). Activities related to the FinTech industry are intended to become an increasingly important source of revenue for the CWA SA Capital Group. Among the 15 entities we listed, this company has the lowest level of brand recognition - 75.40%.

In the ranking of the FinTech brands least known to the surveyed millennials, it was followed by Kundi, an insurance recommendation platform created in 2016. According to the information posted on the website Kundi.pl (2020) it is a mobile application of peer-to-peer insurance. As emphasizes information from cashless.pl (2020), the concept of the solution assumes the creation of customer groups, insuring e.g. electronic equipment of similar value. The insurance policies are expected to be cheaper thanks to group purchases. Accordance with bankier.pl (2020) it should be highlighted that policyholders are intended to know each other, which is supposed to discourage extortion of claims and additionally lower the cost of insurance. As Kurek (2019) notes, a part of the premiums paid by customers is put aside to create a reserve fund for the payment of damages, and the money not thus spent would go back to customers. Only 10.36% of millennials in Poland have used the company's offer (see Fig. 6).

VT Cyber was founded in 2012. The FinTech's activity is focused on preparing organizations for the changing needs of IT and OT departments, both in the area of infrastructure and application security and that of legal regulations e.g. related to personal data protection or critical infrastructure security. The mission of VT Cyber (2020) is to increase security and resistance to cyber-attacks directed at IT and OT infrastructure and at services provided by a given company. This brand was known only to 26.21% of millennials in Poland and merely 11.57% of them had already used its services.

A Swedish FinTech called Klarna has exactly the same percentage as VT Cyber of respondents who are not aware of the brand - i.e. 74.79%. According to the information posted on the website 300gospodarka.pl (2020) Klarna was founded in 2005 and is one of the leading European providers of online payment methods. The scope of its activities depends on the country. In Poland, it is currently limited to brokering online payments, which does not have a significant impact on consumer experience. Stores can choose the company as a provider of instant transfer service within

which a customer is transferred to his bank's website to log in and confirm the payment. [i] As bussinessinsider.pl (2020) highlights, interesting is that in 2019 this company was indicated as the most expensive start-up within the FinTech sector in Europe.

In order to determine the level of Polish millennials' openness to FinTech services, taking an subjective approach, the authors built a five-step scale. The fifth level was assigned to people who have used the services of all the 15 FinTech companies mentioned in the question (see Fig. 6), while the first level was assigned to people who have so far used only one FinTech. The results obtained are presented in Fig. 7.

Fig. 7: Levels of Polish millennials' openness to FinTech services in Poland – subjective approach (n = 924 millennials who have already used FinTech services)
Source: own study.

Although millennials; readiness to embrace FinTech services is high, much in line with the authors' expectations, most of the respondents using FinTech services are limited to one or two companies. Only 3 millennials out of 1236 respondents have used the services of all the 15 FinTech companies listed in the survey (5th level of openness) and only 8 people have used 13 or 14 companies (4th level of openness). Fifty-six respondents declared using the offer of 9-12 FinTech companies, thus creating a group of millennials representing 3rd level of openness. On the other hand, the number of respondents representing 2nd level of openness, i.e. those who had used the services of 5-8 FinTech companies mentioned in the question, was more than a double of that.

Definitely, most millennials (726) were assigned to 1st level of openness (people who have so far used the services of 1-4 FinTechs listed in the survey). Within this group, most people declared the use of 2 FinTechs (269). Additionally, 255 millennials indicated that they have so far used the services of only one company. Among the respondents, 129 people stated that they were clients of three FinTech companies, while 73 millennials were clients of four companies.

It is interesting that given the list of 15 selected FinTech companies, within the group of 924 respondents who have already used FinTech services in Poland, on average each of them used the services of four companies (4.16, to be precise). This means, that using the subjective approach to the Polish millennials' readiness to embrace innovative FinTech services, the average FinTech service user of the Y Generation represents the first, i.e. the lowest, level of openness.

Conclusion

As a result of the study conducted, the research hypothesis formulated in the introduction of the article to read: *the degree of the millennials' openness to innovative services offered by FinTech in Poland does not differ significantly from the financial behaviours displayed in this area by the*

millennials in USA has been confirmed. Both in the USA and in Poland, a high level of openness of the millennial generation to FinTech services is observed. FinTech Adoption Index for US millennials was 59% in 2017, while the value of this ratio in Poland in 2019 was around 75%. The analysis of financial behaviours of the examined generation also proves that in Poland, just like in the USA, payment services were the most popular.

Millennials' openness to FinTech services is also demonstrated by the number of FinTech entities they use. In order to analyse the popularity of FinTechs in Poland, in the context of both their brand recognition and services use, the respondents were presented with a list of 15 FinTech companies, the composition of which corresponded to the types of FinTech services identified in the article. In this context, PayU emerges as the unquestionable leader. A vast majority (92.15%) of the surveyed group declared their awareness of this brand and as many as 71.12% of Polish millennials have already used PayU services.

The five-step scales, created by the authors for the purpose of determining the millennials' openness to innovative FinTech services, were applied to determine the level of adoption of FinTechs, using objective and subjective approach. In both cases, most respondents represent the first, lowest level of openness - 46.84% of millennials used only one type of FinTech service, and 78.57% used the offer of 1-4 FinTech companies. Both using objective and subjective approach, the group of respondents with the highest level of openness was the least numerous. Only 3.93% of millennials took advantage of all the types of FinTech services mentioned and only 0.32% of them have so far used the offer of all the FinTech companies listed in the survey (5th level of openness).

An in-depth analysis of the financial behaviours of the Y Generation in the area of study allowed determining the degree of openness of an average millennial in Poland. He uses nearly two (1.94) types of FinTech services and the offer of four (4.16) FinTech companies.

To sum up the study results presented in the article, it can be stated that the overall level of openness millennials to FinTechs in Poland is high, even if they use a small number of types of services, choosing a limited number of providers.

In the authors' opinion, this market will develop dynamically in the coming years. Research conducted by the authors shows that among the 312 millennials who have not yet used FinTech services in Poland, 97 respondents (31.09%) intend to use FinTech services within 6 months and as many as 131 respondents (41.99%) declared their intention to use them in further future.

The most frequently selected responses to the question about the reasons why Polish millennials have not used FinTech services include: "I have never heard the term FinTech before" and "I don't know which companies belong to the FinTech sector" (Table 3).

Table 3: Reasons why Polish millennials have not used FinTech services

Why don't you use FinTech services? (a multiple choice question)	Response rate (n = 312)
1. I have never heard the term FinTech before	39.62
2. I don't know which companies belong to the FinTech sector	28.19
3. I do not trust such companies	20.76
4. I trust traditional financial institutions (e.g. banks) much more	19.43
5. The risk of using such companies is significantly higher (they are not covered by the Banking Guarantee Fund or Insurance Guarantee Fund, nor by the supervision of Financial Supervision Authority)	11.62
6. Using modern financial services causes an additional risk because of operations on the web and new technologies (e.g. data theft)	12.19

7. I do not like to use technological innovations	5.52
8. I can't use modern technological solutions and I avoid them	8.57
9. I see no sense in using FinTech services	15.62

Source: own study.

While comparing the study results obtained with the results presented in the Ernst & Young's report, *FinTech adoption index-Germany (2016)*, it should be emphasized that in both cases the lack of awareness was given as the most important reason of not using FinTech services (67.81% for millennials in Poland vs. 53.2% globally for 7 countries). Another important reason indicated by the respondents in both studies is the low level or even lack of trust in this type of modern institutions. This is the second most frequently selected response from Polish millennials (40.19%) and the fifth one in the study conducted by E&Y (11.2%). The third most important reason, according to Polish millennials, was the lack of need to use FinTech services (15.62%), while globally it is the second most frequent response (32.3%), in the light of E&Y's study.

The authors intend to conduct further research on the issue of millennials using innovative financial intermediation services - FinTech. One of more interesting research issue seems to be the identification of expectations of the Y Generation towards financial services in Poland. Another area of interest is the identification of determinants of their selection of financial services by millennials.

Abstract

The perception and acceptance of people with different types of disabilities in the workplace are key to their full inclusion and the use of the potential they represent for the development of modern societies. The aim of this article is to try to answer the question whether demographic factors such as gender, age and education have an impact on the acceptance of disability in the workplace. The article presents the results of research conducted in 2019 among Internet users from eight European countries using computer-assisted interviews (CAWI).

Keywords: People with Disabilities in The Open Labour Market, Acceptance of Different Types of Disabilities, Statistical Analysis of Survey Results.

Introduction

On the one hand, processes such as the aging of societies or the development of modern technologies cause the percentage of people with disabilities in Europeans countries to grow constantly - one can notice that different disabilities occur more often in the group of older people. On the other hand, it is easier to overcome the barriers to full participation of this group in social and professional life. However, despite increasingly modern technical solutions that facilitate the inclusion of people with disabilities, the phenomenon of their significantly lower professional activity compared to the able-bodied part of society is still visible in most European Union countries. One of the reasons for the low interest of employers in potential employees from the group of people with disabilities is the low social acceptance of different types of disabilities. This social acceptance depends on many different factors, among which one should mention macroeconomic and social factors creating the framework for the functioning of a given community, as well as individual ones. Macroeconomic and social factors include primarily the policy of the government towards employing people with disabilities, the disability model that prevails in a given community, or the openness of society to diversity. They are of great differential importance, and the results of the research conducted in selected European Union countries revealed significant differences between countries when it comes to the acceptance of different types of disabilities in the workplace (Kwiatkowska-Ciotucha, Załuska, Grześkowiak, 2020). It should be noted that acceptance strongly depends on the level of individual knowledge about disability, and appears to be different for people with various demographic characteristics, such as gender, age or education. In the research carried out on representative samples of Polish respondents, significant differences were noted primarily due to age and gender (Kwiatkowska-Ciotucha, Załuska, Grześkowiak, 2020). In this article one attempts to check whether such differences resulting from demographic characteristics also occur in the international sample.

Theoretical background

High significance of the subject of acceptance of people with disabilities in the workplace has been confirmed by the literature research carried out as part of publications indexed in two databases: Web of Science and Scopus (compare Table 1). The authors of the publications present the results of research on the attitudes towards people with disabilities, factors determining these attitudes, openness to various types of disabilities and related opportunities for adaptation and full inclusion of people with disabilities in the workplace.

Table 1: Quantitative summary of search results concerning scientific articles from 2017-2019 in the databases of Web of Science and Scopus

Phrase	WoS	Scopus
Disabilities in the workplace	40	112
Employee acceptance, relationship, reaction, response, attitude	122	437
Employees with disabilities	116	176
Workplace diversity	2	185

A lot of attention is devoted to attitudes towards people with disabilities and ways of measuring them (Palad et al., 2016; Antonak, Livneh, 2000). The results of many scientific studies confirm that the attitude of employers and able-bodied co-workers is crucial for the successful adaptation of people with disabilities in the workplace (Giermanowska 2016; Chan, Strauser, Gervey, Lee, 2010; Dunstan, Maceache, 2014). A multifaceted evaluation of attitudes towards people with disabilities in the workplace was presented, among others, by Stone and Coella (Stone and Coella, 1996), distinguishing such conditioning factors as personal characteristics of people, the environment and rules prevailing in the organization. In the case of many disabilities, the main barrier to their acceptance in the workplace is the lack of knowledge about them, primarily regarding the possibilities and competences of people with intellectual disabilities (Vornholt, Uitdewilligen, Nijhui, 2013). In the above mentioned study, the significance of demographic and professional characteristics on the perception of disability was also checked. The results indicate that men have more discriminatory attitudes towards people with disabilities than women. Additionally, more educated and younger people display a more positive attitude towards people with disabilities than those who are older and less educated. Diversity related to gender was also confirmed by the study discussed by Popovich et al. (Popovich et al., 2003), where greater openness was found in women's attitudes. Diverse attitudes of employers towards different types of disabilities has been confirmed, among others, by the results obtained by Swedish researchers (e.g. Strindlund, Abrandt-Dahlgren, Ståhl, 2018).

Research Methods and Research Sample

The results presented in this article are based on the data obtained as part of the research conducted in October-December 2019 among Internet users from eight European countries using computer-assisted interviews (CAWI). In total, the research covered 4209 people from the age of 18 to the official retirement age from Belgium, Bulgaria, Greece, Spain, Germany, Poland, Sweden and the United Kingdom. The share of respondents from individual countries was comparable and ranged from 12% to 13% (over 500 people in each country, compare Figure 1). The research sample was representative at country level for features such as gender, age, education and regions. The structure of the sample within the first three features is presented in Figure 1. The share of respondents according to categories distinguished for gender and age groups was comparable (around 50% and 33% respectively). When it comes to education level, the majority of respondents were people with secondary education (43%), followed by higher education (35%) and lower than secondary education (22%). The respondents were also diverse in terms of the following characteristics: place of residence (villages and cities of various sizes), professional situation (students, self-employed, working for someone else, unemployed, professionally inactive, pensioners), type of work performed (blue-collar work, white-collar work,

mixed) and decision-making in the field of employing people (the main decision maker, co-decision maker, a person with little or no influence).

The questions asked to the respondents concerned the perception of people with disabilities in general and in the work environment, the acceptance of various types of disabilities in the workplace displayed by co-workers, the evaluation of the government policy, the knowledge of employers, special privileges for people with disabilities at work and work atmosphere concerning the employment of people with disabilities. In this article one focuses on the question concerning the acceptance of different types of disabilities in the workplace by co-workers. The respondents answered it by choosing one of the options on the 5-point Likert scale, where 1 meant "completely disagree", whereas 5 – "completely agree".

Fig. 1: Sample structure, N = 4209.

The research was focused on assessing differences in the perception of different types of disability depending on demographic and social characteristics. In the case of factors taken into account in the research (gender, age, education level), one has distinguished two or three categories of respondents. In order to assess the differences between the two groups, one used Student's t-test based on comparing the means for two independent samples. The null hypothesis of the test assumes that the observed differences are the result of the difference in sampling distribution (Munro, 2005, p. 138). The adoption of an alternative hypothesis leads to the conclusion that there are significant differences between the analysed groups. The evaluation of differences between the three groups of respondents was carried out using the analysis of variance (ANOVA), which is a generalization of the t-test for any number of groups, allowing comparison of means in relation to many categories of the independent variable (Warner, 2008, p. 215). In the case of significant differences between the groups, post-hoc tests are used to interpret the detected patterns (see Cardinal & Aitken, 2006). For multiple comparisons, one used Tukey honestly significant difference (Tukey HSD) test. For all the tests carried out, one assumed the significance level of 0.05.

Results Discussion

First, one evaluated the overall acceptance of various types of disabilities in the workplace by co-workers. The results are presented in Figure 2, together with percentage of responses that indicated the acceptance of a given type of disability (answer 4 or 5).

Fig. 2: Acceptance of different types of disabilities in the workplace

The analysis of Figure 2 clearly indicates the disproportion between the acceptance of different types of disabilities. It appears that co-workers display the most positive attitude towards people with mobility impairments. In this case, over 50% of respondents indicated that it is acceptable or fully acceptable. The second place in terms of the number of indications took sensory disability, that is, related to vision, hearing or speech problems. At this point, the option concerning acceptance or full acceptance was indicated by 1/3 of respondents. However, the situation looked much worse in the case of disability resulting from mental disorders and intellectual disability resulting from genetic issues (e.g. Down syndrome). The percentage of responses indicating the acceptance of this type of disability is below 25%, which means that in the opinion of more than ¾ of respondents, these disabilities are not accepted by colleagues or potential co-workers of people who suffer from them. According to previous analyses, the situation varies in different countries covered by the CAWI research, but the overall evaluation is not optimistic in the context of inclusion of people with different types of disabilities in the labour market.

Based on the collected data, one analysed differences in the assessment of acceptance of different types of disabilities in the workplace depending on such demographic and social characteristics as gender, age and education. While analysing the differences according to the gender variable in two categories, one used the Student's t-test, whereas for factors such as gender and education level having more categories, one used ANOVA. The results of the tests are presented in Table 2.

Table 2: Assessment of differences in the acceptance of different types of disability according to demographic and social characteristics

Mobility impairments			
Factor	t statistics or F statistics	p-value	Conclusion
Gender	t = 0.303	0.762	no difference
Age	F = 13.823	0.000	differences exist
Education	F = 13.321	0.000	differences exist
Sensory disability			
Factor	t statistics or F statistics	p-value	Conclusion
Gender	t = -3.443	0.001	difference exists
Age	F = 7.815	0.000	differences exist
Education	F = 4.345	0.013	differences exist
Intellectual and genetic disability			
Factor	t statistics or F statistics	p-value	Conclusion
Gender	t = -3,014	0.003	difference exists
Age	F = 0.522	0.594	no differences
Education	F = 2.203	0.111	no differences
Mental disorders			
Factor	t statistics or F statistics	p-value	Conclusion
Gender	t = -2.006	0.045	difference exists
Age	F = 22.924	0.000	differences exist
Education	F = 1.137	0.321	no differences

The results from Table 2 indicate that there is no clear dependency of connections between demographic and social characteristics and the evaluation of the degree of acceptance of particular types of disability in the workplace. Only in the case of sensory disability did significant differences occur in reference to all three considered characteristics. The acceptance of mobility impairments is similar among men and women, but it varies between age groups and people with different levels of education. In the case of acceptance of intellectual and genetic disability, gender is the only polarizing factor. The approach towards mental disorders was assessed differently by men and women and by people from different age groups. There were no significant differences in the perception of such dysfunctions by the representatives of groups with different levels of education.

When noting differences in opinions according to age and education level with the use of ANOVA, it was necessary to make the analysis more detailed in order to identify the differences between the various categories of these variables. To this end, Tukey's post hoc test was used, the results of which are shown in Table 3.

Table 3: Results of post hoc (Tukey's) tests for age and education in the ANOVA analysis

Mobility impairments			
Comparison		p-value	Conclusion
Age	18-34 years – 35-49 years	0.196	no difference
	35-49 years – 50-65 years	0.002	difference exists
	18-34 years – 50-65 years	0.000	difference exists
Education	Lower than secondary – secondary education	0.177	no difference
	Lower than secondary – higher education	0.000	difference exists
	Secondary – higher education	0.000	difference exists
Sensory disability			
Comparison		p-value	Conclusion
Age	18-34 years – 35-49 years	0.460	no difference
	35-49 years – 50-65 years	0.020	difference exists
	18-34 years – 50-65 years	0.000	difference exists
Education	Lower than secondary – secondary education	0.923	no difference
	Lower than secondary – higher education	0.035	difference exists
	Secondary – higher education	0.029	difference exists
Mental disorders			
Comparison		p-value	Conclusion
Age	18-34 years – 35-49 years	0.000	difference exists
	35-49 years – 50-65 years	0.179	no difference
	18-34 years – 50-65 years	0.000	difference exists

The analysis of the results from Tables 2 and 3 and average values in specific groups leads to the following conclusions:

- men assess the acceptance of sensory, intellectual and genetic disabilities as well as dysfunctions related to mental disorders in the professional context better than women,
- women and men express similar acceptance of mobility impairments,
- respondents from the oldest age group (50-65 years old) display much more acceptance of motor and sensory disabilities in the workplace than representatives of younger groups,
- respondents from the youngest age group (18-34 years) perceive the acceptance of mental disorders in a clearly better way than older respondents,
- respondents with the highest level of education assessed the acceptance of mobility and sensory disabilities in the workplace better than people with secondary or lower education.

Conclusions and future study

The research results confirmed the existence of significant differences in the perception of various types of disability not only due to the different situations in different countries or macroeconomic and social factors, but also due to the demographic characteristics of respondents. Age appeared to be the most differentiating characteristic, and the biggest differences were observed between the oldest (range

50 - 65 years) and younger groups. It is worth noting that the opinions were more diverse in the case of more acceptable disabilities. Importantly, all types of disabilities received all assessment values, that is, from 1 (totally no) to 5 (completely yes), which proves that the opinions on the perception and acceptance of disabilities are diverse. The importance of the subject justifies the necessity of conducting further research and answering the question whether differences related to demographic characteristics occur in other countries. What is more, it is important to find out whether the place of residence – villages and cities with a different number of residents – also represents a differentiating characteristic.

Acknowledgments

The project is financed by the Ministry of Science and Higher Education in Poland under the programme "Regional Initiative of Excellence" 2019 - 2022 project number 015/RID/2018/19 total funding amount 10 721 040,00 PLN.

The authors would like to thank Agnieszka Draminska (Wroclaw University of Economics and Business) for useful help with conducting the bibliometric analysis and the systematic review.

Abstract

The article explores the issues of ensuring accelerated innovative development of Russia. In particular, issues of the implementation of a number of state programs, national and federal projects in the field of supporting the creation of new technological solutions and innovations were considered. Special attention is paid to the structure of national projects, including goals, objectives and targets. Attention is drawn to the features of the functioning of the economic complex of Russia, which in turn are considered as the main economic prerequisites for the accelerated technological development of the country. Among them: historical, sociocultural, resource, territorial, geopolitical. A detailed description of these prerequisites is presented, with emphasis on the country's potential for further fundamental and applied research, allowing Russia to make a significant contribution to the formation of a new technological structure. Also emphasized is the possibility of organizing balanced production throughout the country, taking into account the rational specialization of regional production complexes and their simultaneous mutually beneficial coordination.

Keywords: Innovative Development, Technological Development, State Participation, National Project, Economic Growth.

Introduction

Modern conditions for the functioning of the world economy, including a high level of competition for technology, which can significantly increase labor productivity, optimize production costs, bring business to a fundamentally new level of goals in relevant development strategies and programs, require special attention from the state and business entities , scientists and society as a whole on the acquisition and implementation of such technologies.

The problems of accelerated innovative and technological development are investigated in the works Kharchenko Ye.V., Shirokova L.V., Alpeyeva Ye.A. (2015), Ruban D.A. (2018), Bannikov S.A., Khvostova N.V. (2018), Ganichev N.A., Koshovets O.B. (2019), Yermakov A.S., Liman I.A. (2019), Komkov N.I. (2019), interconnection and mutual influence of innovative safety and quality of life of the population - in work A.A. Kuklin, A.V. Bagaryakov, N.L. Nikulina (2013), the impact of fiscal mechanisms on the innovative development of the country – Sevriukova, L. V., & Trusova N. C. (2014), Tkacheva T.Yu., Sevryukova L.V. and Afanasyeva L.V. (2016), Tkacheva T.Yu., Afanasjeva L.V., Goncharenko L.Iv., Sevrukova L.V., Panskov V.G. (2019), the impact of regional foreign economic activity on economic growth – Polozhentseva Y.S., Zhukov P.V., Bayanduryan G.L., Borisova A.A., Vasiliev V.P. (2017) etc.

Results and Discussion

In practice, technological development, the dissemination of advanced scientific solutions has a tremendous impact on the pace of development of states. At the same time, developments are more

and more intersectoral in nature, allow research and significant scientific results at the junction of different technological approaches (digital, manufacturing technologies, robotic systems, big data processing systems, artificial intelligence, etc.).

Currently, the fundamental documents reflecting the goals, objectives and tools for the development of the innovative component of the Russian economy are strategic planning documents (table 1).

Table 1: The system of basic documents of strategic planning for the development of the innovative component of the Russian economy

Type of documents	Title of the document
Strategies	1. The national security of the Russian Federation. 2. The innovative development of the Russian Federation. 3. The spatial development of the Russian Federation. 4. Economic security of the Russian Federation. 5. The development of the information society in the Russian Federation. 6. Scientific and technological development of the Russian Federation.
Government programs	1. Scientific and technological development of the Russian Federation. 2. Economic development and innovative economy. 3. The development of industry and increasing its competitiveness. 4. The information society.

Source: compiled by the authors based on an analysis of the current legislation (http://government.ru/ – official website of the Government of the Russian Federation, http://programs.gov.ru/Portal/ – official portal of state programs of the Russian Federation).

Moreover, indicators of the innovative component of the development of the domestic economy are reflected in the strategic documents of the country (Table 2).

Table 2: Indicators of the innovative component of the development of the Russian economy, reflected in the relevant strategic documents

Nature of the document	**Indicators**
1. The concept of long-term socio-economic development	- the proportion of industrial enterprises engaged in technological innovation; - the share of innovative products in the total output; - the share of the knowledge economy and the high-tech sector in gross domestic product; - internal costs of research and development; - expenses on education and health care from public and private sources.
2. National Security Strategy	- the share of expenses in gross domestic product for the development of science, technology and education.
3. Economic Security Strategy	- the share of investment in fixed assets in gross domestic product; - the degree of depreciation of fixed assets; - industrial production index; - the share of investment in machinery, equipment and vehicles in the total investment in fixed assets; - the share of innovative goods, works, services in the total volume of goods, works, services shipped; - the share of high-tech and high-tech products in the gross domestic product; - the proportion of organizations engaged in technological innovation; - the share of innovative goods, works, services in the total volume of exports of goods, works, services of industrial enterprises.
4. Innovation	I. Formation of competencies of innovative activity (8 indicators);

Development Strategy	II. Innovative business (12 indicators); III. Effective science (6 indicators); IV. Innovation State (7 indicators); V. Innovation infrastructure (2 indicators); VI. Participation in the global innovation system (4 indicators); VII. Territories of innovation (2 indicators); Viii. Financial support (4 indicators).
5. Information Society Development Strategy	The list of indicators for the implementation of the strategy and the values of these indicators reflect: - an assessment of the development of information and communication technologies in the Russian Federation; - an assessment of the development of the information society in the Russian Federation; - the parameters of the formation of the digital economy, an assessment of its impact on the growth rate of the gross domestic product of the Russian Federation; - the state of the transition to the use of high technology by organizations.

Source: compiled by the authors based on an analysis of the provisions of the current legislation (http://government.ru/ – official website of the Government of the Russian Federation)

The results of the analysis of the indicators presented in Table 2 indicate that there are currently opportunities to increase the level of interconnection and structural unity of these indicators to provide a comprehensive and comprehensive assessment of the participation of innovative factors in the development of the Russian economy.

The theoretical substantiation of economic development prospects requires raising the question of what quantitative and qualitative indicators to measure the development of the corresponding innovative component.

According to the results of the study of the Global Innovation Index of 2019, Russia took 46th place, having risen two steps since 2015 (Table 3).

Table 3: the Dynamics of the positions of the Russian Federation in the Global Innovation Index in 2015-2019.

Indicators	2015	2016	2017	2018	2019
Global Innovation Index	48	43	45	46	46
Innovation resources	52	44	43	43	41
Innovation Results	49	47	51	56	59

Source: compiled by the authors based on the Global Innovation Index Reports 2015-2019 (The Global Innovation Index [Electronic resource]. URL: https://www.globalinnovationindex.org/Home)

The data in Table 3 show that there is a steady improvement in the situation regarding the subindex of innovation resources, but the country's position has declined in terms of the impact of the results of innovation on the economy and society.

In 2018, a number of national goals and strategic objectives of the country's development for the period up to 2024 were designated at the state level in Russia. Among them - Russia's entry into the five largest economies of the world, acceleration of technological development, growth in the number of organizations implementing technological innovations (Decree of the President of the Russian Federation of May 7, 2018 No. 204 "On national goals and strategic objectives of the development of the Russian Federation for the period until 2024").

To achieve these goals, from the end of 2018 to the present, several national projects and a national program are being implemented, the activities of which are described in more detail in the content of the corresponding federal projects that are part of them.

In particular, we are talking about the national projects “Labor Productivity and Employment Support”, “Science”, “International Cooperation and Export”, “Small and Medium-Sized Enterprises and the Support of Individual Entrepreneurship Initiatives”, as well as the national program “Digital Economy”. These documents, in addition to the narrative, also contain target values (http://government.ru/ – official website of the Government of the Russian Federation).

For example, the national project “Labor Productivity and Employment Support” is aimed, inter alia, at stimulating the introduction of advanced management, organizational and technological solutions into the work of domestic enterprises. As a result of the project, annual productivity growth should be ensured in medium and large enterprises of the basic non-resource sectors of the economy (http://government.ru/ – official website of the Government of the Russian Federation).

National project "Science" - to create advanced scientific and innovative infrastructure; updating the instrument base of leading organizations carrying out research and development (special attention is paid, according to the Ministry of Education and Science of Russia, to the construction of installations through which fundamentally new technologies are developed); the creation of world-class scientific and research and educational centers; formation of a holistic system of training and professional growth of scientific and scientific-pedagogical personnel (http://government.ru/ – official website of the Government of the Russian Federation).

As a result, it is necessary to achieve Russia's presence among the five leading countries of the world that carry out research and development in areas determined by the priorities of scientific and technological development (according to the Russian Ministry of Education and Science, an increase in the number of articles in leading international databases and patents is expected

2 times, financing of research and development - by 50%); to ensure the attractiveness of work in Russia for domestic and foreign leading scientists and young promising researchers; outstripping increase in domestic spending on research and development from all sources compared with the growth of the country's gross domestic product (http://government.ru/ – official website of the Government of the Russian Federation).

It should be noted that a lot of work to support the development of promising industries in Russia (quantum technologies, artificial intelligence, robotics, biotechnology, etc.), scientific and innovative projects are already carried out by the Competence Centers as part of the national program of measures "National Technological Initiative", the Russian Fund for Fundamental Research, Russian Science Foundation and other authorized organizations. Also, a fairly large innovative scientific and technological center “Sirius” will soon begin work (Decree of the Government of the Russian Federation of November 8, 2019 No. 1428 “On the establishment of an innovative scientific and technological center“ Innovative scientific and technological center “Sirius”).

The national project “International Cooperation and Export” presupposes, among other things, the orientation of state policy towards achieving the international competitiveness of Russian goods, as well as the development of financial instruments to support export activities (http://government.ru/ – official website of the Government of the Russian Federation).

As a result, it is planned to form globally competitive non-primary sectors in the manufacturing industry, agriculture, and services, the total share of export of goods (work, services) of which will be at least 20 percent of the country's gross domestic product.

The national project “Small and Medium-sized Enterprises and the Support of Individual Entrepreneurship Initiatives” is aimed, inter alia, at improving the conditions for doing business, improving the procurement system carried out by major customers from small and medium-sized enterprises, simplifying access to preferential financing, creating a digital platform, focused on supporting the production and marketing activities of small and medium-sized enterprises (http://government.ru/ – official website of the Government of the Russian Federation), Ruban D.A. (2018).

As a result of the project, an increase in the number of employees in the field of small and medium-sized enterprises is expected. It must be emphasized that world practice indicates the success of using the experience of small innovative enterprises in the framework of the development of new technological solutions. The national program “Digital Economy” is focused on creating a system of legal regulation of the digital economy, based on a flexible approach in each area, creating a global competitive transmission, processing infrastructure and data storage, as well as end-to-end digital technologies; transformation of priority sectors of the economy and social sphere through the introduction of digital technologies and platform solutions (http://government.ru/ - the official website of the Government of the Russian Federation).

As a result, it is planned to create a stable and secure information and telecommunications infrastructure for high-speed transmission, processing and storage of large amounts of data, accessible to all organizations and households.

At the same time, the implementation of the state program "Scientific and technological development of the Russian Federation" for the period until 2030 (stage I - 2019-2024, stage II - 2024-2030) in accordance with the provisions of the Strategy for Scientific and Technological Development of the Russian Federation affects issues of national intellectual capital, conducting fundamental scientific research, implementing comprehensive scientific and technical programs, improving the infrastructure of scientific, scientific, technical and innovative activities, ensuring globally the competitiveness of Russian higher education and others. At the same time, the values of the target indicators of this state program and the financial support of the relevant events are interrelated with the content of national projects (Decree of the President of the Russian Federation of December 1, 2016 No. 642 “On Approving the Strategy for Scientific and Technological Development of the Russian Federation”, decree of the Government of the Russian Federation of March 29 2019 No. 377 “On approval of the state program“ Scientific and technological development of the Russian Federation ”for the period until 2030”)

Conclusion

Today we can talk about a certain level of integration of national projects into the existing tools of federal targeted, state programs, both from an organizational and financial point of view. At the same time, national projects made it possible, among other things, to strengthen the prioritization of the distribution of various resources at all levels of government, to identify promising areas for the implementation of the socio-economic potential accumulated over recent years in various sectors, and to ensure the rhythm of the process of transferring budget allocations to the regional level.

An analysis of the preliminary results of the implementation of the above national projects and relevant programs indicates that in 2019, more attention was paid at the state level to the creation of a normative and organizational-methodological basis for the implementation of relevant measures, including for the subsequent acceleration of the country's innovative and technological development.

In this regard, judgments about the effectiveness of solving the problems of implementing national projects are still preliminary. At the same time, it seems that at the federal level there are currently economic prerequisites and the necessary conditions have been created for intensifying the processes of technological development of Russia.

Taking into account the historical, sociocultural, resource, territorial, geopolitical and other features of the functioning of the economic complex of Russia, we note that all these features may well serve as the main economic prerequisites for the accelerated technological development of Russia. Moreover, this development implies the formation of incentives for the accelerated introduction of innovative solutions by domestic business, the government’s assistance in attracting investment in the scientific, technical and innovative sectors of the economy, the development of technology transfer mechanisms, scientific and technological cooperation and the building up of high-tech export of international cooperation, etc.

So, for example, the personnel and intellectual potential historically accumulated in the country, the experience of successful implementation of breakthrough scientific and technical projects, creates the basis for further fundamental and applied scientific research that allows Russia to make a significant

contribution to the formation of a new technological structure, improving domestic production in terms of increasing labor productivity, increase their competitiveness, and generally offer the world market demanded and competitive the innovative solutions, to form new high-tech markets through the use of modern technological solutions (Bannikov S.A., Khvostova N.V. (2018)).

This is facilitated by the sociocultural characteristics of the country, the specificity of the national mentality, which allows domestic scientists and practitioners to implement ambitious projects as soon as possible in conditions of limited resources.

Russia's resource capabilities (climatic, financial, human, informational and other) that determine the country's general socio-economic potential and directions for its effective implementation at different levels (including international) also create significant prerequisites for accelerated technological development of the state, ensuring effective activity of development institutions, objects of innovative and scientific and technical infrastructure (for example, the development of innovative scientific and technological centers and innovation territorial clusters).

At the same time, a significant differentiation of the country's regions both in terms of resources, the current level of innovative development, and the existing prospects for socio-economic development, on the one hand, requires close attention of the state in terms of scientific substantiation of the directions of the most efficient use of available resources. On the other hand, it creates additional economic prerequisites for accelerated innovative development of regions and various industries, including high-tech sectors of the economy, for specialization and creation of modern technological solutions, which may have no world analogues. That is, it implies the possibility of organizing balanced production throughout the country, taking into account the rational specialization of production complexes in the regions and their simultaneous mutually beneficial coordination.

Of great importance for the technological development of Russia, the growth of high-tech exports are the country's foreign economic relations and various partnerships with foreign countries in the implementation of joint innovative projects, regardless of their scale and investment. Of course, today, taking into account the developing geopolitical situation in the world, participation in the international division of labor, pooling of countries' resources for the benefit of the development of world markets and the economy as a whole are of great importance, including for ensuring the innovative development of national economies. Of course, when creating large-scale developments and conducting research, it is important to form international teams, project teams, and develop scientific and technological cooperation.

Thus, the economic prerequisites for accelerated technological development of the country identified during the study are characterized by a variety of manifestations and testify to the significant potential of Russia not only in improving the industrial structure and territorial configuration of the national production complex, but also in developing technologies at the international level, including the formation of the foundations of a new technological structure.

Abstract

The goal is to determine models for organizing the structure of the tourist information system as a tool for forming a tourist cluster. The reliability of the research results is ensured by applying an integrated approach to the use of scientific methods, methodology and tools, i.e. statistical methods, system-integrated, system-structural, system-resource methods, methods of monitoring, forecasting, qualitative analysis and expert estimates. The authors rely on the study results conducted in 2018 and 2019; about 1000 people acted as respondents. The authors propose a tourist information center model that satisfies the needs of tourists to the greatest extent, ensures a rich interaction between the tourist information center and the tourist, while optimizing the costs of maintaining tourist information offices and call centers. The tourist information center can play the role of an interaction generator between tourism market entities. The horizontal and vertical links formation based on the tourist information center can stimulate the growth of cooperation in order to develop tourism and the increase in the number of economic entities working in the tourism sector.

Keywords: Tourism, Tourist Cluster, Tourist And Recreational System, Tourist Information Activity, Tourist Information Center.

JEL Classification: Z32.

Introduction

The tourist and recreational system of a region with limited tourist resources is able to form a cluster only with a certain state of its subsystems. The main condition for the emergence of a tourist cluster is the synergistic effect of the interaction in the field of tourism of geographically close enterprises of various industries. Even as old reasons for clustering have diminished in importance with globalization, new influences of clusters on competition have taken on growing importance in an increasingly complex, knowledge-based, and dynamic economy (Porter, 2000). Organizational and management subsystems are of particular importance, which include territorial tourism management agencies, tour operators, tourist information centers, public organizations, non-profit associations in the field of tourism and scientific institutions. In achieving a synergistic effect, the tourism and information component of this subsystem is extremely important. The role of information in tourism is considered in various aspects, i.e. its place in the tourism system (also, including in the tourist-recreational system of the region). N. Leiper considers tourist information service as an industrial element of tourist destinations (1979). Goeldner C.R. and Ritchie J.R.B. consider information as an element of the 'tourism environment' (2009).

At the end of 20th century, tourist information centers firmly entered into the structure of territorial tourist and recreational systems. In Russia, this process began only in the 21st century. This activity is aimed at tourism development in the Russian Federation regions. Currently, there are several associations in the Russian Federation that unite tourist information centers, the largest association operating at the federal level is the non-profit partnership 'National Association of Tourist Information Organizations', which includes 164 organizations (at the beginning of 2020) that provide information support for tourism in regions, according to some estimates, their number is larger

(*Nonprofit Partnership 'National Association of Tourist Information Organizations'*, 2020), but these data refer to 2016-17. In the system of tourism cluster development, the tourist information center should be considered as a structural element of the cluster core. Consequently, the model of organizing the activities of the tourist information center should be built taking into account the specifics of cluster processes.

The practice of organizing information activities in tourist regions is very diverse. Studies of modern information management practices as an instrument of territorial tourism management are presented in the works of several scientists such as R. Pierdicca et al., who offer an innovative information and communication technology infrastructure specifically designed and optimized for the tourism sector of municipalities (Pierdicca, Paolanti and Frontoni, 2019). Other authors consider the information as 'connecting capital', uniting the most diverse enterprises of the tourism cluster among themselves, they recognize the importance of information exchange between enterprises and research centers (universities) (Martínez-Pérez *et al.*, 2018). Many authors (Amaro, Duarte and Henriques, 2016) note the importance of information support for tourism clusters. It is noted that one of the most important areas of interaction in the cluster is the exchange of knowledge and information between stakeholders interested in cooperation (Kładź-Postolska and Biegajło, 2018).

The management of tourist information is determined by the features of the regional tourism development strategy, resources and the management system of the tourist and recreational system of the region.

In Russian studies, the issues of the tourist information centers activity are considered in various aspects. The problems of creating and the activity of tourist information centers in Russia (Zhdanchikov, 2015; Kiryanova, Kim and Yumatov, 2016; Kormishova, 2017b), the variety of legal forms of tourist information centers operating in the Russian Federation (Zhdanchikov, 2015; Kormishova, 2017a); the authors attempt to systematize the goals and objectives of the creation and functioning of tourist information centers (Kormishova, 2017a), the ways of their transformation are considered (Akimova, 2007; Kiryanova, Kim and Yumatov, 2016; Kormishova, 2017b). Most Russian authors consider the tourist information centers of the Russian Federation as 'one of the key elements of the tourist destinations marketing system' (Kiryanova, Kim and Yumatov, 2016). Several authors comprehensively study the functioning of tourist information centers in a cluster of tourism development. The results obtained show the place of the tourist information center in the cluster processes of the tourism sector by the example of the municipality 'Tourist information centers should be recognized as an important participant in any tourist cluster' (Karpova, Pesotskaya and Tkachev, 2017).

Methods

The main objective of this study is to determine a model of the tourist information center, which will contribute to the formation of intra-cluster relations and the development of the tourist cluster. When modeling the activities of the tourist information center, we relied on the results of studies conducted in 2018 and 2019. The study used methods developed based on expert assessment methods, sociological studies (about 1000 people were respondents).

The research reliability results is ensured by the use of an integrated approach in scientific methods, techniques and tools, i.e. statistical methods, system-integrated, system-structural, system-resource methods, monitoring methods, forecasting, qualitative analysis and expert estimates.

Results

Based on the collected materials, we saw that two vectors determine the goals of the tourist information centers: information support of the territorial sphere of tourism (formation of the internal information environment of the tourist cluster) and promotion of the territory on the tourism market (formation of the external information environment of the cluster). Achieving each of the goals is

associated with solving a number of tasks that can be considered as the basis for determining the structure of the practical activities of the tourist information center (Fig. 1).

Fig. 1: The practical activities structure of the tourist information center

The traditional model of organizing tourist information support includes an information portal, social media accounts, an office of a tourist information center in the place (s) of tourist arrivals and most visited places. The results of tourist surveys and expert interviews show that the tourist information centers value is falling, i.e. the attendance is decreasing, the maintenance of offices is too expensive (rental costs, utilities, etc.). The number of online requests, on social networks, by phone, is increasing. The interaction of tourists with the offices of tourist information centers is very diverse. All tourists (100%) who took part in the survey noted that they visited the local tourism portal; 63% of them viewed information on the pages of tourist information centers on social networks, 24% purchased souvenirs in the offices of tourist information centers; 19% booked tours; 63% received some consultations (i.e. a request on the portal, correspondence on a social network, by phone, in person). With a clear preference for virtual forms of obtaining information at the place of stay, tourists note that they would like to be able to receive personal consultations at the places of stay, i.e. a large number of offices where they could get information of interest (72%). Some tourists consider the offices of tourist information centers as a form of interaction with the local community, the opportunity to immerse themselves in culture and get impressions (38%).

According to surveys, a wide range of enterprises is interested in attracting amateur tourists, who might consider tourism as an additional area of activity. We are talking about both potential tourists and those, who are already in the tourist center. A survey of 123 owners and managers of enterprises of various fields was carried out in the territory of the Lipetsk Region, 52% expressed a desire to inform tourists about their goods and services. The ones that were interested in informing tourists were folk arts and crafts enterprises, farmers, food producers, medical centers, spa centers, beauty salons, etc.

Discussion

These results make us think about a model of the tourist information center that best meets the needs of tourists, ensures the richness of the interaction between the tourist information center and the tourist, while optimizing the cost of maintaining tourist information offices and cool centers. We offer a model of a tourist information center, for which the presence of a cool center as a subdivision of a city tourist information center is optional. Information for tourists is placed in public spaces, offices, buildings and other structures of enterprises and organizations that in one way or another

interact with city guests, i.e. hotels, catering establishments, souvenir shops, folk art enterprises, theaters, cinemas, museums, shopping and entertainment, wellness centers, etc. The layout of the 'infokiosks' is displayed on the tourist information center portal, Yandex maps, Google maps, as well as in infographics on enterprises facades they are located at. A prerequisite for ensuring the work of 'information kiosks' is their inclusion in the enterprises corporate culture that hosted them. The staff should be aware of the importance of providing tourists with information both for the city as a whole and for their company. Employees of enterprises working in the contact area should receive additional competencies to advise tourists. Obtaining such competencies is provided by continuing education. Thus, the scientific and educational center is included in the interaction system. The basic model of organizing the network structure of the tourist information system of the municipality is presented in Fig. 2.

Fig. 2: The municipal network model of the tourist information system

Information kiosks can be placed in places like accommodation enterprises, catering enterprises, business centers, health institutions, manufacturers and sellers of souvenir products, folk art crafts enterprises, shopping and entertainment centers, museums, entertainment centers, theaters and cinemas, other leisure ones, including sports enterprises and institutions. Interaction with enterprises is dictated by the tourist specialization of the territory (both existing and prospective).

Conclusion

Thus, the tourists' need in information and the interest of enterprises in information interaction with tourists are realized to the greatest extent. This model of activity is relevant in the context of tourism cluster development. The tourist information center can be a generator of interaction between tourism market entities. The formation of horizontal and vertical links based on the tourist information center can stimulate the growth of cooperation in order to develop tourism and the increase in the number of economic entities working in the tourism sector.

Abstract

Under present-day conditions it is necessary to develop a new concept model of legal regulation of occupational safety. The current acting system of the labor safety evolved as a separate direction in the second half of 1990s and the beginning of 2000s. It is based on the so-called reactive approach, which implicates formulation of detailed safety requirements, compliance monitoring, applying measures of response to detected violations and occurrence of adverse effects. Shift of attitudes to the administration of the occupational safety is essential to rise the efficiency and prevent industrial injuries and occupational morbidity, to improve safety and health in the workplace, to reduce administrative burden for employers and to involve the employees in administrating of the labor safety by increasing their awareness. The changes proposed by the authors in the area of occupation safety would contribute to maintain the positive dynamics of decreasing mortality and traumatism caused by industrial accident and work-related diseases, they would also resolve conflicts and eliminate gaps of the Russian labor legislation, put a new impetus to improve working conditions.

Keywords: occupational safety, labor safety, Ministry of Labor and Social Protection of the Russian Federation, improvement of legal regulation, public administration, levels of administration of the occupational safety, industrial accident, industrial injuries, industrial traumatism, causes of employment-related accidents, State Labor Inspectorate.

Introduction

Market-based organization of economy in Russia changed relationship between employers and employees. The facts show that in many enterprises, especially small and medium-sized working conditions do not meet up industrial safety and hygiene standards, which compromises workers' health and often threatens their lives. In many respects it is caused by the employers' pursuit to get the biggest profit out of it and with the least investment. Owners of enterprises, institutions and organizations take advantage of the employment deficit and workers' unawareness in matters of labor safety and pay little attention or completely ignore occupational safety requirements.

Meanwhile, in particular poor state of labor safety is a heavy burden on the economy of enterprises, organizations and state in general. Comfortable and safe working environment is one of the major factors effecting not only the safety but productivity and efficiency of labor.

At present development of a new concept model of legal regulation of occupational safety is a long-felt need. The current acting system of the labor safety evolved as a separate direction in the second half of 1990s and the beginning of 2000s. It is based on the so-called reactive approach (plan-perform-control-promote), which implicates formulation of detailed safety requirements, compliance monitoring, applying measures of response to detected violations and occurrence of adverse effects [The Ministry of Labour of Russia came up with an initiative to implement the concept of zero injuries and to record micromuscular injuries of workers, 2019]. Shift of attitudes to the administration of the occupational safety is essential to

rise the efficiency and prevent industrial injuries and occupational morbidity, to improve safety and health in the workplace, to reduce administrative burden for employers and to involve the employees in administrating of the labor safety by increasing their awareness.

Public administration is implemented through practical activities of government bodies targeting for application of state policies. Features of national and territorial organization in Russia as well as fundamental nature of ownership and management of property resulted in coexisting of several basic levels of administration, i.e. nationwide (federal), regional (federal entity), local (municipal), private (corporate).

Public management uses various forms and methods of exposure (arrangement) on working, social, spiritual activities of human beings in the territory of the state. Essential forms of influence are administrative command and economical (market) instruments. Despite the distinction in kind both are operate (or at least supposed to) fully in the applicable law framework.

German system of the labor safety are primarily of precautionary nature and not repressive one. Initial inspections of economic entities resemble audit rather than supervisory activities as they are understood in Russia. The inspected organization or enterprise is provided with a list of violations to be rectified. Sanctions are imposed on case of the orders being disregarded.

Public administration of the occupational safety in Germany is exercised on two levels. Federal Ministry of Labor and Social Affairs is in charge of the state supervision over compliance and enforcement labor safety legislation on national level. Implementation of labor legislation is administered and controlled on the regional level in federal states. Trade unions are also involved in the system management of occupational safety as well as the network of professional unions. The latter are associations of employers organized according to regional and sectoral characteristics. They are legally entrusted with the function of employers' liability insurance against industrial injuries and work-related diseases. The associations are funded by means of membership dues insurance premiums of business.

Methodological Framework

The empirical framework of the research is formed by Russian laws and regulations in the field of labor safety and legislation of the countries which have experience in the area of interest for the research. It also includes monographs and essays on the system of administration of occupational safety. Economical and law studies on the matter are taken into consideration. IN order to substantiate our position on the issues we used the statistics provided by law enforcement agencies in charge of inspection and supervision over compliance and enforcement labor and particularly labor safety legislation.

The research is based on interdisciplinary approach, which implies considering the system of labor safety management from the viewpoint of various sciences: administrative and civil law, management, marketing, sociology.

System concept directs the work towards revealing the system integrity in administration of labor safety and structural items of the system, showing their interaction and final consolidation of all these elements into a coherent vision.

Universal and specific scientific research methods provide the methodological basis for this research. The approaches were chosen in view of particular purposes of the study. The method of dialectical materialism allows to study the subject in development, interrelation of its certain displays, its interaction with related phenomena, to substantiate advantages and disadvantages of various approaches to the issue.

Such methods of formal logic as description, comparison, analysis and synthesis ensure that law, mental and ethical, other aspects of occupational safety will be developed and thoroughly described. Specific research methods such as comparative legal, technical, statistical, structural-functional methods were used.

Comparative legal method allows to disclose and compare different approaches to development and implementation of the national policy in the field of labor safety, to assessment of its efficiency on the ground of Russian ad German legislation and public opinion.

Technical method helps to draw up recommendations on the ways to advance conceptual and normative instruments in the considered area of knowledge.

Statistical method is supposed to be used for consolidating and compiling of data on importance and consequences of the labor safety management system reformation. The reforms are necessary given to the shifted approaches to administration of labor safety and assessment performance of results from points of employer and employee as well as supervising agencies.

The inner structure of the labor safety administration is defined through the structural-functional method, it also distinguishes elements if the system, gives their functional characteristics, analyzes their interconnections.

Implementation of the abovementioned methods ensured that the study took into consideration linkages and dependencies of the issue, revealed certain tendencies and provided generalization and conclusion. They also allow to compare Russian and foreign experience of application of labor safety administration systems and reveal efficient practice with a view establishing new approaches to the policy concept of labor safety in Russia.

Results

In Russia the system of labor safety administration is represented by the following basic levels: nationwide (federal), regional (federal entity), local (municipal), private (corporate).

The framework of the government administration of the occupational safety is laid down in art. 214 of the Russian Labor Code. It stipulates that the government administration is provided directly by the Government of Russian Federation or under its delegation by a federal executive body in charge for the development of state labor policy and the regulatory framework and other federal executive bodies within their authority.

Federal executive bodies which have been granted the right to perform certain functions of regulatory authority, specific permissive, supervisory and monitoring functions in the field of labor safety, have a responsibility to coordinate their decisions on the matter with the federal body in charge for the development the labor regulation framework.

Ministry of Health and Social Development is the federal executive body in charge for the development of state labor policy and the labor safety regulation framework

There are essentially two critical tasks and functional responsibilities of administrating labor safety on the federal level: 1) developing a legal framework for the activities of all authorities and business entities of the law on the occupation safety 2) long-term (economic) and operational (administrative) management of all these activities. From this point the federal level of administration differs not only has a different place in the management pyramid but operates through the different type of control. In our opinion this type is defined by universality, real power and (relative) independence of the managerial decisions taken.

Although the issue of specific powers and functions at the regional level of governance is fundamental to the practice, the legislator did not decipher it in detail on the reasonable assumption that this is a matter for the constituent entities of the Russian Federation. They have both the authority and the means of regional budgets to do so.

There is a number of critical tasks and functional responsibilities on the regional level of labor safety administration:

1) enforcement organization and adaptation of the labor safety legislation in conformity with regional specific;

2) coordination of activities of the territorial branches of federal executive authorities, including agencies in charge of inspection and supervision, with regional governance structures in the sphere of labor and operational safety administration;

3) organizing of innovation, and education and information infrastructure of the corporate labor safety management (development and regulation of the labor protection services market);

4) operational (administrative) management of all these activities in the territory of the region.

State authorities of the constituent entities of the Russian Federation adopt laws and other labor regulatory legal acts on issues not under the jurisdiction of federal government bodies or not regulated by federal laws and other regulatory legal acts of the Russian Federation.

Specific powers for public administration could be could be transferred to local community governments in the manner and on terms determined by federal laws and the laws of the constituent entities of the Russian Federation.

Main tasks on local (municipal) level of administration are:

- ensuring the implementation of the Labor Code and other labor safety regulatory legal acts of the Russian Federation in the territories of municipal areas and urban districts;
- improvement of legal labor safety regulation and policy;
- ensuring the organization and conduct of activities of municipal programs aimed at improving working conditions, safety and health;
- ensuring coordination of activities of local government bodies, state control and supervision bodies, enterprises and organizations in addressing issues related to improvement of labor conditions and safety;
- development of social partnership in the field of labor protection;
- improvement and coordination of occupational health and safety services;
- organization of continuous training on occupational health and safety for managers and specialists of organizations, verification of knowledge;
- providing practical and methodological assistance in the area of occupational safety to employers;
- strengthening cooperation between local government bodies and government control and supervision bodies in preventing industrial injuries and morbidity;
- increasing the interest and responsibility of employers for working conditions and occupational health and safety, and ensuring occupational health and safety of employees at work.

Social and labour relations, including in the area of occupational safety, are regulated at the private (corporate) level through collective agreements and contracts. The efficiency of corporate governance in the area of occupational health and safety is conditioned by the fact that when entering into collective agreements and contracts, not only the balance of interests of the parties to the labor process is achieved, but also a consensus is established on the issues of financing measures to improve working conditions and labor safety. All this leads to a real increase in the level of social guarantees for employees. For example, in 2015 collective agreements were concluded in 192 municipal companies of the Chuvash Republic [Official report on the state of labor conditions and occupational safety in the Chuvash Republic in 2015, 2016].

Insufficient legal framework and weak economic capacity of local government bodies, unfortunately, lead to their frequent actual self-removal from the real process of labor protection management. And only where the size of the territory and economic potential are significant, local governments can and in most cases make occupation safety management at the municipal level real and realistic. We believe that future development of the municipal level of labor protection management is connected with the possibilities of regulation of corporate labor protection management during registration and licensing of the activity of subjects of law.

The German occupational health and safety system is clearly structured and divided into two areas: state and trade union. In parallel, the two areas have different functions as laid down in labor and social legislation. This structure is headed by the German Ministry of Labor and Social Affairs. Its main task is to draft laws and create laws and all kinds of instructions on occupational safety and health. In addition,

the Ministry initiates research work in this area, advises the State Office for Occupational Safety and Health and supervises the federal states' labor safety authorities. In Germany there are 16 federal states, each has its own labor ministry, state supervisory agencies for every industry and occupational health and safety authorities. All of these institutions are responsible for enforcing and monitoring laws and regulations of the Federal Ministry.

The state system of occupational safety is primarily aimed at preventing industrial accidents. Measures are taken to create favorable working conditions in which the risk of an accident tends to zero, as well as measures to explain to employees and employers the standards of safe production and occupational safety. At the same time, employees exercise self-control over their workplaces and must independently enforce their rights under the contract.

Trade union management system of labor safety in Germany is based on a professional insurance scheme. According to the law, all entrepreneurs in Germany are united into professional communities (Berufsgenossenschaft), which are organized according to the territorial and industry criteria (professional communities of mining, woodworking, health care, metallurgy, mechanical engineering, construction).

The main function of professional communities, assigned to them by the legislation, is to insure the liability of entrepreneurs for cases of industrial injuries or occupational diseases. The professional communities are financed exclusively from the membership or insurance fees of enterprises. The amount of insurance premiums depends on the following factors: the class of danger of the enterprise as a whole or its individual productions, wage fund, the level of industrial traumatism and occupational illnesses. The system of insurance premiums encourages employers to pursue a targeted policy to ensure occupational safety and health of employees.

In implementing the legislatively adopted concept of labor safety, aimed primarily at preventing occupational injuries and occupational illnesses, professional communities are working in the following areas:

- technical supervision over occupational health and safety at enterprises;
- training of different categories of insured;
- insurance protection;
- medical support;
- social assistance;
- research work in all areas related to health and safety at work.

By their legal form, professional communities are corporations of public law, they are non-profit, self-regulating organizations, and the state does not take any part in their activities, including financial contribution. All activities of the communities, including medical care and social assistance, are financed by insurance contributions. The State's role is limited to legal oversight. Since professional communities have no right to receive income, they can only set the amount of contributions that ensure that they fulfill the tasks assigned to them by law.

In general, the German occupational safety management system can be presented as a well-functioning mechanism: at the entrance - company insurance premiums, at the exit - increasing life expectancy, improving quality of life, ensuring social peace in enterprises and in society, improving the economic performance of companies.

Monitoring of labor conditions and safety in Russia confirms the thesis about the necessity to reform the current model of labor protection management. According to information contained in the Federal State Information System for Accounting for the Results of the Special Labor Conditions Assessment in the Russian Federation, the assessment was conducted in 423,300 employers for 20.8 million workplaces for 27.8 million employees between 1 January 2014 and 31 December 2018.

According to the report on the results of monitoring and occupational safety conditions in the Russian Federation in 2015, a special assessment of working conditions was carried out at 4,977,257 workplaces with 6,939,858 employees [Report on State supervision of compliance with labour legislation and other normative legal acts containing labour law standards and supervision in the area of social protection in 2018,

Moscow, 2019], in 2018 at 1 343 169 workplaces with 3 232 981 employees [Report on the activities of the Federal Labor and Employment Service for 2018, Moscow, 2019]. In 2015 working conditions at 76% of workplaces were found to be optimal or acceptable [Report on State supervision of compliance with labour legislation and other normative legal acts containing labour law standards and supervision in the area of social protection in 2018, p. 40], in 2018 at 78,6% of workplaces. In Chuvashia in 2015, a special assessment of working conditions was conducted for 55 566 workplaces [Official report on the state of labor conditions and occupational safety in the Chuvash Republic in 2015].

In 2015, the Federal Service for Labor and Employment found more than 21 000 violations of the established procedure for assessing working conditions at workplaces during control and supervision activities. (in 2014 - about 23 000 violations), in 2018 - 705 cases of violations [Report on the activities of the Federal Labor and Employment Service for 2018]. These figures in the Chuvash Republic are as follows: 2288 violations in 2014 [Official report on the state of labor conditions and occupational safety in the Chuvash Republic in 2014], 2451 in 2015 [Official report on the state of labor conditions and occupational safety in the Chuvash Republic in 2015], 42 in 2016, 48 in 2017, 85 in 2018 [Report on State supervision of compliance with labour legislation and other normative legal acts containing labour law standards and supervision in the area of social protection in 2018].

Table 1: Activities carried out in the Russian Federation on special assessment of working conditions

Indicators	2014	2015	2016	2017	2018
Number of workplaces with special assessment of working conditions	505 774	4 977 257	1 246 142	1 227 983	1 343 169
Number of enterprises that have carried out a special assessment of working conditions	18 620	161251	-	-	-
Number of occupational health and safety trainees	31103	26 726	39 246	34 726	41 084

According to the data of the Russian Ministry of Labor, the tendency to decrease the level of industrial injuries has been continuing for the last three years. Thus, in 2017 there were 6240 occupational accidents with severe consequences, in 2018 their number decreased to 6160. At the same time, despite the decline, the number of deaths at work remains high: 1,722 in 2017 and 1,323 in 2018. If we consider the number of deaths due to industrial accidents in terms of the main economic activities, in 2018 the highest death tolls were in construction - 282 people and in manufacturing - 230 people, while the mining is least affected with 101 fatalities. Main causes of accidents are the human factor and the organization of an employee's workplace not meeting safety requirements [Results of monitoring labor conditions and safety in the Russian Federation in 2018, Moscow, 2019].

The analysis of activities of the Federal Service for Labor and Employment (Rostrud) shows that the most frequently identified violations are still those related to various occupational health and safety issues. At the same time, according to the data of the Russian Ministry of Labor, there is a situation of decline in cases of industrial injuries (the level of industrial injuries remains high only in manufacturing production). Thus, over the past 10 years the number of occupational accidents with severe consequences in the Russian Federation has more than halved: from 13,722 cases in 2007 to 6,240 in 2017 and 6160 in 2018 [Report on State supervision of compliance with labour legislation and other normative legal acts containing labour law standards and supervision in the area of social protection in 2018].

Fig. 1: Occupational injury dynamics in the Russian Federation

Similar positive dynamics are also observed in the Chuvash Republic. According to the State Labor Inspectorate of the Chuvash Republic in the first nine months of 2018, a total of 1879 violations of labor legislation were detected, of which 39.7 % were violations of occupational safety issues, 3849 violations were detected in 2017, 49.1% of them of labor safety regulations [Report on State supervision of compliance with labour legislation and other normative legal acts containing labour law standards and supervision in the area of social protection in 2018]. At the same time the number of registered accidents at work in the third quarter of 2017 was 58, at the end of 2017 - 76, and for nine months of 2018 - 43 accidents (i.e. 25.8% less).

Therefore, the data from the monitoring of working conditions and occupational safety in Russia confirm the expediency of implementing the German experience in the field of occupational safety when reforming the national system of labor safety management.

Discussions

A steady interest in the organizational and legal support and implementation of the principles of occupational safety management system from foreign and national researchers was revealed in the course of our research.

Occupational health and safety has always received a lot of attention. Candidate's dissertations, monographic works, scientific articles of Russian and foreign authors are devoted to the consideration of various aspects of labor protection. The following authors should be mentioned: A.V. Mikhailova (2013), E.V. Kryazheva (1997), A.S. Neverova (2014), S.I. Saydakhmedova (2009), O.V. Kuznetsova (2015), Martina Gogolová (2015), S.S. Kudryavtsev, P.V. Yemelin, N.K. Yemelina (2018), Maureen F. Dollard, Daniel Y. Neser (2013), Veikko Rouhiainen (2018), Ioannis Anyfantis, Georgios Boustras, Alexandros Karageorgiou (2018). The problems of the occupational safety management system development keeping pace with modern international trends in this area are revealed in the works of G.Z. Fainburg (2016), E.A. Kuznetsova (2017), S.N. Kudryashova (2015), A.Ya. Petrov (2016). The authors share the position of some scientists, with some polemize, on the basis of others make their own conclusions.

The research «The Development of Higher Education in Occupational Health and Safety in Estonia and Selected EU Countries» by Karin Reinhold, Virve Siirak, Piia Tint (2014) presents the experience of educational institutions of foreign countries in the organization of training in the field of labor safety, and the inclusion of all specialties (both technical and socio-economic) as a mandatory subject in the curriculum.

Such researchers as E.V. Maslennikova (2018), S.V. Voronkova (2017, 2018) deal with the efficiency problems of state labor protection management. The studies of E.I. Dobrolyubova (2016), D.V. Chernyaev (2017), A.N. Pozdnyakov (2018) are devoted to the study of international experience in labor protection management. Their work is of interest to researchers as a source of experience of states with similar public-law systems and mentality.

Conclusion and Recommendations

In course of the study, the authors confirmed positive dynamics in the field of labor safety in Russia. At the same time, necessaty to improve the existing model of occupational health and safety management in Russia has been justified. In particular, the study of German experience confirms the need to shift the focus from reactive mechanisms to mechanisms for preventing the negative consequences that may be associated with working conditions.

The analysis of a condition and reasons of an industrial traumatism in Russia shows that primarily they are caused by lacks of organizational character and consequence of inefficiency of operating control systems of a labor safety, insufficient attention and exactingness of heads to work on prevention of an industrial traumatism. The main causes of accidents at work include the following: violation of safety requirements during operation of machines and units, including vehicles, non-application of personal protective equipment by an employee, shortcomings in organization and conduct of training of employees on labor protection, constructive defects and insufficient reliability of machines, mechanisms and equipment, unsatisfactory maintenance and shortcomings in organization of workplaces.

The labor safety management system should be preventative, not repressive. Employers should be interested in meeting the requirements for safe working conditions. The concept of occupational health and safety, which is primarily aimed at preventing occupational injuries and diseases, requires further legislative strengthening. In Germany, this is ensured by the labor safety insurance system, which encourages employers to pursue a targeted policy to ensure occupational health and safety at work. The presented experience could be applied in Russia.

Scientific and practical importance of the work is determined by its relevance, scientific novelty, general theoretical and practical conclusions will contribute to further development of theoretical and empirical studies of topical issues in labor protection management systems. The materials of the research can be used in the work on reforming the Russian legislation on labor protection, in the implementation of international cooperation, in the elaboration of a common direction of development in the sphere of safe labor to achieve competitiveness in the regional and world arenas.

Abstract

Human resources management is an important function in the hospitality sector, taking into consideration the fact that organizations within this sector, such as hotels, tourist agencies, hospitality objects, restaurants and resorts, depend on their employees as a source of competitive advantage. Therefore, the processes and human resources management philosophy in the hospitality sector must be applied well in order to ensure the commercial sustainability of organizations in this sector. Human resources are usually the first contact between companies and their clients; therefore, the efficient management of human resources is crucial for the success of the companies operating in the tourism and hospitality fields. The paper explores the precise specificity of human resources management in the tourism and hospitality fields, i.e. the employee training and development processes with a focus on the importance of human resources for the success of the companies operating within the service sector. The paper includes a research study based on the 142 respondents employed in different positions in the catering industry in the municipalities of the City of Belgrade, the Republic of Serbia. The research goal is to identify the needs for employee training and development that have appeared with the introduction of the Hazard Analysis Critical Control Points Standard (HACCP standard) to the facilities included in the research sample.

Keywords: Tourism, Hospitality, Catering Industry, Human Resources, Human Resource Management, Service Sector, HACCP Standard

Introduction

Efficient human resources management is one of the main sources for the competitive advantages of organizations in every activity in modern business conditions. Tourism and hospitality are the industries in which human resources have a special meaning, especially so due to the fact that they are in constant and direct contact with the users of their services. In the paper, a special focus (accent) is on the analysis of the specificities of human resources management in tourism and hospitality, with the goal to point out its importance and (a large number of elements) the numerous factors that are specific for this industry and which must be taken into consideration while managing organizations in tourism and hospitality.

The subject matter of the research published in the paper is human resources management in tourism and hospitality, while a special accent is placed on human resources management specificities in all these activities. Beside the theoretical analysis of the research subject matter carried out in the paper, research in the employees' attitudes towards changes in the organization (employee training and development) was done on the example of the Hazard Analysis Critical Control Points Standard introduction (HACCP Standard).

The research was conducted from 27th October to 13th November 2019. It is based on the answers of 142 respondents in the municipalities of the City of Belgrade, the Republic of Serbia. The research samples included different organizations which provide hospitality services, starting from fast food stands and bakeries all the way to hotel restaurants, all operating in the catering industry. Taking into account the fact that a large number of respondents participated in the research, there were a total of 29 facilities included in the research study. The research goal was to identify the needs for employee training and development that appeared with the HACCP standard introduction to the facilities in the research sample.

Tourism and Hospitality as Economic Activities

Industry Description

Tourism and hospitality are the industries that have a big impact on countries' economies and are ever-increasing in modern business conditions. The term "tourism market" implies the relationship between the offer of and demand for the products and service whose goal is to satisfy certain tourist needs (Cavlek, et al. 2011). As the key elements of the tourism market and tourism as an industry, the following can be highlighted (Galičić & Laškarin, 2016):

- tourist supply,
- demand for tourist services, and
- the organizations that provide different types of tourist and hospitality services.

The tourist offer is a very significant segment of tourism as an industry and can be defined as a segment of the tourism market in which certain services and products are offered according to specific prices for the purpose of satisfying tourist needs (Cavlek et al., 2011). With the help of tourist demand, it represents the total number of the persons who use or want to use tourist services in a future period and are able to pay for it (Martinovic & Tanaskovic, 2014). There are a large number of organizations on the tourism and hospitality market(s) rendering services and selling products to the potential users, i.e. persons interested in such services and such products.

Hospitality is one of the industries directly connected with tourism and has an important role in the process of providing tourist services. Heterogeneity is one of the most significant characteristics of tourism as an industry, which has as a consequence the need for the synchronization of services provided to tourists in order to ensure an equal and appropriate quality of tourist products or services.

Tourism and hospitality are the industries where employees are extremely important for a business success. A huge number of research studies indicate the fact that employees' attitudes towards the customers of tourist and hospitality services in the service industries directly have a high influence on their quality and their satisfaction with and readiness to use a particular service again (Chesser, 2016). The results of these research studies are one of the most significant indicators of the importance of human resources management in tourism and hospitality.

The importance of employees and human resources management in tourism and hospitality is additionally enhanced by the fact that the quality of these services is interpreted in different ways, both by their providers and by their users (Kulic & Markovic, 2011). The users' perception of the quality of a service is entirely subjective and subject to a variety of influences, such as the user's previous experience, education, emotional state at that moment and so forth. The perception of the identical tourist services provided to the same users at different moments may be different, primarily as a consequence of the influence of certain subjective factors existent at the moment of their use of such service.

Tourism and hospitality are interconnected to a great extent, whereby a great number of authors assert that hospitality is the basic and the most important element that has an influence on tourism

development (Chesser, 2016). The term hospitality implies service provision modalities in the accommodation and food industries implemented in hospitality facilities and in facilities for other purposes. The applicable law in the tourism industry (Law on Tourism, 2019) in the Republic of Serbia defines that hospitality implies the services related to providing accommodation, the preparation and serving of food and drinks, as well as the preparation of food and food delivery to users who may be consumers of the same in different locations.

The focus of the activity pertaining to human resources management must be on the creation of the preconditions necessary for employees in every segment of their work in order to create the maximum possible value for service users (Nickson, 2007). An additional factor which has an impact on the complexity of human resources management in hospitality is the fact that, in this industry, a plethora of possible, different and interconnected services are most commonly delivered. Human resources management creates the necessary preconditions for its employees willing to create the maximum possible value for service users (Nickson, 2007).

Human Resources in Tourism and Hospitality

In modern business conditions, characterized by permanent changes in the environments in which tourism and hospitality companies do business, it is necessary for managers to have a wide range of multidisciplinary knowledge. The placement of modern time services assumes respecting not only all business partners – business entities, but also the users for whom a service is ultimately provided. A contemporary approach to services implies adequate competitiveness, which has to establish long-term relationships with services users in terms of a clear differentiation *versus* competition (Popovic Sevic, 2019).

There are a large number of the factors that influence human resources in tourism and hospitality, the most significant amongst them being (Boella & Goss-Turner, 2019):

- the greatest number of tourist and hospitality services are provided in direct contact with users,
- the significant dependence of human work, which cannot be efficiently automated and replaced with technical means, especially not so in the service provision segment,
- user's needs for tourist and hospitality services constantly change; therefore, service companies' offers continuously adapt to these changes on the market, and
- organizations providing tourist and hospitality services must create and maintain a high-quality level of their business, with a special accent on the quality of the services they render to their users.

Human resources, together with material, make up the assets of the companies operating in the tourism and hospitality fields. In modern business conditions, employees' knowledge, experience, creativity, capability and motivation are the basic preconditions for the work efficiency and competitiveness of all companies operating in the tourism and hospitality fields. In the industries such as tourism and hospitality, in which employees are highly significant in the business doing of those companies, human resources management is very complex and requires an overall approach to all the segments of the business relationships with employees.

The development of modern information and communication technologies and the globalization of business activities have led to significant changes in human resources' needs in tourism and hospitality and in their structure. For example, the development of the Internet has led to essential changes in the ways tourist and hospitality services are sold, measured by a very high growth of direct sales, primarily for those made through online channels. These changes have led to the needs of the persons with an adequate knowledge of the information technologies field, as well as online sales and marketing. It is considered that, in the 21st century, services will take place in a shorter period of time, so communication with service users will exclusively be performed with the help of artificial intelligence and through other modern technologies (Sing et al., 2018). Thanks to the support of sales digitalization and marketing activities, service providers will be in a more interactive position *versus* users than it is the case now, mainly through different digital reports and procedural records. The management of the relationship with service users will fundamentally be based on the user's experience prior to, during and after using a service it (Homburg et al., 2017).

Human resources play an important role in ensuring the successful business doing of the companies they represent in the tourism and hospitality sectors. In modern business doing conditions, almost all the resources necessary for a company's operations are easily accessible, except for human resources, which are becoming more and more deficient, due to which fact they are one of the most important resources (Galicic and Laskarin, 2016).

The modern business environment in which service companies in the tourism and hospitality fields operate demands that significant attention should be dedicated to human resources and that they should be centrally positioned in business activities. The mission of human resources management is to responsibly organize all the activities carried out by companies because of their work and select an appropriate person for every workplace. Besides, human resources management must also provide conditions for the advanced training for and progress of all employees. Human resources management needs to provide all the preconditions necessary for employees' motivation and the creation of an awarding system which will make employees invest their maximum effort to accomplish the task assigned to them (Boella & Goss- Turner, 2019).

In the references dealing with tourism and hospitality, there are a large number of research studies dealing with different human resources management practices in these industries. The practice of human resources management in tourism and hospitality is based on the use of the two basic approaches the one being *hard* and the other being *soft*, which significantly differ from one another (Galicic & Laskarin, 2016).

The *hard* approach to the practice of human resources management is based upon emphasizing the activities connected with the management of human resources. The *hard* approach to human resources management in tourism and hospitality uses to a great extent the control system that can be more simply integrated into organizational strategies in comparison with the *soft* approach.

Within the framework of the *soft* approach to human resources management in tourism and hospitality, less attention is dedicated to the control system and their integration into organizational strategies. *Soft* approaches are based on ensuring the high levels of the independence of human resources management and in practice they have proven to be very efficient in the fields based on the provision of services, such as the tourism and hospitality fields, and employees' direct contact with users.

In the practice of human resources management in tourism and hospitality, the conceptual frame based on the three activities of human resources management (i.e. employee training, surveillance and practical training) is often used. In practice, this approach has proven to be a very efficient way to increase the business satisfaction level in employees and decrease the number of those leaving the company (Chesser, 2016). Tourism and hospitality belong to the industries in which business satisfaction has a very significant impact on employees' decisions to leave the company.

Modern business conditions in tourism and hospitality are characterized by an ever-increasing emphasis on the improvement of the quality of the services rendered to users (Boella & Goss- Turner, 2019). Efficient human resources management practice in tourism and hospitality may create an environment which encourages and motivates a positive employee behavior within the framework of the services of a higher quality which are provided.

Human resources management in tourism and hospitality is a very complex set of activities whose purpose is to enable the accomplishment of long-term competitive advantages and the conducting of everyday activities carried out by companies in their performing their business operations. Tourism and hospitality represent the service industries in which the quality of an employee's work and his/her efficiency to a great extent influence a company's success and (customer) satisfaction. Human resources management in tourism and hospitality is a complex process, within which the following activities are carried out (Ilic, 2018):

- human resources planning,
- analysis and business design,
- human resources recruitment,
- human resources selection and their socialization,
- human resources training and their career development,
- the evaluation of employees' individual performances,

- human resources' employee salaries and rewarding,
- managing employment and collective bargaining,
- employee security and protection activities,
- leaving the organization.

The complexity of human resources management and their significance in modern business conditions require all the activities connected with human resources to be carefully planned in full detail (Chesser, 2016). All human resources plan created in tourism and hospitality companies must be aligned with their organizational strategies and directed towards accomplishment and preservation in order to gain long-term competitive advantages.

Employees' career development is a process which continuously takes place and implies a person's formal development, work experience and relationships with other employees, and the evaluation of the capabilities and personalities, i.e. all those elements that allow a person to be prepared for future business (Noe, et al. 2007). This process is future-oriented, necessarily including studying, whereby not being connected with the jobs currently performed by the employee.

Research, Human Resources and the HACCP Standard Introduction

Methodology

The conducted survey was aimed at gaining an insight into the attitude of the employed in the hospitality industry towards the introduction of the changes that significantly affect the ways in which they do their work or provide services. The HACCP is a food safety system based on the rules and procedures that provide for the analysis and control of all potential biological/microbiological, chemical and physical hazards to which raw materials are exposed, possible hazards in the handling, manufacturing, distribution and consumption of the end product (www.eurostandard.rs, 2019)

The application of the HACCP is based on the use of well-defined guidelines and standard operating procedures, which have the task to reduce the levels of risk to the food used in human consumption.

By applying the HACCP (www.eurostandard.rs, 2019):

● identify, evaluate and control any potential hazards that could have adverse effects on food safety,

● food quality and safety management are ensured, with an emphasis on prevention activities, and

● it is ensured that all employees are aware of what they must do, how, when and why they must do that in order to prevent food-related risks, as well as their own responsibility, to enable end-users to consume the foods that are healthy and safe.

In modern conditions, the application of the HACCP standard is one of the basic and the most important preconditions for the successful business doing of all catering organizations. This standard is a hygienic practice, with the help of monitoring the status of the entire food production chain from primary production to the finished product. The application of the HACCP standard prevents food contamination and ensures adequate handling. In addition to being mandatory by law, its application in the hospitality industry is significant because it prevents the occurrence of food accidents, which could have significant negative effects on the image of organizations.

The survey was being conducted on the sample of 142 respondents that which included Belgrade City municipalities from 27th October to 13th November 2019. The survey sample included various catering organizations, ranging from fast food kiosks and bakeries to hotel restaurants. Taking into consideration the fact that the fact that a number of the respondents who participated in the survey came from some catering establishments, the total number of the facilities covered by the survey was 29. The aim of the research was to identify the training and development needs of employees that arose during the introduction of the HACCP standards to the facilities included in the sample.

The research consisted of a total of 17 survey questions, the 13 of which were closed-ended, with a greater number of the answers offered, while 4 were open-ended. Three open-ended questions relate to the basic information about the respondent and the age of the hospitality facility in which he/she works, whereas one question aimed to gather information about the HACCP problems encountered by the respondents not covered by the survey. In addition to the basic information about the respondents, the

questions asked in the survey were intended to provide the information related to the application of the HACCP standards in the catering establishments where the respondents are employed.

Results

Of the total number of the respondents, 75 (52.8%) were female, while 67 where male (47.2%) respondents. The survey participants' average age was 38 years and 5 months. In order to make the results more transparent, the respondents' answers regarding their age were divided into the age categories: "20-30 years old", "30-40 years old", "40-50 years old" and "over 50 years old". The majority of the respondents, i.e. 47 of them (33.1%), worked as chefs; 26 respondents (18.3%) were head chefs, while 22 respondents (15.5%) were restaurant managers. The remaining respondents worked in other workplaces. The result that the two-thirds of the respondents worked as chefs, head chefs and restaurant managers indicates that the sample provides credible information about the employees' attitude towards the introduction of the HACCP standard. The average work experience of the respondents employed in the hospitality industry was 13 years and 9 months, which also confirms the fact that the sample included in the survey provides credible information about the introduction and implementation of the HACCP standards.

The fifth question was about the type of the catering facility in which the respondent works, and as many as ten possible answers were offered within it so as to ensure the maximum possible level of precision in collecting this information, which is very important for the whole research study. When asked "What is the type of restaurant you work for?" the respondents were offered the answers "a restaurant", "a specialty restaurant", "a café", "a bar", "a pizzeria", "a roaster", "a grill", "a beerhouse/a winery", "a coffee-shop" and "a buffet". The majority of the respondents worked in restaurants, i.e. a total of 61 of them (43%), 35 worked in grills (24.6%), and 18 (12.7%) worked in pizzerias. A total of 5% of the respondents said they worked in all other types of facilities. Based on the collected data, it can be concluded that the sample fairly accurately reflects the structure of the hospitality establishments on the market.

The sixth question was "What year was the year when the facility you work for was established?"; the files were collected based on the data about the period of the business operations of the facility collected. In order to facilitate data analysis and their increased visibility, the answers to this question are listed as the age of the catering facility, not as the years they were established in. The average age of the facilities significantly affected the fact that even 8 of the respondents worked at a hotel established in 1908, which resulted in a situation that the average age of the facilities increased by six years in relation to the case in which the hotel was excluded from the sample. The average age of the facilities was 27 years and 3 months, where they were classified into the categories "below 10 years", "from 10 to 20 years", "20 to 30 years" and "over 30 years".

The remaining 11 issues were tasked so as to provide information about the implementation of the HACCP in the catering facilities and the respondents' attitudes towards it, or their attitudes towards the changes the HACCP has led to. All the questions from 7 to 16 were closed-ended, and the four answers were offered: "I don't agree at all", "I generally disagree", "I generally agree" and "I completely agree".

Regarding the question "To what extent do you consider you are familiar with the HACCP requirements?", the largest number of the respondents, i.e. a total of 53 of them (37.3%), replied that they completely agreed with the assertion that they were familiar with the requirements of the HACCP. A total of 39 respondents (27.5%) answered that they were not familiar with the HACCP requirements at all; a total of 29 respondents (20.4%) said that they were familiar with the requirements to a large extent, whereas a total of 21 respondents (14.8%) were familiar with the HACCP requirements to a lesser extent. The answers to the question "To what extent do you consider you are familiar with the HACCP demands?" are shown in Chart 1.

Chart 1: The respondents' answers to the question "To what extent do you consider you are familiar with the HACCP requirements?"

Next question was "To what extent do you agree with the assertion that an adequate implementation of the HACCP is significantly contributing to an increase in food safety?" More than one-half of the respondents, i.e. 78 of them (54.9%), answered they fully agreed with this assertion, while a total of 43 respondents (30.2%) said they agreed with the assertion to a great extent, indicating that employees working at the catering facilities were familiar with the advantages of the HACCP to a great extent, saying it made it easier for them to accept the changes it brought with itself (shown at Chart 2).

Chart 2: The respondents' answers to the question "To what extent do you agree with the assertion that an adequate implementation of the HACCP is significantly contributing to an increase in food safety?"

The ninth question was "To what extent do you agree with the assertion that the catering facility in which you work meets all the requirements of the HACCP?" The majority of the respondents, i.e. 77 of them (54.2%), answered they agreed to a great extent with the assertion that the facility they were employed in met the requirements of the HACCP, whereas a total of 35 respondents (24.6%) fully agreed, indicating the fact that, according to the respondents, the HACCP was adequately implemented in the catering facilities in which they work (shown at Chart 3).

Chart 3: The respondents' answers to the question "To what extent do you agree with the assertion that the catering facility in which you work meets all the requirements of the HACCP?"

Question: "Was a lack of employee education and training a problem in implementing the HACCP?", was asked to determine how the catering facilities were prepared for the implementation of significant changes in business doing due to the HACCP standards. The answers to this question indicate a polarization in the approach to employee education during the introduction of the HACCP. The research study participants who worked in big and well-known catering facilities (hotel restaurants and high-price restaurants) had a lot more training than the respondents who worked in smaller facilities. This difference resulted in the fact that, with respect to the other questions, the respondents who came from different categories of catering facilities indicated that the HACCP was introduced more efficiently to the facilities that had invested efforts in employee education and training (shown at Chart 4).

Chart 4: The respondents' answers to the question "Was a lack of employee education and training a problem in implementing the HACCP?"

The question, "Were complicated documents and bureaucracy a problem in implementing the HACCP?", also pointed to the significant differences between hotel restaurants and higher-price restaurants when the application of the HACCP and other catering facilities are concerned. In the majority of the cases, the respondents from higher-price hotel and restaurants agreed that they did not agree to a great extent with the assertion that a complicated documentation and bureaucracy were a problem in implementing the HACCP, as opposed to the respondents from small dining facilities. After the subsequent interviews with the respondents working in higher-price class hotels and restaurants it became clear that, in those facilities, administrative affairs were connected with the introduction of the HACCP, which was usually performed by the administrative services, as opposed to smaller facilities, where those activities were performed by the employees involved in the research study (shown at Chart 5).

Chart 5: The respondents' answers to the question "Were complicated documents and bureaucracy a problem in implementing the HACCP?"

The twelfth question was intended to indicate whether the catering facilities where the respondents were employed had the appropriate physical characteristics of the establishments in which the HACCP needed to be introduced. The question was, "Was a lack of an appropriate infrastructure (the physical characteristics of the facility) a problem in implementing the HACCP?" The answers to this question also indicated a polarization between the persons employed in higher-price class hotels and restaurants, on the one hand, and those employed in the other catering facilities, on the other. The respondents from the higher-price hotels and restaurants answered as a rule that they did not have those types of problems, or that those problems were smaller, while the respondents employed in the other catering facilities were to a great extent responsible for the significant amount of infrastructural problems in introducing the HACCP (shown at Chart 6).

Chart 6: The respondents' answers to the question "Was a lack of an appropriate infrastructure (the physical characteristics of the facility) a problem in implementing the HACCP?"

One more question that deals with the infrastructure needed to introduce the HACCP, referred to the availability of equipment, reading as follows: "Was a lack of appropriate equipment a problem in implementing the HACCP?" The respondents' answers to the aforementioned question significantly corresponded to the answers to the previous question, indicating that the catering facilities that had problems with the infrastructure most frequently faced the problems connected with the equipment necessary for the introduction of the HACCP. Chart 7 shows the answers obtained from the respondents to the question, "Was a lack of appropriate equipment a problem in implementing the HACCP?"

Chart 7: The respondents' answers to the question "Was a lack of appropriate equipment a problem in implementing the HACCP?"

The fourteenth question was aimed at highlighting the impact of changes in the employee structure on the HACCP implementation process. The question was, "Was the employee fluctuation a problem in implementing the HACCP?" The answers to this question pointed to the fact that the fluctuation of employees did not constitute a significant problem during the application of the HACCP in the catering facilities, where it was present to a slightly greater extent in comparison with the smaller facilities, mostly grillers and coffee confectionaries (shown at Chart 8).

Chart 8: The respondents' answers to the question "Was the employee fluctuation a problem in implementing the HACCP?"

Question "Was the insufficient commitment of the leadership a problem in implementing the HACCP?" were asked upon respondents. There are two types of approaches which managers and owners of the catering facilities had towards the implementation of the HACCP that may be identified in the answers to this question. The first group consists of catering facilities (to a great extent high-price hotel restaurant, bars and restaurants) in which there the leadership were highly dedicated to the

implementation of the HACCP. In these catering facilities, the management as a rule gave their open support to all the activities related to the implementation of the HACCP. The smaller catering facilities were characterized by the significantly lower dedication on the part of the management to the implementation of the HACCP, which in a large number of the cases was observed by the managers of those facilities as an unnecessary cost and a burden in the business operations (shown at Chart 9).

Chart 9: The respondents' answers to the question "Was the insufficient commitment of the leadership a problem in implementing the HACCP?"

The sixteenth question was, "Is there insufficient awareness among the employees of the risk of food safety problems in implementing the HACCP?". The answer to this question clearly points to the importance of reducing the number of employees in the implementation of changes, such as the introduction of the HACCP. Almost all the respondents who answered to the previous question said that the lack of commitment on the management's part was a problem in the implementation of the HACCP; the authorities pointed to the fact that, in their catering facilities, the level of the employee awareness and food safety were a problem in introducing the HACCP (shown at Chart 10).

Chart 10: The respondents' answers to the question "Is there insufficient awareness among the employees of the risk of food safety problems in implementing the HACCP?"

The seventeenth question was aimed at enabling the identification of the problems that appeared during the implementation of the HACCP that, however, were not covered by the survey. Less than one-half of the respondents answered the question, "Is there another problem with the application of the HACCP you have noticed, which is not included in the survey??" Most of the suggestions that the respondents gave in their answers to this question can be classified into the framework of one of the questions involved in the survey. The only suggestion not included in the survey concerned a lack of candidates in the labor market, especially for a chef's jobs.

Conclusive Considerations

In modern business-doing conditions, human resources management is one of the most significant segments of the business doing of all the companies operating in tourism and hospitality. Quality human resources management often represents the main difference between successful and unsuccessful tourism and hospitality companies. The specificity of human resources management in tourism and hospitality can be seen in the fact that companies' business operations can be controlled and their image influenced to a great extent with the help of human resources management.

A large number of employees in tourism and hospitality in the Republic of Serbia have jobs with minimum or slightly higher than minimum salaries; therefore, their motivation for work is very low. Precisely this fact is one of the most important factors exerting an influence on the high rate of employees' abandoning workplaces, which is characteristic of tourism and hospitality. A great number of employees, especially the ones with less-paid jobs, do not plan to work in tourism and hospitality throughout their careers, for which reason they only work in this industry until they receive an offer for a better-paid job another employer. These hiring specificities in tourism and hospitality complicate the implementation of activities within human resources management to a great extent.

The significant specificities of human resources management in tourism and hospitality are all the elements pertaining to employees' progress and their promotion. In this segment of business doing, efficient human resources management has an important role in accomplishing long-term sustainable competitive advantages and increasing the efficiency of the implementation of business activities. Companies in the fields of tourism and hospitality provide clear guidelines for their employees on their progress and provide employee training courses, with a purpose to enable them to master the knowledge and skills required for their current workplaces and a further improvement, thus recording a much higher level of the satisfaction and motivation of their employees, as well as a much lower rate of employee abandoning the company.

Based on information presented in the paper and the practical examples, it can be concluded that human resources management plays an important role in tourism and hospitality. The employees who work in tourism and hospitality have possibilities of creating a positive or negative image of their company in the eyes of their customers through their personal behavior and attitude to work, and to do that to an extent significantly higher than in other industries. It is exactly in this fact that we may notice one of the most important specificities of human resources management in tourism and hospitality.

The influence which human resources management has on the results achieved by the companies operating in tourism and hospitality was the subject matter of many research studies carried out in a recent past. Almost every research study has shown the existence of a positive correlation between the manners of the practical use of human resources management, on the one hand, and the results companies have generated through their business doing. Achieving adequate effects with the use of human resources management in tourism and hospitality can exclusively be ensured in the situations which take into consideration all the specificities connected with the practice applied in this field.

The research results clearly indicate the differences existing among the different types of hospitality facilities when the practices applied in human resources management are in question. Big hospitality facilities, as well as those with longer traditions, dedicate significantly higher attention to human resources management than small hospitality facilities do.

Abstract

Healthcare represents a dynamic domain that constantly compells creativity, passion and faithfulness. Medical marketing represents the process of creating and providing information and interventions valid in health, by using strategies base on science and consumer-oriented in order to promote a better healthcare assistance. Through interactions with patients and consumers, the healthcare organization can get ideas on how to improve their healthcare services. When executed well, the right health marketing strategy should help improve the connection with more clients. A large patient database is equivalent to higher profits for the organization.

Keywords: Digital Trends, Marketing, Healthcare System.

Introduction

Marketing in healthcare incorporates a variety of tactics, integrating them in several channels, designed to gain a certain demographic population in what regards the patients. The success of a healthcare marketing campaign is measured by specific measurable metrics that are appropriate to the medical organization's objectives. Among the healthcare marketing benefits we mention**:**

- Identifying potential patients via specific objectives
- Generating higher incomes due to more qualified data
- The patients' involvement rate remains high due to the relevant timely activities
- Improving loyalty
- Connections with more patient's channels
- Productivity assessments and re-alignment of strategies, as needed, with the analyses performed

Healthcare will always typify an industry that is in permanent change and development. In the past, medical assistance was based on volume, nowadays, it is based on value and in this way, healthcare marketing represents an access gate to the previously mentioned assistance based on value.

Four major technology platforms are needed for health professionals to achieve full success in medical marketing.

- Healthcare customer relationship management (HCRM) - a healthcare customer management system that integrates patient data from a number of sources for launching, optimizing and measuring health marketing campaigns.
- Content management system (CMS) - this platform simplifies, as well as classifies the content of marketing for health. It integrates with the management of client relationships in the

health field to ensure a content aligned with the branding guidelines of the medical organization. Also, CMS offers the opportunity to establish a plan to help efficiently distribute the content.

- Marketing Automation - allows healthcare marketers to distribute the right content to the right patient at the right time. This platform has the ability to mobilize the data provided via HCRM to ensure that the content is aligned with the individual journey of the buyer.

These platforms allow healthcare professionals to purchase, care for and retain more patients by providing professional, personalized and timely content. This also generates considerable revenue growth.

There is a myriad of data available on healthcare consumers. Medical organizations can influence this and target certain groups of patients to convey the right message to them. This process is completed by a center where health data is centralized, similar to the previously mentioned platforms. It integrates all the necessary data: demographic, behavioral, social, etc., to inform the organization about the preferred communication method of the patient.

Healthcare Marketing Trends

Investing in the content marketing

It's been a long time since placing a pop-up ad could produce brand awareness in the medical industry. More and more internet users are using software that prevents pop-up ads, and some browsers are pre-installed with such applications. The orientation towards marketing should be based on the trend with what is popular in today's society, namely content marketing.

Content marketing is a form of marketing focused on creating and sharing content for a well-defined online target audience. It is based on anticipating and meeting the needs of existing customers, as opposed to creating the demand for a new need.

Organizations are increasingly using content marketing strategies to:

- Draw attention
- Expand their customer base
- Generate or increase sales in the online environment
- Increases brand awareness or credibility
- Involve an online community
- Provide valuable customer information
- Increase loyalty

Digital content marketing is a management process that uses electronic channels to identify, forecast and meet audience content requirements. It is imperative that the information is constantly updated and added to influence customer behavior.

Creating a mobile-friendly website to take advantage of new advertising opportunities

In 2019 more than half of the online traffic came from mobile, and if the website of the medical organization was not mobile-friendly, it probably did not receive organic traffic. In 2018, Google launched a new algorithm for mobile search results. Basically, Google has decided that it will only display search results based on the mobile version of the web page instead of the desktop version. Therefore, any non-responsive mobile site will be displayed only for keywords such as the name of the medical organization.

Mobile sites are specifically designed for mobile devices - no one wants to browse from their smartphone on a desktop site. Research on the degree of use of mobile sites shows that mobile-

optimized websites significantly improve user experience and satisfaction, which creates a positive brand impression.

Mobile sites are also designed to provide optimal download speed, which means less waiting time and more time for browsing. A mobile site can be accessed from anywhere, anytime. This level of constant connectivity provides an unprecedented opportunity for the medical organization to connect with the target audience in new ways, wherever they are.

In terms of integration with offline environments, mobile devices are unique in their ability to immediately cover the gap between online and offline environments by using QR codes. QR codes can be displayed in print format and then scanned with a smartphone, translated into electronic messages, such as a website URL, an email address or an SMS message. This means that ads, posters - even panels - can contain QR codes that will direct users to mobile landing pages that contain far more information and interactivity than can be offered on the printed page. This integration between print and web via the smartphone adds a new dimension of communication to any advertising or mobilization effort.

A mobile site is generally a much less restrictive way to build a mobile presence compared to application development. First of all, application development requires the production of different applications for different platforms and sending to an application store, which makes applications more fragmented and more expensive. Most importantly, an app requires users to download the app before it can be accessed. On the other hand, a mobile site is universal for all current smartphone browsers, giving it flexibility and cost efficiency, with fewer barriers between the organization and the target audience.

As for new advertising opportunities, mobile advertising is growing at a rapid pace and presents many new opportunities to reach a target audience with precision. If a medical organization uses Google AdWords / PPC, there is a good chance that the ads will also appear on mobile device listings (depending on the account settings).

Video Marketing to attract new patients

Video marketing is no longer an "up-and-coming" content strategy. This is an increasingly powerful way of communicating the brand story, explaining the value proposition of the medical organization, and building customer relationships.

In terms of engagement, no other form of media can truly rival a video. This is why YouTube ads are becoming more popular compared to other forms of advertising. A lesser known fact is that YouTube is not just a video site, but also a search engine owned by Google. With over 4 billion searches a month, YouTube is actually bigger than Yahoo, Bing, AOL and Ask combined. Given these aspects, as a healthcare marketing professional, you should consider that video marketing is a cornerstone of future marketing efforts.

Providing quality content in a video format can contribute to influencing the consumer selection process and will demonstrate the added value of a private healthcare experience.

Online video content opens up opportunities for physicians to showcase their personalities and professionalism through a video, less formal to show their passion for healthcare and specialty areas. Thus, these videos can help humanize the organization for potential patients, while influencing their decisions.

A Google study found that of the 700 surveyed healthcare administrators, each client reported watching videos to view product demonstrations. After watching, 79% continued browsing the site and 63% communicated with other people about the information they learned. Therefore, video landing pages tend to lead to higher conversion rates, as users can find information from the first touchpoint.(Da

Cuna, 2019) 5 billion videos are watched on YouTube every day, 4.6 billion video ads are watched every year,(Ahmad, 2017) 1200% more video-generated actions than text and images combined, (Templeman, 2017) videos on a landing page increase conversion by 80 %, and 80% of users remember a video ad they saw online last month.

Videos have a compelling way to encourage involvement, generating results such as clicks and sales. It is indeed one of the best tactics to bring more exposure to the medical brand. (*https://www.socialmediatoday.com*)

A major importance has the length of a video, the shorter the length, the greater the attention of the person (more than 80% of people watched a video with a duration of less than 30 seconds).(*https://www.wordstream.com*) Thus, it is essential to introduce as short a content as possible in the video in order to reach the best degree of involvement from those who watch it.

Investing in online reputation and Multi-Channel Initiatives

The medical organization must be active on social media. Facebook, Twitter and Google are some platforms on which the organization should activate. After creating an account on social media, the account must be linked to the blog / site of the medical organization. This represents a huge potential for improving the organization's reputation. It must regularly update its activity to provide the best information to potential customers.

The presence of a blog can prevent negative advertising. If the damage already exists, it is advisable for the organization to hire an ORM (Online Reputation Management) consultant, so that it can contact the site owner who generates content responsible for the negative reputation and request deletion of defamatory content. If he refuses, the organization can always have the right to make a legal move.

In today's digital world, clients seek information about medical organizations by reading and analyzing reviews about them. Reviews play an important role in bringing customers to the organization and can also drive them away.

In many organizations, customers face situations where their feedback is not received by these, despite their contact efforts. Such problems cause the client to lose interest in the organization and leave a wrong review, which is read again by other (potential) customers. The organization must keep track of the latest customer reviews and provide appropriate feedback.

Among the most sought after by patients in the virtual environment are:

- Detailed medical profiles
- Detailed information on medical procedures
- Testimonies of patients

Potential patients increasingly seek out physicians who specialize in the procedure they should have, before scheduling a consultation with them. Before putting their health in the hands of a doctor, patients want to know them, so that they get a sense of confidence beforehand.

Before the advent of the Internet, a company's reputation was almost entirely based on recommendations, various surveys and consumer data, but in the digital age, all of these take place online in the form of reviews.

According to SocialMediaToday, 92% of consumers read online reviews to learn more about the brand, 80% of consumers have changed their mind about purchasing a product after online reviews, and 40% of consumers form an opinion about the organization after they read 1-3 reviews. (Ahmad, 2017)

Networking

Through interactions with patients and consumers, the healthcare organization can get ideas on how to improve their healthcare services. When executed well, the right health marketing strategy should help improve the connection with more clients. A large patient database is equivalent to higher profits for the organization.

Multi-channel marketing campaigns mimic consumer behavior, which, according to a Forbes report, tends to use multiple platforms to research and interact with organizations before buying. (Forbes, 2016)

Multi-channel marketing in healthcare ensures clients experience without interruptions, connections, personalized interactions with healthcare systems, regardless of the method of communication. Multi-channel health marketing has many benefits, including:

- **Improving the brand awareness**

Brand awareness is crucial; strong medical brands inspire consumer confidence and increase revenue. Since it takes five to seven impressions on average for a customer to remember their brand, the more points of contact they need. (https://brandbuddha.com) Multi-channel marketing is an effective method of creating contact points, stimulating impressions and building a strong brand awareness.

- **Customized experience for the patient**

Switching between platforms and devices is common customer behavior, and leveraging multi-channel marketing creates a seamless journey for them, linking interactions to ease the transition from one stage to another.

- **Greater patient involvement**

Increasing patient involvement not only increases the number of purchases and retention, but also creates more patients, healthier. Multi-channel marketing contributes to increasing patient involvement by providing personalized and proactive interactions throughout the patient's life cycle.

- **Increased income**

In the vast majority of industries, 90% of traders make higher profits and sales when using multi-channel strategies, and 52% say they "usually" or "always" reached their financial goals. In the medical sector, in particular, health systems reported an improvement of conversions by over 40% when using multi-channel marketing.

According to Frost & Sullivan's Transformational Health's *"Multi Channel Marketing Global Voice of the Customer - A Digital Perspective"* study, regarding the preferences and needs of healthcare professionals for online and offline channels, the following (Frost & Sullivan, 2017) is noted:

- Independent medical sites, followed by other sites such as Wikipedia, medical applications, e-mails and virtual events, are the most important digital channels for HCPs.
- Channels associated with independent medical organizations are evaluated more, as compared to those offered by pharmaceutical companies.

Recycling in Russia And Abroad: A Model of Circular Economy

Svetlana I. KODANEVA

Candidate of Juridical Sciences, Senior Scientist of Institute of Scientific Information for Social Sciences of the Russian Academy of Sciences
Associate Professor of the Russian Academy of National Economy and Public Administration under the Russian Federation President
Associate Professor of the Russian State University of Oil and Gas named after Gubkin I. M.
Moscow
E-mail: kodaneva.isiss@mail.ru

Abstract

The growth in population and consumption has led to a multiple increase for disposal. In Russia, traditionally, waste management is carried out by placing it at landfills, as well as authorized and illegal landfills. However, this method leads to significant negative consequences for the environment, the economy and public health. This study is aimed at analyzing current recycling practices in Russia and foreign countries. Theoretical and empirical methods were used such as analysis of statistical data, study and analysis of scientific and business literature, systematization, generalization, comparative analysis. The author draws a conclusion that in order to solve the problem of waste management in Russia, it is necessary to ensure a transition to the 'circular economy' model, but this requires a complete restructuring of existing business models, a change in the mentality of the population and the formation of socially and environmentally responsible behavior among citizens.

Keywords: Waste Management, Recycling, Circular Economy, Waste Separate Collection, Joint Consumption Economics.

Introduction

Exponential population growth, combined with rapid industrialization and urbanization, has led to the same increase for waste disposal. According to World Bank, in 2025 the annual production of municipal solid waste in urban settlements should be approximately 2.6 million tons. No less alarming is the situation in rural areas, where, in addition to municipal solid waste, which is typical for cities and consists mainly of paper, glass and plastic, there is about 750 million cubic meters of livestock enterprises and poultry farms waste. One of the directions for the disposal of this waste is to use it as fertilizers, but today only 25% of the generated manure is used. Its improper processing leads to pollution of not only groundwater, but also pressure water, and accumulation leads to inefficient use of agricultural land (Trubilin, et al, 2019).

The cost of waste disposal is constantly growing. Today it is around $205.4 per ton. It is predicted that by 2025-2030 a five-fold increase in this amount is expected (Subhasish, et al., 2019, p. 658).

According to 'Rostekh' the state corporation in Russia, the total mass of waste is 3-4 billion tons per year. Extraction of fuel and energy minerals make 54% of waste, 17% is waste from non-ferrous metallurgy, ferrous metallurgy makes 16%of waste and 12 % is the waste from other industries, including municipal solid waste. Up to 400 kg (or 1.5 cubic meters) of municipal solid waste per year are per capita in Russia. The total mass of municipal solid waste is 55-60 million tons per year. The recycling level is 5–7% (long-term plans include bringing municipal solid waste to 60% in 2024), most of the waste goes to open landfills (Glukhov and Movchan, 2019, p. 160). So landfills occupy an area of more than 4.2 million ha and about 400 thousand ha added each year. (The garbage problem in Russia: scary statistics!. n.d.) The largest landfills are located in the Perm Territory, Moscow, Chelyabinsk, Tomsk, Sverdlovsk and Volgograd regions (The largest landfills, n.d.). Despite the fact that only about five percent of the Russian population live in the Moscow region, the waste generated by them is twenty percent of the country's total waste.

In addition, waste production is inextricably linked to air, soil and water pollution through the continuous discharge of metals and other toxic components. At the same time, municipal solid waste landfills do their most harm to the environment, where the permeability of heavy metals such as lead, chromium and cadmium is much higher than, for example, during incineration. In addition, accelerated rates of solid waste generation lead to an increase in greenhouse gas emissions, especially methane and carbon dioxide. Municipal solid waste landfills occupy third place and account for about 14% of global methane emissions (United States environmental protection agency, 2016); they emit about 800 tons of carbon dioxide annually.

All this leads to an increase in the health negative impact. Residents of houses located in the immediate vicinity of landfills, suffer from diseases such as malaria, dermatitis, gastrointestinal disorders, bronchitis and asthma, and even cancer.

It should be noted that all problems are recognized by the Government of the Russian Federation and are reflected in strategic and program documents in the field of ecology. So, even in the Fundamentals of state policy in the environmental development of the Russian Federation for the period up to 2030 (approved by the President of the Russian Federation on April 30, 2012), the need to ensure environmentally sound waste management was noted, in particular, by reducing the level of waste, its involvement in re-economic turnover through processing, regeneration, recovery and recycling, the infrastructure creation for the environmental disposal of waste; as well as introducing a ban on the waste disposal that has not been sorted, mechanically and chemically treated, as well as waste that can be used as secondary raw materials, and the environmental restoration of waste disposal territories.

Then, similar formulations were included in the Comprehensive Strategy for the Treatment of Municipal Solid Waste, approved by the Ministry of Natural Resources of Russia in 2013. However, the situation in the field of municipal solid waste has not changed much since then.

The purpose of this study is to analyze waste management practices in Russia and the world, to identify the main problems that impede efficient waste management, taking into account the practice of other countries.

Recycling Model in Russia

The most common way to dispose of waste is still the special landfills or illegal dumps. According to the Federal Service for Supervision of Natural Resources Management in Russia, there are a total of 1399 landfills, 7158 authorized landfills and 17498 unauthorized ones (Waste Country, n.d.) (for comparison, in the leading European countries the share of waste involved in reuse is 80 - 87%). At the same time, no protection or control regarding what is brought and dumped on such territories is carried out, as stated Putin V.V. the President of the Russian Federation,in the Message to the Federal Assembly of the Russian Federation in 2019. As a result, there is a real threat of landfills and unauthorized landfills that are not declared and not considered in official statistics of hazardous waste. The scale and volume of illegal I - II hazard classes waste disposal, under the existing system of state control, accounting and regulation, cannot be fully estimated (Decree of the Government of the Russian Federation No. 84-p).

At the same time, in developed countries, an improved type of disposal is called‘sanitary waste disposal’. A sanitary landfill is a modern waste disposal technology that ensures the optimal use of municipal solid waste with minimal risk of pollution. It consists of four layers isolated from the surrounding area with a special primer to prevent odors and pathogens from leaking out of the landfill.

However, in order to ensure sustainable development in the field of ecology, the priority should be the transition from traditional landfills of waste hazardous to the environment to appropriate waste management systems that conserve useful resources in the economy. So, despite the presence of valuable waste fractions in municipal solid waste, at least 9 million tons of waste paper, 2 million tons of polymeric materials and 0.5 million tons of glass are irretrievably lost annually during their burial (Decree of the Government of the Russian Federation No. 84-p). This requires the

development and implementation at the state level of fundamentally new strategies, such as the development of a circular economy (or closed-loop economy), which is aimed at a complete 'restructuring of capital' aimed at expanding the flow of goods and services by revising business models in accordance with three main principles:

1) preservation and strengthening of natural capital by controlling end stocks and balancing the flows of renewable resources;

2) optimization of resource yield by ensuring the circulation of components and materials of the product at the highest possible level of utility;

3) increasing the efficiency of the system by reducing externalities.

In so many words, a circular economy is a continuous positive development cycle that preserves and strengthens natural capital, optimizes resource returns, and minimizes systemic risks by managing end stocks and renewable flows.

With regard to municipal solid waste management, the implementation of the circular economy model means that waste is a source of cost-effective, high-quality secondary materials, the introduction of which into economic activity reduces the cost of primary materials production, on the one hand, and waste disposal, on the other. This, in turn, entails the creation of new enterprises, and hence new jobs. However, this requires the business to develop new cost-effective waste management strategies with priority for reduction, recycling and efficient recovery of materials. Moreover, the state should encourage new investments in the sector to create the necessary infrastructure.

In general, the creation of this infrastructure is an extremely costly project and is not always economically feasible in terms of profitability, especially at the initial stage, when in fact it is not just about conquering the market, but about the need to break long-established business models based on the principle of minimizing costs, often due to the use of illegal dumps.

Analyzing the current state of recycling shows that there are no industrial complex facilities for processing and waste disposal in many constituent entities of the Russian Federation. No attention paid to this problem neitherwhile forming the regional environmental policy nor in the territorial schemes of municipal solid waste treatment. At the federal level, there is practically no interregional and intersectoral cooperation in the field of placement and construction of industrial facilities for the treatment, utilization and disposal of waste. The increase in the share of disposed waste is also constrained by an insufficiently functioning system of state and industrial control in the field of waste management, which is a key condition for the efficient organization of subsequent processes for recycling as well as insufficient market development and low demand for products manufactured using raw materials obtained from waste (Decree of the Government of the Russian Federation No. 84-p).

In this regard, it is obvious that the key role in introducing the model of circular economy should be played by the authorities, and not at the local, but at least, at the regional level. The authorities act as a driving force in the policy implementation of introducing a circular economy. They must formulate strategies, implement measures of economic incentives and / or administrative coercion, and mediate in the creation of new markets through the commercialization of reclaimed waste. The practice of stimulating the reuse of resources derived from waste through the public procurement system is already quite widespread. For example, in France, the Law on Energy Transition 2015 established that the minimum percentage of recycled paper in office supplies purchased by government departments should be 25% by 2017, and 40% by 2020 (Fratini, C., Susse, G., Jørgensen, M., 2019, p. 983).

At the same time, it is important that when developing and implementing a policy in the field of municipal solid waste management, the ultimate beneficiary must be a resident who should receive benefits from both the environmental situation being improved and the creation of new job places as well as the emergence of new services (for example, as part of joint consumption projects).

In this regard, it should be noted that neither the strategic documents mentioned above nor the Russian legislation do not pay attention to the role of the country's inhabitants themselves in introducing new approaches to waste management. Thus, the Integrated Strategy contains only a few references ‘of the population’ in the context of minimizing the harm caused to theenvironment. As one of the strategic principlesthe ‘participation of each citizen and the entire population in organizing activities to minimize the amount of municipal solid waste’ is provided for the main lines of action to solve problems in the field of municipal solid waste management including‘encouraging the population active participation in utilization of municipal solid waste’, as well as‘a resource-saving relationship development among young people when consuming goods, including material resources saving’ (Order of the Ministry of Natural Resources and Ecology of the Russian Federation No. 298).

At the same time, it is obvious that today there are no specific mechanisms for involving the population in solving this extremely urgent problem. As many researchers note, in order for municipal solid waste processing to become economically viable, it is extremely important to ensure the creation of a system for separating waste components into different fractions. To implement this, there are two approaches. The first is the construction of modern multifunctional processing complexes that provide sorting of incoming waste. Such sorting can be done either manually or using robotics and artificial intelligence. The first option is associated with huge labor costs;moreover, such work is dangerous. The second option is based on intelligent recycling technologies such as robotic machines that use artificial intelligence to recognize garbage components and can accurately identify specific waste components in a mixed heap to sort them with their arachnid hands. For example, a plastic packaging material and a water bottle may look the same when examined with an infrared camera, because they consist of the same material. Therefore, manual sorting in this case will be ineffective. In contrast, computer vision systems installed in a robotic sorter are effective for detecting exact differences between materials (O'Connor, 2017). However, this option requires significant investment, which today is far from being economically feasible (due to the lack of sufficient amount of waste to ensure 100% capacity utilization, since it is more profitable for operators of municipal solid waste to work according to established business models, i.e., taking waste to landfills; and also, due to the lack of a developed market for recyclables). Accordingly, without state support, the implementation of the first approach is extremely difficult.

The second approach is a method of dividing municipal solid waste into separate components. This approach is widely used in developed countries. Ideally, the public or employees of the waste generating facilities should share the waste. However, for this, the necessary conditions must be created in the form of special containers or recycling points. However, even more important, is the socially responsible attitude of the residents, consciously taking responsibility for the environmental safety of their hometown. For example, in Paris, local authorities carried out a targeted policy to form environmentally responsible behaviors, which was based on the idea of territorial awareness of belonging to one community and responsibility for its sustainable development.

Without changing the mentality of the population, it is also impossible to implement such elements of a circular economy as the economy of joint consumption or a deliberate reduction in consumption by extending the life cycle of goods.

The success of any waste management strategy is impossible without an effective system for monitoring their generation and movement, as well as accuracy in predicting their quantity. Significant problems in organizing industrial processing and waste disposal are associated with a lack of information, including waste’s composition, resource value, possibilities for producing goods and other information from it. At the same time, for the economic justification of any municipal solid waste processing projects, it is extremely important to determine the composition of waste so that each fraction can be expressed as a percentage if the gross weights of all fractions are known. Seeing this,it is necessary to separate all the waste into biodegradable and non-biodegradable fractions. The non-biodegradable fraction is usually divided into various subcategories, such as plastics, glass and construction waste. At the same time, two main issues are the toxic effects and reactivity of a particular waste fraction. Only having the specified information, as well as data on the volume of the market for recyclable materials, you can calculate the economic model of a business fora particular fractionprocessing, or for the integrated wasteprocessingforfurther reuse.

The territorial schemes developed in the constituent entities of the Russian Federation in the field of waste management made it possible in most cases to carry out a quantitative assessment of the existing volumes of waste, as well as to conduct an inventory of authorized and illegal disposal sites. However, the creation and future development of waste treatment, utilization and disposal complexes, minimizing incoming waste for disposal, the formation and economic feasibility of regional integrated waste management systems, financial and managerial models for the effective functioning of such systems are not reflected in these documents.

At the present time, Russia does not systematize data on the wastemovement in economic sectors by constituent entities of the Russian Federation, economic regions, and industrial clusters (Decree of the Government of the Russian Federation No. 84-p). At the same time, in the modern world, waste monitoring plays a vital role in the development of the urban economy. To improve monitoring and control efficiency, modern traceability technologies, such as radio frequency identification, ultrasonic sensors, geographic information systems and GSM / GPRS systems, have been developed and implemented. So, radio frequency identification is used in European countries for garbage collection, municipal solid waste and their disposal. In Germany, 20% of the collection is managed using radio frequency identification, which allows web-based monitoring of waste collection systems by administrators and citizens in real time, which improves the quality of management decisions and transparency for society (Subhasish, et al., 2019, p. 668). It seems that the introduction of such systems in Russia could have a positive impact on the sphere of municipal solid waste management. For example, the statutory requirement for the mandatory equipping of vehicles transporting waste with GPRS or GLONASS systems, as well as the mandatory requirement for labeling waste of hazard classes I - II, would exclude cases where municipal solid waste is simply dumped at the sidelines and hazardous waste falls into general landfills.

There is also no data on waste treatment, nordisposal enterprises, noron their territorial location. The Federal Law adopted in July 2019, which introduced amendments to the Federal Law 'Production and Consumption Wastes', aimed at improving the waste management system, is dedicated to solving these problems. In addition, a number of short stories are aimed at improving the mechanism of waste management of I - II hazard classes.

It should be noted that the implementation of urgent measures to organize a safe handling system in accordance with environmental, sanitary-hygienic and other requirements, norms, rules, standards is extremely relevant for waste of hazard classes I - II. Despite the existence of a wide range of effective methods and the best available technologies for wastedisposal of hazard classes I - II that are successfully used in world practice, their level of use at Russian industrial enterprises is extremely low due to high capital investments and operating costs, and also due to the lack of a market for the consumption of end products of waste management. Thus, mercury processing enterprises operate only in a number of regions of the country: in the Northwestern Federal District - 4 enterprises, in the Southern Federal District - 3 enterprises, in the Central and Volga Federal Districts - 2 enterprises each. The business in the collection and disposal of lead-containing waste of hazard class II has recently intensified with respect to the collection and disposal of car batteries due to the high content of lead scrap in them. Utilization of other wastes containing highly hazardous lead and its compounds does not develop due to economic inexpediency (Decree of the Government of the Russian Federation No. 84-p). Obviously, without a sound government policy stimulating the creation of appropriate processing enterprises, this problem cannot be solved. It should be noted that the implementation of urgent measures to organize a safe handling system in accordance with environmental, sanitary and hygienic and other requirements, norms, rules, standards and norms extremely relevant for waste of I - II hazard classes. Despite the existence of a wide enough range of effective methods and the best available technologies for the disposal and disposal of the main waste groups of hazard classes I - II that are successfully used in world practice, their level of use at Russian industrial enterprises is extremely low due to high capital investments and operating costs, and also due to the lack of a market for the consumption of end products of waste management. Thus, mercury-processing enterprises operate only in a number of regions of the country. They are the Northwestern Federal District where there are four enterprises, the Southern Federal District runs three enterprises, and the Central and Volga Federal Districts have enterprises each. The collection and disposal of lead-containing waste of hazard class II has recently intensified with respect to car

batteries due to the high content of lead in them. Utilization of other wastes containing highly hazardous lead and its compounds does not develop due to economic inexpediency (Decree of the Government of the Russian Federation No. 84-p). Obviously, without a well-thought-out state policy stimulating the creation of appropriate processing enterprises, a solution to this problem is impossible.

The 'circular economy' model as the basis for solving the waste management problem

Thus, it is important to understand that the introduction of circular economy approaches in regard to municipal solid waste is not only technological (i.e. associated with the development of effective technologies for processing waste into products suitable for further use, for example, in the energy sector, agriculture, etc.) or economic (i.e. related to the creation of effective business models) task. In many ways, this political and social task requires the active participation of authorities and the formation of fundamentally new behavioral patterns among residents. The circular model of municipal solid waste management economics is based on several key points.

Firstly, municipal solid waste is a valuable resource which, when properly processed, gains new economic value.

So, recycling, as well as regeneration (or return to the production cycle after appropriate preparation) and technologies aimed at the reuse of biodegradable materials that prevail in municipal solid waste cities (such as food, paper, textiles, etc.) are becoming more widespread, accounting for 2/3 of all waste. This might be composting or recovery.

Cheaper composting technologies have greater potential for use. Therefore, the experience of the Indian village of Mavlinnong, located in Meghalai, is of great interest. Residents of the village collect garbage in bamboo bins and compost it in a pit on a daily basis. The prepared compost is then used to grow flowers and vegetables in home gardens.

Composting can be defined as the microbiological decomposition of organic waste to produce humus-rich manure. Composting technologies can be classified as traditional pitting composting (i.e. aerobic / anaerobic), traditional heap composting (i.e. aerated), and composting using modern technologies (i.e. composting in vessels, composting in rolls, effective rapid composting based on microorganisms). Only biodegradable waste should be recycled this way.

However, the potential of municipal solid waste composting technology varies greatly depending on the different types of composting. The use of so-called aerated (or rotated) composting reduces greenhouse gas emissions by 47%; small-scale composting technologies, such as 'in-tank composting', reduce greenhouse gas emissions by about 4.5%, and vermicomposting in Germany reduced sulfur dioxide emissions by 60.8%. The main advantages of this system are economy, minimal maintenance, detoxification over time, highly nutritious end product and environmentally friendly agricultural use.

Thus, composting technologies are quite cost-effective. They significantly reduce greenhouse gas emissions, and provide organic manure for soil fertility and productivity.

Recuperation is the use of biodegradable waste in energy production. Global population growth and energy shortages are two closely related phenomena. According to the report of the International Energy Agency in 2016, global energy demand is growing rapidly, with a gradual decrease in oil and gas demand with an increase in the use of renewable energy sources, the most common and effective of which is bioenergy.

There are two types of waste into energy conversion, i.e. the thermochemical conversion and the biochemical conversion.

The first one is technologies such as combustion, gasification and pyrolysis.

The burning occurs with sufficient oxygen supply, which leads to thermal energy and ash residues. As a rule, 65-80% of thermal energy can be obtained from the burning of solid waste (Abramov, et al., 2018, p. 738). This method shows high-energy efficiency, however, it releases toxic substances and dioxides into the atmosphere, and valuable municipal solid waste components that could be reused, are destroyed.

Unlike combustion, pyrolysis is the thermal decomposition of organic materials at relatively high temperatures in a low oxygen environment. The process results in a mixture of highly flammable gases, pyrolysis oil and coal. As a result, air pollution is much lower than burning. Pyrolysis plants are widely used in developed countries. For example, an ordinary UK pyrolysis plant can convert 50-250 tons of municipal solid waste per day, producing about 64% of pyrolysis oil and 2% of coal. However, the operational cost of such a plant is 4680-14040 US dollars per day, which makes this technology too expensive (Subhasish, et al., 2019, p. 663).

Gasification is the process of thermal decomposition of waste in an environment with a limited amount of oxygen, resulting in a mixture of both combustible and non-combustible gases. Gasification gives gas as the main product and glassy slag (used in road construction) as a by-product. Currently, there are 686 gasification plants in the world with a total energy output of 83 MWh. (Subhasish, et al., 2019, p. 671). In addition, gasification is an effective way to utilize agricultural waste, and by-products of their processing can be used as safe organic fertilizer, helping to increase crop yields (Trubilin, et al., 2019). However, gasification requires a significant amount of coal; in addition, it results in toxic polyhalogenated organic compounds.

Biochemical conversion is a process based on enzymatic / microbiological denaturation of waste. Two main technologies of this kind are anaerobic digestion and fermentation. These conversion processes are mainly used for those solid wastes that contain a high putrefactive fraction and moisture content that contribute to microbiological activity. However, these methods are not as widespread at present as thermochemical methods.

Secondly, it is important to extend the life of goods, both by designing them with a view to longer terms of use, and by repair. Both options, however, require active state regulation, expressed, for example, in stimulating the opening of a wide network of repair centers for household appliances, as well as in creating financial instruments to stimulate the introduction of products with longer service life on the market.

Another way to extend the life cycle of household goods is, for example, to sell lower-priced used goods or products with expiring dates that would otherwise not be available to the poor.

For example, in France, a legislation was enacted in 2015 requiring large supermarkets not to throw away expired products, but donate them to charity or turn them into dog food or compost. For failure to fulfill this obligation, a fine could reach as high as 75 thousand euros (Fratini, Susse, Jørgensen, 2019, p. 983).

The third basic element of the circular economy is the economy of shared consumption. The scientific literature notes that sharing initiatives can have a positive impact on the environment, as they significantly reduce consumption (for example, Borawski, et al., 2019; Cherry and Pidgeon, 2018; Fratini, Susse, Jørgensen, 2019), which in itself is the fourth pillar of the circular economy. However, here again we need to emphasize how little attention is paid to the issues of the formation of socially and environmentally responsible behavior of the residents themselves in matters of municipal solid waste, while it is impossible to achieve the formation of these basic elements of a circular economy without revising the existing patterns of consumption. This requires a wide educational program. In addition, attention should be paid to the advertising industry, aimed at the formation of mass consumption models and encouraging buying more, even if the advertised goods are not necessary for everyday life.

Conclusion

Thus, the recycling problem is quite complex and requires the introduction of fundamentally new economic models based on the principles of 'circular economy'. This means the need to create an industry for the collection, sorting and processing of waste, which would make it possible to maximize their involvement in the economic turnover either as a secondary raw material or as a renewable energy source. However, the solution to this problem is possible only if the state implements active measures aimed at stimulating and supporting businesses, implementing public-private partnership projects, and changing existing waste collection and disposal schemes. However, the transition to the model of a 'circular economy' is impossible without involving the population and the formation of socially responsible behaviors aimed, firstly, at building separate waste collection schemes, and secondly, at reducing consumption by extending the life of goods and moving to the sharing consumption models.

Determinants of The Z Generation Entering the Labour Market from The Perspective of Vocational Education Graduates

Tomasz KAWKA, Assoc. Prof.

Department of Human Resources Management, Faculty of Management, University of Gdansk, Sopot, Poland
E-mail address: tomasz.kawka@ug.edu.pl

Abstract

The article presents an analysis of the conditions of professional initiation characteristic of the youngest generation against the background of the results of empirical research of professional expectations of a representative group of students from the last grades of technical and business schools in one of the poviats of the Pomeranian voivodeship. It is a population that is characterized by high declarative mobility, a low degree of further improvement, but strives to emphasize the hallmarks of entrepreneurship in their professional attitudes, and above all they want to take a job that is supposed to meet – often unrealistic expectations associated with moving their interests to the work environment, their projection of attitudes raised from hobbies. The results analysed in the text show the basic conditions that employers will have to prepare for in the coming years, wanting to develop this youth cluster entering the labour market, performing simple but specialized work, and sometimes, as research by the Labour Market Barometer shows – quite niche. On this basis, the implications for current challenges of human capital management are presented. The article is based on the analysis of expectations related to entering the labour market of this group of young people. This provides the basis for formulating the main challenges in the next few years that the changes in the personnel function are to face in relation to this not fully appreciated professional group, which is nonetheless necessary for the smooth functioning of many organizations – performing simple work, but operationally necessary.

Keywords: Human Resources Management, Labour Market, Generation Z, Vocational Education,

Introduction

Young people finishing their education in technical and business schools in 2020 are a specific socio-professional group that will enter the labour market in the coming years in the field of executive, implementation, professional, work and auxiliary work. It is a group that constitutes the fundamental foundation of the current base for the development of the Polish labour market and economy. Young people educated in technical and professional professions today constitute a very scarce range of professions, which supply shortages have been supplemented by immigration for many years, e.g. from Ukraine (UDSC, 2020). Many of the professions that are indicated in the current Labour Market Barometer research, which entrepreneurs have been searching for many years – are professions shaped on the basis of vocational school curriculum. Therefore, a very important confession of modern HRM practice is recognizing the conditions for the professional initiation of this specific professional group. The generation of the youngest employees, which will determine the development of our native economy, has a key responsibility for the direction of entrepreneurship development, organization growth and social well-being of the country (Parment, 2011). In order for employers to prepare for this challenge, they should be prepared for employment and management of this specific human capital. It should be emphasized that many authors point out that this is not the generation that can be entirely and clearly defined (e.g. Kmiotek 2012; Aniszewska 2015; Żarczyńska-Dobiesz, Chomątowska, 2014 ; Smolbik-Jęczmień, 2017; Lipka, Waszczak, 2017). They can be jointly defined as the *generation of a new economy* shaped by turbulent and dynamic changes of the environment, which were not present in our civilization before (Kawka, 2014, Rogozińska-Pawełczyk 2014; Wiktorowicz et al., 2016). The literature on the basis of research considers the weakness of this generation, among others, the so-called soft competences (e.g. verbal communication, empathy, intergenerational cooperation), or strong

resistance to adapt to the organizational culture and acceptance of the hierarchy in the organization (Gursoy, Maier, Chi 2008). It is definitely a generation that exhibits hallmarks of attitudes and behaviours in the work process that require redefining human resource management processes. The current methods of team management, shaping involvement or managing internal communication – they face a significant problem of the need to change them. Therefore, since the key recipient of the personnel function, the client of these interactions – is noticeably changing, one should ask the question whether current solutions in the area of *HRM* are still effective, tailored and adequate to the requirements, possibilities and expectations of this generation, e.g. by implementing the *Job Crafting* approach (Wojtczuk-Turek, 2017). Such a course of reflection gives a new perspective to strategic planning for the development of human capital. The first step to finding answers to such questions is to try to recognize the expectations and perspectives of the self-generation of the new economy in the field of vocational training.

Therefore, this article presents the results of empirical research on the expectations and professional preferences of the Z generation among graduates of technical and business schools, which in the coming years will enter especially the local labour market, most often in the family, small and medium-sized enterprises (Wiśniewski, 2013). Such knowledge about meeting new generations is key to building tailored HRM methods, and there are many myths and prejudices that are unconfirmed by empirical research and create stereotypes that are unnecessarily demotivating and limit employment opportunities for this generation (White, 2011).

Vocational and education training (VET) of the Z generation

Vocational Education and Training (VET) has been the focus of change for some last years in most of developed countries. Many nations have developed VET systems with long-term strategies that benefit their economies, including co-ordinating economic, industrial and VET policies and achieving consensus among major stakeholders in the system (Finlay, Niven, Young , 2005; Oliveira, Rumble 2013). As many international research show, VET should be about enlarging peoples' opportunities to live a flourishing life, rather than simply being about narrow employability and productivity. It argues that human development approaches, while acknowledging the importance of work in its broadest sense, offer a better way of bringing together VET and development than the current human capital-inspired orthodoxy (Cruel, Shneider, Leile 2012; Powell, McGrath, 2019). A lot of studies in this area shown in plenty countries clearly indicate that behaviours and attitudes of this "Z" generation in terms of VET and the impact on labour market are very similar regardless the origin country of such young generation. (e.g. Pilz, Berger, Canning, 2012; Flude, Sieminski, 2013; Finlay, Niven S.Young S, 2005)

This is the first generation that seems to be quite homogenous in their attitudes regardless of the level of education and environmental origin (Kawka, 2019, Walsh, 2016;). Therefore, effective professional education of this generation can play an important role in creating better job market prospects for young people. The key success factors are effective practical classes at the workplace and the role of social partners in defining and organizing curricula. Since vocational training can also provide opportunities for people with low qualifications, students should be provided with basic and comprehensive skills enabling continuous learning and adaptation to changing technological needs and the labour market. It is necessary to ensure an appropriate level of education combined with internships in the workplace.

It is worth emphasizing that the moment when young people leave school and enter the labour market in today's turbulent and virtual-network conditions is not simple and clear to define. It is getting harder and harder to determine when exactly a modern teenager finishes his education and takes up his first stable job, and thus begins to experience adulthood in regular employment. The sequential order of experiences related to education and work – i.e. graduating from school and then starting work – is no longer ordered only according to this logic (Tomaszowska-Lipiec, 2018). The more so that the *Z generation* through virtualization and networking of their behaviour can enter into professional relations in a manner parallel to the period of education. The transfer of the youngest generation of employees begins to rely on a series of different, intersecting activities in the domains of "education" and "the world of work", which overlap with the youth years and early adulthood. As researchers proof, such trend related to VET seems to be very likely in today's, all over the world (Pliz, 2012; Cantor

2017). It seems that due to the specificity of vocational education, which requires strong integration with practice from the beginning of the education process (, in order to optimally ensure the right conditions for the transition from education to professional life, the following steps should be ensured (Bańka 2007, Lettmayr, Nehls 2012):

- good organization of school education and vocational training paths,
- combining school and work;
- creating secure relationships between the school and labour market entities.

Thus, it can be argued that graduates of vocational schools with a specificity of their generation, which is focused on experiencing their sensations in a world outside the real world – are more predisposed and prepared to enter the real labour market than high school graduates.

However, to ensure the potentially high efficiency of technical school graduates entering the labour market, it is worth taking measures in the field of vocational education oriented towards (Gerlach 2018, Bunning 2006):

• preparation for life and work in the conditions of competitions on the domestic market and international competition;
• developing basic skills useful both in professional work in various positions and in non-professional life;
• preparation for flexible forms of employment and work;
• diversifying educational offers and thus creating choices and enabling the use of various sources of knowledge;
• giving a "second chance" to all those who did not obtain education in their youth and thus aiming at limiting the phenomenon of exclusion;
• retraining people who are unemployed and threatened with unemployment;
Summing up this part of the discussion, it is worth saying that as part of the vocational education model at the level of simple and executive competences, we cannot ignore the assumptions of the human capital model (Listwan, 2010). According to R. Gerlach, especially these candidates for employees should be prepared to being a subjective, open to people and relations partner, and not a "thoughtless workforce". In addition to knowledge and skills, traits such as responsibility, loyalty or identification with work and company are important. They will be forced to assimilate their personal development ability, learn to preserve energy and mental performance throughout their employment (Gerlach, op. cit.).

Empirical Study in a context polish determinants - results of research on the professional expectations of the Z generation in the vocational education profile in Poland

There are a lot surveys related to professional expectations of the young people in the vocational education profile and impact for labour market across Europe (e.g. Cruel, Shneider, Leile 2012, Lettmayr, Nehls 2012, Bunning 2006). The main conclusions we can draw from them is that a some kind of gap various expectations (employee and candidates) have been occurring since last decade. Based on the sources, cited in this part of text, it can be taken into account the assumption, about the global trend and then homogenize these changes. The origin of the country does not differentiate this phenomenon much, especially in the EU. Generation Z has no desire and does not fully understand the work ethos and the need to increase their effort to quickly and professionally enter the labour market in the field of vocational and technical education. This can be manifested, e.g. by the high percentage of these young people among the NEET group (OECD, 2016).

In this context, I would like to propose a sample of the research that I carried out regarding the expectations of Polish youth of the Z generation entering the labour market in terms of vocational and technical education.

The research was conducted in 2019 on the entire population of students of the last grades of technical secondary schools and business schools of the first degree in all schools in one of the poviats of the Pomeranian voivodeship. The examined sample amounted to 310 students, of which 63% were students of the last grade of technical secondary schools, and 37% were students finishing their education at the level of first-degree business school (BSI). The main purpose of the research was to diagnose the awareness and possibilities of own professional and educational plans of the generation of technical education graduates. Therefore, the preferences of directions and perception of employment opportunities were assessed, especially in the realities of the local labour market by the abovementioned youth group, which belongs to the so-called Generation Z. The research ends with an analysis of awareness and perception by this group of young people regarding the professional success in the modern labour market.

Educational preferences after graduation

Slightly more than half of all surveyed students (52%) want to continue their education after leaving school and they are the vast majority of students in technical schools. Only (23%) of surveyed trade class students consider continuing their education. The diagnosis indicates that (22%) of all surveyed students do not intend to develop further in the direction of education growth. However, less than (30%) of the surveyed students were undecided at the time of the survey, and these were mainly technical school graduates. This indicates a fairly low level of motivation for further development through the formal education path, as well as a relatively significant percentage of students who have no further idea of their role in the labour market.

All data are based on sources from the own descripted here study.

The most important point of the analysis in this regard is the fact that in their plans after school only (15%) of the surveyed students strongly expressed their willingness to take up work immediately after completing education in the poviat. They are mostly students from business schools. In addition, a larger group – (20%) of the surveyed graduates declared motivation to take up work, but already in the Tri-City. In turn, nearly (25%) of the respondents plan economic or educational migration abroad. In addition, studies have shown that every tenth student in the last grade of technical school or BSI simply plans to do nothing, rest, and (6%) have no knowledge or plans for their future at all.

Fig. 1: What are your educational and professional plans next year after finishing your current school? (classes of technical and business schools)

Answers:

1. Continue the education
2. Take up work in the area
3. Take up work in the Tri-City
4. Change your place of residence
5. Travel
6. Go abroad to work there
7. Go abroad to study there

8. I do not have specific plans as for today
9. Rest and do nothing

Summing up this part of research, it should be pointed out that this is a group quite polarizes as to their educational preferences. In the half of the young population of vocational school graduates, the desire to continue their education prevails (and these are definitely mainly technical schools). On the other hand, the other half of the surveyed students are divided into those who plan to either take up a job, but unfortunately a very small share relates to declarations of taking up a job in the poviat, or it is a group of young people who want to travel or do nothing at all. The group of surveyed technical school students who expressed their desire to continue their education at the university level, in a very small percentage as at the end of the school year – (24%) knew which university they want to go to.

Fig. 2: Do you plan to work in the poviat in the future
Answers: 1. definitely yes **2. rather yes** 3. rather no 4. definitely no **5. hard to say**

In turn, in the case of the most important criteria for choosing further education, about which this group was asked, the following should be included in the first place: further deepening of their specialization, i.e. selection in line with the professional preference offered by the given school – almost half of the respondents pointed to this factor. In addition, it was also noted that it is the percentage of approx. (20%) of the surveyed students that paying attention to the prestige and opinions of the school, as well as the proximity to the place of residence, are important in choosing a university.

One of the potential, but quite likely consequences of this approach to further development, which is illustrated by the low percentage of BSI students who want to continue their education (every fifth student declares their willingness to continue learning) – is the problem with the motivation for further institutional development of this professional group. The above analysis may lead to a certain problem, e.g. the potential difficulties of recruitment to the second-degree Business schools (BSII) from September 1, 2020, from the BSI school graduates group. A small but noticeable part of the surveyed (over 20%) students may be in line with the very natural tendency for the studied generation Z, i.e. entering the so-called disturbing sub-generation called NEET (*Not in Employment, Education, and Training*), i.e. a group that does not want to do anything in life, has no social and professional goals and ambitions. It is a group whose attitudes are quite dangerous for the development of entrepreneurship and activity on the local labour market.

Labour market preferences after graduation

In the surveyed group of graduates, approx. (33%) of students declared in the future that they wanted to work on the local labour market, of which only (5%) was definitely convinced of this opinion. On this basis it should be noted that over (40%) accepts employment outside the poviat region in their professional development plan. They are mainly technical graduates who plan to continue their schooling in higher education. Based on these answers, it should be pointed out that about half of the surveyed students (49%) – say, however, that there are attractive and interesting employers in the region and its surroundings, and over (33%) have no opinion on this subject.

Fig. 3: In your opinion, are there any attractive employers in your area who offer the chance of taking up an interesting job? (T and B)

Answers: 1. definitely yes **2 rather yes** 3 rather no 4 definitely no 5 hard to say

Therefore, it can be concluded that the motive binding this generation's declarations to work on the local labour market is not the real offer resulting from the benefits offered by local employers.

This is the generation that is looking for employment among such employers who realize their motivational preferences through friendly content of work, by matching their interests and hobbies. As other studies of the Z generation on the labour market show, this is a quite unrealistic postulate for today.

In addition, the high level of declared mobility and willingness to leave the home region may also affect the distribution of results that only every third technical school graduate will want to stay on the local labour market.

Fig. 4: Would leaving the place of residence permanently to take up work be a problem for you? (T and B)

Answers: 1. definitely yes 2 rather yes 3 **rather no** 4 definitely no 5 hard to say

Fig. 5: In your opinion, how does education at school prepare you to take up work? (T and B)

Answers: 1. very good 2. good 3. **average** 4. bad 5.very bad 6. I have no opinion

Fig. 6: When making a decision about your professional future, will you be guided by (T and B)
Answers:

1. **work in the profession learned at school**
2. advice from colleagues
3. advice from parents
4. ease of education in this profession
5. fashion for a given profession
6. examples from the family home
7. **your interests**
8. Information gained on the Internet (e.g. YouTube, Facebook, etc.)
9. wages
10. I don't know what I should be guided by

The conclusion from this part of the research may suggest that despite the indirect positive assessment of the possibility of undertaking interesting work in the region created by employers, a significant part of the surveyed students is not interested at this stage of development in work on the local labour market. In addition, the above assumptions are justified by the analysis of the results, which show that about (63%) of the surveyed students declare that they could easily decide to quickly change their place of residence from their current one, right after finishing their education in the poviat. This may additionally affect as a threat factor in the gradual outflow from the local labour market educated in technical and vocational matters in the youth region. On the other hand, it should also be stated that over (25%) of the graduates surveyed finishing their education at the level of secondary school, do not yet have any opinion on their future and role in the labour market. It is also a factor that could potentially have a negative impact in the future on the conscious taking up of jobs by the examined group of students, e.g. adopting the attitude of the already mentioned NEET generation. Over (30%) of the surveyed students claim that the previous education in the specialties selected by them is adequate for taking up a job. In contrast, 1/3 of respondents claim that this preparation is at an average level. What is worrying is the fact that almost ¼ of graduates declare that their school prepares them badly or very badly for entering the labour market. The surveyed students are divided into fairly three equal groups: those who are convinced that the educational offer in poviat schools is helpful in looking for a job, those who have an average evaluation in this area, and those who assess the school's orientation to start their professional career very negatively.

Awareness of labour market mechanisms

As for the type of preferences and interests of the surveyed students in the context of their future work, it should be noted that there are no significantly different fields in which the graduates would like to work. The obtained results of professional preferences basically coincide in most of the surveyed students with belonging to the class profile with specializations that the given classes offer to their students. Students could choose up to 4 indications, so groups of more numerous preferences naturally appeared, but as indicated, they are not strongly dominant.

It can be said that there are no major deviations in this respect when it comes to the "mismatch" of the class profile (whether it is technical school or business school) in terms of assessing the preferences of the course. The learned specialization to a large extent gives professional preference, which is due to the fact that the largest group of surveyed students indicates that they want to work in the learned profession, and this is 1/3 of the studied youth population.

However, it is possible to indicate the most popular directions obtained in this part of the study and the most frequently mentioned preferences for taking a job in a given direction include:

For technical schools:

- ***performing work as a technician in a learned profession (30%)***
- ***starting own business (24%)***
- ***working in commerce (24%)***

However, a similar analysis for the results of students from business schools showed the following distribution of the most common job preferences:

work in industry or business in a learned profession (39%)
work in gastronomy (25%)
work in transport and logistics (21%)
starting your own business (19%)

In the case of answers that received the lowest indication of preferences of interest to take up work after finishing school, in the case of technical schools the following were rated the lowest: work in consultancy and agriculture, while in the case of BSI students – work in budget administration and state institutions.

Table 1: What kind of preferences and interests do you have in the context of future work - Technical schools

1. **work in industry as a technician in a learned profession – 30%**
2. **own business - 24%**
3. **work in commerce – 24%**
4. work in education -23%
5. work in media – 20%
6. work in gastronomy – 19%
7. work in the IT sector -18%
8. work in direct services for the population – 14%
9. work in uniformed services -16%
10. social work -15%
11. work in the tourism sector – 14%
12. work in transport and logistics -15%
13. work in budget administration and state institutions -14%
14. work in the maritime sector – 13%
15. work in agriculture -11%

Table 2: What kind of preferences and interests do you have in the context of your future job - Business schools

1. **work in industry/business in a learned profession – 39%**
2. **work in gastronomy – 25%**
3. **work in transport and logistics – 21%**
4. work in direct services for the population – 19%
5. own business – 19%
6. work in the IT sector – 17%
7. work in commerce – 15%
8. work in the tourist sector – 12%
9. work in the maritime sector – 10%
10. work in agriculture – 10%
11. work in the uniformed services – 9%
12. social work – 8%
13. work in budget administration and state institutions – 7%

Summing up this part of the research, it can be stated that the basic direction of students' preferences is usually to work in a learned direction, most often in trade, gastronomy or logistics, or alternatively – setting up their own business (very family and socially well-established in the region).

An important part of research assessing the preparation for the challenges of the labour market of young students at the technical and industry education level was to diagnose their awareness and subjective perspective of their perception of the local labour market.

By asking the question to the above-mentioned group of students about the jobs most needed in their region that should generate jobs, the following answers were obtained.

In the case of the perception of the labour market by technical school students, the following professions have been identified as key to the labour market:

- **electrician / energy technician (24%)**
- **port and terminal operation technician (23%)**
- **IT / ICT technician (20%)**
- **waiter technician (18%)**

These are clearly professions that are and can be developed by a very flexible and wide range of enterprises and companies in various branches of industry and business.

Occupations which, in their perception, have no future on the local labour market include:

lifting equipment technician (1%) – there may be "cannibalization" of this speciality in favour of the competence and content of work related to the port operation technician
tourist service technician (2%) – and this is quite a surprising answer due to the region's very strong potential and tourism possibilities.
- economist technician (3.5%) – this is probably an unattractive form of the title of profession, where the economist is associated more with higher education, or is usually assigned to secondary school education.

In the case of similar studies for graduates of industry schools, the following results were obtained for the most-developing occupations in the region in their perception of the labour market:

- **seller / trader (33%),**
- **electrician (29%),**
- **chef (21%),**
- **electro-mechanic (18%)**

These are indications which, apart from the dominant role of the seller, which logically results from the desire to take up work in trade, as such, which in their perception does not set too high competence thresholds, to a large extent these are results that generally coincide with the perception of labour market development by graduates of technical classes.

Occupations which, in the perception of students of the last BSI grade, do not give the opportunity to generate jobs include: **locksmith (4%), mechatronic fitter (4%), varnish worker (4%), machine and equipment fitter (7%).**

Such results may be a consequence of the fact that these are professions that closely match the organizational structures of industrial enterprises, which are not represented in large numbers in the poviat. The above results should be interpreted quite cautiously from the perspective of the potential lack of in-depth knowledge of the studied group of young people about the real needs of the labour market, but they are quite important premises indicating indirect preferences and interest of the examined group of young people in employment opportunities on the labour market.

At the end of the research, internal factors, elements of features and competences were diagnosed, which in the opinion of the young generation can give them an advantage in the labour market. On a 5-point scale (*1 – does not matter, 5 – is of key importance)*, the surveyed graduates of technical and business classes together rated the following determinants of their success on the labour market the highest:

Table 3: Assessment of the importance of professional success factors for graduates of technical and business schools

Factors of professional success	Average indications obtained
Thoroughness, diligence, reliability	**4.02**
Knowledge of foreign languages	**3.95**
Professional experience	**3.94**
Personal contacts and good friendships	**3.72**
Acquiring specialized knowledge	**3.71**
Mental resilience and feistiness	**3.62**
Education	**3.51**
Place of residence	**2.67**
Finishing a prestigious school	**2.66**
Searching for a job outside the place of residence	**2.62**
Family traditions in a given profession	**1.89**

Source: own study

At the end of the research, internal factors, elements of features and competences were diagnosed, which in the opinion of the young generation can give them an advantage in the labour market. On a 5-point scale (*1 – does not matter, 5 – is of key importance)*, the surveyed graduates of technical and business classes assessed the following determinants of their success on the labour market the highest: An interesting interpretation of the above results is the fact that, apart from knowledge of foreign languages, which is rather unlikely for BSI students, these are rather competences that describe the normative image of a young graduate of technical school to a small extent. It follows that at this stage of development, they do not yet have well-established factors enabling them to succeed at work. All the more so because they decided that, while knowledge about specialization has an average impact (3.71 p.), they themselves also declare for the most part that the school is unlikely to prepare them for the labour market. The further consistent indication of the lack of influence of family traditions in a given profession as a factor giving the opportunity to succeed at work is interesting and puzzling (1.89 p.).

Conclusions

The above research results are in line with the current characteristic of the ***Z generation***. Generations that in their emotions and attitudes are based on a very façade social communication, based on superficial patterns taken from the Internet, and largely negatively assessing the further need for institutional education, on average appreciate the usefulness of education, and they do not see the role and impact of family professional traditions on their decisions as the basic pattern of professional development. As the analysis showed, no other features of the studied population differentiated the results obtained - especially in terms of gender, origin or level of school grades. Age and belonging to the category of generation Z as the whole population is the only determinant affecting the attitudes, behaviours and expectations of this group towards the labour market. In addition, the surveyed student population declares motivation to independently run their own business in the future. However, numerous studies in the area of the Z generation characteristics indicate that this is a very dependent and reluctant generation to overcome difficulties, which may affect the low quality of running their own business. This indicates a certain lack of professional and social awareness on what running your own business may actually involve. In the general feeling of the surveyed generation, work is to be primarily pleasant, it is to result from their interests, in the work process young people want to feel satisfaction with what they do, and it does not necessarily have to work consistent with the formal education they have obtained in the course of their education. They are rather negative towards the further stages of professional development through formal education. In addition, earnings are not a fundamental value of taking up work, and they also declare that they are very mobile and can take up work away from their place of residence. It can be argued that this is a professional group that will be

difficult to motivate to increased commitment to work that will not be compatible with their profile of interest.

Based on the conclusions described in this article, potential further steps and research directions can be briefly outlined. It would be worth thinking about deepening the scope of the Polish Qualification Framework being introduced as a tool ordering the effective adjustment of the expectations of the Z generation to the current practices of the personal function (HRM) in the field of occupational positions and simple workers' classes.

Identification of The Level of Professional Satisfaction of The Hotel Industry Employees on The Example of Hotels in The Tri-City

Agata BOROWSKA-PIETRZAK, PhD

Department of Human Resources Management, Faculty of Management, University of Gdansk, Sopot, Poland,
E-mail address: agata.borowska-pietrzak@ug.edu.pl

Abstract

The main aim of the article is to present the results of surveys measuring the sense of professional satisfaction and analysis of the attributes that create it among hotel industry employees on the example of a deliberately selected sample of hotels in the Tri-City. Organizing work in specific conditions of hotel services requires appropriate quality of work, commitment and motivation to act on the part of employees in this industry. That is why it seems so important to ensure the efficiency of the business model of hotel services, based on employee behaviour, which is to be stimulated by motivational tools that trigger a high level of professional satisfaction. Therefore, the article focuses on understanding the mechanisms, conditions and factors that can shape satisfaction with the work performed in this industry. The research was carried out using the proprietary P.A.S.Z. methodology. The results clearly show that a high level of satisfaction is dependent on the high quality of human resource management practices in the surveyed organizations and is not necessarily dependent only on material motivating factors. The most critical attributes limiting the satisfaction of hotel industry employees include the possibility of promotion and professional development in the structures of their organizations. The factors that increase a high level of satisfaction include the importance of tasks performed by an employee, as well as the level of individual responsibility for results and the way of working. The average level of satisfaction in the Tri-City hotels surveyed was over [+60 p.], which can be interpreted as a high score, even when compared to other industries and professions examined by the author of this paper.

Keywords: Job Satisfaction, Motivation, Human Resources Management, Hotel Industry,

Introduction

Hotel services are one of the key and most dynamizing parts of the development of the tourist industry of a given country (Sala, 2019, Turkowski, 2010). Tourism is one of the most important economic sectors in the EU. It creates jobs, develops exports and generates many activities in other industries and sectors (transport, entertainment, food industry). According to calculations by the *World Travel & Tourism Council* (Turner, 2019) last year, its total turnover on the European scale amounted to USD 2.2 trillion, which is about 10% of the GDP of the countries of the community. The coastal region of the Tri-City due to its tourist and business values (Gdynia, Gdańsk, Sopot) is one of the more competitive regions in Poland in the scope of hotel services. Organizing work in specific conditions of hotel services requires appropriate quality of work, commitment and motivation to act on the part of employees in this industry. Building friendly relationships with clients who purchase specific hotel services creates a strong bond between the hotel brand, the standard and quality of services in a given hotel. That is why it seems so important to ensure the effectiveness of the business model of hotel services, based on employee behaviour such as high motivation or a positive level of professional satisfaction. Therefore, this article focuses on learning the determinants that can affect the satisfaction of the work performed in this industry. It can be said that today, a modern employee, especially in the *"b2b"* industry, like hotel services, spends almost half his time in work processes. We are also witnessing the implementation of new concepts for organizing human work, which undoubtedly leads to blurring the boundaries between work and personal life. It is an industry that offers its clients 24-hour availability of its services, supported by online tools. An important issue in this regard is configuring the human resource management model in the sphere of services, where there may be a

problem with the *Work Life Balance* concept. Due to the above specificity, the provision of services is becoming a very important challenge, which can be a factor that permanently reduces the sense of job satisfaction (Kawka, 2014).

The essence of a sense of professional satisfaction

These relationships cause that job satisfaction has become an extremely important topic, which is a very vital component of quality of life, but also affects the efficiency and optimization of human resource management processes (Spector, 1997; Stride, Wall, Catley, 2007; Juchnowicz, 2014). Therefore, in the field of management sciences, many researchers have been trying for many decades to interpret the concept of satisfaction and to distinguish factors that shape the sense of feeling this positive emotion accompanying the work process (e.g. Furåker, Håkansson, Karlsson, 2016;Bentley, Coates, Dobson, Goedegebuure, Meek, 2013; Osbourne, 2015; Trower, 2012). To quote the basic canon, but still relevant in this field of world management literature, professional satisfaction can be defined as:

- Pleasant or positive emotional state resulting from the evaluation of one's work experiences (Locke, 1976)
- A positive, emotional, affective reaction to the work performed, which results from comparing the actual working conditions with the conditions desired by the employee (Wanous, Lawler, 1972)
- Implementation of one's own values in a work environment accompanied by a pleasant emotional state (Locke, Henne, 1986)
- Feeling about work performed as a difference between the values achieved and the values that the employee expects (Porter, Lawler, Hackman, 1975)

Analysing the above definitions, it can be assumed that professional satisfaction is related to the difference between the needs and expectations of the employee and the actual level of their satisfaction on the part of the organization through the material and non-material motivation system. Thus, assuming the above postulation, and taking into account the assumptions, e.g. of F. Herzberg's two-factor model in the context of features of the working environment in the hotel industry (Lundberg, Gudmundson, Andersson, 2009), we can distinguish three states of feeling satisfaction in the work process:

a) lack of professional satisfaction, - the employee's expectations regarding his emotions and needs related to the work environment are not met to a large extent by the possibilities of the incentives offered in the employer's human resources management system – it can be conventionally assumed that they are negative in any measurement scale, definitely less than zero,
b) neutral (zero) satisfaction, - there is a minimal difference between the employee's expectations regarding his emotions and needs related to the work environment, and the incentives offered in the employer's human resources management system, - it can be assumed that in any measurement scale these are values oscillating around zero,
c) professional satisfaction, - there is commitment, activity and loyalty, as a result of a significant fulfilment of the employee's expectations regarding his emotions and needs related to the work environment through the offer of incentives in the employer's human resources management system – it can be assumed that in any measurement scale they are positive values, definitely greater than zero.

Considering the above concept, it can be stated that the variables building the sense of satisfaction concern many aspects related to the organization and model of human capital management, as well as individual characteristics of the employee. This classification can be made by grouping satisfaction factors into two basic groups: objective and subjective attributes of creating a sense of satisfaction (Borooah, 2009). The first category concerns determinants that are derived from the work environment and relate to both the **attributes of the work itself**: fair pay, not too much pressure, safety, prestige of work, convenient working hours, opportunities for initiative, rest opportunities, opportunity for achievements and promotion, responsible and interesting work that uses abilities and the possibilities of the employee work climate, being in a group and social contacts, **characteristics of the work**

performed: perceived degree of job security, income received, and perception by the employee of the type of work he does or the level and quality of relationships with other employees. The second group of factors is a kind of subjective catalyst for individual feelings and concerns such issues as **socio-demographic conditions**: gender, age, marital status, stage of professional development, seniority, family and material situation, origin or level of education. On the basis of the above considerations, an original, proprietary research tool was built in the form of a questionnaire under the working name P.A.S.Z (acronym of the words Measurement of Attributes of Professional Satisfaction)

A tool for measuring the sense of satisfaction attributes P.A.S.Z.

One of the most important assumptions of the proposed model is to organize the factors of professional satisfaction into **objective and subjective attributes.** A detailed description of the following methodology is described in, e.g., this position of the authors (Borowska-Pietrzak, 2013). The criterion for the division into the above-mentioned factors results from the assumption that the variables shaping the individual sense of satisfaction are divided into determinants objectively creating, regardless of man, his level of **external underlying, potential satisfaction** (e.g. offer of the remuneration system), and those that **depending on his specific individual characteristics differentiate the perception of this aspect** (e.g. social and income status of a person). Objective factors are, therefore, those components that are designed by the organization for the entire employed population by creating appropriate HRM practices. Therefore, it can be concluded that the organization is directly responsible for shaping the factors determining the sense of professional satisfaction. On the other hand, subjective determinants of employee satisfaction are such employee properties and attributes that are individualized specific "catalysts" for perceiving and assessing the usefulness and purposefulness of tools used to motivate employees. In other words, subjective attributes are variables that differentiate the primary intensity of the impact of objective attributes on employee satisfaction. **Subjective factors therefore differentiate for each individual person employed in the organization the strength of the impact of unified objective factors, which in turn constitute the foundation for the level of satisfaction for the entire organization.**

Based on this assumption, a proprietary measurement tool was designed in the form of a survey questionnaire diagnosing both the perception of subjective and objective factors. Hence, the P.A.S.Z. questionnaire consists of two parts, A and B, in which you assess your perception of satisfaction by valuing the level of subjective and objective attributes, respectively. Objective attributes have been recognized as those factors on which the organization has a direct impact and shapes its motivation system offers. On the other hand, the measurement of subjective attributes was designed in such a way that objective factors potentially offered by the employer are assessed on a subjective scale of importance in the hierarchy of values regardless of the place of employment. In the model presented below, the level of sense of professional satisfaction results from the interaction of objective and subjective attributes.

Fig.1: Model of shaping the sense of job satisfaction

Source: own study

The questionnaire is based on a two-step assessment of the same 23 factors potentially affecting the sense of job satisfaction. The indicated answers should take into account the individual, subjective assessment in two areas:

- **Part A)** The significance of a given factor of professional satisfaction in the life of an employee is assessed, which corresponds to the overall importance of a given factor at a given stage of his/her personal life. In this part, questions are asked about what is important in the life of an employee from the perspective of the given cafeteria of potential attributes. The scale of assessment in this part of the survey is the assessment of the importance of the factor in life: [0 – *does not matter*, 1 – *has low, very low significance*, 2- *has an important, but not decisive significance*, 3, *has a very large, crucial significance, is the most important thing in my life for me;*
- **Part B)** The level of employee assessment of currently offered satisfaction factors by a specific employer is diagnosed. An assessment of current satisfaction with the level of feeling the impact of a given factor in everyday work is indicated. The scale of assessment in this part of the survey is the assessment of the importance of the factor offered by the employer *[-3: unacceptable level; -2: very low level; -1: low level, 0: no opinion, +1: average level, +2: good level, +3: very high level];*

Based on the indicated theoretical and conceptual foundations, a set of disjoint and holistic attributes shaping employee satisfaction was built. The following harmonized attributes of employee professional satisfaction, which are assessed in parts A and B of the P.A.S.Z. questionnaire (Borowska-Pietrzak, 2014):

1) The level of income obtained from the work performed,
2) Adequacy of remuneration for the work performed and position held,
3) Clear and open communication of the rules and criteria for the payment and remuneration,
4) Additional non-wage bonuses obtained on the position,
5) Expressing recognition to the employee by superiors and organizations,
6) The supervisor's management style (the way he works),
7) Organization of work in the employee's cell,
8) Degree of organization of work of the whole organization,
9) The role and significance of the employee's profession compared to others in the company (its importance and prestige),
10) Promoted values, norms and rules of employee behaviour in the organization,
11) Personal direct relations with your superior,
12) Personal direct relations with your colleagues (subordinates – for the manger),
13) Diversity of tasks performed as an employee,
14) Sensibility of tasks performed as an employee,
15) The validity of tasks performed as an employee,
16) The level of individual responsibility for employee results and work method,
17) Form of setting goals and tasks for an employee,
18) Form and scope of delegating tasks to an employee,
19) The level of independence and autonomy in the employee's work process,
20) Method of control and evaluation of the employee by the organization (supervisor),
21) Promotion opportunities in the organization structure,
22) Possibility of professional development and raising one's competences,
23) Achievements and professional successes in the position so far,

Below there are the rating scales for individual parts of the P.A.S.Z. tool divided into parts A and B. As a result of answering both parts (A and B), the product of common points in the nominal range is calculated [-207 p. ; +207 p.]. Based on the results of the author's many years of research with this tool (Alfa-Cronbach coefficient for P.A.S.Z. is = 0.92), it can be assumed that the following tool diagnoses the following ranges of a **S**ense of **J**ob **S**atisfaction in the context of all attributes of its perception (**SoJS**):

SoJS >0: an employee does not negatively assess the sense of professional satisfaction,

SoJS>>0: an employee does not negatively assess the sense of professional satisfaction,
SoJS =<0: an employee positively assesses the sense of professional satisfaction,
SoJS <<0: an employee strongly evaluates the sense of professional satisfaction,

Working environment in the hotel industry

Hotels are a service industry that is part of the new economy based on knowledge and human capital. The basic factor shaping the added value in this service sector is the human capital in the form of commitment, motivation and loyalty, which work value is of great importance in the quality of the offer (Hoque, 2002). The basing of the hotel management business model on the human resources model should affect the achievement of market advantage. It should be remembered that this is a very competitive market and it is necessary to stand out from the entities operating in this industry, and to ensure a special position in the minds of customers. A significant number of studies in contemporary world literature on the subject puts the issue of satisfaction as the research area in the assessment of HRM practices in the hotel industry in the second place (the first place is occupied by the causes of fluctuations) (Sharma, 2019). Material resources of hotel enterprises can easily be imitated by competitors, while the knowledge, skills and attitude of employees in servicing hotel guests can be an important factor of competitiveness on the market. Due to the constantly increasing level of servicization of the economy (Kawka, 2014), the importance of the role of human capital in the process of creating and offering services, including hotel services, is growing. Throughout the world, traditional elements of competitiveness are losing their significance, while the role of human capital is increasing, especially in service enterprises. This is due to the fact that in the service sector, including in the hotel industry, employees should be more strongly involved in creating and delivering customer value than in manufacturing companies. In this type of services, employees' knowledge and skills are a key element determining the competitive advantage of an enterprise (Tokarz, 2009). Without competent employees, it is difficult to improve and maintain the quality of services, or to provide good service to both regular and new customers, who are still increasing, because the demand for hotel services is still growing. This increase is also caused by the increasing mobility of people to Poland, which is also possible due to the development of land and air transport connections. In 2018, Polish airports served over 40 million passengers, an increase of 17.5 percent, compared to the previous year. For comparison, in 2011, it was 21.7 million people, so this number has almost doubled in six years (ULC, 2007). The indicated increase is particularly related to the Tri-City area, i.e. the accommodation facilities of Gdańsk, Sopot and Gdynia. Not without significance in the statistics of people using hotel services in this region are also business stays of such a vibrant and dynamically developing region. Over the first three months of 2018, over 5 million tourists spent the night, of which almost 1.2 million guests from abroad, mainly Germans, Ukrainians, Russians and British. In response to these needs, it is estimated that over the next few years, the number of rooms available to hotel guests will increase by about a third (Emmerson, 2018)

It is not easy to attract new employees and keep existing ones (decreasing unemployment and raising wages), employment costs are rising. More than half of the hotel staff are people in lower positions (room service, waiters, reception). These are the groups that are the most difficult to acquire and maintain. For many of them, working in a hotel thanks to the shift system is an additional occupation performed only while studying. This means that most hotels are constantly looking for employees. The CSO data shows that slightly more than 140,000 people worked in the hotel and catering industry in the third quarter of 2017, and the average salary was over PLN 3280 gross. There will have to be an increase in wages in the industry. Employees, especially younger generations, are looking for professions that offer development opportunities. Therefore, the hotel industry as an industry must change quickly, redefine HRM strategies, build career paths, improve its processes, make work in the hotel easier and bring satisfaction. An additional risk is the ongoing investment boom. Its consequence will be increased competition, which will aggravate the problems of finding and retaining employees. The type of hotel in which an employee works may also affect the perception of the level of satisfaction. A large part of these facilities operate in the segment of tourist hotels located in holiday resorts. In such locations, we find Polish local facilities more often and they are small and medium-sized enterprises, where the level of quality of the personnel function is not very high (Pocztowski, Pauli, 2013). On the other hand, global brands and international networks usually manage business hotels in large cities.

They operate mainly in the markets of the largest agglomerations because they are able to obtain the most reliable return on investment there. Research indicates that these are potentially organizations with a higher standard of implementing personnel practices (Emmerson, 2018)

Empirical Results: Professional satisfaction measurement in the selected Tri-City hotels

Five hotels were deliberately selected for the job satisfaction survey (2 small local ones, 2 regional medium ones and 1 large foreign network one). The choice of a sample constructed in this way largely reflects the share and nature of the size of hotels both in the region and in Poland (BIG, 2018). The study was conducted at the beginning of 2020. 162 employees took part in the presented study. Among 35% of respondents, these were both junior and senior management positions, 12% of respondents occupied specialist positions, 44% were executive positions, and less than 10% dealt with the auxiliary function in the examined hotels. Employees of the surveyed hotels are characterized by a relatively low age, and the largest group -37% were employees aged 20-28 and 29-35 – 24%. The percentage of employees over 45 is very small – 11%, including only 3% over 55 years of age. This indicates a high share in the employment of employees of generation Y, who are characterized by a very low level of loyalty and stability of employment (Kawka, 2019, pp. 69-72). This data is confirmed by the fact that more than half of the respondents (55%) are a group of employees with less than 7 years of service, and in addition, as many as 22% of the respondents working in the hotel for not more than a year are in the surveyed set. Only about 6% of employees were diagnosed in the group of people working for more than 16 years. This indicates a very high level of fluctuation and turnover of employees in recent years, which is very characteristic for the industry and the above-mentioned generational group. The vast majority of respondents (65%) are women.

The average result of perceived satisfaction (PSZ) in the examined hotels was **+53.9 p.** on the potential scale [-207p.; + 207p.]. It is a result that is significantly different from 0, i.e. rather indicating a positive feeling of satisfaction (**SoJS>>0**). Below is a summary of the results of professional satisfaction for all surveyed hotels.

Table 1: Results of professional satisfaction in the examined hotels in the Tri-City

	Medium level of satisfaction (p.)	**Intensity of variability of results dispersion (p.)** $\frac{Standard\ deviation}{Mean}$	**Max/Min (p.)**
ALL HOTELS	**53,90**	**88%**	***-72p./+199 p***
Medium Hotel 1	**62,33**	*72%*	*-18 p./+110 p.*
Medium Hotel 1	**58,92**	*71%*	*-22p./+142p.*
Large Hotel	**63,33**	*87%*	*-72p./+199 p.*
Small Hotel 2	**30,5**	*120%*	*-24p/+98p.*
Small Hotel 2	**54,42**	*90%*	*-49.p/+139 p.*

Source: own study

The data indicate that these are results showing an average high level of satisfaction within the surveyed hotels. As you can see, the size of the hotel increases the value of the sense of satisfaction with work. This could indicate the occurrence of the relationship indicated in the earlier part of the text between employee satisfaction and the size and organizational structure, and indirectly the activity of implemented HR practices in the daily management of these facilities. Nevertheless, it should be assumed that this is an image indicating a definitely positive image of a sense of satisfaction in the studied industry. The justification for adopting this assumptions is the fact that only 10% of negative results were obtained in the examined group of employees. Interestingly, only 50% of negative

indications were the share of executive employees, and 25% of negative responses were indicated by both specialists and managers. The lowest result was obtained at the level of **(-72p.).** In addition, as much as 47% of the surveyed employees were above the average **(+53,9p.)** of satisfaction felt, with quite high results, where the highest result was achieved **(+199p.).**

The intensity of variability of results dispersion (IVRD) was also calculated, which was 88% for the examined sample. ***IVRD*** is interpreter as how much the employees differ in perceived satisfaction against the background of the incentive system offered by the hotel. The achieved result of 88% - this is an average high result, and indicates a rather average differentiation in the perception of your level of satisfaction with working in a hotel. However, it should be pointed out that in previous studies one of the most stable in terms of diversity. For example, the diversity indicator for employees of cultural institutions was 400%, which is an extreme result.

In addition, what is worth referring to as a benchmark, compared to other professional groups examined so far, the result for the Tri-City hotels falls within one of the highest satisfaction levels examined. For comparison, the table below presents the results of the author's research diagnosed in organizations over the past 5 years.

Table 2: Summary of the results of achieved satisfaction levels in a various branches

	Medium level of satisfaction (p.)	**Strengthening attributes (no. in the questionnaire)**	**Limiting attributes (no. in the questionnaire)**	**Intensity of variability of results dispersion (p.)**	**Max/Min (p.)**
Financial services	60	n.12, n. 19	n.2. n.8	78%	+175/-69
Chemical production	92	n. 8, n. 19	n. 4, n. 5	36%	+160/+8
Law firm	47	n. 14, n. 16	n. 2, n. 4	95%	+150/-53
Trade company	53	n. 14, n. 16	n. 4, n. 21	92%	+170/-168
Municipal company of services	45	n. 13, n.15	n. 5, n. 21	95%	+183/-63
University	49	n. 19, n. 23	n.1, n.2	93%	+150/-53
Institution of culture	13	n. 6, n. 12	n.2, n. 4	400%	+119/-113
Secondary education school	38	n. 11, n. 19	n. 8, n. 21	81%	+132/-44
Self-government office	60	n.11, n. 12	n. 4, n. 21	40%	+147/-10

Source: own study

An important scope of research on the attributes of professional satisfaction in Tri-City hotels was to identify which specific attributes have a supporting and dysfunctional effect on the level of job satisfaction. The following are the calculations of the average product of parts A and B of the questionnaire for all 162 employees: The following factors were included in the lowest-rated employee attributes, on the [-9; +9] scale:

- **Attribute 21**: *promotion opportunity in the organization structure*, average **+0.2p.,**

- **Attribute 22**: *opportunity for professional development and raising one's competences* – average **+ 0.7p.,**
- **Attribute 4**: *additional non-wage bonuses obtained in the position* – average **+ 0.8p.,**

These are the factors that most significantly reduce the sense of satisfaction in the sample of Tri-City hotels. These are dimensions that, due to the model and organizational structure, will limit, especially small hotels, as an objective reducer of job satisfaction.
However, the highest rated attributes were diagnosed:

- **Attribute 16**: *individual responsibility for employee results and working method* - average **+ 3.85 p**.,
- **Attribute 15:** *validity of tasks performed as an employee* **+ 3.80p**.
- **Attribute 12:** *personal direct relationships with your colleagues* **+3.51p**.

These are the factors that in most of the examined hotels were recognized as the most valuable in terms of their positive impact on the sense of satisfaction.

Discussion & Conclusion

the role of satisfaction against the background of the personnel function in the examined hotels

An interesting background for interpretation instead of the traditional summary of the results obtained was to assess the relationship between the level of satisfaction and the key goals of the personnel function (Listwan, 2010). Therefore, the level of assessment of three important aspects of HRM was additionally diagnosed according to numerous literature on the subject (Borowska-Pietrzak, 2013) having a strong relationship with creating a sense of professional satisfaction. The surveyed employees were asked to assess their subjective perception of A) the current commitment to work, B) the adequacy of wages received for their professional role and C) the assessment of satisfaction with the implementation of their stage of professional development. The following results were obtained:

A) **4.72** (average high) commitment of the surveyed employees, these were grades on a shortened 6-point Likert scale;
B) **3.01** (average result) assessing the adequacy of their wages for the role performed, these were grades on a shortened 5-point scales;
C) **3.10** (average result) assessing the adequacy of the employee development stage assessment, these were grades on a shortened 5-point scales;

To answer the question whether there is a correlation in the studied population, the Pearson correlation coefficient between the above-mentioned three variables, and the level of professional satisfaction, which was $r_{S/A}$**= +0.41** for factor A; $r_{S/B}$**= +0.43** for factor B; and $r_{S/C}$**= +0.44** for factor C, respectively, was calculated. Therefore, it can be assumed that the studied population was diagnosed with the occurrence of a motivational mechanism described in the literature on the subject with a strong coexisting relationship between an increase in the sense of satisfaction and the rationality of the implementation of the human capital model (strong commitment, adequate wages, and acceptable development by employees). In addition, the range of questions in which employees' expectations were diagnosed is a very valuable context for further interpretation of the results obtained. They were asked whether they would soon expect the following in their organization: D) promotion, E) raise F) and whether they plan to leave/stay with their current employer. In this regard, the following results were obtained:

Table 3: Distribution of expectation results of the surveyed hotel employees

Answer	D) Do you expect a promotion	E) Do you expect a raise	F) Do you plan to stay at work
Yes	27.8%	65.4%	66.7%
No	72.2%	34.6%	33.3%

A very interesting result for interpretation is the calculation for the above-mentioned individual categories of average level of professional satisfaction. The following average levels of satisfaction were obtained for employees declaring:

- D_{YES}: promotion in the near future amounted to **+59.8 p.**
- D_{NO}: no promotion in the near future amounted to **+4.6 p.**
- E_{YES}: receiving a raise in the near future amounted to **+57.6 p**.
- E_{NO}: not receiving a raise in the near future amounted to +**57.04 p.**
- F_{YES} : change of job in the near future amounted to **+36.2 p.**
- F_{NO} : remaining at work in the near future amounted to **+65.7 p.**

Regarding to E_{NO} results, this is one of the most interesting results obtained in these studies, perfectly fits the assumptions of F. Herzberg's Two-factor Theory, which assumes that salaries are a hygiene factor and cannot be a determinant that permanently increases employee satisfaction.

Summarizing the above analysis, we can with some caution divide the surveyed employees into two groups, potentially satisfied, i.e. those who said YES and those who are potentially dissatisfied, i.e. they belong to the NO set. Interestingly, these are relatively equal groups, respectively 53% and 47% of the surveyed employees. The average sense of satisfaction was calculated for such groups of surveyed employees:

- "**YES group".** (expect a promotion, a pay rise and declare staying at the hotel), PSZ = **+61p**.,
- **"NO group"** (do not expect a promotion nor a pay rise and declare leaving the hotel), PSZ = **+32.5p.**

Rational implementation of HRM solutions based on the human capital model can lead to a positive effect of attitudes and behaviours, such as in the "Yes Group". The results presented above may therefore be further evidence that the approach to people in the organization as a human capital is strongly correlated with a higher potential level of professional satisfaction. Research conducted in a selected sample of Tri-City hotels showed this relationship.

In the summary of the described research, it can be stated that in the area of hotel services management – the higher the level of effective HR policy, the higher and lasting sense of professional satisfaction of employees employed in these enterprises is potentially formed. And this undoubtedly builds lasting added value for all stakeholders in this industry.

Social Dimension of The EB Based on The Example of TOP 500 Enterprises

Anna ALBRYCHIEWICZ-SLOCINSKA

Czestochowa University of Technology, Faculty of Management, Department of Psychology, Sociology and Communication in Management, Czestochowa, Poland, anna.albrychiewicz-slocinska@wz.pcz.pl

Abstract

In the changing labour market, where the position of employees is visibly growing, employers look for new Human Recourse (HR) tools to attract and keep new employees. One of such tools is Employer Branding (EB), which means various measures undertaken by organisations in order to create a positive employer brand. Such measures may be undertaken both within and outside an organisation. Regardless of their focus, an important element of such activities is the Employee Value Proposition (EVP), which is a description of the properties and attractiveness of jobs offered by a given employer. An increasingly frequent element of such proposition are social aspects highlighting a personal approach to employees and the organisation's attentiveness and sensitivity to social problems and the growing importance of social needs. The purpose of this paper is to present the opinions of Polish employers from the TOP 500 list concerning the importance of the social elements of EB communication. The list includes organisations that achieved the biggest market and financial success in 2018 according to the methodology adopted by the Polish Rzeczpostpolita newspaper portal. The following tests were used for the purpose of data analysis in the STATISTICA program: the Kruskal-Wallis ANOVA on ranks test, the Mann-Whitney test, the median test and the Pearson's chi-square test. The strength of correlations between the variables was evaluated by means of the Spearman's rank correlation coefficient. Unfortunately, the results of the research show that the responding organisations have little understanding of the new trends in the labour market and the need to work on the image of the organisation as a friendly employer.

Keywords: Employer Branding, Human Recourse

Introduction

Until recently in Poland, given the dominant employer market and rather high unemployment, it was quite easy to hire an employee at a relatively low cost. However, the conditions of today's employee market are different: it is more difficult for an organisation to acquire and, more importantly, to retain an employee. The costs of the recruitment process are also higher. Thus, every measure that helps reduce those costs is important. The HRM Institute research conducted in 2018 (http://www.hrminstitute.pl/raport-employer-branding, 2018) among employers in the Polish labour market showed that the factors that will be the most strongly influencing the completion of business goals in the coming years will be the need to implement new technologies and talent shortage in the labour market. In the light of the above, the importance of recruitment measures, in the broad meaning of the term, as a factor contributing to the success of an organisation is growing. Any negligence at this stage of the HR process (Zavyalova et al., 2011; Listwan, 2005, p.79) results in increased expenditure, not only in the recruitment area but, more importantly, in the area of optimising employee skills and motivation to enable effective task completion. Some HR specialists (Zavyalova et al., 2011) even suggest that expenditure on training will never translate to effectiveness so much as expenditure on acquiring individuals who are tailored to the organisation in terms of their values and who contribute high potential, knowledge, skills or unique abilities to the organisation.

The literature also shows that the goal of both recruitment and selection is to hire an employee with the required competencies corresponding to the employer's needs (Searle 2009, p.151-168). Here, recruitment means mainly that an organisation attracts a sufficient number of candidates to enable

rational selection. Thus, employers are highly creative in communicating with candidates and simplifying application procedures. This involves shortening as much as possible the application and selection process, thereby reducing the number of candidates who resign from applying, discouraged by prolonged decision-making on employment (Gojtowska 2019, p. 217-236). The traditional forms of communicating with candidate employees are no longer sufficient, especially in the case of the youngest generation of potential employees (Decker, 2016, p. 770). Companies attending university job fairs, an increasing number of Facebook fanpages, special smartphone applications to apply for a job, corporate movies featuring employees, chatbots, using VR (Virtual Reality), so-called ambassador programmes, an extensive training offering and social and professional adaptation programmes (onboarding) are but a few examples of measures covered by the new HR trend that has been increasingly popular over the last decade, namely the EB.

The purpose of this paper is to present the opinions of Polish employers from the TOP 500 list concerning the importance of the social elements of EB communication.

EB – introduction to the problem

The number of publications on the EB, both scholarly and practical, has significantly increased in recent years. This is the effect of changes taking place in the labour market (a growing position of employees and a decreasing supply of employees in the labour market) as well as of the necessity to apply new technological solutions associated with the revolution 4.0 (Erro-Garcés A., 2019) and the consequent need to acquire and retain employees that have unique competencies valuable for an organisation. This has also been the case in Poland over the last five years. However, the term EB was mentioned in scholarly literature much earlier than that. Its progenitors and popularisers were Ambler and Barrow (1996). In their paper, "The employer brand", they defined EB as "the package of functional, economic, and psychological benefits provided by employment, and identified with the employing company" (Ambler and Barrow, 1996). Other authors (Ambler, 2003; Berthon et al., 2005, Barrow and Mosley, 2006, p. xvi) highlight that it is the undeveloped concept of internal marketing, internal branding and corporate brand. Kozłowski (2012, p. 14) defines EB more broadly as "all measures undertaken by an organisation, addressed to its existing and potential employees in order to build the image of the organisation as an attractive employer and also supporting its strategic business objectives".

According to many authors (Berthon et al., 2005; Cable and Judge, 1996; Eisenberg et al., 2001; Frook, 2001; Lievens and Highhouse, 2003), the idea of the EB is based on the assumption that a company, as an employer, is treated as a product that needs to be sold. This is a marketing-based approach to the functioning of an organisation and it means specific and regular measures aimed at satisfying the current and future needs of customers. Kucherov and Zavyalova (2012) suggest that the EB is an important element of the HRD (Human Recourse Development). Authors such as Gojtowska (2019) or Mosley (2007) claim that the EB has its rational and emotional attributes. The importance of emotions in recruitment processes and in building Candidate Experience (CE) is also emphasised by Polish reports developed by the HRM Institute (EB Book 2018).

The EB may be divided into the internal EB – focusing on the company employees and external EB – focusing on persons potentially interested in working for a given organisation (Backhaus and Tikoo, 2004). The superior goal of the internal EB is to increase employee efficiency by initiatives aimed at improving working conditions and social environment at work and presenting the advantages of working for a given company (Sartain, 2007; Kozłowski, 2012, Gojtowska 2019). The HR tools that help implement the internal EB are: internal communication, career paths, training, periodic employee evaluation system, satisfaction surveys, wage and non-wage incentives, employee integration projects, organisational value system, work-life balance (WLB) or Corporate Social Responsibility (CSR) measures targeting the employees. Meanwhile, the external EB is addressed to potential company employees. Its effect are all kinds of information and opinions that a potential candidate may hear about the company. Two categories may be identified within the external EB: image-related and recruitment-related. The purpose of image-related measures is to increase the target group's awareness of the enterprise and the advantages of working for that enterprise. Such

measures are usually conducted on a large scale and their goal is to reach as many recipients as possible. Meanwhile, recruitment-related measures are associated with ongoing recruitment processes. Their goal is to reach valuable candidates and to persuade them to apply for a specific job. Recruitment-related measures are usually conducted on a smaller scale and are supposed to reach a specific target group. It is also worth noting that image-related and recruitment-related measures are interconnected. It is important that all measures undertaken within the framework of the external and internal EB are consistent and based on a common strategy (Andreassen and Lanseng, 2010).

EB in Poland

An analysis of 2012-2018 reports made by the HRM Institute (https://www.hrminstitute.pl/raporty-eb/) shows a growing importance of the EB in HR policies in enterprises. Early reports clearly show lack of an EB strategy in the organisations that participated in the research and their inability to link the EB area with the personal function of the organisation. EB measures were mostly undertaken by units or personnel responsible for marketing operations and mainly focused on propaganda. It is currently observed that organisations spend the same amount of time and energy on employer brand as on consumer brand. With their brands, companies influence not only their customers but also potential candidates – regardless of whether or not they control how it happens. It is not only about increasing the number of applications for advertised vacancies but also about attracting appropriate high-quality employees who may strengthen the company's competitive position (EB Book, 2020). Although the early editions of the reports clearly showed that employers were ambivalent about the EB, now, most of them are aware that it is not an optional measure but a must in our times. According to the 2018 report, more than 50% of companies have a more or less structured employer branding strategy, including a strategy to support the employer brand within the organisation. 42% of the organisations participating in the research declared that the EB measures were mainly implemented by HR departments and 11% of them even had specialist EB departments. Even though most of the responding organisations still report major problems in implementing EB measures, they definitely appreciate their importance and significance for the HRD (Human Resource Development). In recent research conducted by the HRM Institute, respondents highlight the importance of not so much employee satisfaction but the joy they get from work and from being in their place of work (the 2018 Fun at Work Report), and are increasingly aware of the need for material and non-material appreciation of their employees and for creating a sense of work (Raport Index Doceniania, 2019).

Methodology

The research results presented in the paper are a part of the Polish quantitative research of enterprises under the project: "Innovative trends in human resource management in large enterprises". The research was conducted in 2019 at the Faculty of Management at the Częstochowa University of Technology in collaboration with the specialist outsourced company MRW Market Research World.

The research was conducted using quantitative survey methods with mixed techniques: the Computer Assisted Web Interview (CAWI) and the Computer Assisted Telephone Interview (CATI). The combination of the two quantitative methods helped increase the response data coefficient. The research population were the top 500 Polish companies (according to the Rzeczpospolita portal 2018 ranking). Random sampling was used by the company conducting the research. Questions concerning the organisations under review were answered by representatives of senior managerial personnel (HR departments) or employees delegated by the employer. Following the sampling, the representative sample was examined based on the following parameters: the size of the general population 500, the estimation error 6%, the level of trust 95%.

The paper uses a fragment of the research concerning the EB in the examined enterprises. The questions are original and they were formulated by the members of the research team of the Faculty of Management of the Częstochowa University of Technology.

The following problem was formulated in the research: What are the opinions in the examined enterprises from the TOP 500 list concerning the attractiveness of selected EB elements for job candidates. These opinions were correlated with the organisation's evaluation of its own market position and data concerning the organisation, such as the type of activity (TA) , revenue (AR) or size of the organization (NE). The structure of organisations in terms of the latter parameters is presented in Table 1.

Table 1: Parameters of the organisations under review

Characteristics of the organisations	Number	Percentage
Number of employees/size of the enterprise (NE)		
201 – 500 employees	131	73.18
More than 500 employees	48	26.81
Total	179	100.00
Annual revenue (AR)		
Revenue between 51 and 200 million PLN	122	68.15
Revenue above 200 million PL	25	13.96
Revenue from 5 to 50 million PLN	32	17.87
Total	179	100.00
Type of activity (TA)		
Manufacture	75	41.89
Manufacture and services	26	14.52
Services	49	27.37
Commerce	15	8.37
Manufacture and commerce	14	7.82
Total	179	100.00

Source: Own elaboration.

The significance of differences with respect to the abovementioned independent variables and correlations between the other variables were examined and described using the STATISTICA program. The significance of differences was tested using the Kruskal-Wallis ANOVA on ranks test, the Mann-Whitney test, the median test and the Pearson's chi-square test. The strength of correlations between the variables was evaluated by means of the Spearman's rank correlation coefficient.

Results of the Research

The research tool was a standard questionnaire with closed-ended and semi-open-ended questions. The questionnaire contained both questions and statements. The questions contained responses in the five-level Likert scale, where the respondents could respond to the respective statements by selecting one of the answers (1 - I strongly disagree, 2 - I partly disagree, 3 - I neither agree nor disagree, 4 - I partly agree, 5 - I strongly agree).

To evaluate the opinions of the organisations under review on the attractiveness of selected EVP elements for job candidates, the following social EB indicators were selected: environmental protection projects of the organisation (V1), employee volunteering (V2), relations with the local community (V3), prosumer programmes (V4), onboarding programmes (V5) and the WLB (V6).

The first observation shows that the most frequent response to all EB-related questions of the social nature was "I neither agree nor disagree" (the percentage distribution of this category of responses to the respective questions ranged from 34.6% (V6) to 41,3% (V4)). Concerning the opinions of representatives of the organisations under review on whether the fact that the organisation undertakes measures in V1 is important for candidates, 46.9% of the respondents said this was not vital for the applicants and only 14.5% thought that it was an important element of EB communication. Measures in V2 constituted an important element of EB communication according to 15% of the respondents, and 49.7% of them believed it was not relevant for candidates looking for employment. Somewhat better was the situation with measures in V3 – 36.8% of the respondents thought they were not an essential element of the employer's image, while 25.1% believed them to be an important element of EB communication for the candidate. The distribution of responses concerning the importance of V4 is interesting. Here, the largest percentage of respondents chose a neutral response, but at the same time almost the same percentage of organisations (40.7%) thought this factor to be irrelevant and 17.8% agreed that it was important in building a positive image. It seems that the importance of V5 was evaluated more positively: only 27.4% of the respondents thought it was an irrelevant element of the EB, while 35.7% believed it to be an important indicator of employer attractiveness for the candidate. By far, the most attractive element for potential candidates, in the opinion of employers, was V6. As many as 41.3% of the organisations agreed that it was an important factor of EB communication, and only 24% thought it to be of little relevance.

When analysing the impact of independent variable, such TA, using the Pearson's chi-square, a statistically significant difference was reported only in the distribution of responses concerning the indicators V4 and TA (Table 2). Manufacturing companies and manufacturing and service providing companies were sceptical about the importance of V4 in developing the EB image more often than other organisations. Meanwhile, service providing companies were most often neutral or rather positive about this particular element.

Table 2: Type of activity vs the importance of prosumer programmes for the EB

Statistics	Statistics: V4 x TA		
	Chi-square	df	p
Pearson's Chi^2	27.71549	df=16	p=.03418
Chi^2 NW	26.78096	df=16	p=.04398

Source: Own elaboration based on research results.

The research concerning significance of differences using the Kruskal-Wallis ANOVA on ranks test, the Mann-Whitney U test and the median test did not reveal any significant relationships for the level $p < 0.05$ between the other indicators of the perception of the EB and variables such as NE, AR.

Representatives of the organisations under review were also asked to evaluate the market position, financial position and level of innovation of their respective enterprises. These statements were correlated with the assumed EB indicators by means of the Spearman's rank correlation coefficient R. Numerous statistical hypotheses were made concerning those relationships (the H0 hypothesis of no relationship and the alternative H1 hypothesis assuming that there existed correlation between the variables). The statistical analyses conducted confirmed a statistically significant relationship only in a few hypotheses, which will be discussed further on in the paper.

The breakdown of the R correlation indicator with respect to the selected variables presented in table 3 makes it possible to reject hypothesis H0 and assume alternative hypotheses concerning the relationship between them.

Table 3: Spearman's rank-order correlation for *p<0.05, **p<0.001, ***p<0.0005

Situation of the enterprise	EB indicator					
	V1	V2	V3	V4	V5	V6
Net profit increase	-	-	0.16992*	-	-	-
Releasing new products	-	0.15020*	-	-	-	
Implementing new technologies	-	-	-	-	-	0.19782**
Growing resources of the enterprise	0.18431*	-	0.16504*	-	0.22218**	0.27033***
Growing customer portfolio	-	-0.16650*	-	-	-	-
New outelts	-	-	-	-	-	0.14972*

Source: Own elaboration based on research results.

The values of the above R-indicators are not high, which suggests that the relationship between the variables is rather weak, however, in the case of three relationships, the p-level of significance is very low, suggesting a statistically highly significant regularity of correlation.

Discussion

An analysis of the statistical results led to a number of general conclusions. More than one third of the respondents representing the organisations under review were neutral about all the indicators of the social factors that significantly affect the employer's image in the eyes of candidates. According to the respondents, most of the indicators had little relevance to shaping the image and only the WLB was considered by them to be important for potential employees. Considering the fact that the organisations under review had a very good position in the market (they were ranked among top 500 organisations in 2018), this is a surprising result, to say the least. It seems that those organisations do not consider social indicators of EB communication to be important for attracting new employees. This is striking given the significant economic growth and development of companies in Poland in 2018 and 2019 and the resulting increasing problems with attracting and retaining employees. According to Eurostat data, the unemployment rate in Poland by the end of 2019 was 3.3% (https://www.gov.pl/web/rodzina/eurostat-polska-wciaz-w-czolowce-krajow-z-najnizszym-bezrobociem). In this situation, many EB reports as well as HR practitioners emphasised the need for changes in the means and content of EB communication, focusing on its social aspects, which are particularly important to retain employees in an organisation. In the light of the above, the attitude of the examined employers reveals their fossilised, traditional perception of the EB, which, until recently, focused mainly on the material and financial benefits of working. A strong market and economic positions seems to release an organisation from the obligation to attract an employee and offer unique and specific benefits corresponding to his or her contemporary sensitivity to social aspects. The only exception are WLB programmes that have been a fixed element of the HR strategy, especially targeting working women, for almost two decades now. It should be noted however, that some employers believed women rights provided for in the Labour Code, associated with the need to reconcile the role of a mother and an employee, to be an element of the WLB. There were some significant changes in this regard only in the last few years in Poland. First of all, the WLB measures were extended to include the other employee groups, in recognition of their subjectivity and right to satisfy their needs outside work. Secondly, organisations developed a range of benefits available under WLB programmes to meet the various needs of employees.

It was also determined in the research that increase in net profit was linked only with the opinions of the representatives of the organisations under review concerning the importance of efforts to build a relationship with the local community for candidates looking for jobs. Due to lack of a relationship between increasing profitability of the organisations under review and their size, type of activity or

annual income, it is hard to conclude on what type of organisations they are. Thus, an attempt was made to associate the parameter of growing profit with other indicators of the financial and market situation of an enterprise. By applying the Spearman's rank correlation coefficient for the level $p<0.001$, it was determined that net profit growth in the year under review was related to: profit growth in the year preceding the year under review, revenue growth in the year under review, asset growth, productivity growth and increased market activity. In the light of the above, it should be supposed that growing market activity stimulated by very good financial condition could lead to increased local activity of an enterprise and its strong promotion to attract employees from its most immediate environment.

A similar conclusion may be drawn with respect to another indicator, namely acquiring new outlets, which correlates with the conviction that job candidates are interested in whether an organisation implements WLB programmes. This also applies to the indicator of implementing new technologies. Here, the same as in the case of the former indicator, it was difficult to define the type of organisations we were dealing with. Interestingly, there is no such relationship with respect to releasing new products by an organisation. Meanwhile, the latter indicator correlated with the conviction that employee volunteering measures were important for the strength of EB communication.

Focus on social aspects was the most visible in enterprises that reported a growth in resources. This indicator very strongly correlated with almost every element of the social communication of the EB. It should be noted, however, that growth in the resources of an organisation was related to growing demand for personnel, as a result of which those organisations were forced to implement new EB strategies to attract employees using social elements that promoted the organisation as an institution that cared both for its employees and for the local community and environment.

Another interesting conclusion of the research is that none of the indicators of the market situation, financial situation or innovation level correlated with the conviction that it was important for a candidate looking for an employer whether an organisation implemented prosumer programmes. It is an evident signal that the examined organisations do not notice that currently, the employer brand is strongly linked with the product brand and the market brand of an enterprise. Numerous publications (Heffernan 2015, Gojtowksa 2019, Machnicka 2020) emphasise the fact that, for a contemporary candidate, especially a candidate representing the younger generation, those are almost identical brands. Any bad experiences they might have with the products of a company will have a significant impact on their perception of an organisation as an employer and vice versa. Any negative experiences associated with recruitment or employment will cause rejection of products. This relationship may also be due to the fact that the examined organisations do not implement any prosumer programmes, which is also a negative signal. This means that the organisations cannot or do not want to open to cooperation with consumers and encourage them to engage in processes that streamline organisational processes.

Since the research asked about measures in the area of the social elements of the EB undertaken by organisations, it turned out, by the way, that, unfortunately, most organisations do not undertake any such measures. Thus, the existing employees of the examined organisations, who do not benefit from any such measures, cannot be reliable ambassadors of the employer brand. Meanwhile, EB guidebooks addressed to HR specialists emphasize the important role of employees who, using generally available social media, may contribute to strengthening the employer brand through "whisper marketing". Thus, it could be concluded that, unfortunately, the examined organisations do not implement a conscious and reliable policy of either external or internal EB.

Conclusion

The general conclusion of an analysis of the research material is, unfortunately, that the strongest Polish organisations still do not understand or notice the changes taking place in the Polish labour market. Persisting in their market hegemon position, they do not think it is necessary to create any

special EB communication highlighting the image of a candidate-friendly employer. They anachronistically assume that a market leader automatically becomes a labour market leader.

When analysing information from HR reports, it seems that the EB will remain important for job candidates, especially from the younger generations of employees, even though forecasts about the labour market after the COVID-19 epidemics are not optimistic. Economic analysts suggest a likely growth in the unemployment rate, which will be followed by changing attitudes of employers who have enjoyed a strong position in the labour market so far. It seems that the EB will remain important, but preferences concerning the EVP will change. Until now, there has been a tendency for self-employment and freelancing, which give a sense of independence and do not require a relationship based on loyalty to the employer. Where such solutions were applicable, both the employers and employees seemed to be satisfied. The current problems associated with COVID-19 show that Poland needs reorganisation of labour processes so that it is possible to work remotely in crisis situations (engaging new IT solutions) and at the same time that the situation of workers who do not have an employment contract is very bad. It seems that in the future, the form of employment and the possibility to work remotely will constitute an important element of the EVP. Also the way that organisations deal or try to deal with the current epidemiologic crisis will constitute an important element of the narrative concerning the description of the employer brand in the future. This factor will illustrate the actual rather than the declared attitude to the social and ethical elements of HR management. Undoubtedly, post-COVID-19 EB research will constitute an important element of an analysis of changing relationships in the labour market.

The Institutional Environment and New Venture Creation In A Transition Economy: Evidence from Poland

Justyna ZYGMUNT

Opole University of Technology, Opole, Poland, j.zygmunt@po.edu.pl

Abstract

This paper uses data from Poland to present evidence of factors influencing new venture creation in a transition economy. Specifically, the focus is on the institutional environment. Using data combined from multiple sources, a country-level dataset for the period 2006–2017 was created to study the extent to which the institutional environment impacts new firm entry in Poland. The hypothesis was tested with the Ordinary Least Squared estimation with robust standard errors. This paper contributes to the literature on venture creation, which is largely absent of transition economies studies, by providing evidence that incentives to start a firm in a transition economy are dependent on the quality of formal institutions (rule of law, government size, regulatory efficiency, open markets), control of corruption, and the perception of safety. The findings may be useful for formulating strategies and public policies that reinforce creation of new venture in a transition economy.

Keywords: Venture Creation, Transition Economy, Institutional Environment, Entrepreneurship, Formal Institutions, Informal Institutions

Introduction

Firms have been found meaningful in fostering innovation and economy development (Aidis et al., 2012). While it has been argued that entry into entrepreneurship depends on heterogeneous dimensions (e.g. Urbano et al., 2019), a great deal of interest has been devoted in recent years to the institutional environment, as it appears to play an important role in determining whether entrepreneurial initiative arises. More specifically, the institutional environment seems to have a significant influence on decisions to go into informal entrepreneurship (Autio and Fu, 2015), opportunity driven entrepreneurship (Aparicio et al., 2016), and the way entrepreneurship impacts the growth of economy (Estrin and Mickiewicz, 2010).

The issue of factors encouraging entrepreneurship seems to be particularly important in a transition economy, since creation, survival and growth of firms have been found especially pivotal for successful move from a centrally planned to a market economy (Jackson et al., 1999; McMillan and Woodruff, 2002). Although growing entrepreneurship literature devotes substantial attention to recognise how the institutional environment may relate to entry into entrepreneurship (e.g. Anokhin and Schulze, 2009), still little is known how the process of institutional change in transition economies affects firm creation. It may be attributed, at least partially, to the different paths of transition to a market economy which is followed in such economies, leading to the ambiguity in the recognition of factors influencing entry into entrepreneurship. Hence, there is limited understanding of the role that institutions play in encouraging entrepreneurship in these economies. The goal of the paper is to fill this gap by referring the extent to which the institutional environment impacts new firm entry in Poland. The influence of institutions on new venture creation was tested with the Ordinary Least Squared estimation with robust standard errors.

The article adds to the literature on the institutional environment and entrepreneurship in transition economies by investigating the consequence of formal and informal institutions for the incentives to start a new firm in Poland. This issue is relatively less studied but more important, since Poland is regarded as one of the most successful economies among these that underwent transition from a centrally planned to a market economy (Jackson et al., 1999; McDermott, 2004). Hence, focusing on

Poland may provide valuable insights into how the institutional environment may alter the incentives to be entrepreneurial in a transition economy.

The paper proceeds as follows. First section provides theoretical background and hypothesis development. Section two describes the research method, and is followed by the description of the sample and variables. Then findings are presented. Last section concludes.

Theoretical background and Hypothesis Development

A previous body of work documented that firms' creation and growth are dependent on multiple factors, especially innovation and R&D (e.g., Zygmunt, A., 2018a; Zygmunt, A., 2018b; Zygmunt, J., 2018), human capital (e.g., Klemens, 2018; Maj, 2018; Rokita-Poskart and Mach, 2019; Zygmunt J., 2019), and the institutional environment (e.g., Álvarez and Urbano 2011; Klapper et al., 2006).

The institutional environment refers to constraints, such as regulations, norms and values which are designed to shape interactions between people (North, 1990). According to Autio and Fu (2015), institutions exert an influence of whether entry into entrepreneurship and, if so, how each stage of the entrepreneurial process should be accomplished. Hence, the quality of the institutional environment may be associated with the variance in the impact of entrepreneurship on growth across regions and countries (Urbano et al., 2019). Subsequently, the extent to which the entry into entrepreneurship is dependent on the institutional environment may rely on the type of institutional factors. Formal institutions pertain to e.g., entry regulations, property right, rule of law, access to external capital (Krasniqi and Desai, 2016), while informal institutions regard to e.g., attitudes towards entrepreneurship, entrepreneurial and business skills, perception of corruption (Aparicio et al., 2016). Different dynamics between these type of institutions have been observed, with informal institutions considered as more likely to change slower that formal institutions (Estrin and Mickiewicz, 2010), and having a stronger influence on opportunity entrepreneurship (Aparicio et al., 2016).

In transition economies, the move from a centrally planned to a market economy involves the creation or rebuilding the institutional environment. At the beginning of the transition, when the entrepreneurial activity is no longer suppressed, the institutional environment mostly lacks stability and predictability which may lead to the constraints in pursuing new born entrepreneurial opportunities (Welter and Smallbone, 2011). With predominance of state-run firms and public ownership (Krasniqi and Desai, 2016), and high level of distrust (Estrin and Mickiewicz, 2010), the radical change in institutions is necessary. With growing complexity of firms' activities in a transition economy, the need for changes in formal institutions escalates (McMillan and Woodruff, 2002). This may result, in most cases, in economic liberalization reform (Peev, 2015) and, consequently, in a sharp increase of private businesses (Welter and Smallbone, 2011). However, the rate of new ventures creation may be handicapped by the volatility in formal institutions (e.g. frequent changes of regulations). That may cause confusion and uncertainty of the conditions to run a firm which, as claimed by Krasniqi and Desai (2016), may encourage firms "to "play it safe" and take fewer risk" (p. 1079). While changes in formal institutions in a transition economy may be rapid (McMillan and Woodruff, 2002), changes in informal institutions are largely less dynamic. It seems obvious since changes in informal institutions are dependent on the shift in attitudes, norms, and values (Aparicio et al., 2016) and need more time to occur. However, in a transition economy such changes may be collaterally inhibited by deeply rooted distrust and values which may not be conducive to entrepreneurship (Estrin and Mickiewicz, 2010). This suggests the following hypothesis:

(H1): New venture creation in Poland tends to grow when the institutional quality improves.

Research Method

To test the research hypothesis, the Ordinary Least Squared regression with heteroscedasticity-consistent robust standard errors was used. The model was specified as follows:

$$New\ Venture\ Creation_i = \beta_0 + Quality\ of\ Institutions_i\beta_1 + Procedures\ for\ Starting\ a\ New\ Venture_i\beta_2 + Control\ of\ Corruption_i\beta_3 + Perception\ of\ Safety_i\beta_4 + GDP\ per\ capita_i\beta_5 + FDI_i\beta_6 + \varepsilon_i \quad (1)$$

The statistical significance of the model was verified with F-test. To check for autocorrelation, the Breusch-Godfrey LM test was employed. To control for the high level of collinearity among explanatory variables, Pearson's correlation coefficient was used.

Sample and Variables

The dataset used in this paper covers a period from 2006 to 2017. In line with McDermott (2004), the country-level approach was employed. Data were combined from multiple sources: the Statistics Poland, the Wall Street Journal and Heritage Foundation, Transparency International, Eurostat, and the World Bank.

Dependent variable is *new venture creation*. While there are various ways to conceptualise a new firm birth (for more discussion see: Reynolds, 2017), *new venture creation* was measured on the basis of initial registration in the National Official Business REGON as the number of new venture recorded in the REGON per 10 thousand population. These data were taken from the Statistics Poland.

The explanatory variables are *quality of institutions*, *procedures for starting a new venture*, *control of corruption*, and a *perception of safety*.

The *quality of institutions* represents formal institutions and comprises four dimensions (rule of law (property rights, judicial effectiveness, government integrity), government size (tax burden, government spending, fiscal health), regulatory efficiency (business freedom, labour freedom, monetary freedom), and open markets (trade freedom, investment freedom, financial freedom)). In line with Autio and Fu (2015), the *quality of institutions* was measured by the Index of Economic Freedom composed by the Wall Street Journal and Heritage Foundation. This index ranges on a scale of 0 to 1, with 1 signifying the highest quality of institutions. It is expected that the *quality of institutions* correlates positively with *new venture creation*. Another variable for formal institutions is *procedures for starting a business.* As it was observed by e.g. Aparicio et al. (2016), capacity of regulations might have an impact on the incentives to start a business. Such capacity might concern the number of procedures, cost, paid-in minimal capital, time to start a new venture. As it was noticed by e.g. Alvarez and Urbano (2011), together with an increase in the number of procedures the incentives to start a new venture diminish. In this paper, *procedures for starting a new venture* is proxied by a vector of four variables: *the number of procedures to start a new venture, cost to start a new venture, paid-in minimal capital to start a new venture,* and *time to start a new venture*. It is expected that when the procedures for starting a new firm increase, the number of new firms tends to be lower. Data for *procedures for starting a business* were taken from Doing Business developed by the World Bank.

The *control of corruption* and a *perception of safety* embody informal institutions. The *control of corruption* was measured by the Corruption Perceptions Index composed by the Transparency International. This index shows perceptions conveyed by business people and country experts of the level of corruption in the public sector, and ranges between 0 and 100 (with 100 indicating an economy very clean from corruption). It is expected that a rising *control of corruption* is followed by an increasing number of new firms. A *perception of safety* is a proxy for cultural-cognitive dimension, such as e.g., required skills and risk taking. A relevant issue with measuring this

dimension is that such data for Poland are mostly not available at the country level to allow for a longitudinal study (e.g., Global Entrepreneurship Monitor, from which such data as e.g., perceived skills and knowledge to start a business, or fear of failure might be sourced, provides periodically annual country-level data for Poland starting just from 2011). Only the Statistics Poland appears to provide some scant country-level longitudinal data that might serve as a proxy for cultural-cognitive dimension. One of them is a *perception of safety* measured by a percentage of persons who believe that Poland is a safe place to live. It was assumed that an increasing perception of safety enhances confidence which transfers to greater incentives for starting a new firm. Hence, a positive relationship between a *perception of safety* and the number of new venture is expected.

Since it has been observed that the creation of new venture might be affected by the economic growth (e.g. Urbano et al., 2019), in line with Estrin and Mickiewicz (2010) a control variable is logarithm of real G*ross Domestic Product (GDP) per capita* (in euro). It is assumed that an economy with an increasing level of GDP per capita demonstrates a growing number of new firms. Another control variable is *foreign direct investments (FDI).* While the impact of FDI on entrepreneurship is still not entirely recognised, some studies provide evidence that FDI might influence entrepreneurial activity (e.g. Wach and Wojciechowski, 2016) by affecting the accumulation of technological and human capital (Anokhin and Schulze, 2009). Hence, a positive relationship between *FDI* and *new venture creation* is expected. *FDI* was measured by a direct investment (flows) as a percentage of GDP. Data for *GDP per capita* and *FDI* were taken from the Eurostat.

Descriptive statistics of variables are shown in table 1.

Table 1: Descriptive statistics of variables

Variable	Min	Max	SD	Mean
new venture creation (per 10 thousand population)	77.000	104.000	7.608	90.333
quality of institutions (Index of Economic Freedom)	0.581	0.693	0.039	0.641
procedures for starting a new venture				
number of procedures (number)	4.000	10.000	2.417	6.250
cost (% of income per capita)	12.000	21.400	3.468	16.000
paid-in minimal capital (% of income per capita)	10.700	204.400	80.567	57.075
time (days)	30.000	37.000	2.429	32.083
control of corruption (Corruption Perceptions Index)	37.000	63.000	8.512	53.917
perception of safety (%)	43.000	89.000	11.741	67.750
GPD per capita (ln, in euro)	8.985	9.377	0.117	9.191
FDI (%)	0.200	6.200	1.644	3.300

Source: Own estimation based on data sourced from the Statistics Poland, the Wall Street Journal and Heritage Foundation, Transparency International, Eurostat, and the World Bank.

Findings

Since the explanatory variables capture different aspects of the institutional environment, it is not surprising that they are highly collinear. Similar observation has been indentified in prior research (e.g. Aidis et al., 2012), and leads to some variables exclusion. Hence, the variables: *the number of procedures to start a new venture, cost to start a new venture,* and *paid-in minimal capital to start a*

new venture were excluded as highly correlated, leaving *time to start a new venture* as the representative for the *procedures for starting a new venture.* The issue of multicollinearity in other institutional variables was addressed by entering each of these variables into a separate regression. That approach allows avoiding an arbitrary exclusion of variables and is in line with previous studies (e.g. Klapper et al., 2006). However, since *time to start a new venture* shows no multicollinearity with the other explanatory variables (except for the *perception of safety*), this variable was included in first two estimated models (which did not count for the *perception of safety*). In controls, *GPD per capita* was excluded as highly correlated with most explanatory variables.

Results of estimation are reported in Table 2.

Table 2: Estimation results

	Model 1 *quality of institutions*	**Model 2** *control of corruption*	**Model 3** *perception of safety*
const	43.3836*	65.2641***	78.3874***

Source: Own estimation based on data sourced from the Statistics Poland, the Wall Street Journal and Heritage Foundation, Transparency International, Eurostat, and the World Bank.*

In Model 1, the impact of *quality of institutions* on the *new venture creation* was tested. As it was assumed, the results show that the effect of the raising quality of institutions on the number of new venture recorded in the REGON per 10 thousand population in Poland is positive and statistically significant. The Hypothesis 1 is supported. Interestingly, *time to start a new venture* shows no relevancy for new venture creation, which is contrary to the research expectations. The results for the control variable are consistent with the research assumptions, as the positive, statistically significant relationship between FDI and the firm birth has been found.

As Model 2 (in which the relationship between *control of corruption* and the *new venture creation* was tested) reveals and as expected, together with the growing freedom from corruption the number of new born venture increases. The Hypothesis 1 is supported. The results for the *time to start a new venture* are the same as in Model 1 – they are not significant. Contrary to Model 1, the results for the control variable, while showing expected sign, are not statistically significant.

The results for Model 3, in which the influence of *perception of safety* on the *new venture creation* was tested, provide support for Hypothesis 1. As expected, the *perception of safety* relates positively to the number of new venture recorded in the REGON per 10 thousand population in Poland. The results for FDI are consistent with the research assumptions and found statistically significant.

The findings provide mixed support for the assumption about the relationship between the institutional environment and new venture creation in Poland. While the role of formal and informal institutions in driving firms creation seems to be uncontested when *quality of institutions, control of corruption*, and a *perception of safety* are regarded, the findings indicate that time needed to register a firm has not a direct significant influence on starting a new firm. This observation does not confirm prior research in which the impact of capacity of regulations (such as the number of procedures or time needed to start a new firm) on the incentives to start a business has been identified (e.g. Aparicio et al., 2016). However, with most of previous research not focusing on transition economies, a possible explanation of this lack of consistency could lie in the mediating role of other factors, most likely human capital, that might explicate the insignificance of time needed to register a firm to persons who are exposed to meet formal regulations when starting a firm in a transition economy. The findings also show that the improvement of the quality of institutions has a direct effect on the incentives to start a new firm and may increase the entry into entrepreneurship in Poland. This observation is in line with the previous studies which documented the relationship between the efficiency of the regulatory processes and the entry rates of new firms (e.g. Autio and Fu, 2015).

The findings also suggest that informal institutions could play a significant role in entry into entrepreneurship in Poland. More specifically, it has been demonstrated that when the freedom from corruption rises in a transition economy, the incentives to start a new firm grow. This view is consistent with other studies on the institutional environment in transition economies (e.g. Estrin and Mickiewicz, 2010), providing evidence on the positive relationship between the control of corruption and new venture creation. It has been also confirmed that cognitive aspects are principal in decisions for starting a new firm in a transition economy. Increasing perception of safety could provide the foundation for the incentives to be entrepreneurial. These findings support the view that informal institutions are important in driving entrepreneurship in transition economies (e.g. Krasniqi and Desai, 2016).

Conclusions

In this paper the effect of the institutional environment of new venture creation in Poland has been investigated. Multiple data sources were combined to create a country-level dataset. The paper provides evidence that the quality of the institutional framework built (or rebuilt) after the collapse of a centrally planned economy matters in entry into entrepreneurship. In particular, this paper contributes to the literature by confirming that the motivation to create new venture in Poland is heavily dependent on the following aspects of the institutional environment: quality of formal institutions (rule of law, government size, regulatory efficiency, open markets), control of corruption, and the perception of safety. However, the findings note that, interestingly, such relationship is not as intuitive as it might be anticipated. Specifically, although prior research indicates that time needed to register a firm has influence on the motivation for starting a firm, this link seems to not be evident if Polish economy is considered.

This study has several implications for practice. The findings may be useful for formulating strategies and public policies that reinforce creation of new venture in a transition economy. In order to develop effective and appropriate economic growth strategies, the policymakers should be conscious of those institutional factors which seem to be fundamental to generate and increase the incentives for starting a new venture. Focusing policy on creating a more beneficial institutional environment mostly by reducing the burden imposed by formal institutions, and by encouraging and supporting entrepreneurial attitudes, might account for economic development of a transition economy.

Some limitations of this study should be acknowledged. First, a cultural-cognitive dimension was assessed by measuring the perception of safety. While it seems legitimate since, as it has been observed in previous studies, the level of security might weight to the creation of new firms (e.g. Audretsch and Belitski, 2015), it does not allow to capture the other informal institutions in Poland (business skills and leadership in particular) which are likely to affect the entrepreneurial process. Further research would benefit from examining the extent to which entrepreneurial skills and

knowledge in a transition economy apply to the entry into entrepreneurship. Second, the paper focuses on new venture creation regardless of the form of entrepreneurship. While it enables to investigate the overall significance of the institutional environment, additional research would benefit from focusing on opportunity and necessity driven entrepreneurial activity.

Socio-economic Determinants of Saving for Old Age in Europe: Is Profession an Important Factor? The case of Poland

Damian WALCZAK

Nicolaus Copernicus University in Torun, Faculty of Economic Sciences and Management, Torun, Poland, dwalczak@umk.pl

Abstract

Numerous factors have an impact on old-age savings. Among them, we may distinguish the key ones, such as gender, income, education and age. Those major factors include pensions guaranteed by the state, i.e. the 'generosity' of pension systems. The correlation between old-age savings and state-guaranteed pensions varies depending on the country. The paper points out the fact that, when seeking to equalise their lifetime income, professionally active persons tend to adjust the value of additional voluntary old-age savings to the level of state-guaranteed social security benefits. Thus, there is a correlation between lifetime income and old-age savings. The research presented in the article is part of two representative surveys: 1) 'Household Finance and Consumption Survey' (2nd wave, carried out in 18 Eurozone countries as well as in Poland and Hungary) and 2) 'Social Diagnosis' (conducted in Poland). The paper uses a logistic regression model to analyse the determinants of old-age savings.

Keywords: Pension Privileges, Social Security, Savings, Income.

Introduction

Many factors affect saving for old age. At the beginning, let us mention having children – a factor that has historically been perceived as a form of this saving (Haber, Gratton, 1993). The fact of having children negatively affects saving for old age, as children can be a way of ensuring old-age security that is alternative to making savings (Hammer, 1986). Education and financial awareness are the next factors which influence saving. Education, just like possessing other financial products, has a positive effect on saving for old age (Tavor and Garyn-Tal, 2016).

The level of saving is also related to gender and age (Pieńkowska-Kamieniecka, Walczak, Bera, 2019). Men, along with the elderly, are more likely to save for old age. In the case of elderly people, it is worth noticing that the increased amount of old-age savings is related to the reduction of other savings, such as, for instance, those made by purchasing durable goods (Fernández-López, 2015). Furthermore, Burney and Khan (1992) raise the question of different saving forms practised by residents of villages and cities.

As far as another variable, 'income', is concerned, a link can be found between income and the level of savings. Persons earning better tend to save more (Burney and Khan, 1992). However, when analysing the level of savings, it is equally important to refer to the subjective criterion of satisfying household needs. Income growth is accompanied by an increase in consumption, which means that an increase in the available income is not directly related to increased savings (Jappelli and Pistaferri 2010). Therefore, answering the question analysed in a further section of this work – 'Is the current level of income sufficient for the current level of consumption?' – may provide exhaustive information with regard to the financial situation of the household (Walczak, Pieńkowska-Kamieniecka, 2018).

According to the existing research, pension beneficiaries display various approaches to their social protection and apply different strategies when it comes to saving for old age. Kokrda, Sheran and Cramer (1996) indicated that profession plays an important role in the case of old-age savings. The authors observed that when the tax rates go down, these kinds of savings tend to rise. This is not solely due to the possibility of spending more money on saving, but also results from the predictions that future public benefits to be obtained from the pension scheme will probably be lower. Euwals (2000)

also pointed out to the relationship occurring between the pension scheme and pension savings. According to the author, pension rights negatively affect old-age savings. Similar evidence was provided by Galasso et al. (2009), who stressed the fact that the level of the state-guaranteed retirement insurance (related to the profession performed) negatively affects pension savings, e.g., individual savings for old age. However, Feldstein (1976) indicated a dual impact (indeterminate effect) of the public pension scheme on private savings. Hence, financial behaviour, including savings, depends on the generosity of pension systems (Lusardi, Mitchell, 2011).

This paper presents the generosity of the pension systems in Poland. This generosity also results from pension privileges, which are an essential part of each pension system (Armeanu, 2010; Inglot, 2016), mainly in post-Soviet states (Gugushvili, 2015). According to the World Bank, for financial and transparency reasons, these privileges should be eliminated (World Bank, 2005). In many European countries, such as the Czech Republic, Lithuania and Slovenia, privileges have already been limited (Armeanu, 2010; Barbu, 2016; Guardiancich, 2013).

Unfortunately, in Poland numerous privileges still persist (Jedynak, 2017). Persons working on employment contracts or civil law contracts are covered by the general pension system. However, within this system, some professional groups have obtained special privileges and thus can be referred to as 'privileged' (Armeanu, 2010). These groups include, for example, miners (they receive higher, than in general pension system, pension benefits and can retire after 25 years of work) or persons performing work in particularly difficult conditions who may receive the so-called 'bridging pensions'. The privileged system also includes parallel systems which function alongside the general system: the provision pension system and the agricultural pension system. Uniformed services, as well as judges and prosecutors, share a non-contributory provision pension system in Poland. Farmers as well as persons supporting them in farm works belong to a separate system – the agricultural pension system. Each of these privileges comes down to gaining more favourable terms with regard to retirement age, the amount of pension contributions paid, and the rules applied for calculating retirement benefits.

Given all the information provided in this section, the objective of this paper is to determine the social-economic determinants of savings for old age in Europe and to present the level of savings for old age of the beneficiaries of the pension privileges in Poland.

Thus, the following hypotheses were assumed:

H1: Social-economic determinants have an impact on old-age saving decisions.
H2: Savings for old age are dependent on the level of social security benefits which results from the profession performed.

Old-age savings in Europe. Data and Methodology

This paper was based on data provided by the 'Eurosystem Household Finance and Consumption Survey' (HFCS). This research (2nd wave) was carried out in 18 Eurozone countries, as well as in Poland and Hungary. More than 84,000 households were surveyed (the least from Malta – 999, the most from France – 12,035, and 3,455 in Poland), including over 200,000 individual household members. Household interviews were carried out between the end of 2011 and mid-2015, and, as stated by the European Central Bank, "all HFCS country surveys have a probabilistic sample design. This means that each household in the target population has an ex ante defined non-zero probability of being part of the sample". The aim of the study was to collect household financial statements (household finances, assets and liabilities) about households in Europe, coming from the main household respondent, who is called the financially knowledgeable person, and from members of these households (for more details, cf. ECB 2016). We studied the question connected with old-age savings, phrased as 'Do you have voluntary pension scheme?'.

The analyses of the presented data were made using a logistic regression model (Cramer, 2013), which allowed us to determine the impact of the individual characteristics of households (or of heads of those households) on their chances to save. The dependent variable used in the model, which was having a

voluntary (personal) pension scheme, was a dichotomous (i.e., a binary) variable and took the following form: 1 if a person has voluntary pension scheme and 0 if otherwise.

All data was analysed with the use of the IBM SPSS Statistics 24 software. Based on the data provided by HFCS, nine independent variables were analysed in this work (Table 1). A backward stepwise selection method was used to eliminate the insignificant variables (table 2). Among the analysed variables were values characterizing households (e.g. 'Income') as well as those concerning the financially knowledgeable person (e.g. ‘Education’, ‘Marital status’ or ‘Gender’). The majority of the variables (such as ‘Gender’, ‘Age’, ‘Marital status’ or ‘Education’) do not require explanation as their nature is evident. The variable of 'Income' needs a more detailed description. In this case, the annual gross income of a household from the last 12 months (in EUR) was analysed. This variable was divided into 4 income groups on the basis of the quartiles.

Table 1: Descriptive statistics for the independent variables

Variable	Variable description	Nature of the variables	N	M
Job (number)	More than one job	0 = Yes	4,096	0.95
		1 = No	78,829

The results published and the related observations and analysis may not correspond to results or analysis of the data producers.").

Old-age savings in Europe: results and discussion

While analysing ownership of voluntary pension schemes in Europe, all independent variables indicated in the model were significant (table 2). As concluded in the previous research, older persons and persons obtaining higher income are more likely to save for old age. For instance, the chances for owning savings by people aged 36-50 are higher by as much as 83.2% when compared to people aged 18-24. Income growth in households greatly increases the chances for owning savings for old age. In households where the income falls into the second quartile, the chances for owning savings are higher by 47.4% than in households with lower earnings. A similar positive impact on savings can be observed for education. However, in this case the differences are visible while comparing people having completed the first stage of third-cycle education with those who only have primary education. As for marital status, married people tend save more often. Their chances for owning savings are higher by 21.2% in comparison to single persons.

Work-related factors also have a positive impact on savings. The chances for owning old-age savings by persons who have one job, as compared to those who have more than one, are lower by 36.8% (cf. 'Job (number)'). On the other hand, the chances for having savings in the case of people employed on fixed-period contracts are lower by 21.2%, compared to persons having indefinite time contracts (cf. 'Contract'). As for profession, in accordance with the ISCO classification, we can see that one statistically significant category of professions (Technicians and Associate Professionals) saves evidently more often than the base category, i.e. the Armed Forces Occupations. In this case, the insignificance of the majority of categories makes it impossible to perform a comprehensive analysis of the impact of the profession factor and the generosity of the system associated with it. The base category (the Armed Forces Occupations) is entitled to some form of pension privileges in almost all countries. Hence, making reference to this category would allow us to determine whether security for old age guaranteed by the state has an impact on old-age savings. Unfortunately, the insignificance of the variables does not allow drawing far-reaching conclusions (the pension generosity factor will be further analysed on the basis of the 'Social Diagnosis' in Poland).

The presented in table 2 values are characteristic for the 20 countries studied. It would be interesting to present the models and results for particular countries as well as to analyse the impact of certain factors on savings. Such analysis could be performed based on the HFCS research or based on a more representative study on a larger group of respondent in each country. Hence, the following sections of this paper will present an example of such study, i.e. the 'Social Diagnosis'.

Old-age savings in Poland. Data and Methodology

The research presented in the article is part of a representative survey conducted in Poland in 2015, called 'Social Diagnosis' (Social Diagnosis, 2015). It is a panel study. The study has been conducted on a regular basis since 2000, and starting from 2003, the analysis is done every two years. In 2015, the study examined 11,740 households and 22,208 individual members of those households. The research was conducted in March and April by professional interviewers of the Central Statistical Office. Additionally, the results were appropriately weighted in order to preserve their representative character, both nationwise and when applied to each Polish province and the different categories of place of residence (for more information about the research method, cf. Czapiński and Panek, 2015). In order to extend the interpretive capacity of the study, the household data was compared to data concerning heads of household.

As in the case of data excerpted from the 'Eurosystem Household Finance and Consumption Survey', the analysis of the impact of privileges on saving in Poland is based on a logistic model. Two logistic regression models were used, one dependent variable being 'having savings for old age', and the second one, 'having any savings'.

Based on the data provided by the 'Social Diagnosis', eight independent variables were analysed in this work (Table 3). A backward stepwise selection method was used to eliminate the insignificant variables (Table 4). Respondents (heads of households) were divided into four professional groups. This was done in order to present the results of the study in reference to each of the privileged groups. The classification was based on the profession criterion (current profession, or previous profession, in case of persons who are no longer professionally active) and included the following:

1) miners (N=493),
2) persons covered by the provision pension system (firefighters, policemen, military personnel, etc., as well as judges and prosecutors) (N=375),
3) persons covered by the agricultural pension system (farmers, etc.) (N=1,539),
4) other persons covered by the study (N=9,317).

Table 3: Descriptive statistics for the independent variables

Variable	Variable description	Nature of the variables	N	M
Professional	Professional group	0 = Others	9,317	0.49
		1 = Miners	493

Old-age savings in Poland confronted with the generosity of pension systems: results and discussion

The uniformed services, as well as judges and prosecutors do not make savings for old age, which probably stems from the fact that those professionals do not feel the need to save for this purpose, as their pension insurance is already (more than) sufficient. It confirms the hypothesis presented in the introduction, which concerned the impact of old-age security guaranteed by the state on savings. People tend to compensate the level of income in their lives, and in this case they do not need to do it. When they retire, both the uniformed services officers and judges and prosecutors are guaranteed a level of income which is not only above the minimum wage, but also at a level comparable to the income previously earned Farmers save for old age for the opposite reason, since this group receive pensions which are even a few times lower than those received, for instance, by judges.

A better assessment of one's financial situation has a positive effect on increasing their savings. As we will show for other variables, income has a greater impact on having savings in general, than on making savings specifically for old age. The financial situation of a family primarily affects the decision whether to save at all, rather than deciding on a specific form of saving, in this case saving for old age. Similar to other countries, men in Poland are more inclined to save for old age than women. Gender, just like income, has a greater impact on having savings in general than on saving only for old age. Also, the place of residence determines the level of savings. The chances for owning old-age savings for rural areas residents are about 36.7% lower than for those living in large urban areas. With regard to owning any savings, these chances are about 31.8% lower. While analysing the 'Age' variable, it can be stated that the amount of savings depends on the age of the head of the household. The chances of owning old-age savings increase by 3.3% with each year of age, and the figures are slightly lower (2%) in the case of owning any savings.

The study also shows that the fact of having children, just like having pension privileges, reduces the chances to possess additional voluntary retirement savings. People who possess some insurance also tend to have more and more savings, as they are more aware of everyday risks affecting everybody (which the insurance may protect them against). It is also probably related to the fact that savings are consistent with other financial products (Tavor and Garyn-Tal, 2016).

In Poland risk (including financial risk) has a positive impact on savings. In households having insurance, the chances of having savings are higher by as much as 45.2%. However, this relationship does not occur with regard to saving for old age. In this case, the need to save is not determined by possessing additional financial knowledge. Savings for old age, as opposed to 'Any savings', do not increase in the more financially aware households. This is also partly confirmed by the 'Education' variable. According to previous studies, education plays a significant role in saving in Poland. Our study shows that every single year of education increases the chances of having savings by as much as 11.8%. However, in the case of saving for old age, this variable plays a less significant role. Each subsequent year of education increases the chances of having these savings by an overall of 5.1%.

Conclusions

In both Europe as a whole and in Poland, many variables influence old-age savings, which supports the hypothesis (H1), stating that social-economic determinants have an impact on old-age saving decisions.

This work shows that age (both in Europe and in Poland) and education (education level in Europe, the number of schooling years in Poland) increase the chances to save for old age. In both studies, income plays a significant and powerful role for this type of savings. Yet, as indicated in our study, a subjectively estimated financial situation has an evidently greater impact on old-age savings than the income declared in a given currency. Income growth does not necessarily lead to an increase of wealth, as increased income is always accompanied by increased consumption. Taking into account all aspects of this variable, it may be observed that income growth has an impact on the frequency of saving for old age (the case of Europe), but the sense of financial security turns out to be much more important (the case of Poland).

Depending on the generosity of the system, being entitled to privileges affects saving for old age in Poland. Those who benefit from privileges related to the retirement age and the pension amount, i.e., the uniformed services, judges and prosecutors, are less likely to save for their retirement than 'ordinary' working people. Meanwhile, farmers who are considered to benefit from pension privileges, save for old age much more than the rest of the population. Their privilege comes down to the low contribution they pay, and small benefits motivate them to take individual precautions.

The results of our study may indicate that Poles are rational while planning their income over a lifetime, at least if we take into consideration the impact of profession and the generosity of the system on making pension decisions. Persons who are better protected by the state in the scope of pensions can make less individual savings, and, in fact, do save less for old age. Persons granted a weaker protection within the pension system need to save more for old age and they actually do. Those who decide whether to invest in additional protection for old age take into account the level of future benefits guaranteed by the state. So, the research results support the hypothesis (H2), stating that savings for old age are dependent on the level of social security benefits related to the profession performed.

Acknowledgment

This paper uses data from the ‘Eurosystem Household Finance and Consumption Survey’. The results published and the related observations and analysis may not correspond to results or analysis of the data producers.

Assessment of The Creative Culture and Level of Innovation in A Company- Case Study

Kamila TOMCZAK-HORYŃ

Opole University of Technology, Poland, k.tomczak-horyn@po.edu.pl

Abstract

This study presents a method of assessing the creative culture in a company. The aim of the concept is to support managers in building a creative workplace. The study uses a non-standard research methodology involving a creative culture questionnaire and an innovation questionnaire. The methodology is universal and can be applied in innovative companies.

Keywords: Hierarchy of Needs, Pro-Creative Culture, Level of Innovation.

Introduction

Subject literature on motivation includes various concepts of and empirical evidence for employee motivation as a key determinant of a company's success and development (Hunter, Schmidt 1996). An innovative company should encourage its employees to be creative, as creativity plays an important role in corporate processes and stimulates the company's development. Combined with knowledge and social competences, creativity is the first step in the establishment of innovation (Luecke 2003, Tomczak-Horyń, Knosala 2017). Consequently, managers should take care to build an appropriate organizational culture that stimulates creativity among the employees and improves their engagement in designing innovative solutions. Such a culture should encourage every employee to express his or her opinion freely, experiment, take risks, and admit to making mistakes without fear of punishment (Dyer, Gregersen, Christensen 2011). Organizational culture is also affected by factors such as safety, support for innovation, clearly-defined goals, and task orientation (West 1997). It is important to determine the foundations of creative culture in the company in order to assess the current level of creative culture and determine the areas that need strengthening to obtain the highest possible level.

To help assess the creative culture in a company, a hierarchy of needs was designed based on A. Maslow's hierarchy of needs. According to Maslow, human beings have various needs that can be divided into groups according to their importance: physiological needs, safety needs, love and belonging, esteem, and self-actualization (Maslow 1948, 2017). Needs are our primary motivational force (Uysal, Genc 2017). Maslow's theory states that a human being will only reach for a higher group of needs once the lower needs have been fulfilled (Maslow 1948, 2017). From the viewpoint of an enterprise, physiological needs correspond to appropriate pay and environmental working conditions. Safety needs correspond to the continuity of employment and good employee benefits. Love and belonging concerns social processes; it is the need to form attachments to and be accepted by co-workers. In a company, employees must have a sense of belonging to a team. Esteem corresponds to self-respect and a positive image of oneself and the need to be respected by others. Managers can help to fulfill this need by ensuring that the employees are appropriately motivated and given ambitious tasks that provide a feeling of success. The final category, self-actualization, involves self-development through working towards a promotion (Griffin 2012, Tomczak-Horyń 2020).

The hierarchy of needs according to creative culture contains microfoundations, such as creative working conditions, support from management staff, a positive group of co-workers, rewards for creative actions, and challenges.

Hierarchy of needs from the perspective of creative culture in a company

The first stage of determining the hierarchy of needs related to a creative culture was to analyze the component categories of a creative climate described in a study by Knosala, Tomczak-Horyń, and Wasilewska (2019). The characteristics of creative culture were divided into categories corresponding to levels in a hierarchy of needs. Each level was assessed using appropriate questions included in a creative culture questionnaire (Figure 1).

Fig. 1:Hierarchy of needs within the creative culture of a company

The first level encompasses the basic working conditions that stimulate creativity. These include establishing an appropriate post, allowing the employees to carry out their tasks freely, providing training in creativity and innovation, and establishing the goals and expectations related to creative processes in the company (Tomczak-Horyń 2020).

The second level encompasses support from the management staff. Steps should be taken to make sure that the managers acknowledge and strengthen creativity. Communication between managers and subordinates should be open and effective (Hunter, Bedell, Mumford 2007, p. 105).

The third level is related to a positive group of co-workers that focuses on teamwork (Tomczak-Horyń 2020). Such a group should be supportive, intellectually stimulating, trustworthy and open-minded, and have a good sense of humor and good communication skills. The members of the team should feel well-integrated with the company (Hunter, Bedell, Mumford 2007, p. 105).

The fourth level concerns rewarding creative initiatives by designing a system of motivations for creativity.

The final level of the pyramid of needs encompasses challenges. Each employee should be given tasks that are interesting and challenging, and that support his or her self-development (Tomczak-Horyń, Knosala 2019b).

Creative Culture Questionnaire

A questionnaire was designed based on the hierarchy of needs related to creative culture (Tomczak-Horyń 2020). The questionnaire contains 13 questions concerning each microfoundation of creative culture (Table 1). In questions 9 and 11, the respondents can choose from a selection of types and forms.

Table 1: Questions included in the creative culture questionnaire

Category of needs	No.	Question
CREATIVE WORKING CONDITIONS	1	Are the employees able to allocate some of their work time for creative actions?
	2	Can the employees carry out their tasks freely?
	3	Have any goals or expectations concerning creative processes in the company been set?
	4	Does the company have a break room for the employees?
SUPPORT FROM THE MANAGEMENT STAFF	5	Does the company conduct training in creativity and innovation?
	6	Do the employees submit their ideas for improvement?
	7	Does the company have an idea box or an IT system for managing ideas?
POSITIVE GROUP OF CO-WORKERS	8	Are there dedicated work teams for specific tasks?
	9	Does the company make use of creative problem-solving methods?
		If so, what methods are used most often (brainstorming, crushing, De Bono Six Thinking Hats, analogies, etc.)?
REWARDS FOR CREATIVE ACTIONS	10	Are there competitions held for the best idea or improvements for the company?
	11	Are the employees rewarded for implementing the ideas they submit within the company?
		If so, what types of rewards are given (bonuses, vouchers, integration trips, in-kind prizes, etc.)?
CHALLENGES	12	Does the company offer development programs and individual career paths for employees?
	13	Is there in-house staff responsible for mentoring and coaching the employees?

The level of creative culture and innovation is assessed on a five-point scale, where 1 denotes a very low level and 5 denotes a very high level (Table 2). One point can be scored for each question in the creative culture questionnaire.

Table 2: Indicators of creative culture and innovation in a company

Level		Points
V	very high	12-13
IV	high	9-11
III	average	6-8
II	low	3-5
I	very low	1-2

A score between 12 and 13 points indicates a very high level of creative culture in the company.

Innovation Questionnaire

The innovation questionnaire consists of 13 questions (Table 3) divided into four categories:

1. Company development and investments (questions 1–3);
2. Innovations implemented in the company and forms of funding innovations (questions 4–6);
3. Company initiatives related to the implementation of innovative solutions (questions 7–8);
4. Methods and techniques of lean production (questions 9–10).

Both closed-ended and semi-open questions are used. In questions 4, 9, and 13, respondents can choose more than one answer. Innovation in a company is assessed by means of a semi-structured interview (Blandford 2013) in the form of a personal conversation. Additional questions not included in the interview plan may arise during the interview.

The level of innovation is also assessed on a five-point scale. Four points can be scored for question 4 and one point can be scored in each of the other questions.

Table 3: Questions included in the innovation questionnaire

Category	No.	Question	Answers				
Development and investments	1	Has the company's economic situation improved?	yes	no			
		How would you evaluate the company's economic condition?	greatly improved	improved	unstable, changing	gradually worsening	rapidly worsening, endangering the company's operation
	2	In recent years, employment in the company has...	increased	remained the same	decreased		
	3	Has the company made any investments within the last three years?	yes (please specify)	no			
Innovations and forms of financing innovations	4	What type of innovations did the company introduce between 2016 and 2019?	product-related	process-related	organizational	marketing	none
	5	Did the innovations introduced between 2016 and 2019 have a novelty value on the market?	yes	no			
	6	Does the company allocate funds exclusively for innovative activity?	yes	no			
		What forms of financing does the company use?					
Plans related to innovative activity	7	Is the company planning to carry out innovative processes between 2020 and 2023?	yes (please specify)	no			
		What are the company's plans regarding innovative activity?	increase	no change	decrease		
	8	Are there any barriers to innovative activity in the company?	yes	no			
		What is the most significant factor that discourages the company from making innovative decisions?	high operational costs	difficult access to market information	insufficient technical knowledge	high risk of failure	other
Methods and techniques of lean production	9	Does the company conduct training in the improvement of production processes and system?	yes	no			
	10	Does the company implement methods and techniques of lean production?	yes	no			
		What methods and techniques of lean production are used in the company?	Quality Function Deployment	Total Quality Management	continuous development (Kaizen)	Lean Six Sigma	Total Productive Maintenance
			5S	Single Minute Exchange of Die	Just in Time	other	

Assessment of Creative Culture in A Large Construction Company

Creative culture and innovation were assessed in a large construction company specializing in the production of security and access control systems. The assessment was conducted among nine high-ranking employees, including the Information Flow Leader, Head of the IT Department, Lean Specialist, Health and Safety Specialist, Logistics Specialist, Constructor, Technologist, and Manufacturing Engineer. A semi-structured interview was conducted with the Information Flow Leader. The other employees completed electronic versions of the innovation questionnaire (Tomczak-Horyń, Knosala 2019) and the creative culture questionnaire. The average time to complete the questionnaire was 10 minutes.

The company scored 10 points in terms of innovation, which indicated a high level of innovation. In recent years, the company's financial situation has improved while the number of employees has remained the same. Lately, the company purchased a machinery park. Between 2016 and 2019, the company introduced innovations related to products, processes, and organization. However, they did not have a novelty value on the market. The company allocates some funds exclusively for innovation. Among the factors that had a negative impact on innovative decision making in the company, the respondents listed high operational costs, difficult access to market information, high risk of failure, and limited means of promoting a new product. The company is considering introducing innovative processes and increasing innovative activity between 2020 and 2023. Currently, the company is conducting training on the improvement of products and systems. It also applies lean production methods and techniques, including Total Quality Management, continuous improvement (Kaizen), Lean Six Sigma, Total Productive Maintenance, 5S, Single Minute Exchange of Die, and Just in Time.

Next, creative culture in the company was assessed based on the aforementioned hierarchy of needs. Most of the categories of needs related to creative culture were fulfilled. The first category concerns working conditions that support creativity. The employees of the company are able to dedicate some of their work time to creative actions, and are free to carry out their tasks the way they want. On the other hand, no goals or expectations related to creative processes in the company have been set. Furthermore, the company does not have a break room for the employees.

The second category of needs concerns support from the management staff. Currently, the company does not organize training in creativity or innovation. However, the employees are showing initiative in introducing innovative solutions and submitting their ideas for improvement. A system for supporting idea management has also been implemented.

The third category of needs concerns a positive group of co-workers that focuses on teamwork. The company forms work teams and applies creative problem-solving methods, primarily brainstorming and analogies.

The fourth category concerns rewards for creative behavior. The company holds competitions for the best ideas for improvement. If an idea is implemented, the employee who suggested it is rewarded with a bonus and vouchers. The company also arranges trips and organizational meetings.

The fifth category of needs is challenges. The company does not take any action in this respect.

Each level of the pyramid of needs related to creative culture has its own characteristic factors, which correspond to the questions included in the creative culture questionnaire. In Figure 2, the microfoundations that need improvement in order to achieve a high level of creative culture are marked in white.

Fig. 2: Creative culture of a large construction company

The company scored 8 points in the assessment of creative culture. According to the scale used, this indicates a moderate level of creative culture. Most of the categories of needs have not been fulfilled. The company should establish goals and expectations related to creative processes and create a break room for the employees. The company also should organize training in creativity and innovation. The final category of needs has not been fulfilled. The company does not offer its employees any individual development plans or career paths. Furthermore, there is no staff responsible for coaching and mentoring the employees.

Summary

This study used a research methodology involving questionnaires. The methodology is universal and can be applied in innovative companies. The level of innovation was assessed using an appropriate questionnaire. The article also presents a method of assessing creative culture in a company. The method uses a pyramid of needs composed of the microfoundations that make up a creative culture. The creative culture questionnaire was designed based on this pyramid.

Creative culture was assessed in a large construction company specializing in the production of security and access control systems. The assessment indicated the areas that the company needs to strengthen in order to obtain the highest possible level of creative culture.

Research on creative culture in companies will be continued. Selected manufacturing and services companies of different sizes will be assessed. The research will primarily include innovative enterprises that introduced innovations related to processes, products, organization, or marketing between 2016 and 2019. The aim of the research will be to validate the assumption that introducing innovative solutions in a company is impossible without an established creative culture. The results of the research will be provided in future publications. Currently, another study is ongoing to validate this assumption. Its results will be provided in future publications.

Abstract

State regional policy in all countries is aimed at ensuring balanced territorial development. In this connection, the main vector often comprises of the equalization of levels of social and economic development, a decrease in differentiation, which is achieved using various economic and administrative tools.

Keywords: Regional Development, Equalization, State Regional Policy.

Introduction

Almost all nations of the globe, regardless of the size of the territory, are faced with regional differentiation issues. The uneven development of territories leads to an increase in migration flows towards more prosperous ones as well as to increase in social strain in less developed regions and their further degradation. Considering the above, the authorities of all countries of the world note the problems of leveling the levels of social and economic development as a threat to economic and national security.

Main part

The development of each state is associated with building relationships between central authorities and regional governments. In federal states and integration associations, the authorities are faced with the issue of ensuring the uniform development (as far as possible) of the entire territory. Thus, the challenge arises of ensuring balanced regional development.

The main tools of state stimulation of regional development and equalization of the corresponding social and economic levels can be divided into two main types that are used in symbiosis: administrative and economic ones (some authors also distinguish social and psychological) (Timofeeva O.G., Kovarda V.V., 2019). Mechanisms and tools are built on the basis of the principles of regional development policy and mechanisms for their implementation (Khodachek A.M., 2016).

In Russia, the state regional policy evolved through a number of stages, and the functions of governing bodies of the constituent entities of the Russian Federation also transformed. Currently, the main tools for stimulating regional development are transfers and territories with special legal status, which can be attributed to economic mechanisms, while they are combined with administrative tools.

In general, foreign and domestic experience proves that the state regulation of economic and social development and regional economic policy often give a much greater effect than a centralized impact.

The most successful option is a coordinated combination of centralized and regional impact on business entities, in which the centralized impact plays a strategic, guiding role, and most economic and social tasks are implemented at the regional level through a specific social and economic policy of the regions (Sidorenko O.V., Bondarenko T.N., 2014). Sustainable and balanced development of the national economy can be achieved only with the creation of the necessary conditions and prerequisites for the development of regional economic systems through the activation of endogenous factors (Uskova T.V., Voroshilov N.V., 2015). The above requirements are implemented through the use of a set of instruments of state influence on the regional social and economic system.

There are many options for classifying instruments of state regulation of regional development, the main of which can be represented as Figure 1.

METHODS AND TOOLS OF STATE REGULATION OF REGIONAL DEVELOPMENT				
Classification feature	*By tools (areas) of impact*	Forecasting, planning, development programming	Fiscal system	Use of various regulatory tools, creation of special zones and territories
	By the nature of impact	Direct and indirect	Active and passive	Stimulating and limiting
	By management level	Macroeconomic policy tools	Mesoeconomic policy tools	Microeconomic policy tools

Fig. 1: Methods and tools of state regulation of regional development

Some authors draw attention to the advisability of grouping all tools and methods of state regulation of regional development into two groups: economic and administrative; in this case, the classification can be represented as Figure 2.

Fig. 2: Classification of tools and methods of state regulation of regional development into two groups

Others note that the content of the state regional policy consists of the coordinated implementation of two independent policies: regional and selective. The regional policy is aimed at creating common prerequisites for regional development, selective regional policy is an independent type of regional economic policy, and it is formed on the basis of public goals and priorities outlined in the concept of territorial development of the country, which sets strategic guidelines for spatial development (Figure 3) (Kovarda V., Laptev R., 2018).

The selective regional policy is the conscious activity of government bodies, consisting in the selective influence on certain territories, in order to achieve an effective and/or even distribution of economic activity across the country (Kovarda V.V., Laptev R.A., Nekhoroshikh I.N., 2019).

Fig. 3: Main types of selective regional policy

The stimulating regional policy is primarily implemented in economically developed countries in relation to depressed industrial and agricultural territories, and limiting policy is implemented in relation to overpopulated urban areas.

Polarizing selective policy is aimed at stimulating regions with the greatest economic development potential in order to maximize national income (these regions are considered as "locomotives of economic growth" or "growth poles"), and it is used primarily in economically developing countries (Kovarda V., Laptev R., 2018).

Some authors distinguish differentiated approach to the regulation of regional development, considering the elements of a certain set as independent objects of management (Shevyakin A., 2018). An important aspect of the differentiated approach of the state's regional policy is the typology of regions, i.e. their classification by a certain feature.

Within the framework of selective economic policy and differentiated approach, the state uses a system of administrative and economic tools at all management levels. In modern conditions, it is the combination of mechanisms of state regional policy, their timeliness and focus that the effectiveness of the measures implemented depends on.

An important tool for implementing the goals of regional and local policies is the full development of local self-government and its equitable and constructive interaction with regional authorities (Chaplygina M.A., Dobrinova T.V., Bolycheva E.A., 2019).

In general, the government of each state pursues a regional policy based on relevant laws and regulations, state strategies, programs and investment projects aimed at narrowing the gap between the levels of socio-economic development of regions. Ways to solve regional problems vary in different countries, but some common features can be identified. In many countries, the main functions of state regulation of regional development are performed by one or more authorized central agencies. E.g., in Germany these are the ministries of transport, construction and housing, in Italy these are the ministries for regional affairs, and in the Netherlands these are the ministries of housing, physical planning and environmental protection. In the United States, the development and implementation of regional policies are distributed between the Department of Commerce, the Office of Policy Development and the Office of Management and Budget under the President of the United States, as well as the Federal Advisory Council, the Commission on International Trade and the President of the United States, which is entitled to establish rules for the development and consideration of federal programs and projects that have a significant impact on the economic development of certain regions (Sidorenko O.V., Bondarenko T.N., 2014).

The supreme legislative bodies of most countries have special committees on regional policy, and the upper chambers of bicameral higher legislative bodies are often chambers of regional representatives.

In general, state regional policy in all countries is aimed at ensuring balanced territorial development. In this connection, the main vector often comprises of the equalization of levels of social and economic development, a decrease in differentiation, which is achieved by direct-acting economic tools (transfers, subsidies, etc.). Many economically developed states apply elements of a leveling selective limiting policy that is implemented by administrative measures (for example, "industrial production certificates" in the UK, or a decree of 1955 prohibiting the construction of new industrial facilities in Paris) (Kovarda V., Laptev R., 2018).

In addition to the aforementioned, the policy of supporting cluster formations and the unification of regions into integration associations (for example, the macro-region) got widespread use. So, in China, state regional policy includes the formation of macro-regions using the principle of combining "economically strong" and "economically weak" regions. The main goal is the unification and/or redistribution of human and social, industrial, agricultural, environmental, recreational capital. As a result, more urbanized industrialized regions get the opportunity to create recreational areas and reduce anthropogenic pressure on the environment. Less economically developed regions within the macro-region get the opportunity to exchange experiences, increase employment, expand production, i.e. there is a deepening of economic development, expansion of specialization.

It should be noted that the state policy of regional development of most countries seeks to enhance the internal advantages of specific territories.

The policy of ensuring the balanced development of territories of integration associations is of particular interest. Thus, the European Union policy in the field of stimulating regional development is gradually transforming towards the activation of endogenous growth factors and increasing the competitiveness of territories. However, overall, an equalization strategy still prevails, despite significant changes. Since 2014, three groups of regions have been allocated for the distribution of credits from the EU structural funds responsible for cohesion policy.

Within the framework of regional policy, the countries of Latin America were guided by the experience of economically developed countries. In recent decades - since the 1980s - you can find a lot in common in the Latin American and Russian features and problems of regional policies.

In Japan, the state regional policy in the 1970s was aimed at the territorial deconcentrating of science and production — the transfer from Tokyo to neighboring (including specially built) cities. In the 1980s, this vector of regional policy continued to be implemented (technopolises began to be created).

South Korea initially followed a polarizing selective policy, however in the 1990s the emphasis was on balanced development.

In general, it should be noted that all the instruments of state regulation of regional development and the provision of balanced growth, used in different countries, have their own advantages and disadvantages, and are quite well known to the scientific community. The effectiveness of applying this or that method of implementing regional state policy is determined by many factors, and the modern economy uses combined system of tools, which forms a set of mechanisms for the influence of central authorities on territorial development of the territory.

Conclusion

In conclusion, it can be noted that the methods and tools of state stimulation of regional development and ensuring balance (overcoming differentiation) are essentially the same in all countries, however the number of used tools and their combination in each country are individual.

Abstract

The article analyzes the prospects for the spatial development of Russia on the basis of stimulating the specializations of each region (according to Federal State Statistics Service). We study the specific weight of each region in the all-Russian values of social and economic indicators, which allows us to determine the most developed industries in the studied territories. As a result, it was possible to distribute the constituent entities of the Russian Federation by relative specialization, e.g. the Kursk and Belgorod regions make the largest contribution to the Russian economy through the production of agricultural products, others have a pronounced character in mining (Khanty-Mansiysk Autonomous Region - Ugra), and the third are multilaterally developed (Moscow region). Cities of federal significance play a special part in the Russian economy due to the concentration of scientific and industrial capital. It is proposed to create and implement the state policy of spatial development considering specializations of each constituent entity of the Russian Federation. In this case, the formation of macro-regions using the PRC as example is of certain scientific and practical interest. China tries to redistribute the load on its constituent entities via the creation of macro-regions. In Russia, macro-regions are legislatively described in the Spatial Development Strategy of the Russian Federation, however, due to the short period of validity of this document, significant effects have not yet been obtained. In the future, it is advisable to develop strategies for the development of endogenous factors of economic growth of territories.

Keywords: Region, State Policy, Regional Specialization, Spatial Development, State Regulation Tools

Modern Russia is characterized by significant differentiation in the levels of social and economic development of the constituent entities, which is noted in the Economic Security Strategy of the Russian Federation (Decree of the President of Russia No. 208). At the same time, federal executive and legislative authorities constantly strive to equalize the regions according to the degree of development, by exercising managerial influences in a direct and indirect way (direct financing (including transfers, subsidies, etc. (Budget Code of the Russian Federation No. 145-FZ)), creating favorable conditions for entrepreneurial activity (Kovarda V., Laptev R., 2018)) (Fig. 1). Also, grants are allocated to the regions that show the highest growth.

Fig. 1: Main types of managerial impacts for developing the regions

Thus, within the framework of regional development, a system of tools and mechanisms of state stimulation is used, combining direct impact, indirect promotion of economic growth, as well as the creation of a competitive environment between territories.

However, it is necessary to note that the systematic approach is insufficient for the formation of the state policy for regional development due to the lack of single goal-setting, i.e. there is no systematic and long-term unambiguous understanding of the desired position. Some experts look with favor on the adoption of the Strategy for Spatial Development of the Russian Federation until 2025, in which promising economic specializations of each constituent entity of the Russian Federation are noted (Order of the Government of the Russian Federation No. 207-R). At the same time, the phased (gradual) development of these specializations seems important.

As a result, we can conclude that the spatial development of Russia must be carried out through regionalization, the development of existing specialization and involvement in regional, national and international value chains, as well as the effective use of the potentials of the regions.

In connection with the foregoing, the study set the goal of analyzing the degree of difference in the specializations of the regions of the Russian Federation and exploring the main directions of improving the state policy of regional development by identifying promising specializations of constituent entities of the Russian Federation.

Regulatory documents within the ConsultantPlus reference system, data from Federal State Statistics Service, government information materials, as well as researches carried out by the authors and other Russian scientists were sources for this article.

It is revealed that, at present, each region of Russia has a certain specialization, which can be traced by proportion of a specific indicator in all-Russian values. Moreover, many constituent entities of the Russian Federation are characterized by low values despite the presence of growth potential, while others, on the contrary, are characterized by significant values. E.g., Moscow in 2016 occupied the first place in Russia in terms of GRP with a value of 20.6% (i.e., a fifth of the country's GDP was formed in Moscow). A similar situation applies to such an indicator as “mining”, which amounted to 9.14% in 2016. In fact, it is due to the fact that many large companies operating in other constituent entities of the Russian Federation are registered in Moscow and pay a significant portion of taxes there (13.9% of all-Russian value in 2017) (Regions of Russia. Social and economic parameters).

According to the share of the constituent entity of the Russian Federation in the all-Russian values of indicators, it is possible to identify its primary specialization. For example, in the Kursk region, agriculture (2.6% in 2017) and electricity production (1.12%) predominate, which is understandable

and is associated with the region's potential - black soils (crop production - 2.9%) and a nuclear power plant. In the Belgorod region, agriculture predominates (4.4%), as well as manufacturing (1.62%). At the same time, mining predominates in the Khanty-Mansiysk Autonomous District - Ugra (21.44% of the all-Russian value), while manufacturing amounted to 1.38% in 2017, electricity, steam and gas production amounted to 4.01%, and agriculture wasn't developed due to the geographical and climatic features of the region. At the same time, this constituent entity of the Russian Federation provided 21.7% of all tax revenues to the federal budget of the Russian Federation in 2017 (i.e., more than 1/5 of the total).

Thus, according to the results of the analysis, it is possible to suggest further development of agriculture and processing industry in the Kursk and Belgorod regions in order to supply more northern constituent entities of the Russian Federation, such as the Tver and Vologda regions, the Khanty-Mansi Autonomous District - Ugra, and St. Petersburg. In turn, some of the above regions have specialization in the manufacturing industry, which causes the need to stimulate the development of these areas in order to supply other regions. Thus, at this stage, it is necessary to consider specialization through the prism of geographical location and the existing structure of the regional economic system.

It is necessary then to analyze the potential opportunities of each region within the imperative of the development of new areas of activity (both separately and through the prism of all-Russian significance). For example, the Kursk region has transit potential (the Moscow-Simferopol section of the highway passes through the region, as well as a highway to Kiev) (Tikhomirov M.E., 2018), with prospects for the development of agriculture and processing of agricultural raw materials, as well as integrating enterprises and organizations in regional, national and international value chains.

In this aspect, it is necessary to stimulate the development of the business climate using two complementary vectors (Fig. 2).

Fig. 2: Basic principles for the development of a favorable business climate

Thus, the development of the region's investment potential through the activation of endogenous growth factors should be supported by sufficient investment activity. In this case, it is possible to use the mechanism of public-private partnership (PPP) in order to expand the investment attractiveness of the constituent entity of the Russian Federation.

In this context, overcoming significant differentiation in the levels of social and economic development of regions in PRC is of particular interest. In 2015, the main provisions of the synergetic development of the Beijing-Tianjin-Hebei region (a kind of macro-region) were approved, including decentralization of Beijing, integration of transport infrastructure, environmental protection, modernization of industry and other key sectors (Ilyin V.A., Shabunova A.A., Gulin K.A., Mao Zh., 2017). As a result, regions with different levels of economic development and urbanization should achieve a balanced state.

In Russia, such projects are not implemented by administrative measures, however the relative influence of more economically developed constituent entities of the Russian Federation on relatively less developed ones can be observed. Moscow and neighboring territories can be used as example

(List of special economic zones).

Thus, when forming regional strategies for social and economic growth, it is necessary to consider the spatial development strategy of Russia, and, accordingly, authorities should develop and implement incentive methods and tools. At the same time, investment strategies should be divided into two complementary and interacting areas: the development of existing potential and the production of "new" (for the region) products (Fig. 3).

Fig. 3: Strategic directions for the development of regional social and economic systems in terms of increasing attractiveness

In this case, the algorithm of actions is aimed at integrating each constituent entity of the Russian Federation into the all-Russian spatial map by identifying areas of activity in which the region uses existing resources in a more efficient manner. If the territory does not have a pronounced specialization, then its potential is considered, which can be unlocked in the first place. Otherwise, the areas of activity initially develop in accordance with specialization, and the potential in the form of endogenous factors is gradually included in the functioning of the territorial social and economic system.

Ultimately, the implementation of the state policy for regional development should be coordinated with the Strategy for Spatial Development and carried out in two main directions: expanding existing specializations and activating the potential capabilities of constituent entities of the Russian Federation (Fig. 4).

Fig. 4: The main stages of the implementation of the spatial development strategy of Russia within the vector of stimulating the development of specializations

It should be noted that these stages can be carried out in parallel or sequentially. At the first stage, the formation of a system of specializations of the regions of the Russian Federation is carried out, and priority directions of development are identified by specific indicators in all-Russian values (or by the range of exported products to neighboring regions of Russia or abroad). In this case, the principle of balanced spatial development must be observed, as well as key guidelines in the field of import substitution. The next step is the development and implementation of a system of measures and tools to stimulate specialization industries.

At the second stage, an analysis of the potential of a particular constituent entity of the Russian Federation is carried out, endogenous growth factors (for example, transit potential, recreational, etc.) are identified, based on which a spatial map of the distribution of promising industries and sectors is developed (planning element). Then, a system of measures should be formed to stimulate the development of potential specializations.

An important component of the given scheme is the establishment and development of interregional cooperation. As a result, there will be a gradual change in the structure of the economy in the direction of production of highly processed products and high-tech industries.

Conclusion

There is the need to direct efforts towards the formation of regional specializations within the framework of the spatial development strategy of Russia. At the same time, it is advisable to pay special attention not only to established specializations, but also to promising ones (based on the potential of a particular region and cooperative ties), which will entail a change in the structure of the economy and evolution from resource-based economy to high-tech industries and services.

The Industry 4.0 Development and Influence on Labour Migration in The VISEGRAD Group Countries

Remigiusz ZIELINSKI

The Management Faculty, Czestochowa University of Technology, Armii Krajowej 19B, 42-201 Częstochowa, Poland, remigiusz.zielinski@pcz.pl

Abstract

This study analyses changes in the labour markets in the Visegrad Group countries (V4) under the influence of the fourth industrial revolution (Industry 4.0) with regard to labour immigration. Industrial production in the countries concerned accounts for a significant part of GDP, and most vacancies in the individual markets concern unskilled positions requiring secondary education. The low level of citizens' interest in such positions results in employment of workers from other countries. The changes taking place in the industrial sector, caused to a large extent by automation and robotization of processes, lead to gradual replacement of the workforce with machines. This study focuses on an analysis of the relationship between the immigrant workforce with selected characteristics and macroeconomic indicators reflecting the impact of the industrial revolution in V4 countries. The analysis was based on basic and publicly available statistical measures taken from Eurostat and European Commission databases.

Keywords: industry 4.0, Visegrad Group countries, labour market, migration

Introduction

A new factor emerging in the context of industrial revolution 4.0 is dynamic development of breakthrough technologies, which have very quickly and fundamentally started to outperform previously used technologies (Autor, 2015; Rajiani, Ismail, 2019). Industry 4.0 is created by "smart factories", where the machine is an intelligent device with a level of automation that enables it to function independently. This is possible thanks to the use of, among others, the "Internet of Things", the "cloud" technology and big data (Frey, Osborne, 20015) which are integrated in a joint system and which can function independently thanks to applied algorithms based on artificial intelligence (Graetz, Michaels, 2018).

However, the abovementioned solutions are being implemented too abruptly. According to Mokyr et al. (2015), in terms of processes, this is a revolution preceded by an evolutionary phase characterised by gradual and continuous development (Ślusarczyk, 2018). In case of too rapid development, companies are not prepared for such dynamic changes, therefore, the fourth industrial revolution involves not only technological changes, but also changes at the administrative or service level, and the effects can be observed in the whole society (Nordhaus, 2015).

Initially, the changes will be visible in the labour market as a decline in unemployment in developed countries, with a declining nominal wage growth and declining gross domestic product (GDP), whose level as a key macroeconomic factor indicates a weakening position of labour with regard to state capital and higher labour hire costs (Gregory et al. 2015; Ungerman et al. 2018).

The International Labour Organisation (ILO) has been tasked with identifying the factors which form the basis of development, such as technological progress, trade globalisation, financial development and declining significance of trade unions. The ILO states that the most important development factor is financialisation, i.e. increasing the impact of the financial sector on the economy (Pilloni, 2018). In

turn, the OECD claims that it is technological changes and capital accumulation (OECD, 2019). How may this affect the labour market?

The World Trade Organization estimates that by 2020 about 7 million jobs could disappear (Ślusarczyk et al. 2019). McKinsey claims that by 2030 the labour market will reduce the number of jobs by about 400-800 million (WTO, 2019). PwC forecasts that in the United States alone, 60 million jobs will have to be cut by the same year (PwC, 2018). In turn, the International Federation of Robotics focuses on jobs emerging in response to the ongoing processes and optimistically estimates that 3.5 million new jobs will be created by 2021 (OECD, 2019). The OECD evaluates its geographical area, where, according to studies, 9% of jobs will be closed in the coming years (Frey, Osborne, 2017).

To sum up, all breakthrough technologies and innovations implemented in enterprises constitute a revolutionary change in broadly-defined processes and are referred to as Industry 4.0 (Bazzi, 2017; Nagy et al. 2018). Despite the positive effects of this change, it also represents a threat to the labour market. Research specialists in this field agree that Industry 4.0 can have many different consequences and there may be various ways of solving them (Rodič, 2017; Durana et al. 2019). Being at the beginning of this change, it is impossible to accurately predict the consequences of the processes taking place. These forecasts pay little attention to the population's demographic structure and development in the context of the industrial revolution or varying stages of development in individual countries, or to the social and cultural environment of the population in those countries. In this study, special attention is paid to changes taking place in the labour markets in the Visegrad Group countries in connection with Industry 4.0 in the context of economic immigration.

Objective and Methodology

The aim of this study is an attempt to answer the question of how the labour market will change as a result of the changes brought about by the introduction of the Industry 4.0 concept and whether it will affect employment resulting from migration movement in the Visegrad Group countries.

The changes currently observed in economic and social development discussed in the concept of Industry 4.0 affect the volume of production and are related to the labour market, namely the nature and intensity of work and the structure of the proposed positions. It is a well-known fact that labour migration is a factor that has a significant impact on the labour market, which is why the study focuses on determining whether the Industry 4.0 concept will affect this movement and, if so, how it will affect the labour market.

The study was carried out on the basis of selected labour market indicators and is based on basic statistical measures taken from *Eurostat* databases and European Commission data. For data analysis purposes, a licensed *STATISTICA v.7.1 PL StatSoft* package was used.

Publicly available statistical methods were used in the study: correlation analysis using r-Pearson correlation coefficients, which provided the basis for examining the correlation between macroeconomic indicators and Industry 4.0 indicators, and the intensity and scope of labour migration in different countries. The focus was on compiling, analysing and comparing the collected results.

First of all, the study showed how factors such as:

- human resources,
- attractiveness of research systems,
- innovation-friendly environment,
- funding and support,
- business investments,
- innovators,
- connections,
- intellectual assets,

- impact on employment and sales,

affect the innovation index in V4 countries. The next step was to analyse the correlation between immigration and selected indicators. The selected indicators in this case were:

- immigrants,
- GDP,
- employment,
- level of unemployment,
- income,
- vacancies,
- innovation index,
- human resources.

Results and Discussion

The Polish innovation index was the lowest within the V4 countries in the analysed period, but its growth over the years was the fastest. In 2018 it reached 61.10%, i.e. almost 8 percentage points more than in 2011. On the basis of the results included in Table 1 it can be concluded that in the case of Poland all the factors under the innovation index are characterised by constant growth, except for funding and support, innovators and connections. A significant increase was noted for the "innovation-friendly environment" factor. This may result from a particular emphasis on support and creation of innovation by human resources (a factor with stable growth) and promotion of the attractiveness of research systems in the country.

Source: European Commission

The innovation index of the Czech Republic (Table 2) in the analysed period was the highest among V4 countries in each year. In the case of the Czech Republic, there was a decrease compared to the base year for the following factors: funding and support, innovators and impact on sales. However, there was an increase in human resources, attractiveness of research systems and creation of an innovation-friendly environment, which undoubtedly had a positive impact on employment.

Table 2: Czech Republic Innovation Index 2011-2018 (in %)

Indicator		2011	2012	2013	2014	2015	2016	2017	2018

Source: European Commission

The innovation index of the Slovak Republic reached its highest value for the analysed period in 2018 at 69.1% (Table 3). Its decrease year to year was found between 2013-2014 and 2016-2017. Taking the base year 2011 as a starting point, human resources and innovators saw the most significant decrease. These factors are interrelated. If a country does not have adequate human capital and does not innovate, innovators refrain from creating new businesses or jobs. Investment in research and development of innovation is only valid if there are specialised and trained staff available for that purpose. Business investments create new jobs and thus affect employment.

Table 3: Slovak Republic Innovation Index 2011-2018 (in %)

Indicator		2011	2012	2013	2014	2015	2016	2017	2018

Hungary is ahead of Poland, but lags behind Slovakia in terms of the observed innovation index (Table 4). The index decreased slightly compared to the base year. Factors such as human resources, connections and impact on employment also showed a decline. On the other hand, however, the factors concerning creation of an investment-friendly environment and attractiveness of research systems increased significantly, which was reflected in an increase in business investments and development of

innovation centres. On that basis, it can be concluded that putting emphasis on the growth of innovation can have a very positive impact on the development of the country.

In order to determine the correlation of the country's innovation index reflecting the degree of development of industry 4.0, GDP was taken into account as the main macroeconomic indicator (quantity of goods and services produced in the country per annum). Development of this indicator over time shows the state of the country's economy. Employment, unemployment and vacancies were considered to assess the state of the labour market.

According to economic theories, the unemployment rate and the number of available jobs in a given country are important factors when choosing a country for potential economic emigration. Labour supply and demand determine the level of wages, which is another factor that may help make that decision. Empirical studies show that the most important motivation for individual migration to work abroad is the wage level (Hariharasudan, 2018; Ślusarczyk, ul Haque, 2019). The presented macroeconomic indicators were correlated with each other in order to determine the most important factors influencing the volume of migration in V4 countries.

Table 5: Mutual correlation between immigration and selected indicators for Poland*

	Immigrants	GDP	Employment	Unemploy--ment	Earnings	Vacancies	Innovation indicator	Human resources
Immigrants	x							
GDP	0,90138	x						
Employment	0,84261	0,96639	x					
Unemployment	-0,72970	-0,90217	-0,95857	x				
Earnings	0,92627	0,99077	0,94818	-0,85815	x			
Vacancies	-0,02599	0,82605	0,85707	-0,81040	0,55317	x		
Innovation indicator	0,32354	0,84796	0,75384	-0,78281	0,48953	0,90494	x	
Human resources	0,48444	0,68940	0,77582	-0,72648	0,81602	0,59965	0,41873	x

*Source: Own calculations based on Eurostat data (*statistical significance level of α = 0.05)*

In Poland, as shown in Table 5, there is an almost ideal correlation between the number of immigrants and GDP generated in the country. This reflects the fact that a large number of immigrants from third countries enter Poland. Immigrants significantly affect the level of employment. This is due to the growing tendency among Poles to emigrate for work, which causes an even greater mismatch between the market and needs. As regards the innovation indicator, the correlation is moderately negative, but the human resources factor is moderately positive. This means that among individuals coming to Poland there are also employees, especially from third countries, motivated by higher earnings.

Table 6: Mutual correlation between immigration and selected indicators for the Czech Republic*

	Immigrants	GDP	Employment	Unemploy--ment	Earnings	Vacancies	Innovation indicator	Human resources
Immigrants	x							
GDP	0,93177	x						
Employment	0,65245	0,81177	x					
Unemployment	-0,68336	-0,86484	-0,90351	x				
Earnings	0,90281	0,97238	0,83941	-0,80166	x			
Vacancies	0,89597	0,94814	0,87967	-0,94858	0,73607	x		
Innovation indicator	-0,01597	0,73331	0,58039	-0,69173	0,32419	0,78604	x	
Human resources	0,61557	0,86128	0,93813	-0,85494	0,87890	0,86977	0,49463	x

*Source: Own calculations based on Eurostat data (*statistical significance level of α = 0.05)*

In the Czech Republic the development of the correlation is completely different than in Poland (Table 6). Labour market indicators show a moderate correlation between immigrants and GDP, national income and filling vacancies - especially in jobs that are not of interest to the citizens. The result is an increase in GDP, which in turn creates new jobs and increases wage levels. This is a factor that attracts labour immigration to the country. However, no significant correlation can be observed for the innovation index. The "Human Resources" indicator reflects the inflow of highly qualified labour and human resources to the Czech Republic to improve their living conditions, especially from the Slovak Republic and to a lesser extent from Poland and Hungary. The Czech Republic has also become a destination for scientists and researchers working on international projects.

Table 7: Mutual correlation between immigration and selected indicators for Slovakia*

	Immigrants	GDP	Employment	Unemploy--ment	Earnings	Vacancies	Innovation indicator	Human resources
Immigrants	x							
GDP	0,96499	x						
Employment	0,81772	0,86009	x					
Unemployment	-0,76371	-0,87062	-0,95128	x				
Earnings	0,97679	0,98753	-0,77367	-0,77367	x			
Vacancies	0,44165	0,61879	0,84226	-0,91323	0,34746	x		
Innovation indicator	0,33621	0,52427	0,47817	-0,43608	0,38672	0,29301	x	
Human resources	0,02049	0,07737	0,12702	-0,18004	-0,07647	0,12346	-0,46021	x

*Source: Own calculations based on Eurostat data (*statistical significance level of α = 0.05)*

The correlations of selected indicators and immigration for the Slovak Republic in the years under review, compiled in Table 7, show an increasing positive correlation between immigration and

employment and vacancies, and a negative correlation with unemployment, which in general terms translates into decreasing unemployment figures. The correlation between immigrants and the innovation index is 0.33621, which is a medium correlation. This is not a satisfactory result, given the extensive human resources available in the country. However, this is a reflection of the situation prevailing in this country in recent years, where the number of foreigners has increased, mainly with regard to individuals with secondary education. Direct foreign investments in the country are decreasing and the share of immigrants from the European Union (EU)/European Economic Area (EEA) is gradually decreasing. The result may be worsening conditions for science and research in Slovakia, which in turn explains the decline in innovation.

Table 8: Mutual correlation between immigration and selected indicators for Hungary*

	Immigrants	GDP	Employment	Unemploy--ment	Earnings	Vacancies	Innovation indicator	Human resources
Immigrants	x							
GDP	0,79745	x						
Employment	0,91644	0,91644	x					
Unemployment	-0,33223	-0,33223	-0,33223	x				
Earnings	0,83595	0,83595	0,83595	0,83595	x			
Vacancies	0,83954	0,85300	0,83954	0,83954	0,83954	x		
Innovation indicator	0,52132	0,86537	0,71934	-0,73412	0,62470	0,85296	x	
Human resources	-0,32051	-0,71238	-0,56545	0,56384	-0,37802	-0,74756	-0,80933	x

*Source: Own calculations based on Eurostat data (*statistical significance level of α = 0.05)*

In the case of Hungary, there is an almost ideal correlation between the number of immigrants and employment and only a moderate negative correlation with unemployment. The level of income and number of vacancies are factors encouraging people to move to this country. The innovation index is at an moderately satisfactory level. The country also faces a shortage of human resources, as shown by the negative correlation coefficient.

Conclusions

Due to their history and cultural and political issues, the Visegrad Group countries are characterised by an anti-immigration attitude. In order to mitigate or change this attitude, integration processes have been carried out, but this did not have the intended effect. The easing of migration policy was only due to economic growth in recent years, as reflected in GDP and employment growth and decreasing unemployment.

Incompetent human resources management and changes in the methodology of job development have led to a lack of interest in labour positions by the citizens, but these positions are gladly taken up by immigrants.

This labour market mismatch in the V4 countries has encouraged politicians to exert pressure in favour of partial liberalisation and relaxation of labour markets, in particular for economic migrants and vacancies that prove difficult to fill. Better economic opportunities in the analysed countries proved to be an effective factor in attracting potential immigrants from Southern and Eastern Europe, who, being members of the European Union, enjoyed a much easier access.

It is important to examine the established trend with regard to breakthrough innovations, which is connected to the level of the fourth industrial revolution. Therefore, in this study it is shown at the level of the innovation index of V4 countries saturated with particular factors. The results show that the country with the highest innovation index is the Czech Republic, while Poland is the country where the innovation index was at the lowest level. In Hungary, the correlation between immigrants and

innovation is the highest among the analysed countries, at 0.51219. There is a moderate correlation between the indicators in Poland and Slovakia. In the Czech Republic the human resources and immigrants factors show a high correlation with each other, while in Poland this is a moderate value. The presented results reflect the economic conditions in the individual Visegrad Group countries. The Czech Republic is the country with the most stable economic growth, the highest share of GDP invested in science and innovative research and a high share of people with higher education, and it is known for supporting higher education of foreigners.

The situation in Poland is completely different. Although the country achieves significant economic growth, it relies mainly on low value added industrial production. Poland has long been struggling with relatively high unemployment. At present, there are many vacancies in the economy that cannot be filled with domestic resources. Poland has eased administrative barriers to employment of foreigners, especially those coming from Ukraine. However, it is mainly a low skilled and unspecialised workforce. The demand for highly skilled workers and human resources remains at the same level. Poland also needs support in creating highly qualified and innovation-generating employees. Innovation is the starting point for maintaining economic growth under the conditions of Industry 4.0, which forces both low-skilled and skilled workers to give up industrial production and routine administrative work.

To sum up, the concept of Industry 4.0 brings many benefits and modern solutions, but by its nature, i.e. the speed of the changes it introduces, it is also likely to create a lot of negative effects, especially for unskilled workers in the labour market. It is therefore important to monitor the situation and respond appropriately to the changes. By comparing the information received as part of the conducted research, it is possible to understandably determine the changes taking place on the labour markets of the Visegrad Group countries in the context of the development of the Industry 4.0 concept. However, comprehensive research should carefully analyse the risks associated with its implementation.

Furthermore, the carried out examination does not exhaust the subject and will be elaborated on in the future together with the performance of a more detailed analysis.

Transformatica As A Doctrinal and Strategic Tool of Governance in A Crisis

Elena POZDNYAKOVA

Southwest State University, Kursk, Russia, e-mail: elena.pozdnakova@mail.ru

Abstract

This article deals with the problems of development of administrative legal transformatic as innovative directions in the state regulation of crisis situations. The emergence of this term is the result of updating of relations of livelihood in Russia, Western Europe and other countries. Historically, this development passes a number of stages, from legal cameralistics, then the police and administrative law. The author notes that a variety of transformationaly law relations of ownership and all economic, socio-cultural and administrative-political life have felt the need for scientific management of a variety of interconnected, vital to the economic and legal phenomenas. Executive authorities of different levels have to consider this phenomenas which are reflected in administrative-legal science. The results of the study concluded that the management of the protection of constitutionality, safety, and welfare of the country in a crisis is represented by the impact of the system of state and municipal management based on the knowledge and use of doctrinal-strategic patterns inherent in the administrative system of transformational in order to optimize operation, development and achieving goals.

Keywords: Administrative and Legal Transformation, Crisis Situation, Life Values, Guarantees of Rights and Freedoms.

Introduction

Managing the life support based on of constitutionality, safety and welfare of humanitarian change in the modern world is one of the largest cross-national, national and supranational problems, which are solved by measures of administrative-legal transformation.

Administrative and legal laws, the relations, the need for new reforms, incentives and experiments in the field of life of the people are means, on which the Executive authorities of all levels rest on. The unfolding global and then national economic crisis, geopolitical complexity, sanctions and various restrictions had a negative impact not only on the development and cooperation of these authorities, but also on the economic and legal thinking, on the field of interaction of law, economics, culture, administration and government. The latter ones create the base of the newest cameralistical system life-supporting relationships, which is distinguished by the anti-corruption direction of legal and administrative transformation in the livelihood of the people. Modern Executive power unthinkable without effective legal complex of life support and desire to develop and influence it. It is necessary to raise the quality of welfare; directions and priorities of management of protection of the constitutional order, security and well-being of citizens.

Transformation of Executive is an outstanding managerial multi-faceted phenomenon which affects to overcome the gap, first of all on the level of productivity. Neither centralized administrative economy with absolute dominance of the state, nor subsequent inertial-raw model had not reduced this backlog, although the gap in the level of welfare over the last 10-15 years had definitely decreased (Medvedev D.A., 2015).

All of this allows to speak about the diverse universal phenomenon of Executive power that is deserves a special study to highlight the separate area of knowledge – the administrative legal transformatic of subsistence as science. This science embraces progressive administrative and legal

movement of relations of constitutionality, safety and welfare of Russia and subsistence of people. Here we are talking about humanitarian changes in Russia and foreign countries.

Legal and administrative transformation of subsistence through the enriching of authorities and officials of governance, emanating primarily from the economic, socio-cultural, and anti-corruption interests of all people should send legal funds to meet the needs, requirements and demands for different segments of the population.

In the context of administrative-legal transformation of life support, beginning with the administration of the process of improving welfare of the population, the state should implement of the legal regulation of new market relations, provision of economic, social and other support to industries and individual enterprises of public importance. This is achieved by providing soft loans, tax reduction and financial support for small businesses and ensure competition producers. Through implementation of the investment policy authorities should achieve a uniform and sustainable development of economy, culture, regions and municipalities. Funds derived from taxation, investment and other income should used by the Executive authorities to support the population, including its socially vulnerable layers with implementing and pursuing appropriate economic, financial and fiscal policy.

Transformational legal process of realization of Executive power and life support and safety of the citizens have to some influence on the behavior of other people. If this influence wisely and initially pursues transformational goals, it can be called life supporting management. Consequently, not every authority is such a management as not every authority is life-affirming and legal. The main thing here is to learn to be better and faster in the process of transformation. If managers do not consider that it is necessary to comply with this requirement, but act in each case at its own discretion, their rights are replaced by arbitrariness. Discussions arising from this often relate to the extent and nature of modernization of the legal content of the process of forming a new social state.

The ensurence of unity and differentiation of administrative-legal regulation is of great importance in the economic, socio-cultural, administrative-political spheres, where the Executive authorities are often associated with the legal, economic and moral incentives. We are constantly faced with unjustified differentiation, disunity, fragmentation of management and legal regulation by departmental mark in the transformation process of life support of the people.

Such differentiation of legal regulation of Executive authorities only on a departmental basis leads to inconsistent, unjustified differentiation of the norms contained in law. All this has a negative, inhibitory affect on the development of the social sphere, which determines the quality of human capital and directly depends on import substitution and competitiveness in the country.

The conditions have riped for enshrined in legislation of major new provisions in the sphere of regulation of import substitution and its innovative nature. Administrative legal transformatic of life support can become a relevant new and very perspective direction, allowing to avoid the transformation of Executive authorities in the administrative-command structure, dealing with the replacement of foreign products by the domestic ones. It represents a legal regulation, the purpose of which stems from the ideas and traditions of old, new and latest transformatic. Of course, there are special areas and specific types of products, when it is necessary to substitute the imports by any means, except of course, corruption ones.

However, the best import substitution is the creation of domestic products competitive both domestically and in foreign markets. It is this substitution that is supported by the state with all legal means.

This direction in the law of the national economy unites norms applicable in various spheres of the Executive, including the administrative law, its Specific part. Firstly, it regulates the macroeconomic of country, mainly solving such large problems like prices, foreign trade, credit and finance, competition, employment of the working population. Secondly, one of the major concerns of the

Executive agencies is the preservation of a balance of all factors of well-being, life support and security (economic, legal, socio-cultural, administrative-political).

With the aim of improving life support and corruption control the Executive authorities regulate relations in the economy, socio-cultural, political and administrative development (Vorontsov A.L., 2015).

This is achieved in particular by public contracts and agreements with enterprises and institutions. This measure is regulated by the administrative legislation, especially in the public sector of the economy, socio-cultural and administrative-political development that constitute the basis of the administrative legal transformation. Therefore, the primary object of regulating relations of life support is state-owned enterprises and institutions of education, culture, health, etc. It is not only about the development of laws and regulations in these areas, but monitoring their application, the resolution of administrative-legal conflicts of interest.

Administrative legal transformation of the regulatory authorities promote competition in the areas of security and life support. This transformation is aimed to the eradication of formal and informal existing in these authorities of so called "ticket quota system" that usually lead to actions contraring to reason.

The obligatory conditions for an effective administrative legal transformation are the development of adaptive environment for laid-off workers, their retraining, new forms of employment, the flexibilization of the labour market. This is require the highly developed social infrastructure.

It should be noted that up to the present time in the Russian ecological law science questions as well as questions associated with the administrative legal transformation of the mechanism of protection of environmental security have been studying with the general theoretical positions (Vorontsov A.L., 2018), the standpoint of comparative legal analysis of the development of environmental legislation, and also in the context of the assessment of environmental security as a global and domestic issues. However, as a holistic and self-issue the administrative legal transformation of the mechanism studied in this article has never become the subject of scientific analysis.

Conclusion

The system of administrative-legal transformation of relations of sustenance and security needs the state protection of rights, economic freedom, creative freedom, rights and liberty as a whole, which is a crucial component of administrative legal transformatic of life support. Executive bodies, their officials should try to improve the lives and security of the people. As the property is the basis of economic power, it also should be the basis for administrative legal transformation.

The State Apparatus of Administrative and Legal Transformation in The Management Mechanism at The Stage of Overcoming the Consequences of The Economic Crisis

Elena POZDNYAKOVA
Southwest State University, Kursk, Russia, e-mail: elena.pozdnakova@mail.ru

Elena MIKHAILOVA
Southwest State University, Kursk, Russia, e-mail: iog1983@rambler.ru

Abstract

The authors by taking into account the theory of administrative-legal transformation of management protection of the constitutional order, security and prosperity of Russia, determine the legislative regulation of anti-crisis relations as the process of defining impact on this relations by the apparatus of administrative-legal transformation of the system of legal regulatory institution, acting primarily in the interests of human life support and liquidation of the consequences of economic crises.

The article notes that the aggravation of problems in the management of rights protection issues by the state at the stage of post-crisis development of Russia clearly reveals some contradictions that cannot be presented only as imperfection of state regulation of economic and social processes or explained by mistakes of heads of ministries and departments.

The results of the study concluded that the main reason is the contradictory development of the economy that assotiated with its systemic and structural crises, causing acute and long-term problems which can be overcome only in the conditions of ensuring the stable development of management mechanism of legal protective system (complex) of the Russian Federation.

Keywords: Administrative and Legal Transformation, Management Problems, Crisis Situation, Life Support.

Introduction

Any Federation that, due to the economic crisis and its internal contradictions, when entering a period of declining economic growth and worsening social conflicts, makes new demands, first of all, on the apparatus of transformation of administrative law-making as the most important state-legal regulator of relations in the field of managing the protection of the constitutional system, security and well-being of Russia. This is written by scientists and publicists in a very critical tone, although many problems are overly dramatized and reduced to calls to abandon the management of not only state and municipal property, but also state regulation of the economy as a whole. Therefore, the understanding and assessment of modern phenomena in the legal regulation of state and economic development, and above all in the state apparatus of administrative and legal transformation, requires a versatile and balanced approach based on the doctrine of the state and law, analysis of the current management system for the protection of the constitutional system, security and well-being of the Russian Federation.

Now this is the moment of realization that the state-legal regulation of relations of management of the constitutional system protection, security and well-being of Russia is at the stage of overcoming the consequences of the economic crisis. All this is necessary in order that the legislation does not unilaterally focus only on private interests, which must be combined with the public legal interests of the mechanism for managing the legal and protective structure of the state.

The combination of public and private principles is particularly evident in the crisis conditions of the state, its authorities and economic structures, when the problems of administrative and legal regulation of socio-economic relations are particularly clearly manifested in the activities of the

system of public administration, which becomes dual in nature. On the one hand, they are forced to maneuver, creating conditions for achieving state and market goals, while simultaneously supporting the anti-crisis interests of the population of the Federal subjects and municipalities. On the other hand, the development of a system of state-legal administration of protection of the constitutional order, security and prosperity to Russia is considered from the standpoint of the national security strategy, formation of jural state and the anti-crisis protection of the population (employment, unemployment, training and retraining, suspension of growth in the number of citizens trapped in poverty due to the "liberalization" of prices, etc.).

Among the functions of this mechanism for managing legal protection, it is also necessary to note the activities of authorities for the rational use of multi-purpose resources: land, water, and air basin. There is a tense situation in many regions of Russia. The scale of resources is extremely limited, and the number of entities claiming resources is constantly growing. In this regard, based on the interests of market development of the territories administrative regulator defines priorities and limits on the use of resources to regulate the business partnership between the regions, their management and production structures, which are based on the principles of economic feasibility, expediency and competitiveness (Pashin A.L., 2003).

At the same time in our opinion state and municipal regulation of market relations will act as an element of marketing support from government authorities, affecting national economic structures through contracts, legal norms, regulations, etc. The greater the degree of decentralization in economic units, the greater the need for market infrastructures independent of the center and the less the scope of functions in the sphere of direct state management. In parallel, there is a redistribution of functions from the Federation to its subjects, based on the experience of strengthening federalism, and not on a mechanical reduction in the number of levels of the human rights complex management apparatus.

In fact, the current attempts at market reforms reflect the desire to transform the entire legal, economic, and socio-political way of life, not only in the Russian Federation, but also in a number of other countries.

One of the areas of activity whose management has undergone the most notable transformation in recent years is education. This was repeatedly indicated in studies of Russian authors. These are mainly works devoted to modern trends in the development of Russian education (Vorontsov A.L., Vorontsova E.V., 2015), the integration of educational systems in Russia and Europe (Vorontsov A.L., Vorontsova E.V., 2016), the formation of a new educational paradigm (Vorontsov A.L., Vorontsova E.V., 2016), etc.

Such a reform cannot be implemented without the theory and practice of administrative and legal transformation of Russian federalism in the interests of improving the administrative and legal transformation of the mechanism for managing the protection of the constitutional order, security and well-being of Russia (Porfirev A., 2009).

This means that the protection of the constitutional order, security and well-being of Russia within the borders of the constituent territories of the Russian Federation is managed in accordance with the principle of federalism within the state administration of the Russian Federation as a whole.

The administrative and legal regulation of the human rights system (complex) takes into account the national and territorial features of the Far North, the North Caucasus, the Volga region, the territories of all subjects of the Russian Federation, along with zones of environmental disaster, emergency, etc. The large therritory of Russia, the diversity of its national and socio-economic structure, climate and other factors require a flexible combination of Federal and various regional interests. On this basis, the Institute of territories of advanced socio-economic development has emerged.

Organizational support for the management of the protection of the constitutional order, security and well-being by strengthening the ties of the Federal government with regions and their economy is

possible in various ways. These may include: the creation of authorities specializing in the national economic direction of these relations; the formation of divisions for these purposes gathering together the interested authorities; the assignment of appropriate tasks and functions for participation in the management of legal protection to a certain authority or its division. Here we can include the formation of a group of representatives of Federal and regional authorities to develop coordinated anti-crisis solutions, creation in regions of the Russian Federation, its own regional authorities wich will interacte with the Federal agencies concerned in the management of the protection of the constitutional order, security and well-being of Russia from the economic crisis.

The significant potential of Russian federalism for integrating Federal interests into the regional differenciation of labor can be found in the program-target regulation and anti-crisis strategic planning. But while using the territorial and program-target principles of strategic planning we should avoid extremes. Indeed, at various stages of the study of the consequences of the economic crisis, many authors give preference only to these principles. They see in the strengthening of regional governance the main, almost the only direction of development of administrative and legal theory (Sidorenko A.V., 2009).

But we should remember that parochialism is no better than narrow institutional interests and therefore according to the theory and practice of development of federalism it is poorly fit into the system of relations of administrative-legal transformation management protection of the constitutional order, security and well-being of Russia. Symptoms of monopolism (bans on export of products outside the region, closing of sales markets, administrative resources, etc.) can provide dangerous consequences for the Russian Federation and the existing system if they are not promptly transformed into a redevelopment of the management of the structural and functional system on an innovative legal basis.

A powerful and unified Russian state is possible only upon condition of real independence which is characterized the correct balance of international, Federal and regional interests in managing the protection of the constitutional order, security and well-being of Russia.

Conclusion

For the successful operation of federalism in administrative law theory of the transformation of the transition from the cyclicality to the reconstruction of management of the protection of the constitutional order, security and wel-being of Russia we should proceed from the fact that the theory of administrative-legal transformation of management excludes the replacement of market relationships by scientifically unfounded command ones neither in the legal nor in the economic life of the Russian Federation. There is a state regulatory apparatus that performs administrative and legal transformation functions to manage the protection of the constitutional order, security and well-being of Russia. Namely:

- preparation of forecast and plans (indicative plans) and state programs that define the main scales, proportions and goals in anti-crisis strategic planning;
- development of decision making and the adoption of regulations that directly effect the structure and management of the protection of important infrastructure, security of constitutional order and the related allocation of centralized investment and other state-controlled resources;
- application of the system of state regulators, such as taxes, subsidies, compensation, pricing, tax and credit benefits, customs rules, taking into account the views of the relevant state and local authorities;
- state support for the development of science in the field of administrative and legal transformation of the management of the structural and functional system.

These functions of the state apparatus of transformation should ensure a balance of human rights relations in this system based on the market and Russian law. The corelation between these functions should be variable and depending on the specific situation. At the same time, the administrative and legal theory of transformation is designed to facilitate the implementation of these functions, ensuring

the state impact of power on the economy, purposefully investigating methods and forms, the legal status and activities of public administration.

Abstract

The development of the world economy has involved a corresponding intensification of trade, causing the total traffic of the ports of the world to increase, now reaching the order of tens and hundreds of millions of tons per year. Therefore, this industry becomes extremely important, being necessary the digitization of processes, the use of artificial intelligence and the latest technologies to evolve and facilitate the access / use of data. The authors propose a digital web platform model for e-contracts used in maritime transport. The platform wants to offer contract models that can be completed online, digitally signed and accessed from anywhere as long as users have an account.

Keywords: E-Contracts, Digital Signature, Process Digitalization

Introduction

Culture / digital revolution deeply affects our economic, political, social and cultural life, marked by a rapid and continuous technological change, as people are increasingly connected and inclined to suppress the paradigms of the past. It also has the potential to change power structures and relationships, allowing for switching from rigid, pyramidal power structures to more fluid and transverse power systems.

The expansion of the digital space not only facilitates the economy and global exchanges, but also allows for an unprecedented interconnection of people; in addition, it has the potential - and it already plays - to change its ways of doing, thinking, relating between them in regards to information, knowledge and learning. Increased interconnection and mobility - whether for work, pleasure or for economic and political reasons - bring more and more people in physical and virtual contact closer to each other.

The platform was designed for legal or natural persons, for whom the time and financial resources allocated to obtaining an enforceable title should not be a risk but a standardized and predictable procedure. The only requirement is to have a qualified certificate for the electronic signature issued by a Service Provider of qualified European level trust. The platform offers time savings and financial resources by securing legal relationships, consolidating debts, minimizing the legal risk by digitally democratizing the judicial procedures for obtaining an enforceable title and implementing it.

State of The Art

Alharby (2017) does a research regarding all the scientific information related to smart contracts taking into consideration only the technical part. He also identifies contract applications that use this type of contracts. There are gaps that must be fulfilled as a conclusion.

Smart contracts are used mainly in a process of transferring money under some rules. More and more platforms which use smart contract were proposed and implemented. Bartoletti (2017) analyzes the significance of smart contracts in some of the platforms and the patterns.

Online platforms are suited to explain all the requirements of contracts, Carvalho (2020). He gives a better look to the idea of that companies that receive service from another one are mostly online and he researches through specialized literature to provide an overview of the European framework regime designated to them.

Kruijff (2017) remarks that there is no unified ontology for smart contracts. Through his research it is used enterprise ontology and architectures that are model driven to get the essence of smart contracts. The paper is introducing the concept of commitment in smart contracts that can be seen like a business exchange.

Lauslahti (2017) studies the binding rights and obligations of parties when used smart contracts. His results show that for smart contracts formation is best to use a vending machine that performs contractual obligations.

Lauslahti (2018) analyzes the mechanism for general contract law principles in the context of smart contracts and shows that it can be created a bound between rights and obligations of the parties.

According to Wang (2019) is stating that smart contracts are still at the beginning, therefore there are still a lot of issues regarding security and privacy. He proposes a framework having a six-layer architecture for smart contracts and also presents future trends.

As e-commerce is expanding, Wang (2019) identifies the need of digital contracts. An important aspect is treated by him and it consists in the framework of the platforms and the legal landscape.

Business processes are reshaped by smart contracts. Contractual terms can be enforced automatically, without the participation of a third party. Zheng (2020) displays the challenges of this contracts and their lately evolution. In his article is also made a comparison of two contract platforms through examples.

Business Digital Environment

Every year, the European Commission publishes the DESI report - the degree of digitization of the economy and society (Digital Economy and Society Index). According to it, Romania ranks in the last positions of the European Union in terms of digitization.

Fig. 1: Digital Economy and Society Index rank – 2019 (www. https://ec.europa.eu/, accessed at 15 march, 2020)

The DESI index is calculated for each of the countries of the European Union, taking into account 5 aspects:

1. Connectivity - fixed broadband, mobile broadband and prices
2. Human Capital - use of the Internet, basic and advanced digital skills (for example, number of IT employees, number of IT faculty graduates)
3. How to use the Internet - citizens' use of content, communication and transactions
4. Integration of digital technology - digitalization in business and e-commerce
5. Digital public services - e-government and e-health solutions

The European Commission Digital Economy and Society Index (DESI) 2019 situates Romania on place 27/28 compared to the other EU Member States. Even though the total progress was slow, Romania's rank remained stable. The best index of Romania is represented by the Connectivity due to the broadband capacity of the networks. Despite this fact, the digital economy is not keeping up because there is still a lack of basic digital skills among Romanian citizens. When it comes to e-government services, Romania is last on the rank.

Fig. 2: Romania's evolution over the last 6 years (www. https://ec.europa.eu/, accessed at 15 march, 2020)

Digital Model of Maritime Agreement

In order for this process of agreement between the two parties to have a faster flow, the authors propose a model of web platform. Its purpose is to provide pre-established types of contracts, which can be signed by both parties through a digital signature. The process thus becomes digitized, and the information is organized systematically, and can be accessed from anywhere. The role and satisfaction of a client is also described by Barbu (2018).

Any person can use the web platform to make legally assisted contracts in the online environment using digital signature. The platform differs as an interface for a user requesting an executory title over that of a lawyer, which is simplified. The last one only reviews the contract and sends it for approval to the persons involved, i.e. X and Y.

The platform includes payment methods of the operations performed by card. The process consists of the following steps:

1. A person which holds an account accesses the web page. He/She authenticates with the required credentials: username and password being redirect to the homepage.
2. A person who does not have an account accesses the website. He/She creates a new account, filling in the data fields and selecting whether he/she is a legal entity or not. If they are a legal entity, a new page holding fields for the company data is opened. An email notification which validates the created account is sent to the person.
3. On the homepage there are displayed all the documents of a person, as well as the possibility of creating a new contract. It can be selected from a list of predefined contracts or upload an existing one from the personal computer. If there is a new contract that must be signed, the person is notified immediately after logging in.
4. After a new contract is added, it is filled with the data of the person initiating that contract and those of the person participating in it. An email notification is sent to the lawyer for approval and modification, if applicable.
5. After the lawyer validates the contract, a notification is sent to X and Y to give their final agreement. They sign the document using their digital signature.
6. The payment is made by withdrawing the related amount of money from the card saved in the platform and transferred to the lawyer.
7. The contract remains saved on the homepage of the platform, the most recent ones being on the top of the page. Contracts can also be identified by using the Search field. Documents can be viewed at any time and downloaded locally.

This platform can be used through web browsers on any smart device. Data security is ensured by protocols, but also by GDPR. This comes to the aid of the people by organizing and including the contracts in one place, as well as their access in an online environment through a few clicks, all being legal. The existence of predefined contract models is a plus of the application, due to the multitude of different examples found over the Internet, which can be incomplete or outdated. The ones offered by the platform will be in conformity with the new laws and provisions.

Fig. 3: Workflow of model for e-contracting

Conclusions

Digitalization is already part of the life of companies and brings, not only new business models, but also efficiency in business processes, from those in the production and operational departments, to those in marketing and sales.

The authors have proposed in this article a model for a web platform to obtain the following advantages:

- Organization of contracts
- Accessing contracts in real time
- Wide range of contract models
- Online completion of contracts
- Status of the contract completion process
- Maintaining contracts within the platform

- Digital payment
- Digital signature

The platform can only be used if the users are registered. By owning an account, a full access to the platform facilities is given and all the contracts are stored on it online. Therefore, the platform may contribute to the digitalization of the contract signing process.

Safety of Institutional Facilities in The Light of Deficiencies in Project Final Acceptance

Jacek BIL

Military University of Technology in Warsaw, Poland
E-mail: jacek.bil@wat.edu.pl

Abstract

The article discusses issues related to actions taken by individuals (or organizations) whose scope of authorization and responsibility includes acceptance of projects consisting in construction or expansion of institutional facilities. Diligent performance of a public contract or due execution of a commission given outside the public contract awarding procedure requires not only choosing the bid in accordance with expectations, but also following a process of reliable acceptance of the performed scope of work. An analysis of adjudications on cases concerning structural collapses and less significant events has shown that the causes of such events were not faulty designs, but a process of accepting completed work during which the identified irregularities were not revealed. In many cases, individuals responsible for preparing work acceptance protocols take incorrect actions because they are venal and willing to attest false information in exchange for a financial advantage. Presently, most of the entities responsible for work related to construction or repairs of institutional facilities (including critical infrastructure) only declare their readiness to participate in the development of a system for informing on irregularities, without taking any actual action.

Keywords: Public Contracts, Commercial Partnerships And Companies, Corruption, Whistleblower, Security.

Introduction

The safety of institutions and critical infrastructure facilities is seen mainly as an issue of technical and personal security. The following discussion of the research problem pertaining to the safety of such facilities is an innovative analysis of the undisturbed functioning of the society and of the state economy. Designing safe facilities consists in creating conditions that enable elimination or minimization of hazards to people that may emerge during the use of the facility (as a result of adopted design solutions or impact of the environment), as well as elimination or minimization of hazards to the surroundings of the facility. Preventing hazards to the functioning of a facility consists in taking actions both in the construction and in the operation stage (Baryłka 2015, pp. 10-12). The subject matter of the research covers the facility creation (construction) time, particularly the stage consisting in evaluation and acceptance of the implemented project.

As a result of the discourse on the safety of institutional facilities and critical infrastructure, many papers have been published which discuss the issues of securing the functioning of such facilities against acts of terrorism, as well as the issues of fire and technical safety. Technical safety is defined as ‘a state impacted by the manner of fulfilling obligations that consist in maintaining due technical and aesthetic condition of the facility, in accordance with the principles of engineering knowledge, while ensuring, amongst others, fulfilment of basic requirements concerning safety of structure and its use, and suitable sanitary and health-preserving conditions’ (Supreme Chamber of Control, 2013). Although the deliberations proposed by the author of this article fall within the scope of technical safety, they do not concern the safety of an existing facility or issues related to its design. They pertain to the relations occurring in the process of work acceptance between the contractor and the contracting authority or the customer, which are or are not in conformity with the adopted design conditions.
This manuscript has been prepared with the use of an empirical method. It consisted in an analysis of the contents of statements on projects involving institutional facilities and critical infrastructure made

by individuals responsible for preparation of statements of work (SoW) and of terms of reference (ToR) in the area of public contracts, or for preparation of documents related to offerer selection by commercial partnerships and companies, and by representatives of the mentioned entities who had taken part in the process of accepting the completed work (Bil 2019). Additionally, contents of open sources of information have been analysed, with a reference to the monitoring of legal and organizational solutions regarding the methods of limiting deficiencies occurring at the time of acceptance of completed project for the purpose of ensuring safety of institutional facilities and critical infrastructure. The article analyzes three cases related to the catastrophe caused by human error.

Circumstances pertaining to improper acceptance of a completed project

Corruption (caused by receiving money for accepting a project with defects) in the public sector increases the likelihood of technological disasters. It can therefore be argued that the higher the level of corruption in the public sector, the greater the risk of industrial, transport or other accidents. Technical disasters are less common than road accidents, but they cause greater economic and social losses (Yamamura, 2013).

Choosing the most advantageous offer for carrying out work, providing a service or supplying a specific product is an undertaking that is extraordinarily complex in terms of its organization. The most popular criterion for bid selection remains (in the public contracts area) its price, based on which the contractor is chosen (the so-called most advantageous offer that provides the best balance of the price or costs and other criteria pertaining to the contract subject). It is obvious that the contractor must meet the requirements specified in the statement of work and subsequently in the terms of reference. As regards the functioning of commercial partnerships and companies, which are not obliged to observe the Public Procurement Law of 29 January 2004, the selection of the contractor consists first of all in an evaluation of the essential aspects of the presented offer, and then in an evaluation of its commercial aspects (that is price). It seems that the selection of an offer based on its merits and not price is a decision that proves that the offer was correctly prepared. Since the offer selection criterion is not the subject of this analysis, it is not discussed further here. The selection criterion is important when a contract is awarded to an entity that uses subcontractors. It must be stated here that in the relations between the contracting authority/customer and the actual contractor (subcontractor) the general contractor remains present, which has tools for verifying and accepting particular stages of work. An executed contract for carrying out specific work determines conditions of acceptance of particular items of work, and of project completion in terms of the scope of such acceptance and the parties involved therein. A correct procedure for accepting completed work enables revealing workmanship defects or use of unsuitable materials. Of course, the said errors are not present in each implemented project. The author aims to draw the reader's attention to the fact that individuals responsible for accepting work may fail to fulfil their obligation by means of knowingly authorizing the use of facilities where different than designed technological solutions have been used or replacement materials have been incorporated. The attitudes of such individuals are not necessarily a result of corruption. It many cases they may be (or actually are) a consequence of an intention to meet the work completion deadline, or of a decision made by superiors.

From time to time information is published in the media on structural collapses or defects of technical infrastructure facilities. The General Office of Building Control (Główny Urząd Nadzoru Budowlanego, GUNB) has informed that there are several hundreds structural collapses in Poland every year (a structural collapse means an unintended, violent destruction of a civil engineering structure or a part thereof, or of structural components of scaffoldings, components of forming equipment, sheet piling and excavation support systems - Article 73 (1) of the Building Law of 7 July 1994 (Dz.U. {Journal of Laws} of 1994 No. 89 item 414)). In most of the disclosed cases no lives were lost. However, it must be stressed that there were collapses that resulted in deaths or in environmental pollution. The most significant structural collapses of institutional facilities or critical infrastructure in Poland include: Katowice International Fair (Międzynarodowe Targi Katowickie, MTK) building roof collapse in 2006, gas explosion at the PKO Rotunda office in Warsaw in 1979, high-rise building collapse in Gdańsk in 1995, tenement house collapse in Świebodzice in 2017 (Murator Plus 2018),

breakdown at the wastewater lifting station in Gdańsk in 2018 (Wójtowicz, 2019), and collapse of the sewer main under the Vistula river (Chełmiński 2019).

Pursuant to the Regulation of the Minister of Infrastructure of 19 November 2001 on the types of civil structures whose construction requires appointment of an owner's representative (Dz.U. 2001 No. 138 item 1554) an owner's representative must be appointed if certain civil structures are built. Such civil structures include critical infrastructure and institutional facilities. The responsibilities of an owner's representative include, amongst others, checking and inspecting temporary work and work to be covered up, taking part in tests and pre-operational inspections of systems, technical equipment and chimney flues, as well as preparing and taking part in completion inspections and commissioning of civil structures. If, during inspections, the owner's representative finds errors, he/she indicates such departures from the design, which are classified as either minor or major ones. Minor departures do not require obtaining a decision on amendments to the building permit. On the other hand, major departures from the approved building plans and specifications or from other requirements of the building permit can be accepted only when a decision on amendments to the building permit has been obtained. It has been noted, however, that owner's representatives sometimes commit serious offences, which may shake the foundations of safety. Such offences include careless inspections of the quality of construction work and of materials used for carrying out such work, absence of the owner's representative in the course of testing and acceptances of temporary work or work to be covered up, absence during the tests and pre-operational inspections of systems, and failures to confirm the actually completed work (Lenarcik, 2016).

Analyses of court cases concerning the causes of public building collapses have shown that they include negligence on the part of individuals responsible for supervision, including amongst others failures to discharge their duties. An example can be a verdict by the District Court in Warsaw concerning the MTK building roof collapse with which the Court convicted not only the designer and members of the management board, but also a building control inspector.

There are many reasons for such behaviours. The first group of problems identified by the author are behaviours caused by the need to meet deadlines for accepting or settling a project. This concerns particularly projects financed from aid resources. Here the identified deficiencies are not disclosed, as it is believed that the losses that may be caused by such deficiencies are "potentially smaller" than financial losses including, amongst others, the need to return the funds received for project implementation if work is not completed on time. Superiors of the inspectors have knowledge on the identified deficiencies. The inspector's willingness to report major problems is perceived as their disloyalty to the superiors. Another separate group includes behaviours of individuals responsible for work acceptances, which consist in accepting work even though problems have been found, such as departures from the design or incorporation of unsuitable materials. Both in the first case, and in this situation an offence is committed, which consists in attestation of false information and obtaining a financial advantage by the contractor. This is also acting to the detriment of the customer. The third group of problems includes corruption, where the individual responsible for accepting work finds problems with the quality of workmanship or of the used materials, and demands or accepts financial benefits from the contractors in return for refraining from taking actions that would result in performing the commissioned tasks again, this time correctly. At the same time it must be assumed that if a structural collapse occurs, such individuals will bear criminal responsibility for having caused an occurrence threatening the lives or health of many individuals or resulting in a large-size loss of property. It also needs to be stressed that criminal responsibility for a structural collapse resulting in death of an individual or in serious injuries suffered by many people is stricter (Criminal Code of 6 June 1997).

Mechanisms for preventing occurrences that may threat the operations of institutional and critical infrastructure facilities as a consequence of offences committed by individuals responsible for work acceptances.

Insufficient supervision over coordination and implementation activities at the levelthe operational process is a threat to the correct implementation of the project. Providing training is also an important factorand selection of appropriate staff and contractors (Celik, Er, 2007).

The causative behaviours discussed above are penalized under the criminal law with imprisonment, personal restraint or other penalties. Other sanctions include penalties under professional responsibility. It needs to be considered, however, whether penalizing such behaviours is the only countermeasure against such misdeeds. Probably not. Projects which promote reacting to such misconducts have been appearing in business culture and in social responsibility awareness. It is extremely difficult to inform about irregularities in an environment where whistleblowing is seen as something negative. According to deep-rooted beliefs, informing about identified cases of acting contrary to the adopted law or norms is denouncing and is disapproved by the society. Solutions limiting the occurrence of the discussed pathologies in the economic and social life should be adopted on the basis of organizational achievements of companies that have been operating in free market conditions since their inception, and on the foundation of values promoting attitudes that are characteristic of civic society. For about five years more and more voices have been be heard in the Polish public space that the institution of a whistleblower should be introduced and recognized. Currently, Polish law does not contain any legal solutions that would provide legal protection to an individual informing about an activity that is contrary to the adopted legal standards. It needs to be stressed however that more and more companies of both private and public sectors have been introducing anti-corruption policies that include instruments for protecting whistleblowers at such organizations. It is whistleblowers who are a kind of an instrument for revealing irregularities in, for example, acceptances of work carried out as a part of construction of institutional and critical infrastructure facilities. Implemented anti-corruption systems based on, amongst others, the recommendations contained in ISO 37001, which is an international standard on anti-bribery management system, or in the adopted recently (on 25 September 2019) Directive of the European Parliament and of the Council on the protection of persons who report breaches of Union law, can be used as a foundation for developing mechanisms that will facilitate identification of undesirable actions which might undermine the safety of institutional and critical infrastructure facilities. Unless such regulations are introduced and observed, informing on cases of coercing individuals into accepting deficiencies or on identified defects in workmanship will be much more difficult.

Acknowledgement

The safety of public utility buildings and efficient operation of institutional facilities depend on the quality of their construction. As regards contractors carrying out work on such types of structures and installations, cases of accepting and commissioning facilities that do not meet the assumptions agreed upon in the design stage have also been identified. Breaches related to the performance of work and consisting in departures from the planned technological solutions, and in negligent carrying out of particular stages of work with the use of materials not specified in the design documentation may result in a structural collapse or in environmental pollution jeopardizing the health and lives of people. The adopted legal solutions provide for penalizing the perpetrators (officials) for committing torts consisting in a failure to discharge one's obligations or in giving or accepting bribes. It must be stressed however, that they will not enable initiating behaviours that would result in informing about identified deficiencies. The burden of introducing mechanisms that will encourage taking social responsibility and protect whistleblowers should be borne both by the state, and by entrepreneurs which perform tasks aimed at proper functioning of institutional facilities and critical infrastructure. The examples of structural collapses referred to in this article are single events of the type. Nevertheless, it must be remembered that the consequences of negligence related to faulty workmanship and commissioning of defective facilities are disclosed during investigations conducted after the occurrence of events threatening state security.

Abstract

Increasingly, local authorities have to satisfy a great variety of citizens' needs efficiently, resulting from the transfer of competences from Central Administration. However, the scarcity of public resources often requires an increased tax burden, as a way to gather income to finance public expenditure. This can be of various types (general, social, economic and other functions) and determined by various factors (institutional, economic, budgetary and political, among others). There is a clear need for politicians/public managers to have mechanisms to control and inspect public expenditure, in order to avoid an increased tax burden or debt. In this context, this study aims to identify public expenditure by functions in Portuguese local authorities, so as to help politicians/public managers to control this. The results obtained reveal that the illiteracy rate, size, purchasing power index and the form of governance are determinants of some types of expenditure by municipal functions.

Keywords: Public expenditure, Functional expenditure, Public Administration, Municipalities.

Introduction

In fulfilling its functions and responsibilities, the State incurs public expenditure, according to law, this being identified and authorised annually in the State Budget. For Sousa Franco (2015) public expenditure consists of public entities spending money or using goods to create or acquire goods or provide services that can satisfy public needs.

Nowadays, the State assumes functions of a more classic nature, related to health, education, justice, social assistance, etc., but also others of a more economic character, which puts great pressure on public expenditure. This situation is not always accompanied by increased public income which could finance the increased expenditure, leading to an increase in public deficits, and consequently, debt. This is often due to the situation of increased public income not being innocuous regarding citizens/electors' perception, which leads politicians/managers to prefer debt to increasing the tax burden.

In establishing an efficient budget policy, the need arises therefore to ensure that public expenditure adheres to legal rulings but at the same time fulfils the requirements of the economy, efficiency and effectiveness.

In this context, it is essential for politicians/managers, as well as external controlling bodies to have thorough knowledge about the factors influencing public expenditure, to be able, pro-actively, to control and manage this, which will contribute to better spending.

In a situation of increasing decentralization, Local Administration has more competences delegated by Central Administration and faces the same problem, aggravated by that fact that it has no capacity to create taxes, i.e., to increase its income. So it is fundamental to control its spending, but without putting efficient satisfaction of residents' collective needs at risk.

This study aims to identify the determinant factors of expenditure, specifically by functions, namely general, social, economic and other functions, for the year 2016, and focusing on Portuguese local authorities.

To this end, the study is structured in five sections, following this introduction. The second contains a review of the literature on the determinants of public expenditure. The third presents the methodology, namely the objectives, research hypotheses and variables and the data treatment technique. The results are presented in the fourth section, followed by their discussion. Finally, the main conclusions are presented.

Determinants of Public Expenditure

Studies about the determinants of public expenditure by functions are still scarce. Various authors have studied these determinants, associating them with different factors of analysis. Specifically, Sanz and Velázquez (2002), Ollé (2005), Balmas (2015), Alcalde and Martín (2015) and Martins and Correia (2015) studied the determinants of public expenditure, with all of them raising different questions and topics associated with these determinants. Sanz and Valázquez (2001), questioned spending needs or fiscal capacity. Alcalde and Martín (2015) questioned the responsibility of the financing system in relation to the inequality of spending. Ollé (2015) addressed the same topic, associating the study with the influence of the expenditure's composition on the distribution of expenditure by functions. Balmas (2015) made a comparison of local government in Poland and Spain, aiming to find out what determines the distribution of public expenditure in each country. In the same line, Martins and Correia (2015) also studied the determinants of public expenditure, associating them with deviations from budget in Portuguese local authorities.

Table 1 describes the different approaches adopted in studies related to the determinants of public expenditure.

Table 1: Studies about the determinants of public expenditure

Author(s)	Approach
Balmas (2015)	Determinants of public expenditure at a sub-national level: comparison of governments in Poland and Spain.
Alcalde and Martín (2015)	Determinants of autonomy spending: is autonomous regions' financing system responsible for unequal spending?
Pérez and Cucarella (2016)	Needs and spending of autonomous regions.
Ollé (2005)	Determinants of local public expenditure: Spending needs or fiscal capacity?
Sanz and Velázquez (2002)	Determinants of the composition of government expenditure by functions.
Amaral and Oliveira (2010)	Composition of public expenditure and economic growth.
Saraiva (2017)	Efficiency of expenditure by municipal functions: an assessment of Data Envelopment Analysis.

Nogueira, Saraiva and Silva (2017)	Analysis of public expenditure by functions in Portuguese local authorities.
Ferreira (2014)	Functional structure of public expenditure and economic growth.
Martins and Correia (2015)	Determinants of budget deviations in Portuguese local authorities.
Mourão (2004)	Determinants of public expenditure in Portugal – an econometric assessment.
Sanz and Velásquez (2001)	Evolution and convergence of the composition of government expenditure in OECD countries: an analysis of functional distribution.
Aragão, Sobral, Melo and Melo (2012)	Impact of public expenditure by function on growth and the economy in Brazil.

Mourão (2004), Amaral and Oliveira (2010), Ferreira (2014), Nogueira, Saraiva and Silva (2017) and Saraiva (2017) carried out their studies on topics associated with public expenditure, although their main approaches are not directly related to this subject. Amaral and Oliveira (2010) and Ferreira (2014) studied the composition/structure of public expenditure, associating it with economic growth. Mourão (2004) analysed public spending in Portugal, considering its evolution over time. Finally, Nogueira, Saraiva and Silva (2017) and Saraiva (2017) carried out research on public expenditure by functions, the former analysing only Portuguese local authorities and the latter analysing public expenditure, with an emphasis on financial efficiency. So in recent years, study of the determinants of public expenditure has grown significantly, more in the international than in the national sphere, since the determinants of public expenditure and its distribution are considered as appropriate bases to assess and indicate the quality of that expenditure (Amaral and Oliveira, 2010).

Table 2 presents the authors' subjects and objectives in carrying out their research.

Analysis of Table 2 reveals that countries or local authorities were subject to study, with some of these samples being collected over several years, which allowed the authors to use different methodologies, emphasizing the time factor.

Table 3 presents the dependent and independent variables used by the different authors, to respond to the respective research questions.

The authors are found to use diverse variables, both to explain (explanatory or independent variables) and to justify the results obtained (explained or dependent variables), noting a great variety of variables. That variety, directly or indirectly, represents variables of a general, social and economic nature.

Table 2: Subject and objectives of research

Author(s)	Subject	Objective
Sanz and Velásquez (2001)	OECD countries in the period 1970 to 1997.	Verify the existence of convergence in relation to the structure of public expenditure by functions of activity.
Sanz and Velázquez (2002)	OECD countries in the period 1970 to 1997.	Analyse the determinants of functional distribution of public expenditure.
Mourão (2004)	Portuguese public expenditure between 1947 and 2002.	Describe the behaviour of public spending and indicate the determinants explaining the long-term behaviour of public expenditure.
Ollé (2005)	Local authorities in the province of Barcelona with more than 5000 inhabitants for the year 1996.	Determine the influence of municipal public spending needs according to the different levels of public expenditure.
Amaral and Oliveira (2010)	Member states of the European Union between 1998 and 2008.	Analyse tendencies in the evolution of public expenditure by functions in the European Union.
Aragão, Sobral, Melo and Melo (2012)	Expenditure by function in Brazil between 1980 and 2010.	Determine the effect of public expenditure on economic growth.
Ferreira (2014)	European Union countries.	Understand the importance of reallocating public expenditure as a factor stimulating economic growth in the short and long term.

Balmas (2015)	Spain: 1344 local authorities Poland: 307 local authorities.	Investigate the difference between the Polish and Spanish governments concerning the impact of political, geographical and socio-demographic factors in terms of public expenditure.
Alcalde and Martín (2015)	17 autonomous regions from 2002 to 2012.	Study the determinant socio-economic factors in the provision of basic public services.
Martins and Correia (2015)	278 local authorities in mainland Portugal between 2010 and 2012.	Determine and understand in what way budget deviations influence Portuguese local authorities.
Pérez and Cucarella (2016)	Autonomous regions from 2012 to 2017.	Analyse the sufficiency and distribution of expenditure among autonomous regions.
Saraiva (2017), Nogueira, Saraiva and Silva (2017)	308 Portuguese local authorities.	Analyse the efficiency of expenditure by functions in Portuguese local authorities.

The variables most used by researchers are expenditure on health, education (Pérez and Cucarella, 2016), infrastructure (Balmas, 2015) and social services (Alcalde and Martín, 2015). Besides using the variables already mentioned, Amaral and Oliveira (2010) also apply expenditure on transport and communications, economic matters, policing, leisure activities, general public services and defence.

As well as the variables described, other authors use fiscal, socio-demographic, geographical, institutional and economic variables (Balmas, 2015; Alcalde and Martín, 2015; Nogueira, Saraiva and Silva, 2017). Others again use variables related to economic growth (Mourão 2004; Amaral and Oliveira, 2010) and GDP (Aragão, Sobral, Melo and Melo, 2012; Ferreira, 2014).

Summarising, the variables used by the authors are seen to differ according to the nature and specific objective of each study. It stands out that the most relevant variables for the study in question are those of a more general (public administration's general services, public safety and order), social (education, health, safety and social action, housing and collective services, cultural, leisure and religious services) and economic (agriculture, stock-raising, forestry, hunting and fishing, industry and energy, transport and communications, commerce and tourism, other economic functions) nature, and other functions. Fiscal, geographical, institutional and economic variables are also considered.

Table 3: Dependent and independent variables

Author(s)	**Variables**	
	Dependent	**Independent**
Sanz and Velázquez (2002)	Convergence of expenditure.	Health; public services; education; defence; transport and communication.
Mourão (2004)	Growth of public expenditure.	Real GDP; nº of unemployed; nº of Central Administration employees; rate of openness of the Portuguese economy; current transfers.
Amaral and Oliveira (2010)	Economic growth.	Transport and communications; education; economic matters; health; policing; leisure activities; public services; defence; housing.
Aragão, Sobral, Melo and Melo (2012)	GDP per capita.	Administration and planning; social welfare; public safety; education; culture; agriculture and industry.
Ferreira (2014)	Real rate of growth of GDP per capita.	Health; education; policing; economic matters; general services of public administration.
Balmas (2015)	Total expenditure; health; education; culture; infrastructure.	Fiscal, socio-demographic, geographical and political variables, and rate of fiscal decentralization.

Alcalde and Martín (2015)	Health; education; social services.	Demographic, geographical, political-institutional, economic and financial indicators.
Martins and Correia (2015)	Deviations from income and expenditure; debt.	Economic, political, institutional and other variables.
Pérez and Cucarella (2016)	Health and education.	Size of population; standardized spending needs; adjusted spending needs; price index; weight of salaries.
Saraiva (2017)	Public Administration's general services; education; housing; cultural, leisure and religious services; transport and communications.	All licences granted; total electricity consumption; new buildings; nº of pupils in nursery schools; nº of pupil in 1st, 2nd and 3rd cycles; buildings; waste channels produced; urban waste collected; cinemas.
Nogueira, Saraiva and Silva (2017)	Public Administration's general services; education; housing and collective services; cultural, leisure and religious services; transport and communication.	Location; degree of isolation.

Ollé (2005) concludes that local authorities' expenditure needs are explained in 44% by resident spending, 38% by fiscal capacity, 9% by political and institutional factors and 9% by the interdependence existing between nearby governments. Alcalde and Martín (2015) find that demographic factors are relevant in determining public expenditure. This fact explains that public services present scale economies and budget restrictions that influence levels of spending per inhabitant. Alcalde and Martín (2015) also conclude that the government's regional political ideology has a direct influence on the amount of public expenditure and that the government financing system has no significant repercussions on the distribution of social expenditure.

Balmas (2015) finds the existence of political cycles in both Spanish and Polish local authorities, with increased public spending on public goods and services functions in pre-election periods. The author also concludes that excessive manipulation of fiscal aggregates can create debt in local government, and consequently prevent the growth of regional economies. Martins and Correia (2015) conclude that in 2012, of the 278 Portuguese local authorities, 191 present an amount of expenditure greater than the amount of income received. In a year of a general election, the budget balance is greater, whereas deviations from expenditure are less, meaning that political power has a direct influence on public expenditure. They also conclude that the greater local authorities' purchasing power, the less out of line are income forecasts and, in turn, the expenditure made is greater.

Briefly, all the authors present some similarities, since they seek to understand the determinants of public expenditure. Although the topics of the studies are the same, the authors use different explanatory variables, methodologies and data treatment, according to the aims they propose to achieve. In most cases, depending on the case studied, the authors use social spending, spending on education and spending on health as dependent variables and demographic, fiscal and political factors as independent variables. Regarding the methodology chosen, considering that in all the work analysed the time factor is relevant according to the sample, the most commonly used methodology, in these cases, includes panel data analysis, estimation of elasticities and hypothesis testing.

Methodology

Objectives, Research Hypotheses and Variables

The basic issue in this study is related to the increasing need to find out the determinant factors of public expenditure, in the specific case of local authorities. The intention is to contribute to local authority managers, as well as external controlling bodies, having mechanisms allowing them to manage and control expenditure.

Therefore, the aim is to identify the determinant factors of spending by functions, namely general, social, economic and other functions, for the year 2016. This year is studied due to a great many Portuguese local authorities not publishing their accountability documents or when they do so, a considerable period of time has passed since the year they should have been published.

The study is classed as quantitative research, considering the need to resort to instruments of statistical analysis to validate the hypotheses defined (Pardal and Correia, 1995).

The research is exploratory, since it will analyse a sample of 79 local authorities, of the total 308, obtained according to the availability of data on expenditure by functions on their websites, through consulting accounting documents. The intention is not to extrapolate the results to all Portuguese local authorities, but the results could be a starting point for future research.

According to the literature review, an adaptation is made, so as to define a group of hypotheses, aiming to contribute to solving the problem studied. It is considered that the determinants of expenditure by functions in local authorities could be fundamentally related to institutional and political factors.

The research hypotheses to be tested are now presented. It should be noted that the choice, besides being related to the literature review, is related to access to reliable municipal data.

H_1 - Location (coastal/inland) influences municipal expenditure by functions.

H_2 – Size influences municipal expenditure by functions

H_3 – The resident population under fifteen years old influences municipal expenditure by functions.

H_4 – The resident population over sixty-five years old influences municipal expenditure by functions.

H_5 – The resident population's rate of illiteracy influences municipal expenditure by functions.

H_6 – The purchasing power index influences municipal expenditure by functions.

H_7 – Unemployment influences municipal expenditure by functions.

H_8 – Financial independence influences municipal expenditure by functions.

H_9 – The form of governance influences municipal expenditure by functions.

H_{10} – The ideology of the governing party influences municipal expenditure by functions.

Table 4 presents the independent variables associated with each hypothesis, how they are constructed/calculated, and the source of information used.

The dependent variable is the value of expenditure by functions (general sovereign functions (GSF), social functions (SF), economic functions (EF) and other functions (OF)) referring to the year 2016. To standardize the variable, the total amount of expenditure will be divided by the number of inhabitants in the local authority, and so expenditure by functions per capita will be used.

Table 4: Independent variables

Hypothesis	Variable	Form of calculation	Source
H_1	Location (LOC)	Value of 1 for local authorities on the coast	National Programme for Territorial Cohesion
		Value of 0 for inland local authorities	
H_2	Size (DIM)	Number of inhabitants	National Statistics Institute
H_3	Population under 15 years of age (POP<15)	Percentage of population under 15 years of age	National Statistics Institute
H_4	Population over 65 years of age (POP>65)	Percentage of population over 65 years of age	National Statistics Institute
H_5	Illiteracy (ILLIT)	Rate of illiteracy	National Statistics Institute
H_6	Purchasing power index (PPI)	Purchasing power index	National Statistics Institute
H_7	Unemployment (UNEMP)	Number of unemployed	Employment and Occupational Training Institute
H_8	Financial independence (FININD)	Own income/Total income	Local authority portal
H_9	Form of governance (FORGOV)	Value of 1 if the local authority is governed by a majority	National Election Commission
		Value of 0 if the local authority is governed by a minority	
H_{10}	Political ideology (IDEOL)	Value of 1 if the local authority is governed by a right-wing party	National Election Commission
		Value of 0 if the local authority is governed by a left-wing party	

Statistical Data Treatment

The hypotheses formulated are studied through multivariate analysis. This analysis resorts to the linear regression model, in order to assess if the independent variables, as a whole, explain municipal expenditure by functions, and in what way. The multiple linear regression model by the Ordinary Least Squares method is used, considering that several (independent) variables explain expenditure by functions.

Estimation of the linear regression model requires fulfilment of some assumptions (Marôco, 2010), with various tests being necessary to carry out this analysis. For the multi-collinearity analysis, the Variance Inflation Factor was used. According to this author, if VIF values are above 10, the assumption is violated, and multiple linear regression cannot be applied. Heteroskedasticity is tested through the White test. Error auto-correlation is examined through the Durbin-Watson test.

A multiple linear regression model was defined, based on the hypotheses formulated, for the expenditure of the four major groups GSF, SF, EF and OF, which will be the dependent variable. Therefore, the model to test will be as follows:

$$\mathbf{GSF}, \mathbf{SF}, \mathbf{EF}\ \&\ \mathbf{OF} = \alpha + \beta_1 \mathrm{LOC} + \beta_2 \mathrm{DIM} + \beta_3 \mathrm{POP} < 15 + \beta_4 > 65 + \beta_5 \mathrm{ILLIT} + \beta_6 \mathrm{PPI} + \beta_7 \mathrm{UNEMP} + \beta_8 \mathrm{FININD} + \beta_9 \mathrm{FORGOV} + \beta_{10} \mathrm{IDEOL}$$

Findings

The results of estimating the different models are presented, beginning with the study of multi-collinearity. Table 5 reveals that no variable presents a VIF value above 10, and so there is no violation of the assumption. In addition, the tolerance values (1/VIF) are not close to zero, which means, as stated by Marôco (2010), that the regression coefficients are stable in magnitude and sign.

Table 5: VIF of the Multiple Linear Regression Model – General sovereign functions

Variable	VIF	1/VIF
LOC	2.32	0.4315
DIM	4.71	0.2122
POP<15	2.15	0.4662
POP>65	3.61	0.2771
ILLIT	5.65	0.1771
PPI	3.58	0.2795
UNEMP	3.68	0.2714
FININD	1.91	0.5231
FORGOV	1.22	0.8163
IDEOL	1.07	0.9323

In relation to heteroskedasticity, the results of applying the White test demonstrate that the assumption is violated. Therefore, as suggested by Veloso and Bornhold (2016), estimation was performed using the robust (vce) tool of STATA, to resolve the problem.

The results of the F test confirm that, for a 1% level of significance, there is significant statistical evidence, confirming that regressors present values other than zero and explain, as a whole and satisfactorily, the variations found in GSF and SF expenditure. No significant statistical evidence was obtained for the models of EF and OF, and so only analysis of the results obtained for GSF and SF is presented

The results of estimating the model of the determinants of GSF present a relatively low R^2 of 0.11, and so the independent variables explain only 11% of the variations found in GSF expenditure.

For a maximum level of significance of 5%, the variables of DIM and ILLIT are found to be statistically significant. In relation to ILLIT, this presents statistical significance through estimation of the model using OLS. Therefore, the results allow the conclusions that:

- Larger local authorities present lower expenditure on GSF;

- The illiteracy rate has a positive influence on municipal expenditure on GSF.

It is noted that significant statistical evidence was not obtained in relation to LOC, POP<15, POP>65, PPI, UNEMP, FININD, FORGOV and IDEOL.

The model of the determinants of SF expenditure shows an R^2 of 0.19, revealing therefore that the independent variables explain 19% of the variations occurring in expenditure in these functions.

Table 6: Results of the Multiple Linear Regression Model

Variable	GSF	SF	EF	OF
	(1)	(2)	(3)	(4)
LOC	24.80	4.20	-0.64	-2.54
	(1.45)	(0.07)	(-0.01)	(-0.12)
DIM	-0.0005***	-0.0006	0.0001	-0.0004
	(-2.82)	(-0.91)	(0.31)	(-0.86)
POP<15	-18.71	353.20	1091.00	881.00
	(-0.06)	(0.23)	(1.15)	(1.51)
POP>65	-187.90	-650.5	-393.10	370.70
	(-0.83)	(-0.96)	(-0.85)	(1.31)
ILLIT	8.82**	27.63***	23.89**	2.06
	(2.44)	(2.84)	(2.27)	(0.37)
PPI	0.57	2.33**	0.82	0.14
	(0.80)	(2.15)	(1.02)	(0.18)
UNEMP	0.003	0.002	-0.002	0.001
	(0.44)	(0.16)	(-0.22)	(0.13)
FININD	18.46	-27.24	-22.65	22.68
	(0.76)	(-0.66)	(-0.84)	(0.89)
FORGOV	-5.90	73.27**	12.76	-55.92
	(-0.17)	(2.42)	(0.56)	(-1.21)
IDEOL	2.84	2.92	18.77	-26.03
	(0.19)	(0.10)	(0.82)	(-1.32)
_cons	-11.22	-164.20	-222.20	-100.90
	(-0.18)	(-0.73)	(-1.53)	(-0.92)
F	3.306***	4.625***	1.187	1.194
R^2	0.11	0.19	0.23	0.16
N	79	79	79	79
* p<0.10, ** p<0.05, *** p<0.01				

For a 5% level of significance, the variables of ILLIT, PPI and FORGOV are seen to present statistical significance. So in relation to estimation of the model:

- The illiteracy rate has a positive influence on municipal expenditure on SF;
- Local authorities with a higher purchasing power index present greater expenditure on SF;
- Local authorities governed by a majority present greater expenditure on SF.

Concerning the variables of LOC, DIM, UNEMP and FININD, they do not present statistical significance, and so the results of the relations found in the bi-variate analysis are not validated.

Discussion of the Hypotheses

Discussion of the results can contribute to improving the way expenditure is allocated in local authorities, considering that those responsible will have information about its determinants, by functions.

Table 7 presents the results related to each hypothesis. The hypothesis is validated whenever there is significant statistical evidence in at least one of the functions.

Table 7: Determinants of expenditure by functions

Variable	GSF	SF
LOC		
DIM	(-)	
POP<15		
POP>65		
ILLITL	(+)	(+)
PPI		(+)
UNEMP		
FININD		
FORGOV		(+)
IDEOL		

Concerning size, the results allow **validation of H_2**, and so the larger the local authority, the lower the expenditure on GSF. This finding seems to show that larger local authorities manage to obtain some synergies when carrying out expenditure. The results do not allow validation of the hypothesis for SF expenditure.

The hypothesis related to ILLIT is corroborated for two groups of expenditure, GSF and SF, **validating H_5**. This result confirms that local authorities with higher rates of illiteracy have a greater need for general and social expenditure.

In relation to **H_6**, this is only **validated** for SF expenditure. Here, the greater the PPI the greater the social expenditure, which may show that residents' higher income leads to greater social inequalities. These inequalities may lead to a greater need for municipal expenditure in the attempt to remedy them.

The results also allow **validation of H_9** for SF expenditure, and so there seems to be evidence that local authorities governed by a majority present greater social concern, shown in the amount of expenditure of this nature.

Conclusion

Local authorities have limited resources, meaning they must manage their expenditure efficiently and avoid excessive debt. Considering their various competences, local authority managers are expected to make decisions on the type of expenditure to be made, with the aim of satisfying residents' collective needs. In this context, it is extremely important for them to know the determinants of public expenditure on the different functions, to be able to decide pro-actively.

Discussion of the results could contribute to improving how municipal expenditure is carried out, considering that those responsible will have information about its determinants, by functions.

This study aimed to identify the determinant factors of expenditure by functions, namely, general, social, economic and other functions in Portuguese local authorities, for the year 2016.

The results reveal that, regarding expenditure on general sovereign functions:

- Larger local authorities present lower expenditure;

- Local authorities with higher illiteracy rates present greater expenditure.

Regarding expenditure on social functions:

- Local authorities governed by a majority are more likely to have greater social expenditure;
- Local authorities with a higher purchasing power index present higher amounts of social expenditure;
- Local authorities with higher illiteracy rates present higher amounts of social expenditure.

As for the limitations of the study, various problems arose regarding both data collection and the quality of the data. Firstly, the difficulty in collecting indicators from the local authorities. Some do not publish annual accountability reports as requested by the Court of Auditors. Some of the data published are illegible due to the documents' lack of quality. So these factors limited this study, considering that the sample does not represent the country as expected.

Future research could extend the study to a longer period of time, including explanatory variables related to other dimensions, which would allow the application of more robust statistical methods. It will also be important to extend the study to all Portuguese local authorities so as to achieve more significant results regarding the distribution of public expenditure.

Abstract

U The article presents statistical methods that can be used to determine the impact of attributes on the valuation of real estate. The influence of attributes will be determined in two ways: on the basis of valuations of property valuers and on the basis of transaction prices of real estate. The empirical part of the research (based on the data obtained from the land estate market in Szczecin) will be aimed at verifying the hypothesis on the usefulness of the proposed statistical methods for determining the weights of attributes and the influence of individual states of attributes in the mass valuation of real estate value.

Keywords: Mass Valuation, Statistical Methods, Weights of Attributes, Real Estate.

Introduction

The value of the property is estimated based on the features (attributes) of the property. In the process of property valuation, there can be taken into account: surface, technical condition, neighborhood, environment, transport access, location, soil and water conditions, and many more features of a property. The catalog of attributes that can affect the value of a property is an open catalog, and the choice of features depends on the type of property being valued and the availability of information. There are several ways to consider the impact of individual attributes on the value of a property. The degree of attributes influence on a real property value can be defined depending on the condition of a market, taking into account:

1. the results of the data analysis concerning the market prices and characteristics of similar real properties being the subject of real estate trade in a real estate market specified for the needs of an appraisal;

2. the analogy to the local markets similar in terms of their type and area;

3. the examination and/or observation of the preferences of potential real property buyers;

4. another reliable manner.

Real property appraisers typically employ the second or the third method, while the first one raises the greatest doubts, since it involves conducting a statistical analysis in accordance with the assumption of quantitative studies.

The article presents the use of the dependency coefficient to determine the impact of individual attributes on the value of real estate. When choosing the appropriate coefficient, the description of individual attributes should be taken into account - usually these are the features presented on the ordinal scale. In addition, there is no linear relationship between the examined features. The specific characteristics of the attributes describing the properties affect the selection of the appropriate

measure of dependence. The development of the conducted research was the estimation of dependency coefficients based on data from two sources: a database on real estate values and a database on real estate prices. In both databases, real estate has been described by the same set of attributes. Selected properties were valued twice, in the same way - using the Szczecin Mass Real Estate Valuation Algorithm (SAMWN), using relationships estimated based on real estate values or prices. The comparison of the usefulness of both databases was based on the measures of matching estimated property values with property values valued by property appraisers in an individual valuation.

Two research goals have been formulated: to present the use of correlation coefficients to determine the influence of attributes of the property on its value and to compare the results of the valuation based on the database on the value and price land properties.

Mass Appraisal of Real Estate

Mass property valuation (Jahanshiri et al 2011) is discussed when the following conditions are simultaneously met (Hozer et al 2002; Telega et al 2002; Kuryj 2007)

- the subject of valuation is a large number of properties of one type,
- the valuation is to be carried out using a uniform approach, resulting in comparable results,
- all properties to be measured are valued 'at one time', using the same dates of inclusion and price levels.

Organizational mass valuation, in general, takes place in two stages: collecting all necessary information and data concerning all the properties being valued and the relevant market, and performing calculations of the value of all the properties being valued using an appropriate algorithm. Whether a given valuation is a mass appraisal is not determined by the purpose of the valuation or formal considerations, but the subject matter, scope, nature of work and the way they are organized.

The following should be regarded as characteristic areas of usefulness of mass valuation (Hozer et al 1999):

- property valuation for the purpose of updating annual perpetual usufruct fees,
- property valuation for the purpose of estimating the economic effects of adopting or amending local spatial development plans,
- monitoring of the value of the property sets constituting collateral for the bank's credit exposures in order to calculate LtV for the bank's credit portfolio (Cho and Megbolugbe 1996; Korteweg and Sorensen 2016; Tzioumis 2017),
- common real estate taxation (Bradbury et al 2001),
- in certain situations other purposes, such as sale of dwellings from municipal resources, expropriation for linear investments, etc.

The large number of properties being valued and the appropriate sequence of analytical activities entail the necessity to standardize the whole process, including the standardization of the set of market characteristics, their variants (classes, states) and the relatively objective method of their measurement. Organization of the mass valuation process and standardization of market features makes it susceptible to algorithmization.

Concepts for the use of mass valuation models have emerged worldwide with the development of new technologies and informatization (McCluskey et al 2013), but these methods have flourished as a result of constantly improving availability of large databases, information processing techniques and the ability to visualize results. Real estate markets, which consist of thousands or even millions of individual properties, have naturally become an interesting area of research and scientific exploration. The need to explore the unknown also concerned real estate market analyzes in the context of rapid (automated) real estate valuations, including mass valuations (Clapp 2003).

An attempt to classify quantitative methods useful in the mass valuation process is presented in a book edited by Kauko and d'Amato (2008). Mass valuation methods were divided into four groups: modeling-based methods, data-based methods, machine-based methods and expert methods. The study provides an overview of mass valuation techniques used worldwide. According to the authors, price surveys should aim, on the one hand, at spatial tools and, on the other hand, at pragmatic tools (satisfactory from the point of view of estimation accuracy). The balance between sophisticated econometric techniques and practical aspects of valuation accuracy and the possibilities of applying valuation algorithms in practice remains an important aspect (which would also allow the use of tools such as computer simulations, artificial intelligence or machine learning methods).

Jahanshiri et al (2011) also reviewed the models of mass property valuation. The authors pointed out that the real challenge for those applying mass valuation methods are two aspects: the first one concerns the accuracy and consistency of valuations, and the second the speed with which the valuation process can take place. It is also a requirement that the property is regularly revalued so that the taxes calculated based on them are accurate and fair. Automated valuation models use databases of property values and property characteristics and current information about transactions in the markets concerned. The second important part of automated valuation models are statistical methods of property value estimation. The third part is the output information and a graphical interface for communication and visualization of modelling results.

An outline of Automated Valuation Models (AVM), which can also be useful in mass valuations, was presented by d'Amato (2017). In the article he also described other methods (MRA, spatial models) and their evolution in recent decades, he also discussed standards resulting from AVM.

A general overview of quantitative methods used in mass valuation can also be found in Pagourtzi, Assimakopoulos, Hatzichristos and French (2003). Here, the methods are divided into traditional (MRA – regression models, step regression models, methods based on the following approaches: comparative, cost, income, investment) and advanced, such as ANN (artificial neural networks), hedonic valuation methods, spatial analysis methods, fuzzy logic and ARIMA models.

An interesting comparison of modern approaches in mass valuation is presented in McCluskey et al (2013). The study compared the effectiveness of such modelling approaches as MRA, SAR, GWR, ANN. Many useful proposals concerning the accuracy of valuations were also given. The authors emphasize that traditional hedonic models, popular in the early 1960s, were subsequently subject to criticism, which resulted from errors in specification and problems arising, among others, from non-linearity of compounds. Currently, the research focuses rather on the applications of non-parametric (geostatic) regression and artificial neural networks.

Currently, groups of methods using machine learning are often used. This group of methods includes Artificial Neural Networks (ANN), rough-set theory, fuzzy logic, genetic algorithms, etc. An interesting application of machine learning methods was reported by Zurada, Levitan and Guan (2011). In the article they presented a comparative study, in which several methods of regression and artificial intelligence are used in property valuation. The results indicate that non-traditional methods lead to more accurate valuations.

In the literature, mass valuation methods based on modeling include mainly: econometric models (MRA), hedonic regression models and spatial econometric models. The bibliography regarding the possibility of using econometric methods in valuation is quite extensive (Isakson 1998; Benjamin et al 2004; Zyga 2004; Pawlukowicz 2006, 2007; Parzych and Czaja 2015; Dell 2017; Doszyń 2018). Dell (2017) emphasizes that regression and other parametric tools can be very useful in valuation, but in practical applications they often do not bring satisfactory results. He also states that data science and big data as well as a statistical approach can be the future of the mass valuation process.

Also in Poland regression models have been explored for years, this phenomenon was favoured by the legislation in force, which already allowed the use of statistical analysis methods of the real estate market, i.e. as part of a comparative approach: the method of statistical market analysis. At the turn of

the 20th and 21st century in Poland many attempts were made to apply econometric models (most often linear regression models) to model real estate prices or values (Czaja and Żak 1993; Sawiłow 1995; Cellmer 1999; Dacko 2000a; 2000b; Lipieta 2000; Źróbek and Bełej 2000; Pawlukowicz 2001; Zadumińska and Sztaudynger 2001; Źróbek 2002; Lis 2005; Renigier-Biłozor 2008; Zbyrowski 2010; Doszyń 2012; Walkowiak and Zydroń 2012; Doszyń and Gnat 2016; Gdakowicz and Putek-Szeląg 2018). In these models, real estate prices were described by various features, e.g. purpose in the local zoning plan, utilities, transport accessibility, area, development, shape of the plot, year of construction, quality of the land, land configuration. Examples of numerous incorrect valuations and poor application of econometric models in practice and described in the literature are summarized in Prystupa (2016).

A non-classical approach to mass real estate valuation under the market statistical method is the Szczecin Mass Real Estate Valuation Algorithm (SAMWN), detailed and for the first time described in the work of Hozer et al (1999). Initially, the algorithm was used to assess the economic effects of changes in the spatial development plan for the city of Szczecin, and then - to update the fees for perpetual usufruct of land (also in this city). Practical application of this model several times and analysis of the obtained results confirmed its high predictive qualities of real estate values (Hozer and Kokot 2002).

Using SAMWN, it is necessary to determine the influence of individual attributes on the value of the property. This can be estimated based on an econometric (Doszyń 2018), statistical (Dmytrów et al 2019; 2020) or expert (Dmytrów and Gnat 2019) approach. The statistical approach is based on the study of the interdependence between the property value of 1 m^2 and the attribute values describing the real estate. The way in which such a correlation can be studied depends to the greatest extent on which scales the values are measured. The value of 1 m^2 of property is measured on the strongest, quotient scale. In turn, the values of attributes are measured on a much weaker, orderly scale. If one wants to carry out any actions on variables measured on different scales, one should convert them to the weakest scale (Walesiak 1996). The influence of attributes on the value of 1 m2 of property can be estimated using correlation coefficients. When studying the correlation between the attributes in the real estate market and the value of 1 m2 the following problems are encountered (Dmytrów et al. 2019):

- the attributes describing the properties being valued are very often of a qualitative nature - they are measured on an orderly scale (Walesiak 1996),
- the differences between successive values of attributes measured on an ordinal scale are not necessarily constant (changes are not linear),
- when examining correlations between the value of 1 m^2 and individual attributes, the influence of the remaining attributes, which may significantly disturb the examined correlation, should be eliminated.

Considering the above, rank-based correlation coefficients should be used to describe the interdependence of such characteristics. The use of correlation coefficients for qualitative variables in the real estate market was proposed (Barańska 2009; Kulczycki and Ligas 2014; Doszyń 2017; Babatunde 2018; Dmytrów et al. 2019; 2020). The best known are the correlation coefficient of Spearman's rank ς and Kendall's τ coefficient (Aczel 2005). Although both coefficients are based on ranks, both have a different philosophy of calculation. Spearman's ς coefficient is calculated on the basis of differences between the ranks of both variables, and Kendall's τ coefficient is based on the ratio of superiority between the observation pairs of both variables – hence the use of Kendall's τ coefficient is much more justified. This coefficient occurs in several varieties: τ_A, τ_B and τ_C. Coefficient τ_A is calculated assuming, that there are no bound ranks. The factor τ_B assumes, that there are bound ranks, while the factor τ_C is the most suitable for data in the form of contingency table. In the case of data used in the study, where the number of observations is much higher than the number of varieties of tested attributes, bound ranks will certainly occur. Therefore Kendall's τ_B factor was applied.

The dependency coefficients were estimated twice as:

- the relationship between the value of the property estimated in the individual valuation by property appraisers and the attributes of these properties;
- the relationship between the price of the property (transaction price) and the attributes of the property sold.

Therefore, empirical data came from various sources. In the first case, it was a specified area of the city of Szczecin, with identified land properties. The properties were described by a set of attributes, and then valued in an individual approach by authorized property appraisers. In the second case, the analysis used real estate that was the subject of purchase and sale in Szczecin. Also these properties were described with the same set of attributes. Data obtained from the Register of Real Estate Prices and Values (RREPV) maintained by the Municipal Surveying and Cartographic Documentation Center in Szczecin.

RREPV is the public register kept by a starost (county chief) which include data on real estate prices given in notarial deeds and (sometimes) real estate values given by real estate appraisers in appraisal reports which extracts are provided to the register of land and buildings. RREPV is defined by The Order of Ministry of Regional Development and Buildings (RDB). The following data are recorded in RREPV: real estate's price and value, real estate's address, numbers of parcel being estate's components, estate's type, estate's area, the date of authenticated deed signing or the date of real estate valuation, other data concerning real estates. Register of Real Estate Prices and Values is a register to which all land ownership change transactions are mandatory, and buy-sell transactions are also recorded there.

Research Methodology

An algorithm for mass valuation of real estate that meets the assumptions of such a procedure is the Szczecin SAMWN mass valuation algorithm. Property valuation is based on the form algorithm:

$$w_{ji} = wwr_j \cdot pow_i \cdot w_{baz} \cdot \prod_{k=1}^{K} \prod_{p=1}^{k_p} (1 + A_{kpi}) \tag{1}$$

where:

w_{ji} – market value (or cadastral value) of i- th property in j- th location attractiveness zone,
wwr_j – market value ratio in j- th location attractiveness zone (j = 1, 2, …, J),
J – number of the location attractiveness zones,
pow_i – the area of i- the property,
w_{baz} – the estimated value of 1 m^2 of the property with the worst attribute states in the worst location attractiveness zone,
A_{kpi} – the influence of p- th category of k- th attribute for i- th property (k = 1, 2, …, K; p = 1, 2, …, k_p),
K – the number of attributes,
k_p – the number of k- th attribute category,
N – number of properties being valued (i = 1, 2, …, N),
R – number of representatives (r = 1, 2, …, R).

The algorithm determines the market or cadastral value of the property, not the price. The reference point for determining the value is the base value, i.e. the value of 1 m^2 of the property with the worst state of attributes, in the worst zone of location attractiveness. The base value is multiplied in the algorithm by the influence of attribute states of the property being valued.

The impact of attribute states (A_{kpi}) can be determined by quantitative methods, for example by statistical methods. The value of a property depends not only on its attributes. The value is also influenced by factors on the demand side. Two properties that are very similar in terms of their

attributes can have different values if they are located in different location attractiveness zones (SAL). In the algorithm the influence of such factors is taken into account by market value factors (wwr_j). These coefficients are determined for each location's attractiveness zone and show the location's influence. The market value coefficient for the *j*- th location attractiveness zone can be determined as:

$$wwr_j = \sqrt[n_j]{\prod_{i=1}^{n_j} \frac{w_{ji}^{rz}}{w_{ji}^{h}}} \tag{2}$$

where:

w_{ji}^{rz} – the value of *i* – th property in *j*- th location attractiveness zone determined by a property appraiser,
w_{ji}^{h} – the hypothetical value of *i*- th property in *j*- th location attractiveness area,
n_j – the number of representative properties in *j*- th location attractiveness zone.

The market value coefficients are on the basis of representative real estate valuations carried out by property valuers. Appraisers value representative real estate on an individual basis, which results in real property values (w_{ji}^{rz}). On the other hand, hypothetical values (w_{ji}^{h}) are calculated on the basis of (1), but excluding market value coefficients:

$$w_{ji}^{h} = pow_i \cdot w_{baz} \cdot \prod_{k=1}^{K} \prod_{p=1}^{k_p} \left(1 + A_{kpi}\right) \tag{3}$$

If the values of randomly selected or appropriately selected representative properties are known (w_{ji}^{rz}), attribute states, influence of attribute states, base value (w_{baz}) and surfaces, then for each zone of location attractiveness it is possible to estimate market value coefficients by calculating the geometric mean from the quotients of real values and hypothetical real estate. Knowing the market value coefficients for individual location attractiveness zones, it is possible to estimate the market (cadastral) value of each property located in it, taking into account the property attribute states.

When estimating the influence of the state of attributes on the value of real estate, Kendall coefficients and partial values of these coefficients (Parker et al 2011; Han and Zhu 2008). In the case of the data used in this research, where the number of observations is substantially higher than the number of varieties of the examined attributes, tied ranks are certain to occur. Which is why, τ_B Kendall coefficient was applied and computed as follows:

$$\tau_B = \frac{n_c - n_d}{\sqrt{(n_0 - n_1)(n_0 - n_2)}} \tag{4}$$

where:

$n_1 = \frac{\sum_i t_i(t_i - 1)}{2}$, $n_2 = \frac{\sum_j u_j(u_j - 1)}{2}$,
t_i – number of observations in a sample featuring the same *i*- th rank value of *x* property,
u_j – number of observations in a sample featuring the same *j*- th rank value of *y* property.

In order to eliminate the impact of the remaining attributes during the correlation test between a given attribute and the value of 1 m^2 partial correlation coefficients were calculated:

$$\tau_{yx.z} = -\frac{R_{yx}}{\sqrt{R_{yy} \cdot R_{xx}}} \tag{5}$$

where:

y – vector of the explained variable value,
x – vector of the explaining variable value,
z – vector (or matrix) of the remaining variables,
R_{yx} – determinant of a matrix cofactor obtained by removing the row corresponding to y variable and the column corresponding to x variable,
R_{yy} – determinant of a matrix cofactor obtained by removing the row and column corresponding to y variable,
R_{xx} – determinant of a matrix cofactor obtained by removing the row and column corresponding to x variable.

On the basis of these partial coefficients, weights were determined, i.e. the influence of particular attributes on the value of 1 m^2 of property. The weights were determined as a percentage share of individual coefficients in the sum of all coefficients:

$$w_k = \frac{\tau_{yx_k.z}}{\sum_{k=1}^{K} \tau_{yx_k.z}} \cdot 100\% \tag{6}$$

where:

k – number of an analysed attribute,
K – number of attributes.

The greater the share of the value of a partial correlation coefficient of a given attribute is in the sum of the values of all attributes coefficients, the greater the weight ought to be assigned to a given attribute.

Additionally, it was assumed that due to the scaling of attribute levels (a higher attribute level means a higher value of 1 m^2 of real estate) all correlation coefficients should have a positive value. If the value of the coefficient is lower than 0 then a negligible impact of this attribute on the value of the property is assumed, and in further calculations, zero is assumed. To determine the impact of each attribute state in the SAMWN the formula was used (Doszyń and Dmytrów 2019):

$$1 + \alpha_{kp} = e^{\ln\left(\frac{w_{max}}{w_{baz}}\right) \cdot u_{kp}} \tag{7}$$

where:

w_{max} – the theoretical, maximum property value for the best attribute states, in the most expensive location attractiveness zone,
w_{baz} – the base value,
u_{kp} – the state p of the attribute k is calculated as follows:

$$u_{kp} = \frac{w_k}{k_p - 1}(p - 1) \tag{8}$$

where:

w_k – weight of k- th attribute, $p = 1, 2, \ldots, k_p$.

The procedure for estimating the impact of individual attributes on the value of real estate was carried out twice. First, the relationship between the property value estimated in the individual approach by property appraisers and individual property attributes was calculated. The second case involved examining the relationship between real estate transaction prices and individual real estate attributes. The dependency coefficients obtained in two approaches were used as a basis for calculating the impact of individual attributes on the value of the property (formula 6). Then the same group of real estate was valued twice using SAMWN and two cases of calculating the impact of attributes (based

on real estate values and prices). The obtained valuation results were compared by determining the error between the values of 1 m^2 of real estate estimated by property appraisers and the values estimated by the algorithm. For this purpose, the mean absolute percentage error *MAPE* (Mean Absolute Percentage Error) was used:

$$MAPE = \frac{100\%}{n} \sum_{i=1}^{n} \frac{|w_i - w_{t,i}|}{w_i} \tag{9}$$

where:

w_i – the value of 1 m^2 of property estimated by a real estate appraiser,
$w_{t,i}$ – the value of 1 m^2 of property estimated by SAMWN.

An error (9) at a low level will indicate a good adjustment of the algorithm to real data – valuations obtained on the basis of the algorithm will be at a level similar to individual valuations. A high *MAPE* error rate will indicate the divergence from the actual valuations algorithm. The first situation is desirable - convergence of individual valuations with SAMWN algorithm valuations. The *MAPE* error was counted twice for the two methodological approaches using SAMWN.

Empirical Study

Data

Valuation of SAMWN was performed on 118 land properties located in the northern part of Szczecin (fig. 1). The properties were grouped into 17 location attractive zones. These properties have been valued by property appraisers (fig. 2).

Fig. 1: The northern region of Szczecin

Source: authors own study.

Fig. 2: Szczecin area with marked local attractiveness zones
Source: authors own study.

A set of features (attributes) has been defined for each property:

- Area: 1 – large, 2 – average, 3 – small;
- Technical infrastructure: 1 – none, 2 – partial, 3 – complete;
- Neighbourhood: 1 – troublesome, 2 – unfavourable, 3 – average, 4 – favourable;
- Access: 1 – unfavourable, 2 – average, 3 – favourable;
- Physical properties: 1 – unfavourable, 2 – average, 3 – favourable.

Number 1 is assigned to the least favourable state and the largest to the most favourable state.

The real estate value estimation by SAMWN

For the selected properties Kendall dependence coefficients B (formula 4) and partial coefficients (5) were calculated. Coefficients have been calculated for the relations between the value of 1 m^2 and the attributes of the property (Table 1) and between the price of 1m^2 and the attributes of the property (Table 2).

Table 1: Kendall's τ_B coefficients and $\tau_{yx.z}$ partial correlation coefficients the value of 1 m^2 versus the value of the property attributes

Coefficient	Area	Technical infrastructure	Access	Neighbourhood	Physical properties
τ_B	-0.009	-0.005	**0.306**	0.093	-0.007
$\tau_{yx.z}$	0.055	0.059	**0.315**	0.099	-0.036

Bold marked statistically significant dependencies.
Source: authors own study.

Table 2: Kendall's τ_B coefficients and $\tau_{yx.z}$ partial correlation coefficients the price of 1 m^2 versus the value of the property attributes

Coefficient	Area	Technical infrastructure	Access	Neighbourhood	Physical properties
τ_B	0.220	0.218	0.150	0.164	0.253
$\tau_{yx.z}$	0.178	0.167	0.062	0.047	0.185

Source: authors own study.

In the first case (table 1) Kendall's correlation coefficient generally indicate a lack of correlation between the value of 1 m^2 and the levels of attributes. Only the relationship between the value of 1 m^2 and access is relevant, although the strength of the relationship is quite weak. In addition, most of the coefficients have a negative value, which should not be the case. For the partial coefficients, the results improved significantly. In each case, the strength of the relation is greater and in addition, the coefficients in most cases are positive. Only for physical properties coefficient is negative, but very weak and statistically insignificant, so this attribute is omitted.

In the second case (table 2) Kendall's correlation coefficients indicate significant positive relationships. The strongest correlation was between the price and physical properties, the weakest between the price and access – that is quite contrary to the previous case. Lower values of partial correlation coefficients were recorded for all attributes. Additionally, two of them stopped indicating a significant correlation. Such a disproportion between partial and coefficients indicates the collinearity of features. Such differences between the values of correlation coefficients in both cases may result from different identification of the impact of particular features on the real estate market.

Based on the above partial dependency coefficients, the impact of individual attributes on the property value was calculated (formula 6). The results are summarized in Table 3.

Table 3: weights to individual attributes the value and the price of 1 m^2 versus the value of the property attributes (%)

Attributes	Area	Technical infrastructure	Access	Neighbourhood	Physical properties
Value	0.220	0.218	0.150	0.164	0.253
Price	0.178	0.167	0.062	0.047	0.185

Source: authors own study.

In the first case (table 3) the bigger influence on the property value had access (almost 60%), neighborhood (19%) and technical infrastructure (11%). The relation between the value of 1 m^2 of real estate and physical features was negative, therefore the weight assigned to physical features was equal to 0%. For the price the bigger impact had physical properties (almost 30%), area (28%) and technical infrastructure (26%). All attributes affected the price.

Attribute weights (from table 3) were used to calculate the impact of the individual attribute levels on the property value and price (according to formula 7).

Table 4: attribute influence vector in SAMWN

Attributes	Level of attribute	Value	Price
		$1 + \alpha_{kp}$	
Area	Large – 1 Average – 2 Small – 3	1 1.014 1.029	1 1.039 1.079
Technical infrastructure	None – 1 Partial – 2 Complete – 3	1 1.015 1.031	1 1.131 1.262
Access	Unfavourable – 1 Average – 2 Favourable – 3	1 1.085 1.178	1 1.047 1.098
Neighbourhood	Troublesome – 1 Unfavourable – 2 Average – 3 Favourable – 4	1 1.017 1.035 1.053	1 1.024 1.049 1.073
Physical properties	Unfavourable – 1 Average – 2 Favourable – 3	1 1 1	1 1.145 1.290

Source: authors own study.

The weight for the attribute of the physical properties was set at 0, so for each level the influence is equal to 1. The successive transitions between the attribute levels increased the value of the property the most for access (the weight of this attribute was the greatest). For the first case – values of 1 m^2 – a property with average access was worth 8.5% more than a property with unfavourable access. On the other hand, the favourable access attribute increased the value of 1 m^2, the property was worth 17.8% more than the unfavourable access (table 4). In the second case – prices – the value of real estate was increased the most by the improvement of physical attributes – almost 30% and technical infrastructure – 26%.

Using the obtained results of correlation coefficients, the values of selected land properties were estimated using SAMWN (formula1). Theoretical values were compared with property values estimated by property appraisers (this is called true values). The algorithm was used twice – once for the coefficients calculated between the value and the attribute level, the second time for the coefficients calculated between the price and the attribute level. On the figure 3 there are plots of 3 property value distributions. Two of them are property values estimated by an algorithm and both are very similar.

Fig. 3: Comparison of estimated real estate values (by SAMWN) with true values
Source: authors own study.

The values of the properties estimated by SAMWN were less volatile (in both cases) than the actual values (fig. 3). The medians of the estimated values are below the median of the true values.

In the next step, measures were calculated to investigate the differences between the real values and the property values estimated by SAMWN. The mean absolute percentage error (MAPE) (formula 9) was used:

$$MAPE_{value} = 14.24\% \qquad MAPE_{price} = 14.97\%.$$

The application of property values or purchase prices of real estate in the process of valuation does not have a significant impact on the results of errors. Valuation errors in both cases are at a similar level.

Summary

Property valuation is becoming increasingly important on a massive scale. In models that enable mass property valuation, it is important that the valuation process is standardized and limits the share of the human factor to a minimum. The Szczecin algorithm of mass real estate valuation is such a model. Additionally, the applied statistical approach ensures objectivity of obtained results. However, the question may arise on the basis of which information to determine the influence of particular attributes on the value of the property: whether on the basis of relations observed on the buy-sell market or on the basis of expert knowledge of property appraisers. Both approaches have their advantages and disadvantages.

The advantage of using the first approach is a direct reference to the relations observed on the market. As customer preferences change, dependencies will change. It is also a relatively cheap solution, because information on the sale and purchase of real estate is placed in the public Register of Price and Value (in some cases a small fee is required). The use of statistical methods in the analysis of dependencies requires that the database on the basis of which the calculations are made should be of

adequate size. Thus, in local markets, where there are not enough buy and sell transactions, the use of data from the Price and Value Register can be problematic, which is a disadvantage of the proposed method of calculating the impact of attributes on the value of real estate.

In the case of the second approach - the use of individual valuations - the advantage is the possibility of valuing the necessary number of properties, regardless of market size. Even in underdeveloped markets, it is possible to value an appropriate number of properties. The disadvantages of this approach include the necessary time and financial expenditure. Since an individual valuation must be prepared for a sufficiently large community, appraisers must have time to prepare it. Each individual valuation involves an individual payment for the work done. This significantly increases the cost of the mass valuation process.

The article presents the possibilities of using statistical methods in Szczecin's mass valuation algorithm. The choice of statistical method should take into account the specificity of the attributes (e.g. the type of scale – ordinal). The correlation coefficients necessary to estimate the vector of influence of attributes may be calculated on the basis of the value or price of the property. The use of property value requires individual valuations by property appraisers – the right time and money is needed. The use of transaction prices is faster and cheaper, but a sufficient number of transactions is necessary. For small, local markets it will be more convenient to use the value of the property, for large, developed markets – prices.

Support of European Regional Development Funds for NUTS2 And NUTS3 Regions In Romania

Corneliu RUSSU

Center of Industry and Services Economy, Romanian Academy, Bucharest, Romania
Email: corneliu_russu2007@yahoo.com

Abstract

The article deals with the significant contribution of the European structural and investment funds to the economic and social progress of Romania and its counties. The motivation for choosing such a theme is that lately I have dealt with the economic and social development of the NUTS2 and NUTS3 regions in Romania and the convergence of their development level with that of corresponding regions in other European Union member states. The methodology used is that of the comparative analysis between different entities (countries, counties) of some relevant indicators regarding the absorption of the European structural and investment funds and their effects on the development of the compared entities. The very large differences between the Romania's counties regarding the absorption of European funds are highlighted, the main cause of the low degree of absorption being the reduced administrative capacity of the regional and local authorities to create the conditions necessary to access these funds to a greater extent. The achievements registered in the implementation of the national programs financed from European funds, although presented only partially, are convincing through their contribution to the economic and social development of the country and its counties. The conclusion is that the support of European funds is particularly beneficial for Romania and its counties, constituting a strong spring for their development

Keywords: European Funds; Absorption Rate; Project of Regional Policy; Priority Axe

Introduction

The regional policy of the European Union is based on two pillars: the application of the political principle, according to which the most developed countries and regions must be in solidarity with the least developed ones; the application of the economic principle, from the perspective of which the levels of economic development of some less developed member countries and regions and those where the unemployment rate is high determine the reduction of the economic development potential of the whole Union.

The consistent application of these two principles aims, in essence, at reducing the economic and social differences between the member countries and regions of the Union, which continue to be significant, with regional and sectoral investments being made mainly in infrastructures and intangible assets (education and training, transfer of know-how, professional services) in less developed regions and sectors of activities in difficulty. These investments means the financial solidarity of the member countries, i.e. the allocation of an appreciable part of the Community budget, to which all Member States contribute, to regions and social groups with developmental deficits.

For the period 2014-2020 the objectives of the European Union's regional policy correspond to the coordinates of the Europe 2020 Strategy for smart, sustainable and inclusive growth in the EU and are as follows: 1. Supporting R&D and innovation activities; 2. Supporting the digital economy, information and communication technology (ICT); 3. Increasing the competitiveness of SMEs; 4. Supporting the shift towards "low carbon economy".

The instrumental side of the European Union's regional policy consists of a range of funds intended to help member countries to achieve the mentioned objectives: Structural Funds (European Regional Development Fund - ERDF, European Social Fund - ESF); Cohesion Fund (which aims to develop and improve transport networks, environmental protection by promoting the expansion of the "green economy", connectivity and accessibility to the broadband infrastructure at regional level); The EU Solidarity Fund – EUSF (to respond to major natural disasters and express European solidarity to disaster-stricken regions within Europe)

The paper presents as novelty elements the critical analysis of the low absorption of European funds in Romania and its counties compared to other countries in Central and Eastern Europe, as well as the main causes of poor absorption so far. These elements can be found in the paper dealing with: how the European Union differentiates the support provided according to the level of development of the regions; absorption of European structural and investment funds at the level of Romania and its counties; the beneficial effects of Community funding of national projects; the main aspects resulting from the critical analysis achieved.

Differentiation of community support depending on economic situation of the regions

The coverage of all regions of the Union by its regional policy is differentiated, depending on the level of regional GDP / inhabitant relative to the average on the Union as a whole: regions considered less developed, where the mentioned level is less than 75% of the Union average; regions considered in transition, where the mentioned level is between 75% and 90% of the Union average; regions considered more developed, where the mentioned level is over 90% of the Union average.

The highest share of the structural funds is allocated to support the economic and social development of the less developed regions through regional policy projects funded by the ERDF and ESF, as well as the Cohesion Fund.

The regions considered less developed are numerous and scattered throughout the Union as follows (these are NUTS2 regions): all regions of the former communist member countries - Bulgaria, Croatia, Czech Republic, Estonia, Latvia, Lithuania, Poland, Romania, Slovakia, Slovenia, Hungary - with the exception of a region that usually includes the capital of the country, in Bulgaria, the Czech Republic, Croatia, Poland, Romania, Slovakia, Slovenia, Hungary; France - 4 regions (from overseas territories); Greece - 6 regions; Italy - 5 regions in the south of the country; Portugal - 4 regions; Spain - a region.

The regions in transition receive funding through the mentioned funds lower than that destined to the regions considered less developed. It should be noted that the significant enlargement of the European Union by the admission of new member countries in 2004 and 2007 has led to a reduction of the average level of GDP / capita, which has made some regions of the old member countries to exceed the threshold mentioned by their GDP / capita of 75%; as a result, the support granted to these regions was a transitional one, phasing-out in the 2007-2013 budgetary exercise; the regions that exceeded the threshold of 75% and before the enlargement mentioned, so during the period of the existence of the EU15, were progressively supported (phasing-in) through the 'Increasing the regional competitiveness and the use of the labor force' objective. The regions in this category in the financial year mentioned were scattered as follows: Austria - 1; Belgium - 4; Denmark - 1; France - 10; Germany – 8; Italy – 3; Malte – all; Portugal - 1; Spain - 5.

The more developed regions, which receive the smallest funds as a whole, are supported to improve their business climate and increase their attractiveness for investors; under these conditions financing projects aimed at supporting universities and scientific research institutions, micro, small and medium-sized enterprises, business and job creation, training and professional capacity improvement. The distribution of these regions in the member countries was as follows: Austria - all but one in transition; Belgium – 7; Cyprus - all; Czech Republic - 1 (Capital); Denmark - all; Finland - all; France - 13; Germany - 31; Greece - 1; Hungary – 1; Ireland - 3; Italy - 13; Luxembourg - all;

Poland - 1; Portugal - 2; Romania - 1 (Capital); Slovakia - 1 (Capital); Slovenia - 1; Spain - 13; Sweden - all; The Nederlands – all.

The picture of the development regions of the European Union, most of them in the NUTS2 category, is highly diversified on the scale of the community as a whole and that of both developed and less developed member countries. Despite this diversification, several main aspects can be highlighted: all the former communist countries have, in overwhelming proportion, less developed regions; the Nordic countries - Denmark, Finland, Sweden, the Netherlands, - have only developed regions; the countries with the highest economic and commercial potential in the Union - Germany, France, Italy, Spain - include regions from all three groups shown; in most former communist countries, the developed regions are those that comprise the capital.

The presented division of the regions of the European Union is, unfortunately, not relevant for the NUTS3 regions as the disparities between them, components of the NUTS2 regions, are in many cases greater than between the latter, as the inter-regional disparities within each member countries are larger than those between countries. In addition, the overwhelming majority of studies and analyzes of economic development disparities within the European Union focused on NUTS2 member countries and regions within them, without extending to NUTS3 regions, the main cause being the lack of detailed statistical data regarding the last category of regions.

The absorption of European structural and investment funds at county and national level

Through the effects of applying the regional development policy of the European Union evaluated at the end of the last budgetary exercise, the respective policy has proved its appreciable role in the faster development of the regions lagging behind and, implicitly, in reducing inter- and intra- regional disparities.

In the EU budget 2014-2020, the European Union regional development policy is in fact transposed through a series of operational programs that continue those of the previous EU budget 2007-2013, of which we are particularly interested in the OPRD - Operational Program for Regional Development; through this program, managed by the Ministry of Regional Development and Public Administration as Managing Authority, Romania can access the structural and investment funds from the ERDF.

The general objective of the OPRD is to increase the economic competitiveness and to improve the living conditions of the regional and local communities. The objective was detailed in 11 priority axes of action, for which the initial allocation of funds was € 8.25 billion, of which € 6.7 billion is the European Union support through the ERDF and € 1.5 billion the national contribution.

Of the 11 priority axes, the ones with the most significant impact on the regional development are the following: PA1. Promoting the technological transfer (206.51 million of euro); PA2. Improving the competitiveness of SMEs (877.11 million of euro); PA3. Supporting the transition to a low carbon economy (2375.56 million of euro); PA4. Supporting sustainable urban development (1386.86 million of euro); PA6. Improvement of road infrastructure at national level (1068.36 million of euro); PA10. Improvement of the educational infrastructure (352.19 million of euro).

The experience of Romania's access to European funds has demonstrated the existence of numerous chronic deficiencies that have resulted in a reduced absorption rate, lower than that achieved by most other Central and Eastern European countries.

At the level of counties, the value of the attracted European funds varies widely from one county to another, regardless of the extent of their economic and social development, as shown by the figures in the following table.

Table 1 : Ranking of counties according to the value of contracts signed for projects financed from European funds, 07/07/2019 (million of euro)

County	Value	County	Value	County	Value
Ilfov	**2159.4**	**Brașov**	**235.4**	**Suceava**	**160.0**
București	**1445.7**	**Bacău**	**213.1**	**Neamț**	**155.1**

Vâlcea	**245.5**	**Mehedinți**	**160.0**	**Teleorman**	**42.1**

Source: *Ziarul Financiar – reproduction: Government of Romania, Ministry of European Funds, Communication Department. Contracts signed for projects financed from European money, 2014-2020, Bucharest, July 7, 2019*

The NUTS3 units that managed to attract the largest European funds were, in decreasing order of funds value, Ilfov, Bucharest, Constanta, Cluj and Bihor, that is three of the most developed counties; at the opposite pole, the counties with the lowest performances in attracting European funds were, in increasing order of funds value, Teleorman, Ialomița, Giurgiu, Covasna and Călărași, all counties less developed, with the GDP / inhabitant level well below the national average.

From the point of view of the European funds attracted, it cannot be considered that there are differences between the developed and the least developed counties since, for example, counties in the first category such as Brașov and Sibiu attracted significantly smaller funds than Dolj or Vâlcea in the second category. The explanation of this situation lies, in our opinion, to the different extent of the involvement of local authorities in ensuring the preparation, elaboration and support of projects financed from European funds at the qualitative level required by the community bodies with responsibilities in the field. Such involvement implies the creation at local level of a body of specialists with expertise in the elaboration, endorsement and support of projects submitted for financing from structural and investment funds, able to effectively support the efforts of potential beneficiaries of funds.

At the same time, the potential differences between counties in attracting European funds also reflect the interest and actions of the local authorities in: improving the business environment; ensuring transparency; stimulating communication between local institutions of different profiles in order to correlate the plans and programs established on these profiles; intensifying the involvement of action groups and associations set up locally to improve these plans and programs; stimulation of collaboration with neighboring counties and outside the development region for exchanges of experience and the higher capitalization of available resources.

The difference of involvement of local authorities in accelerating regional development and modernizing economic activities in counties based on the progressive building of the digital economy with the help of European funds is also illustrated by the large disparities between counties regarding the absorption of the funds allocated to digitization, presented in the following table.

Table 2: Ranking of counties according to the amounts absorbed until November 2019 from European funds dedicated to digitization for the period 2014-2020 (million of euro, amounts paid)

County	Value	County	Value	County	Value
Ilfov	87.8	**Arad**	1.8	**Brașov**	0.3
București	62.8	**Maramureș**	1.6	**Teleorman**	0.2
Cluj	27.9	**Brăila**	1.3	**Alba**	0.2
Iași	19.9	**Vâlcea**	1.2	**Covasna**	0.1
Sibiu	9.7	**Tulcea**	1.2	**Vaslui**	0.08
Prahova	8.4	**Constanța**	1.1	**Neamț**	0.06
Mureș	7.6	**Ialomița**	0.9	**Bistrița-Năsăud**	0.04
Dolj	7.4	**Bihor**	0.9	**Botoșani**	0
Olt	6.2	**Gorj**	0.8	**Hunedoara**	0
Giurgiu	5.1	**Suceava**	0.8	**Mehedinți**	0
Dâmbovița	4.9	**Argeș**	0.5	**Sălaj**	0
Galați	3.3	**Vrancea**	0.4	**Bacău**	0
Timiș	3.3	**Buzău**	0.4	**Caraș-Severin**	0

The hierarchy of counties established according to the level of this indicator is dominated by Ilfov county and Bucharest, followed closely by Cluj and Iași counties, strongly committed to digitizing the economy and society thanks to the university centers, research institutions and private IT services units they have. Other developed counties such as Sibiu, Timiș or Brașov have attracted much smaller European funds for this purpose, which is surprising given that they also have a wide range of mentioned institutions.

Under these conditions it is worth highlighting the performance of counties with a lower level of development - Dolj, Giurgiu -, which have managed to attract European funds in notable amounts for digitizing their activities, a realization all the more remarkable since the last county lacks the university and academic institutional framework which many other counties are endowed with.

The existence of seven counties that did not attract European funds at all for the digitization of their activities and many others that spent derisory amounts for this purpose denotes the widespread lack of awareness by some local authorities and companies in the private and public environment of the considerable benefits the digitization generate in increasing the competitiveness of the county economies, reducing bureaucracy, improving the living conditions of the local communities. At the same time, the figures in the table above highlight that the notable progress at national level, although still limited, is largely due to some top NUTS3 regions - the four mentioned above -, which were detached, by their performances, from most of the other counties with much more modest or even zero results.

The so varied involvement of the local authorities in the counties is also one of the main explanations of the low rate of access to European funds achieved by Romania, significantly lower compared to that of the other countries of Central and Eastern Europe.

At the national level, the rate of absorption of the European funds was, at the end of 2019, 36%, the total financing being € 11,045 billion out of € 30,883 billion allocated in the EU budget 2014-2020. Reaching this level has been progressively and relatively slow, as shown in the figures in the following table.

Table 3 : Total payments from EU structural and investment funds for Romania, 2015.... 2020 (billion of euro /%)

	2015		2016		2017		2018		2019		2020

Source: *European Commission. Structural and Investment Funds. Country data for: Romania, 2020*

The total absorption rate of the European Union's structural and investment funds registered by Romania at the end of 2019 is the penultimate (last - Slovakia) and equal to that achieved by Bulgaria in the hierarchy of countries of Central and Eastern Europe established according to the level of this indicator ((see table below). The countries of Central and Eastern Europe were chosen for comparison on the basis that they belong to the group that went through the difficult process of transition from the centralized economy to the competitive market model, have relatively close characteristics and levels of economic and social development significantly lower than Western member countries and, as a result, receive more substantial funding from European funds.

Table 4 : Total absorption rate of the EU structural and investment funds, achieved by Central and Eastern European countries at the end of 2019 (%)

Country	%
Bulgaria	36
Csech Republic	40
Estonia	49
Latvia	44
Lithuania	41
Poland	42
Romania	36
Slovakia	33
Slovenia	40
Hungary	42

Source: *European Commission. European Structural and Investment Funds. Country data for: diverse countries*

The rate of absorption of European funds by Romania means the loss of a considerable amount (at an absorption rate of 42% as recorded, for example, by Hungary, the value increase would have been € 1.84 billion, which would substantially have contributed to achieving objectives corresponding to the priority axes mentioned above. The low absorption rate of European funds registered by Romania is

explained by the many existing deficiencies in this regard: the lack at the level of regional and local authorities of expertise and administrative capacity to support applicants in their efforts to prepare files according to Community rules; the lack of the necessary transparency in the dissemination of information on support funds and the detailed conditions for accessing them; corruption at regional and local level that sometimes thwarts the efforts of fair applicants.

Achievements within the national programs financed from European funds in the period 2014-2020

The appreciable contribution of the European funds to the development of the NUTS2 and NUTS3 regions in Romania is demonstrated by the results recorded in the implementation of the programs ensuring the financing and aimed at resolving the malfunctions, non-conformities with the community standards and the delays existing at regional level. It is obvious that the results would have been much better if the absorption of the European structural and investment funds allocated to Romania would have been more intense in all the development regions and counties, especially those highlighted above as having modest or even zero performances in this regard.

The data on the achievements registered by Romania in the application of the eight national programs financed by the European structural and investment funds, published by the European Commission, are numerous and their full presentation would occupy a much too extensive space in this paper. As a result, we will limit ourselves to highlighting, for example, some achievements relevant to regional development recorded in the period 2015-2018, underlining that the figures are at national level and are not detailed by development regions or counties.

The achievements of the few objectives outlined in the table are modest or derisory even in 2018, so two years before the end of the budgetary exercise, their level is so low that has determined, during the period analyzed, in most cases, the reduction of the target targets initially set. This situation was generated by the very heavy start of the project implementation actions at the beginning of the EU budget 2014-2020, in 2015 and 2016 with zero project implementations.

Even projects whose implementation did not involve very complex and difficult actions such as, for example, the organization of training programs in which a significant number of people participate, resulted in 2018 with profoundly disappointing outcomes.

Conclusions

The main conclusions that can be drawn from the analysis are presented below.

- According to the provisions of the regional policy of the European Union, the Community support granted to the NUTS2 and NUTS3 regions is differentiated according to the regional GDP / inhabitant compared to the Union average; in the category of regions considered less developed, which receive the most substantial support, are included all the regions of the former communist member countries, except those that comprise the Capital;
- In Romania, the rate of absorption of European funds is among the lowest among the countries of Central and Eastern Europe, reaching the level recorded at the end of 2019 of 36% being made at a slow pace during the EU Budget 2014-2020;
- The counties and the Capital of the country have registered extremely varied levels of the absorption rate of European structural and investment funds, a reality confirmed both by the value of contracts signed for projects financed from this source and by the value of funds absorbed / paid for projects of digitization the activity of companies and the public system;
- The substantial contribution of Community support to the overall development of the country and its counties is convincingly highlighted by the appreciable results obtained in the implementation of the programs financed by the European structural and investment funds. These results are expressed in concrete terms such as the number of companies that received support, number of companies which received grants, number of supported start-ups, length of reconstructed and modernized railways and roads rebuilt, number of people who benefited from modernized schools, number of people who participated in training programs, etc .;

- The large differences between the counties regarding the access to these funds highlight, among others but with a main role, the very varied interest and efficiency of the regional and local authorities in order to capitalize on this considerable source of economic growth and prosperity;
- Accessing and spending efficiently the European Union's structural and investment funds is a complex, laborious and difficult endeavour for applicants for funds, for specialists who endorse the projects to be financed from European funds, and for the staff of management agencies in the field. The gains from accessing and absorbind European funds are, obviously, appreciable and constitute a powerful source of economic and social development of the beneficiary territorial units.

Abstract

International trade, production, investment are increasingly organized within the global value chains (or GVCs), in which the different stages of the production process are located in various countries. Companies are restructuring their activities at the international level, optimizing their production processes and placing stages of production at different sites due to the globalization.
The article analyzes the features of global value chains formation and provides quantitative estimates of countries participation in GVCs. The study of GVCs involves both an assessment of the extent to which countries are involved in the global economy, and an analysis of factors that influence the integration of country enterprises in value chains. The latter is of particular interest in connection with the need to improve industrial and trade policy instruments in order to create conditions for increasing the competitiveness of enterprises in the world market - to ensure growth based on non-resource exports and the development of industries and services.

Keywords: integration, global value chains, international trade, medium-sized enterprises.

Introduction

Nowadays, integration and globalization issues are important elements that determine the development of world economic relations. An urgent aspect characterizing the change in the world reproductive value chains is the growing role of new industrial countries, such as South Korea, Brazil, South Africa, China etc.). According to some authors (Streltsov, Yakovlev and Bulavko, 2019, pp. 32–46) it is extremely important to find new segments of potential growth found, primarily in developing countries, growth rates production in which they began to exceed similar indicators of developed countries (Kondrat'ev, 2018, p. 5).

International production, trade and investment are organized within the framework of global value chains (or Global Value Chains - GVC), in which the production of goods and services is carried out in different countries in order to optimize and redistribute financial, labor, and technical resources.

GVCs are a complex network structure of goods flows, services, capital and technology, which predetermines the development of world trade and the global economic system.

Traditionally, all production stages take place in one country; therefore, the entire value of the product is attributed to one state, i.e. the final exporter. In connection with the spread of the outsourcing practice and production transfer to other countries, different stages of value creation can occur in different parts of the world.

With the GVCs advent, there has been a structural shift in the international division of labor. Global transformations in the field of information and communication technologies (or ICT) and transport, combined with the development of increasingly complex types of products, have enabled firms to create complex and efficient chains distributed around the world. Currently, GVCs have become a driving force for global economic growth; they have transformed the conditions under which trade is conducted, i.e. instead of producing the entire product domestically, they specialize in specific tasks that allow them to integrate into the value chain and achieve large-scale production.

The main participants in GVCs are MNEs (or Multinational Enterprises - MNE), which form global production processes at various geographical points through a complex network of branches, as well as through outsourcing. Cross-border trade between MNEs and their affiliates accounts for a significant share of modern international trade. According to data on the volume of export-import operations, a limited number of large, often multinational, companies carries out exports. For example, Mayer and Ottaviano show that 1, 5 and 10% of companies account for at least 40.70 and 80% of total exports in Europe, respectively (Mayer and Ottaviano, 2008, pp. 135–148). Similar results were obtained in the USA (Bernard et al., 2007, p. 105), as well as for low-income countries (Cebeci et al., 2012).

SMEs (or Small and medium-sized enterprises) are a necessary attribute of the implementation of all economic processes, both in developed and developing countries. The policy priority for the G20 countries is to strengthen the integration of SMEs into the global markets for goods, services, investments and knowledge (Cadestin et al., 2018). At the same time, it is the export that plays an important role in improving all economic indicators of enterprises and developing the economy. Empirical studies show that firms that are connected to the global economy through export, foreign direct investment or FDI or as suppliers to exporters are generally more productive than firms serving only the domestic market.

In countries with high export intensities, workers in firms and sectors typically receive significant wage increases and demonstrate higher than average labor productivity (Cusolito, Safadi and Taglioni, 2016).

A more open domestic market is a source of competitive strength, especially when complemented by a number of other policies aimed at ensuring sustainable economic growth and diversification. (Baldwin and Gu, 2003, p.634–657).

The separation of tasks and business functions specific to value chains expands opportunities for participation in global markets without the need for off-the-shelf product development. The policies of developing countries with the fastest growing participation in GVCs are aimed at a comprehensive solution to the problems of investment in the supply and expansion of trade, have a growth rate of gross domestic product per capita of 2% above average.

Many low-income countries are becoming increasingly involved in GVCs, and their participation brings economic benefits in the form of increased productivity, increased complexity and diversification of exports (*Participation of Developing Countries in Global Value Chains*, 2015). There has been a clear trend indicating increased participation in GVCs since the early 2000s, especially in low-income countries.

The study objective is to analyze the global value chains formation characteristics, give a qualitative assessment of the countries participation in GVCs and assess the involvement extent of different countries in the global economy.

Problem Statement

MNEs have many ways to enter foreign markets; in addition to trade and local sales by affiliates, they are increasingly using other methods, such as franchising, licensing and other forms of partnership.

The powerful growth of global value chains (or GVCs) in recent decades has challenged the existing economic perceptions and political globalization implications. Production organization in international networks that extend across numerous borders has led to an increase in interconnectedness between countries, which has a significant impact on a wide range of national and international strategies (*Mapping Global Value Chains*, 2013; OECD, 2015). Therefore, for example, if we conduct a retrospective analysis, we can conclude that in the period from 2000 to 2014, the global gross output of foreign branches increased from 7 to 20 trillion. US $ Continuous growth in foreign production fell sharply during the economic crisis (in 2009). The average annual growth rate after the crisis from 2010 to 2014, i.e. 5% less than half of the pre-crisis from growth 2000 to 2008.

MNEs play an important role in the modern global economy, accounting for about a third of world production and global GDP, as well as half of world exports.

MNEs are an important driver of international production fragmentation within GVCs (Baldwin and Gu, 2003, pp. 634–657). Theories of MNEs traditionally distinguish between horizontal and vertical MNEs. Horizontal MNEs are distinguished by their desire to place production close to consumers and avoid trading costs, while realizing economies of scale. These are multi-factory firms that produce similar products both in their own countries and in the host countries, which allows saving on export costs. Vertical MNEs go through various stages of production in different countries and are of particular importance in GVCs after reducing transaction costs of cross-border production (MNEs focused on increasing efficiency). Production in one country serves as the starting material for production activities in other countries, and the location of the various stages depends on where the production factors that they intensively use are relatively less expensive (i.e. cost advantage is often achieved by economies of scale or access to knowledge).

The relationship between international trade and investment has traditionally been a widely debated political theme, and the growing importance of MNEs has only strengthened it. Initially, prior to GVCs, trade and investment were usually seen as substitutes directly related to the tradeoff between proximity and concentration, i.e. when trade barriers are high, it is more profitable for firms to directly produce products in the consumer market through FDI.

In the modern global economy, MNEs are increasingly functioning as networks within the international production networks of GVCs, sometimes the boundaries and structure of GVCs will intersect with the boundaries and structure of MNEs, but in many cases, they will not completely coincide. Creating such a network across multiple boundaries provides MNEs with a greater degree of strategic and operational flexibility.

MNEs are currently among the most important actors in the global economy. A growing number of companies are creating branches abroad to serve local markets and capitalize on favorable placement factors (i.e. natural resources, low labor costs, specialized knowledge, etc.). However, despite their generally accepted significance in the modern global economy, empirical evidence on MNEs is not widely available and largely incomplete.

Research Questions

The Role of MNEs in the Global Economy

Between 2000 and 2014, the global gross output of branches opened by many companies increased from 7 to 20 trillion. US $ Foreign production growth stopped during the economic crisis in 2009, as world trade and FDI declined sharply during this period. The production of MNEs abroad returned to the pre-crisis level of 2007, but the average annual growth rate after the crisis in the years from 2010 to 2014 of 5% is less than half of the pre-crisis, i.e. from 2000 to 2008, the growth of 13%.

Because of the crisis, the production share of foreign branches decreased by 4 percentage points between 2007 and 2010, which indicates that foreign branches were more affected by the global crisis than domestic companies were. This can be explained by the fact that foreign affiliates are actively

involved in GVCs, and as a result, their production is very sensitive to final demand (Altomonte, 2012).

At the global level, MNEs and their overseas subsidiaries are estimated to produce 33% of global output. While foreign affiliates account for 12% of gross output, the headquarters of MNEs and domestic plants in the home country account for another 21% of global production.

The EU is by far the largest recipient of foreign partnerships, which accounts for 7.5 trillion dollars. The activity of foreign affiliates has grown, most strongly in the BRICS (Brazil, Russia, India, China, South Africa) countries, especially after the economic crisis with an average annual growth rate of 9% (from 2010 to 2014).

The activities of foreign affiliates in the Organization for Economic Co-operation and Development countries have been severely affected by the global crisis. In particular, foreign firms in the EU recovered to their pre-crisis level only in 2014, which was mainly due to the recession in the Eurozone. In contrast, foreign affiliates in the United States have already recovered to their pre-crisis level.

The position and role of foreign affiliates vary by country and region. Foreign affiliates account for 15% of gross output in Organization for Economic Co-operation and Development countries. In the EU, foreign companies account for almost one fifth of production compared to 12% of foreign affiliates in the NAFTA (or North American Free Trade Agreement) region. Due to the creation of a single market, the production of foreign affiliates in Europe between 2000 and 2014 grew annually by 9%, i.e., doubled the growth rate of foreign companies in the United States.

In BRICS countries, foreign affiliates produced 8% of production, which reflected the presence of large domestic markets in these countries. The value of foreign affiliates has declined in the rest of the world, which reflects the significant growth of (some) national economies in this group of countries. In general, these changes reflect the growing globalization of economic activity and a change in the structure of MNE investment flows.

At the country level, most of the exported production is controlled by a small group of advanced economies (i.e. the United States, Germany, Japan, France, the United Kingdom, the Netherlands and Switzerland), which control almost 70% of the global production of foreign affiliates. In particular, US affiliates account for the majority of products in most countries.

In general, the presence of foreign affiliates has increased in most countries, with the exception of some countries with emerging economies, such as Brazil, India, Indonesia and Russia, as well as some high-income countries such as Australia, Canada, Ireland and South Korea. At the country level, the presence of foreign companies can be significant compared to the size of the host economy.

It is not surprising that the production volumes of foreign affiliates differ not only in home countries and host countries, but also in industries. In the primary sector, foreign affiliates account for less than 1% of total agricultural production, while in ‘construction’ the presence of foreign affiliates is about 3%. On the other hand, the share of foreign branches in the output of products is high (from 20 to 30%) in the production of ‘chemicals’, ‘base metals’, ‘electrical equipment’, transport equipment and ‘financial intermediation’. The general trend is that foreign affiliates have increased their presence in the manufacturing and services sectors, with the exception of ‘mining and mining’, ‘chemical industry’ and ‘transportation equipment’.

Foreign affiliates in the BRICS countries specialize in manufacturing, which account for one fifth of the global output of foreign affiliates in the manufacturing sector. In particular, more than 50% of foreign subsidiaries in the sectors ‘textiles and clothing’ and ‘electrical equipment’ are located in emerging economies. At the country level, China is the main recipient of foreign affiliates in the manufacturing industry and in 2014, it accounted for 20% of global production by foreign affiliates. On the other hand, in 2014, the Organization for Economic Cooperation and Development countries

accepted almost 80% of foreign branches in the services sector, of which 50% are in the European Union.

Purpose of the Study

It is necessary to rely on the existing theoretical basis while describing the level and depth of scientific and practical development of the contemporary problems of global value chains.

Modern characterization of GVCs has received a thorough theoretical and practice-oriented description in the scientific works of such authors as Gereffi, G. & Lee, J. (2016, pp. 25–38), Strange, R. & Zucchella, A. (2017, pp. 174–184), Lee, J. & Gereffi, G. (2015, pp. 319–339), Amador, J. & Cabral, S. (2016. pp. 278–301), Alfaro, L., Antràs, P., Chor, D., Conconi, P. (2019, pp. 508–559), etc.

Methods

In the study process, methods of stochastic, retrospective and comparative analysis were applied. The article used empirical research methods, as well as methods of analogy, interpretation, comparison and generalization. The applied statistical methods helped to obtain quantitative characteristics, allowing rejecting minor deviations in the research process.

Results

Cross-regional differences are very significant in how countries integrate into GVCs around the world. Southeast Asia is a region in which the most comprehensive and deepest agreements on regional integration can be found, has the highest average participation rate of intra-regional GVCs. East and South Africa, Latin America and the Caribbean demonstrate a higher level of regional integration than Central and West Africa, the Middle East and North Africa and South Asia. In the period from 1995 to 2008, the increase in the share of value added in the export of these countries was due to low-income countries.

GVCs affect trade and investment ties between low-income countries. Emerging economies are currently important sources of FDI exports. For example, the volume of foreign direct investment by BRICS companies like Brazil, Russia, India, China and South Africa increased from $7 billion in 2000 to $145 billion in 2012 and $200 billion in 2013, accounting for almost a third of global FDIs.

SMEs are the backbone of the economies of several developing countries. SMEs account for more than half of all formal jobs in the world. A cross-country study of 49,370 firms in 104 countries showed that although SMEs (<100 employees) have a comparable share of total employment, as do large firms, small firms (<20 employees) have the largest share of job creation and the highest sales (Ayyagari, Demirguc-Kunt and Maksimovic, 2014, pp. 75–99). These findings are also common in countries of the Organization for Economic Co-operation and Development (OECD), where 75% of new jobs are created by SMEs. However, over the past few years, additional studies show that size is not a relevant indicator, but rather the age of the firm determines its contribution to the net creation of jobs. Data for Colombia (Eslava et al., 2013, pp. 135–158), Morocco and Tunisia (Cebeci et al., 2012), USA (Haltiwanger, Jarmin and Miranda, 2013, pp. 347–361) show that there is no systematic relationship between firm size and job creation, emphasizing the role of startups and young firms in promoting job creation.

High growth potential SMEs can grow over time and become leading firms in GVCs. Participants and connections in GVCs can evolve as competitive (smaller) firms streamline their operations and strengthen their position. High growth potential SMEs may open up new business opportunities abroad. Those SMEs whose competitive advantage is mainly cost-based or that specialize in certain types of services requiring direct interaction are more likely to participate in GVCs as domestic suppliers to the export sector.

Meanwhile, as a rule, it is SMEs that are at the forefront of technology or that manufacture parts and components with high benefit that are directly internationalized (Farole and Winkler, 2014). The supply base of the automotive industry or the aerospace industry, for example, is a two-tier one, with large firms in leading positions, but also includes many small specialized (and smaller) global suppliers (that is, suppliers of the second or even first level), which often produce very specialized and individual parts and components.

Production fragmentation, combined with advances in ICTs, also creates new entrepreneurial opportunities for SMEs in terms of accessing markets abroad, creating a new category of so-called micro-multinational companies, which are small firms that have been developing global activities since their inception. The Internet and new business models enable these small companies to enter foreign markets at the lowest cost (Mettler and Williams, 2011).

However, the existence of GVCs poses certain problems for SMEs. First, the leading role played by large MNEs has led some to suggest that the emergence of GVCs could pose a threat to the development of small firms as a whole. MNEs, which often have their own know-how and technology and many potential sources of supply, can dictate contract terms to their smaller suppliers.

Secondly, meeting stringent requirements regarding standards and product quality for GVCs can be difficult for smaller and younger firms, and market failures that inhibit their development are different from those faced by large firms. Smaller firms face specific difficulties limiting their growth, ranging from limited access to credit and insufficient scale to support the costs of special research and development and training, to a lack of lobbying power compared to larger firms and a limited ability to diversify and absorb local and global turmoil.

In addition, smaller production SMEs typically extend the recovery period for any fixed investment or information costs, and a smaller 'pool' of workers limits the ability to redistribute labor between different or new tasks compared to larger firms. Young, innovative, and entrepreneurial SMEs may encounter additional problems, such as lack of access to risk capital or poorly adapted entry and exit rules that prevent firms from experimenting with new technologies or business models (OECD, 2015) and which may prevent them from reaching sufficient scale to enter global markets.

In general, the ability of SMEs and firms in low-income countries to succeed in GVCs (to quickly introduce new technologies, learn from practice, innovate and optimize their production) is more dependent on the framework conditions and external factors related to the operating environment. We are talking about a wide variety of public goods and external factors, i.e. from world-class logistics to open markets, the business environment, the education and training system, the existence of a well-functioning innovative infrastructure and effective forms of financing.

Conclusion

Modern production systems are complex business models with multilevel international networks of suppliers and rapidly developing, based on technologies that increasingly allow developing cross-border economic activity. Modern global value chains (or GVCs) require a high level of precise coordination. More unified global production systems and markets provide countries with greater opportunities to specialize in specific aspects or stages of development and production of goods and services where comparative advantages exist. Instead of developing and managing the entire complex manufacturing process independently, GVCs provide opportunities for small and medium-sized enterprises and firms in low-income countries. The problems of manufacturing products to world standards, as required by GVCs, can be difficult to solve for small and young firms, and market failures that inhibit their development are more serious than those faced by large firms. In the future, the implemented systems and business models can give an economic effect, improve the innovation and investment activities of global companies, and increase their image in the international arena.

Abstract

In the modern Russian economy, which is focused on the innovative way of development, the effective functioning of economic entities is due to their ability to implement progressive changes based on the achievements of scientific and technological progress, market methods of management and management. Competitive advantages are achieved at the expense of knowledge, information, and innovation. Each country, region, economic entity has a certain aggregate potential: scientific, technical, resource, raw material, economic, production, etc.. Recently, innovation potential has also become one of the components of the overall (aggregate) potential. The solution to the problems of methods for assessing the innovative potential of economic entities should, of course, be based on a serious theoretical Foundation. Research of the best practices of using innovative potential, methods of its analysis and evaluation determined the purpose of this article, which is to assess the innovative potential of organizations using a process-product approach. The proposed assessment includes the calculation of indices, criteria and indicators that form a matrix for positioning the organization's innovative potential, characterized by the use of a relatively small amount of primary information, and ease of use.

Keywords: Innovation, Innovative Enterprises, Human Potential.

Introduction

The country's development is impossible without innovations based on intellectual resources, knowledge-intensive and information technologies, effective use and qualitative improvement of all factors of production.

Each country has a certain innovative potential, which is one of the most important elements that determines its future competitiveness.

Comparison of Russia with the leading countries allows us to draw a conclusion about the significant lag of domestic enterprises in the development and implementation of scientific and technical

achievements. A large number of enterprises prefer to adapt already invented goods, services and technologies to create their own innovative developments (Stepanova, Yu.N., 2019). The structure of implemented innovations is dominated by technological innovations, mainly related to the purchase of machinery and equipment. In this regard, the literature pays much attention to the formation and use of innovative potential of enterprises (Morkovina, S.S., 2015). The innovative potential of an enterprise in the most General sense is interpreted as a set of various types of enterprise resources necessary for the implementation of innovative activities (Volosatov, V.D., 2010). This approach is described in the literature as a resource approach (Vertakova, Y., 2013). Quite widely in the literature, the effective approach is considered, which is expressed in the form of avant-garde knowledge and their application in practice when evaluating the innovation potential (Bendikov, M.A., 2007).

The formation of innovative potential is influenced by a set of conditions and factors, ranging from research and development to mass production of a product or the use of innovative technology (Drapalyuk, M.V., 2014). To assess the innovative potential of enterprises, many methods are used, both official (Oslo, etc.) and developed in the framework of scientific research by separate groups of scientists (OECD 2019 Eurostat).

Following the Oslo Guidelines, the minimum requirement for innovation is that the product, process, marketing method, or organizational method must be new or significantly improved for organizations. This includes products, processes, and methods that organizations are the first to develop, as well as those that have been adopted by other organizations. The initial point of evaluating the innovative potential, according to researchers of this issue, is to determine the current internal capabilities of the organization in the innovation sphere using economic criteria (Morkovina, S.S., 2018). Czech researcher M.Špaček suggests calculating a comprehensive innovation index to assess the organization's innovation potential (Špaček, M., 2019).

Dziallas, M. And Blind, K. in their review article, they analyze scientific publications on indicators of innovation created between 1980 and 2015. In their research, they identify enterprise-specific indicators for assessing innovation potential, which are important for preliminary and current assessment. 82 unique indicators for evaluating innovation were identified, including 26 indicators for evaluating the innovation of the offer (Dziallas, M. and Blind, K., 2019).

Over the past two decades a significant number of methods for evaluating innovative potential have appeared in Russian science adapted to Russian conditions (Vertakova, Y.,2016). However, at the moment the problem is the lack of comprehensive research to assess the innovative potential of regional enterprises and the effectiveness of its use in creating process and product innovations. The purpose of the research is to develop a methodology for assessing the innovative potential of enterprises based on the study of best practices for analyzing and using the innovative potential of organizations in Russia.

Theoretical, Informational, Empirical, and Methodological Grounds of the Research

The initial point of assessing the innovation potential is to determine the internal capabilities of the enterprise in the innovation sphere using economic criteria.

In the course of the research, we used methods of comparison and generalization to reveal the essence of innovative potential, identify cause-and-effect relationships and patterns between innovative potential and innovative activity of enterprises, as well as to substantiate the initial concept for solving the problem determined by the purpose of the study.

12 official and unofficial methods of assessing innovation potential used in Russia and abroad were analyzed. The analysis of methods for assessing innovation potential has been used to study tools for

evaluating innovation potential, indicators, including algorithms for calculating them, for evaluating the innovative potential of organizations.

The information base necessary for analyzing the innovative potential of enterprises, as well as the advantages and disadvantages of existing methods, was studied.

This made it possible to take into account many factors, such as the information base for assessing the innovative potential of organizations, the size of enterprises, specialization, human and scientific and technical potential, and others.

Results

The proposed methodology for assessing the innovative potential of organizations is based on the process-product approach. The main tools of the assessment methodology are indexes, criteria and indicators, and a square matrix of innovation potential. The main quantitative technique for analyzing the results of evaluating innovation potential is comparison.

The assessment of innovation potential is based on two indices: the economic and technological index, which evaluates innovation as a product, and the ability to innovate index, which evaluates innovation as a process.

Each index is decomposed into ten (10) criteria that reflect the human resources, scientific and technical, production and technological, organizational and managerial potential, ability and readiness of the organization to innovate.

This assessment is made by comparing the criteria of the reporting period and the previous one, which allows you to assess the trends in the development of the organization's potential.

The dynamics of the criterion is set for each organization with a gradation:

- positive (having positive dynamics – 1 point);
- stable (having dynamics equal to-0 points);
- negative (having negative dynamics – 0 points).

The level of the economic and technological index and the ability to innovate index is assessed in points, on a 10-point scale.

The assessment of innovative potential is carried out in accordance with the following order:

1. selecting source data from an information database;
2. the calculation of the evaluation criteria according to certain algorithms;
3. calculation of the growth (decline) rate of criteria;
4. evaluation of changes in the criteria on the evaluation scale;
5. positioning the company within the matrix;
6. forming an analytical conclusion based on the evaluation results.

To position the organization and determine the level of innovation potential, a square matrix is used, which includes three columns containing the values of the economic and technological index score arranged as they increase, and three rows containing the values of the innovation ability index score as they increase.

Each economic and technological index and ability to innovate index corresponds to one of the zones of the organization's innovation potential (green, yellow, red), as shown in figure 1.

Based on the organization's positioning within the matrix innovation potential is assigned the status:
- "Innovative leader", high level of innovative potential (matrix: IP1, IP2, IP3, IP4);

Fig. 1:Matrix for positioning an organization's innovative potential (green, yellow, red zone)

- "Moderate leader", average (satisfactory) level of innovation potential (matrix: IP5, IP6, IP7);
- "Modest innovator", low level of innovation potential (matrix: IP8, IP9).

Conclusions and recommendations

This method was tested on ten organizations, and based on the results of the assessment of their innovative potential, they were given a conclusion about their innovative activity, table 1.

Table 1: Results of assessment of innovative potential of organizations

Name of the organization	Place in the matrix	Type of innovation potential
JSC ZRM Bobrovsky	IP_6	A moderate traditionalist
LLC Plant for the production of heavy mechanical presses	IP_8	A moderate innovator
Logus-agro LLC	IP_7	A moderate traditionalist- a successful innovator
Kosmos-Neft-Gas LLC	IP_1	The absolute innovation leader
JSC NVP PROTEK	IP_4	Innovation leader-innovation integrator
JSC BTEK	IP_9	A modest innovator-traditionalist
NGO Energosvyaz'proekt	IP_9	A modest innovator-traditionalist
CBM BTS	IP_6	A moderate traditionalist
BTMK LLC	IP_6	A moderate traditionalist
JSC Buturlinovka	IP_9	A modest innovator-traditionalist

Based on the results of the assessment of the innovative potential, we will draw the following conclusions.

Kosmos-Neft-Gas LLC (EP_1) is an absolute innovation leader by type of innovative potential. The organization has received the highest rating of the IET and ISPI indices, therefore it has a high innovative potential. This organization is a leading market player, implements the strategy of "leadership in competition", which contributes to improving the efficiency of innovation, in particular, reducing the period from the moment of development to the practical implementation of innovations.

JSC NVP PROTEK (EP_4) is an innovative leader - integrator of innovations by type of innovative potential. The organization received an average rating of the I et index and a high rating of the ISPI index. Therefore, it has an innovative potential for active growth, in which it is possible to quickly increase competitive advantages, primarily due to intellectual and scientific potential. The innovation potential of this type is characterized by a positive dynamics of indicators for assessing its level of development and the implementation of the strategy of "following the leader" and"innovation growth". The organization is focused on creating innovations.

CJSC ZRM Bobrovsky, CBM BTS, BTMK LLC (EP_6) by type of innovative potential are moderate traditionalists. Organizations received an average rating of the IET index and a low rating of the ISPI index. Consequently, these organizations have a low-growth innovation potential, where it is possible to increase it at the expense of the existing economic potential. Innovative potential of this type, on the one hand, does not currently provide competitive advantages of organizations, but, on the other hand, when changing the policy of business owners, it can be considered as an important element of the organization's innovative development strategy, the practical implementation of which will help to strengthen the competitive position of the organization in the market. The organization is focused on the acquisition and copying of innovation.

Logus-agro LLC (EP_7) is a moderate traditionalist - a successful innovator by type of innovative potential. The organization received a low rating of the IET index and a high rating of the ISPI index. Innovation potential of moderate growth, where it is possible to increase it due to high scientific and intellectual potential. The synergistic effect of interaction of structural elements of innovative potential with an emphasis on economic resources allows ensuring the stability of the level of innovative development. The organization is focused on creating innovations, developing R & d and adapting the successful experience of the leader.

LLC Plant for the production of heavy mechanical presses (EP_8) by type of innovation potential is a moderate innovator. The organization received an average rating of the ISPI index and a low rating of The IET index. Innovation potential of low growth, in which it is possible to increase it through the development of research activities. Innovative potential of this type, on the one hand, does not currently provide competitive advantages of the organization, but, on the other hand, when changing the policy of business owners, it can be considered as an important element of the organization's innovative development strategy, the practical implementation of which will help to strengthen the competitive position of the organization in the market. The organization is focused on the creation of innovations, reproduction and innovation.

JSC BTEK, NGO Energosvyaz'proekt, JSC Buturlinovka (EP_9) by the type of innovative potential is a modest innovator-traditionalist. The organization received the minimum rating of the IET and ISPI indices. An extremely low level of innovation potential is typical for this organization, it does not pay due attention to innovation, but focuses on achieving short-term goals and objectives, i.e., making a profit in the current period. Drastic measures are needed to develop the innovative component of the organization's activities, which will be an essential part of long-term goals aimed at improving competitiveness

The methodological basis for the development of the author's assessment of the innovative potential of the organization based on the process-product approach was the research of implemented methods that take place in practice.

In General, the proposed assessment of innovation potential is a monitoring of the components of innovation potential in order to compare its actual level at a certain moment with existing ideas about this level. The level of innovation potential remains in constant dynamics, which can be either positive or negative.

Based on the results of the assessment of the innovative potential of organizations, it can be seen that it meets the following requirements:

- provides systematic analysis of results;
- simplicity and transparency in the assessment;
- provides comprehensive analysis of innovation activities;
- reflects the specifics of the industry;
- based on a retrospective analysis;
- allows you to make a forecast of innovative development, and form reliable recommendations.

This assessment of the innovative potential of organizations is complex based on the fact that (Stepanova, Yu.N., 2019):

1. the system of evaluation indicators provides a comprehensive characteristic of innovation processes, including all its main stages and gives a real result.
2. The set of indicators is flexible, i.e. it reflects all changes taking place in the innovation sphere of the region and characterizes all aspects of innovation activity.
3. The number of indicators is limited and is associated with the peculiarities of obtaining information.

The implementation of these requirements allowed us to quantify and qualitatively assess the innovative potential of organizations, which will allow us to make scientifically-based management decisions on the formation, use and development of innovative potential of organizations.

Abstract

Analysis and prediction of selected security factors in public passenger transport based on the example of the capital city of Warsaw were made. Then, the most common criteria for assessing public passenger transport found in the literature are presented. For public passenger transport safety, as well as the criteria suggested by other authors listed in the first part of the paper, the factors were selected for analysis. Data used for the purposes of this paper were collected on the basis of a statistical guide kept by the Public Transport Authority in Warsaw. The time range of the study covers the period from January 2017 to December 2019. Artificial neural networks (time series) ANN were used for predictions. The purpose of time series analysis using ANN is to predict future values of a variable or variables, based on previous values of the same or another variable or variables (dependent variable values may go beyond the data range). The range was set for 12 months. A total of 320 network designs were trained for 8 selected factors, of which 5 best were selected for each factor and a prediction was made for a period of 12 months. The quality of the neural network learning process was obtained at >80%. On this basis, the development trends for selected factors in the near future were demonstrated.

Keywords: Security, Public Passenger Transport, Artificial Neural Networks

Introduction

The development of technology brings about changes in other sectors of the economy. Over the last several years, a dynamic increase has been observed in the number of available applications, being both universal technological solutions dedicated to all market segments, as well as individual, tailor-made solutions. The common denominator for all these efforts is security, both collective and individual, but also security of information, data transmission or transaction security.

This also includes security in transport, including public passenger transport. There is an increase in the use of public transport in large metropolitan areas. The reasons for this are, among others, traffic congestion, shorter travel times offered by public transport, or quality of services offered. Quality is understood, among others, as accessibility, efficiency and security. There has also been a noticeable increase in access to public transport information and services through mobile applications, in the number of ticket vending machines, including mobile ticket machines. Further, the scope of the service has been dynamically changing, if only through CCTV (Closed-Circuit television) monitoring of public passenger transport means, voice and LCD (Liquid Crystal Display) screen-communicated information, as well as care for the surroundings through the environment impact of transport. All these fall within the scope of public passenger transport security. This applies to the use of the means of transport as such, passengers, drivers, as well as all the facilities offered. In addition, in-service operational analyses of vehicles, including buses, most often address the minimization of costs associated with their use and the ways to ensure a maximum reliability of the transport system, as well

as the environmental impact of the use of vehicles, or the security aspect. Therefore, public passenger transport is assessed using various criteria and methods.

The authors of this paper focus on the criterion of security in public passenger transport. This criterion was decided to be the starting point for further analysis and research. Without a sense of security among those actually using public transport services, no other facilities can convince passengers to use public transport.

In view of the above, in this paper the authors set out to analyze and predict selected security factors in public passenger transport based on the example of the capital city of Warsaw.

Research methods used in the study included deduction, analysis and systematic synthesis, induction, correlation analysis and neural modeling. The deduction method was used to assess insights and facts in public passenger transport. The methods of analysis and systematic synthesis enabled the identification of security factors. The induction method was used to propose conclusions based on the collected assessment facts. Correlation analysis was used to identify relationships between selected factors. The neural modeling method using artificial intelligence algorithms was used to predict the size of selected factors.

State of the Art

Public passenger transport is one of the most critical components of the entire logistics system. The need to develop and accelerate means for the movement of people makes it necessary to take into account multiple variables, which may include:

- society's mobility, which grows year by year, necessitating ways for ever faster movement and use of more and more advanced equipment or machines,
- growing expectations of urban transport users, which do not arise only from the basic needs, but those created and instilled as prerequisite, resulting from the technological and technical progress,
- increase in the quality and reliability of the means of transport, which is key to competitiveness of carriers,
- increase in popular demand for tourist and recreation services,
- rapid development of management systems for transport infrastructure, both linear and point-based.

The quality of public transport services comprises a set of criteria which, in accordance with the standard PN-EN 13816:2004P Transportation. Logistics and services. Public passenger transport. Service quality definition, targeting and measurement, Polish Committee of Standardization, Warsaw 2004, were divided into the following 8 categories :

- availability: coverage of public transport service offered in geographical, time, frequency and transport type units,
- accessibility: access to the public transport system, including connections with other modes of transport,
- information: regular provision of knowledge about the public transport system to help in travel planning and execution,
- time: time-related aspects of travel planning and execution,
- customer care: aspects of the service to meet passenger requirements,
- comfort: aspects of the service to provide travellers with relaxation and rest options,
- security: a sense of personal safety of passengers.
- environmental impact: environmental impact resulting from the provision of the service.

From the point of view of public passenger transport indicators by which passengers evaluate public transport include:

- attractiveness;
- performance;
- security.

There are many definitions of the term security in the literature on the subject. These definitions differ in the assumed perspectives on selected issues. From the point of view of public passenger transport, security should be understood as both the security of passengers and the security of drivers of public transport vehicles. The driver's profession can be stressful; it is important that the driver responds in time to the changing road situation, emerging hazards and correctly reads road signs and intentions of other drivers. Vehicles that have broken down or have had a road accident need repair. Costs incurred for the repair and maintenance of vehicles are an important parameter of the entire transport system. The sense of security in public transport is also affected by the crowding of means of transport. Passengers in an overcrowded vehicle experience discomfort, anxiety and even fear that they will not reach their destination on time because off too many of those getting on and off. The Sense of security and general trust in others, or strangers, influence the choice of public transport as a way of getting around.

Passenger transport services are a type of transport services that are characterized by:

- complexity - the transport service consists of a very large number of components and relationships between these components;
- probabilism - it is impossible to predict all states and events,
- dynamism - interventions are made in the transport service process both in real time and in space.

Therefore, various criteria for assessing public passenger transport can be found in the literature. The standard defines the criteria by which the quality of public passenger transport can be analyzed; in addition, the standard defines the measures of customer satisfaction and the calculation measures. Table 1: presents examples of performance and customer satisfaction measurements used in public passenger transport for the security criterion.

Table 1:Examples of performance and customer satisfaction measurements used in public passenger transport for the security criterion

Criteria	Customer satisfaction measure	Performance measure
7. Security 7.1 Safety from crime	CSS - Feeling safe*	Target score: Providing a safe and reliable service for passengers Performance measure: DPM - Indicators of reported offences against passengers DPM - Indicators of reported offences against employees
7.2 Safety in terms of accidents	CSS - Sense of safety*	Target score: Safety of customers and road users Performance measure: Recorded accidents and/or rates of injuries
* An example of a more detailed definition is given in Table C.2. CSS - Customer Satisfaction Survey MSS - Mystery Shopper Survey DPM - Direct Performance Measures		

In order to identify trends, the level of customer satisfaction is surveyed on the ongoing basis. Another important factor follows from this requirement, namely the regular and timely reporting and monitoring of public passenger transport. The standard provides for CCTV monitoring, among others, for the security criterion: safety from crime. CCTV monitoring can be a useful tool especially for the driver, as they he can use cameras to detect passengers behind the bus, □ and have the surroundings under a better control. The prevalence of CCVT monitoring in buses and trams of the capital city of Warsaw in the years 2017-2019 is presented in Fig. 1.

Fig. 1. Prevalence of CCVT monitoring in buses and trams of the capital city of Warsaw in the years 2017-2019 □

The graph shows that the number of buses equipped with CCTV monitoring steadily increased year by year and is currently at the level of 83%. Compared with January 2017 (74%), with a simultaneous increase in the overall number of buses from 1709 in January 2017 to 1851 in December 2019, the number of buses equipped with CCTV monitoring increased by 105 buses. Based on the above, it can be concluded that all new buses are purchased with the CCTV option. The number of trams equipped with CCTV monitoring is at a constant level (38% of the rolling stock).

One of the aspects in the development of public passenger transport security may be environmental protection and the deployment of transport means that are safe for the environment. It is therefore reasonable to introduce electric vehicles. The deployment of electric buses in the municipal transport system □, or the use of buses equipped with internal combustion engines that meet the highest EURO emission standards is a good example. The number of public passenger transport buses operating in the capital city of Warsaw in 2017-2019 with a breakdown by EURO emission standards and electric buses is shown in Fig. 2

Fig. 2. Number of public passenger transport buses operating in the capital city of Warsaw in 2017-2019 in breakdown by EURO emission standards and electric buses

The graph shows that the number of buses meeting the highest Euro VI emission standards grew systematically and currently accounts for approximately 42% of all buses. One should also note the high number of buses meeting the Euro EEV standard (Enhanced Environmentally Friendly Vehicles; the standard between Euro V and Euro VI, which can only be achieved by engines powered by compressed natural gas (CNG), which account for approximately 21% of the fleet. At the same time, a negligible share of buses meeting the oldest emission standards - Euro I, Euro II and Euro III can be observed.

Methods for Measuring Security in Public Passenger Transport

One of the methods for studying security in public passenger transport may be the indirect measurement method of sample-based surveys. Professional public transport drivers were surveyed using a special questionnaire. They answered questions related to their experience as professional drivers, their age, working hours, timetables and traffic incidents and accidents. The results confirmed that stress and workload affect the safety of work of professional drivers. The use of the binomial random-effects and conditional autoregressive models in public passenger transport security studies in Melbourne has shown that a greater use of public transport instead of individual transport results in fewer accidents. The technical condition of vehicles and their systems plays an important role in safety. One of the most important systems is the braking system; statistical analysis was used in the studies on brake fluid. The results have shown that monitoring the levels of this operating fluid and observing the exchange dates have an impact on the condition of the entire vehicle. Another method for studying road safety can be the multi-criteria method of analytical hierarchy process (AHP). By this method, individual factors can be ranked in various ways. Delphi methods can also be used to assess security. These methods have demonstrated the components that can significantly improve safety in and on buses. The results show that it is important to introduce the systems of automatic door opening, braking assistance and CCTV monitoring in the vehicle and its surroundings.

For many years, linear modeling has been the most common mathematical technique used to describe processes and objects (for the purposes of their assessment). However, wherever there is no basis for linear approximation of phenomena and processes, linear models did not work well, sometimes leading to incorrect opinions on the total inability to mathematically describe such or other systems. In these cases, when solving difficult and troublesome issues, the quickest and most convenient way to solve the problem may be to fall back on neural networks (i.e. models that map non-linear relationships).

Artificial neural networks operate more or less in the same way as the human brain. The range of applications of the method is wide; it has been used, among others, in problems related to mechanics to analyze the results of cylinder pressure tests. A created network learns itself, by analyzing the examples fed into it and using the trial and error method to seek a solution to a problem, without any

specific method of operation imposed on it. Medical research can be another example of a field for use of ANN. Based on the heuristic capabilities of the method, it can help healthcare professionals make decisions when in uncertainty. Other uses of artificial intelligence include, for example, the assessment of the quality assurance of transport means, risk assessment, route optimization, evaluation of logistics systems.

In view of the above, a conclusion can be made that artificial neural networks fit well in the research area as a method to achieve the assumed objective, to enable predictions for selected factors.

Research Method and Object

On the basis of the literature review and available data, selected security factors in public passenger transport were collected based on the example of the capital city of Warsaw. Taking into account the standard quality guidelines, including for public passenger transport safety, as well as the criteria suggested by other authors listed in the first part of the paper, the factors were selected for analysis. The set of factors used for modeling is presented in Table 2:.

Table 2:Set of factors used for modeling

No.	Factor designation	Factor name	Factor value
1.	A_p	Vehicle failures	Number
2.	Z_p	Devastated vehicles	Number
3.	N_{ptp}	Violence offences in public passenger transport	Number
4.	W	Accidents	Number
5.	K	Collisions	Number
6.	Z_r	Traffic stoppages (for other reasons)	Number
7.	S_k	Complaints received by PTA	Number
8.	O_{ma}	CCTV monitoring in buses	%
9.	O_{mt}	CCTV monitoring in trams	%
10.	P_r	Persons injured in accidents	Number
11.	P_s	Fatalities in accidents	Number
12.	L_a	Buses	Number
13.	L_t	Trams	Number

Data used for the purposes of this paper were collected on the basis of a statistical guide kept by the Public Transport Authority in Warsaw. The time range of the study covers the period from January 2017 to December 2019. Collected study data for the city of Warsaw in the form of a graph are presented in Fig. 3.

Fig. 3. Collected study data covering the period 2017-2019 for the capital city of Warsaw

The graph shows that especially in the winter time, the PTA receives a larger number of complaints than in other seasons. This may be attributable to delays due to road conditions. The failure rate of vehicles increased during the periods under consideration, with a decrease at the end of 2019. The number of accidents, collisions and traffic stoppages resulting from factors other than those listed above remains more or less stable, and thus may not contribute to changes in the sense of security among passengers.

Based on a reference to the standard and the collected factors, a conclusion can be made that the Public Transport Authority in Warsaw monitors the level of quality of public passenger transport services in accordance with the guidelines contained in the standard.
In addition, correlation analysis of selected factors was made (Table 3:).

Table 3:Correlation analysis of selected factors

	A_p	Z_p	N_{ptp}	W	K	Z_r	S_k	O_{ma}	O_{mt}	P_r	P_s	L_a	L_t
A_p	1.00												
Z_p	-0.21	1.00											
N_{ptp}	-0.14	0.07	1.00										
W	0.45	-0.01	-0.20	1.00									
K	-0.05	0.34	-0.10	0.09	1.00								
Z_r	-0.01	0.33	0.34	0.24	0.24	1.00							
S_k	0.14	0.36	0.12	0.32	0.11	0.22	1.00						

O_{ma}	0.24	-0.43	-0.43	0.09	0.00	-0.53	-0.38	1.00					
O_{mt}	-0.01	-0.39	-0.04	-0.27	-0.04	-0.58	-0.56	0.49	1.00				
P_r	0.23	0.29	0.07	0.64	0.03	0.37	0.56	-0.47	-0.41	1.00			
P_s	0.16	0.19	-0.04	0.19	0.08	0.11	0.18	-0.08	-0.15	0.25	1.00		
L_a	0.32	-0.15	-0.29	0.22	0.12	-0.24	-0.02	0.74	0.15	-0.34	0.11	1.00	
L_t	-0.28	0.35	0.52	-0.15	-0.08	0.43	0.21	-0.91	-0.29	0.48	0.02	-0.86	1.00

The table above shows which factors are strongly correlated with each other (positive and negative correlations). The number of persons injured strongly correlates with the number of buses and trams. As the number of buses increases, the number of injured increases, and as the number of trams increases, the number of injured decreases. This relationship is mainly due to the fact that rail transport is characterized by higher safety than road transport. A strong correlation can also be seen between the presence of CCTV monitoring in buses and the number of violence offences in public passenger transport. As the former indicator increases, the latter decreases, which has a significant impact on the perceived sense of security.

Neural Modeling

Among the many types of neural network models, the study used Multilayer Perceptron, a neural network with radial base functions (RBF). It was decided to choose these types of networks due to the fact that they solve linear and non-linear problems, achieve efficiency results at the level of >80%; further, they have also proved to be sufficient to solve the problem. The following learning algorithms were used: steepest descent method, conjugate gradient method; BFGS method (*Broyden - Fletcher - Goldfarb - Shanno)*.

The purpose of time series analysis using ANN is to predict future values of a variable or variables, based on previous values of the same or another variable or variables (dependent variable values may go beyond the data range).
Data are presented on a monthly basis. Sample data inputs for predicting selected factors are presented in Table 4:.

Table 4:Sample data inputs for predicting selected factors

Period	A_p	Z_p	N_{ptp}	W	K	Z_r	S_k	O_{ma}	O_{mt}	P_r	P_s	L_a	L_t

Oct 18	1632	100	2	78	442	578	792	78%	38%	96	2	1809	727

Using Statistica 13.3 software, predictions were made for selected factors. Then the basic network parameters were specified, i.e.

- network type (multilayer perceptron - MLP),
- minimum number of hidden neurons,
- maximum number of hidden neurons,
- number of learning networks,
- number of networks preserved,
- activation function of hidden neurons,
- activation function of output neurons,
- weight reduction values for the hidden layer and the output layer.

Along with defining the input data, the size of the training set was defined. It was determined that:

- 70% of the data will be a training set used to modify weights,
- 15% of the data will be a test set for ongoing monitoring of the learning process,
- 15% of the data will be a validation set for assessing the quality of the network after learning.

Six selected factors were analyzed, each of them individually. For each factor, a number of learning networks of 40 was determined, and the top 5 neural network designs for individual factors were preserved and shown in the graphs. The number of delayed values equal to 12 was assumed for the neural network learning process. Due to the fact that the data were collected for a period of 3 years, the natural period for one year to detect trends in the data is the number of 12 months. This means that the first 12 data collected will serve as a model in the learning process.

Further in the analysis, it was determined that the prediction starts from the 30th period (from the 30th month) and the prediction horizon was determined at 18 periods. In view of the fact that 36 data periods were collected, the prediction using neural networks was defined for 12 periods (12 months).

To sum up the study assumptions, a total of 240 network designs were trained for 6 selected factors, of which 5 best were selected for each factor and a prediction was made for a period of 12 months. The broader the time horizon, the less accurate the prediction and the more varied behaviour of individual networks. This is influenced among others by the number of data and the data sample, which was randomly assigned to individual ANN sets. The prediction of ANN designs for selected factors for time horizon 18 is presented in figures 4-9.

Fig. 4. Prediction of 5 ANN designs for factor A_p - vehicle failures for the time horizon 18

In the analyzed case, 3 out of 5 at a similar level. On this basis, it can be argued that the number of vehicle failures will increase slowly but steadily. Based on the correlation

analysis, a conclusion can be made that this is related to, among others, the ever growing number of buses.

Fig. 5. Prediction of 5 ANN designs for factor Z_p - devastated vehicles for the time horizon 18

In the analyzed case, 4 out of 5 neural networks predict data at a similar level. One neural network (MLP 12-6-1) completely differs from the others, so it should not be included in further analyses. Based on the graph, a conclusion can be made that the number of devastated vehicles will decrease. Correlation analysis shows that this is related to, among others, the growing number of public transport vehicles that are equipped with CCTV monitoring.

Fig. 6. Prediction of 5 ANN designs for factor *W* - accidents for the time horizon 18

Fig. 7. Prediction of 5 ANN designs for factor *K* - collisions for the time horizon 18

In the analyzed cases, all 5 neural networks predict data at a similar level. The collected data show that the number of accidents and collisions remains at a similar level, and their cyclical nature may be due to the current season, among others. In the spring and autumn, a higher number of accidents are recorded, hence the neural network prediction with a clear indication of cyclicality.

Fig. 8. Prediction of 5 ANN designs for factor S_k - *complaints received by PTA* for the time horizon 18

In the analyzed case, 4 out of 5 neural networks predict data at a similar level. Data collected for analysis, as well as data predicted by neural networks, strongly indicate the seasonality of the number of complaints. The largest number of complaints received by PTA falls in the autumn period. A conclusion can be made that weather conditions strongly affect the level of transport service, as well as the level of perceptions among passengers.

Fig. 9. Prediction of 5 ANN designs for factor P_r - persons injured in accidents for the time horizon 18

In the analyzed case, all 5 neural networks predict data at a similar level. The prediction and the collected data show that this number steadily decreases despite the increase in the number of buses and people using public passenger transport. This factor also strongly correlates with the number of accidents (Fig. 6).

Conclusions

The study covered an analysis of selected security factors in public passenger transport. The object of the research are transport services provided in the capital city of Warsaw by the Public Transport Authority. It has been shown that security and the sense of security are among the most important expectations that should be guaranteed, while their perceptions vary widely. This paper set out to analyze and predict selected security factors in public passenger transport based on the example of the capital city of Warsaw. The following conclusions can be made based on the study carried out:

- PTA as the organizer of public passenger transport in the capital city of Warsaw, through its efforts, ensures security in public transport;
- the bus fleet is systematically replaced with newer vehicles that offer higher quality;
- buses are adapted to meet the applicable Euro standards of exhaust emissions, which translates into their less negative environmental impact;
- the number of means of transport equipped with CCTV monitoring grows constantly, thus reducing the number of devastated vehicles or the number of complaints received by PTA;
- despite the dynamic increase in the number of buses, the failure rates decrease, which also demonstrates the quality and security of public passenger transport;
- the number of injured in accidents decreases dynamically, which results from the use of a more advanced and safer fleet of transport vehicles and the use of driver assistance systems;
- predictions of individual factors made using MLP neural networks - time series have shown the forecast number of events that may occur in the future for the analyzed factors;

Further research in the subject of this paper may relate to the analysis of other security assessment criteria in public passenger transport using other assessment and prediction methods.

Abstract

We consider the results of business information technologies development for decision support within geo-information management. While studies, we used methods of data bases constructing in case of distributed information platform, web-technologies and virtual reality tools. Also, we used Foresight technologies, theory of decision making under uncertainties, risk management approach. While study, we used a structural model of a geo-information distributed platform (GIDP) containing heterogeneous databases in the format of a multi-level architecture "data - processing - interface". We suggest to use a mechanism for preprocessing heterogeneous data, which includes a virtual data processor and a data preparation unit. Then, there is no need to convert data to the format used by the system, they remain in the original form. While research, we used platform https://www.researchgate.net/profile/Valery_Abramov2/ for data exchange and preliminary discussion.

Keywords: Business Information Technologies, Decision Support, Geo-Information Management

Introduction

Recently, a digital transformation, named Industry 4.0, extends in the global economy, during which a lot of enterprises and infrastructure-intensive companies (Borremans, 2018) plan and implement wide spectrum of information technologies (Baikov, 2019), (Bidenko, 2019), (Drabenko, 2019), (Frolova, 2019), (Lukyanov, 2019). This leads to serious business information technological changes in decision support within geo-information management (Kirsanov, 2014), especially in natural risk management (Gogoberidze, 2014), (Ershova, 2018), (Garcia, 2018), (Isaev, 2015), (Istomin, 2018), (Shilin, 2019).

In the article, the authors describe the results of business technologies development in geo-information management area (Burlov, 2018), (Fokicheva, 2016), (Fokicheva, 2015), (Istomin, 2015), (Kirsanov, 2014), (Lednova, 2014), (Malakhova, 2014), in large environmental projects (Mandryka, 2019), (Popov, 2014), (Popova, 2019), (Rumyantseva, 2017), (Zhigulsky, 2018) within environmental economics (Chusov, 2019), (Golosovskaya, 2014), (Karlin, 2014), (Karlin, 2009), (Popov, 2016). Significant attention in the implementation of such business information projects should be paid to geo-information support of natural risk management (Fokicheva, 2018) in the context of climate change (Mikheev, 2019), (Bournashov, 2014), (Gogoberidze, 2014), including the issues of information collection and processing (Fokicheva, 2019), (Khaimina, 2014), (Popova, 2019).

Methods and data

While research, we used: methods of data bases (DB) constructing in case of distributed information platform (DIP), web-technologies (WT), big data technologies (Novikov, 2019), (Sokolov, 2019), geo-information technologies (Veretennikov, 2019), (Yaily, 2019) and virtual reality (VR) tools. Also, we used Foresight technologies, theory of decision making under uncertainties (Palkin, 2019), risk management approach. From the point of view of geo-information management, we structured geo-space to allocate the interconnected components of the solution space (Istomin, 2015).

Results

While study, we considered a structural model of a geo-information distributed platform (GIDP) containing heterogeneous databases in the format of a multi-level architecture. Proposing GIDP contains three levels of data representation: "data - processing - interface". The advantages of such representation are the independence of the system from the number of software components included in each level and its own set of protocols and application interfaces for each level, which defines its own architecture. Note that the client-server connection model, based on the principles of structural programming and separation of input-output and computational processing, has recently failed to cope with the growing needs of developers in the field of reliability and performance of systems. Then, we propose to form a flow model, based on the selected structural model, which represents the structure of information data flow in GIDP (figure 1).

To avoid the difficulties of multi-user access to data, we suggest to use a mechanism for preprocessing heterogeneous data, which includes a virtual data processor (VDP) and a data preparation unit (DPU). A VDP is a software module that allows uniform access to all system data via standard interfaces (protocols), while hiding the features of data placement, data structures and formats. A DPU aims at collecting and first processing the data requested by the user from the system. When using this mechanism, there is no need to convert data to the format used by the system, they remain in the original view and can be used locally by their applications.

The VDP in more detail, you can say that it is a virtual data bank (VDB), which consists of a set of non-specified virtual databases, a virtual data bank (figure 2). Information sources of actual state databases are the actual cycle of functioning of organizational subsystems of a complex management object, when considering the geo-information system as a system for making managerial decisions.

The information sources of the databases of planned States and regulatory States can be input documents, virtual results of management decision-making, as well as the results of solving regulated tasks.

Figure 1 - Flow model of a GIDP based on heterogeneous databases

To solve the problems of decision support within geo-information management or in non-regulated management situations, it is necessary to create personal databases for an individual user of this system based on a VDB and results of processing situations. Accordingly, the location of the decision-maker (DM) will be the criterion for creating a personal database and accessing the nearest pre-processor data preparation mechanism.

After the user takes appropriate actions to solve the necessary tasks and generates requests for specific data, data from different local databases is determined for inconsistency. If there is one, databases of mismatched states are formed. They mostly contain data from heterogeneous local databases, after which they go through complex reconciliation procedures and end up in consistent states databases (CSDB), where data from identical, mostly relational databases can be found. From CSDB, data is written to the appropriate database of routine, normative or probabilistic States. It should be noted that the virtual personal databases form the basis of a geo-information management.

In addition to various state databases, it is necessary to introduce an integrated database into VDP mechanism, where data about the objects under study are merged and transformed. With this approach, it is still possible to use a single database management technology. From all the above types of databases, in accordance with the time parameters of the technology for creating a virtual

personal database, you can create a dependency diagram between the modules of subsystems represented in VDP.

It should be noted, all data control and transformation procedures in the data subsystem are performed by an intelligent system for analysis, control and transformation of information. This system can be considered as a superstructure to traditional data management systems.

All the above reasoning is especially important when there is a need to consider systems management as a set of interrelated subsystems in the network view, with fixed spheres of competence in the decision-making of the whole system. In these conditions, it becomes an urgent task to ensure coordination and interaction when solving individual subtasks that are solved in the network subsystems.

Figure 2: General diagram of dependencies between data subsystem modules in VDP

Note, the set of drivers in the data preparation block for the virtual data processor and its other components can be expanded if necessary without any significant restrictions and problems. The most important thing in extensions is to ensure continuity of software interfaces (protocols).

Discussion

In GIPD, there must be a condition for the autonomy of integrated databases. To maintain this condition, a Protocol for managing modifying global transactions is required. We propose to use global serializability, as the correctness criterion. Such Protocol should have the following characteristics:

- each local database management system (DBMS) must guarantee local serializability and non-cascading histories;
- local transaction execution histories should be without dead ends.

The use of this transaction management Protocol provides a specific model for managing GIPD, which ensures the integration of disparate databases into a single information space (figure 3).

Figure 3: Model of GIDP based on heterogeneous databases

In figure 3, we actually show a model for the GRID architecture consisting of heterogeneous separate databases, each of which can be accessed using the same access methods in multi-user mode.

Conclusion

We present the results of business information technologies development for decision support within geo-information management. We used methods of data bases constructing in case of distributed information platform, web-technologies and virtual reality tools. Also, we used Foresight technologies, theory of decision making under uncertainties, risk management approach. While study, we used a structural model of a geo-information distributed platform (GIDP) containing heterogeneous databases in the format of a multi-level architecture "data - processing - interface". We try to avoid the difficulties of multi-user access to data and we suggest to use a mechanism for preprocessing heterogeneous data, which includes a virtual data processor (VDP) and a data preparation unit (DPU). A VDP is a software module that allows uniform access to all system data via standard interfaces (protocols), while hiding the features of data placement, data structures and formats. A DPU aims at collecting and first processing the data requested by the user from the system. When using this mechanism, there is no need to convert data to the format used by the system, they remain in the original view and can be used locally by their applications. In GIPD, there

must be a condition for the autonomy of integrated databases. To maintain this condition, a Protocol for managing modifying global transactions is required. We propose to use global serializability, as the correctness criterion. Transaction management Protocol provides a specific model for managing GIPD, which ensures the integration of disparate databases into a single information space.

Acknowledgment

Associate professor Nikolay Popov, head of geo-information systems laboratory in Arctic and Subarctic Institute at the Russian State Hydrometeorological University, gave us very useful consulting while research. The platform https://www.researchgate.net/profile/Valery_Abramov2/ gave us excellent opportunities for preliminary discussion and data exchange while this research.

Place of Clusters and Cluster Policy in Economic Policy in Germany And Poland

Anna H. JANKOWIAK

Wrocław University of Economics and Business, Wroclaw, Poland

anna.jankowiak@ue.wroc.pl

Abstract

In the global economy, more and more emphasis is placed on cooperation between various entities. Networking has become the basis for understanding the international business, in which enterprises achieve better results being a part of a more extensive network covering an increasing number of countries. One of the types of regional networks are clusters that bring many benefits to associated entities and regions in which they operate, and it is the basis for creating and conducting cluster policy in many countries, or for including clusters in broadly understood economic policy. The authorities saw the potential, especially in the field of creating innovation, raising the level of competitiveness and stimulating entrepreneurship. Therefore, clusters have become a pillar of economic development in many national economies. The article aims to present the place of clusters in the economic policy of two selected European countries - Germany and Poland. These countries are at different levels of economic development, and hence the development of cluster policy and clusters is varied. The methods used in the article are a critical analysis of the literature and a comparative method that allows examining the similarities and differences in the approach to clusters in the studied countries.

Keywords: Clusters, Cluster Policy, Economic Policy, Germany, Poland.

Introduction

Clusters are interconnected companies and local institutions (or national as well), aiming to increase competitiveness, increase innovation, and new working places. Clusters, by the specificity of their character, combine regular business operations, local government agencies and scientific entities, thus contributing to the rapid growth of local economies. They also allow many small and medium-sized companies operating locally to start international activities. Therefore they constitute the right business environment, which drives economic growth. The clusters are present in most national economies, but they reach various stages of development in different economic conditions.

The shape of the clusters is affected by several factors connected with the location and nature of associated companies. Therefore it is not possible to create two identical clusters. Even a group created by the same corporation in different markets will never be the same. Cooperation and competition at the same time give the possibility of shaping the company competitiveness, raising its level through the continued development and improvement of processes in the units. The cluster can increase the attractiveness of an investment location, which leads to a better competitive position among the regions. Cluster help to increase the innovation of the associated units, to create new products, new companies and new jobs. The clusters combining the activities of entrepreneurs, local government institutions and research units contribute to the dynamic growth of local economies.

One of the more common definitions of clusters is that formulated by Porter, according to which clusters are "geographic concentrations of interconnected companies and institutions in a particular field, linked by commonalities and complementarities". Clusters include linked industries and other entities (suppliers), distribution channels and customers (demand), related institutions (research organization, universities, training entities, etc.) (Porter, 2001). A cluster is a set of interdependent organizations that contribute to the realization of innovations in an economic sector or industry (Preissl 2003). In the UNIDO context, a cluster is understood to refer to a sectoral and geographical concentration of enterprises and/or individual producers that produce a similar range of goods or services and face similar threats and opportunities (What are clusters…).

By simplifying the definition of clusters it can be assumed that (1) a cluster is a group of affiliated companies operating in the same geographic region; (2) there are market and non-market relationships between companies, as well as formal and informal ones; (3) cluster development is closely related to the competitiveness of the enterprise and the region in which it operates.

Due to its dynamic nature, there are many types of clusters, divided according to different criteria. According to Enright (2000), there are five different types of clusters:

- working clusters – associated companies utilize a critical mass of expertise, local knowledge, human resources and resources arising from the location to compete with other firms outside the cluster. Between companies of the cluster comes to different interactions and quantitatively compared to firms outside the cluster. They attract investors, resources and skilled workers to the region;

- latent clusters – existing critical mass is sufficient to reap the partial benefit of belonging to a cluster. However, there is no developed interaction and flow of information among its participants, which are necessary for the extensive use of the location and operation of the group of companies. This situation is often caused by the lack of knowledge of other participants in the cluster, the lack of common purpose and vision, and the absence of mutual trust between entities. In this case, individuals do not think of themselves as participants in the cluster and consequently do not use the opportunities offered by cooperation;

- potential clusters – in this type of connection, it is reasonable and possible to develop the cluster, but it must be deepened and extended to the efficient use of the location. There are often gaps in the contacts and exchange of information, which is essential for the development of the cluster. There is no awareness of the hidden function of the cluster, but factors are demonstrating the presence of connections;

- policy-driven clusters –governments choose a cluster to support and develop, but there is no critical mass and conditions favourable to economic development. However, clusters are created by political decisions and are financed by the government. It is based on the assumption that the government can create a cluster on any terrain, regardless of the economic analysis;

- wishful thinking clusters – there is a lack of all the factors of cluster development; there is no critical mass and no benefits for economic development.

An interesting classification of clusters was made by Ketels, who divided the clusters into industry groups (e.g. pharmaceutical, automotive etc.) but also drew attention to the perceived location of the market and dependence on the model of business. Ketels distinguished:

- local industries - clusters associated with a local recipient, whose location is determined by geographical proximity to major customers of companies associated in clusters. This type of clustering caters only to the needs of local markets. Clusters of this type are created to improve the competitiveness of products, but have a little effect on the business localization patterns in the region;

- natural resource-dependent industries - clusters associated with the local resources, which attach the company to a specific location. It meets the needs of the global market, but due to the nature of the region, companies are forced to function in the cluster;

- traded industries - clusters focused on trade, in which the companies are free to form units that produce goods for the international market. In these clusters, the location does not matter, and the creation of them in a specific region is a decision of business community and cluster initiatives. High stability characterizes this type of cluster and their presence is a crucial aspect of the attractiveness of the location (Ketels, 2003).

Activities of clusters are visible in the region in which they are located. The following effects can be indicated: the creation of new jobs; attraction of foreign direct investment; structural changes in the region; economic development of the region; emergence and development of specific factors of production, both in the electronic and automotive industry; creation of innovation culture and development of entrepreneurship in the region; development of large-scale production network consisting of specialized suppliers and subcontractors; creation of an attractive labour market, attracting skilled workers, changes in the local labour market; increasing in the share of exports from the region..

Cluster Policy – Theoretical Approach

Cluster policy can be understood as a set of instruments supporting the creation of strong bonds between enterprises, science and local institutions occurring in a given territory. It is usually an element of innovation policy, but also of industrial policy and a broad development or economic policy. Foster linkages between cluster stakeholders can see the role of cluster policy; build relationships between companies and institutions; facilitate joint programs building; encourage trust-building and support the cluster's institutional network. Policies supporting clusters can be divided into three categories based on motivations and policy objectives. The first type is the most horizontal model concerns "facilitating policies". In this case, the local government is focused on creating favourable microeconomic business conditions for growth and innovation that indirectly, stimulate the cluster growth. A second type is connected more with "traditional framework policies" like industry policy, research and innovation policy and regional policy. The last category is "development policies" aiming at creating, mobilising or strengthening a particular cluster and sectoral cluster initiatives and this type of policy can be named as a pure cluster policy (The Concept of Clusters).

A cluster policy character can be described by:

- Cluster development policies directed at creating, mobilizing, or strengthening a particular cluster, e.g. a national funding competition for the best life science cluster strategies.

- Cluster leveraging policies that use a cluster lens to increase the efficiency of a specific instrument, e.g. an R&D subsidy provided only to companies in regional clusters where the subsidy is likely to incur spill-over effects beyond the recipient firm.

- Cluster facilitating policies directed the elements of the microeconomic business environment to increase the likelihood of clusters to emerge, e.g. regional or competition policies that remove barriers for competition between locations (Cluster policy in Europe).

The models of the cluster policy can be classified according to the different levels of economic development of the country in which the model exists. The type of the cluster support activities depends on the political structure, size and resources of a country (Boekholt P., Thuriaux B., 1999). The difference in models, depending on the level of development, may apply to various aspects of such a policy (Uyarra E., 2014): understanding the role of the clusters and the clusters themselves (cluster definition); the scope of the policy and level of policy formulation (national, regional or local policy); policy objectives (subjects) (industrial areas, industries, specific groups of companies); principles of identification and selection of clusters to be

supported; institutional forms of cluster operation; instruments used for support, and the moment or period of cluster support.

There is a different approach to cluster policy implemented in various countries (see figure 1). In some countries, it can be noticed that the government offers a dedicated support program for the cluster as a part of its policy to create stronger linkages between units. This situation can be seen in Korea, Catalonia, Mexico and Poland. On the other side, there are countries with strategic cluster-based policy, where they use clusters and networks as organizational infrastructure for policy action. In this group, Germany, France, Basque can be found.

Clusters and cluster policy in Germany

Relying on the German data from Federal Ministry for Economic Affairs and Energy in Germany there were 90 clusters (as of March 2020, see figure 2), which were characterized by a formal character and efficiently worked for their members and recipients.

Figure 2: Clusters in Germany

Source: Clusterplattform Deutschland, Federal Ministry for Economic Affairs and Energy, https://www.clusterplattform.de/CLUSTER/Navigation/Karte/SiteGlobals/Forms/Formulare/EN/karte-formular.html [access 10.02.2020]

According to the European Cluster Excellence Initiative, there were 19 Bronze Label clusters in Germany, 46 Silver Label certified clusters and 11 Gold Label clusters. German clusters have been around for many years, and their average age is much longer than in other countries, especially Eastern European and Asian. It can also be noted that German clusters are less numerous than other such connections because the key is the degree of involvement of cluster entities. In essence, companies can be treated as cluster actors only when they commit to co-create the cluster (often such an obligation has a written form in which the company undertakes to pay membership fees, which allows the elimination of artificial clusters). A characteristic feature is also the broad geographical coverage of German clusters, which include entities located in various, often distant regions. In German clusters, more than half of the entities are companies from the SME sector, and the share of research and development units is about 15%. Clusters have a high degree of formalization of tasks divided between participants, and their operation is formalized and based on association agreements (Meier zu Köcker, Garnatz, 2012).

Clusters in Germany can be combined with development, innovation and technology policies. They are monitored because they are perceived as driving elements of the local economy.

In Germany, the first public grant program focuses on the clusters support, and to strengthening it, 25 regional developments were established in 1995 followed by general nationwide programs to support businesses. Cluster policy in Germany has a rather central character and aims to build a bridge between business and science to achieve economic growth and a higher level of innovativeness. The primary instrument is the financial support (e.g. 1.2 billion EUR worth support combined of public and private funding in the cluster program called Leading-Edge Cluster competition). However, the main idea, and at the same time quite innovatory, is to support the connection between not only different industries but

various companies if we look at the size of firms (connect huge, transnational corporations with freshly established starts-up).

Cluster support activities take place at two levels in Germany - at the national and federal level (federal states). A comprehensive strategy has been developed at the federal level to cover clusters under the "high-tech strategy". The assumptions included both activities targeted at SMEs and modular activities on a local scale, taking into account new technological solutions and promoting the most efficient clusters. The essential initiatives supporting clusters at the federal level in Germany:

- Cluster Competition- the Federal Ministry of Education and Research (BMBF),
- "Network management" module as part of the Central Innovation Program
- The „go-cluster" programme provides a stimulus to improve cluster management and help turn German clusters into highly effective international clusters. This program aims to support the transformation of the most efficient national innovation clusters into global clusters of excellence; promote new cluster services to stimulate cluster managers to offer new services; increase the international visibility of participating innovation clusters and analyse trends of international cluster policy to work out recommendations for the German perspective (The German programme).

The federal states, on the other hand, have various ways to support networks and clusters. They can direct their help to specific industries and fields of technology. The local authority can determine the relationship with the economic support provided by a given Land, as well as to engage in activities of entities from outside the given Land (Meier zu Köcker, Garnatz, 2012). All of 16 federal states have launched numerous measures to support the development of efficient clusters – across technology, business or innovation. The cluster support at the federal level provides financial help for cluster management, innovation projects, educational activities and joint public relations initiatives (Clusterplattform).

Clusters and cluster policy in Poland

It is challenging to provide the number of clusters in Poland because some of the registered clusters do not meet the definition conditions and do not function daily. It can be assumed that there are about 150 clusters and cluster initiatives, of which about 50 are operational. According to the European Cluster Excellence Initiative in Poland (as of 18.03.2020) there are 6 clusters labelled Bronze Label, only one was qualified to the Silver Label group. In contrast, no cluster received the Golden Label (one Polish Silesian Aviation Cluster cluster was in this group until February 15, 2020).

Clusters found themselves as one of the pillars of the Polish economic development plan, which was named Responsible Development Plan and was announced in 2016 (see figure 3). The objectives of the government for 2020 (extended till 2030) include an increase in investment to over 25% of the GDP; increase in the share of R&D expenditure to 2% of the GDP; increase in the number of medium-sized and large enterprises to over 22 000; more Polish foreign direct investment (increase by 70%); growth of industrial production exceeding the GDP growth; GDP per capita of Poland at the level of 79% of the EU average (Responsible Development Plan). Clusters, together with industrial valleys, are in the target audience called reindustrialization. According to the plan's assumptions industry is a natural environment for innovation and the core of expenditure for research and development. Innovative companies create necessary cooperation chains and high-quality jobs. The challenge for the next years is to support the existing and develop new competitive advantages and specialisations. Clusters are therefore in the centre of interest of national authorities because they combine both the process of creating innovation through close cooperation of companies and create jobs through an increased degree of industry concentration in a given region.

Figure 3: Five pillars of the economic development of Poland

Source: Responsible Development Plan, https://www.gov.pl/web/fundusze-regiony/plan-na-rzecz-odpowiedzialnego-rozwoju [access 7.03.2020]

Cluster policy in Poland results in away from European policy and is carried out in similar time horizons, which is most often the result of the functioning of EU budgets. Assumptions for current activities have been included in such documents as National Development Strategy until 2020, Enterprise Development Program for 2020 and Directions and assumptions of cluster policy in Poland by 2020. In the National Development Strategy until 2020, clusters are perceived as a factor improving the country's competitiveness and deepening regional specialization. In this document and many others, clusters are to constitute an essential lever for the development of Polish exports, both in traditional and modern industries, such as ICT or automotive. The task of active cluster policy will be, inter alia, to support the most innovative and showing the highest potential for the development of Polish clusters that are able to create highly-competitive products and services constituting Polish and European export specialities (Jankowiak, 2019).

The principal aim of the Polish cluster policy is to strengthen the innovativeness and competitiveness of Polish economy through intensified cooperation, interactions and knowledge transfer (that is through providing support for existing and newly created clusters) as well as through supporting the development of vital economic specializations (that means selecting critical national and regional clusters and focusing part of public support on them).

The achievement of the principal aim involves the fulfilment of the following specific goals (Lindqvist, Ketels, Sölvell, 2013):

- stimulation of internal interactions, knowledge transfer and cooperation as well as the creation of necessary social capital;
- expansion of the external networking of clusters and entities operating within them, especially in a cross-sector and international dimension,
- strengthening of joint and integrated strategic planning processes within clusters,

- increase of the number of innovative goods and services offered on domestic and international markets by companies and entities operating within clusters, which should lead, among other things, to the growth of export,
- mobilization of private investment in clusters, including the creation of new companies and inflow of foreign investment as well as increasing private spending on R&D and innovation-oriented activities,
- the development of the ecosystem of supporting institutions (e.g. education and research institutes, technological parks and technology transfer centres, etc.) and better customization of their offer and activities to the needs of companies operating within the clusters,
- boosted the effectiveness of using public funds by their concentration and obtaining synergy between different policies and support instruments (e.g. concerning infrastructure development, human capital, R&D, promotion, internationalization, etc.).

According to the assumptions adopted by the Working Group on Cluster Policy, the main goal of cluster policy should be to strengthen the innovation and competitiveness of the Polish economy. It should be done based on the intensification of cooperation, interaction and knowledge flows within clusters and supporting the development of strategic economic specializations (Key National Cluster). Key National Cluster in Poland is a cluster of significant importance for the national economy and high international competitiveness. Key National Cluster is identified at the federal level, including based on criteria regarding critical mass, development and innovation potential, past and planned cooperation as well as statement and potential of the coordinator. In Poland, there are currently 16 vital national clusters that have been selected in the national competition. The Organizer of the Competition for the status of the Key National Cluster (KNC) is the Ministry of Development, which runs the Competition in cooperation with the Polish Agency for Enterprise Development (Jankowiak, 2019).

Comparison and Conclusions

Comparing both clusters and cluster policies in Germany and Poland, many differences can be pointed out. It can be assumed that the development of clusters in Germany and, consequently, the implementation of cluster policy is a process started much earlier than in Poland. Hence the experience and achievements of both countries are varied. Although the number of clusters in Germany is smaller than in Poland, they are characterized by a higher degree of formalization, which can be assumed that the number of actually operating clusters in Germany is higher than in Poland. It is also shown by the European Cluster Excellence Initiative (table 1), which awarded more distinctions to German clusters than Polish ones. This may mean that German clusters are at a more mature stage of their development.

Table 1: European Cluster Excellence Initiative in Germany and Poland

	Germany	Poland

Silver Label	46	1
Gold Label	11	0

Source: Author's work based on The European Secretariat for Cluster Analysis (ESCA), available at https://www.cluster-analysis.org/ [date of entry 20.03.2020]

Cluster policy in Germany was created in the 1990s, i.e. a decade earlier than cluster policy in Poland, hence it is at a different level of development (Table 2). In both countries, there are units dedicated to cluster policy, but this is not their only task - only one of the areas of activity. On the one hand, this is the right thing to do, as in both cases cluster policy is part of broad innovation policy, but the lack of specialized cluster units can lead to a reduction in the scale of cluster policy. In Germany, most cluster support programs operate at the national level, and only two are regional programs. The opposite situation occurs in Poland,

where local programs dominate (22 programs). It can be interpreted that in Poland clusters are more local initiatives while in Germany are seen as a national instrument. However, regional cluster support programs in Poland are not financed from regional sources, but national and European sources. In Germany, on the other hand, funding for regional programs is funded through regional sources.

The cases of cluster policy in Germany and Poland examined in the article show that there are no significant differences in the assumptions and implementation of these policies in both countries. It can be assumed that due to the long-term nature of the clustering process in Germany, German cluster policy can serve as a model and starting point for cluster policy in Poland.

Table 2: Cluster policy in Germany and Poland

Abstract

In recent years, considerable attention has been devoted to the exigency of sustaining the attentiveness of children and adult learners in formal school settings and in informal educational environments. The research project described in this paper aims to present the pedagogical opportunities offered by including *Mindtoyness* teaching sets in the educational work with children and adults. The *Mindtoyness* collection is informed by the idea that, for such work with children and adults to be effective, learning environments should combine elements of play, collaboration, and the development of mindfulness, resourcefulness, and sensitivity. The inclusion of play and free exploration in didactic interventions for children and adults with disabilities is expected to support and naturally sustain their involvement and cognitive activity.

Keywords: Interactive Didactics, The Polarization of Attention, Didactic Methods, Didactic Toys

Introduction

The idea of the *Mindtoyness* collection grew out of our fascination with laboratory work with children in the field of early education. The project was also inspired by the thought of Maria Montessori (1913, p. 40) and her dedication to arranging settings furnished with developmental aids. The central role in such settings was ascribed to the developmental aids which promoted play and helped alternate activity and contemplation. This unique concept of in-depth learning was grounded on Montessori's discovery of what she called the polarization of attention. Modern research on the learner's mind has shown that the Italian physician's insights were correct. The key component of the theoretical underpinnings behind the idea of *Mindtoyness* lies in creating conditions conducive to concentration (the polarization of attention), which catalyzes the process of normalization as a factor in the individual's developmental growth. Today, educators underscore the importance of a similar phenomenon which has come to be known as mindfulness, i.e., heightened attentiveness and, more profoundly, a type of secular meditation. As defined by Jon Kabat Zinn (2016, p. 9), mindfulness is awareness which involves paying close attention to every experience through which we go, which helps us arrive at an improved self-knowledge and make changes in our lives. Mindfulness can be cultivated through a range of practices at various levels: as a strategy for coping with everyday difficulties, by somatic and breathing exercises, and, ultimately, in the form of deeper spiritual practices leading to what Montessori viewed as normalization. Modern educational studies offer information on the methods of fostering mindfulness in the cognitive sphere. Our aim is to transplant the issues of mindfulness and concentration training on to education and identify the didactic and developmental benefits occasioned by the cultivation of this practice. Etymologically evoking

mindfulness, the *Mindtoyness* collection as framed in our research project may provide teachers with tools for working both with children and with adults with disabilities.

The Theoretical Justification of The Project

Given the contemporary the polarization of attention by Maria Montessori (1913), cultural context and the changes in theoretical perspective which it triggers, our framework seeks to integrate the principles of *interactive didactics* (Author, 2012) into the interventions using the *Mindtoyness* collection. We understand interactive didactics as an approach to cognitive processes which combines interactions in environments organized so as to stimulate extensive information sharing among the participants with exercises for heightened concentration.

Equally importantly, the premises of our project also come from observations of experimental practices in laboratories which have revealed that insight and intervention in the studied phenomenon are the prevalent characteristics of such experimentation. Following Ian Hacking's (1985, p. 135) imperative finding "Don't just peer: Interfere", if this idea is applied to educational realities, we can construe it as encouraging a learner's inner activity, which involves exploring, constructing, producing representations of knowledge, collecting perceptual data, and transforming them into procedural knowledge. Self-reliance and team collaboration which are triggered in laboratory conditions are equally valuable.

It is our intent that didactic methods involving *Mindtoyness* should bring together play, manual manipulation skills, and readiness for sensory integration, while implementing varied methodological ideas which use the collection. For this purpose, it is necessary to create conditions for concentration, which is prerequisite for heightened cognitive activity when studying and manipulating the components of *Mindtoyness*. This assumption is aligned with modern psychological justifications of the pedagogical practices in which the learner's concentration level and duration determine the phases of his/her cognitive activity from exploration to understanding. It is of particular relevance in the case of children and adults with disabilities, especially for improving their outcomes in the capability to sustain attention when involved in a longer cognitive activity. Our assumption is that, by performing manipulations when using the *Mindtoyness* kits, learners naturally maintain their activity (waiting for the final effect of the game or play), while cognitive processes – of analysis and synthesis, categorization, and other formal operations – are constantly unfolding in the background and communicative competences are also being developed (Bruner, 1978; Wygotski, 1989; Tomasello, 1999). These outcomes can be achieved as, so to speak, "by-products" of play, an activity which is all too rarely appreciated enough in relation to adults (Tartakovsky, 2012).

The Object and Strategy of Research

As our research project aims to establish **what are the developmental, cognitive and social effects of working with the *Mindotyness* collection**, and **what is the specificity of cognitive mindfulness manifesting in** we chose to rely on the research strategy founded on good communication and inclusion of all participants. The collection is supposed to support the competences defined in the instructions, but their list continues to be extended and corrected by the members of this community. Adopted by us in the project, the **action research** strategy made it possible to negotiate the direction of actions launched at the educational facility and to modify particular stages and the activities of the participants, if suggested by their interpretation of their insights and perceptions (Elliot, 2010).To this purpose, at the first stage of the project, we launched collaborations with educational facilities, and teaching professionals began to use *Mindtoyness* sets in their work. The practitioners had earlier had the *Mindtoyness* work protocols explained to them and received manuals for all the kits, complete with their descriptions. The significance of **independent initiative-taking** both by the professionals and by the learning and playing children and adults was emphatically highlighted. All the participants in the project were asked for feedback both as verbal opinions articulated in group discussions and as written assessments of the sets in evaluation forms. When collecting data now, we primarily concentrate on the most important aspects related to cognitive mindfulness: (the level and span of) focused attention, analysis, synthesis, comparison, generalization, abstraction, categorization and the construction of cognitive representations, as complex processes involved in passing from concrete

operations to formal ones. The techniques applied in the collection of data include observation supported by visual recording and focus group interviews with the participants (with additional questionnaires to be filled in by the staff).

Mindtoyness Sets: A Description

In the first phase of the project, three sets were developed in two Montessori preschool facilities and in two institutions dedicated to adults with disabilities as the initial kit of *Mindtoyness.* All are suitable for playing in pairs and for individual work:

A. *Dominoes*–a set of elements arranged in sequences, as is the case in the regular dominoes, but according to the features determined by the participants. Any set of ***Dominoes*** consists of colored blocks of different shapes, colors, and markings (a dot or no dot). The basic aim of using ***Dominoes*** is to develop proficiency in composing sequences of pieces based on the previously defined characteristics. The domino sequences are usually arranged in pairs, but individual or group work is also possible. By playing dominoes, the participants can develop the following dispositions:

- cognitive mindfulness;
- skills of analysis, synthesis, comparison, abstraction, and categorization.

B. 3D *Tic-tac-toe* is a set of blocks of various colors which are planted on rods and can be spatially arranged in the semblance of the tic-tac-toe game. ***Tic-tac-toe*** is suitable both for children and for adults, and can be employed by educators in an array of exercises or be individually used by the participants when playing in pairs. While the rules generally resemble those of the traditional tic-tac-toe game, the three elements can be spatially arranged in thee dimension – horizontally, vertically and diagonally. Besides, the players have pieces of various shapes and colors at their disposal. This is helpful in fostering the development of the following dispositions:

- cognitive mindfulness and anticipation capacity;

- composing and re-modeling of spatial arrangements when needed;

- skills of analysis, synthesis, comparison, generalization, and abstraction.

C. *Black-and-white* ***Balltoyness***– is a set of black and white balls held within a frame which can be arranged in various patterns and used to play a game similar to the Chinese game of Go. By means of the toy, we can compose black images against the white background and the other way round. The form of *Balltoyness* is adjusted to both children's and adults' capabilities of manual manipulation. *Balltoyness* facilitates grasping, developing, and/or understanding:

- cognitive mindfulness;

- theory of the mind through playing in pairs;

- skills of analysis and synthesis;

- shapes of letters, numbers, figures;

- reproduction of shapes;

- numbers and simple arithmetical operations;

- notions of mirror reflection and raster, together with their application.

Expected outcomes

We realize that the introduction of *Mindtoyness* into didactic practice is merely an initial step in the assessment of the utility of the kits. At this moment, the observational material we have compiled is not extensive enough to corroborate any comprehensive reflection on the collection. Nonetheless, at the currents stage, the insights we have already obtained from the first facility for adults with disabilities have proved surprising, as they suggest an image which we did not take into account when formulating our research questions. Specifically, the clients take over the initiative far more often than we expected them to, and they search for and come up with their own, inventive applications and solutions using the *Mindtoyness* kits. Whether similar developments will take place in preschools with which we collaborate remains yet to be seen.

Abstract

The present paper presents a possibility to apply forecasting methods based on autoregressive modeling and annual periodicity profile do determine an anticipated future number of granted building permissions for new dwellings in Poland. Additional value of this research lies in the possibility for utilitarian comparison of applied models that base their autoregressive side on the following structures: AR, ARX, ARMAX, ARI, ARIX, as well as ARIMAX. The research confirmed the possibility to elaborate a predictive model characterized by good qualitative parameters. Modeling quality was verified, inter alia, by determination coefficient and residue distribution characteristics. Forecasts elaborated by means of predictive models showed how the forecasted phenomenon takes shape in the future.

Keywords: Forecasting, Building Permissions, Autoregressive Models, Annual Profile Identification.

Introduction

In market economy, real estate is one of the fundamental resources that influence financial and macroeconomic stability of any country (Liu & Molise, 2019)(Bisht & Kumar, 2016)(Cesa-Bianchi & Rebucci, 2017)(Crowe et al., 2013). Parameters of the real estate market, especially in the domain of market analyses, directly reflect the state of the economy and allow it to be placed in the business cycle. Mapping of the state of the economy and identification of the business cycle phases make it possible to decrease the decision-making risk with regards to allocating investment resources both on the supply and demand side of this market (Shahzad et al., 2019)(Lee et al., 2019). After conducting analyses of the real estate market, should it be possible to conclude that the state of the economy as a whole is good, it is

likely that it will cause increase in investment activity on this market. If, however, the economy is in recession, it will also reflect in inhibiting investment in the dwellings market. Further, since the real estate market condition influences the condition of the entire economy, and such condition implicates decisions on many dimensions of real sector management, the question of which determinants of the construction process directly translate onto the situation of the market of dwellings seems key. Considering stages of the dwellings construction process, its first component is the number of building permissions granted for the construction of new dwellings. The number of granted building permissions may form a significant barometer that reveals the condition of the market of dwellings and the economy as a whole. We assume that when the number of granted building permissions increases, investors who operate on the market of dwellings expect that the macroeconomic and financial situation is stable and will continue developing for a minimum of the upcoming 2-3 years. Assumption that the economic situation will not change or will develop further for the next 2-3 years results from the length of time required from the moment of obtaining the dwellings construction permission to their completion and introduction to the market. The same is true in the opposite situation, namely when the number of granted building permissions decreases. The decrease reflects the situation when investors identify unacceptable investment risk and introduce prudent behaviors. One of the explanations for real estate investors' protective behaviors lies in a possibility that some factors of market downturn or even recession appear in near future. In summary of the above, it becomes crucial to examine implementation of a number granted building permissions over time and to identify the time-frequency components of this number. This will make it possible to perform an analysis of the course over time of the number of granted building permissions and to construct predictive models. Assuming that obtained predictive models will be characterized by satisfactory quality, it will become possible to use them to forecast the way the examined phenomenon shapes in the future. Information obtained on the basis of predictive models as well as forecasts determined with their use will be useful in decision-making processes both on the supply and demand sides of the real estate market. It will be useful, because it will make it possible to predict, with acceptable precision, the crisis phenomena that might possibly take place. All analyses of the number of granted building permissions refer to Poland.

Validity of Forecasting Market Phenomena - Literature Review

This literature review presents the latest examples of applying various forecasting methods in corporate activities. These investigations will show practicality of various forecasting methods on the one hand and the possibility of constructing combinational models in the process of constructing a forecasting model. The purpose of the presented review of the latest forecasting literature is to reveal its applicability in daily business activity. The fact of the existence of annual forecasting M-Competitions proves how important theoretical and practical forecasting is. The purpose of these competitions is to constantly perfect forecasting methods; they form an opportunity for experts who use forecasting methods in theory and practice to meet annually. The various challenges faced by participants in the fourth edition of the competition can be found in the following works (Agathangelou et al., 2019; Ferbar Tratar, 2015; Ha et al., 2018; Hasni et al., 2019; Hyndman, 2019; Jaganathan & Prakash, 2019; Januschowski et al., 2019; Makridakis et al., 2019; Moon et al., 2013; Petropoulos & Svetunkov, 2019; Spiliotis et al., 2019). It is also important to mention the importance of using and perfecting forecasting methods in the domain of supply chain. Much research in this domain examines the issue of electing an appropriate forecasting method in global supply chain, where forecasting is indeed an important indicator of operational efficiency. The paper by (Acar & Gardner, 2012) examines a case study that selected a forecasting method for a global manufacture of lubricants and fuel additives. Another paper describes demand forecasting methods in a supply chain that applied smoothing and denoising. Exponential smoothing is a widely used method in supply chain models. In order to improve cost effectiveness of supply chains, the studies introduce signal theory analysis. Wavelet denoising is a way to apply this method in forecasting. Results obtained with the use of exponential smoothing are then compared against results obtained by means of wavelet denoising. Two different methods were tested and the results show that wavelet denoising is superior to exponential smoothing in terms of costs (Ferbar et al., 2009). The work by

(Tascikaraoglu, 2018) is an interesting example of time-space application of forecasting methods. The author assessed time-space forecasting methods in managing an intelligent city. The topic is very current and important, because the issue of growing urban populations brings about difficulties in managing information necessary for managing urban processes. Advanced measurement and telecom technologies require applying more and more complex predictive methods in order to render it possible to determine event forecasting and social activities in large cities. Another paper describes application of tide forecasting method based on dynamic weight distribution for operational evaluation. Using this approach, forecasting prediction and stability were proven (Qiu et al., 2009). Two other forecasting methods that proved effective are short-term load forecasting method based on fuzzy time series, seasonality and long memory process (Sadaei et al., 2017) as well as fuzzy time series forecasting method based on hesitant fuzzy sets (Bisht & Kumar, 2016). Other interesting studies presented complex assessment of macroeconomic forecasting methods. Using a dataset of seven developed economies, the authors examined forecasting usefulness of the following four classes of multidimensional models: Factor models, BVAR models, MIDAS models and DSGE models (Carriero et al., 2019).

Another set of studies concerns forecasting in the domain of demand. One of the papers presented the Bayesian forecasting approach (Bergman et al., 2017). Forecasting demand is a fundamental component of a series of industrial issues (e.g. managing stock or equipment conservation). Forecasts are of crucial significance for precise assessment of demand for spare parts in order to determine stock. The studies presented an interesting approach to forecasting demand that uses the Bayesian method to improve precision. When validating, effectiveness of the proposed Bayesian method was compared against traditional forecasting methods in terms of forecasting precision and overall efficiency of stock fill indicator. Analyses showed that in particular situations the Bayesian forecasting approach more precisely forecasts the demand for parts, hence influencing their availability (fill indicator) and stock costs. Other studies into demand management are about forecasting demand for spare parts for consumption goods in the context of post-production; ways to predict a required number o spare parts that will be necessary in future (Kim et al., 2017). Other studies showed usefulness of forecasting in tourism; the authors reviewed key papers published between 1968 and 2018 in order to better understand how methods of forecasting demand for tourism evolved over time. Key conclusions drawn from comparisons of efficiency profile methods over time show that forecasting models became more diverse, more combined, and more precise. Considering the complexity of determining demand for tourism, no single method is verifiable in all situations and forecasting methods continue to evolve (Song et al., 2019). Other analyses present modified Grey Model (GM) in order to forecast increase in the number of air transport passengers. Such forecasting methods as Holt-Winters, autoregressive models, exponential smoothing, neural network, fuzzy logic, GM model calculated very high increase in this domain. The GM model was modified to suppress calculation of trends over time. Results of this simulation show that the modified GM model decreases the increase in exponential estimations of the model; it makes it possible for the GM model to forecast reasonable passenger demand values in long-term forecasts (Carmona Benítez et al., 2013).

The domain of energy widely uses forecasting method results in analyses. An interesting study forecasts electricity prices on day-ahead energy markets with the use of a mixed data model and a hybrid forecasting method. The hybrid method is composed of cascading forecasts made up of a neuron network (NN) and evolutionary algorithms (EA) (Amjady & Keynia, 2008). In the domain of energy, the studies also examined forecasting methods of wind speeds with the use of nonlinear set of time series and extreme optimization. In this paper, a novel method called EnsemLSTM is proposed by using nonlinear-learning ensemble of deep learning time series prediction based on LSTMs (Long Short Term Memory neural networks), SVRM (support vector regression machine) and EO (extremal optimization algorithm). The proposed EnsemLSTM is applied on two case studies data collected from a wind farm in Inner Mongolia, China, to perform ten-minute ahead utmost short term wind speed forecasting and one-hour ahead short term wind speed forecasting. Statistical tests of experimental results compared with other popular prediction models demonstrated the proposed EnsemLSTM can achieve better forecasting performance (J. Chen et al., 2018). Another application of forecasting methods is described in a paper

that presents short-term power load probability density forecasting method using kernel-based support vector quantile regression and Copula theory (He et al., 2017). Methods of forecasting probability density may effectively quantify forecasting uncertainty of power loads. The paper proposes using the probability density forecasting method for short-term loads using kernel-based support vector quantile regression (KSVQR) and Copula theory. Because the kernel function may influence forecasting efficiency, the paper also compares three kernel functions in order to select the best one for learning. The authors assessed precision of predictive intervals considering two criteria: prediction interval coverage probability (PICP) and prediction interval normalized average width (PINAW). The factors of uncertainty and explanatory variable correlation are of great significance for load forecasting precision. Another paper presents forecasting methods in energy planning models that analyzes forecasting methods in terms of precision. Fifty different forecasting methods were identified. The most frequently used artificial neuron network (ANN) is applied in 40% of all studies. Other popular methods, in descending order, are as follows: support vector machine (SVM), autoregressive integrated moving average (ARIMA), fuzzy logic (FL), linear regression (LR), genetic algorithm (GA), particle swarm optimization (PSO), grey forecast method (GM), as well as autoregressive moving average (ARMA). In order to fully integrate benefits of a number of forecasting models and improve precision of load forecasting results, the studies presented application of integrated forecasting method to forecast loads on the electricity grid. Evolutionary programming and fuzzy methods of complex assessment were used. Utilitarian benefits were examined with the use of two methods and tested in terms of feasibility and effectiveness (G. J. Chen et al., 2001). In this vast research area of energy, it is also important to pay attention to studies that assess forecasting of the efficiency of photovoltaic systems (Litjens et al., 2018) as well as studies that present the widely used adaptive method of short-term forecasting of customer thermal load. This method used a linear regression method (Nigitz & Gölles, 2019). A paper by (Wang et al., 2018) presents an interesting approach to forecasting. It showed an improved grey model optimized by multi-objective ant lion optimization algorithm for annual electricity consumption forecasting. Another forecasting method is described as a monthly electricity consumption forecasting method based on vector error correction model and self-adaptive screening method (Guo et al., 2018). At the end of this literature review, it is important to cite studies into the use of an integrated forecasting method that includes ARIMA, GARCH, as well as Bootstrap (Nieto & Carmona-Benítez, 2018), as well as studies into the improvement of concrete creep prediction with probabilistic forecasting method under model uncertainty (Jin et al., 2018) and studies into probabilistic forecasting of wave heights for the maintenance of offshore wind turbines (Taylor & Jeon, 2018).

The presented examples of theoretical and practical applications of select forecasting methods, identified in most recent scholarly studies show how diverse forecasting modeling is. Presentation of forecasting literature confirms the importance of this topic in supporting corporate activity.

Identification and Validation Data

The goals of the present studies is to perform comparative analysis of select forecasting methods. We verified usefulness of described methods basing on data that represented one of the stages of a building process. In order to conduct the comparison procedure of those select forecasting methods, we collected data about permissions granted for building new dwellings. The data used to construct predictive models and forecasts are characterized by a monthly measurement interval for the years of 2005-2018. Overall dataset was divided into two clusters: data for 2005-2017 are clustered into the learning dataset and data for 2017-2018 are clustered into a validation dataset.

In the first step of the analysis, we created graphic visualization of the run of the phenomenon under study. Additionally, for analytical needs, we separated development tendency and periodical components from the non-transformed entry data (see Figure 1). It is important to note that we subtracted a trend from non-transformed time series and as a result we obtained the run of the G_{pv} variable component ($G_{pv}=G_p-G_{pt}$). The upper graph (see Figure 1) presents the original run of the measurement for the years of 2005-2017. The middle graph presented in Figure 1 is a run of the separated G_{pt} trend, mapped out with the use

of Savitzky-Golay filter with averaging time of 37 months; the filter used first-degree polynomial. Then, we subtracted the trend from the original run and as a result we obtained the run of the G_{pv} variable component. In the end, the analyses adopted the following designations: G_p - Granted permissions, G_{pv} – Granted permissions variable component (detrended value), G_{pt} – Granted permissions trend (low frequenecy component). As stated above, the trend was calculated using the Savitzky-Golay filter with a 37-month range. Basing on the characteristics of the run of the time and decomposed series, we noted that this run is characterized by clear annual periodicity and that the run of the variable component does not have a trend and is located around the zero mean.

Fig. 1: Structure of types of rented premises (entire house vs. private room). Source: own study

Figure 2 illustrates the run of the validation sequence that includes the period starting from the beginning of 2018 and ending at the fourth quarter (Q4) of 2019. These data will be used to verify quality of constructed predictive models. The data were divided into learning and testing sequences because the assumption is that the learning sequence is used to identify models and the test sequence is used to validate these models. Validation data are not used to learn, and the learning data are not used to verify the model's quality.

Fig. 2: Validation data (2018-2019)

Figure 3 illustrates the way the original G_p run was decomposed into the G_{pt} trend signal and the G_{pv} variable component.

Fig. 3: Estimation of variable component of Granted permissions

With an identified trend signal and variable component (constant level of the forecast variable), we ran a procedures of identifying an annual profile of the variable under study. The profile will be useful, because identification of a predictive model is conducted by means od separating and then adding the following components:

- trend signal modeled with the use of a linear autoregressive model and
- signal of the variable component modeled with the use of the identified annual profile.

Figure 4 shows the process of estimating the annual profile of the variable component of granted permissions.

Fig. 4: Estimation of annual profile of variable component of granted permissions

The G_{pv} variable was decomposed into a set of 18 segments for the years ranging from 2005 to 2017. The decomposition was performed for individual 12-month periods. As a result of this segmentation, we created a profile map. Then, we calculated mean profile values for each 12-month period basing on the 18 individual annual profiles. After averaging, we obtained an annual profile, which Figure 5 illustrates.

Fig. 5: Estimated annual profile of variable component of granted permissions, according to identification data.

Describing the characteristic of the annual profile, we noted that the extreme value appears in April, whereas the smallest value appears in January. Considering the profile's annual characteristic, we note that generally, from spring to fall the values obtained for the profile are greater than those in winter months. This characteristic reflects specificity of the building market, whereby construction is more intensive from early spring to late fall. Having identified the annual profile, we performed its initial validation by means of the model's output simulation for 2005-2017 and then verified the model's quality with the use of the ARX4 method. Figure 6 presents the set of measurement data and model output.

We assumed that the quality of the model hence obtained will be proved by determination coefficient, which amounted to 0.76. We may assume, therefore, that the constructed predictive model is characterized by acceptable quality. The next step was to determine model residues that aimed at

verifying their distributive characteristics. To identify the model's residues, we subtracted theoretical from empirical values. Figure 7 illustrates the run of the residues. Basing on the model's residues, we examined the process of shaping the probability density distribution of the residues with the use of the Gauss model, residue randomness, and autocorrelation attributes, in order to confirm correctness of the model and possibility of its utilitarian application.

Figure 6: Simulation of Annual profiler model output for the G_{pv} variable component

Fig. 7: Residues of simulation output model

Residue distribution is symmetrical in shape and is similar to normal distribution, which is confirmed by applied statistical tests (see Figure 8). In order to verify randomness of the residues, we determined their autocorrelation functions. At zero, the residues have high values when compared with deterministic components, which indicates high share of the random component in the run of the model's residues. This attribute is a positive characteristic that process good quality of the model. It is also important to note that

a value for 48 delay exists and exceeds noise whiteness, which indicates that the model has limited application for long-term time periods. this characteristic results from the averaging constant of the Savitzky-Golay filter (see Figure 9). In summary, considering the above, we may assume that the variable component model is characterized by good quality and may be used to determine the forecasting values with regards to the number of granted building permissions.

Fig. 8: Test of gaussianity of probability density of simulation residues (model output errors)

Fig. 9: Auto correlation of model output for checking the whiteness of residue noise

Forecasting of granted permissions in Poland

Determination of the forecast values for the number of permits issued for the construction of new dwellings in Poland is the step that follows construction of the predictive model (see Section 3 above). The forecasts were determined in keeping with the so-called forecasting procedure. Figure 10 illustrates its outline.

In order to determine the forecasting values, we first modeled the slow trend with the use of autoregressive models. Figure 11 shows the model's realization structure. In the second step, we applied the identified annual profile. The end value of forecasts is a composite of two components described above, namely slow trend and annual profile.

Fig. 10: Forecasting procedure

Fig. 11: General-Linear Model Structure

Considering the fact that trend changes are small in comparison with the G_{pv} component, it is possible to use low-order autoregressive model to determine forecasting values. The slow trend does not have periodical components and we cannot identify within it any significant seasonalities. With the use of the trend we can only indicate a general developmental tendency of the examined phenomenon, which represents a drift of changes in the number of permissions granted for building new dwellings. This drift is an indirect derivative of a macroeconomic situation. If the tendency of changes is of an increasing character, it indicates a good economic situation and if that character is decreasing, it may prove that the country's economic situation is not so good. In summary, in the present study, the above autoregressive model is used to make a prediction and forecast of the long-term slow trend component. Adding an annual model here makes it possible to equip the forecasting model with an attribute of seasonal (monthly) variation predictions.

Validation is the next stage in the process of forecasting. The present study assumes the validation to be conducted on a set of data for ranging from the beginning of 2018 to the 4th quarter of 2019. While validating, we conducted model output prediction with the use of autoregressive model and prediction with the use of annual profiles, and the end result of the model output is an additive composition of these two components. Figure 12 illustrates the results of the validation. As stated above, it can be read for the data range of 2018 to 4th quarter of 2019. It is worth to note that the forecast based on validation data correctly reflects actual changes in empirical time series. The process of determining and validating forecasts for the years 2002-2024 was conducted on the basis of a composition of the ARX4 model and annual profile. Basing on obtained results, it is possible to state that the trend model anticipates small growth of the slow trend component, the effect of which is raising the end result.

Fig. 12: Forecasting of granted permissions with identification data, model output, model prediction and forecast using annual profile and ARX4 - autoregressive model.

The final stage of our examinations was to verify the behavior of the proposed predictive model of the different autoregressive models. The forecasting procedure was divided into three stages. The first one verified significance of delay orders in order to determine the order's proper value. The second stage identified the following structures of autoregressive models: AR2, ARX2, and ARMA22. On the third stage, we determined the forecasts for integrated models characterized by the following structures: ARI2, ARIX2, and ARIMAX22.

We then identified the values of significant delay. Figure 13 shows results of forecasts for delays 1, 2, and 8. The results show that the delay range for the ARX model does not significantly influence obtained simulations.

Fig. 13: Comparison of ARX model order for forecasting results

In step two, we verified the different structures of the autoregressive models, especially the AR, ARX, and ARMAX models. For each model, we adopted second-order delays. Figure 14 shows comparisons of obtained results. We determined that the AR model does not predict trend increase, but models with exogenous input (the "X" parameter) do predict the increase.

In step three, we conducted the last stage of testing the autoregressive models, including noise integration (the "I" parameter). We tested the ARI, ARIX, and ARIMAX models and ran calculations for the delay amounting to 2. Figure 15 illustrates the results.

Results obtained for the models with noise integration are characterized by trend stability for forecasted periods as well as by the fact that each of the three applied models obtained similar forecasting results.

Fig. 14: Comparison of autoregressive model type (AR, ARX, ARMAX)

Fig.15: Comparison of autoregressive model with noise integration (ARIMA, ARIX, ARI)

Conclusion

The goal of the above studies was to verify the possibility for a utilitarian application of forecasts determined for various autoregressive models corrected with the annual profile of the phenomenon under investigation. The analysis was conducted on the basis of data representing the number of permissions granted for building new dwellings. Data measurement interval amounted to one month and data used to construct the predictive model was collected for the period ranging from 2005 until the 4th quarter of 2019 r. The investigation was conducted in a number of stages. In the first one, we conducted a literature review of the phenomenon in the domain of forecasting. Basing on research examples, the literature review revealed a need to apply forecasting methods in various situations that characterize the market. It also showed that applying forecasting methods renders it possible to decrease the decision-making risk. On the second stage, we conducted a two-level procedure of identifying forecasts with the use of autoregressive modeling. On the first level, we identified data used to construct the predictive model and ran a validation process basing on proposed model. Considering positive validation results for the proposed model, we ran the second level of investigations, namely comparison of different autoregressive models with an aim of creating a forecast of a number of permissions granted for building new dwellings in Poland. The studies confirmed usefulness of examined forecasting methods. Using the obtained forecasts in terms of the number of permissions granted for building new dwellings may be helpful for companies operating on the market of dwellings to make accurate (meaning with the lowest possible decision-making error) investment decisions.

Abstract

The research reported in this paper explores the applicability of harmonic models based on Fourier transforms for the purposes of parameterization of the dwelling construction market. Throughout the present study, the structural parameters of a single, dual and triple harmonic models were evaluated, the last of which was found to demonstrate the best degree of empirical data fit. The resulting models provide a manner in which the identification of phenomena occurring in this market can be performed effectively in terms of the results for number of building permits issued, number of dwellings under construction and the number of new dwellings completed. The adequate determination of the phenomena in the housing market can help reduce the information gap, thus minimizing the likelihood of a failure during housing investments. Such decision-making mistakes apply with regard to both the development of the finance and macro-precautionary principle on the macroeconomic scale of the nation–state, as well as investors operating on the housing market.

Keywords: prediction model, Fourier transform, harmonic model, housing, macro-precautionary principle, financial stability.

The paper presents the personal opinions of the authors and does not necessarily reflect the official position of the Narodowy Bank Polski or the Warsaw School of Economics or the Opole University of Technology or the Angelus Silesius University of Applied Sciences in Wałbrzych

Introduction

Dwelling construction forms one of the branches of the economy that have a significant effect on the financial and macroeconomic stability in the sphere of the management (Wang et al. 2019), (Carmichael and Coën 2019), (Mach 2019), (Ouyang and Guo 2019), (Cesa-Bianchi and Rebucci 2017). The significance role of the housing market on economic parameters means that the adequate identification of phenomena occurring on it forms a pre-requisite for development and

implementation of economic programs. The identification of the phenomena occurring on the housing market can be accomplished by parameterizing this market, and this can be carried out by application of one of its three components. This identification can provide the data for the analysis of the time-frequency waveforms that represent the implementation of the number of building permits issued, the number of flats under construction and the number of flats completed. When an attempt is made to analyze the components of the construction process, it is necessary to examine whether the phenomena occurring in the market are characterized by systematic nature in terms of annual changes and over successive years. The identification of annual and long-term variability of the processes can provide insight into the seasonal and periodic fluctuations occurring on the housing market. The parameterization of fluctuations plays an important role in the process of implementing macro-precautionary principle and ensuring financial stability, since the analysis of the slow and fast changeable variations can provide means for the optimal implementation of economic policy. One of the possibilities of the analysis involves the use of predictive modeling which is based on harmonic models. In such models, the spectra of individual peaks with harmonic frequencies can be derived by application of the Fourier transform. As a result of the use of the Fourier transform it will be possible to identify the value of the amplitude fluctuation of the components and the phase shift. The process of the analysis concerned with the adequate identification of the phenomena occurring in the subsequent stages of the housing construction process, i.e. the number of building permits issued, the number of dwellings under construction and the number of completed dwellings, undertaken in this paper has been concerned with various harmonic model structures. The tested structures will provide an answer two basic questions. What is the nature of harmonic variability in terms of seasonality and periodicity of the investigated components of the construction process? What parameters of the harmonic model can be applied to most adequately describe the construction market in terms of the adopted criteria? As a consequence of gaining answers to such questions, we will be able to undoubtedly provide an support in the decision-making process, both on the macro- and micro-economic scale.

Influence of housing market on financial and macroeconomic stability

Analysis of housing market has two main tasks. The first ones is concerned with placing an emphasis on the importance of the financial stability policy as well as macroeconomic policy on the condition and development of the potential of the housing market. The first task is designed to indicate the indirect correlation between macro-precautionary principle in the economic policy and finance and the parameters characterized by the housing market. These parameters can be expressed by means of the time-frequency waveforms representing variables that affect this market. The second task adopted in the literature analysis involves the identification of selected analyses that adopt time series in the research on housing market. The purpose of this analysis is to provide a report on current research in the issue undertaken in this paper.

The important role of financial and macroeconomic stability has been recognized in a variety of scientific studies. In this context, we should mention the close relation between financial stability and its direct effect on the price of flat on the real estate market (Liu et al. 2020) and on the level of increases or decreases in total prices on this market (Kirchner 2018). The residential prices growth and the change in the CPI level have a significant effect on the potential of the housing market. The second significant dimension is associated with macro-precautionary principle in the economy. An adequately implemented macro-precautionary principle is aimed at reducing the vulnerability of the economic system to threats, and the adequate selection, calibration and adjusting its instruments should ensure stability on the housing market (Claessens, Ghosh, and Mihet 2013) as well as in the area directly related to the housing market, i.e. the area of mortgages and loans (Calem, Correa, and Lee 2019) (Lyons 2018). The detailed and comprehensive analysis of the housing market makes it possible to contribute to the effective decision making for both the business sector and to the development of the domestic macroeconomic and market policy in the area of housing. The development of a relation between the potential of the housing market and the financial and macro-precautionary principle in the specific market conditions can be performed by means of technical analysis that applies time-frequency parameterization of the phenomena occurring on the housing market. An in-depth analysis of the time course of phenomena occurring in the housing market can

offer provide the means for the detection of unusual conditions that occur on this market (Kauškale and Geipele 2017). Some papers report the results of studies concerned with a framework applied for monitoring vulnerability in the residential market. This framework provides intuitive and transparent early warning guidelines by aggregating data from three dimensions, i.e. housing valuation, household debt and the credit cycle (Bengtsson, Grothe, and Lepers 2018). Further, the state of economic stability is directly affected by a healthy housing market, which should be characterized by relative stability, which is reflected in reasonable fluctuations in housing prices (He and Xia 2019).

Throughout the second stage, an attempt was made to discuss the state-of-art in the area, with particular emphasis on the time-frequency analysis of factors responsible for the conditions in the housing market. This analysis was conducted by describing the time-frequency fluctuations of the residential market, in particular by discussing issues related to investing in dwellings and the risks associated with it. Among research, the first area of focus includes the issues related to investing in the housing market. Badarinza and Ramadorai (2018) attempt to assess whether foreign capital is responsible for changes in residential property prices. The research applied large record of transactions in the housing market for this analysis. The conclusion is that international risk strongly affects house prices. The effects are long-term and are associated with both the effects of secure investment in real estate and immigration, which in global cities has a significant impact on the price of housing resources (Badarinza and Ramadorai 2018). The study reported by Taderera and Akinsomi (2020) undertakes an attempt to answer the question regarding investments in the commercial real estate as a tangible form of securing from inflation. Using the vector error correction model (VEC) for coordinated time series, long-term dependence between return rate on housing property and inflation was investigated. Another issue involved the question inflation increases the rate of return on housing investments. The second group of research deal with broadly understood risk. An important decision-making issue is associated with estimating credit risk and finance risk of investing in the housing market. The study in the work of Bessler et al. (2015) discusses issues regarding the claim that throughout the period of stagnation, credit risk and the risk of finance associated with investing housing investment increase significantly and they often harmful to the business. Another risk analysis involves the estimation of both in the process of investing in the housing market, as well as in private and public sector real estate. This study uses an asset valuation approach to assess the exposure of private real estate funds to risk factors in both the private and public markets. The analysis involves creating specific performance indicators and applying methods to address some of the inherent problems of private property fund data, such as the high degree of series correlation of returns (Farrelly and Stevenson 2019). Another analysis of the issues related to the area of risk assessment involves the examination of the occurrence of crisis situations in conjunction with the circumstances marked by political changes. This paper presents wavelet analysis including the minimax threshold. Wavelet analysis with the minimax threshold provides a comprehensive and powerful approach to the analysis of data in the housing market (Hui et al. 2016). Other studies concerned with the analysis of time series and the housing market deal with the detection of sudden change points using empirical distributions and demonstrate how they impact on the economy (Lam et al. 2016), examine the effect of the location of an investment on the price of real estate (Fernandez, Mukherjee, and Scott 2018) and report the results of a study into the relations between the real estate cycle and the number of population (by means of a dynamic model) (Fernández, Marrón, and Rodríguez 2016). Another study shows the multidimensional aspects of variation of yield and prices of housing to the NASDAQ composite index (Leone and de Medeiros 2015). The main purpose of another study involved the determination of the side effect of property regulatory policies issued by major cities on surrounding cities in large urban agglomerations, derived on the basis of regional dependencies that are specific to the Chinese housing market within the area of research applying time series analysis, there are also studies conducted with the aim of aimed describing the development of land values (McAllister, Shepherd, and Wyatt 2018) and indicating determinants of urban development in terms of housing market development (Zhang and Su 2016).

Harmonic Models

When an attempt is made to develop time runs representing variables that describe the stages of the housing construction process, harmonic models based on Fourier transform were applied. The starting point involved the adaptation of Fourier transform designed with the purpose of extracting from the spectrum single peaks with harmonic frequencies (Equation 1).

$$H(k) = \alpha_k \sin(k\omega t + \varphi_k) \tag{1}$$

We can note that the single harmonic component is characterized by two parameters. Parameter α_k represents the amplitude of the component, whereas parameter φ_k represents the phase shift, i.e. the shift of the periodic component over time. The reverse of one year was taken as the basic frequency (Equation 2).

$$\omega = \frac{2\pi}{12}\frac{rad}{months} \tag{2}$$

Taking into account the above assumptions, the general equation of the model was expressed by the dependence in 3 and contains the total of several periodic harmonics components of different amplitudes.

$$M = \sum_{k=1}^{N} H(k) = \sum_{k=1}^{N} \alpha_k \sin(k\omega t + \varphi_k) \tag{3}$$

The analysis of the harmonic characteristics representing the phenomena investigated in this paper involved the testing of six harmonic models with the structures whose summary can be found in Table 1. The designs of these models applied analogy in detailed markings, i.e. the model designated as H1 assumes value 1 in its parameters ω, and similarly, model H2 applies 2ω, etc. Taking into account the above assumptions, Table 1 contains the list of the parameters applied in the detailed structures for models H1, H1+H2, H1+H3, H1+H4, H1+H2+H4 and H1+H3+H4.

Table 1: Harmonic models used in analysis

Model name	Model structure	Model Equation
M1	H1	$\alpha_1 \sin(\omega t + \varphi_1)$
M2	H1+H2	$\alpha_1 \sin(\omega t + \varphi_1) + \alpha_2 \sin(2\omega t + \varphi_2)$
M3	H1+H3	$\alpha_1 \sin(\omega t + \varphi_1) + \alpha_3 \sin(3\omega t + \varphi_3)$
M4	H1+H4	$\alpha_1 \sin(\omega t + \varphi_1) + \alpha_4 \sin(4\omega t + \varphi_4)$
M5	H1+H2+H4	$\alpha_1 \sin(\omega t + \varphi_1) + \alpha_2 \sin(2\omega t + \varphi_2) + \alpha_4 \sin(4\omega t + \varphi_4)$
M6	H1+H3+H4	$\alpha_1 \sin(\omega t + \varphi_1) + \alpha_3 \sin(3\omega t + \varphi_3) + \alpha_4 \sin(4\omega t + \varphi_4)$

The models presented in Table 1 were applied to develop prediction models and to check their quality. The quality of the resulting models will provide the basis for decision-making in terms of their applicability in modeling variability that occurs at individual stages of housing development, i.e. in the phase of gaining building permits, flats under construction and new flats completed. In Figure 1 procedure of model parameter's estimation is presented.

Fig.1: Model parameters estimation procedure

Data Preparing

When the research aimed at building predictive models is carried out on the basis of the model structures presented in Table 1, the procedure aimed at removing the developmental trend line representing the investigated relations was first implemented, followed by the selection of an optimal window width for RLOESS filtration, and the subsequent identification of the leading harmonic parameters for the analyzed phenomena. For the purposes of this research, monthly data for granted permits, construction began and construction completed was used. Data was collected for Poland from Q1 2005 to Q4 2019.

Procedure of trend removal by application of RLOESS filter

The procedure of decomposition of the resulting time series was carried out taking into account the data collected for the number of issued building permits, the number of dwellings under construction and the number of dwellings completed. The process of identifying the trend components was executed by application of the RLOESS model (locally estimated robust quadratic regression) . The effect of the transformations takes the form of a variable component comprising three sets of data: granted permits, construction began and construction completed. A graphical presentation with the implementation of time series waveforms for untransformed variables, the characteristics of the trend function and the time series waveform corresponding to a constant level of the analyzed variable are presented in Figs. 2,3,4, respectively.

Fig. 2: Granted permits, original data and data with trend removed using RLOESS filter

Fig. 3: Construction began, original data and data with trend removed using RLOESS filter

When a preliminary analysis of the received time-frequency waveforms is performed, we can see that in each of the examined series there is an annual periodicity in which annual seasonal trend is followed in each respective year. By consideration of the above, already at this stage of research we can put an initial research hypothesis regarding the number of building permits issued, the number of dwellings under construction and the number of new dwellings completed. These hypotheses can form a relevant but general indication of the characteristics of the relations that have been developed. They play an important role in the view of the demand and supply in the housing market. We can also note that this knowledge can also play a practical role in the assessment of both the macroeconomic and financial stability of the economy as a whole.

Fig. 4: Construction completed, original data and data with trend removed using RLOESS filter

Selection of the window length in RLOESS filter

The following research step was aimed at indicating the mean constant that should be adopted in the process of decomposition of the investigated time series. The averaging time of RLOESS models was selected in two parallel stages, i.e. RLOESS models with various averaging window lengths were determined and the determination coefficient was verified in each for each. As a result, the waveforms were developed for three investigated relations (granted permits, construction began data, construction completed data) with regard to an example model with the H1+H2 characteristic, as presented in Figs. 5,6,7.

In the summary of the simulations carried out for different averaging window lengths, we can see that in each case the optimum value of the averaging window width was in the range from 30 to 40 months, with the extreme located around 36 months. In conclusion, the three-year value of the RLOESS filter parameter was used.

Selection of harmonic parameters in the analytical model

When a selection is made with regard to the harmonic parameters to be applied with regard to three investigated phenomena, the housing construction process applied data for Welch averaged spectrum density. The resulting spectra have components with different lengths for various harmonic frequencies. The highest values of H1 harmonic component were obtained in each of the analyzed models. H2, H3 and H4 components for the number of building permits issued, for the number of dwellings under construction and for the number of new dwellings completed are considerably different. The characteristics of spectral densities for analyzed data are illustrated in Fig. 8. We can note at this point that the power density spectrum has discrete peaks for subsequent harmonic values, which confirms and justifies the application of this harmonic model. For example, for granted permits spectrum density, the value H2 is greater than H3 and H4, while for construction began spectrum H4 is higher than H2 and H3.

Fig.5: Optimal RLOESS filter window length for model H1+H2, granted permits data

Fig.6: Optimal RLOESS filter window length for model H1+H2, construction began data

Fig.7: Optimal RLOESS filter window length for model H1+H2, construction completed data

Fig. 8: Spectral densities for analysed data (Welch averaged spectra). H1-H5 are harmonics that correspond to consecutive years (H1 – 1 year, H2 – 2 years …).

The obtained results of spectral densities provide an answer the question regarding the selection of the harmonic characteristics that are crucial in terms of identifying the parameters of the developed predictive models.

Analysis of harmonic models for defining variables to describe the implementation of housing development model

The following harmonic structures were applied throughout the research process designed for purposes of verifying the feasibility of harmonic models for the development of utilitarian prediction models (models are marked by Mi, where i – model number):

M1: H1 model with a single harmonic
M2: H1+H2 dual harmonic models including a single harmonic and an odd harmonic H2
M3: H1+H3 dual harmonic models including the first odd harmonics
M4: H1+H4 dual harmonic models including a single harmonic and harmonic H4
M5: H1+H2+H4 triple harmonic model with even harmonics
M6: H1+H3+H4 triple harmonic model including harmonics H3 and H4

The optimization of the values of model parameters from number 2 to 6 applied Levensberg-Marquard method. Models were determined and analyzed for all stages of dwelling construction process (building permits, flats under construction, new flats completed).

Analysis of Harmonic Models for Granted Permits Data

In the first stage, the modeling process of model parameters M1–M6 was carried out with regarding to data concerned with the number of building permits issued. Figs. 9–14 contain the waveforms representing the results obtained for individual harmonic structures. This presentation is intended to check the applicability of the resulting models. Fig. 9 presents the results of calculations for the single harmonic model. The determination coefficient $R^2 = 0.611$. Taking into account the resulting value of the R^2, we can assume that the degree of the fit of the model is at an acceptable level. However, we can note that the analyzed model gives an inaccurate representation of the peaks

occurring for negatively declining data waveforms and is characterized by too much generalization in representing changes in housing that occur in the summer period.

Fig. 9: Harmonic model with one sinusoidal component (H1) for granted permits variable component data

Figs. 10–12 present the results of calculations derived for the two harmonic models. We should note that among the structures of the described two harmonics models, the best matching factor was obtained by the M2 model: H1+H2, for which the calculated coefficient of determination $R^2 = 0.815$. The relatively high value of the R^2 coefficient indicates a very high fit of the model to the empirical data. M2 model can be applied to faithfully represent the negative peaks of the variable component of granted permission and also correctly shows the increase of permission data in April each year (see Fig. 10).

Fig.10: H1+H2 harmonic model with two sinusoidal components for granted permits variable component data

The second dual harmonic model with odd harmonics is formed by the M3 model: H1+H3 (cf. Fig. 11). When we analyze the results, we can see that the M3 model relatively poorly represents the data for the number of building permits issued in the winter season. Similarly, the model M4: H1+H4, for which time series are presented in Fig. 12, poorly performs in terms of the number of construction permits issued for the colder months of the calendar year. In this case, the determination coefficient $R^2 = 0.621$.

Fig.11: H1+H3 harmonic model with two sinusoidal components for granted permits variable component

Fig.12: H1+H4 harmonic model with two sinusoidal components for granted permits variable component

On the basis of the analysis of the M5 and M6 models (cf. Fig. 13 and Fig. 14), we can conclude that both models with the harmonic structures H1+H2+H4 and H1+H3+H4 perform well. However, we can note that as a result of using the model M5: H1+H2+H4, the highest value of the determination coefficient R^2 equal to 0.825 is obtained. This model correctly represents the variability in the data for granted permission data in the winter months, as well as for the increase in the spring months and the slight increase in the autumn months of each year, as well as to adequately represent the slight decrease in granted permission throughout the middle of the year.

Fig.13: H1+H2+H4 triple harmonic model for granted permission VC data

Fig.14: H1+H3+H4 triple harmonic model for granted permission VC data

Fig.15: Comparison of harmonic model for granted permission variable component data

In the summary of the research regarding six harmonic structures represented by M1–M6 models, taking into account the variable component defining the number of building permits issued, Fig. 15 was compiled. This chart contains the graphical representation of the fit of the data to the annual profile determined by the median values for individual months throughout the period Q1 2005 to Q4 2019.

Analysis of harmonic models for construction started data

The following stage of the research involved the process of modeling parameters of the models M1–M6 for data regarding construction started. Figs. 16–22 present the results derived for individual harmonic structures. Fig. 16 presents the results of calculations for the single harmonic model. IN this case, the determination coefficient was $R^2 = 0.413$. When the value of the R^2 coefficient representing the investigated phenomenon is analyzed, we can conclude that the single harmonic model is characterized by poor degree of fit. In addition, the analyzed model can neither be applied to accurately represent peaks for negative data slopes nor provide correct representation of the characteristics of changes in the investigated phenomenon throughout the middle months of the year.

Fig. 16: Harmonic model with one sinusoidal component (H1) for construction started variable component data

Fig.17: H1+H2 harmonic model with two sinusoidal components for construction started variable component data

Figs. 17–19 contain the results of calculations obtained for the two harmonic models. We should note that among the structures of the described two harmonics models, the best level of the fit was obtained in the M2 model: H1+H2, for which the calculated $R^2 = 0.506$. The mean value of the R^2 indicates at it most the average degree of the fit of the model to real data. The M2 model underestimates the negative and positive peaks of the construction started variable component data, whereas it can be applied to adequately represent the characteristics of changes in the investigated variable in summer periods (see Fig. 17).

Fig.18: H1+H3 harmonic model with two sinusoidal components for construction started variable component

The M3 model: H1+H3 (cf. Fig. 18) forms another two-harmonic model with odd harmonics that was tested for data collected with regard to data for housing under construction. When the results are analyzed, we can see that the M3 model poorly represents positive and negative peaks, and equally poorly demonstrates the variable characteristics of the investigated variable in the summer months. The determination coefficient (R^2) for this model is equal to 0.416. M4 model forms the third of the investigated harmonic models, and the values derived from simulations are presented in Fig. 19. On the basis of the results, we can conclude that this model has no ability to either represent the positive or negative outlier data. Nevertheless, this model can be applied to well represent the trends of change in the summer period.

Fig.19: H1+H4 harmonic model with two sinusoidal components for construction started variable component

When we carry out an analysis of M5 and M6 models (see Fig. 20 and Fig. 21), we can note that both models with harmonic components H1+H2 +H4 and H1+H3+H4 demonstrate a moderate level of the fit to the actual data. None of the triple harmonic models has the ability to correctly realize the values for outliers. Both discussed models, the values gained by application of the M5 and M6 models can be considered as moderate and even poor.

Fig.20: H1+H2+H4 triple harmonic model for construction started VC data

Fig.21: H1+H3+H4 triple harmonic model for construction started VC data

Fig. 22 was complied with the purpose of summarizing the research carried out for the six harmonic structures represented by M1–M6 models, taking into account the variable expressed by the number of dwellings under construction. This figure contains a graphical presentation of degree of the fit of the data to the annual profile determined as the median values for individual months from Q1 2005 to Q4 2019.

Fig.22: Comparison of harmonic model for started construction variable component data

Analysis of harmonic model for construction completed data

The last and third phase of the research was concerned with the process of modeling parameters of the M1–M6 models with regard to data regarding completed dwellings. Figs. 23–28 contain the results derived for individual harmonic structures. Fig. 23 presents the data gained from the calculations applying a single harmonic model. In this case, the coefficient of determination was R^2 = 0.421. By consideration of the resulting value represented by R^2, we can assume that the single harmonic model is characterized by poor degree of fit. The poor value of the determination coefficient stems from the unusual phenomenon that occurred in the investigated phenomenon. The outlier, which took place at the end of 2008, is associated with the specific circumstances that occurred at that time in Poland. In Poland, legal regulations have been implemented since January 2009 that stipulate the requirement to perform energy certificates in newly erected residential buildings. This fact led to the acceleration of construction works and an unusual market condition, in which non-standard values of the number of completed dwellings, was encountered. In addition, the analyzed model inaccurately represents the peaks occurring for positive data slopes and does not provide an adequate representation of the characteristics of the changes occurring in the examined phenomenon in the middle months of the year.

Fig. 23: Harmonic model with one sinusoidal component (H1) for construction complete variable component data

Fig.24: H1+H2 harmonic model with two sinusoidal components for construction complete variable component data

Fig.25: H1+H3 harmonic model with two sinusoidal components for construction complete variable component

Figs. 24 – 26 contain the results of calculations derived for the dual harmonic models. We can note that among the structures of the dual harmonics models discussed here, the total of the values representing the coefficient of the model fit demonstrate approximate values. For the model M2: H1+H2, the coefficient of determination R^2 assumed a value of 0.492, for model M3: H1+H3, the value R^2 was equal to 0.476 and for model M5: H1+H4, the value of R^2 was equal to 0.490, respectively. The mean value of the R^2 coefficient demonstrates an average fit of the model to actual data from the housing market. We can again emphasize at this point that the values of the resulting coefficient of determination are to a considerable extent decreased by the occurrence of a value that significantly deviates from the standard result characteristic for the investigated time series.

When an analysis is carried out with regard to subsequent harmonic models for data that describes the number of new completed dwellings, i.e. M5 and M6 (see Fig. 26 and Fig. 27), we can note that the application of both models with the harmonic structure H1+H2+H4 and H1+H3+H4 yielded only satisfactory levels of the fit between the data from the model and actual one. None of the triple harmonic models provided the opportunity to adequately represent the values gained for outliers. In terms of the values of the coefficients of determination, both investigated models (M5, M6) should be

considered to be of moderate quality. However, we can also note that the above models can be applied to accurately represent the negative values recorded in the form of the courses.

Fig.26: H1+H4 harmonic model with two sinusoidal components for construction complete variable component

Fig.27: H1+H2+H4 triple harmonic model for construction complete VC data

Fig.28: H1+H3+H4 triple harmonic model for construction complete VC data

Fig.29: Comparison of harmonic model for construction complete variable component data

Fig. 29 was developed to provide a summary of the research performed with regard to 6 harmonic structures representing M1–M6 models taking into account the variable describing the number of completed dwellings. This figure contains a graphical presentation of the fit of the results to the annual profile determined as the median for individual months in the period Q1 2005 until Q4 2019.

Summary

In the summary the results of the present study, Tables 1–3 contain the parameters of all harmonic models. Table 2 summarizes the results with regard to six harmonic models developed for data regarding the number of building permits issued. In Table 3, the results for the models developed with regard to the data on the number of dwellings under construction, while in Table 4 for the data gained with regard to the number of dwellings completed.

Table 2: Harmonic model coefficients for granted permission VC data

Model	R^2	α_1	α_2	α_3	α_4	φ_1	φ_2	φ_3	φ_4
H1	0.611	-4.06	0	0	0	1.41	0	0	0
H1+H2	0.815	-4.06	-2.35	0	0	1.4	0.702	0	0

H1+H3+H4	0.635	-4.05	0	-0.614	0.517	1.41	0	5.48	0.845

Table3: Harmonic model coefficients for construction started VC data

Model	R^2	α_1	α_2	α_3	α_4	φ_1	φ_2	φ_3	φ_4
H1	0.413	-2.16	0	0	0	1.23	0	0	0
H1+H2	0.506	-2.16	-1.03	0	0	1.22	0.493	0	0
H1+H3	0.416	-2.16	0	-0.168	0	1.23	0	-0.026	0
H1+H4	0.476	-2.16	0	0	0.844	1.23	0	0	1.17
H1+H2+H4	0.567	-2.16	-1.02	0	0.832	1.22	0.492	0	1.16
H1+H3+H4	0.478	-2.16	0	-0.161	0.842	1.23	0	-0.091	1.17

Table 4: Harmonic model coefficients for construction completed VC data

Model	R^2	α_1	α_2	α_3	α_4	φ_1	φ_2	φ_3	φ_4
H1	0.421	2.42	0	0	0	2.03	0	0	0
H1+H2	0.492	2.43	0.988	0	0	2.03	1.69	0	0
H1+H3	0.476	2.42	0	0.875	0	2.03	0	2.03	0
H1+H4	0.49	2.42	0	0	0.979	2.03	0	0	0.235
H1+H2+H4	0.56	2.43	0.981	0	0.972	2.03	1.69	0	0.247
H1+H3+H4	0.544	2.42	0	0.866	0.971	2.03	0	2.02	0.249

On the basis of the results, we can conclude that the model with a single harmonic performed poorly. This model could be employed in practical applications, under the assumption of the use of a simple model that is computationally stable. However, the best quality parameters were established to occur with regard the triple harmonic model with the structure H1+H2+H4. This model demonstrates the best results in each of the research stages, i.e. for each investigated variable. In the summary of the above, if the criterion for model selection is based with the best value for the fir of the model to empirical data, we should apply the model with even harmonics to apply to data on the construction started, completed and granted permissions. The disadvantage of this model is associated with the need to determine the extremums of the function of six variables, which requires complex calculations. The intermediate model i.e. the model comprising dual harmonics has four parameters and poses an easier task in terms of determination of the results in comparison to the model with six parameters. This model has always outperformed H1 model but also always worse than the model with 3 harmonics. However, we should note that in many cases it has very similar results to the model H1+H2+H4. If there is a need to use relatively simple models, it is recommended to use H1+H2 model with dual harmonics, which proved to perform better in each than H1+H3 and H1+H4 models.

Conclusion

This study involved the development of a procedure applied to develop and verify the performance parameters of six harmonic models. The research confirmed the applicability of predictive modeling based on the Fourier transform for the purposes of analyzing the variability of phenomena, such as:

building permits issued, dwellings under construction and new dwellings completed. The ability to adequately represent the above phenomena can provide the measure for parameterization of data in the area of housing development. Assuming that housing construction forms one of the key determinants affecting the condition of the economy in general, the insights in the area of the developments in the housing market can reduce the information gap in the decision-making processes in this field. In the macroeconomic terms, this will provide a measure to develop responsible financial and implement macro-precautionary principle in the economy. However, from the point of view of microeconomic activities, it will help decision makers operating on the market to take the right decisions. Such decisions are taken on both the demand and supply sides of this market. When the summary of computational engineering was carried out, it should be emphasized that among the tested models comprising a single, double and triple harmonics, the best performance parameters were recorded for the case of the model with three harmonics.

The resulting harmonic prediction models have demonstrated utilitarian value. This provides the foundation for the potential to apply such models in the estimation of structural parameters to develop scenarios for the analysis of the investigated phenomena in the future.

Abstract

Marketing represents the ability of company's operations to initiate different activities for business success. Marketing research as part of marketing activities will determine the marketing requirements which could be achieved with business activities. The marketing tools should recognize the results of business activities to keep the level of competition and business success of organization as well. The marketing's main goal is to enable all requiriments keeping in mind the existing environment as well as technologies in order to achieve maximum results from the business activities. Digital communication are is ordinary daily basis communication present in the office and back home as well. Today is not posible to have any business activity or subject without use of digital technologies. There are certain jobs and business activities which could be achieved and executed only electronicaly. The specific progres in the society have been made with mobile techologies. The time line and space do not have importancy as before due to information avialibilty to everyone at the same real time. Traditional aproach is more replaced with modern one based on the information technologies.
The paper subject is about digital marketing in order to improve marketing activities. It is specificaly related to development of certain quality related to promotions and activities in function of media advertisment.

Keywords: Marketing, Digital Marketing, Media Advertisement, Social Networks

Introduction

The aims of marketing concept in business organizations are modern and innovative promotion as well distribution on the new markets in order to accomplish the customer's needs, volume sale and profit. The modern company marketing and business concept is channelled to accomplish the customers' requirements according with varieties, quality, quantity and prices including successful business.

It should be kept in mind that the best sailed products are the one required or demanded by customers and clients. If they do not know where to get or find some products or services, the organization will

be out of profit and customers will choose their competition which has found modalities to introduce the customers with their offer and products on the market.

The paper's subject is to introduce the various communications through digital channels and their activities in the marketing area. There will be efforts to establish the differences in use of digital marketing within different organizations (differences related to capacity as well as level and length of business).

Theoretical- Methodological Framework

Paper's Subject

Marketing presents the systematically specific and functional business approach in micro as well macro level of business activities focused on the effective accomplishments for individual or social needs related to products and services based on rational business with available resources.

The importance of scientific research conducted in this paper is based on the fact that successful management of marketing strategy requires the service providers to seek accurate, reliable and timely feedback from the customers. (Radnovic, 2015)

The paper's subject is a digital marketing, it's role and position in the area of media advertisement which is the part of modern promotion methodology enabling to overcome the space as well as time barriers in order to provide sufficient answers at the same moment when the question come up.

The company's business and economy today completely relay on information technologies and database. The influence of information technologies initiating development of new business activities which are directing human resources and their knowledge for collecting a new information's. (Filipovic, Kostic, 2003). The computerization and global trends in the last two decades had a crucial influence on expansion and perspectives of business development. According to Murphy and thanks to new trends the world market became much smaller and all actors independent as well. (Murphy, 1991) Before it was not possible to monitor the business activities in all parts of the world at the same time, but with computer technologies it became possible to get trade despite on the seller or customer location. The customer has a many offers and options to trade. From that reason the business companies must fight with competition using appropriate as well unique approach utilizing internet technologies.

Good marketing is one of the conditions for success on the marketing competition game. The modern media advertisement is mandatory requirement in order to achieve adequate marketing position and recognition as well. Based on the researched results it is possible to find out the current status using of digital marketing and suggestions for the future corrective measures as well.

Mr. Kotler in modern book referring to marketing delivery as customer satisfaction obtaining at the same time profit as well. Practically, marketing is profitable satisfaction and full filled the customer needs. The marketing roll is the most important in the business of any organization, public, government or voluntary based.

Digital marketing presenting the promotion of products and brands, using one of more electronic medias for it. The digital campaign begins with creation of appropriate web page and context, including selection of platforms as well public presentation strategies with choice of adequate graphic and textual tools to make a brand recognizable to the customer in Google research. (or some other browser). After the solution, the context will be presented as well with measurement of the company results and public presentation.

Using the tools of directive marketing through the social networks and the other ways of Communications it is possible to connect with potential clients and users, for example through the advertisement on social networks Facebook, LinkedIn, Twitter, etc. Further with email campaigns, AdWords creating positive brand presentation, what will call users action.

The internet marketing is unique stakeholder for all types of network marketing. It concludes all marketing activities, which are using internet as channel of marketing communication. The internet marketing has a stronghold in traditional phases of marketing process: situational analysis, marketing planning and implementation. (Reedy, et al 2000)

Mobile marketing presenting the use of wireless media, first mobile phones and PDA- Personal Digital Assistant as a for integrated context delivery as well direct answers as a part of multimedia marketing program. The modern devices in use are smart, such as smart phones and tablets (Dushinshi, 2009)

The main purpose of business web page is to promote and sell products/services. The example of web site page use in business activities includes research of products through online catalogue, its sale within online shops, getting specific services through the internet and etc.

Regarding the social medias and connection with digital marketing, Mr. Hollensen stating that social media currently includes wild spectre of online word-of-mouth forum, friendly sites, blogs, chat rooms, customer's emails, internet discussions, groups and forums which comprise digital, audio, photo and video clips.

The basic characteristic of Twitter is to overcome complexity of the other social medias. Simply, there is the field for 140 text characters which will enable customer connection with the other users of Twitter network. Therefore, it is the question of simple infrastructure. Most of the subjects presented on Twitter network are people life events, news, and etc. The users also could exchange photos as well links with the other users. Currently, the Twitter is progressing due to the users who are famous in public (Treadaway, Smith, 2010).

Paper's Goal

Research goal was to determine digital marketing presence in media advertising as modern shape of presenting an organization in the market. The goal was to obtain data about current usage of certain digital marketing instruments based on samples, and that according to results establish current state, development directions and improvements.

Scientific goal was to find adequate solutions for performance on the market, through digital medias which will be available to target group and contribute to final organization's success. Scientific goal is stated in contribution of theoretical knowledge in marketing science, digital marketing and digital communications.

Practical goal are suggestions for digital marketing improvement, as well as methods for quality increase of organization's presentations in digital world. No matter how quality product/service an organization have, successful organized management within organization and competitive price, without adequate information placement about products/services and their advantages, business success will fail, and organization's market position will be violated.

Research Hypotheses

In the paper a starting hypothesis was situated: Modern business methods and digitalization in each social segment influence on increasing the digital marketing role in area of media advertising, in the way that big number of information's can be available to wide auditorium in the same time period.

Besides starting hypothesis in the paper were situated three auxiliary hypotheses:

H 1 – Organizations are increasingly casting off traditional advertising methods, and turn to modern advertising through digital marketing
H 2 – Organizations do not use enough possibilities of digital marketing
H 3 – Differences in organizations (size, business level and length of business) only partially effect on differences in quality and frequency of marketing activities.

Work Methodology

The paper consists three parts, by which are given the basics of empirical research. In theoretical part is used bibliographic- speculative method. This method implies gathering, analysis and interpretation of data overwhelmingly by theoretical- contemplative method. Basic source of data are relevant bibliographic units (books, textbooks, magazines etc.), as well as modern electronic sources of data.
In the paper were used following methods:

- Analysis - scientific method which consists from complex knowledge form to its simpler parts,
- Synthesis - thoughtful assemblage of simpler parts to logical entities,
- Induction - cognition process in which conclusion flow is from special and individual to general,
- Deduction - cognition process of conclusion from general to individual,
- Classification - editing (non)related terms into one logical system in which every term will have its place and roll.

Research was conducted as transverse study empirical character. Sample of 50 organizations in Republic of Serbia was included in period from June till October 2019. Results were collected by personally sharing the questionnaire, as well as sending the questionnaire through email. For collecting data special questionnaire was made.

Questionnaire consisted following independent variables:

- How many employee's organizations have?
- Organization's business market
- Organization's business length
- Does organization have web page
- Does organization have Facebook page

Besides independent variables, questionnaire also consisted following dependent variables:

- Web page quality grade
- Organization's Facebook page quality grade
- Organization's You Tube movies quality grade
- Frequent performance of marketing activities within organization grade
- Frequent planning marketing activities through digital media grade
- Organization's promotion through TV channels grade
- Organization's promotion through radio stations grade

All collected data was processed in applicative SPSS system by descriptive and comparative statistics (ANOVA and χ^2 test).

Research Results

Research results will be presented through descriptive and comparative statistics. First will be describes the sample with descriptive statistics, then the result of all dependent variables will be presented.

Sample Description

In observed sample of micro organizations (which have up to 9 employees) is 10, small organizations which have 10 to 49 employees is 9, middle organizations which have from 50 to 249 employees is 22 and organizations which have over 250 employees is 9. Percentage review of included organizations according to its size is shown on figure 1.

Figure 1: Percentage review of organizations according to its size

In observed sample 21 organization operates on local level, 15 organizations operate on national, 9 on regional and 5 on international level. Percentage review of organizations according to operation level is presented with figure 2.

Figure 2: Percentage review of organizations according to operation level

In observed sample two organizations operate till 3rd year, also 2 organizations operate from 4 to 7 years, eleven organizations operate from 8 to 15 years, while over 15 years operate 35 organizations from the sample. Percentage review of organizations according to operation length is shown with figure 3.

Figure 3: Percentage review of organizations according to operation length

In observed sample 42 organizations have a web page (84%), while 8 (16%) does not have a web page.

In observed sample 23 organizations have Facebook (46%), while 25 organizations (52%) does not have Facebook, and in 2 organizations (2%) did not know if they have Facebook.

In observed sample 9 organizations have twitter account (18%), 39 does not have (78%), while in 2 organizations did not know if they have twitter account (4%).

Presentation Quality Through Digital Path

Research results have shown that quality of web pages in highest number have organizations which are included in the sample is rated as good (46%), as extremely good quality of web pages was rated in 28% of organizations, and in 8% of organizations was rated as average, while in 18% of organizations doesn't have a web page. (Table 1)

Table 1: Quality of web pages in organizations

Web Page Quality	Absolute Frequencies	Relevant Frequencies (Percentages)
Don't have web page	9	18.0
Bad	0	0
Average	4	8.0
Good	23	46.0
Extremely good	14	28.0
TOTAL	**50**	**100.0**

Table 2 shows Facebook page quality for observed organizations. In 58% organizations Facebook does not exist, while in 18% organizations it was rated as good and extremely good, and average quality was rated in 6% organizations.

Table 2: Quality of Facebook page

Facebook Page Quality	Absolute Frequencies	Relevant Frequencies (Percentages)
Don't have Facebook page	29	58.0
Bad	0	0
Average	3	6.0
Good	9	18.0
Extremely good	9	18.0
TOTAL	**50**	**100.0**

In Table 3. Quality of YouTube movies in organizations is presented from the sample. We can see that 78% organizations do not have YouTube movies, in 10% quality is good, in 6% is average, in 4% extremely good and only one organization has rated quality of YouTube movies as bad.

Table 3: Quality of YouTube movies

Quality of Youtube Movies	Absolute Frequencies	Relevant Frequencies (Percentage)
Don't have YouTube movies	39	78.0
Bad	1	2.0
Average	3	6.0
Good	5	10.0
Extremely good	2	4.0
TOTAL	**50**	**100.0**

Marketing Activities in Organizations

In observed sample highest percentage of organizations (34%) marketing activities are done from time to time, 26% organizations perform frequently marketing activities, 22% mostly does, 12% mostly do not, while 6% organizations do not perform any marketing activities (Table 4.).

Table 4: Frequency of performing marketing activities in organizations

Frequency of performing marketing activities in organizations	Absolute Frequencies	Relative Frequencies (Percentage)
Marketing activities are never performed	3	6.0
Marketing activities are mostly not performed	6	12.0
Marketing activities are performed from time to time	17	34.0
Marketing activities are mostly performed	11	22.0
Marketing activities are frequently performed	13	26.0
TOTAL	**50**	**100.0**

In table 5. is presented frequency of planning marketing activities through digital medias. In highest percentage of organizations (28%) marketing activities are monthly not planned, in 26% organizations are planned from time to time, in 16% marketing activities are frequently planned, and in the same percentage in organizations was responded that marketing activities are never planned, while in 14% organizations marketing activities are mostly planned.

Table 5: frequency of planning marketing activities through digital medias in organizations

Frequency of planning marketing activities through digital medias	Absolute Frequencies	Relative Frequencies (Percentage)
Marketing activities are never planned	8	16.0
Marketing activities are mostly not planned	14	28.0
Marketing activities are planned from time to time	13	26.0
Marketing activities are mostly planned	7	14.0
Marketing activities are frequently planned	8	16.0
TOTAL	**50**	**100.0**

Highest percentage of organizations (64%) don't promote themselves at all through TV channels, in 20% organizations promotions through TV channel is primary, in 6% promotions through TV channels is very rare or is done from time to time, while in 4% organizations was responded that they promote mostly through TV channels, which is presented in table 6.

Table 6: Promotions of organizations through TV channels

Promotions of organizations through TV channels	Absolute Frequencies	Relative Frequencies (Percentage)
Don't promote through TV channels	32	64.0
Promote very rare through TV channels	3	6.0
Promote from time to time	3	6.0
Promote mostly through TV channels	2	4.0
Primary promotion is through TV channels	10	20.0
TOTAL	**50**	**100.0**

In table 7. is presented organization's promotion through radio stations. It can be seen that biggest percentage of organizations (68%) doesn't promote at all through radio stations, for 12% of organizations promotion through radio stations is primary, 10% of organizations promotes from time to time, 6% mostly promotes through radio stations, while 4% of organizations this type of promotion use rarely.

Table 7: Radio station promotions

Radio station promotions	Absolute Frequencies	Relative Frequencies (Percentage)
Don't promote at all through radio stations	34	68.0
Promote rarely through radio stations	2	4.0
Promote from time to time through radio stations	5	10.0
Promote mostly through radio stations	3	6.0
Primary promotion is through radio stations	6	12.0
Total	**50**	**100.0**

Differences in existence of web page, Facebook and Twitter account in different characteristics organizations

Differences in existence of web page, Facebook and Twitter account in different characteristics organizations (size, business level and length) are determined by using χ^2 (Chi-Square) test. For difference existence was taken the value 0,05 (for all values ≤ 0,05 exists meaningful difference).

Differences in existence of web page in organizations with different characteristics

If we look graph 4. the biggest number of middle size organizations have web page, while biggest number of micro organizations do not.

Figure 4: Differences in existence of web page in different sizes organizations

In the table we can see differences significance in existence of web page in different sizes organizations. Namely in column Sig for Pearson Chi-Square there is value 0,004, which is less than 0,005, so it is concluded that organization's size significantly effects on differences in existence of web page.

Table 8: Differences significance in existence of web page in different sizes organizations

	Value	df	Asymp. Sig. (2-sided)
Pearson Chi-Square	13.211(a)	3	.004*
Likelihood Ratio	14.290	3	.003
Linear-by-Linear Association	8.873	1	.003
N of Valid Cases	50		

With Figure 5. are presented differences in different business level organizations in terms of web page existence. In highest number organizations which perform on local level web page exists, and also on local level operates the highest number of organizations which do not have web page.

Figure 5: Differences of web page existence in different business level organizations

With Table 9. was presented significance of differences in terms of web page existence in different business level organizations. We can see that Sig.=0,284>0,05, so it is concluded that level of performance does not significantly effects on differences of web page existence.

Table 9: significance of differences in terms of web page existence in different business level organizations

	Value	df	Asymp. Sig. (2-sided)
Pearson Chi-Square	3.798(a)	3	.284
Likelihood Ratio	5.902	3	.116
Linear-by-Linear Association	3.199	1	.074
N of Valid Cases	50		

With figure 6 are presented differences in existence of web page in organizations which perform in different time period. Highest number organizations which perform over 15 years have web page, and also there are the most of those which do not have web page, and they perform over 15 years.

Figure 6: Differences in existence of web page in organizations which perform in different time period

With Table 10. was presented significance of differences of web page existence in organizations which perform in different time period. Sig.=0,005<0,05, so it is concluded that length of business significantly effects on differences of web page existence.

Table 10: Significance of differences of web page existence in organizations which perform in different time period

	Value	df	Asymp. Sig. (2-sided)
Pearson Chi-Square	13.010(a)	3	.005*
Likelihood Ratio	11.897	3	.008
Linear-by-Linear Association	1.803	1	.179
N of Valid Cases	50		

Differences of Facebook page existence in Different Characteristics Organizations

With figure 7. are shown difference in Facebook page existence in different size organizations. We can see that in the most middle size organizations there is Facebook page, and highest number of middle size organizations do not have Facebook page.

Figure 7: Difference in Facebook page existence in different size organizations

Table 11 is presented significance of difference in Facebook page existence in different size organizations. We can see that Sig=0,400>0,05, so it can be concluded that most of organizations affects significantly on differences in Facebook page existence.

Table 11: Significance of difference in Facebook page existence in different size organizations

	Value	df	Asymp. Sig. (2-sided)
Pearson Chi-Square	6.208(a)	6	.400
Likelihood Ratio	5.092	6	.532
Linear-by-Linear Association	2.631	1	.105
N of Valid Cases	50		

In figure 8 can be seen differences in Facebook page existence in organizations of different business level. We could see that organizations on local level do not have Facebook page, and on the same business level are also those organizations which do not have Facebook page.

Figure 8: Differences in Facebook page existence in organizations of different business level

In Table 12. is presented significance of differences in Facebook page existence within organization of different business level. Sig =0,862>0,05, so it is concluded that business level significantly effects on differences in Facebook page existence.

Table 12: Significance of differences in Facebook page existence within organization of different business level

	Value	df	Asymp. Sig. (2-sided)
Pearson Chi-Square	2.557(a)	6	.862
Likelihood Ratio	2.633	6	.853
Linear-by-Linear Association	.086	1	.769
N of Valid Cases	50		

With figure 9. are presented differences in Facebook page existence within organizations which perform in different time period. It is shown that the biggest number of organizations which perform over 15 years (same number) are ones which have and do not have Facebook page.

Figure 9: Differences in Facebook page existence within organizations which perform in different time period

In Table 13. is presented significance of differences in Facebook page existence within organizations which perform in different time period. It can be seen that Sig=0,881>0,05, so it is concluded that business length doesn't significantly effects on differences in Facebook page existence.

Table 13: Significance of differences in Facebook page existence within organizations which perform in different time period

	Value	df	Asymp. Sig. (2-sided)
Pearson Chi-Square	2.387(a)	6	.881
Likelihood Ratio	3.402	6	.757
Linear-by-Linear Association	.609	1	.435
N of Valid Cases	50		

Organizations Twitter Account Differences

If we take a look at figure 10. we can see that the biggest number of middle size organizations do not have Twitter account, and also the biggest number of middle organizations have Twitter account.

Figure 10: Organizations Twitter account differences

With table 14. is presented significance of differences in Twitter account existence within different size organizations. It can be seen that Sig=0,674>0,05, so it is concluded that organization's size does not affect significantly on Twitter account existence.

Table 14: Significance of differences in Twitter account existence within different size organizations

	Value	df	Asymp. Sig. (2-sided)
Pearson Chi-Square	4.017(a)	6	.674
Likelihood Ratio	4.269	6	.640
Linear-by-Linear Association	1.412	1	.235
N of Valid Cases	50		

In figure 11. are presented differences in Twitter account existence in organizations with different business level. It is shown that the biggest number of organizations which perform on local level do not have Twitter account, while the biggest number of organizations which perform on local level have Twitter account.

Figure 11: Differences in Twitter account existence in organizations with different business level

In table 15. is shown significance of differences in Twitter account existence in organizations on different business level. It can be seen that Sig=0,323>0,05, so we can conclude that level of business does not affect significantly on Twitter account existence.

Table. Significance of differences in Twitter account existence in organizations on different business level

	Value	df	Asymp. Sig. (2-sided)
Pearson Chi-Square	6.972(a)	6	.323
Likelihood Ratio	8.219	6	.222
Linear-by-Linear Association	3.863	1	.049
N of Valid Cases	50		

With figure 12. are presented differences in Twitter account existence within organizations that perform in different time period. It can be seen that Twitter account mostly do not have organizations which perform over 15 years, and also that organizations which perform more than 15 years in biggest number have Twitter account.

Figure 12: Differences in Twitter account existence within organizations that perform in different time period

If we look at table 16. it can be seen that significance of differences in Twitter account existence in organizations which perform in different time period. Results have shown that Sig = 0,036<0,05, so it is concluded that business length significantly effects on Twitter account existence.

Table 16: Significance of differences in Twitter account existence in organizations which perform in different time period

	Value	df	Asymp. Sig. (2-sided)
Pearson Chi-Square	13.500(a)	6	.036*
Likelihood Ratio	7.465	6	.280
Linear-by-Linear Association	2.694	1	.101
N of Valid Cases	50		

Impact of organizations differences on quality and frequency of marketing activities

Impact of organization's size on quality and frequency of marketing activities was confirmed by ANOVA test, with significance level 0,05 (for all values Sig. ≤0,05, exists significant difference).

Impact of organization's size on quality and frequency of marketing activities

In table 17. it can be seen that Sig., only for web page quality is different in organizations of different sizes (micro, small, middle and big). Namely, Sig=0,011<0,05, so it is concluded that organization's quality significantly depends on organization's size. On the other hand, no matter organization's size

Facebook page quality, You Tube movies, promotions through TV channels and radio stations is not different.

Table 17: Impact of organization's size on differences in quality and frequencies of marketing activities

Organization's size		Sum of Squares	df	Mean Square	F	Sig.
Webpage quality	Between Groups	19.992	3	6.664	4.186	.011*
	Within Groups	73.228	46	1.592		
	Total	93.220	49			
Facebook page quality	Between Groups	4.107	3	1.369	.457	.713

	Total	132.500	49			
Radio station promotions	Between Groups	3.490	3	1.163	.530	.664
	Within Groups	101.010	46	2.196		
	Total	104.500	49			

Relation of web page rates in different size organizations was presented in graph 13. where it can be seen that highest number of middle size organizations has rated web page as good or extremely good.

Figure 13: Web page quality of different size organizations

Since the difference in web page quality was observed in different size organizations, additional Turkey test was determined between which organizations difference exists. Significant difference in web page quality exists especially between micro and middle organizations (Sig=0,010<0,05), which is presented in table 18.

Table 18:Differences in web page quality in different size organizations

WEB PAGE QUALITY		Mean Difference (I-J)	Std. Error	Sig.	95% Confidence Interval	
(I) Organization's size	(J) Organization's size	Lower Bound	Upper Bound	Lower Bound	Upper Bound	Lower Bound
Micro organization	Small organization	-.622	.580	.707	-2.17	.92
	Middle organization	-1.582(*)	.481	.010	-2.86	-.30
	Big organization	-1.400	.580	.088	-2.95	.15
Small organization	Micro organization	.622	.580	.707	-.92	2.17
	Middle organization	-.960	.499	.233	-2.29	.37

	Middle organization	-.182	.499	.983	-1.51	1.15

Impact of business level to quality and frequency of marketing activities

In table 19. are presented differences in quality and frequency of marketing activities in different business level organizations. Differences are only appeared in terms of web page quality (Sig=0,027<0,05). Results show that business level does not affect significantly on differences in Facebook page quality, You Tube movies, frequencies in performing marketing activities, planning marketing activities through digital media, promotions through TV and radio channels.

Table 19: Differences in quality and frequency of marketing activities in different business level organizations

Business level		Sum of Squares	df	Mean Square	F	Sig.
Webpage quality	Between Groups	16.655	3	5.552	3.335	.027*
	Within Groups	76.565	46	1.664		
	Total	93.220	49			
Facebook page quality	Between Groups	.739	3	.246	.080	.970
	Within Groups	141.041	46	3.066

	Within Groups	119.327	46	2.594		
	Total	132.500	49			
Radio station promotions	Between Groups	5.440	3	1.813	.842	.478

	Within Groups	99.060	46	2.153		
	Total	104.500	49			

In figure 14. are presented web page rates of different business level, where it can be seen that organizations on regional level in highest number have rated quality as extremely good, while organizations which perform on national and local level rated as good quality of web page.

Figure 14: Web page quality of different business level organizations

Difference was spotted in web page quality within organizations of different business level, so with additional Turkey test was determined between which organizations difference exists. Significant difference in web page quality exists especially between organizations which perform on local and regional level (Sig=0,033<0,05), which is shown in table 20.

Table 20: Differences in web page quality within organizations that perform on different level

WEB PAGE QUALITY		Mean Difference (I-J)	Std. Error	Sig.	95% Confidence Interval	
(I) Business level	(J) Business level	Lower Bound	Upper Bound	Lower Bound	Upper Bound	Lower Bound
Local level	National level	-.571	.436	.561	-1.73	.59
	Regional level	-1.460(*)	.514	.033	-2.83	-.09
	International level	-1.305	.642	.191	-3.02	.41

	Regional level	-.156	.720	.996	-2.07	1.76

Impact of business length to quality and frequency of marketing activities

In table 21 is presented an impact of organization's business length to quality and frequency of marketing activities. Based on results differences are spotted only in terms of web page quality (Sig=0,004 < 0,05), and business length doesn't affect significantly on differences in Facebook page quality, You Tube movies, frequencies in performing marketing activities, planning marketing activities through digital media, promotions through TV and radio channels, which is presented in table 21.

Table 21: Differences in quality and frequency of marketing activities in organizations that perform in different time period

Business length		Sum of Squares	df	Mean Square	F	Sig.
Webpage quality	Between Groups	22.898	3	7.633	4.993	.004*
	Within Groups	70.322	46	1.529		
	Total	93.220	49

	Within Groups	98.017	46	2.131		
	Total	104.500	49			

In figure. are presented web page rates of organizations that perform in different time period. Organizations which perform over 15 years, have rated the best web page quality.

Figure 15: Web page quality of organizations that perform in different time period

Since the difference in web page quality was spotted in organizations that perform in different time period, with additional Turkey test it was determined that difference especially exists between organizations that perform up to 3 years and the ones which perform from 8 to 15 years (Sig=0,009<0,05), as well as with organizations that perform up to 3 years and the ones that perform over 15 years (Sig=0,019<0,05), which is shown in table 22.

Table 22: Differences in web page quality within organizations that perform in different time period

WEB PAGE QUALITY		Mean Difference (I-J)	Std. Error	Sig.	95% Confidence Interval	
(I) Business length	(J) Business length	Lower Bound	Upper Bound	Lower Bound	Upper Bound	Lower Bound
Up to 3 years	From 4 to 7 years	-1.000	1.236	.850	-4.30	2.30
	From 8 to 15 years	-3.182(*)	.950	.009	-5.72	-.65
	Over 15 years	-2.743(*)	.899	.019	-5.14	-.35
From 4 to 7 years	Up to 3 years	1.000	1.236	.850	-2.30	4.30
	From 8 to 15 years	-2.182	.950	.114	-4.72	.35
	Over 15 years	-1.743	.899	.226	-4.14	.65

From 8 to 15 years	Up to 3 years	3.182(*)	.950	.009	.65	5.72
	From 4 to 7 years	2.182	.950	.114	-.35	4.72
	Over 15 years	.439	.427	.735	-.70	1.58
More than 15 years	Up to 3 years	2.743(*)	.899	.019	.35	5.14
	From 4 to 7 years	1.743	.899	.226	-.65	4.14
	From 8 to 15 years	-.439	.427	.735	-1.58	.70

Conclusion

The research which was conducted within 50 organizations in highest percentage has included middle size organizations, which perform mostly on local and national level and operate for more than 15 years. Highest percentage of organizations (84%) have web page, while more than half do not have Facebook page (52%). Also, more than half organizations which were included (78%) do not have Twitter account.

Results show that organizations use web page as presentation of themselves through internet, but it is not their primary way of presenting. They do not use enough more aggressive strategies in reaching customers through social networks and getting feedbacks about accepting organization and its activities from social networks visitors.

For highest percentage of organizations web page quality was rated as good, while Facebook page (ones that have it) in same per cent (18%) was rated as good and extremely good. Big percentage of organizations do not post You Tube movies (78%), and ones that do post have rated the quality in highest percentage as good.

Highest percent of organizations marketing activities perform from time to time (34%), while 22% perform them mostly frequently, and always frequently 26% of organizations. Planning marketing activities which are done through digital media mostly do not perform (28%), or plan from time to time (26%).

Results refer that organizations do not plan enough marketing activities, especially one through digital media, which indicated to still insufficient understanding the importance of this promotion type within organizations.

More than half organizations (64%) do not promote themselves through TV channels at all, and it is even higher percentage of those which do not promote themselves at all through radio stations (68%). *The conclusion is that traditional ways of promotion have been left, and further research should answer why is that, is it because of pricing, more usage of digital media, due to deficit in financing, customers disinterest or some other reason.*

Results show that differences in web page existence appears in different size organizations and business length. Differences in Facebook page existence do not exist regardless to characteristics of organizations itself. Namely, descriptive statistic has shown that more than half do not even have Facebook page, which is only confirmed in relation to organizations differences. Differences in Twitter account existence appear only in organizations which perform in different time period.

Results show that quality and frequency of marketing activities is different only in terms of web page quality and in organizations same size, level and business length. Other indicators refer that differences in organization's characteristics do not significantly affect to observed variables.

Based on theoretically and empirically research it's been accepted starting hypothesis according to which modern business ways and digitalization in each social segment effects on incensement of digital marketing role in media advertising, in a way that big number of information can be accessible to wide auditorium in the same time period.

Besides this auxiliary hypothesis are confirmed. It was proven that increasingly organizations are leaving traditional advertising methods (results showed exceedingly small percentage of organizations which promote themselves through TV channels and radio stations), and they turn to modern. Nevertheless, other hypothesis was proven, thus was shown that organizations in highest percentage have web page, but they do not use enough other advertising methods, such as social networks. Also, it was proven that different characteristic organizations are different only in terms of web page quality, while they are not different regarding other quality indicators and frequencies of marketing activities, by which third hypothesis was confirmed.

Abstract

The aim of this paper is to investigate the initial recognition of identifiable intangible assets (IIAs) disclosed by classes in purchase price allocation process. As disclosures related to IIAs constitute significant value in the financial reports prepared after business combinations, the research question is: what is the scope of IIAs recognized by Polish companies? Our study provides empirical evidence on the initial recognition of IIAs while other studies mainly concentrate on subsequent measurement. The empirical approach was based on a manual qualitative analysis of 100 consolidated financial reports published by Polish companies between 2012 and 2016. All companies chosen for the research are the publicly traded firms listed on the Warsaw Stock Exchange and indexed in WIG 20.Our study shows that the most frequent groups of IIAs are customer-related and marketing-related classes. Contrary to other research, we observed very few technology-based intangible assets. Although the frequency of IIAs disclosed by classes in our sample is relatively low, it is justified by the materiality of disclosures.

Keywords: Identified Intangible Assets, Purchase Price Allocation, Business Combinations, Financial Reports, Consolidated Financial Reports

Introduction

In the era of knowledge economy intangibles are becoming more important than tangible assets (Deloitte, 2017; Ernst and Young, 2018; Giuliani and Brännström, 2011; Grant Thornton 2013; Grobel and Forbes, 2008; KPMG, 2010; Wyatt, 2008).Many studies emphasize the growing role of intangibles in the evaluation of performance and in the number of total assets (Bauman and Shaw, 2018; Wyatt et al.,2001; Zeghal and Maaloul, 2011). However, intangible assets are difficult for outsiders to observe and monitor (Wyatt, 2005), their economic substance is all the more complicated and the recognition of intangibles is problematic (Penman, 2009; Skinner, 2008).

Business combinations (hereinafter BCs) are transactions with intangibles playing a crucial role, as they are value drivers for acquirees, assurance for future synergy effects and strategy determinants of the joint entity. This creates the expectation that accounting for BCs provides information about the effects of transactions, such as details about the nature and amounts of certain economic resources with no physical substance. During purchase price allocation it is allowed to recognize new identified intangible assets (hereinafter IIAs) although the acquiree had not disclosed them in the financial report prior to the acquisition.

Recent literature reveals that management has discretion to recognize separately identified intangible assets and aggregate goodwill (Wyatt, 2005; X. I. Zhang and Zhang, 2017), whereas the capitalization of intangibles (separate from goodwill) signals the intellectual investments made by the firm (Wyatt, 2008). Furthermore, previous studies show higher analyst following and more accurate earnings forecasts (Matolcsy and Wyatt, 2006; Ritter and Wells, 2006), value relevance of research and development, as well as human reporting (Ahmed and Falk, 2006; Lajili and Zeghal, 2006). The allocation decision has important accounting consequences, because goodwill is usually capitalized without amortization. Managers are given broad discretion to capitalize unidentified intangible assets (called goodwill) without amortization as most IIAs.

Since managers have more comprehensive information than other stakeholders, their discretion to allocate some value to IIAs becomes of crucial importance. Moreover, to reduce the information asymmetry more effectively, managers should describe in details classes of acquired IIAs. The high scope of disclosures in financial statement is also consistent with the legitimization theory (Łada and Kozarkiewicz, 2013). According to the legitimization theory, reporting as an information channel between the company and the society is a factor enabling social acceptance. Achieving social acceptance is possible by publishing reliable and transparent reports.

This paper investigates the initial recognition of identifiable intangible assets disclosed by classes in purchase price allocation. Detailed information about acquired IIAs is crucial for deep understanding the economic nature of business combination, especially considering managerial discretion in purchase price allocation and information asymmetry between managers and financial statements' users. The research method adapted for this study is qualitative analysis of 100 consolidated financial reports published by Polish largest companies between 2012 and 2016.

The remainder of the paper is structured as follows: first section reviews prior related literature. The subsequent sections describe the design of the study followed by the presentation and discussion of results. The paper ends with conclusions and suggestions for future research.

Literature Review

The IASB defines an intangible asset as 'an identifiable non-monetary asset without physical substance' (IAS 38, 2004). An intangible asset is identifiable if it meets either the separability criterion (is capable of being separated from the entity and sold, licensed etc.) or the contractual-legal criterion (it arises from contractual or other legal rights).Based on the definition of asset and accounting problem with the notion of 'control' of an asset, standard setters limited categories of intangibles to two groups: internally generated intangibles and externally generated ones. Externally generated intangibles are regulated as the price paid for the intangible serves for the measurement purposes. In this context, goodwill represents aggregated figure encompassing several dimensions and facets of intangibles externally generated and purchased in a business combination. As distinct from these unidentified intangible value-drivers, an entity shall recognize separately intangible assets that meet the criterion of identification.

One of the first studies about intangibles separated from goodwill evidenced that British firms voluntary recognized acquired brands (Muller, 1999). Muller finds out that a limited number of firms recognized and measured the value of acquired brand names separately from goodwill due to the fact that brands were not amortized at that time in the UK. Firms' decisions to separate brand names were influenced by the impact of goodwill direct write-off to equity upon acquisition and its impact on the increase of firms' reported leverage ratios.

Jeny et al.(2016) assume that the amount of recognised goodwill may convey a different signal to investors compared to IIAs. Both the amounts of purchased goodwill and separately presented IIAs are value-relevant for market participants in the sense that they are positively associated with market value of equity. Although the value relevance of separated IIAs seems to be stronger than the value relevance of goodwill, the authors cannot provide strong evidence that it is statistically significant difference.

Kimbrough (2007) provides empirical evidence that decomposition of the purchase price yields useful information to investors and that the separate recognition of intangible assets apart from goodwill is value relevant. He finds out that investors appear to respond most strongly to purchase price allocation where the proportion of total assets allocated to IIAs apart from goodwill is greater that the industry average.

Eales and Abbey (2009) highlight that recognition of differentiated intangibles is difficult and not always possible. Also Carvalho et.al. (2016) investigated the magnitude of goodwill recognised in Portuguese BCs. Further, Rupo and Sidoti (2014) examined the level of disclosure of intangible assets, especially goodwill, resulting from BCs in Italy in years 2008-2011. The large amount of intangibles arising from BCs is often found in the balance sheet under the heading of unallocated goodwill, rather than under specific items of intangible assets. This negatively affects the reliability of financial statements and compromises the true and fair view of financial performance.

The other studies focused on subsequent measurement of IIA (Bepari et.al. 2014; Huikku et.al., 2017; Lapointe-Antunes et.al. 2009; Li and Shroff, 2011; Schultze, 2005; Seetharaman et.al. 2004; Seetharaman et.al. 2006).This study is concentrated on the recognition of identifiable intangible assets as a result of BCs.

Economic determinants of intangible assets recognition were subject to Wyatt's research (Wyatt, 2005). She examines the extent to which management made accounting choices to record intangible assets based on their insights into the underlying economics of their firm. Her result suggests that limiting managements' choices to record intangible assets tends to reduce, rather than improve, the quality of the balance sheet and investors' information set.

Another stream of research examines the classification of intangible assets with consideration also given to goodwill and other identifiable assets. Blair and Wallman (2000) proposed three major categories of intangibles, pointing out the control concern (Blair and Wallman, 2000): intangibles for which property rights are relatively clear and for which a market exists, intangibles that are controlled by the firm but for which well-defined and legally-protected rights may not exist and markets are weak or non-existent, and intangibles for which the firm has few, if any, control rights and a market does not exist, and which are tied to the people who work for the firm.

Studies with the aim of examining the quality of disclosure of intangibles also reveal the classification of intangibles. Garcia-Meca and Martinez (2005) conducted their research on disclosure quality based on the classification of intangibles into six different groups: human capital, customers, processes, technology, innovation with R&D and strategy. Unlike Garcia-Meca and Martinez (2005), Wyatt (2008) classifies intangibles as follows: technology resources, human resources and production resources. The above three categories of intangibles relate to three broad types of the firm's resources: technology, human and production wealth. Although these three categories are not exhaustive and overlap, Wyatt's classification covers internally and externally generated intangibles.

In the most recent study, Sacui and Szatmary (2015) considered five categories of intangible assets that meet the criteria for recognition as assets (apart from goodwill) in accordance with IFRS 3. They suggest that there are intangible assets specific to a number of industries while others might be called common (or well-accepted). Trademarks, research and development, and patents are among the common intangibles disclosed regardless of the industry.

Table 1: The classification of intangible assets

Authors	Classification
Blair and Wallman (2000)	Intangibles for which property rights are relatively clear and for which a market exists (e.g., patents, copyrights and trade names)
	Intangibles that are controlled by the firm but for which well-defined and legally-protected rights may not exist and markets are weak or non-existent
	Intangibles for which the firm has few, if any, control rights, a market does not exist and which are tied to the people who work for the firm, for example, human assets, organizational assets, relational assets encompassing intellectual capital
Garcia-Meca and Martinez (2005)	Human capital (that relates to the skills and knowledge of employees and managers)
	Customers (relations with customers)
	Processes (organizational processes)
	Technology
	Innovation, research and development (relates to a firm's ability to innovate, research and tackle new projects)
	Strategy (culture, firm ethics, environmental investments, leadership)
Wyatt (2008)	Technology resources (including research and development and related intellectual property)
	Human resources (human capital)
	Production resources encompassing: advertising, brands and related intellectual property, customer loyalty, competitive advantage, goodwill
Sacui and Szatmary (2015) based on IFRS 3	Technology-based intangible assets
	Contract-based intangible assets
	Customer-related intangible assets
	Marketing-related intangible assets
	Artistic-related intangible assets

Source: Own elaboration

The above classifications show that it is a complicated process encompassing adequate grouping and proper valuation of each specified class that might be defined dissimilarly depending on the entity's sector, historical systematization or management's consideration. The complexity of intangible assets recognition process was also confirmed by studies conducted among Polish entities. Janowicz (2016a; 2016b) in her studies clearly indicates that financial reports narrowly disclose information about the economic underpinnings of business combinations (including old as well as newly recognized intangibles), while Grzybek suggests that intangibles are used as discretionary accounting policy choices (Grzybek, 2015). Further, previous studies suggest (Grzybek and Maruszewska, 2016; Luty,

2018) that goodwill and other intangibles disclosure often lacks economic underpinnings and thus they are sensitive to manipulations. Overall, accounting for intangibles, especially in BCs, is much more than a technical implementation of sophisticated standards (Maruszewska and Strojek-Filus, 2016).

Research Sample

In our research we have analyzed the content of the consolidated financial reports of companies listed on the Warsaw Stock Exchange, one of the largest stock markets in Central-Eastern Europe. All firms chosen for the analysis were included in the WIG 20 Index that comprises the largest publicly traded companies in Poland. Our final sample comprised 125 BCs revealed in 100 financial reports prepared in accordance with IFRS for the period 2012 - 2016. The analysis focused on the quantitative and narrative information disclosed in financial reports publicly available on firms' websites. Table 2 presents descriptive statistics for the whole research period.

Table 2: Descriptive statistics

	Acquisition cost (mln PLN)	IIAs (mln PLN)	IIAs / acquisition cost	IIAs disclosed by classes (mln PLN)	IIAs disclosed by classes / IIAs
Mean	487	109	0,74	391	0,84
Median	29	3	0,11	50	0,94
Range	13 279	7 759	55	7 755	1
SD	1 654	710	4,89	1 419	0,23
Skewness	5,54	10,33	11,00	5,18	-1,79

Source: Own elaboration

The above descriptive statistics show that on average IIAs disclosed constitute big portion of acquisition cost (0,74) as well as IIAs disclosed by classes constitute in total IIAs (0,74). Few transactions were characterized by high amounts and the distribution is strongly right-hand.

Figure 1 presents a summary of analysis of the average amounts allocated to IIAs and the share of IIAs in the acquisition cost over the research period.

Fig. 1: Share of IIAs in acquisition cost

Source: Own elaboration

On average, more than a fifth of the purchase price is allocated to IIAs (22%). The highest proportion of the acquisition cost was allocated to IIAs in 2014 (50%), followed by 2016 with 38% and 2015 with

24%. High amounts allocated to IIAs confirm that intangible assets are key value - drivers in business combinations. This share was significantly lower in 2012 and in 2013 as the relatively high average acquisition cost was hardly allocated to IIAs. In contrary, from 2014 to 2016 although the declining trend in the amount of acquisition cost can be observed, the share of IIAs in average acquisition cost is much bigger. Thus, the share does not correspond with changes in the amounts of IIAs.

Results and Discussion

In the following section we examine in detail IIAs disclosed by class in the purchase price allocation. In particular, we investigate their frequency and materiality as two complementary dimensions of analysis. Then we analyze the types of IIAs to identify which are commonly recognized in purchase price allocation process and which are unique and specific to an entity.

Fig. 2: Frequency and materiality of intangible assets identified by class
Source: Own elaboration

Most often BCs are related to acquiring some intangible assets that meet the criteria of identification - 74% of BCs assigned some value to the recognized IIAs. But only in one third of those BCs there were IIAs disclosed by class, representing only 24% of all analyzed BCs. It indicates that companies may not be eager to disclose detailed information about purchase price allocation. This finding is consistent with previous research (Janowicz, 2016b).

Nevertheless, we must consider not only the frequency but materiality of disclosed amounts as well. When we consider the amount of IIAs disclosed by class, we can observe that a great part of IIAs are disclosed by category (86% on average). Altogether it suggests that Polish companies identified intangible assets quite often and they disclosed detailed information if it could be useful for financial statement's users.

The frequency of recognizing IIAs in BCs in our sample (74%) is similar to other findings in prior studies (77% Eales and Abbey, 2009; 75% Jeny et al., 2016). Comparing our results with those of KPMG for 56 transactions in Poland in previous years (2008 to 2010), the frequency of IIA recognition is higher in later years (74% for the years 2012 to 2016 and 53% for 2008 to 2010; KPGM Report, 2011). Moreover, according to KPMG, only 17% of BCs were transactions with IIAs disclosed by classes, whereas this proportion is 24% in our sample, suggesting positive changes.

A comparison of our results with the findings of Carvalho et al. (2016) confirms that the largest Polish companies make a great effort during BC presentation as well as preparing financial reports in the

context of IIAs. Although the frequency of IIAs disclosed by class is relatively low, it is justified by the materiality of disclosures. In our sample, 22% of the acquisition cost was allocated to IIAs, in which more than 19% of the acquisition cost was allocated to IIAs disclosed by class, in comparison to only 4% to 5% in Portugal.

Recognition and fair value measurement of the acquiree's assets on the date of acquisition is among the key elements of the acquisition method required by IFRS 3. In practice however, detecting or 'finding' IIAs in particular may be a complex matter that requires intensive research into the acquired business. According to accounting standards, one can distinguish between IIAs, unidentifiable intangible assets or goodwill. IIAs can be grouped into five categories: technology-based intangible assets, contract-based intangible assets, customer-related intangible assets, marketing-related intangible assets and artistic-related intangible assets (IFRS 3, Illustrative examples IE16-IE44). Table 3 presents the IIAs recognized in our research sample.

Table 3: Identifiable intangible assets specific to different companies

Types of IIAs	Company-specific IIAs
Technology-based	– Software and licenses
Contract-based	– Concessions (x2) – Carbon emission allowances, coal purchase agreements, electricity sales agreements, agreements for the sale of certificates of origin – Licenses conferring the right to undertake the production of oil from deposits in the territory of Lithuania
Customer-related	– Customer relations (x11) – Present value of future profits (x3) – Broker relations (x2) – Customer relations and client base – Customer relationships in the area of deposits – Favourable contract – Intangible assets due to signed services sales contracts – Orders backlog – Revaluation of the acquired deposits of individual and business customers as well as customer relationships – Revaluation of the insurance agreements
Marketing-related	– Trademark (x6) – Brand (x3)
Artistic-related	– Programming assets
Other	– Software developed by the acquired company and its customer relations (x2) – Other (x2) – Customer relations and internally generated software – Capitalized expenditures for the development of products – Goodwill – Intellectual property – Intangible assets in realization and prepayments

Source: Own elaboration

The most frequent group of IIAs are customer-related intangible assets encompassing for example: customer relationships, customer lists, favorable contracts, broker relations, etc. It is also worth mentioning that, across Table 3, there are many specific IIAs for particular industries such as carbon

emission allowances, coal purchase agreements, electricity sales agreements or licenses conferring the right to undertake production. In the presented table, 'other intangible assets' have been added, which covers assets that are impossible to assign to one particular group because of insufficient descriptions or the situation in which the disclosed amount could be assigned to two or more groups. The above shows inconsistency in labelling different classes of IIAs. Moreover, it has been observed that in the case of one company, goodwill has been qualified among the 'other intangible assets' group, which is incorrect.

The next step of the analysis was assessing the frequency of different classes of IIAs together with the materiality of their amounts. Frequency was calculated as the number of BCs with a particular class of IIAs to the total number of BCs with intangible assets identified by classes (30 transactions). Materiality is understood as the amount assigned to a particular class to the total amount of IIAs disclosed by class. Figure 3 presents the results.

Fig. 3: Frequency and materiality of different classes of IIAs
Source: Own elaboration

Customer related intangible assets have been identified in 23 BCs constituting 50% of the amount of intangible assets – it was the most material group in our sample. The class 'Other intangible assets' was also identified as relatively frequent. This group was identified in nine BCs, but its magnitude is relatively low – only 8% of the amount of intangible assets identified by class were assigned to this position. Another frequently occurring class is marketing-related intangible assets with the frequency of 30%. However, when including the combined value of all intangibles from this group, it only constitutes 12% of the total amount, which appears to be relatively low.

The findings of Giffin et al. (2017) and DeLuke et al. (2018) for US companies confirm that brands (in our case, marketing-related intangible assets) are one of the most frequently identified intangibles, but their amounts are rather insignificant. Our findings in this area are also similar to the results of Eales and Abbey (2009), in which the most frequently recognized classes of intangible assets were customer relationships and brands. In their survey, customer-related assets were disclosed separately in 44% of BCs followed by brands with 31% and technology with 20%. The FRC (2010) confirms these findings for UK companies.

It is also worth mentioning that the least numerous groups among IIAs were artistic-related intangible assets and technology-based intangible assets. The latter were only disclosed in BCs in 2016 – the last year of the research period (one recorded case). This result may be surprising considering the very

rapid development of modern technologies. It may be the basis for continuing the research in the future and examining whether this value increases in subsequent years.

Conclusions

Intangibles are increasingly important for entities conducting business operations based on knowledge and cutting-edge technologies. The particular instance of their recognition and disclosure in the financial statement is a purchase price allocation in BCs.This study adds knowledge to the debate about the practice of purchase price allocation in Poland. As there is a small amount of research on this subject in Central and Eastern Europe countries, the results of this study are worth emphasizing.

We described different classes of IIAs recognized during the purchase price allocation. The most frequent groups of IIAs are customer-related and marketing-related intangible assets. Customer relationships, brands and trademarks are the most common intangible assets recognized in BCs. Although it is one of the most frequent identified classes, the amounts of marketing-related intangible assets are quite insignificant. Our findings on this issue are consistent with previous research. Some other studies also indicate that technology-based intangible assets are also commonly disclosed. Nonetheless, this was not found in our research. Moreover, we observed that the share of IIAs disclosed by classes is relatively high for years with a great part of acquisition cost allocated to intangible assets overall, while it is relatively low for the years when intangible assets represent only a small part of the acquisition cost. This suggests that Polish companies make an effort to prepare detailed and useful information, at least as far as materiality is concerned.

Previous studies conducted worldwide proved that recognition of differentiated intangibles is difficult if not always possible (Eales and Abbey, 2009). Empirical evidence on the allocation of purchase price in emerging markets is limited. This study contributes to the ongoing debate on purchase price allocation by showing how Polish firms translate accounting standards into practice in regards with allocation of purchase price to identifiable intangible assets. We investigate types of IIAs to show what are commonly recognized in purchase price allocation process and whether specific IIA exists in relation to certain types of entities. Our study provides empirical evidence on the initial recognition while other studies mainly concentrate on subsequent measurement (Bepari et.al. 2014; Huikku et.al. 2017; Lapointe-Antunes et.al. 2009; Li and Shroff, 2011; Schultze, 2005; Seetharaman et.al., 2004; Seetharaman et.al. 2006).

The above findings shall be interpreted with respect to the limitations of the study. The main limitation refers to one country where study was conducted and manual collection of data. The second limitation is connected with quite a significant number of BCs ending with bargain purchase that is rather unusual when compared to past research.

Although our study is limited somehow, it suggests future paths of research. One possibility is to broaden the group of entities encompassing other publicly traded companies from past communist countries located in Central and Eastern Europe or diverging the subjects based on an industry sector either macroeconomic situation when BC was accounted for. Another interesting research might investigate to what extend the disclosed IIAs represent knowledge and/or intellectual capital acquired with purchased business. Further, economic phenomena standing behind each category of intangibles as well as their relations between financial position of the entity or discretional accounting policy choices might be investigated in deep.

Tax Administration in the Conditions of Development of IT-Sphere and Digitalization of Economy

Anton M. PETROV

Scientific Research Institute "Education Development", Plekhanov Russian University of Economics, Moscow, Russia
E-mail: petrov.prue@bk.ru

Abstract

The article considers the role of modern information technologies in the process of transformation of tax authorities activity. The author analyzes the online services of tax organizations in several countries, discloses current trends in the development of tax administration in accordance with the requirements of the digital economy. Modern information technologies allowed, according to the author of the article, not only to ensure the electronic interaction of tax authorities with taxpayers, but also to provide a service-oriented model in their activities. This way of development of tax authorities creates the conditions for streamlining and simplifying tax procedures, forms and methods of tax administration. The purpose of this article is to review the established practice of electronic interaction between tax authorities and taxpayers and to identify the areas of digitalization of tax administration. Based on the use of general research methods, the process of digitalization of tax authorities in modern conditions is distinguished by the author.

Keywords: Tax Authorities, Tax Administration, Taxpayers, Online Services, Digital Economy.

Introduction

As noted in the Digital Economy 2019 Report presented at the United Nations Conference on Trade and Development in 2019, the digital economy continues to grow at an incredible speed due to its ability to collect, use and analyze huge amounts of machine-sensible information (digital data) in practice about everything. Over the past decade, many digital platforms have appeared in the world that use business models based on data and transforming many sectors of the economy. In connection with the development of the digital economy, the tax landscape is changing, which forces state authorities to actively act and seek adequate solutions to tax issues in the new conditions for the functioning of the economy. The digital economy requires a wide variety of new knowledge and skills, fundamentally new approaches to the regulation of the economy by the state and its fiscal policy (United Nations Conference on Trade and Development, 2019).

Currently, tax authorities in developed countries have come a long way, having come to the automation of most of their processes and the formation of a wide range of online services in cooperation with different categories of taxpayers. With the help of them, taxpayers, among other things, gain the ability to easily and quickly pay certain taxes, submit documents (information) to the tax services in non-eligible form, quickly receive results on the services of tax authorities. The tax administrations themselves increase the efficiency of their functions, including, on the accuracy of calculation, completeness and timeliness of taxes and fees in the relevant budget, on the identification of unscrupulous taxpayers (Nascimento *et al.*, 2009; Efremova and Efremova, 2015; Kashin and Ponomareva, 2018; University of Tyumen (Tyumen, Russian Federation) and Ogorodnikova, 2019; Boboshko, 2020).

The purpose of the study is to identify the main changes in tax administration in the conditions of informatization of society and digitalization of the economy, as well as the vector of development of tax authorities in the 21st century.

Methods

For our study, in accordance with its purpose, a sample was formed on the online services of the tax administrations of Germany, Denmark, Australia and Russia. In the work, special attention is paid to the successes of the tax authority of Russia in familiarizing with modern challenges and risks. In the course of work, theoretical research methods were used, including: analysis of documents and materials, their generalization and systematization.

Digital Tax Administration

Now, as practice shows, already in all developed countries, the tax returns from taxpayers are collected through electronic communication channels. Computers are processing this returns (primary - almost without human intervention), tax inspectors check taxpayer reporting with extensive use of data base. The tax refund is already written out by the computers themselves. Moreover, now in a number of tax administrations, in particular, in some Scandinavian countries, using available and constantly updated data base, independent tax returns are prepared for taxpayers. The tax authorities in many countries are now less and less based on compulsion and more and more on providing citizens with various kinds of information services, among which the maintenance of tax payments remains the main, but not the only thing (Kashin and Ponomareva, 2018, p. 306, 307).

Note that, for example, the tax department of the German Federal Ministry of Finance applies various forms of online interaction with taxpayers. The Ministry offers a range of digital services for citizens, from social networks (communicating via Twitter, Instagram) to special applications (for example, to determine the amount of transport tax per year for a personal car) and tax calculators (for example, to calculate the amount of payroll tax fee). The ministry also has its own YouTube channel. The development of online services by the government of the country made it possible in 2019 to ensure that the number of people who submitted their tax returns electronically in Germany reached 23.8 million (almost a third of the country's population) (Bundesministerium der Finanzen, 2020; Statista, 2020).

One of the most successful countries in the world in digital tax administration is Denmark. Back in the 1970s, it began to use the first digital solutions to automate the process of paying citizens income tax. In 1995, the online technology TastSelv was launched in Denmark, which minimized manual and routine data entry work and, thus, allowed the authorities to concentrate significant resources for new tasks, such as analysis, control and development of the service. The information systems being implemented further were crucial both for collecting taxes and for ensuring confidence in the tax system of the country and financing public expenditures.

In addition, the modern challenges and errors in the operation of existing electronic tax administration systems have led to the decision in 2018 to start preparing measures for the modernization and replacement of these systems. Modernization and replacement of systems is planned to be carried out systematically and taking into account the recommendations of experts. This means, among other things, that conversions relate first to systems that are of the least importance and have the least complex connections with other systems, while at the same time forming the necessary idea of the possibilities of extending the life time and subsequent modernization of more complex IT systems. In accordance with the Finance Act for 2019, 612 million Danish krone were allocated for these purposes in Denmark. In general, it is expected that the project will be implemented over the next 15 years, and is expected to cost several billion (Skatteministeriet, 2019).

Registered taxpayers (individuals, self-employed entrepreneurs, companies, tax agents) in Australia also get access to a wide range of online services that allow you to receive tax, information and other services in electronic form in one place, including filing a tax return and tax reports activities, as well as information on tax liabilities. It is convenient, safe and accessible at any time. In addition, the tax administration presents special mobile applications, by downloading which it is possible to obtain tax services, relevant tax information at any time and place. A number of developed tools and calculators

available for the country's business, for example, allow you to calculate the amount of your taxes, deductions, determine tax benefits, etc. In addition, due to access to more information, the Australian tax administration has increased tax compliance by large corporate groups operating in the country (Australian Taxation Office, 2019, 2020).

The Federal Tax Service of Russia is also continuously improving online services on its website and is actively introducing the practice of electronic interaction with taxpayers via telecommunication channels. It has long been customary for Russians to provide tax reporting via the Internet, receive electronic services from the Federal Tax Service of Russia (hereinafter referred to as the Federal Tax Service of Russia) (information on tax arrears to the budget, information from the Unified State Register of Legal Entities, etc.). (Efremova and Efremova, 2015, p. 460). The country's tax service has introduced an automated information system (AIS 'Nalog-3') to consumers, which is a unified information system of the Federal Tax Service of the Russian Federation (Federal Tax Service of Russia, 2019) in order to automate the activities of the Federal Tax Service of Russia for all functions performed, including receiving, processing, providing data and analyzing information, generating information resources of tax authorities, statistical data, information necessary to provide support for making managerial decisions in the field of its powers and providing external information .The situation was fundamentally changed in terms of unfair tax competition in the business environment as a result of the introduction of an automated system for monitoring the reimbursement of value added tax (ASK-NDS). According to the Federal Tax Service of Russia, using the ASK NDS-2 system, it was possible to reduce the proportion of doubtful operations to 0.47%, which demonstrates a high result of the system (Federal Tax Service of Russia, 2020a).

Thus, all these measures implemented by the tax authorities are aimed at transforming them into a more service structure that would be focused on the interests of all taxpayers. The expected results of changes in tax authorities will be not only an expansion of the range of services they provide to taxpayers, an improvement in informing the public and business about tax legislation and, and, as a result, an increase in the share of taxpayers who positively assess the quality of tax administration, but also ensuring the stability and security of the economy (Efremova and Efremova, 2015, p. 460).

Digital services are the trend line in the development of tax administrations of the modern 21st century

Today, in the context of the development of the digital economy, the activities of companies and organizations are associated with conducting an increasing number of business operations in the virtual space of the Internet. With the help of modern information and communication technologies, automated information systems and developments in software, it is possible to remotely open and conduct a business, negotiate with contractors and customers, receive orders from them, and conduct cashless payments with them, as well as to provide many services in an interactive form. Globalization, the development of the electronic services market and the spread of blockchain technologies, the emergence and active use of electronic wallets, digital currencies (cryptocurrencies), the introduction of digital technologies have contributed not only to the growth of economic activity of the population, the emergence of new types of businesses, the increase of information exponentially, 'virtualization' of more and more of people's life-sustaining activity, but also the development of the 'shadow' sector of the economy, conducting business operations and settlements on them outside the control of the government. The latter opens up the opportunity not only for illegal enrichment of people, their commission of illegal transactions and other illegal actions of a fraudulent nature, the sale of prohibited goods and services, but also for terrorist activities, which is a threat to national and international security.

Nowadays, the quality, reliability and convenience of Internet services are coming to the fore, despite these negative aspects, which are opening up in the new conditions of society development, which all countries of the world are actively fighting today, including through the joint implementation of international projects to counter these negative trends. 'Internet services' are services (e-mail, Internet Relay Chat, File Transfer Protocol, etc.) that are provided on the Internet to users, programs, systems, levels, and functional blocks. Some of the services can be developed for users of a specific

subject area, in particular, used by subjects of tax relations (Evstigneev and Viktorova, 2016, p. 233). Today, in our opinion, there is a shift from 'Internet services' to a wider sector of services – 'digital services'. According to the Order of the Ministry of Communications of Russia d.d. August 1st, 2018 No. 428, a digital service is understood as 'an integrated solution based on digital products aimed at significantly improvement or acceleration of vital processes, organizational or business processes, including production processes' (Ministry of Digital Development, Communications and Mass Media of the Russian Federation, 2018). In the new conditions, it is very important, on the one hand, that state authorities keep pace with the changes, introducing and developing modern and safe online services for interacting with the country's population, and on the other, quickly respond to digital risks and threats. In these conditions, illustrative examples are the processes of informatization of tax authorities.

Note that already in 2014, 190 member states (according to the UN) introduced automated financial management, with 179 countries using such systems for customs clearance, and 159 for tax administration. One form or another of digital identification has been introduced in 148 countries. The use of a variety of information systems, cloud technologies and computer algorithms for data processing has already been recognized and evaluated by tax administrations of many developed countries as an effective tool for tax administration. In Russia, state regulatory authorities are also actively improving information technologies and introducing new digital systems during monitoring activities (University of Tyumen (Tyumen, Russian Federation) and Ogorodnikova, 2019).

'The digitalization of tax administration has made it possible to practically abandon the traditional forms of inspections, and create the conditions when tax evasion becomes unprofitable. All transactions with tax risk automatically fall into the attention of the tax authorities through remote monitoring and predictive analytics tools with a clear gradation of taxpayers by risk zone '(from a speech at the meeting of the All-Russian Tax Forum in 2019, of the head of the Federal Tax Service of Russia M. Mishustin). The result of the joint work of the state, business and self-employed citizens was the introduction of a tax on professional income. Using the My Tax mobile application, the self-employed were able to register as taxpayers and legalize their activities in a couple of clicks and interact with the Federal Tax Service of Russia online in the 24/7 mode (Federal Tax Service of Russia, 2020b).

It should be noted that at present, personal accounts created in Russia for all categories of taxpayers enable contactless communication with tax authorities from anywhere in the 24/7 mode. By the end of 2019, 29.2 million people registered in their personal account for individuals, every second entrepreneur also registered a personal account and uses it. 'In the near future, this service will be updated,' according to the Federal Tax Service of Russia, 'individual entrepreneurs will be able to pay taxes online as well as individuals' (Federal Tax Service of Russia, 2020a).

Conclusion

In general, tax administrations today are subject to the rapid transformation of their systems as a result of the digitalization of the economy. So according to the data presented in September 2019 at the global forum on tax administration (FTA - Forum tax administration) in the eighth issue of the 'OECD (Organization for Economic Co-operation and Development) Tax Administration Series', there are quite clear trends in the states, of which the following:

- firstly, the expansion of electronic administration, which is accompanied by: expanding the possibilities of filing online declarations, as well as making online payments, growing digital communication channels (via online services), using or planning to use artificial intelligence (in more than 40 tax administrations);

- secondly, an increase in the use of information about taxpayer behavior, which is accompanied by: the development of the use of behavioral representations and analytics of data on taxpayer actions as an instrument of tax control, research on the behavior of taxpayers and the use of this data (in more than 35 administrations) for tax purposes control.

Consequently, the main vector of the development of tax administration in the digital economy is electronic administration and the use of a number of technological tools. New sources of data and analytics, developing tax monitoring and expanding international cooperation allow tax authorities to improve the quality of tax administration in accordance with current trends, national interests and international requirements (Orlova, 2019, p. 30, 31; OECD, 2019).

Thus, 'digitalization' has led to a change in economic processes and economic business management, to the expansion of people's opportunities for self-realization and entrepreneurship. The authorities in response to these changes 'digitized' their methods and instruments of regulation, as well as the state apparatus: the creation of electronic government; an increase in the number of services provided by authorities in electronic form; active implementation of the concept of 'open data'. Tax administrations, as one of the important state authorities and one of the few structures with which almost the entire population interacts to one degree or another, strive in the new conditions to meet the needs of people in a modern and efficient digital service. Thus, they conduct effective and efficient tax control, monitoring (invisible, without harm and pressure on responsible taxpayers) when people pay taxes, fill in various reporting documents and applications for certificates and other information, etc.

Abstract

The work reveals the essence of intergovernmental relations explores the mechanism of legal regulation of intergovernmental relations, assesses the principles of their construction in the existing legal system of the country. In this publication, the author specifies the role of intergovernmental relations in balancing the budgets of the constituent entities of the Russian Federation.

Keywords: Intergovernmental Relations, Balanced Budgets, Principles of Intergovernmental Relations, Fiscal Federalism.

Introduction

The main aspect in the development and functioning of the state is the budget structure, which implies the organization and principles of the country's budget system, its structure, and the relationship between individual links. The local budget is an element in the state's budget system. The local budget is intended to provide financial support for the tasks and functions of local self -government. Despite the independence of budgets, there are relations between them, which are called inter- budgetary relations.

Results

The study of the role of inter-budgetary relations in ensuring the balance of budgets of the subjects of the Russian Federation should begin with the consideration of the essence of such a concept as " inter – budgetary relations". The essence of inter- budgetary relations is revealed in the scientific research of a large number of authors, both in the field of legal disciplines and in the field of budget and financial sphere. The concept of inter- budgetary relations is very multifaceted and includes a number of essential characteristics. Let's consider the interpretation of the essence of inter-budgetary relations from the position of various authors, namely:

1) I.A. Avetisyan (2018) believes that inter- budget relations are a system of relations between authorities that are aimed at establishing and delineating rights and responsibilities in the field of organizing the budget process and budget regulation. The key definition is the mechanism for establishing and delineating budget rights and responsibilities;

2) D.V. Bakharev and G.R. Yartik (2018) believe that inter- budgetary relations are a mechanism of interaction between state authorities of the Russian Federation at various levels of management within the organization of processes of formation and execution of budgets of a particular level. The key definition is building a system of state regulation of budget processes;

3) D.V. Krasnobryzhiy and V.A. Okolelova (2017) tell us that inter-budgetary relations are a generalized model of financial and legal interaction between public administration bodies at various levels of the budget and financial system within the framework of the budget process. The key definition is the model of financial and legal interaction between public legal entities in the Russian Federation;

4) M.N. Smagina and G.T. Mukenge (2017) believe that inter- budgetary relations are the organization of procedures for allocating budget resources in order to achieve a balanced budget at a certain level. The key definition is a tool for achieving balanced budgets at different levels.

Thus, we can conclude that there is no unambiguous unity in the scientific literature regarding the essence of the concept of "inter -budgetary relations". Each of the authors considered in this paper tries to reveal the essence of inter- budgetary relations through the prism of their vision of this issue.

The essence of inter-budgetary relations is also revealed in legal acts, the most relevant of which in this aspect is the Budget code of the Russian Federation. Taking into account the provisions of the Budget code of the Russian Federation, it can be concluded that inter-budget relations are a complex of legal and financial and economic relations between public legal entities at various levels of government in Russia within the framework of building a system of regulating budget legal relations and quality organization of the budget process.

When considering the essence of inter-budgetary relations, it is important to determine the main target that is used in their construction and formation. Most authors agree that the main goal of building inter-budgetary relations is to achieve the necessary level of balance of the country's budget system as a whole and the specific budget of a certain level of public administration, in particular. According to Yu.G. Shvetsov (2017), the achievement of this goal is carried out with the help of inter-budget transfers, which are aimed at replenishing the revenue part of the budget of a particular level. Due to the use of inter-budget transfers, the revenue part of the budget increases approximately to the level of its expenditure part, which ultimately leads to a balance in the overall budget size. The amount and procedure for implementing inter-budget transfers are determined based on the budget position in the country's budget system and on the projected size of the budget deficit.

The main features that characterize the essence of inter- budgetary relations in the Russian Federation:

1) Aimed at establishing budget rights and responsibilities;

2) The main goal is to achieve a balanced budget system;

3) Form the basis for building the budget process;

4) Include procedures for the allocation and use of budgetary resources;

5) Aimed at optimizing budget execution processes at different levels;

6) Carried out within the framework of relations between public legal entities.

The list of presented features in the most General form reveals the essence of building and forming inter-budgetary relations in the Russian Federation.

A significant discussion issue that characterizes the specifics of inter-budgetary relations is the problem of substantiating their subjective composition. M.A. Aseeva et al. (2016) consider the debatable nature of determining the subjective composition of inter-budgetary relations in his monograph. The author notes the fact that there are several main points of discussion on this issue:

- within the framework of the first direction, it can be noted that its representatives include state authorities of the Russian Federation, subjects of the Russian Federation and local self-government among the subjects of inter- budgetary relations;

- as part of the second line of research on this issue, its supporters include all participants in the budget process who take part in all stages of its implementation as representatives of inter-budgetary relations;

- the third area of research in this area includes the budgets of all levels of the budget system represented by their authorized bodies as subjects of inter budgetary relations;

- in the legislation of the Russian Federation, in particular, the provisions of the Budget code also describe the subjects of inter -budgetary relations.

In the interpretation of the legislator, representatives of subjects of inter-budgetary relations include public legal entities.

From the position of most authors and in our opinion, the most relevant is the last interpretation of the essence of the subjective composition of inter-budgetary relations.

As noted earlier, the main goal of implementing inter-budgetary relations in the budget system of our country is to achieve the necessary level of balance of a particular budget. In addition to this General goal of implementing inter-budgetary relations, L.B. Mokhnatkina (2019) in the materials of her scientific article identifies a number of tasks that need to be solved in the process of implementing this type of relationship. Based on the materials of this author's publication, it is possible to identify the main tasks that are solved in the process of implementing inter-budgetary relations:

- formation and consolidation of powers in the field of budget revenues and expenditures between separate parts of the country's budget system;

- building a mechanism for delegating spending authority from a higher budget to a lower budget;

- differentiation of regulatory revenues on a permanent or temporary basis;

- accumulation of financial resources to cover the amount of certain expenses;

- providing free or paid financial assistance and support to other entities of the country's budget system in order to achieve the necessary level of balance;

- organization of control over the implementation of current legislation in the formation of revenue and expenditure powers of lower-level budgets.

Disclosure of the essence of inter-budgetary relations requires consideration of their main types.

Classification of the main types of inter-budgetary relations:

1) In content:

- material;

- organizational;

2) In the direction of the flow of budget funds:

- ascending;

- outbox;

- horizontal;

3) By the level of state power:

- federal;

- regional;

- local;

4) On repayment of funds:

- onerous;

- unpaid.

Among the many classification features of inter-budgetary relations, we will highlight the most relevant of them. In The publication of I.U. Davydov et al. (2017), the main feature of the classification of inter-budgetary relations is the feature of their content. According to the content, inter-budgetary relations can be divided into material and organizational ones. Material inter-budgetary relations are directly related to the distribution of financial resources between different parts of the country's budget system. Organizational inter- budgetary relations include issues of their regulatory and legal regulation and organization of control over the movement of financial flows.

G.Yu. Tsaregorodtseva (2016) recommends classifying inter-budgetary relations based on the criterion of the direction of the flow of budget funds. Based on this criterion, it is advisable to distinguish three main types of inter-budgetary relations:

- Ascending-represent inter – budgetary relations that are related to the formation of the necessary amount of Federal budget revenues;

- Top-down-characterize inter – budget relations, in which financial resources are distributed among lower budgets to achieve the necessary level of balance;

- Horizontal – relations are inter-budgetary relations in which certain tasks are solved at a particular level of the country's budget system.

In the normative legal acts of the Russian Federation, budget relations are primarily classified by levels of state power:

- Federal, which characterize inter-budgetary relations between the Federal budget and other lower-level budgets of the country's financial system;

- Regional, which characterize inter-budgetary relations between the regional budget and the Federal budget, as well as between regional budgets and budgets of lower levels of the country's financial system;

- Local, which are based on inter-budgetary relations between local budgets and budgets of other levels of the country's financial system.

Inter-budgetary relations in the course of their functioning within the country's financial system perform a certain list of functions.

The main functions of inter- budgetary relations:

1) Foundation;

2) Stimulating;

3) Distribution;

4) Leveling;

5) Regulatory;

6) Compensation;

Let's take a closer look at the content of inter-budgetary relations in the country's financial system. The implementation of the Fund-forming function of inter-budgetary relations is primarily aimed at creating a certain Fund of financial resources necessary for solving socio-economic problems at a particular level of the country's budget system. The amount of the revenue part of these funds must correspond to the size of the expenditure part. If there is a lack of own revenue resources of the budget of a certain level to cover the amount of expenditure obligations on the basis of inter budgetary relations its level is leveled in order to achieve the necessary balance.

The essence of the stimulating function of inter-budgetary relations is to create a certain incentive for regional and local authorities to increase the tax potential and increase the revenue part of the budget of a particular level of the country's financial system.

The leveling function is one of the main functions of inter-budgetary relations, which is aimed at achieving their main goal. Through the implementation of the leveling function, the necessary level of budget balance is achieved by replenishing its revenue part from the higher-level budget.

The distribution function is in some ways similar to the leveling function of inter-budget relations. The main goal of implementing the distribution function of inter-budgetary relations is also to achieve a balanced budget for a particular level of the country's financial system. The implementation of this goal is carried out within the framework of the distribution of financial resources between the links of the financial system.

The compensation function of inter-budgetary relations is related to the implementation of procedures for compensating lower budgets from higher budgets for expenditures on the organization of public administration and solving socio-economic problems.

The regulatory function of inter-budgetary relations is at the heart of the implementation of the policy of budget alignment for the qualitative solution of socio-economic problems in a particular territory of the country.

Conclusion

Thus, we can conclude that inter-budgetary relations are a key tool for achieving the necessary level of balance of budgets at different levels of the country's financial system, including the regional budget. The concept of budget balance is a key concept in the overall budget process management system at any level. The formation of a balanced budget is the main goal of the government's activities at the Federal, regional and local levels. The principle of budget balance is the main principle of the country's budget system, since if this principle is not observed, the entire mechanism of budget management is fictitious. Achieving the necessary level of budget balance is essential for the normal and stable functioning of all authorities at various levels of government. In the most General form, inter-budgetary relations are a generalized model of financial and legal interaction between public administration bodies at various levels of the budget and financial system within the framework of the budget process. The main goal of building inter-budgetary relations is to achieve the necessary level of balance of the country's budget system as a whole and the specific budget of a certain level of public administration,

in particular. Achieving this goal is carried out with the help of inter-budget transfers, which are aimed at replenishing the revenue part of the budget of a particular level.

Abstract

This article is devoted to the study of a new form of state financial control – internal financial audit and the practice of its implementation at the level of constituent entities of the Russian Federation. The article analyzes the changes made to article 160.2-1 «Budgetary powers of individual participants in the budget process to organize and implement internal financial audit» and came into force on January 1, 2020. The article draws conclusions and defines three main models for organizing an internal financial audit in the constituent entities of the Russian Federation: in the form of empowering one or more (two to three) officials of an executive authority, a subdivision of an executive authority (department, management) and in the form of a transfer of authority to conduct an internal financial audit to one of the subordinate institutions.

Keywords: Budget, Budget Legislation, Financial Control, Public Audit, Internal Financial Audit.

Introduction

From January 1, 2020 article 160.2-1 of the Budget Code of the Russian Federation (hereinafter BC of the Russian Federation) «Budgetary powers of individual participants of the budget process to organize and implement internal financial audit» came into force all changes adopted in 2019 [2]. It should also be noted that in 2019, section IX of the BC of the Russian Federation, devoted to state and municipal financial control, was significantly changed.

Results

One can agree with the view of I.I. Kucherov, N.A. Povetkin, and N.E. Abramova (2016), that at present «the main obstacle to the development of domestic financial control in Russia to date has been the imperfections of the legal and regulatory framework. First of all, there was no clear legislative distinction between the concepts of internal and external public audit, internal financial audit and internal control, as well as a link between departmental financial control and internal control».

It should be noted that the internal financial audit (hereinafter VFA) appeared in the BC of the Russian Federation as early as 2013 together with the adoption of the new federal law «On the accounting chamber of the Russian Federation», but only in 2019 the regulatory legal acts clarifying its implementation, which entered into force on January 1, 2020, were developed and adopted. These normative legal acts were adopted in accordance with the Program of development of federal standards of internal financial audit for 2018-2020 in the Ministry of finance of the Russian Federation approved in 2018 (approved by the Ministry of finance of the Russian Federation on 14.11.2018).

According to this program, 9 Federal standards of internal financial audit should start working in 2020: «Definitions, principles and tasks of internal financial audit»; «Grounds and procedure for organizing internal financial audit»; «Rights and obligations of officials and employees in the implementation of internal financial audit»; «Planning, determining the scope of work and forming an audit program»; «Conducting internal financial audit»; «Implementation of the results of internal financial audit»; « Confirmation of the reliability of budget reporting»; «Preparation of proposals to improve the economy and efficiency of the use of budget funds»; «Procedure for transferring authority to perform internal financial audit».

At the time of preparation of this article, the following federal standards of VFA – «Definitions, principles and tasks of internal financial audit» were approved (The order of the Ministry of Finance of the Russian Federation of 21.11.2019 № 196n «About the approval of the federal standard of internal financial audit «Definitions, the principles and tasks of internal financial audit»); «Grounds and Procedure of Organization, Cases and Procedure of Transfer of Authority for Internal Financial Audit» (The order of the Ministry of Finance of the Russian Federation of 18.12.2019 № 237n «About the approval of the federal standard of internal financial audit "The bases and an order of the organization, cases and an order of delegation of power on implementation of internal financial audit»); «Rights and obligations of officials (employees) in carrying out internal financial audit» (The order of the Ministry of Finance of the Russian Federation of 21.11.2019 № 195n «About the approval of the federal standard of internal financial audit «The rights and duties of officials (workers) at implementation of internal financial audit»).

Thus, in accordance with article 160.2-1 of the Budget Code of the Russian Federation dated 31.07.1998 № 145-FL, the VFA is a special activity to form and provide management with the necessary information on the results of the assessment of the performance of budgetary powers, Including conclusions on the reliability of budget reporting, as well as proposals to improve the quality of financial management, Including on improving efficiency and cost-effectiveness in the use of budgetary resources, Conclusions on the results of execution of decisions aimed at improving the quality of financial management.

That is, if the system of internal financial audit is created in the structure of the executive authority of the subject of the Russian Federation, being a participant in the budgetary process, the official, unit or agency, Which are empowered to carry out an internal financial audit, shall provide the head of the executive authority with information on the work of the structures of the authority, responsible for the implementation of budgetary powers, to analyze the organization of mechanisms for the implementation of these powers and to submit proposals to the head to improve the budgetary activities of the executive power body of the subject of the Russian Federation.

In this regard, it is important to emphasize that the requirement for the compulsory organization and implementation of the WFA does not consider the peculiarities and capabilities of individual executive bodies (their structure, staffing, existence or absence of subordinate institutions, etc.).

So, who can within the structure of the executive branch be empowered to implement the VFA.

First, the power to exercise the VFA may be vested in an individual official of the executive branch (or several officials who, by order or order, report to him).

Questions that may arise in this regard: what level should this official be (from among the leadership or non-leadership of the executive body (the leader or one of his deputies). An important requirement for such an official should be that he/she should not be given powers related to budgetary and other financial relations, such as approval of the state assignment by subordinate institutions and/or acceptance of reports on the execution of the state assignment, etc. Otherwise, the said official will analyze his/her own activities in the framework of the internal financial audit. However, it should be noted that in certain executive bodies of the constituent entities of the Russian Federation there is one deputy acting as head in case of his absence. If the VFA is carried out by the manager himself, who will carry it out by the VFA if he is absent. In any case, it is necessary to amend the job descriptions of

the relevant officials to indicate the authority to implement the VFA. Moreover, it is necessary to identify officials who will issue documents on VFA (action plan, reports and acts on the results of these measures).

Secondly, a division of the executive authority (referred to as a subject of the VFA and approved by an order or order of the executive authority) may be empowered to implement the VFA. As a rule, in many executive bodies, the decision to give anyone the power to implement the VFA is made according to the principle, If it is a financial audit, it should be implemented by entities performing financial functions, which is fundamentally not true, as it is these structures that are directly involved in financial and economic activities and, first of all, their work will be included in the subject of the VFA study. This is the financial management specified in clause 2 of article 160.2-1 of the BC of the Russian Federation, which was introduced by Federal Law №199-FL of 26.07.2019.

Third, powers may be transferred by an executive authority to one of the subordinate institutions and another entity, which must also be issued by an order or order of the executive authority or other regional normative legal act. In this regard, there may also be an error in which such a body is a central accounting office, which is involved in the execution of the budget and the verification of its activities is also within the framework of the WFA and reports to whom it will check within the framework of the WFA. The law also provides that the budget administrator has the right to transfer the authority to implement the VFA to the chief budget administrator under his authority, or to another budget administrator under the authority of this chief budget administrator, in accordance with the federal VFA standards. The VFA Standard «Grounds and procedure of organization, cases and procedure of transfer of powers to carry out internal financial audit» defines the conditions for transfer of these powers, such as: there is no possibility or necessity to form a subject of VFA; there is no possibility to conduct VFA in a simplified manner.

It is important to note that article 160.2-1 in paragraph 3 establishes the principle of functional independence of structural subdivisions or in cases provided for by federal standards of the VFA, authorized officials (workers) of the chief manager of budgetary funds, the administrator of budgetary funds, the given authority on implementation of internal financial audit, and in cases of transfer of powers to them on implementation of VFA - structural divisions or authorized officials (workers) of the chief manager of budgetary funds (the administrator of budgetary funds) to whom the specified powers are delegated. Moreover, it is necessary to consider anti-corruption legislation in the organization of the WFA.

Also, the standard of the VFA «Grounds and procedure of organization, cases and procedure of transfer of powers for implementation of internal financial audit», which was approved by order of the Ministry of Finance of the Russian Federation No. 237n of 18.12.2019, provides for the possibility of implementing the VFA in a simplified form in case: there is no possibility to create a subject of the V; Transfer power to implement the VFA; head of budget chief administrator (s) performs operations (actions) to implement budget procedures; There are no subordinate budget administrators; there are no subordinated budgetary, autonomous institutions and state unitary enterprise (municipal unitary enterprise).

Conclusion

In general, in summary, it can be concluded that at present Russia is only forming the main approaches to the organization of internal financial audit in the executive authorities, both at the federal and regional levels of government. At the same time, it is important to understand that in relation to the regions, even the proposed model cannot be fully implemented due to the lack of conditions in all executive bodies of the constituent entities of the Russian Federation for the implementation of an effective model of internal financial audit. The options proposed in the standard for a simplified system of internal financial audit organization can only be temporary, as they do not allow to build a normal methodology of work.

Developing E-Business Competences A Challenge for Economic Universities in Poland

Kinga KRUPCAŁA
UTP University of Science and Technology, Bydgoszcz, Poland, e-mail: kinga.krupcala@utp.edu.pl

Dorota KUREK
War Studies University, Warsaw, Poland, e-mail: d.kurek@akademia.mil.pl

Abstract

Higher education institutions, especially those with an economic profile, not only in Poland, but also worldwide, are currently facing a huge challenge, which is to make changes in the curricula in response to the labour market needs. The dynamic development of the e-economy causes that there is, currently and in the future, a constant increase in market demand for employees with e-business competences. The development of these competences will allow for equipping university graduates with skills and knowledge which will be their advantage on the labour market. With the above in mind, this article makes e-business competences, which should become a part of curricula at universities, the subject of research. The authors of the article presented the results of theoretical and empirical research, which allowed to identify key competences of e-business. By referring to domestic, foreign reports, such as the results of own research using the method of diagnostic survey, it was confirmed that the key competences in the field of e-business include building websites and e-shop by using, among others, WordPress, as well as many other modules used for complex construction and administration of websites.

Keywords: E-Business, Digital Competence, Universities, CMS, Wordpress, Management

Introduction

The e-economy is nowadays considered to be the fastest growing market sector. Digitalisation of business activity connected with technological development, change of customers' purchase preferences, accessibility to the Internet and possibilities offered by the use of modern technologies is becoming a driving force for modifications, including changes in the labour market and educational challenges, connected with the necessity of both anticipating future competence requirements and the dynamics of these needs and possibilities of meeting them, which is confirmed, among others, by Daniel E. Hecker emphasising that *Electronic business both stimulates and dampens employment in many occupations and industries* (Hecker, 2001:3).

The professional competences of the future are a constant object of interest for both theoreticians and management practitioners, including representatives of sociological, pedagogical and psychological sciences. The challenges to be faced in the labour market in the future have, or at least should have a significant impact on the fields of study offered by universities. The adaptation of educational programmes to the needs of the labour market must result from the recognition of future market transformations and changes, not only the technological ones, but above all changes in the competences which should be available to young people after completing their education – the graduates who will be looking for their place on the national, European or global labour market. It can therefore be considered that the challenge of universities, especially those with an economic profile, is to prepare educational programmes (including the use of on-line learning) in such a way as to respond to the labour market needs of the future (Mehall, 2019). Some students do not improve those competences which would allow them to adapt to the requirements of the labour market more quickly. Therefore, the change of educational programmes is a challenge that not only Polish, but also foreign universities have to face.

With the above in mind, the aim of the conducted research was to identify e-business competences, which, due to the requirements of the future labour market, should be developed by students. The main research problem was formulated as a question: What e-business competences should become the subject of education at universities of economic profile in order to prepare students to meet the requirements of the future labour market? The research hypothesis took the form of the following assumption: in the process of education at universities, students should develop their digital competences necessary in e-business, such as: building websites and e-shop on one of the most popular CMS, which is WordPress, as well as many other modules used for complex website building and administration.

In order to respond to the main and detailed research problems, theoretical (including analysis of university curricula in Poland, e-commerce market research reports, etc.) and empirical methods were used. Among the group of empirical methods used, the method of diagnostic poll carried out using the survey technique is notable. The research was conducted in 2020 on a sample of 98 students. The results of the research were analysed with the use of Microsoft Excel, which enabled extensive data scrutiny.

Professional competences, competence mismatch and the labour market

Over the years, philosophers, psychologists, sociologists, as well as representatives of the management sciences have been paying attention to competence issues. The very term competence originates from the ancient Rome, deriving from the word *competentia*, meaning: compliance, suitability, readiness for something. Etymologically, the word is related to the English *compete – to struggle, to fight.* A competent person was considered to be someone who was ready to carry out certain activities, including the decision-making process (Filipowicz, 2014). The issue of competence was transferred by R. Meyer from the sphere of philosophy to the sphere of practical considerations in his 1782 work on the competence of entrepreneurs and traders (Meyer, 1782). The key work in the area of competence, however, was the article by D. McClelland from 1973 entitled *Testing for competence rather than for intelligence*, in which the author emphasised that it is competence that determines the quality of an employee and her/his functioning on the labour market (McClelland, 1973). R. Boyatzis also paid special attention to the issue of competence; he is known, among others, for distinguishing three levels of competence: a relatively stable level of motives and personality traits, a modified level of social roles and the fastest modified level of skills (Boyatzis, 1982). R. Boyatzis' model is described in detail in his publication *Competence at work*:*The model for Superior Performance* was presented by L. M. and S. M. Spencer. This publication is considered by many scientists as a key work on competences (Spencer and Spencer, 1993).

However, particular interest in the issue of competence does not translate into the definition of homogeneity of the term under consideration (Rozhkov et al. 2017), which results in the possibility of identifying, among others, supporters of identifying competence with the skills or abilities necessary to perform tasks in a given organisation (Filipowicz, 2004), combining competence with personal qualities (including motives, attitudes, values), knowledge and procedural (Sidor-Rządkowska, 2006) skills and showing competence as a result of permanent internal predispositions, as well as features acquired during human life (Filipowicz, 2004).

In this article, the term competence has been adopted after R. Boyatzis, who emphasises that it is: *an underlying characteristic of an individual, which is causally related to effective or superior performance in a job' and as 'a motive, trait, skill, aspect of one's self image or social role, or a body of knowledge which he or she uses* (Boyatzis, 1982:23).

The main reason for identifying competences is considered to be, inter alia, the determination of standards of behaviour in the workplace (Yonghak, 2009) resulting from the possession of specific competences (Crowl, 2007), as well as the indication of competence requirements resulting from the education and training of employees. The issue of competence requirements of employees – prospective graduates should be given special attention by universities, whose faculties should be modified taking into account market changes, dynamics of development of particular sectors of the

economy, and thus also competence needs. The unfavourable situation from the perspective of the labour market is the situation in which employees with a competence mismatch operate on the market, which in turn affects labour productivity and wages (Badillo-Amador and Vila, 2013; Sam, 2018; Gambin et al., 2016; Montt, 2015).

The E-Economy and the Labour Market

One of the most dynamically developing sectors of the economy is the electronic economy. The e-economy is a term that has become widely used, together with the terms e-business and e-commerce. E-economy is defined by A. Hartman as a virtual arena where business is conducted (Hartman, 2001). On the one hand, it is an alternative market to the traditional one, while others consider it a complement to the traditional one. Within the e-economy, it is worth paying special attention to e-business defined as electronic business, i.e. business based on the use and adaptation of modern technological solutions to the needs of market practice (Deshmukh, 2019). One of the processes carried out in the e-space is e-commerce, defined as e-commerce. The relation between the indicated terms can be presented as follows: e-commerce < e-business < e-economy (Gregor and Stawiszyński, 2002) however, in the American literature e-commerce and e-business are used interchangeably and this approach is also presented by the authors of the article. The development of the e-economy has a huge impact on the whole market by transferring some or all of its activities to the virtual world, including activities encompassing: presentation of products and services (and thus brand building), order processing, product service delivery, payments, promotions, settlement of mutual transactions, contacts with customers, suppliers and issuing invoices.

Information about the size and value of the e-commerce market in the world can be found in eCommerce Report 2020, at statista.com. According to the report: revenue in the e-commerce market amounts to US$2,237,959m in 2020 and is expected to show an annual growth rate (CAGR 2020-2024) of 7.6%, resulting in a market volume of US$3,004,191m by 2024. The value of the market in Poland is estimated at US$11,249,4m (eCommerce Raport 2020). However, taking into account both current data and forecasts for the coming years, it should be noted that with the development of the e-market, there are also significant changes in the competence requirements, which must be at the disposal of both the employees who want to relate their future to the indicated industry, as well as entrepreneurs themselves, who face the need to digitalise their business (which is related to, for example, the choice of an e-commerce platform supplier, the ability to use the potential of marketing automation, creating their own website, knowledge of ERP, CRM, cloud applications, or B2B, B2C, B2G e-commerce models, etc.).

Supporting the traditional form of sales by means of, for example, a website, using social media in the process of brand building, applying interactive forms of communication to create personalised products, using the potential of mobile payments, popularising Voice Commerce solutions, as well as increasing the awareness of both organisations and customers of the dangers associated with e-business, are challenges faced by the modern e-economy, and at the same time a great opportunity for many entrepreneurs.

E-business competences as competences of the future

The willingness to use modern information technologies forces organisations to look for employees with specialist competencies on the labour market. Therefore, dynamic changes taking place on the market translate into the competence needs of modern and future organisations, which is shown in many reports such as: *Future Work Skills 2020* and *The work of the future: Shaping Technology and Institutions.*

The Future Work Skills 2020 report was prepared by the Institute for the Future for the Phoenix University Research Institute. According to the report, the competence needs of the future are a result of, among others, the following extreme longevity, rise of small machines and systems, computational word, new media ecology, the rise of superstructed organisations and globally connected world (Future Work Skills 2020). The willingness to maintain competitiveness therefore

requires looking for employees on the market with such competences as: sense-making, social intelligence, novel &adaptive thinking, cross-cultural competency, computational thinking, new-media literacy, transdisciplinarity, design mindset, cognitive load management and virtual collaboration (Future Work Skills 2020).

In turn, according to the report *The work of the future:Shaping Technology and Institutions*, it is worth noting that: New technologies often enable or require new tasks that demand human expertise, judgement, and creativity (The work of the future...). The authors of the report, referring to the publication of David H, however, emphasise that new technologies do not affect the changes to the same extent in organisations, especially with regard to jobs located lower in the organisational structure, as well as those related to broadly defined services. Ironically, digitalization has had the smallest impact on the tasks of workers in low-paid manual and service jobs. Those positions demand physical dexterity, visual recognition, face-to-face communications, and situational adaptability. Such abilities remain largely out of reach of current hardware and software but are readily accomplished by adults with moderate levels of education (The work of the future...; Autor, 2015). However, the development and increasing use of automation, robotics, and artificial intelligence influences changes in competence requirements. Despite the common view that robotisation will radically reduce the number of workstations, it is worth pointing out that currently man and robots/systems complement each other, while the increase in the scope of robotisation, automation of AI use entails the necessity of including digital competences in competence profiles.

The importance of digital competences in the future is also stressed in the report *Competences of the Future. How to shape them in a flexible educational system?* E. Włoch and K. Śledziewska (2019) point out that in the conditions of the digital transformation, in addition to cognitive competences and social, digital and technical competences are also becoming important. From the research shown The report, carried out in 2018 and 2019 in seven Polish cities on a sample of 1062 students and graduates, shows that in the opinion of nearly half of the surveyed universities allow to acquire the skills of using digital programmes and tools only at a basic level, and one in three respondents was of the opinion that they do not teach these competences at all. The above results in the context of needs and challenges of the 2030 market related to automation and robotisation, including the intensification of implementations using Artificial Intelligence (AI) will cause that: *In the perspective of 2030, success in the professional career of employees will be strongly conditioned by the level of their digital competences. A low level will be associated with the risk of a weak position on the labour market and low wages. The high level will be a guarantee of competitiveness on the labour market, employment security and the highest salaries* (Głomb and Kniaź, 2019:26-27).

Within the framework of key digital competences, special attention needs to be paid to: planning, implementation, use and evaluation of effectiveness of digital solutions in business applications, programming and development of systems/tools used in e-commerce, application of national and EU law in the area of digital solutions, as well as use and development of the potential of existing IT tools, including social media in the implementation of professional tasks. Future will bring an increased labour market demand for jobs such as: e-Commerce Manager, Key Account Manager, Digital Marketing Manager, CRM Manager, Digital Brand Manager, CRM analyst, SEO specialist, SEM specialist, having competences in: social marketing, content marketing or e-mail marketing.

Previous e-business education at universities in Poland

The popularity of e-business and the increasingly dynamic growth of companies of this type (A big overview of E-commerce…) make the aforementioned professions already popular. Poland is the fastest growing European country in e-commerce (Bartczak, 2016). Pure IT or managerial competences are becoming insufficient for future employers. The combination of these two directions in the era of broadband Internet and 5G communication is in a way an obligatory element of the employee's profile. In order to meet the requirements of the market, universities are somehow forced to adapt their curricula in this area, create new subjects or even entire fields of study or areas of expertise (such as Business Informatics, E-commerce, E-business). This does not mean, however, that these curricula, apart from the name of the subject, have adapted their teaching content and thematic

range to the competences actually needed in the labour market. The greatest challenge is faced by universities with an economic profile, which while teaching management or related subjects (such as management and production engineering, management and marketing, etc.), seem not to see the need to teach the practical dimension of such a dynamically developing branch of the economy.

The above observation is the result of research conducted for the purposes of this article, which consisted in the analysis of curricula at 22 faculties of economic universities related to e-business (i.e. University of Science and Technology in Bydgoszcz [UTP], University of Rzeszów, Częstochowa University of Technology, Maria Curie-Skłodowska University in Lublin, University of Warsaw, Krakow University, Collegium Civitas, University of Szczecin, Warsaw University of Technology, University of Gdańsk, University of Łódź, Nicolaus Copernicus University in Toruń, University of Economics in Wrocław, The University of Science and Technology in Wrocław, University of Science and Technology [AGH], University of Zielona Góra, University of Warmia and Mazury in Olsztyn [UWM], University of Social Sciences in Łódź [SAN], University of Economics in Katowice, Warsaw School of Economics), as well as getting to know students' opinions on the programme implemented at the University of Science and Technology in Bydgoszcz as regards its usefulness for future work and the skills acquired.

According to the research into syllabuses, e-commerce/e-business is quite a popular subject in economics studies at both public and non-public universities in Poland, but one can also find such a subject in fields related to information technology (e.g. Krakow University), and even typical humanities such as journalism (University of Warsaw, CMS and sites navigation). Recently, one can also make use of special, dedicated e-business courses (e.g. Warsaw School of Economics, University of Economics in Katowice). However, the popularity of the subject, major or course does not translate into a practical dimension of teaching, which from the point of view of e-commerce becomes a key competence for future work. Out of 19 universities (22 fields of study), only about half (53%) conduct classes in the form of labs (computer work), of which 6 universities work on the currently most popular CMS market – WordPress (Netcraft). However, from this list of universities, IT faculties need to be subtracted, as a result of which only 2 schools (UTP in Bydgoszcz and Collegium Civitas – an optional subject after gathering an appropriate number of applicants) teach practical e-business (building websites and Internet shops) to students of economics. Some universities use HTML language to transfer knowledge, which, however, is too difficult for management students and does not give the opportunity to learn how to create an extensive website, especially within 30 or 15 teaching hours. The results also indicate that universities do not have the knowledge about the popularity of WordPress in the world and the number of websites built on it, or the possibility to work in an attractive profession with new competences.

Doubts about the content of learning also arise from the fact that 21% of the surveyed entities (e.g. University of Szczecin, Gdańsk or Łódź) devote 15 lesson hours to lab classes (which significantly reduces the amount and quality of knowledge transferred), during which students do not have classes in the form that would indicate the name of the laboratory (Jak wyglądają…)[i] During them, they have case studies to solve, make PowerPoint presentations on e-business or small group projects. Even universities, which allocate 30 hours each to laboratories (e.g. UWM in Olsztyn) often do not use the time given to them for comprehensive, practical learning of e-business.

However, the number of approaches to teaching e-business is much higher. For example, universities such as the Nicolaus Copernicus University in Toruń or Wrocław University of Economics have given up all the forms of exercises or laboratories whatsoever and the subject is conducted only as a 30-hour lecture. On several occasions, the syllabuses also included an information that during the classes the students carry out a theoretical project of creating a company operating in the e-commerce sector, build a business plan, prepare and analyse company documentation. According to the syllabuses, it is also possible to conduct 30 hours of e-commerce in the form of auditory exercises (subject "management in e-business", AGH), although the authors cannot imagine what such a form of classes has in common with computers, the Internet and e-shops. Several universities try to use Customer Development methodology[ii]. This concept, however, mainly refers to building start-up

companies. The authors of the syllabus (e.g. AGH) had to assume that e-business is every start-up that is created, which seems to be an exaggerated hypothesis.

Therefore, it should be borne in mind that the specificity of organisations operating in the network is different from traditional companies. Also, the multitude of projects based on business plans or analyses of the functioning of companies through all the years of studies in economics cause that the e-business classes conducted using one of the above methods do not stand out from other management classes and do not contribute to the acquisition of new skills useful in future work.

Changes in The Profiles Of E-Business Education at Economic Universities

A poll conducted in January 2020 (using a survey questionnaire technique) on a group of 98 students[iii] of the Faculty of Management of UTP in Bydgoszcz[iv] (including 41 women and 53 men) confirmed that new professions, such as digital manager, are now needed in the labour market and students are already aware of this. 25 people from each group (women and men) admitted that this profession is highly sought after by employers. Only 3 people (2 women and 1 man) considered that it is not a future-oriented occupation (Fig. 1).

Fig. 1: The answer to the question whether the profession of digital manager is sought after on the labour market (in %)

In each profession it is possible to define a competence profile. In the case of positions such as the above-mentioned digital manager or e-commerce front-end developer, digital marketing consultant, e-commerce country manager, the ability to build a website and e-shop becomes one of the basic skills. However, we are still talking about the manager, i.e. the person in charge, and not the IT specialist who runs a website using typical technical skills. Particularly, in companies from the SME and micro-businesses sector, it can be seen that an employee should know not only how the website, slider or any marketing element should look like, but most of all, he or she must be able to create and modify it according to the needs. Organisations expect their employees to be independent in their actions and not to involve a staff of people to help (in this case computer scientists, graphic designers, etc.) in some aspects of their work. That is why economic universities should prepare for this type of work. Not every graduate will join the ranks of a corporation with more possibilities of technical support in everyday work. Therefore, the research asked whether practical classes based on CMS WordPress should take place at universities with economic profiles at all. According to the survey, as much as 79% of the respondents are of the opinion that they need such classes and they should be present not only in IT studies, but also in management studies. 15% are indecisive, while only 6% of respondents believe that they do not need such a subject.

During the classes at the University of Science and Technology in Bydgoszcz, students learned not only the general structure of the site, but also its individual elements (the list of all modules is shown in Fig. 2).

Fig. 2: Which of the listed WordPress tools you know and can easily use

The results indicate that such detailed, thirty-hour laboratories have resulted in a comprehensive knowledge and ability to independently reconstruct each taught component of the site and shop. The results on a scale of 80-90% of the knowledge of a given module also allow us to deduce the level of involvement in the classes (both the teacher and the participants, as shown in Fig. 3). The greatest difficulty (40% of respondents) was caused only by the modification of the sidebar, which was due to the fact that this issue was only partially addressed when modifying the footer. Apart from the skills listed below, the students received a majority of other, practical tips and learned how to optimise the pages for SEO, which was not included in the survey.

Fig. 3: Aspects of practical e-business activities positively assessed by the respondents (in %)

During the research, students were also asked what they liked the most during the classes (Figure 3). The respondents indicated, among other things, the possibility of gaining completely new skills and experiences (31.8% of the respondents). The fact that it is possible to later include the acquired competences in the CV, and thus make the employee's profile more attractive, did not escape the attention.

The acquisition of new competences already during classes at the university also broadened students' thinking horizons regarding their future work and generally gave them the opportunity to participate

in the recruitment process for positions they did not know about or which they thought were "reserved" for IT graduates. Figure 4 shows that although 56% of the respondents do not yet know whether they will use their knowledge in the future, as many as 19% (including as many as 12 women and 6 men) declared that this is something they would like to do in the future. In turn, 20% of the respondents will use the acquired skills at the moment when they decide to start their own business.

Fig. 4: Usefulness of the ability to build websites on WordPress and their administration in future work in the opinion of the respondents

Summarising the presentation of research results, it can be seen that the development of key e-business competences for the modern labour market by economic universities significantly affects the development, experience and skills of the students. It also gives a chance to take up employment in new professions sought after by companies, such as digital manager.

Conclusion

Taking into account the results of theoretical and empirical research, it can be unequivocally stated that the research hypothesis put forward has been verified in its entirety positively. Digital competences do not have to, and should not even be a purely IT domain, but should primarily concern managers who, thanks to the skills already acquired during studies, will be better prepared for their work. Due to its specificity, e-business must be considered in a completely new way. It results from the way the company is managed, its structures, information transfer models, communication when using advanced IT systems. All these elements make these organisations significantly different from traditional companies. Therefore, it is also impossible to teach about e-commerce in an equally traditional way. Since the activity of the whole company is based on the Internet, it seems logical that universities should educate on the basis of this network, as well as prepare the future employee to the requirements and expectations of the market. Only in this way they will give the opportunity to take up employment in new, sought-after professions or run their own business (reduction of initial costs).

Turquoise Management Model - Teal Organizations

Małgorzata RUTKOWSKA and Anna Maria KAMIŃSKA

Department of Management and Organisation, Faculty of Computer Science and Management, Wroclaw University of Science and Technology, Wroclaw, Poland

E-mail addresses: malgorzata.rutkowska@pwr.edu.pl, anna.maria.kaminska@pwr.edu.pl

Abstract

The article is devoted to new concepts and management methods. In this paper, the management of the turquoise management model has been analysed. Modern management methods in companies promote self-organization, trust, strong teams and a departure from the directive management method. Therefore, this article examines the management of the turquoise management model. Management colors were discussed according to Frederic Laloux, creator of the turquoise management model. The next part of the article analyzes new ways of communication between people and ways of organizing enterprises. What's more, the role of self-discipline in the implementation of turquoise in the organization was emphasized and the basic differences in organizational structure were compared to traditional structures. Turquoise Management Model can be the future of management. It is not easy to implement it to organisation that already exists, but it is possible.

Keywords: Colourful Management Models, Teal Organizations, Turquoise Management Style, Self-Management

"Could we invent a more powerful, more soulful,
more meaningful way to work together,
if only we change our belief system?"
Frederic Laloux

Introduction

The new organizational model is a result of a new way of cooperation. The approach to the world has changed over the centuries and both moral and cognitive and mental abilities among employees and managers have changed (Sus and Organa, 2019). This resulted in new cooperation and, what follows, a new organizational model. Next to the perception of the business ecosystem and there was a change in coexistence with a natural environment and shift from brown to the green economy (Sulich, 2018). The democratic attitude and shared vision and strategy are visible in each economic sector worldwide – among then it is possible to indicate both a new style or type of management (Sulich, 2019).

Currently, traditional management methods are becoming inadequate for the conditions in which enterprises operate. What is more, traditionally managed companies usually talk about the so-called "carrot and stick" method, i.e. a remuneration system based on bonuses and commissions (Stańczyk-Hugiet and Niemczyk, 2012). Striving for development and what to do to increase our goals and success, acting consciously and not blindly has become a priority. Then a new management model has been developed. It is a so-called turquoise organization.

The turquoise color applied refers to the nomenclature used in the integral theory of the American sociologist Ken Wilber (Wilber, 1999). He is associated with the theory of satisfying needs (Pietrzyk, 2016). There is no hierarchy of power in this type of management style. What is more, the place where the commands are issued takes independent decisions. This is done according to the following rule: everyone can take any decision if he takes responsibility for it and nobody reports a firm veto

(Eichelberger, 2017). As wrote Ziębicki *"A turquoise organization is a broad concept of creating an organization based on self-management in which, thanks to values, trust, cooperation, partnership, and the creation of self-fulfillment opportunities, we succeed in achieving effects that were not achieved with the traditional, hierarchical management model*" (Ziębiecki, 2017).

Turquoise is the name that describes the Seventh Level of Consciousness, the so-called free unit. If a man has reached this level of consciousness, he means that (Dębowski,2016):

- His worldview is open, tolerant and expects the world, including the company, partnership, and work-life balance.
- He wants to work to develop himself and pursue his passions. He wants to be flexible, overcome different challenges, exchange with other tasks.
- Money does not count for him, but self-fulfillment, honesty, authenticity.

In a turquoise organization, a well-developed system of motivating employees is the result of partnership and cooperation. Let's take a closer look at him.

Stages of Development of Colourful Organisations

Laloux used the theories of such thinkers as Robert Egan and Ken Wilber to study companies and use colors to designate different types of organizations (Web-1). In his book titled "To Work Differently", Frederic Laloux describes the development of an organization from the point of view of the development of human consciousness (Fig. 1). Management colors range from red, amber, orange, green to turquoise.

Fig. 1: Frederic Laloux and the colors of the organization (Based on: Web-6)

The characteristics of each of these management models are presented below (more in: Laloux. F., 2014):

- Red color - this style dominated in Antiquity. Currently, it is an anachronistic style and it is rejected by most managers. this style is characterized by forcing obedience. Punishment and fear are the foundation of this style.
- Amber color - the basic features of this style of management are the hierarchy and subordination and compliance of employees with precisely described procedures. The form of motivation in such a management culture is the so-called the "carrot and stich" model.
- Orange color - this style is characterized by a hierarchical structure that remains open to promotions and all other autonomous forms of organization. In addition, the management of the organization makes sure that all goals are effectively implemented by the lower levels of the organization.

- Green color - this style focuses on maintaining harmony and a sense of community within the organization. What's more, the hierarchy in the company is preserved, although many decisions are made at lower levels.
- Turquoise (Teal Organizations) **-** the most modern management style. It is a holistic concept of perceiving a man with all his needs. What matters here are not only professional needs, but also private needs. What's more, the work must on the one hand provide for life and be a stay to be proud of, on the other. Frederic Laloux characterizes this style as follows: "When we act in deep honesty and respond positively to the vocation we feel in us, the universe does everything to help us."

It should be emphasized that the last hierarchical style is green. The four management styles are governed by democratic decision-making rules, and the leading values are equality, freedom and justice. Turquoise organizations are destroying the current model of the world and reversing the order of things (Web-8).

Now is also the time to start promoting values, ideas and business models from a different level of consciousness on a wider scale. Turquoise is a term describing the 7th level of consciousness, a so called 'Free Individual'. If someone achieves that level, it means that their worldview is open, tolerant and expects partnership and work-life balance from the world and/or the company he works for. What is important, therefore, is personal fulfillment, honesty and authenticity. This approach guarantees high flexibility of action and a fast rate of change that leads to efficiency (Web-9).

This awakening, in turn, creates a new, fuller vision of the world. It begins to take the place of our lasting over five hundred years of preoccupation with the problems of survival and making life more comfortable. Although this technological approach was an important step in the development of civilization, it is only a spiritual awakening to coincidence that opens us to understanding the real purpose of human life on this planet and the true nature of the universe (Redfield, 2009).

The basis for the functioning of the turquoise organization is the belief that employees are willingly involved in various tasks, and the roles they assign themselves are connected to their individual skills. They choose work in a given organization because they feel good in it. Turquoise organization does not have a job stand but functions. The change of function takes place as a result of the evolution of the ability or is a result of the will to try something new. When we look at management it this kind of organisation we need to be aware of the difference between self-management and self-organization.

Self-management is associated with issuing orders by the manager and controlling their performance. In turquoise organizations we are dealing with team-making decisions on the division of tasks, not with team-issuing commands, so it is rather "self-organization" than "self-management" (Blikle, 2016).

Taking the above into consideration, the key differences between colours have been shown in Figure 2.

Guiding methaphor	Key breakthroughs	examples
	RED	
Wolf pack	Division of labor Command authority	Street gangs Tribal militias
	AMBER	
Army	Formal roles Stable, replicable process	Military Catholic Church goverment
	ORANGE	
Machine	Innovation Accountability	Multinational companies Investment banks
	GREEN	
Family	Emprovement Stakeholder model	Businesses known as idealistic practices
	TEAL	
Living organism	Self-management Evolutionary purpouse	A few pioneering organisations

Figure 2: Key differences between colours (Based on: Web-7)

Organisation without a boss

In the traditional approach of the enterprise, the main responsibility for the functioning of the organization lies with the manager/leader, that is characterized by several attributes as creativity, responsibility, charisma, openness, ability to cope with difficult situations, and a kind of stubbornness in pursuing goals. Nowadays a leader (or CEO) should have also emotional intelligence as it can ensure effectiveness (Azouzi,2003).

Traditional management methodologies place a strong emphasis primarily on planning and controlling the implementation of the plan. Modern approach focus on the relationships between team members, dynamic planning, continuous value delivery to the client, actual measurement of work progress and value elements produced. Good communication requires a strong emphasis on personal elements and understanding of organizational roles (Kopczyński, 2014). In the literature there are different classifications of managerial roles. Szczepanik (2009) distinguished the most commonly accepted managerial roles: firefighter (extinguishing fires and doing everything at once), democrat (supporter of collective decision-making), bureaucrat (caring for rules, regulations and order), autocrat (independently deciding and manager) and an advocate of participation and delegation.

The best way to manage modern society is through developing a “systems thinking” capability, as organizations operate in a zone between stability and predictability on the one hand, and chaos and unpredictability on the other (Van der Merwe., 2007). Additionally in modern organization each person must have the skills to work as a team member, solve problems and make decisions, be creative and, above all, communicate effectively with others (Gillen, 2002).

As regards project management, it was stated that teamwork is one of the basic design characteristics. It protects the project from being identified only with one person. It causes that in one place and for one purpose different personalities, ideas, goals, skills, and sometimes nationalities meet. The project team must be selected so that it can deal with different types of situations and tasks. The project team must be effective in its operations (Haffer, 2009). Often, however, teamwork forces the eager manager through insistence and pressure, which do not take into account the realities that come into play (Morgan, 2001). However, this is not a good approach. It is a dislike for teamwork. The role of the manager / leader is therefore undermined.

At a time when team work is necessary, many managers forget about the importance of time spent alone with each of their employees (Buckingham, 2001), hence there is a need to change not only the style of management but also thinking.

The concept of turquoise organization (teal organizations) is based on the assumption that the effectiveness of activities is possible without a formal hierarchy, without a formal incentive system, thus self-regulation and self-management (Powichrowska, 2018). The basis for self-management is

the independence of employees, their autonomy. So where is the gap for such enterprises? Mainly in companies focused on dynamic development, operating in risk conditions, those in which flexibility and commitment are key success factors (Ziębicki 2017). However, there are many doubts, like (Powichrowska, 2018):

- Are people prepared for functioning in self-governing organizations?
- Are they characterized by self-discipline?
- Are modern managers prepared to act as leaders?

In traditional organizations, leaders are at the head of the teams (very large teams are divided into smaller ones - also with the leaders at the forefront). Leaders of smaller teams form a higher-level task team. Of course, such a hierarchy can have many levels. In the case of turquoise, there is no hierarchy or order. Connections occur between the units actually cooperating with each other, and the graphic presentation of such a structure may look almost chaotically (Fig. 3). One of the differences between such a structure is, above all, variability in time, because in the case of a classic structure - changes occur sporadically, and in the case of a turquoise organization – dynamically (Blikle, 2016).

Figure 3: Traditional (left) and turquoise (right) structure (Blikle, 2016, pp. 43)

Self-management can appear as an easy process, but it is not. It requires a set of interlocking structures and practices. The decision rights and power flow to any individual who has the expertise, interest, or willingness to step in to oversee a situation. The replacement of traditional hierarchy requires specific training. People should truly be themselves, and for some it is necessary to learn how to do it at work (Laloux, 2015).

Ryan and Edward L. Deci and Julius Kuhl (2017) and the team have drawn attention to the difference between self-regulation and self-control. Self-control was defined by them as a negative, authoritarian type of action control, based on coercion and pressure, with a repressive nature. Self-regulation, on the other hand, means democratic control. Traditional management concepts have focused on self-control processes related to coercion and commitment to take a specific action. Self-regulation refers to an activity that is consistent with internal standards (a system of values, preferences, needs), where one of the driving forces for the operation of individuals is the interest or value and importance of the goal (Ryan, 2017).

The turquoise organization achieves its effects thanks to: values, trust, cooperation, partnership, and the creation of opportunities for self-realization. The most important rules for creating turquoise organizations are (Blikle, 2016):

- implementation of important goals contributing to the change of the environment for the better;
- basing the organization on trust, responsibility and partnership;
- cooperation instead of competition,
- motivating through self-realization, identifying with the goals of the organization and participation;
- self-management based on autonomous teams instead of traditional prescriptive-control management;
- network process structures, instead of hierarchical systems.

Creation of a turquoise organization and self-management carries many risks, such as chaos, bureaucracy, fuzzy responsibility, instability, lack of a coherent vision of development, multiple roles and fragmentation of work or inadequacy of remuneration for the value of work.

But the most important advantages are: flexibility, reliability, commitment and motivation, sense of community, creativity, quick decisions, development of individual competences, efficient communication, process approach, results orientation (Ziębicki, 2017).

Teal Management in Poland

Turquoise organizations (teal organizations) can also be found in Poland (more can be found in Web-3). The first of them are companies from the IT industry, packaging manufacturers, kindergartens, producers of mineral waters, and internet portals dealing with booking doctor visits and others. It is easy to notice that each of the listed companies operates in a different industry. Therefore, whether the company is turquoise is not determined by the industries but by need. As entrepreneurs point out, employees engage in believing in company missions and the deeper meaning of their own work. It is due to the fact that the employees no longer feel like a part of a large machine but become the operator of this machine (Web-3).

A positive phenomenon is also the fact that entrepreneurs see the need for change, which results not only from the needs of the market but also from the needs of employees who need to be appreciated. The trust that such an employee should get is connected with power. Nevertheless, building such trust continues. It is necessary to be open and ready to admit an error. However, when the parties trust each other - teamwork is not only more efficient, but time and money are also saved (Web-4).

Turquoise organizations are still new in Poland. Not every company will be able to call itself turquoise, and those who will attempt to change the way of management needs a change in mentality. It will be surprising for employees that there is no bonus in the teal organization. There is, however, unlimited access to information. Everyone is responsible for raising their own competences and bearing the consequences of their own deeds. An obstacle in introducing turquoise into an organization may be a basic document such as a contract of employment which stipulates strictly a position according to the law, not a function and defines the scope of duties (Web-5).

Conclusions

By meeting the foregoing, the following conclusions shall be presented:

- There is no one good management style. What's more, you cannot say that one style of management is better than the other. Each style of management is well adapted to certain contexts and can deal with certain complexities.
- In order to change something and develop it is necessary to build a new model that will make the currently inactive model become obsolete.
- It is necessary to break the old management paradigm and adjust to modern needs.

Teal management is a challenge for the economies of the future. The idea is to remove aberrations in various types of organizations. It is obvious that turquoise structures cannot be implemented in every organization, but it is worth considering changing the rules when other measures to achieve success fail.

Abstract

The goal of this article is to present how to carry out processes of deployment CRM systems in internal client way. Monitoring is an important part of management principals. Managing of CRM systems requires continuous process of monitoring for most important system's parameters. In multi-org CRM systems implementing of monitoring tool is a crucial part of proper management process. There are repeatable parameters in all CRMs like licenses, limits, critical updates, test environments variables that should be aggregated in one place. Monitoring tool allows to use text, tables, graphs, diagrams to create dashboards alerting administrators and stakeholders in case of need. That helps to automate, eliminate human errors and optimize management processes in the system. Every preparation of monitoring tool is a project where the aim is automatizing and increasing quality of control processes. Monitoring tool should be developed, implemented on UAT – User Acceptance Testing – environment and then placed in production environment and improved with next releases. Most of IT projects focus on external client to deliver expected value. Aspects of managing and monitoring processes with internal client as important as processes with external customer and should be measure. Authors suggest a simple way to monitoring processes tied with CRM deployment and define important areas of measurement during such activities.

Keywords: CRM, System, Management, Monitoring

Introduction

Information systems support the most important processes occurring in enterprises. They are divided into classes: from basic accounting and transaction systems, through systems supporting material management, manufacturing processes, logistics, to integrated, complex information systems that support all the processes occurring in the enterprise [1]. One of those systems is CRM – Customer Relationship Management. The system reflects the CRM marketing concept, which puts the external and internal customer at the center of the company's marketing activities. The starting point in every process is the customer and customer information. It is gathered in databases. Information on an external client usually regards their shopping preferences, the frequency of placing orders, the time of delivery. Based on that information the system processes data in order to obtain information that allows to make a decision – be it marketing, business or strategic [2]. Nevertheless, CRM systems are mostly useful for all internal clients of the organization, who work on the collected data with the help of the system's interface. Data in the CRM system should be uniform and standardized, which means that good management practices of the CRM IT system should be used [3]. One of them is monitoring. Monitoring is one of the basic functions of management [2]. CRM management has developed specific methods for monitoring system performance in enterprises.

CRM System Elements Monitoring

Monitoring of the CRM system is especially useful for multi-org organizations in which more than one production environment used by end-users is managed. Monitoring can also be used in the case of sandbox test environments, on which functional development tests and so-called UAT – User Acceptance Tests are carried out before implementation. With the use of monitoring, system elements that should be subject to control depending on their parameter value are distinguished. Therefore one tool can allow to control aspects such as: the frequency of system users logging in correctly or errors resulting from single-sign-on (SSO) settings in organizations in which you can use many applications in many environments with uniform login data. Monitoring tools allow you to set alarms that, by e-mail communication or various visualizations, automate alert processes in the event of a potential system error or exceeding the set limit. The table presents the elements of the CRM system and the ways in which they can be monitored when collecting relevant data for the database.

Table 1: Monitoring of CRM system elements

CRM system elements	A way of monitoring
User login	Alarms are set, by which system administrators are informed about errors in logging - no access to the environment. The environment should be configured so that there is a clearly defined point (e.g. number of login attempts, time of no access) of the alarm.
Test environments	Data on test environments are downloaded - most often including the frequency and refresh time, type of environment, its instance number.
User licenses	Information related to user licenses in the environment is defined - license types, permission sets, features. Data on free licenses and their expiration dates is collected.
Limits	Alerts are applied regarding restrictions of individual system elements, e.g. remaining numbers of external users having access to the system module. When the limit is exceeded, administrators automatically receive a warning.
Environment Variables	Each CRM system has Environment Variables, such as storage usage, daily usage of API values (Application Programming Interface), the number of custom settings, validation rules, remaining data batches, license expiration dates. Each variable can be monitored in real time.
Critical updates	A multi-environmental CRM system should be provided with critical updates along with their dates. Critical updates include data migrations, changes to environmental instances, introducing new releases, improvements.

CRM Monitoring Tools

An enterprise with over 10,000 end users and 20 production environments depending on the region and the specifics of operation in a given environment was examined. The company's activity mainly concerns sales. The implemented monitoring tool uses visualizations of specific limits, which allow tracking of specific parameters by system administrators and action when these are not within the scope tolerated by the organization. The following tools, possible to obtain in a form of a so called monitoring dashboard, were used:

1. Tabular summaries – data has been collected using tabular summaries, mainly for collecting information on values that do not change often in environments. Types of test environments, administrative information, instances, quantities and types of licenses as well as critical updates were determined.
2. Bar gauge graphs – using the bar gauge graphs the variables for user licenses are presented. In case of a specified number of other licenses, the graphs turn red, an alarm is sent to administrators. Information about the number of remaining licenses is visible.
3. Active bar graphs – for data with 1-0 values (true-false, active-inactive) navigation visualizations of a green color were chosen when the system parameter is active, and of red – when it is inactive. A change in the parameter determines sending the alarm.
4. Single stats graphs – this statistics were used when examining licenses and their expiration times. Licenses in the examined environment expire on the first day of the calendar year, so the color of the statistics changes when the license is expired or the last year of its availability lasts. There is alert implemented too.
5. Traffic lights graphs - visualizations allow to track especially environment variables with frequent changes in value. They allow to specify 3 levels synonymous to traffic lights (green, yellow, red). Depending on exceeding a given threshold, a message is sent to the system administrator and people authorized to view the dashboard can see the changes.
6. Time series graphs - a type of visualization that allows you to track changes over time, especially useful when monitoring the possibility of logging into a particular environment. Trend lines allow you to observe deviations, it is possible to set a time limit for an alarm determined by a potential system or user error.

Access to the dashboard should be given to its administrator and developers, as well as the CRM system administrator and key stakeholders. Dashboards allow management in the organization to clearly track key changes from the internal client side. This affects the efficiency of the CRM system and one of the management processes in the organization. The implementation of the monitoring process in an organization with a CRM system (especially multi-org) should be treated as a project. It is crucial to remember about the improvements that monitoring development allows – testing new variables, introducing better tools and alarms. A team should be created, that will work on preparing the monitoring plan, choosing the scope to be subject to it and the variables that should be tracked. Due to an efficient implementation of monitoring dashboards, CRM system administrators can optimize their work by automating operations. Key stakeholders can have access to any statistics of their choice at any time without logging in to the system or several of its environments at once. The response time to a system error is shortened due to the fact that if the set limit is exceeded, the information is sent via an alarm the moment it happens. The surveyed organization also noticed an increase in the quality of control processes through a uniform and standardized way of using data. Human errors have been eliminated, as well as the lack of possibility to check the history of changes in limits, critical updates, environment variables. The dashboard presents the system status in real time with the possibility of refreshing and tracking changes up to a year back. All data can be collected and stored as archival, and used for subsequent research. Monitoring of CRM system variables is important for the internal client of the organization - especially the system administrator, managers of individual departments, as well as end users, for whom system efficiency is the basis of properly performed work.

rafalplwl@gmail.com

Abstract

The article presents the results of research on the safety of transportation of dangerous goods in Poland. The volume of the goods transported by roads is constantly growing, and this fact also causes an increase in the number of threats. The road transportation system in Poland, despite the adoption of legal regulations, does not function properly. To prevent this fact, the road transportation system should operate in an efficient and effective manner. Its objective is to ensure a smooth and safe transportation process. The purpose of paper is to evaluation of present state of safety of road transport of dangerous goods, in Poland, taking into account legal and organizational requirements as well as current and future threats.The research problem of the article is formulated as follows: What does the safety of the dangerous goods road transport system in Poland depend on, in the context of current and future threats?Referring to the aforementioned problem, the research hypothesis was formulated: The road transport safety system for dangerous goods should function reliably to ensure safe and effective transport of dangerous goods in an unimpeded manner. It depends mainly on the professional competence of the staff, moreover from technical condition of the rolling stock, organization and monitoring of transport, minimizing the effects of hazards.
The following research methods were used to solve the research problem: theoretical methods and empirical methods: diagnostic survey, expert interview.

Keywords: Safety, Security, Dangerous Goods, Threats, Empirical Researches.

Introduction

The basic legal act regulating this issue is the European Agreement concerning the International Carriage of Dangerous Goods by Road, ADR (1957). Dangerous goods means such materials and objects whose international carriage by road is prohibited or permitted under certain conditions laid down in Attachments A and B of the Agreement. The transport of dangerous goods imposes specific obligations on all participants in the transportation process: manufacturer, sender, carrier, recipient and inspection services, according to Directive 217 (2018) and 1846 (2018), Act (2011, 2017), Ordinance (2019). Kopczewski et al (2017) mentioned that everyone must act in such a way that transportation safety is maintained at an appropriate level, including monitoring of vehicles and cargo. Poland has ratified this ADR Convention in 1975.

In 2018, 187.3 million tons of dangerous goods were transported in Poland (Small Statistical Yearbook, 2019) and in 2017 174.7 million tons (Small Statistical Yearbook, 2018). This volume of transported goods per year (2018) gives the result of 513 thousand tons per day, i.e. the need for 28,508 18-tonne trucks per day. In a research study by Gendek (2018) in Poland, 72% of the goods transported are liquid fuels, about 19% are liquefied gases, and about 3% are toxic and corrosive substances.

Kubicka-Żach (2018) mentioned, that The Supreme Audit Office alerts that there is inadequate control and poor monitoring of the transportation of dangerous goods in Poland.

In the years 2012–2017 8,592 incidents involving vehicles transporting dangerous goods took place on Polish roads, and their number increased by 50% during that time. According to NIK (2018) and Asystent BHP (2018) in these events 5,982 people were affected, 188 of whom were killed Every year the State Fire Service eliminated the effects of events (spills, collisions) involving about 500 various materials, 30% of the events concerned particularly dangerous substances.

Madej and Pająk (2019) mentioned that road transport of dangerous goods should include the risk analysis, it means the societal risk for communities living or staying within a radius of six kilometres from all national roads in Poland, employed the GIS software. The possibility of assessing the risk level associated with this kind of transport is one of the components affecting the level of public safety. The risk level may vary significantly for the same area.

The United Nations has developed mechanisms for the harmonization of hazard classification criteria and communication tools, and for transport conditions for all modes for transport. UNECE also administers regional agreements for effective implementation of these mechanisms for road transport of dangerous goods.

The Committee adopted a set of amendments to the Model Regulations concerning, *inter alia*, electric storage systems (including lithium batteries installed in cargo transport units and defective batteries), explosives, infectious waste of Category A, waste gas cartridges, harmonization with the 2018 Edition of IAEA's Regulations for the Safe Transport of Radioactive Material, listing of dangerous goods, update of LC_{50} values for some toxic gases and use of *in vitro* skin corrosion methods for classification.

In light of the current situation related to the coronavirus (COVID-19), some ADR contracting parties coordinated their efforts to prepare a multilateral agreement: M324 (2020), M325 (2020), M326 (2020) and M326 (2020).

The purpose of the M324 contract is to prevent the expiry of the drivers' ADR certificates and training certificates for the advisers on the safety by introducing a derogation consisting in extending the validity of these certificates and these certificates by 30 November 2020.

M325 agreement is aimed at preventing the expiry of validity certificates of admission of vehicles for the carriage of certain dangerous goods by introducing a derogation consisting in extending the validity of these certificates by law until 31 August 2020.

The M326 agreement applies to periodic inspections and tests of pressure vessels for the transport of class 2 gases. It is valid until August 31, 2020 in the case of transportation within the territory of the countries that signed it.

The M 327 multilateral agreement concerns periodic or indirect testing of portable tanks and multi-element gas containers. The all periodic or indirect testing of portable tanks and multi-component gas containers (MEGCs), shall remain valid until August 31, 2020.

Empirical Research Results

The purpose of paper is to evaluation of present state of safety of road transport of dangerous goods, in Poland, taking into account legal and organizational requirements as well as current and future threats.
The research problem of the article is formulated as follows: What does the safety of the dangerous goods road transport system in Poland depend on, in the context of current and future threats?

Referring to the aforementioned problem, the research hypothesis was formulated: The road transport safety system for dangerous goods should function reliably to ensure safe and effective transport of

dangerous goods in an unimpeded manner. Achieving this state means overcoming many obstacles: technical, legal, organizational and depends mainly on the professional competence of the staff, moreover from technical condition of the rolling stock, organization and monitoring of transport, minimizing the effects of hazards.

In order to solve the main research problem and verify the research hypothesis, qualitative and quantitative research methods were used:

- system analysis, enabled the solution of the complex problem of the road transport safety system for dangerous goods,
- analogy, it was used to formulate a research hypothesis and for similarities between some issues,
- statistical method, allowed for the acquisition, presentation and analysis of data describing incidents in the transport of dangerous goods,
- the analytical method, allowed for the consideration of the organization of dangerous goods transport,
- a comparative method, on the basis of which basic mechanisms of safety implementation in the field of transport of dangerous goods were examined and analyzed,
- behavioral method, which made it possible to recognize and explain by observing the behavior of persons responsible for the transport of dangerous goods,
- empirical methods: diagnostic survey, expert interview.

Within the adopted research methodology, an independent variable was distinguished: *the road transport environment in the Republic of Poland* and a dependent variable*: the safety state of dangerous goods transport.*

Empirical research was conducted on an expert sample (109 people) in the following institutions: Ministry of Infrastructure, Inspectorate of Road Transport, Government Security Centre, Provincial Crisis Management Centres, Police, State Fire Service, National Atomic Energy Agency, Technical Inspection of Transportation, Environmental Protection Inspection, transportation companies, teaching staff of transportation faculties in polytechnics.
The respondents were asked the following 21 questions.

Question No 1: Have you benefited from training on dangerous goods? If so, what was this training about?

Table 1: results of people's responses on the Health and Safety of Work (HSW) training (as applicable)

Categories of responses	the number of responders	%
1. ADR, RID	28	25.7
2. Health and Safety of Work (HSW), road traffic safety for drivers	24	22.0
3. None	**57**	**52.3**

Most of the respondents (52.3%) did not participate in the training. 25% of the respondents participated in the ADR and RID training, and 22% in HSW training.

Question No 2: What is your assessment of your training on provisions regarding the health and safety at work? (please mark X in the selected column in <u>each</u> row).

Table 2: the results of the responses to the question No 2

The possible responses	the number of responders	%
1. No response	8	7.3
2. Insufficient	2	1.8
3. Sufficient	34	31.2
4. Good	**47**	**43.1**
5. Very good	18	16.5

Most of the respondents positively assessed the level of the training provided (43% as good and 16.5% as very good). Nevertheless, 31.2% of respondents assessed the level of training as only sufficient.

Question No 3. How do you assess the impact of staff competence on the safety of dangerous goods transport? (please mark X in the selected column in each row, 5 - highest rating, 1 - lowest rating).
Most of the respondents (53%) assessed the impact of competence as high, 40.4% as very high.

Table 3: the results of the responses to the question on competence

The possible responses	the number of responders	%
5. Very high	44	40.4
4. High	**58**	**53.2**
3. Sufficient	5	4.6
2. Low	2	1.8
1. No opinion	-	-

Question No 4. How do you assess the technical condition of roads in Poland?

Table 4: the results of the responses to the question No 4

The possible responses	the number of responders	%
1. Very good	1	0.9
2. Good	44	40.7
3. Sufficient	48	44.4
4. Insufficient	15	13.9

The results of question 4 show that there is a minimum percentage (1%) of respondents who think that the technical condition is very good, while 14% of them think that it is insufficient. 44.4% of the respondents believe that the roads in Poland are of sufficient quality, as there are many infrastructure elements that need to be improved. The elements that need improvement the most are presented in the next question.

Question No 5. Which elements do you think should be improved in the road infrastructure to improve the safety of the transportation of dangerous goods? (please indicate up to 3 elements of the road infrastructure).

Table 1: the results of the responses to the question No 5

The possible responses	The number of responders	%
1. Length of highways and expressways	53	48.6
2. The number of ring roads	69	63.3
3. Number of guarded car parks	33	30.3
4. Technical condition of roads	72	66.1
5. Road traffic signs	26	23.9
6. Intelligent Transportation Systems	24	22.0
7. Loading/unloading areas	11	10.1

The majority of respondents chose the technical condition of roads in the first place (66.1%). Definitely a large number of people chose the number of ring roads (63.3%) and the length of highways and expressways (48.6%). It is worth noting that 22% of respondents chose Intelligent Transportation Systems as an under-invested element of road infrastructure. It must certainly be said that the use of modern technologies, which will be a very important part of the concept of road safety of dangerous goods, together with the improvement of road infrastructure, will reduce potential threats and increase the quality of the entire transportation process.

Question No 6. What is the impact of the length of highways and expressways on the level of safety when transporting dangerous goods? (Please mark X in the selected column of each row).

Table 6: the results of the responses to the question No 6

The possible responses	the number of responders	%
1. No impact	6	5.5
2. Low impact	38	34.9
3. High impact	44	40.4
4. Very high impact	17	15.6
5. No response	4	3.7

40.4% of the respondents believe that the length of highways and expressways has a high impact on the level of safety, while 15.6% of the respondents believe that it has a very high impact. Statistical data on Poland show that there are the fewest accidents on highways and expressways in Poland, so this factor is very important. In 2017, the length of expressways was 1,768 km, and highways - 1,637 km (Small Statistical Yearbook, 2018). In 2019 the length of highways was 1,696.2 km, expressways 2,450.3 km (GDDKA, 2019). The network of highways and expressways in the Republic of Poland is to be about 7,980 km, including about 2,100 km of highways (the Ordinance by the Government, 2019).

Question No 7. What is the influence of the modern technologies on the level of safety when transporting dangerous goods? (Please mark X in the selected column of each row).

Table 2: the results of the responses to the question No 7

The possible responses	the number of responders	%
1. No impact	3	2.8
2. Sufficient impact	41	37.6
3. High impact	**51**	**46.8**
4. Very high impact	8	7.3
5. No response	6	5.5

46.8% of the respondents believe that modern technologies have a high impact on the level of safety, while 37% believe that they have a sufficient impact.

Question No 8. What is the influence of the modern technologies on the level of safety when transporting dangerous goods? (Please mark X in the selected column of each row).
39.4% of respondents believe that Intelligent Transportation Systems has a high impact on the detection of threats, while 24.8% believe that it has a very high impact.

Table 3: the results of the responses to the question No 8 (detection of threats)

The possible responses	the number of responders	%
1. No impact	9	8.3
2. Sufficient impact	25	22.9
3. High impact	**43**	**39.4**
4. Very high impact	27	24.8
5. No response	5	4.6

Question No 9. What is the influence of the Intelligent Transportation Systems on the localisation of vehicles and on a level of safety when transporting dangerous goods? (Please mark X in the selected column of each row).

Table 9: the results of the responses to the question No 9 (the monitoring of vehicles)

The possible responses	the number of responders	%
1. No impact	3	2.8
2. Sufficient impact	33	30.3
3. High impact	**49**	**45.0**
4. Very high impact	**20**	**18.3**
5. No response	4	3.7

63.3% of the respondents believe that the monitoring of vehicles by using Intelligent Transportation Systems has a high impact on safety levels, while 30.3% believe it has a sufficient impact. Studies show that the benefits of ITS are very large (Njord & others, 2006), including: increase in transport infrastructure capacity by 22.5% on average, improvement in road safety (reduction of accidents by 60% in the undeveloped area and 50% in the built-up area), significant reduction in travel times and energy consumption (by nearly 60%), reduction of exhaust emissions by 40% on average, improvement of travel comfort and traffic conditions for drivers, reduction of costs of fleet management, reduction of costs related to maintenance and renovation of road surfaces, even by 30-35%.

Question No 10. What is the impact of emergency rescue on the level of safety during transportation of dangerous goods? (please mark X in the selected column of each row).

Table 4: the results of the responses to the question No 10

The possible responses	the number of responders	%
1. No impact	11	10.1
2. Sufficient impact	30	27.5
3. High impact	30	27.5
4. Very high impact	24	22.0
5. No response	14	12.8

Analysing the results of the question in more detail, it should be noted that the respondents (50%) rated that the emergency rescue has a high impact on safety.

Question No 11. Can the signage of the vehicle carrying dangerous goods be visible? If you chose the responses 3 and 4, what would you do to improve visibility.

Table 11: the results of the responses to the question No 11

The possible responses	the number of responders	%
1. Perfectly visible	11	10.1
2. Visible	**77**	**70.6**
3. Poorly visible	16	14.7
4. Not visible	4	3.7

It is worrying that only one in ten of those surveyed is of the opinion that the signage of such safety-sensitive dangerous goods is perfectly visible and 15 % think it is poorly visible. The vast majority say the signage is visible (70.6%).

Question No 12. What do you think is the organization of transport of dangerous goods in Poland? (please mark one response!).

Table 15: the results of the responses to the question No 12

The possible responses	the number of responders	%
1. Very good	4	3.7
2. Rather good	**51**	**46.8**
3. Average (such as itself)	38	34.9
4. Bad	4	3.7
5. Very bad	1	0.9
6. It's hard to say	11	10.2
7. No response	4	3.7

The level of organization of dangerous goods transportation in Poland was assessed positively by 46.8% of respondents, as average by 35%. Although people who have chosen to say that the organization is bad or very bad, then the result of this question is satisfactory, because only 5% say it is bad. By contrast, 10% of those surveyed had no opinion on the subject, and this may indicate a lack of direct contact with the dangerous goods or lack of knowledge about them.

Question No 13. What do you think may be the biggest organizational problem in the transportation of dangerous goods? (please mark one response!).

Table 13: the results of the responses to the question No 13

The possible responses	the number of responders	%
1. Lack of appropriate vehicles	11	10.2
2. The securing of loads	26	24.1
3. Legal provisions	8	7.4
4. Incompetence of employees	39	36.1
5. Poor work organisation	15	13.9
6. The monitoring of loads	9	8.3
7. Other problems (like what?)*	3	2.8

The research shows that 39 respondents (36.1%) have the opinion that the main organizational problem is employees' incompetence. The problem also turns out to be the securing of loads (24.1%). When verifying the results of the questionnaires, the organizational problem also turns out to be the inadequate organization of work, which may be due to the lack of competence of employees.

Question No 14. How do you rate the safety control of transported dangerous goods? (please choose one response!).

Analysing the evaluation of the control of dangerous goods it should be considered positive, more than half (53.3%) of the respondents believe that these activities are carried out good, while 5.6% believe that they are very good. However, it is important to stress that only 3% of the respondents believe that controls are not carried out adequately. On the other hand, 38.3% of those surveyed assessed that the controls are carried out in a sufficient manner.

Table 6: the results of the responses to the question No 14

The possible responses	the number of responders	%
1. I rate the control very good (is strict, efficient, accurate)	6	5.6
2. I rate the control good (is rather strict, quite efficient, accurate)	57	53.3
3. I rate the control sufficient (not too restrictive, too long, not too accurate)	41	38.3
4. I rate the control insufficient (not efficient, not accurate)	3	2.8

This may be due to the fact that in Poland, the number of inspections in relation to the number of vehicles driven is not large, but the officers have more and more modern equipment, they undergo a number of trainings (more and more competences) and are restrictive.

Question No 15. Do you think that the law on the transportation of dangerous goods is satisfactory in Poland?

Table 15: the results of the responses to the question No 15

The possible responses	the number of responders	%
1. Yes	**68**	**63.0**
2. None	40	37.0

63% of respondents responded that the law is satisfactory in Poland, while 37% considered it unsatisfactory.

Question No 16. If the law is not satisfactory, what are the biggest problems in law? (please mark the responses). Question 11a. - Multiple response question (data does not add up to 100%).

Table 16: the results of the responses to the question No 16

The possible responses (to mark)	the number of responders	%
1. It's complicated	23	21.1
2. The rules are mutually exclusive, the law is inconsistent	6	5.5
3. The law is not adapted to practice	28	25.7
4. The law does not take into account European regulations	4	3.7

Apart from the fact that the second part of the question was to be responded by people who were not satisfied by the law, then 62 people responded the second part of the question.
The vast majority of the respondents who responded this question had the opinion that the law was not adapted to practice (28 people), while 23 people were had opinion that the law was complicated.

Question No 17. Do you think the security system and alarm system is sufficient? (please choose one response!).

As regards the alarm system and security system, the majority of respondents said it was good (56%), while 12% thought it was rather bad. However, 26.6% did not have an opinion on this issue, which may indicate that they had no direct contact with the security of dangerous goods or that they have no knowledge about it. When examining this area, it should be stressed that only one person believes that these systems are very good.

Table 17: the results of the responses to the question No 17

The possible responses	the number of responders	%
1. Very good	1	0.9
2. Rather good	**61**	**56.0**
3. Rather bad	13	11.9
4. Bad	4	3.7
5. I don’t know, it’s hard to say	29	26.6

Question No 18. Do you think that cooperation between institutions dealing with the safety of transportation of dangerous goods is appropriate? (Please choose one response!).

Table 18: the results of the responses to the question No 18

The possible responses	the number of responders	%
1. Very good	1	0.9
2. Rather good	**62**	**56.9**
3. Rather bad	19	17.4
4. Bad	3	2.8
5. I don’t know, it’s hard to say	24	22.0

The results of the research show that the majority of the respondents (56.9%) assess the cooperation between institutions well, which is very positive in the context of the manifestation of threats in the transportation of dangerous goods, as the proper functioning of institutions and their cooperation contributes to an increase in safety levels. 22% of respondents do not have an opinion on the subject, which may be due to their occupation or seniority, these respondents do not have experience and knowledge of cooperation between national authorities.

Question No 19. How do you think the rescue services in Poland react during a dangerous incident involving the transportation of dangerous goods? (please choose one response!).

Every fifth respondent has the opinion that public services react very well, and 57.8% that they react well, which may be reflected not only in their competences but also in their organisation. Analysing the answers in this respect, it should be pointed out that the number of conducted rescue operations in Poland is increasing. In addition, there are indications that the number of threats will continue to increase due to the increasing amount of dangerous goods transported, and moreover, the result of the study is important and satisfactory as rescue services operate effectively and efficiently in the event of an emergency, as confirmed by the respondents.

Table 19: the results of the responses to the question No 19

The possible responses	the number of responders	%
1. Very good (professionally)	22	20.2
2. Rather good	**63**	**57.8**
3. Rather bad	10	9.2
4. Very bad (unprofessional)	1	0.9
5. I don't know, it's hard to say	13	11.9

Question No 20. What measures would improve the safety of transportation of dangerous goods? (please choose one response!).

As far as safety measures are concerned, the analysis of the surveys in this context clearly shows that the competences of employees and their continuous improvement are rated highest, with 72.5% of respondents indicating this point. It should be stressed that no question has received such a percentage score. 13.8% of respondents believe that the monitoring of dangerous goods is important and action should be taken to ensure that such a monitoring system is established. No one indicated the answer "other", which is undoubtedly due to the fact that it is, however, the competence of the staff that is the most crucial element that can improve safety in the transportation of dangerous goods.

Table 7: the results of the responses to the question No 20

The possible responses	The number of responders	%
1. New procedures	7	6.4
2. Continuous improvement of employee competence	**79**	**72.5**
3. The monitoring of dangerous goods	15	13.8
4. Technological innovations	8	7.3
5. Others, like what?	-	-

Question No 21. What effects can be brought by the road transportation system of dangerous goods enabling the real time monitoring (please choose any number of responses!).

Table 21: the results of the responses to the question No 21

The possible responses	the number of responders	%
1. Improvement of transportation safety	**70**	**64.2**
2. Traceability	55	50.5
3. Appropriate route selection/the updating of routes	52	47.1
4. Detection of threats	46	42.2
5. Improving cooperation between carriers and rescue services	45	41.3
6. Quality of transportation performance	29	26.6
7. Effective and fast communication between an enterprise and a driver	27	24.8
8. The selection of parking spaces	27	24.8
9. Others.	1	0.9

In question 21, the respondents could choose any number of statements, so the data does not add up to 100%. 64.2% of respondents indicated that real-time monitoring would improve transportation safety. More than half of those surveyed (50.5%) claim that such a system would allow for continuous tracking of vehicles, which is important during a potential accident or incident. Only 25% of respondents believe that such a system would make it possible to improve the selection of parking spaces. This may be due to the fact that only 6% of the respondents work as drivers, and they are the ones who have a direct problem to choose places to stop safely.

Summary

The research problem of paper was solved on the basis of theoretical and empirical research and the hypothesis adopted by the authors has been positively confirmed in full.

The safety of the transportation of dangerous goods depends mainly on: the professional competence of the staff, in addition on the technical condition of vehicles, the organisation and the monitoring of the transportation and on the minimisation of the consequences of threats.

The professional competence of the staff (carriers, drivers, control services, emergency services) is a key element of the safety of the transportation of dangerous goods by road, and relates to knowledge, experience and training of the staff, operational supervision and quality control being a part of their tasks.

The development of new technologies (including ITS) requires the selection, commensurate with the risk analysis, of means of transportation of dangerous goods, which should be kept in good technical condition.

The organisation and monitoring of transportation is based on meeting legal and organisational requirements, controlling the movement of vehicles, detecting and updating risks, procedures should be based on an integrated approach to risk and the use of Intelligent Transportation Systems.

Minimising the effects of threats is about coordinating the actions of all those responsible for the transportation safety and for preventing and effectively eliminating the effects of threats, as well as conducting rescue operations.

The conducted research showed that in relation to current and future threats in the studied area, there are technical and procedural conditions to reduce the risk of their occurrence. But it should be made clear that at present it is not possible to create a system that would meet security conditions in a uniform manner in relation to all the requirements discussed. Nevertheless, on the basis of the information collected, it can be emphasized that taking into account chemical, biological, ecological or radioactive hazards, there is a necessity for continuous analysis of the studied area. More

specifically, it is impossible to fully protect the transport of dangerous goods by road, but most of the potential risks can be significantly reduced so that there are as few as possible in the future.

Many elements affecting the proper operation of the system are negatively assessed. Respondents are of the opinion (most of them) that the condition of road infrastructure in Poland is unsatisfactory, which should be definitely improved, while the organization of transport of dangerous goods is assessed positively. However, the biggest problem in organizing the above process is low competence of the staff, which should be described as a negative phenomenon.

Some aspects considered in this paper require further, more detailed research. Nevertheless, the authors hope that the research and conclusions drawn will become an inspiration or contribute to the discussion on increasing the safety of road transport of dangerous goods.

Acknowledgment

The empirical researches was conducted as part of the research project RMN No. 959/2019 - Concept of road transport safety system for dangerous goods, financed by the Minister of Science and Higher Education.

Abstract

Corporate governance is the process or structure used to direct and manage the business and financial matters to enhance business and corporate accountability with the ultimate aim of acquiring shareholders ' long-term value, as well as taking into account the interests of other stakeholders. The effective corporate governance system will maximize the shareholders ' return. Therefore, it is important to have a good corporate governance practice in order to control the relationship between other stakeholders, the Board and the management of an organization. Corporate governance can prevent the misuse of its power and interest and the imprudent and non-risk behavior of the employees, as well as to resolve conflicts of interest between the management and the committees of the Board. In addition, corporate governance for the financial sector has important implications for the strength of the entire economy. The UAE has accomplished various extraordinary triumphs authorize by key worldwide reports and markers. The Country positioned 23rd universally in the Corruptions Perceptions Index issued by Transparency International in 2015 though it positioned 35th in 2008, which mirrors the incredible accomplishment in this regard.

Keywords*:* Corporate Strategy, Abu Dhabi Accountability, and Authority, Corporate Governance, Organizational Culture

Introduction

Corporate governance mechanisms are used by the organization in order to resolve problems related to governance. The purpose of the system is to control the managers in relation to the conflicts of interest (dart, 2013:63). However, Weimer and Pape, 1999 cited in the Muftah Otman, 2014 pointed out that the mechanism will very much depend on the internal and external systems. Dart than further explained that corporate governance mechanisms could be divided into two; internal and external mechanisms. For the internal mechanisms it will encourage the managers to maxims the company which includes the board of Directors, Audit Committee, auditors, ownership structure, co-monitoring and supervisory board. Meanwhile the purpose of the external mechanism is to avoid the conflict that may arise between shareholders and managers. As a whole corporate governance mechanism, whether it is internal or external, plays an important role in assisting the company in providing quality audit reports (Fan, Lau & Wu, 2002, Al-Janadi et.al 2013). Corporate governance is the process or structure used to direct and manage the business and financial matters to enhance business and corporate accountability with the ultimate aim of acquiring shareholders ' long-term value, as well as taking into account the interests of other stakeholders. The effective corporate governance system will be maximizing the shareholders ' return. Therefore, it is important to have a good corporate governance practice in order to control the relationship between other stakeholders, the Board and the management of an organization. Corporate governance is able to prevent the misuse of its own power and interest and the imprudent and non-risk

behavior of the employees, as well as to resolve conflicts of interest between the management and the committees of the Board. In addition, corporate governance for the financial sector has an important implication on the strength of the entire economy

Literature Review

Corporate governance can be referred to as trust, ethical, moral value and confidence, which is referred to as the community, namely, the stakeholders, including the government, the public, professionals, service providers and the private sector (Aras & Crowther, 2008). Here, corporate governance is important in enhancing transparency, accountability and business integrity. However, the implementation of corporate governance impact will be a benefit in the long term for the organization.

Allocation of Resources

The allocation of resources is closely related to the corporate strategy of a business to ensure that resources are allocated in a timely and it should be sufficient to ensure that the organization can meet the targeted objectives and goals. The importance of creating resource allocation controls is to ensure that the company is able to manage in the business in accordance with the laws and ethical values of good business. The good control element is able to strengthen the Board's roles and responsibilities in ensuring competitive profits in addition to effective risk management made (Maritan and Lee 2017:2412). According to NCHRP (2010), the private sector does not have a universal agreement on whether or how to associate the target achievement with the distribution of resources.

Organizational Design

Byran and Joyce (2007) from McKinsey Consulting take a more nuanced stance by positing that "organizational design should be about developing and implementing corporate strategy." Woren (2018) in Organization Design: Simplifying complex systems, observes that managers face organizational design challenges on an almost daily basis coupled with empirical research confirms the potential impact of organizational design on the functioning and performance of organizations, but yet business schools have placed little emphasis on organization designs. Business schools are not the only ones avoiding the centrality of organizational designs to corporate strategy. Furthermore, Byran and Joyce (2007) have stridently argued that multinational organizations in the 21st Century have become massive, talent-driven and suffers from organizational inertia; added to the hard work and time-consuming nature of organizational design, it is not surprising that many CEOs typical have opted for ad hoc structural, big acquisition, coupled with a focus on where to and how to compete. They further elaborate that good corporate governance is an important feature to attract investments into e companies and create an efficient financial market.

Portfolio Management

From the perusal of literature portfolio management has evolved over the last few decades as one of the most quintessential developments in management theory and practice. The portfolio management process is the process taken by the investors to assist in the investment objectives (Fraser 2017). Portfolio management is an action to establish and maintain an investment account, while financial planning is the process of developing financial goals and creating a plan of action to achieve it. In other words, the portfolio management involves investing in various types of assets: securities, bank deposits, properties, art, jewelry, intellectual property, and more. In the easiest sense and spirit, the portfolio means investing free funds in assets that do not require spending time or money, but at the same time bringing a steady income (Trivedi 2013:2). Drawing the voluminous scholarly literature on asset management and portfolio management Kevin (2015: 2) concludes that portfolio management is fundamentally about the constitutive processes involved in the creation and maintenance of investment

portfolios. He goes to compartmentalize the process into phases. Accordingly Kevin (2015) identifies and lists the phases within the process Figure 1.

Source: Kevin (2015)

Figure 1: Portfolio Management Process

This five phone typology by Kevin (2015) finds expression with Fraser (2017) who notes that portfolio management reinforces the need for an effective and efficient process that includes a disciplined process for identifying, prioritizing and selecting the most attractive investment opportunities.

UAE Economic Development

UAE is not left behind in the formulate policy in relation to implementing good corporate governance in line with the development at the international level. The ongoing effort is part of the movement by the government to develop a corporate governance policy that is able to create new opportunities and economic growth. UAE has realized the impact and role of the world's major economic challenges. For this, it has made proactive efforts to strengthen its advanced position among countries in the world to ensure economic stability. The UAE government continues to study and evaluate the ever-changing and social landscape, economy and politics to increase its ability to respond to unprecedented speeds on any challenges by developing and implementing new economic policies and regulations. This section examines the economy, investment, and the financial sector in the UAE.

Strengthening the National Economy in the UAE

Dubai is the capital of the United Dubai (Emirate of Dubai), one of the seven states which form the country of the United Arab Emirates (United Arab Emirates-UAE). Six other United-formed UAE is Abu Dhabi, Ajman, Ras Al Khaimah, Fujairah, Umm quwwine and Sharjah, each having the same capital name as the name of all the United Nations. From all the above, the United Abu Dhabi is the largest united in terms of geographic areas than the others. Due to its geographical size and also the

wealth of petroleum and gas owned by Abu Dhabi, UAE's political power is based in Abu Dhabi, where the president of UAE now being held by the Abu Dhabi ruler, Sheikh Khalifa bin Zayed Al Nahyan.

The main economic indicators of the UAE in 2018 confirm its ability to adapt to financial crises and to social and economic changes:

Table 1: UAE Main Indicator (KPI)

Indicators	2014	2015	2016	2017	2018
GDP (billions USD)	401.96	370.30	371.35	407.21	435.70
GDP (Annual % Change)	3.1	3.8	2.7	1.5	4.4
GDP per Capital (USD)	43,213e	38,650e	37,678e	40,162	41,772
General Government Gross Debt	15.6	18.10	19.30e	19.1	19.0
Inflation Rate (%)	2.3	4.1e	1.8e	2.8	3.7
Current Account (billion USD)	40.33	12.31	8.78	14.37	16.97
Current Account (in % of GDP)	10.0	3.3e	2.4e	3.5	3.9

Note: (e) Estimated Data
Source: IMF – World Economic Outlook Database, December 2018

Generally, almost all the united in UAE depends on the national income from petroleum as a source of the economy but Dubai is an exception. Due to the greater efforts of the Dubai ruler, the visionary to diversify its economy based on the smaller oil reserves, compared to Abu Dhabi, Dubai is not entirely dependent on oil products as the main source of its economy where 85 percent of UAE's economic source is derived from oil exports (Askari & Jaber, 1999).

Table 2: The UAE Ranking on Various Global Economic

Indicators	Rank
Economic Openness	3rd
Business Environment, Infrastructure & Technological Advancement	4th
Global Readiness Index	5th
Change Readiness Index	5th
World Competitiveness Index	15th

***Source**: National Centre for UAE Statistics, December 2018*

The above table shows that there is a success that has been done by the UAE government in its efforts to mitigate economic activities and to reduce dependence on oil during the economic-financial crisis facing the world economy. In 2008, the nominal GDP for the UAE grow high at an annual rate of 27.4 percent to 253.2 billion USD as compared to the year 2007, the growth rate was 16.8 percent to 198.8 billion USD. This is due to strong growth from the oil sector, non-hydrocarbon sector activities and non-oil sectors contributing to the economic organization. The GDP grew at 7.4 percent (2008) from the annual 2007 of 5.2 percent. Between the GCC countries, UAE is the second-highest country for per capita earnings after Qatar. The income per story increased by 35 percent from 2005 (35056.7 USD) until 2008 (53,996.7 USD).

UAE has emerged as the number one destination in the Arab world due to its strong infrastructure, framework, energy supply, quality education, and business facilities. UAE administrators want to be comparable to London and New York, the world's leading business center. With significant events such as the World Expo, 2020 is expected to attract 22 million tourists, and the report shows a healthy pipeline project worth $705 billion which is scheduled in the next 10 years, the country's economy UAE is on the right track for a consistent growth

Organizational Culture

Importantly all organizations have their unique organizational culture. Thus, in thinking deeper about the concept conjures up the question of what is organizational culture. Alvesson (2013: 3) explains how a "quick glance of literature or scholarly works the use the term organizational culture will reveal enormous variations in definitions of this and even more in the use of the term culture." This is precisely why Schabracq (2009) noted that as a concept, organizational culture is simply hard to define. Notwithstanding the multiplicity of definitions, Reddey (2017:7) noted the despite the "various definitions and connotations about organizational culture, however most researchers have developed a shared understanding of culture." As an umbrella term, Alvesson (2013) takes organizational culture to mean or include values and assumptions about the social reality of an organization. Ahmadi et al. (2017) in their well-developed scholarly publication titled, Relationship between Organizational Culture and Strategy Implementation: Typologies and Dimensions briefly outlined the historicity of research on organizational culture, by noting that "researches on the subject of "organizational culture and its effect on other organizational variables became widespread during the 1980s" (2012:287). The pervasiveness of research of the said topic is indicative of what Alvesson (2012:2) regards the "significant way of understanding organizational life in all its richness and variations." Klien (2011) cited in Reddy (2017:20) suggests that organizational culture can be regarded as both an internal resource and a dynamic capability." From the perspective of approaches, the organizational culture exists within that variants at multiple- levels within an organization, and it is most pronounced in global corporations, that have operations across different markets. Kokina and Ostrovska (2013: 366) illustrates how "there are three basic approaches to organizational culture: symbolic, when the organization is examined as a system with an indefinite internal environment; cognitive, when the organization is examined as a multitude of knowledge, beliefs and regulations which the organization members have comprehended; and systematic which, at creating the organization climate, functions as the basic determinant of culture which is being formed under the influence of organization's objective qualities and is characterized by the situation of a psychological environment."

Corporate Governance and Organizational Culture

The organizations in the Global Economy of the twenty-first century undergo a drastic change, due to competing within the industry, to gain economic advantages. The changes in how to do the next activity in a better way, over the competitors in the industry are observed. The phenomenon of how to do or know-how is the corporate governance that is involved in many aspects of the government sectors. The work environment of many persons is transformed into critical activities in the organization (Austin, 2012). The transformation in critical activities to face the challenges requires empowering the persons and enabling them to realize it. From the previous studies it is understood that superior paybacks will be obtained by allocating more funds in corporate governance implementations (Reus et al., 2009). In the substance of corporate governance changes, a significant feature is whether the implementation of corporate governance principles and organizational culture has a positive impact on corporate strategy. The literature analysis of the relationship between different corporate governance principals and organizational culture is wide-ranging. Over time, a lot of corporate governance's principals were studied in relation to corporate strategy.

Aoki (2017) in article Corporate Governance Affects Corporate Strategy on the Japanese Stewardship Code, which was released in 2014 as a code of conduct and the amendment of the Companies Act; cautiously reflects on how the need to need to strengthen corporate governance structures within

Japanese companies in order to protect institutional investors has impacted positively on the corporate strategy.

Corporate Strategy and Governance Principles in UAE

The term corporate strategy is some of those over-used terminologies by scholars and business practitioners alike. Thus, it is imperative to contextualize the isolated meaning of both terms. Al-Azzam, Al-Qura'an and Al-Mohameed observers that "in its simplest form a corporation is defined as an organization having its own legal entity separate from its owners thereby having its own rights, responsibilities, and obligations. They operate for a profit motive, capitalizing on their expertise, resources and networks" (2015:58), taken together corporate strategy refers to a strategy pertains to the entire company, which covers all business units (Saee 2007:9; Ahmad et al., 2009).

Corporate governance involves the manner in which the business and affairs of banks are governed by their boards of directors and senior management, which affects how they: set corporate objectives; operate the bank's business on a day-to-day basis; meet the obligation of accountability to their shareholders and take into account the interests of other recognized stakeholders; align corporate activities and behavior with the expectation that banks will operate in a safe and sound manner, and in compliance with applicable laws and regulations, and protect the interests of depositors" (p.4). Moreover, no doubt there is no single standard definition or statement of corporate governance (Du Plessis et al., 2010). Evidence suggests that most of these definitions. Finally, no doubt there is no single standard definition or statement of corporate governance (Du Plessis et al., 2010). Evidence suggests that most of these definitions represent points of view comprising different frameworks such as: management; organizational behavior; accounting; legal structure; social responsibility; and politics

Corporate governance is the system by which business corporations are directed and controlled. The corporate governance structure specifies the distribution of rights and responsibilities among different participants in the corporation, such as, the board, managers, shareholders and other stakeholders, and spells out the rules and procedures for making decisions on corporate affairs. By doing this, it also provides the structure through which the company objectives are set and the means of attaining those objectives and monitoring performance" (OECD, 1999). In summary, based on the constitutive elements of this aforementioned framework Furrer (2011) believes that a corporate strategy creates value as a system when its' five elements fit together as a system.

In the globalized business, organizations need key reasoning and just by developing great corporate strategy would they be able to end up deliberately focused. Abu Dhabi public organizations need these types of study as most of the corporate strategy is done in private sectors and there is no such type of study was done in Abu Dhabi Emirate. To be specific, Abu Dhabi Accountability Authority (ADAA) that affirms the commitment to the highest standards of transparency and accountability as adopted by the UAE, ADAA in Emirate of Abu Dhabi plays an important role in public and private organizations in the Emirate. These organizations attract many resources such as human resources, financial management, and equipment and counterpart the efforts of public organizations in providing services in the Abu Dhabi Accountability Authority (ADAA). This is why the corporate strategy and performance of these organizations has continued to attract attention from many stakeholders, including development partners, government and the public sectors.

Conclusion

The UAE has accomplished various extraordinary triumphs authorize by key worldwide reports and markers. The Country positioned 23rd universally in the Corruptions Perceptions Index issued by Transparency International in 2015 though it positioned 35th in 2008, which mirrors the incredible accomplishment in this regard. The UAE achieved the top four positionings in various markers in the Global Competitiveness Report issued by the World Economic Forum. The UAE has likewise positioned the most joyful Arab Country and the twentieth internationally in the World Happiness

report distributed by the United Nations. Further, the Country was positioned first locally in the "Simplicity of working together" classification as indicated by a report issued by the World Bank.

Abstract

In paper, we present results of improving technologies in geo-information and geo-ecological support for territory development within environmental economics while climate change. While studies, we used methods of data bases constructing within digital platforms, web-technologies and virtual reality tools. We make statement that territory development is to be carried out in the environmental economics paradigm as related set of large natural-industrial projects within common space area and time period. We present a block model that combines the investment objectives of such project set with cost of adequate geo-information and geo-ecological support, including natural risks management goals and tasks. We suggest to use geo-information distributed online platforms as the main technological tools in the tasks of geo-information and geo-ecological support while the development of territories. In study, we used platform https://www.researchgate.net/profile/Valery_Abramov2/ for data exchange and preliminary discussion.

Keywords: Information Technologies, Geo-Information Support, Geo-Ecological Support, Risk Management, Environmental Economics

Introduction

Recently, digital transformation, named Industry 4.0, extends in the global economy, during which a lot of enterprises and infrastructure-intensive companies plan and implement wide spectrum of information technologies (Baikov, 2019), (Bidenko, 2019), (Drabenko, 2019), (Grachev, 2017), (Frolova, 2019), (Lukyanov, 2019). This leads to serious information technological changes in decision support while territory development within geo-information management (Kirsanov, 2014), especially in natural risk management (Berboushi, 2014), (Ershova, 2018), (Garcia, 2018), (Isaev, 2015), (Istomin, 2018), (Shilin, 2019).

In the article, we describe the results of improving technologies in geo-information and geo-ecological support for territory development in geo-information management area (Burlov, 2018), (Fokicheva, 2016), (Fokicheva, 2015), (Istomin, 2015), (Kirsanov, 2014), (Lednova, 2014), (Malakhova, 2014), in large environmental projects (Mandryka, 2019), (Popov, 2014), (Popova, 2019), (Rumyantseva, 2017), (Zhigulsky, 2018) within environmental economics (Chusov, 2019), (Golosovskaya, 2014), (Karlin, 2014), (Karlin, 2009), (Popov, 2016). Significant attention should be paid to geo-information support of natural risk management (Fokicheva, 2018) in the context of climate change (Mikheev, 2019), (Bournashov, 2014), (Gogoberidze, 2014), including the issues of information collection and processing (Fokicheva, 2019), (Khaimina, 2014), (Popova, 2019).

Methods and data

In research, we used: methods of data bases constructing in case of digital online platforms, web-technologies, big data technologies (Novikov, 2019), (Sokolov, 2019), geo-information technologies (Veretennikov, 2019), (Yaily, 2019) and virtual reality tools. Also, we used Foresight technologies, theory of decision making under uncertainties (Palkin, 2019), risk management approach while territory development (TD). From the point of view of geo-information management, we structured geo-space to allocate the interconnected components of the solution space (Istomin, 2015).

Results

We make statement from the point of view of geo-information management (GIM), that territory development (TD) in recent stage is to be carried out in the environmental economics paradigm as related set of large natural-industrial projects (NIPs) within common space area and time period. In fig.1, we present a block model of investment structure while TD that combines the investment objectives of such NIPs (blocks 1-5) with cost of adequate geo-information and geo-ecological support (blocks 6-8), including natural risks management goals and tasks (block 7). Our analysis shows that the largest part of the cost of geo-information and geo-ecological support is the environmental monitoring (block 8), the essence of which is determined by the content of block 7. Significant part of the cost in block 8 is hardware and software, the cost of which varies significantly.

On basement of above mentioned model, we proposed to develop the geo-information and geo-ecological support system (GIGESS) with combined structure for access, storage and analysis of information from open geo-spatial data sources, including archives and operative mode web tools. Reducing the cost of GIGESS is an important direction of TD.

As a result of the research performed using foresight technologies, the authors suggest to use geo-information distributed online platforms (GIDOP) with cloud technologies (OT) as the main technological solutions for GIGESS while territory development. We give preference to open platforms such as Google Earth. Also, we recommend to use GIDOP EOS eos.com, which allows to operate with space images from the Landsat-8 and Sentinel-2 satellite systems with limited open access.

Figure 1 :Block model for investment structure while territory development: 1 – block of distribution of resources; 2 – block of formation of resources; 3 - block of formation of private income; 4 - block of formation of total income; 5 – block of formation of the investment share of resources; 6 - block of comparison with the permissible level of risk; 7-block of formation changing in time set of natural risks, including climate risks; 8 – block of environmental monitoring

In this research, essential was block of environmental monitoring. Reducing the cost of GIGESS is an important question for TD. we proposed to use GIDOP EOS eos.com as basement for low-cost GIGESS while territory development. In figure 1-4, we present imagery of developing territory on north-east part of Saint-Petersburg, Russia, taken freely from EOS eos.com for 25th May 2017 and 18th June 2018. The pictures obtained with EOS's agriculture tools https://eos.com/agriculture-band/, that combining satellite bands SWIR, NIR, Blue. In figures, bare ground has magenta color, vegetation has green color, roads and buildings appear as bluish objects.

Figure 1: Image of developing territory for 25th May 2017

Figure 2 : Image of developing territory for 18th June 2018

Figure 3 : Image of developing territory with its measuring characteristics for 25th May 2017

Figure 4 : Image of developing territory with its measuring characteristics for 18th June 2018

Comparing the images in figures 1 - 4 allows you to clearly see the changes that have occurred in the developed area for almost a year. Using EOS's tools, you can fast and simply determine the linear and area characteristics of selected objects and see their dynamics over time (figures 3 and 4). A detailed analysis of above mentioned changes is not the purpose of this article.

As essential result, we propose to use GIDOP EOS eos.com as basement for low-cost GIGESS while territory development.

Discussion

As basement for low-cost GIGESS while territory development, GIDOP EOS eos.com can be used in educational and training purposes. The essential task of university practical learning (UPL) in the field of territory development is to teach students the practical aspects of work with GIDOP EOS tools, which requires a developed learning base within special geo-information systems (GIS) laboratory. In some cases, real practical work in special GIS laboratory can be undergoes with virtual reality (VR) technologies (Popov, 2019), that can reduce total cost of learning process.

Conclusion

We consider results of improving technologies in geo-information and geo-ecological support for territory development within environmental economics while climate change. In research, we used methods of data bases constructing within digital educational platforms, web-technologies and virtual reality tools. We make statement that territory development (TD) is to be carried out in the environmental economics paradigm as related set of large natural-industrial projects within common space area and time period. We present a block model that combines the investment objectives of such projects set with cost of adequate geo-information and geo-ecological support, including natural risks management goals and tasks. We suggest to use geo-information distributed online platforms as the main technological tools in the tasks of geo-information and geo-ecological support while the

development of territories. As essential result, we propose to use GIDOP EOS eos.com as basement for low-cost GIGESS while territory development, including educational and training purposes.

Acknowledgment

While study, associate professor Nikolay Popov, head of geo-information systems laboratory in Arctic and Subarctic Institute at the Russian State Hydrometeorological University, gave us very useful consulting. The platform https://www.researchgate.net/profile/Valery_Abramov2/ gave us excellent opportunities for preliminary discussion and data exchange while this research.

Using The ISO 9001:2015 Standard As An Organization Tool When Figthing Against Coronavirus In The Context Of Increasing The Level Of Organization Safety - Outline The Problem

Małgorzata DĄBROWSKA–ŚWIDER

Military University of Technology in Warsaw, Warsaw, Poland
malgorzata.dabrowska-swider@wat.edu.pl

Abstract

The aim of the paper is to analyze the possibility of using the quality management tool, i.e. ISO 9001:2015, to fight against the disease, which is spreading among people from all continents, and to introduce systemic solutions which could be the first barrier to protect employees of a given organization, and thus their families.

Keywords: ISO 9001:2015 Standard, Safety And Security, Coronavirus Pandemic, Risk, Epdemiological Threat

Introduction

The attempt to address the global problem of the threat to human health and life caused by the coronavirus pandemic is a fundamental problem, the solution to which spends the sleep of probably every conscious inhabitant of our planet. Every day, people all over the world are following the disease statistics and, unfortunately, the increasing number of deaths with great concern. The lack of a drug and vaccine makes the time for reaction shrink more and more and more frustrating. No one doubts that we have sailed into unknown waters and do not see the shore to which we can safely reach. The European Union is not taking any systemic and effective action, which is lacking because no one has made a risk analysis taking into account this type of event. Of course you can insure yourself against various types of cataclysms, but no one has done so. There was a lack of unanimity to take the same steps to increase the level of security of the members of the European Union. The reactions of national governments have shown how they were trying to do something in the dark. Each country applied its own scenario for dealing with the pandemic, although it was already possible to build on the experience of the countries that were the first to fight the pandemic. The aim of this article is not to assess the adopted solutions and consider what economic effects the pandemic will bring in the near future, but an attempt to analyse whether something can be done at the stage of an organization which has a quality management system implemented based on ISO 9001:2015.

An Organisation As A Guarantor Of Its Welfare And The Environment In Which It Operates

If we look at the organization with the quality management system implemented and try to compare it to something, we can see an efficient system, which consists of a number of interconnected elements. Each of these elements pursues its own goals, which, as you know, serve to achieve the success of the whole. At this point, we're already wiser to make a pandemic a fact. Therefore, it is enough to place this element as a risk, which is and properly classify it, additionally assessing what impact it will have on the activity of our organization, but first of all it is necessary to develop a whole set of measures that will allow to secure employees (meeting the requirements of point 6.1 of this international standard ISO 9001:2015). If each of us took part in a fire training at least once, he understands the meaning of this action and can quickly evacuate. It is therefore worth thinking about applying certain routine actions to protect one's health in the event of an epidemic. This will certainly make sense not only if such threats occur in the future, but will also help to solve other problems more quickly. Here, we can cite the example of one of the Spanish companies in Poland, which

recommended the use of disinfectants and masks to its employees and trained them in how to act at work and outside of work, making recommendations on how to move to and from work. In addition, a ban was introduced on employees and their families leaving their place of residence while on holiday. Such guidelines have also been extended to workers' family members, which has had an additional positive impact on the extension of the group of people who have been trained and made aware of it. These rules of conduct were established much earlier than it was done in Poland as part of the introduction of subsequent stages of restrictions related to the spreading epidemic. This example shows how positive solutions adopted by the organization have an impact on its environment. The effectiveness of such simple solutions is undoubtedly the best safety barrier. If we make the assumption that most people spend more time at work and on the way to work (at least until now), the sense of safety and security created by our organization is of great importance to every employee. And that translates into his immediate surroundings. This is how you build a sense of safety and security. We're dealing with the phenomenon of connected vessels, so why don't you fight for it.

Inserting protective solutions in the content of ISO 9001:2015

A very good place to place new ISO 9001:2015 normative solutions to increase the level of organization safety is certainly item 7 the Support. With regard to the order of the individual subsections, attention should be paid to the possibility of including new solutions in them. Starting with 7.1 the Resources (Polish Committee for Standardization: PN-EN ISO 9001:2015), a new procedure or instruction for supplementing internal resources with additional personal protective equipment in the event of an epidemiological emergency can be introduced in a very simple way and with little effort, and can even be extended to include the provision of such protective equipment for all customers of the organisation. No one is surprised to find that there are people in the organisation who are directly responsible for the whole of its operation. Therefore, nothing stands in the way of thinking about hiring or establishing permanent cooperation with a person who will operate the process of training, awareness of the epidemiological safety rules for all workers (7.1.2. of this standard). In addition, it can be ensured that all regulations and legal requirements in this respect are met. Each organisation shall have infrastructure to the extent necessary for its operation (7.1.3 of this Standard). The examples of grassroots initiatives observed in the media show how some organisations are able to quickly switch their production to other tracks and produce, for example, respirators. Similar examples can be found in the chemical industry of PKN ORLEN - a Polish oil industry corporation started to produce disinfectants very quickly. The President of the United States even called on General Motors and Ford to produce respirators. Both General Motors and Ford, each company separately, have announced their collaboration with other companies to manufacture respirators (Trump wants car companies to start producing respirators 2020). General Motors has announced that it will produce the equipment at its plant in Kokomo, Indiana and will deliver it in April. Suddenly, all the countries affected by the pandemic lacked literally all the necessary protection measures. The crisis affecting each country has led to a situation where fear for one's own security has prevented mutual supply assistance. Dependence on a single producer on a global scale has resulted in a situation where an interruption of the supply chain has led to disaster. Fortunately, this is a temporary collapse, from which we manage to get out slowly. If appropriate system solutions were introduced at the level of the organization's operation in accordance with the requirements of the standard, the situation would certainly be easier to control. With reference to section 7.1.4 (Polish Committee for Standardization: PN-EN ISO 9001:2015), which defines the process environment, the very fact of having additional safeguards by the organization has an impact on the emotional protection of employees and their families, and this in turn increases the sense of security. The importance of the goal of protecting human health and life requires that such activities of the organization and processes that are necessary for the effectiveness of management systems be recorded in the form of documented information (7.5 of this standard). It is important that such documents contain a description of people's competences and the scope of their responsibility for the implementation of individual processes.

Conclusion

Every day we are more and more aware and learn how to act in a new reality. It is worth sharing knowledge and helping each other at every stage of the pandemic's development, the more experience we gather, the better we will be able to defend ourselves against other dangers. We can see many examples of the actions taken by the medical community to share knowledge about, for example, treatment methods and drugs used. The names of the medications used are officially published in the mass media, may be difficult to understand for the average citizen to understand, but for professionals these are concrete guidelines for action. Many Chinese physicians have written guides to the experience gained in Wuhan and have sent them out to medical practitioners around the world. This kind of behaviour is very valuable and shows not only social but also international solidarity. Every day we learn how to protect ourselves against an invisible enemy more and more effectively. Before our very eyes a great transformation and renewal is taking place, mechanisms of solidarity and social responsibility are emerging. Every day a pandemic attacks our safety and destroys our sense of security. Taking into account the fact that important reasons guide the decisions of the leaders of all countries in the world, all of whose attention is focused on countering the threat of a pandemic, it is worth doing everything to protect humanity from this kind of threat and to include in this kind of action all possible means at our disposal. One such tool is the use of ISO 9001:2015. It is therefore to be hoped that the Technical Committee of ISO/TC 176 "Quality Management and Quality Assurance" will take some constructive action on this issue. Assuming that our lives will change radically, it is possible to significantly increase the intellectual potential of any organization in which a quality management system has been implemented through a small amount of work. Awareness-building for workers (7.3 of this standard) is a process that seems difficult at first, given the attitude of all participants in this process. Most of them are afraid of the new challenges and the changes they will bring, and they take a defensive attitude. However, we must do everything we can to protect ourselves from this kind of situation in the future and reduce the pandemic of fear which is now starting to paralyze everyone and everything.

Abstract

Proponents of foreign direct investment (FDI) argue that FDI can be a major trigger for the growth of the real economy in the host country; however, they are not as keen-edged when it comes to FDI in the financial-banking sector, and numerous examples from Central and Eastern European (CEE) countries from the last decades more than prove these contradictions in the ways of thinking concerning FDI. Researches has identified a number of positive aspects brought by foreign banks, such as: better risk-management, improved knowledge transfer, products and management techniques, innovative ways to increase financial intermediation, improved resource allocation, institutional development, employment opportunities, attracting additional FDI. In the same time, we acknowledge that the effects of FDI on the domestic financial institutions and the increase of competition that will ultimately lead novel and cheaper financial services for consumers are ambiguous, and identifying of possible long-term effects upon developing economies is difficult. This papers aims to examine the impact concerning the presence of foreign banks in several countries in CEE (Romania, Hungary and Bulgaria), to understand whether and how foreign participation in the banking sector of these countries has or has not had an effect upon the economic growth, and, respectively, to identify and understand the effects upon the availability and costs associated with the crediting of the private sector. We are interested in and concerned with finding out whether there are any particularities and associated developments, varying and differing from country to country, and whether events such as the recent economic and financial crisis or reaching a dominant threshold of a foreign presence in their domestic banking systems have conclusively changed the behavior of foreign banks in relation to the economic evolution and the private sector from these countries.

Keywords: Foreign Banks Assets; CEE Countries; Macroeconomics Indicators.

Introduction

The relationship between the entry of foreign banks onto the domestic markets and the macroeconomic stability of these markets is more than often associated with the effects that this entry has upon the financing of the real economy. Political and economic decision-makers alike, as well as the beneficiaries of financing activities, are worried regarding the fact that foreign banks will affect and influence the competition and the functioning of the domestic banks, aggravating, in times of crisis, the existing problems (Badulescu & Petria, 2011). In this paper we are interested in analyzing this fear that foreign banks will have a “cherry picking” behavior, meaning that foreign banks will be able to select the best debtors, while neglecting other market segments such as small and medium-sized enterprises (SMEs) and whether this behavior will weaken the power of domestic banks,

drastically diminishing the overall availability of financing sources for SMEs that heavily rely on bank loans for debt financing and development (investments).

Literature review regarding the foreign banks' entry and the financing of the real economy

Ever since the 1980's, considerable evidence and studies have shown that in several developed countries, larger banks devote a smaller proportion of their total loans to SMEs, as compared to other small (and domestic) banks. By default, the merger or takeover of small domestic banks in a developing country by larger foreign banks may thus imply a reduction in loans for small domestic businesses, although there are other conditions and influences, namely the type of entities that merge or which are purchased, the policy of the corporate/parent bank, the internal conditions and regulations, the possibilities of expanding upon profitable market niches, etc. (Peek & Rosengren, 1996), (Strahan & Weston, 1998), (Berger, et al., 2000), (Clarke, et al., 2003), (Badulescu and Simut, 2012), (Onder and Ozyildirim, 2016) that could impact this availability.

What is more, literature has shown that the process of corporate consolidation (through mergers and acquisitions of domestic banks) can also have a strong "external effect". Banks that are not in the process of consolidation can respond to the decrease of some types of loans from large institutions (which are in the process of being acquired and/or expansion) by increasing their credit offers aimed at those area not considered any more by larger foreign banks. Berger et al. (2000) note, however, that although the external effect completely compensates for the effects of corporate consolidation in terms of the amounts of loans, some firms are still affected given they have transaction costs (searching for new sources of financing, as a result of the disruption of the initial situation) and may have less favorable lending conditions from the new financing providers, this until a mutual relations matures.

In undesirable terms, regarding concerns generated by the entry of foreign banks onto the domestic banking systems of the emerging or developing countries, we can acknowledge the fact that, in general, foreign banks seem to allocate higher shares of their lending portfolios to large, consolidated, commercial and industrial customers. Peek et al (1999) warn that foreign banks tend to buy domestic banks which are underperforming, and that their restructuring has the potential to reduce (at least temporarily) the loan granted to industrial clients, by modifying, on the short term, lending policies, especially with regard to small businesses. This situation could partly explain the large and constant disparities that exist between the structure of the loan portfolio of foreign banks and domestic banks, this situation being as similar and as noticeable in developing countries as it is in already developed countries. There is substantial evidence that large banks, but not necessarily of foreign banks, lend a small share of their portfolio to SMEs, as compared to smaller banks (Berger & Udell, 1995), (Peek & Rosengren, 1996), (Strahan & Weston, 1998). According Focarelli and Pozzolo (2000) the majority of international banks tend to be larger in size; what is more, they can be discouraged by diseconomies of scale and by the difficulties imposed by the management, organization and control of the process of granting loans to SMEs, which tends to be inefficient in nature, as opposed to the efficiency of corporate services (structural lending, consultancy services, capital markets operations). Even when they grant small sized loans, large banks must make use of standardized credit-worthiness evaluation methods, by using available information, and both hard (information from financial statements) and soft (relational information) (Berger & Udell, 1995), (Berger & Udell, 2002). The latter is not easily quantifiable and proves to be some-what inaccessible to large banks, this type of information being relationally and physically local in nature. Soft information tends to be flexible to a certain extent, and it is this flexibility that facilitates the setting up and development of a relationship between small banks and small debtors (Badulescu et al, 2014).

An essential area of concern for economic and financial banking policies refers to competition. If the competition stemming from newly entered banks (mostly foreign) forces several small domestic banks to leave the market upon which they are already present, the supply of loans and credit lines headed towards small and informationally opaque enterprises will decrease. Even so, the evidence

supporting this is indirect in nature, and is not sufficiently convincing. It is possible that, given that pressure will be aimed at reforming and increasing the profitability of domestic banks, this will have as a result the fact SMEs with mediocre financial statements and opaque or unconvincing information will not receive loans, regardless of the characteristics of the existing banks (big or small, domestic or foreign) (Clarke, et al., 2003).

Love et al. (2013) have examined the impact that the credit increase in CEE and Latin America has had upon banks, both before and during the economic crisis of 2008. They note that the increase in the volume of loans granted by foreign banks was higher/larger before the crisis only in CEE, and that the loans granted by foreign banks have decreased more than the loans granted by domestic banks in these countries during the crisis period, largely due to an excessive decrease of the number of credited companies. Similarly, De Haas and van Lelyveld (2014) have reported that during the global crisis of 2007-2009, the decrease growth rate of loans from the subsidiaries of multinational banks was almost three times faster than that of domestic banks. What is more, some studies investigating the behavior of banks during the financial crisis of 2007-2009 (Claessens & Van Horren, 2013) show that global banks, given the unfavorable financing shocks, have diminished the weight and importance of lending done through their local branches.

Nevertheless, there are opinions that also point to the positive effects accompanied by the entry of international/foreign banks upon crediting of the private (non-banking) sector. Navaretti et al. (2010) consider that loans granted by the subsidiaries of foreign banks throughout ECE aimed both towards corporations and also to the retail sector (SMEs and the households), have been stable and have even witnessed a slight increase between 2007 and 2009. Berger and Mester (1997) point to the fact that the entry of large banks into developing countries is likely to coincide with the larger restructuring and consolidation of the banking sector in the host countries. If the economies of scale associated with this consolidation would generate more electronic banking, this in turn could improve the accessibility to some types of financial services, even for small customers. Technological advancements and market openness provide SMEs with new opportunities for receiving financing (often non-bank financing), which until recently were only accessible to large companies (Clarke, et al., 2003). These factors could make it less necessary for a bank to have a physical presence in all the geographic areas in which it operates (Petersen & Rajan, 2002) and could help large foreign banks overcome fears of diseconomies of scale and difficulties of lending to small debtors. There is enough evidence, from 1980's to 2010's (from Latin America, and from CEE countries) that, although foreign banks, as opposed to domestic banks, have allocated a smaller share of their loan portfolio to SMEs, these foreign banks have managed to direct almost half of the total credit to SMEs, meaning that, even though it is a gradual process, foreign banks do not discriminate against SMEs in their lending policy (Badulescu, 2011), (Morutan & Badulescu, 2016).

Clarke et al. (2001) have used a survey of more than 4,000 businesses throughout 38 developing and transition economies in order to study whether borrowers' perceptions concerning interest rates and long-term loan access are positively correlated to the presence of foreign banks. Their results support the claim that the penetration of foreign banks onto the domestic market improves firms' access to credit, by providing lower interest rates and increased access to long-term loans. Moreover, the advantages of high levels of penetration of foreign banks do not seem to benefit only large companies, the authors finding strong arguments that small businesses are also presented with benefits in some respects and there is no consistent evidence that small companies would be negatively affected by inflow of capital from foreign banks.

Methodology

In this paper, for the analyzed countries, i.e. Romania, Hungary and Bulgaria, we have made use of a series of macroeconomic and financial indicators. Their purpose is to create an evolving image of several economic aspects that took place during the analyzed period and to show if there is a connection between these variables and to determine what results have generated these influences. The variable used in this present paper are: *assets of foreign banks* – as an exogenous/independent

variable, and, as dependent variable: *Economic Growth* – the rate of change of real Gross Domestic Product (GDP), and two financial/banking indicators - *Interest rates on bank credit to the private sector*, and *Bank credit to the private sector* (as a percentage of GDP). We will make use of annual data to the 1996-2016 time period (see the evolution of these indicators in Table 1 – Appendix). All variables have been measured in percentage points and the information has been collected from World Bank and BERD databases (TheGlobalEconomy.com, 2018). In our study we will analyze the relationship between the presence of foreign banks and the above mentioned indicators, for the selected countries, by using two regression models.

Therefore, the first model, used to determine the impact that the percentage of foreign banks' assets in total foreign banks has on the indicators presented above is the following (Model I):

$$ln(Y)_t = \alpha + \beta ln(X)_t + \sum_{i=1}^{2} \gamma_i \left(ln(X)_t * D_i \right) + \varepsilon_t$$

where:

Y_t represents the dependent variable (macro-economic and financial indicators)
α - intercept
ß – the parameter of the *Foreign Bank Assets* dependent variable
ln –natural logarithm
γ_i – the parameter of the dummy variable *i* multiplied with independent variable *Foreign Bank Assets*
D_i – dummy variables for the time period in which the assets of foreign banks register less than 60%, respectively over 60% until the pre-crisis period, thus Di = 1 the time period *i* and 0 otherwise.

Because 50% foreign presence is not a certainty of/for dominance in the medium and long term, we have considered the 60% percentage as being relevant for indicating the threshold from which foreign banks have achieved majority in the total assets of the banking system in the respective country.

In order to determine whether the relationship between the presence of foreign banks and the previously mentioned has changed in the crisis years and throughout our sample, we have proposed the following model (Model II):

$$ln(Y)_t = \alpha + \beta ln(X)_t + \sum_{i=3}^{9} \gamma_i \left(ln(X)_t * D_i \right) + \varepsilon_t ,$$

Where:

D_i – annual dummy variables for the pre-crisis, crisis, and after-crisis time periods, where $D_i = 1$ for year i and 0 otherwise.

The dummy variables indicate:
- The pre economic crisis time period – i = 3 (year 2007 - D_{2007}),
- The time period during the economic crisis – i = 4 (year 2008 - D_{2008}), i = 5 (year 2009 - D_{2009}) and
- The time period after the economic crisis – i = 6 (year 2010 - D_{2010}), i = 7 (year 2011 - D_{2011}), i = 8 (year 2012 - D_{2012}), i = 9 (year 2013 - D_{2013}).

Results and Discussion

The following tables present the estimated coefficients for model I and II, by explaining the relationship between Foreign banks assets and macro-economic indicators (GDP), and also financial

indicators, namely interest rate of bank loans granted to the private sector and bank loans granted to the private sector, in Romania (Table 1), Hungary (Table 2) and Bulgaria (Table 3). Thus, in the case of Romania, we can notice a positive and significant association between the share of foreign banks in the banking system and the GDP, meaning that the increase in size of the assets of the foreign banks had a significant growth effect on the GDP during the sample period. What is more, we can state that an increase in the share of foreign banks in the banking system causes a decrease of the interest rate. Moreover, if we look at the two dummy variables, we notice that when the share of foreign banks assets is below the mentioned threshold of 60%, at a 1% increase of this weight, the interest rate of bank loans granted to/aimed at the private sector increases with 0.22%. When the share of foreign banks' assets is above the threshold of 60% of total assets, at a 1% increase in this share of foreign banks, the interest rate of bank loans granted to the private sector has decreased to 0.01%. The compelling decrease in interest rates could be caused by two factors. The first factor is determined by the increase of the presence of foreign banks on the Romanian market, which leads to an increased competition in the banking system and a gradual decrease of the interest rate margins in the market. The second factor is a repercussion caused by economic crisis after 2008. Even if in the short term, this crisis has caused a dramatic decrease as regards volume of lending, an accelerated decrease in the basic interest rate of the major global currencies has lowered the basic interest rate with which the parent banks could refinance. By default, the costs of financing for their subsidiaries and, of course, the loans granted by them have also gone down. Returning to the analysis of the situation of Romania, we find that, with regard to the bank loans granted to the private sector (as a percentage of GDP), when the share of the assets of foreign banks increases by 1%, the bank loans granted to the private sector increases by 0.38%.

Table 1 : Estimation of parameter for Models 1 and 2 in Romania

	Dependent Variable Macro-economic and Financial Indicators					
	Economic Growth		Interest rates on bank credit to the private sector (%)		Bank credit granted to the private sector (percentage of GDP)	
Model	I	II	I	II	I	II
	Coefficient (std. error)					
Constant			4,58*** (0,56)	4,89*** (0,79)	1,90*** (0,42)	1,64** (0,62)

In the case of Hungary (Table no. 2), regardless of the used estimation method, we observe a positive and significant association exists between the share of foreign banks in the banking system and GDP - an increase in the size of the assets of foreign banks has had a significant growth effect on the GDP during the sampling period. Furthermore, the share of foreign banks' assets in the Hungarian banking system has a statistically significant influence on the interest rate of bank loans granted to the private sector (%), but in a negative sense, an increase in the share of foreign banks in the banking system causes a decrease in the interest rate of bank loans granted to the private sector. When the share of foreign banks' assets in total assets is below the 60% threshold, we find that with a 1% increase in the share of foreign assets in total assets and the interest rate of bank loans granted to the private sector increases by 0.14%, whereas when the share of banks 'assets is above the 60% threshold, at a 1% increase in the share of foreign banks' assets in total assets, we find that the interest rate of bank loans granted to the private sector has decreased by 0.01%. Finally, we can state that there is a significant/important and positive connection between the evolution of the share of foreign banks' assets in total bank assets and the bank loans granted to the private sector in Hungary. Thus, when the share of foreign banks' assets increases by 1%, the percentage in GDP of the bank loans granted to the private sector also increases (by 1.2%).

In the case of Bulgaria (Table 3), the estimated coefficients illustrates a positive and significant relation between the weight of foreign banks' assets in the banking system and GDP, i.e. the increase of the size of foreign banks' assets in the banking system of Bulgaria had a significant growth effect on the GDP during the sampling period. What is more, the evolution of the share of foreign banks' assets in the Bulgarian banking system influences the interest rate of loans granted/provided to the private sector, but conversely, an increase in the share of foreign banks in the banking system causes a decrease in the interest rate of loans granted to the private sector. By relating and considering the two dummy variables, the situation in Bulgaria differs from the situation in Romania. We thus notice that when the share of foreign banks' assets is below the 60% threshold, at an increase of 1%, the interest rate decreases only by 0.02%. Regarding the connection between the assets of foreign banks and the bank loans granted to the private sector (as a percentage of GDP), we notice a direct connection. Thus, when the share of foreign banks' assets increases by 1%, the percentage of bank loans granted to the private sector also increases by 0.96%.

Conclusions

There are numerous studies and intensive research has been carried out regarding the relationship between the presence of foreign banks and the financing of the real economy of the host country, and especially, the financing of small and medium enterprises. The results of these various studies are quite diverse, ranging from beneficial effects, such as reduction of costs associated to financial intermediation, the increase of access to credit lines, growing competition and diversity of products and services, to negative effects, such as - increasing economic-financial instability, selective customer behaviors, affecting the availability of local banks to provide loans to the other sectors, especially aimed at small and medium-sized companies.

In this paper, we have analyzed three countries from Central and Eastern Europe, the time frame of the study being the 1996-2016 time period. We have analyzed the relationship between the evolution of the share of foreign banks and the evolution of GDP, of the interest rate of loans granted to the private sector and the share of private loans in GDP, so as to better understand the evolution of some economic and financial-banking aspects that took place during the studied time period. We found, given only small differences from country to country, that there is a positive and significant association between the share of foreign banks in the banking system and GDP, respectively, a negative and significant association between the increase of the share of foreign banks in the banking system and the interest of loans granted to the private sector; finally, we have found a positive, but not always strong association/relationship between the share of foreign banks and loans granted to the private sector (as a share of GDP). We acknowledge that some of these evolution are similar in their nature, but, in other instances, the influence exerted by this foreign presence is ambiguous or inconsistent, and this is the reason for which, in our future research, we propose to develop a model that will generate an overview of these evolutions and correlations in the analyzed region. We will thus better be able to answer the question of whether the positive effects (regarding the entry of foreign banks) upon the economic development as a whole justify and exceed the costs of attracting foreign investors in the financial sector and the negative risks and consequences.

Abstract

Purpose – This research aims to build a hierarchical composition of factors influencing the process of consumer decision-making by means of Internet technologies. **Design/methodology/approach** – In order to address the purpose of this research, factors influencing consumer decision-making by means of Internet technologies were identified and ranked. The methodology of this study is based on the use of such methods as descriptive statistics method; the method of grouping personal data and the method of average assessment; the method of correlation analysis; matrix method; Saaty hierarchy analysis method. **Findings** – The widespread use of Internet technologies leads to the transformation of the consumer behavior model. Producers of goods and services should pay attention to the multidirectional changes in consumer behavior, namely an increase in the rationalization trend, on the one hand, and standardization of consumer decisions, on the other. In order to achieve the above-mentioned tasks, the authors proposed the model of a hierarchical composition of factors that influence consumer decision-making. **Originality/value** - The advantage of application of the proposed hierarchical composition is that consumer decisions management system is based on a modular principle, and therefore is stable and elastic at the same time. The elasticity of such a system is provided by the possibility of changing one or several modules, not the entire system. Modular (partial) changes also guarantee the stability of the system, since they are aimed only at correcting the system, not at destroying its integrity.

Keywords: Internet technologies, Transformation, Behavior model, Consumer decision-making, Hierarchical composition

Introduction

Nowadays, fierce competition in all spheres of economic activity necessitates the search and application of the most effective ways of delivering information about goods and services to the ultimate consumer, which is a prerequisite of the successful functioning of business structures (Baker, 2003; Assael, 2004; Bhatnagar and Ghose, 2004). The active use of Internet technologies by enterprises is considered to be one of these effective ways (Bikhchandami *et al.*, 1992; Metcalfe, 1998; Wenjing *et al.*, 2008; Kautish and Sharma, 2019). It is necessary to take into account the fact that on the one hand, Internet technologies provide enterprises with wide opportunities for their positioning in the market, and on the other hand, they have a transformational impact on the market behavior of a potential customer (Granovetter and Soong, 1986; Chyi, 2009; Sassatelli, 2012; Nikolova and Inman, 2015; Parsons and Maclaran, 2017; Haugtvedt *et al.*, 2018).

In this regard, the primary task for the majority of enterprises that actively use Internet technologies in the course of their economic activity is to figure out what makes a potential customer look for information about goods and services in the web and make purchases online and what factors in the process of consumer decision-making are determining.

The main hypothesis of the research is as follows: identification and ranking the factors affecting the process of consumer decision-making by means of Internet technologies allows to increase the efficiency of production and commercial activity of an enterprise.

This research aims to build a hierarchical composition of factors influencing the process of consumer decision-making by means of Internet technologies.

In order to address the purpose of this research, the following tasks have been realized:

an original methodology for assessing factors that influence consumer decision-making by means of Internet technologies has been suggested;

a survey on the use of Internet technologies in the consumer decision-making process among the residents of the Opole Voivodeship has been conducted;

the matrix of weighted average of factors influencing the process of consumer decision-making by means of Internet technologies has been developed. It was served as a scientific background for modeling the hierarchical composition of these factors.

Questionnaire details of respondents who use Internet technologies in consumer decision-making process in 2018 serve as information background of the research.

Literature Review

The factors influencing the process of consumer decision-making by means of Internet technologies are being researched worldwide. The following scientific works in this field deserve attention.

Wenjing D., Gu D., Whinston A., Gupta P. and Harris, J. study the effects of electronic word-of-mouth on consumer decisions and find the relationship among customer motivation, speed of decision-making and rationality of consumer choice. Based on the findings, it was concluded that those consumers who have high motivation to process information make decisions longer, but select the most optimal products. And the other way around, buyers with low motivation make decisions faster, but irrationally (Wenjing et al., 2008; Gupta and Harris, 2010).

Munkácsi N. devotes his research to the process of forming consumer decisions based on the exchange of information and experience on the use of products, both through personal contacts and through contacts on the Internet. In his articles, the author identifies the sources of information that consumers turn to when making a purchase decision and concludes that consulting with other users of the product (not a manufacturer) plays a pivotal role in the consumer decision-making process (Munkácsi, 2018).

A recent study by Khatwani G. and Srivastava P.R. is aimed at investigating the impact of information technology on the choice of information channel in the process of consumer decision-making. The authors analyze real cases of making multi-criteria consumer decisions by means of Internet technologies and propose a methodology for determining consumer preferences (Khatwani and Srivastava, 2017; Khatwani and Srivastava, 2018).

In scholarly studies of Willman-Iivarinen H. into the ways of transformation of the consumer decision-making process under the influence of modern technologies the author emphasizes that consumer choice is increasingly influenced by social networks, processes of social identification and self-branding. Willman-Iivarinen H. comes to the conclusion that in the future the choice of strategy for making consumer decisions will strongly depend on the social potential of products (Willman-Iivarinen, 2017).

Pantano E., Rese A., and Baier D. do research into the impact of augmented reality technology on consumer behavior in the online trading environment by comparing the youth markets of two

countries (Germany and Italy). The findings of the conducted research reflect the similarities between the markets and reveal differences related to consumer motivation to make consumer decisions using Internet technologies (Pantano et al., 2017).

The articles of such scholars as Manahova I., Rezaei S., Wee C.H., Valaei N., Hall A., Towers N., Zhang Y., Feng Y., Homburg C., Yang, L., Fang E., Yeon J., Kuttschreuter M., Hilverda F. are also devoted to the study of consumer decision-making based on the use of various types of Internet technologies (Zhang and Feng, 2011; Homburg et al., 2015; Yang et al., 2015; Fang et al., 2015; Manahova, 2016; Rezaei et al., 2017; Hall and Towers, 2017; Yeon et al., 2019; Kuttschreuter and Hilverda, 2019).

Despite a certain diversity of all the above scholarly studies, the findings reveal the impact of Internet technologies on the process of consumer behavior transformation, which has two main directions.

The first direction is connected with the process of further rationalization of consumer behavior. According to the theory of consumer choice, the consumer seeks to maximize utility based on three determining factors: their preferences, income and prices for goods / services (Lawson, 2000; Burke, 2002; Hawkins at al., 2004). Today, due to Internet technologies, the consumer has a wider access to information about goods and services, which makes it possible to further optimize the consumer decision-making process in terms of maximum compliance with consumer preferences and incomes (Ha¨ubl and Trifts, 2000; Ha¨ubl and Trifts, 2000; Lee at al., 2001; Dennis at al., 2004; Dennis at al., 2004; Grewal at al., 2004; Harris and Dennis, 2008; Cho and Chan. 2019). In other words, nowadays, consumer decision-making largely depends on the multi-alternative choice the Internet provides a consumer with. This direction of consumer behavior transformation is associated with the intensive development of Internet technologies themselves, which not only contributes to optimizing consumer decisions, but also shapes new consumer preferences, both material and non-material (Ratchford at al., 2001; Parasuraman and Zinkhan, 2002; Zerbini at al., 2019).

The second direction of consumer behavior transformation is associated with the emergence of information cascades due to the wide use of social networks (Bikhchandani et al., 1992; Alevy et al., 2007). The mechanism of information cascades operates as follows: the exchange of information leads to an increase in sales, and the growth of sales leads to the most intensive exchange of information (Senecal and Nantel, 2004). Due to the creation of informational cascades, consumers form so-called “herd behavior”, based not on individual rational choice, but on copying someone else’s most common consumer behavior (Kennedy, 1997; Senecal and Nantel, 2004). Let us call this phenomenon standardization of consumer behavior. Standardization of consumer behavior in its essence contradicts the process of rationalization of consumer choice.

Thus, on the one hand, the amount of information processed by a consumer increases, which in its turn increases the rationality of their decisions, and on the other hand, consumer actions are largely justified by the process of social self-identification, which includes the effect of a standard consumer decision. The authors argue that modern marketing policy should be based on continuous monitoring of the process of consumer behavior transformation. At the same time, the current studies do not propose a universal scheme for identifying and ranking the factors influencing the consumer decision-making process.

Research Methodology

In order to address the purpose of this research, factors influencing consumer decision-making by means of Internet technologies were identified and ranked.

The methodology of this study is based on the use of such methods as descriptive statistics method to identify the main trends associated with the process of consumer decision-making by means of Internet technologies; the method of grouping personal data and the method of average assessment to identify and rank the factors influencing the purchase of goods via the Internet; the method of correlation analysis to identify how close the relationship between the analyzed factors is; matrix

method for calculating the weighted average of factors influencing consumer decision-making by means of Internet technologies; Saaty hierarchy analysis method to build a hierarchical composition of factors influencing the process of making consumer decisions by means of Internet technologies (Saaty, 1980).

Step-by-step procedure for conducting research is presented in Fig. 1.

In order to address the purpose of this research, the data obtained on the basis of a survey of residents of the Opole Voivodeship in 2018 were used.

520 respondents took part in the survey. The sample of respondents is representative. The sample was calculated using the calculator of the optimal size of respondents, presented on the website of the company Partner in Business Strategies. According to the sampling calculator used and on the basis of population data in the Opole Voivodeship at the end of 2018 – 990096 people. The number of respondents in a representative sample may vary within 383 people. (with a confidence level of 95%) up to 663 people. (with a confidence level of 99%).

The factors that determine the respondent's profile as age, gender, place of residence, income level, education, and marital status were not taken into account in the research.

In the first phase of the research, a questionnaire on the use of Internet technologies in the process of consumer decision-making is designed, surveys and accumulation of data obtained from respondents are conducted, and a preliminary analysis of data obtained through questionnaires is carried out. During the preliminary analysis of personal data, the respondents are ranked according to the criterion of the frequency of using Internet resources to search for information about goods and services. As a result of this ranking, inactive Internet users are eliminated and further research is carried out without taking into account the results of a questionnaire. In the result of the preliminary analysis of personal data it is possible to form the respondent's profile.

The second phase of the research is devoted to the assessment of factors motivating a potential consumer to make a purchase by means of Internet technologies. Initially, at this stage, the factors that motivate them to search for information about goods and services on the Internet are assessed, and according to this criterion, potential buyers are grouped. The further analysis of three formed groups of respondents is carried out: within these groups the ranking of factors that encourage them to search for information about goods and services on the Internet as well as evaluation and ranking of factors that influence the purchase by means of Internet technologies are conducted.

In the third phase of the research, a matrix of weighted average of factors influencing the purchase of goods and services by means of Internet technologies is created, which is based on the construction of the vector of indices and the matrix of indices of the analyzed factors.

The fourth phase completes the research process by creating a hierarchical composition of factors influencing the consumer decision-making process, summarizing the findings, and drawing conclusions.

Analysis of data obtained during the survey

Phase 1: "Questionair"

In order to identify the factors influencing the process of consumer decision-making by means of Internet technologies, a survey was conducted among the residents of the Opole Voivodeship.

The first question of the questionnaire "How often do you use the Internet to search for information about goods and services?" served as a background for the process of selection of respondents in terms of their Internet activity.

The following answers were received: 25.0% of all respondents are looking for information about products and services on the Internet daily; 67.3% - several times a month; 1.9% - once a month, 5.8% of respondents less than once a month.

Data on the frequency of using the Internet to search for information about goods and services allow us to distinguish three groups of consumers by level of activity. The first group of respondents who look for information on a daily basis can be called “active users”; the second extensive group, searching for information several times a month - "moderate users". The third group of respondents is inactive Internet users who search for information once a month and less often (this group makes up 7.7% of the total number of respondents). We exclude the third group from further analysis, since the opinion of inactive Internet users is not representative. The analysis is carried out based on the results of the survey of the first and second groups of respondents, those who search the Internet for information about goods and services daily and several times a month.

Figure 1: Study Methodology Scheme

Source: developed by the authors

It has been already mentioned that the transformation of consumer behavior takes place in two directions: the direction of increasing the degree of rationalization of shopping due to the large amount of available information on the Internet and in the opposite direction - standardization of consumer behavior (weakening the validity of purchases) due to the "herd effect" formed by information cascades. Information cascades are created on the basis of widespread use of social

networks for commercial purposes. In this regard, respondents were asked the following question: “Do you use any social networks to search for information about products and services on the Internet?”.

More than 93.75% of those analyzed responded positively to this question (respondents who search the Internet for information about goods and services every day and several times a month).

Among these respondents, the most popular social networks are Facebook (91.66% of respondents), Instagram (27.08% of respondents) and YouTube (18.75% of respondents). Less popular are: Google+ (10.42% of respondents); Linkedin (6.25%) and Twitter (4.17% of respondents). Thus, the interviewed respondents actively use social networks, which means that to a large extent their consumer decisions can be formed not on the basis of a rational choice, but under the influence of the “consumer herd effect”.

At the same time, only 10.41% of respondents were able to specify the name of the Internet pages that they most often use. That testifies that the consumer does not have any strong attachment to certain Internet resources.

Then, in order to form the consumer profile of the respondents, they were asked the question: “Information about which goods and services do you most often search on the Internet?”. Respondents could choose from 1 to 3 answer choices for this question. The results of the answers are presented in Tab. 1.

The most popular among the respondents questioned is the information about such goods and services as “Clothing and Footwear” (81.25%) and “Entertainment” (56.25%), the third place is taken by “Household appliances, computers and software” (43.75%). The categories of goods and services that more than 30% and less than 40% of respondents are interested in are the following: “Drugs and cosmetics” and “Education” (39.58%), “Books and audio / video” and “Travel services and sports "(37.50%). Less than 30.00% but more than 10% of respondents is interested in the following categories of goods and services: “Furniture” and “Transportation services” (20.83%), “Consumer goods” (18.75%), “Hotels and accommodation” (16.67%), "Sports Equipment" and "Financial Services" (12.5%). The least popular products and services are the following: "Cars and accessories" and "Legal services", 8.33% and 2.08% of respondents respectively showed interest in them.

Table 1: Categories of goods and services a potential consumer most often searches for on the internet

Group of goods	Categories of goods and services	Number of responses	% of the total number of respondents
1st group of goods	Clothing and Footwear	423	81.25
	Entertainment	293	56.25
	Household appliances, computers and software	228	43.75
2nd group of goods	Drugs and cosmetics	206	39.58
	Education	206	39.58
	Books and audio / video	195	37.50
	Travel services and sports	195	37.50
	Furniture	109	20.83
	Transportation services	109	20.83
3rd group of goods	Consumer goods	98	18.75
	Hotels and accommodation	87	16.67
	Sports Equipment	65	12.50
	Financial Services	65	12.50
4th group of goods	Cars and accessories	44	8.33
	Legal services	11	2.08

Thus, based on the above data, it is possible to form the respondent's profile: this is an active Internet user (searches for information about goods and services daily or more often than once a month), the one who actively uses social networks in the consumer decision-making process, does not have strong attachments to specific Internet resources, most often this respondent searches the Internet for information about goods and services that surround them in everyday life (clothing, footwear, entertainment, household appliances and computer equipment). This means that the consumer behavior of this respondent can be transformed simultaneously in the two aforementioned directions: further rationalization of consumer decisions due to an increase in the processed information about goods and services; standardization of consumer decisions arising from the active use of social networks and generating the risk of "herd consumption".

In other words, the respondent is an average modern consumer, who represents the overwhelming majority of the entire population of consumers. In this regard, the results of this study have practical value for a mass producer who actively uses Internet technologies to promote their products and services.

Phase 2: "Assessment and ranking of factors affecting the purchase of goods and services by means of Internet technologies"

In this phase, it is necessary to identify the factors encouraging the potential consumer to search for information about products and services on the Internet.

When asked the question "What is the decisive factor for searching information on the Internet?", the majority of respondents under analysis identified the following as decisive factors (score 5): "a wide range of goods and services" - 294 respondents or 61.35% of all respondents analyzed, "usability and ease of navigation"- 243 respondents or 50.58%," time saving "- 161 respondents or 33.46% (Fig. 2).

2a) Wide range of goods and services **2в) Usability and easy navigation** **2c) Time saving**

2d) Reviews of friends and acquaintances **2e) Advertising, %**

Figure 2: Assessment of factors that encourage a potential consumer to look for information about products and services on the Internet (% of respondents from the total number of respondents analyzed)

The average assessment of factors encouraging the potential consumer to look for information on the Internet is shown in Fig. 3. According to the calculations, the factor “Wide range of goods and services” has the highest average assessment - 4.51 points out of 5 possible, second place – “Usability and easy navigation” 4.42 points, and the lowest rating is given to "Advertising"- 2.49 points out of 5.

Figure 3: The average assessment of factors encouraging a potential consumer to search for information on the Internet for the entire analyzed sample of respondents

For a more in-depth analysis based on the obtained data, it is possible to find the average assessment of the factors encouraging the potential consumer to search for information about products and services on the Internet using individual questionnaires. This will allow us:

first, to assess the degree of objectivity of the rating submitted by the respondents to the final ranking of factors that encourage a potential consumer to search for information about products and services on the Internet;

secondly, to form consumer groups according to the degree of satisfaction with the search mechanism for information about goods and services on the Internet (more satisfied users will give top rating, less satisfied, respectively, will strive to undervalue their ratings).

The average assessment of respondents varies from 2.6 to 5.00 points, which allows to form three groups with a rating step of 0.8 (formula 1).

$$Step = \frac{(F_{\text{cp}_max} - F_{\text{cp}_min})}{3} = \frac{(5{,}00 - 2{,}60)}{3} = \frac{2{,}40}{3} = 0{,}80 \quad (1)$$

Where

Step – assessment step,
$F_{\text{ср.max}}$ – the maximum average assessment,
$F_{\text{ср.min}}$ – the minimum average assessment.

Using the average maximum and minimum assessment indicator and the given step, we obtain three groups of respondents (out of the analyzed respondents), formed according to the degree of satisfaction with the process of searching for information about goods and services on the Internet (Tab. 2).

Table 2: Groups of respondents, formed according to the degree of satisfaction with the process of searching for information about goods and services on the internet

Groups of respondents	**Group 1**	**Group 2**	**Group 3**
Average assessment($\bar{F}_i$)	$\bar{F}_i \leq 3.40$	$3.40 < \bar{F}_i \leq 4.20$	$4.20 < \bar{F}_i$
Respondents searching the Internet for information about goods and services every day and several times a month	29.17	58.33	12.50

The first group of respondents is a group with an average assessment of all factors that were taken into account in this survey up to 3.40 inclusive; the second group - a group with an average assessment of all factors in the range from 3.40 to 4.20 inclusive; the third group is a group with an average assessment above 4.20. Thus, in the third group there are respondents (they are also potential consumers) who are most satisfied with the search mechanism for information about goods and services on the Internet. Accordingly, in the first group there are respondents who pay the least attention to these factors, and the second group is an intermediate option. The largest number of respondents (53.8%) belongs to the group 2. Groups 1 and 3 include 26.9% and 11.5% of respondents respectively.

According to the data presented in Tab. 3, the priority of factors influencing the decision to search for information on the Internet will be different for different groups. However, for all formed groups, the last place in the rating is taken by such factors as “Reviews of friends and acquaintances” and “Advertising”.

The close correlation among the ratings in different groups of respondents indicates a fairly high reliability (objectivity) of these ratings given by the respondents (Tab. 4). With k = 3, as well as the level of significance (for a two-sided criterion) of the correlation coefficient according to the Pearson 0.01 critical values table. The correlation coefficient is reliable above or equal to 0.934. This brings us to the conclusion that the respondents' assessments are objective.

Table 3: Ranking of factors encouraging a potential consumer to search for information about products and services on the internet (by respondent groups)

Factors encouraging a potential consumer to search for information on the Internet	Groups of respondents					
	1st Group		2nd Group		3rd Group	
	Rank	Average assessment	Rank	Average assessment	Rank	Average assessment
A wide range of goods and services	2	3.86	1	4.61	1	5.00
Usability and easy navigation	1	4.00	2	4.54	2	4.83
Time saving	3	3.71	3	4.18	2	4.83
Reviews of friends and acquaintances	4	2.21	4	3.61	3	4.33
Advertising	5	1.71	5	2.64	4	4.17

Table 4: The correlation coefficients of assessment of factors that encourage a potential consumer to search for information about goods and services on the internet (by groups of respondents)

	Group 1	Group 2	Group 3
Group 1	1		
Group 2	0.954	1	
Group 3	0.978	0.950	1

It should also be noted that, based on the results of the significance assessment of factors encouraging the potential consumer to look for information about goods and services on the Internet. It is higher in the second group than in the first one and lower than in the third one. In other words, the respondents of the second group give the most objective assessments (their decisions are less susceptible to both positive and negative emotions). This may mean that this group of potential consumers of goods and services largely perceives Internet technologies as an integral part of everyday life, which simplifies and accelerates the process of finding the necessary information about goods and services.

It should be emphasized that the factors analyzed above are factors that encourage potential consumers to search for information about goods and services using the Internet technology. The process of searching for information does not always result in making a purchase. In this regard, this study further analyzes the factors affecting the purchase by means of Internet technologies.

Based on the analysis of respondents' answers to the question "What is the decisive factor in the purchase of goods and services via the Internet?". We can conclude that the key factors are the availability of goods – usability and easy navigation, the lowest price and time saving. Advertising occupies the last place in the rating taking 2.646 (on a five-point scale) (Fig. 4)

Tab. 5 presents the average assessment of the decisive factors that encourage shopping by means of Internet technologies for the three groups of respondents formed above. All the factors presented in the table are divided into two categories: "factors that are determined by the rationality of consumer behavior" and "factors that cause herd consumer behavior".

Since the groups of respondents are singled out according to the "degree of satisfaction", the respondents belonging to different groups tend to underestimate, or to overestimate, or to average the assessment. The close correlation between the estimates in different groups of respondents indicates a fairly high reliability (objectivity) of the ratings given by the respondents (Tab. 6).

Analyzing the data presented in Table 6. we can conclude that the most significant factors affecting the purchase by means of Internet technologies are "availability of goods and services", "lower price", "usability and easy navigation", as well as "time saving". These are factors that are determined by the rationality of consumer behavior. The factors that form informational cascades and cause herd behavior have less influence on consumer behavior. In other words, the results of the survey showed that under the influence of Internet technologies, consumer behavior is more transformed towards rationalization. And the information cascades created by social networks help in making rational decisions based on the reviews of another consumer.

Figure 4: The average assessment of factors influencing the purchase of goods and services by means of Internet technologies, according to respondents from the analyzed sample

Table 5: Ranking of factors affecting the purchase of goods and services by means of internet technologies (by groups of respondents)

Factors affecting the purchase of goods and services by means of Internet technologies	Groups of respondents					
	1st Group		2nd Group		3rd Group	
	Rank	Average assessment	Rank	Average assessment	Rank	Average assessment
Consumer Behavior Rationalization Factors						
Availability of goods and services	2	4.00	1	4.71	2	4.83
Lowest Price	4	3.79	2	4.50	2	4.83
Usability and easy navigation	1	4.07	3	4.43	2	4.83
Time Saving	3	3.93	4	4.29	1	5.00

Consumer Behavior Standardization Factors						
Brand and online store loyalty	5	3.36	5	4.04	2	4.83
Reviews of friends and acquaintances	7	2.57	6	3.64	3	4.00
Reviews of other Internet users about the product or service	6	3.00	7	3.61	4	4.67
Advertising	8	2.00	8	2.68	3	4.00

Table 6: The correlation coefficients of assessment of factors affecting the purchase of goods and services by means of internet technologies (by groups of respondents)

	Group 1	Group 2	Group 3
Group 1	1		
Group 2	0.96*	1	
Group 3	0.91**	0.81***	1

** correlation coefficient is reliable at a significance level of 0.0005*
*** correlation coefficient is reliable at a significance level of 0.005*
**** the correlation coefficient is reliable at a significance level of 0.01*

Phase 3: "Creating a matrix of weighted average of factors influencing the purchase of goods and services through Internet technologies"

The first step in the third phase is to determine the indices of each individual factor affecting the purchase of goods and services using Internet technologies. Indices allow to determine the degree of importance of each individual factor from 0 to 1 and are calculated by the formula:

$$I_i = \frac{\Sigma\left(M_{ij} * W_j\right)}{5} \tag{2}$$

Where

I_i - the index of the i-th factor affecting the purchase of goods and services by means of Internet technologies;

M_{ij} is the average assessment of the i-th factor influencing the purchase of goods and services by means of Internet technologies in relation to the j-th group of respondents;

W_j - percentage of questionnaires selected for analysis (respondents who search for information about goods and services daily or more often than once a month)

5 - the maximum possible rating of the i-th decisive factor affecting the purchase of goods and services by means of Internet technologies.

The calculated indices can be written as the following vector (Tab. 7).

Table 7: The vector of indices of factors affecting the purchase of goods and services by means of internet technologies (for the entire analyzed sample of respondents)

Y	=	0.904	=	A - Availability of goods and services	Consumer Behavior Rationalization Factors
		0.867		B - Lowest Price	
		0.875		C –Usability and easy navigation	
		0.855		D –Time Saving	
		0.788		E - Brand and online store loyalty	Consumer Behavior Standardization Factors
		0.675		F –Reviews of friends and acquaintances	
		0.713		G - Reviews of other Internet users about the product or service	
		0.529		H - Advertising	

The second step of the third phase is the calculation of indices for individual factors for individual groups of respondents (potential customers), which can be presented as the following matrix (Tab. 8).

The indices in tab. 8 were calculated using the following formula:

$$Iij = \frac{M_{ij}}{5} \tag{3}$$

where I_{ij} - the index value of the i-th factor for the j-th group.

Table 8: Matrix of indices of factors affecting the purchase of goods and services by means of internet technologies by groups of respondents

	The first group of respondents	The second group of respondents	The third group of respondents	
A	0.800	0.942	0.966	Consumer behavior rationalization factors
B	0.758	0.900	0.966	
C	0.814	0.886	0.966	
D	0.786	0.858	1.000	
E	0.672	0.808	0.966	Consumer behavior standardization factors
F	0.514	0.728	0.800	
G	0.600	0.722	0.934	
H	0.400	0.536	0.800	

The third step of the third phase is the construction of matrix of weighted average of factors influencing the purchase of goods and services by means of Internet technologies (Tab. 9).

To do this, we calculate the weighting values of each specific i-th factor for the j-th group (data from Tab. 8) and for the entire analyzed sample of respondents (data from Tab. 7).

The weighting values of individual factors are calculated by the formula:

$$P_{ij} = \frac{I\ ij}{\Sigma(I\ ij)} \tag{4}$$

Where

P_{ij} – the weighting value of the index of the i-th factor for the j-th group.
$\Sigma(Iij)$ is the sum of all values of the indices of the i-th factors for the j-thgroup.

The obtained matrix of weighting values allows to determine the significance of each factor taken together which influence consumer behavior by groups of respondents and for the entire analyzed sample of respondents.

Table 9: Matrix of weighted average of factors affecting the purchase of goods and services by means of internet technologies

	The first group of respondents	The second group of respondents	The third group of respondents	For the entire sample	
A	0.150	0.148	0.131	0.146	***Consumer behavior***
B	0.142	0.141	0.131	0.140	

C	0.152	0.139	0.131	0.141	***rationalization factors***
D	0.147	0.135	0.135	0.138	
E	0.126	0.127	0.131	0.127	***Consumer behavior standardization factors***
F	0.096	0.114	0.108	0.109	
G	0.112	0.113	0.126	0.115	
H	0.075	0.083	0.107	0.084	

Phase 4: "Creating a hierarchical composition of factors affecting consumer decision-making"

The resulting matrix of weighted average allows to create a hierarchical composition of factors influencing the process of making consumer decisions. A model of such a composition is presented in Fig. 5.

Figure 5: Model of hierarchical composition of factors influencing the process of consumer decision-making

This hierarchical composition allows to understand how the changes in priorities at the second level affect the changes in priorities at the third level and, on this basis, create a system for managing consumer decisions. In other words, the use of the proposed hierarchical composition allows to "encourage the consumer to make purchases" by increasing the influence of consumer behavior rationalization factors or consumer behavior standardization factors. The consumer decisions management system generated in this way can be used both for the entire set of potential customers and for selected groups.

For example, a certain hypothetical entrepreneurial enterprise having researched the market in which it operates decided that customers belonging to the first group are the most important (generate the most profit. are the most promising from the point of view of expanding the range of product sales. etc.). In this case, the most attention should be paid to such factors: C - "usability and easy navigation" (the weighting value of the factor for this group of clients is 0.152). A - "availability of goods and services" (0.150). D - "time saving" (0.147). In other words, the personal comfort of making a purchase has a greater impact on consumer decisions of potential customers of this group. In this case, it is the comfort of the consumer decision-making process that encourages the consumer to make purchases. This means that a hypothetical manufacturer must take certain steps towards improving the comfort zone of a potential customer. At the same time, the price does not have to be the lowest on the market (the weighting value of the factor for this group of clients is 0.142) and the cost of advertising can be reduced or at least not increased (the weighting value of the factor is 0.075).

Thus the created hierarchical composition provides more detailed information on the directions of transformation of consumer behavior and allows the producer of goods and services to optimize the process of managing consumer decisions.

Conclusions

The conducted research allows us to draw the following conclusions.

1. One of the most distinctive features of a modern economy is the intensification of the use of Internet technologies, both in the process of running business and in the process of making consumer decisions. The widespread use of Internet technologies leads to the transformation of the consumer behavior model. Entrepreneurial enterprises should take into account these transformation processes when developing their marketing strategies. In this regard, entrepreneurial enterprises need to constantly monitor changes in the consumer behavior of their customers, as well as respond quickly and efficiently to these changes.
2. Producers of goods and services should pay attention to the multidirectional changes in consumer behavior, namely an increase in the rationalization trend, on the one hand, and standardization of consumer decisions, on the other. To ensure its influence on both trends, entrepreneurial enterprises need to provide the customer with the most comprehensive information about their products and services, which increases the rationality of consumer decision-making, and at the same time takes part in the formation of information cascades, which determine the standardization of consumer choice.
3. In order to achieve the above-mentioned tasks, the authors proposed the model of a hierarchical composition of factors that influence consumer decision-making. The advantage of application of the proposed hierarchical composition is that consumer decisions management system is based on a modular principle, and therefore is stable and elastic at the same time. The elasticity of such a system is provided by the possibility of changing one or several modules, not the entire system. Modular (partial) changes also guarantee the stability of the system, since they are aimed only at correcting the system, not at destroying its integrity.

Trends of Digital Technologies Implementation in Nonprofit Activities of Foreign Countries and the Russian Federation

Varvara GORIACHEVA

Plekhanov Russian University of Economics, Moscow, Russia
E-mail: goriacheva.prue@bk.ru

Abstract

The subject of the study is digital technology in nonprofit activities. The goal is to identify experience in the application of digital technologies in this field. Research hypothesis: Russian nonprofit organizations are in line with global trends of digital technologies implementation in the charitable and social activities. The method of comparative analysis of the use of digital technologies in the activities of foreign and Russian nonprofit organizations is applied. Results 1) The popularity of crowdfunding and crowdsourcing as elements of digital technologies is growing all over the world. 2) Crowdsourcing and crowdfunding are innovative instruments of conducting charitable and social activities well developed in European countries and in the USA. 3) Russian Federation is in line with world tendency of expanding the use of digital technologies in nonprofit activities. 4) Though the dynamics is high, the volume of funds collected via online platforms in Russian Federation is much lower than in European countries and the USA due to a certain historic lag in the development of nonprofit activities.

Keywords: Nonprofit Organization, Digital Technologies, Social Entrepreneurship, Crowdsourcing, Crowdfunding.

Introduction

In the European countries, in the USA the nonprofit sector development is characterized by the search for social innovations to solve problems in the social sphere. Nonprofit organizations are in need for diversification of the ways of attracting funds for realization of the nonprofit projects in order to boost their sustainability (Farinha et al., 2020; Garcia-Rodriguez and Romero-Merino, 2020). It becomes relevant to use the achievements of scientific progress, computer technology, expanding the range of investment activity instruments and assessing the social results of the funds spent (Salamon, 2014; Jensen, 2017). The technological direction of the nonprofit activities development arose at the intersection of information technology and traditional nonprofit activities. This direction involves the implementation of economically sustainable solutions to alleviate socially significant problems and meet the needs of socially vulnerable groups of citizens, which are based on the use of digital and information technologies (Howe, 2006; Salamon, 2014).

The research in the field of digital technologies implementation for boosting nonprofit activities is affected by the lack of a systemic understanding of the features of the functioning and development of the nonprofit organizations at the present stage. It also concerns the lack of practical knowledge in the field of digital technologies that are used for fundraising, for the nonprofit projects implementation and as a method of involving a wide range of people in nonprofit activities. The problems mentioned turn to be an obstacle to the sustainable progressive development of the nonprofit organizations and their effective participation in the state social policy implementation. These problems may be solved by studying the principles of functioning of nonprofit organizations and entrepreneurs in the social sphere at the present stage, by studying the concept and essence of social innovations and possibilities of digital technology for boosting nonprofit activities (Howe, 2006; Salamon, 2014; Baran, 2020).

The use of digital technologies in nonprofit activities affects the development of human capital, as it helps to reveal the creative and labor potential of the population, including citizens from socially

vulnerable groups. Promoting the development of human capital, in turn, contributes to the development of technological and social innovations. For the current stage of development of the nonprofit sector concerning digital technologies, it becomes relevant to assess the financial and social results of the activities of nonprofit companies and other participants in the nonprofit activities, including partnerships among the state, business and society in projects for the development of the social sphere. B. Weisbrod was one of the first to study the level of production of social effects in nonprofit organizations and the characteristics of intersectoral interaction with government and business representatives (Weisbrod, 1997). At the moment, the nonprofit project social results are as important as the financial ones and require measuring. The project relevance to the organization's mission is also investigated. That's why the administrative expenses of a nonprofit organization should be partly spent on professional management of a project portfolio (Ang, Sankaran and Killen, 2016). The use of methods for measuring social results and the use of digital technologies to collect this information allows to obtain significant amounts of data on social performance, make social forecasts and identify problem areas in the development of the nonprofit sector as a whole, and improve the nonprofit activities practice. In this way, the nonprofit organizations social impact should be measured individually and in aggregate, which should always be the ultimate goal of collecting information (Branch et al., 2019).

The nonprofit sector, including a wide range of organizations, is subject to all the changes taking place in society associated with increasing informatization. Active development of digital technologies gives the sector both new opportunities and challenges. Thus, the process of interaction and exchange of experience is greatly facilitated through the information technology use. Fundraising, marketing social goods and services is greatly simplified in the virtual world. Features of the implementation of projects through Internet platforms are described in the works of foreign authors (McNutt et al., 2018).

The use of digital platforms is one of the factors that enhance the nonprofit organizations competitiveness. The situation is similar to the situation in industrial production, where modernization is the key to the economic development of the whole country. The choice of a digital platform should be justified by the organizational and legal form of the organization and the features of its functioning (Zavyalov, Zavyalova and Kiseleva, 2019).

At the moment, there exist some online platforms for the exchange of proposals for solving social problems. This approach is based on the concept of open innovation, described by H. Chesbrough in relation to the sphere of production (Chesbrough, 2003). The author substantiates that in order to achieve technological progress and economic growth in modern conditions, it is much more efficient to share the inventions obtained during research and development so that other companies can freely implement them. The exchange of innovations in the social sphere will contribute to the development of the whole society, and scalable and replicated solutions, including those based on the use of innovative technologies, will be implemented in various countries of the world.

The use of digital technologies to engage the population in intellectual volunteering (crowdsourcing) has been studied by J. Howe (Howe, 2006). Currently, crowdsourcing in some areas is used as a form of labor volunteering through Internet services to solve socially significant problems. L. Thompson, a professor at the Kellogg School of Management, USA, has been researching how to improve your search for ideas using written brainstorming, a similar technique used in crowdsourcing (Thompson, 2013). The importance of the development of all forms of volunteering for the successful development of society is substantiated in the works of L. Salamon, V. Sokolowski, M. Haddock (Salamon, Sokolowski and Haddock, 2018). In Russia, the issues of developing volunteering are becoming relevant in connection with the release of the Decree of the President of Russian Federation "On National Goals and Strategic Tasks of the Development of Russian Federation for the Period Until 2024" (Decree No. 204, May 2018), which focuses on taking measures to achieve breakthrough scientific, technological and socio-economic development of the country, including the creation of opportunities for creative and labor realization of human potential. The issues of increasing the possibilities of the population to participate in volunteering, reducing the technological gap from

foreign countries were studied in the report of the Higher School of Economics "Volunteering and Charity in Russia and the Tasks of National Development" (Benevolensky et al., 2019).

The need to use a wide range of tools to raise funds in nonprofit organizations and the use of approaches non-traditional for the charitable sphere was substantiated by L. Salamon (2014). According to the scientist, in order to solve the global problems that humanity faces in the social and environmental spheres, combined with the declining social budgets of governments and traditional benefactors, it is necessary to go beyond the grant approach, funds, and even money circulation. The scientist sees the future of modern charity in the creation of new financial and non-financial tools for conducting nonprofit activities, such as volunteer work platforms, Internet portals, capital aggregators and other organizations and institutions.

An analysis of the literature shows that the issues of introducing digital technologies as a part of innovation element in nonprofit activities are actively explored by foreign authors. This practice has deep historical roots in European countries and in the USA. In Russia these issues are only just beginning to be considered for implementation in the activities of nonprofit organizations, however, there is already positive experience in using digital technologies to solve social problems.

The article sets a goal to conduct a comparative analysis of the practice of introducing digital technologies into the activities of nonprofit organizations in European countries, in the USA and in Russia in order to increase the level of public involvement in nonprofit practices and raise enough funds for the sustainable development of nonprofit organizations.

Research Methodology

The theoretical and methodological basis of the paper was the scientific publications of Russian and foreign scientists on the problems of social development, social innovations generation, functioning of the nonprofit organizations and enhancing economic sustainability and effectiveness of nonprofit organizations. The study consists of four parts: 1) Analysis of digital technologies usage in the practice of nonprofit organizations in the USA, in European countries and in Russia; 2) Examination crowdfunding and crowdsourcing as new tools of conducting nonprofit activities; 3) Determination of the required properties of nonprofit projects; 4) analysis of the practice of digital technologies implementation in the practice of Russian nonprofit organizations.

Another block of information provided concerns facts and statistics of development of crowdfunding and crowdsourcing in Russia and abroad. The article uses a systematic approach to the study of the problem. The following general scientific and special research methods are applied: comparative analysis, synthesis, analogy, as well as logical method. In terms of information, the paper is based on statistics and analytical materials provided by charities and charitable foundations, such as Charities Aid Foundation, Fundly, service of aggregated statistics Statista, official websites of online platforms for giving.

The following terms are used in the article:

- Nonprofit organizations are non-governmental organizations established to achieve socially significant goals, and not to make a profit;
- Fundraising means raising funds from external sources by a nonprofit organization for the implementation of its own projects, with the exception of entrepreneurial activity;
- Crowdsourcing is a way to attract a wide range of people to solving problems, including through Internet platforms, to use their creative potential, knowledge and work experience;
- Crowdfunding is a method of fundraising through online platforms aiming to implement a project in any field, including social.

Results

The technological direction of the nonprofit sector development arose at the intersection of information technology and nonprofit activities. This direction involves the implementation of economically sustainable solutions to alleviate socially significant problems or to meet the needs of socially vulnerable groups of citizens, which are based on the use of digital and information technologies.

Crowdfunding and crowdsourcing can be considered elements of open innovation that combine digital technology and a method of solving problems in the social sphere. They both let potential donors and nonprofit organizations "meet" in the same information space, accelerating the process of finding partners for charitable activities. This service allows to engage in microfinance, providing microloans to individuals, which some researchers consider socially oriented activities (Yunus, 2017). Table 1 presents statistics on the amount of funds raised through crowdfunding around the world for 2012-2019.

Table 1: Statistics on the volume of funds raised through crowdfunding around the world, 2012-2019

	2010	2011	2012	2013	2014	2015	2016	2017	2018	2019
Volume of funds, billion US dollars	0.9	1.5	2.7	6.1	16.2	34.4	No data available	32	-	34
Growth, %	-	66	80	126	165	112	-	-	-	-

Source: compiled by the author according to: Richter, 2013; Fin Tech, 2015; Statista Research Department, 2015; Szmigiera, 2019; Fundly, 2020.

The volume of funds raised through crowdfunding in the world stood at 34 billion US dollars in 2019, which means a 37-fold increase over a ten-year period. The popularity of this instrument of funding projects demonstrated steady growth in the period 2010-2015 and weakened after 2017. Though there's a trend of moderate saturation of the market, the author interprets the skip in 2015 with the changes of methodology of calculation.

Crowdfunding is well developed in European countries and in the USA. The "JustGiving" (United Kingdom) is a platform for giving, where different nonprofit organizations may use crowdfunding to raise money for social and charitable causes all over the world. Since 2000 the platform has helped more than 25 000 charities raise over $4.5 billion for charitable needs from 22 mln donors in 164 countries. "DonorsChoose" (USA, 2000) is an online platform for donations to equip public school classrooms on the principles of trust and transparency. Since it was launched the platform helped raise $953 mln for more than 1,6 mln projects and 39 mln students. "Network for good" (USA) is a certified corporation established to offer software for nonprofit organizations. Since 2001, the corporation has processed over $2.54 bn in donations for more than 300 thousand nonprofits. All the examples provided prove the high demand for digital tools for conducting nonprofit activities not only in developed countries, but all over the world. European experience of launching online crowdfunding platforms is also successful. Such well-known platforms as "CAF Donate" raised £27 mln in 2019. Overall amount of giving in the UK in 2018 remained high at £10.1 bn (Charities Aid Foundation, 2019). "Helloasso" (France, 2009) is another platform letting French associations register and launch their own fundraising campaigns using digital technology. The European Commission harmonized rules to boost European crowdfunding platforms (European Commission, 2019). The new rules aim to enhance investor protection, transparency of the operations and supervision, thus, to create a more open crowdfunding ecosystem.

These examples reveal active process of digital technologies implementation in the practice of nonprofit organizations in European countries and in the USA. The process dates back to the beginning of 2000-th, so almost the 20-year experience in this field is already gained.

The cutting-edge tendency in the development of charitable activities is boosting its financial and economic sustainability combining the following principles: assessment of social impact, fundraising

diversification, innovation. These principles lead to hybridization of nonprofits and blurring the ranks of its activity towards for-profit social entrepreneurship. The origins of entrepreneurship require high level of innovation activity of an organization to attract consumers or to meet the requirements of beneficiaries. Combined with the possibilities of digital technologies the services and products of nonprofit organizations acquire such properties as scalability, openness and replicability, novelty in solving a socially significant goal. In order to boost economic sustainability, the social business or a project should be self-sufficient. Crowdfunding tends to combine the requirements of contemporaneity and provide a tool for socially innovative projects realization.

Crowdsourcing is a way to attract a wide range of people to solving problems, including through Internet platforms, to use their creative potential, knowledge and work experience. The peculiarity of crowdsourcing, in contrast to outsourcing - attracting third-party professional executors - is the voluntary participation in the project. Payment for labor may be absent, be market, or below market. Since crowdsourcing can be used for charitable purposes, it becomes a kind of intellectual and labor volunteering through Internet services to solve socially significant problems.

As part of crowdsourcing, it is possible to use a technique similar to brainstorming - writing brainstorming (brainwriting), that is, recording ideas rather than expressing them, which leads to an increase in the total number of ideas by 20%, and efficiency compared to traditional brainstorming increases by 42 %, according to L. Thomson, professor at the Kellogg School of Management, USA (Thompson, 2013).

There are disadvantages of crowdsourcing as a tool for solving social problems, potentially poor-quality work of volunteers or offering solutions with a low coefficient of innovation, participating in the proposal of solving problems not only with high professional skills, but also without those. There are some problems that are especially relevant in Russia: participation in crowdsourcing for nonprofit organizations may be paid as an “employer”, and it will be difficult to allocate these amounts from the budget and obtain permission to use them; the quality of the proposed solutions may be low due to the relatively low level of competence of the population in social issues and methods of solving them, because of the conviction of the population that volunteering should not require serious efforts, and any developed solutions and innovative ideas should be sold for great reward. But now there is, albeit a small, but modern layer of youth and specialists who understand the essence of the nonprofit sector and seek to use their own potential to solve social issues.

The combination of nonprofit activity with an entrepreneurial approach is a promising direction for the development of the nonprofit sector. The potential of this approach is great, in the conditions of the development of a knowledge-based economy, it can be a valuable source of original ideas for solving problems of the nonprofit sector.

Social innovations and social entrepreneurship in Russia have great potential for development. Since 2008, nonprofit online platforms have been developing, the first of which was “Blago.ru”. Over 10 years, more than 125 million were collected in favor of 117 nonprofit organizations, the platform has more than 32 thousand donors. In 2012, the first crowdfunding platform “Planeta.ru” was launched, and two years later a section with charity projects was established. Since 2017 “Sberbank Vmeste” is a service for regular assistance to nonprofit organizations. It allows to bind a bank card and make donations automatically every month. “MeetForCharity” is an online auction where lots are a meeting with famous people. Funds from the auction are spent on charity needs. The facts above prove that in Russian society is in line with the world trends of nonprofit activity development, but there’s a certain lag in the time of establishment of the platforms. Table 2 shows the statistics on the volume of donations through crowdfunding in Russia over the past six years.

Table 2: The volume of attracted online donations through crowdfunding in Russia, 2013-2018

Year	2013	2014	2015	2016	2017	2018
Mln roubles	23.4	71.2	138	246.5	348.5	407
Annual increase, %	-	204.3	93.8	78.6	41.4	16.8

Source: Khodorova and Bobrova, 2018, p. 7.

The information provided demonstrates the active development of the practice of donations through online platforms. The amount of donated funds for the period under review increased 17 times. However, the growth rate is falling annually. According to the author, this is due to the stabilization of the practice of attracting online donations through crowdfunding and a number of legal and practical restrictions related to the use of this type of fundraising for both nonprofit organizations and donors. Nevertheless, the dynamics of development of crowdfunding in Russia is still high enough. Although the volume of funds collected via online platforms in Russia is much lower than in the USA and UK, this method of conducting charity activities is getting more popular both with donors and nonprofits.

Nonprofit crowdsourcing is actively developing in Russia. Intellectual volunteering platforms are emerging that help nonprofit organizations and civic activists save time and money on resolving legal, financial, and legal issues, using the help of an expert community from the business sector. Russia's first socially oriented crowdsourcing platform, SODEA, was established in 2015. “ProCharity” platform was launched in 2017 by the “Friends” charity foundation. The “Nashe Budushee” Fund has several projects of significant importance for the development of the nonprofit sphere. One of it is the Bank of Social Ideas founded for the exchange of ideas on social entrepreneurship. This service is the embodiment of an open innovation model: users have the opportunity to propose an idea for implementation by other entrepreneurs or gain ideas for developing their own business.

The Russian technological area of nonprofit activity lags behind some developed countries in terms of the amount of funds raised. This is due, first of all, to the later start of the development of crowdsourcing and crowdfunding (Table 3).

Table 3: Information on the time of foundation and the name of socially oriented and charitable platforms abroad and in Russia

	Abroad		In Russia	
	Year	Name	Year	Name
The first charity and nonprofit projects oriented crowdfunding platform	2000	JustGiving*	2008/2014	Blago.ru/Planeta.ru *
The first charity and nonprofit projects oriented crowdsourcing platform	2000	Onlinevolunteering.org	2015	SODEA

Note: The JustGiving and Blago.ru platforms were based on collecting donations, Planeta.ru was founded directly for crowdfunding, where a section with charity projects subsequently appeared.

Source: compiled by the author according to: Khodorova and Bobrova, 2018, p. 6; JustGiving, 2020; United Nations Volunteers, 2020.

Despite the obvious advantages of launching nonprofit projects through online platforms, this method cannot become universally common and universal for nonprofit organizations. At least there are three reasons preventing this: financial instability of nonprofit organizations and lack of additional funds; insufficient qualifications of staff for organizing and managing projects; lack of the necessary skills to evaluate the received or desired social impact. Another problem is the low culture of making donations to nonprofit organizations, which affects the slow spread of charitable fundraising through crowdfunding. Crowdsourcing of charitable projects is also not yet a common practice. A relatively small number of people are involved in innovation, social entrepreneurship, and the implementation

of social projects. This is due to the irregularity of such participation, a low level of personal motivation, and often the coincidence of participation in charity and volunteer activities. At the same time, it is digital technologies that help to bring nonprofit activities to a new level of development, increase the mass participation in it, significantly simplify the collection of charitable donations technically, and facilitate the search for social innovation.

Discussion

Realization of part of the nonprofit activities via online platforms is a call of modern time. Crowdsourcing is one of the new fundraising tools that helps fight sustainability changes and diversify the financial resource for activity. Crowdfunding is an instrument of search of socially innovative ideas that is an essential part of nonprofit activity and social entrepreneurship. Moving towards the standards of conducting traditional business for nonprofit organizations especially in the field of evaluation of social impact and project management is a vivid tendency of nowadays. This result coincides with the position of L. Salamon who argues that a nonprofit organization should diversify its fundraising strategy and evaluate results to become more sustainable (Salamon, 2014). Jensen P. warns that this new neoliberal trend may blur the social mission of an organization and harm its core values (Jensen, 2017). Some researches consider crowdfunding campaigns to be less profitable for nonprofit participants than for others, so this instrument for raising funds for nonprofit projects should be examined better using statistics of a certain country (Makýšová and Vaceková, 2017).

Participating in crowdfunding and crowdsourcing campaigns may bring to the additional costs, which can be problematic for nonprofit organizations experiencing economic instability (McNutt et al., 2018). In Russia about 36% of nonprofit organizations are experiencing financial problems, staffing - another 18%, according to the research of S. Nemgirova (2016). Dolzhenko R. A. points to the need to conduct an expert evaluation of the solutions obtained through crowdsourcing, which in some cases requires the involvement of specialists and additional payment for their labor (2014). But this is not the only difficulty associated with the selection of crowdsourcing projects. Experts are not always able to identify truly innovative projects in view of the large volume of proposals received, or because of their non-standard, complexity, unpopularity - at first glance. In addition, from the author's point of view, crowdfunding can hardly become the main source of fundraising for the implementation of projects for nonprofit organizations: such a source of funds is not financially sustainable and can be used to supplement the organization's core business.

Conclusion

Nonprofit activities that use digital technologies, such as online donation platforms, crowdfunding, crowdsourcing, are recently developing all over the world and in Russia. They are gaining popularity and are undergoing institutionalization in Russian society. Being one of the tools for nonprofit activities, they have their own limitations and opportunities. Limitations are associated with the lack of professional skills of employees, the peculiarities of statutory activities and the financial instability. The use of digital technologies gives nonprofit organizations access to a wide range of people outside the territory of their presence and provides a new vision for solving social problems. Despite obstacles that nonprofit organizations face in Russia, introducing digital technologies in their practice, interest in new tools for nonprofit activities is increasing annually, which encourages nonprofit organizations to gradually widen their participation in electronic platforms.

The Utility Of Electronic Bracelets For Monitorin Hospitalized Patients

Lucia ZEKRA

Ovidius University of Constanta, Clinical Infectious Disease Hospital of Constanta, Constanta, Romania, Luciazekra@yahoo.com

Abstract

The Romanian health system is currently in need of an update regarding the introduction of new devices to make it easier for specialists in the field of healthcare to offer quality medical services, in order to increase the quality of life of patients. The introduction of electronic bracelets for monitoring patients could serve with success in providing a clear picture of their biological functions in dynamics, but also for location within the hospital institution. A disadvantage of these devices could be the psychological effect of continuous monitoring and physical discomfort.The real effects and benefits of introducing such devices cannot be anticipated successfully, requiring further analysis and research on a significant number of patients.

Keywords: Monitoring, Biological Functions, Technology

Introduction

Today's technology has reached a high level of performance, successfully replacing even some occupations, being within the reach of specialists in many fields. Thus, we can meet cars that park alone, robots that perform surgery, etc. Why not we use this technology on a large scale for patients, to monitor and supervise them successly?

In Romania, the health system has a rather low level of technology, but in the same time and a fairly low number of health care personnel per number of patients. The introduction of intelligent patient monitoring devices would bring a number of benefits, both for patients and for medical staff (doctors and nurses). Thus, these devices can monitor both the vital functions of the patient: blood pressure, pulse, saturation and temperature, as well as its exact location in the institution during the hospitalization or even later.

Types of Patient Monitoring Devices

As Dias and Silva (2018) described, currently we can find a variety of electronic devices, connected to the computer or even on smart phones that track the number of steps or distance traveled, heart rate, the number of calories burned over a period of time, among others. These are not medical devices, but they can provide information about the biometric values of the body.

Portable health devices (WHDs) are an emerging enabling technology, continuous patient monitoring of vital signs during daily life (during work, at home, during sports activities etc.) or in a clinical environment, with the advantage of minimization of discomfort and interference with normal human activities.

Accordind to Di Rienzo (2005), the system, called Magic (Computerized Interactive Maglietta), is composed of a vest, including sensors for ECG detection and respiratory activity and a portable electronic sensor for motion detection, signal preprocessing and data transmission, wireless, to a remote monitoring terminal. The Magic system was tested on free-moving subjects at work, at home, at the wheel of the car

and while riding a bicycle. The applicability of the system to cardiac patients is now being evaluated. Preliminary data obtained from the records made in patients at rest and during exercise have shown: good signal quality in most monitoring periods; a correct identification of arrhythmic events and a correct estimation of the average beat / minute rate. These positive results support the further evolution of the Magic system, which aims to adapt it in approaches for routine use in clinical practice and in everyday life.

The use of WHDs enables the capture of vital signs and monitoring of health status extended periods (days / weeks) and outside the clinical setting, according to Dias and Silva (2018). This feature allows collecting vital data during different daily activities, ensuring better support in medical diagnosis and which helps to better and faster recovery after a surgical intervention or trauma. WHDs are also very useful in sports / fitness activities to monitor the performance of the athlete or even the military personnel to evaluate and monitor the response of their bodies in different dangerous situations and to manage them better in effort and health during work. These devices can be used for both medical purposes, as well as / or fitness / wellness activities, always aimed at monitoring the body.

In the research of Paradiro et. all (2005), another comfortable health monitoring system is WEALTHY. The system is based on a portable interface of textile material, implemented by the integration of sensors, electrodes and woven connections, advanced signal processing techniques and modern comunication systems. Sensors, electrodes and connections are made with conductive wires. The capacity of this system to simultaneously capture several biomedical signals (electrocardiogram, saturation, blood pressure or temperature) was investigated and compared with a standard monitoring system. The results show that the information obtained from the integrated systems is comparable with those obtained by standard sensors. The proposed system is designed to monitor people affected by cardiovascular disease, especially in the rehabilitation phase. The system can help, also, professional workers who are subjected to physical and mental considerable stressors and / or both daily and occupational health risks.

Yilmaz et. all (2010) described that the emergence of wireless technologies and advances in the design of the sensor attached to the body of the patient can lead to the change of the conventional system of health care, replacing it with individual distance-based healthcare systems. Portable monitoring systems can provide continuous physiological data as well as better information on the general condition of health for individuals. Thus, such vital signs monitoring systems will reduce patient care costs through disease prevention and will improve the quality of life with disease management.

The advances in wireless technologies, the Internet and the field of interconnected health determine innovations of portable medical devices at an extraordinary rate. Portables sensor systems made of flexible and extensible materials have the potential to interfere better with human skin, while electronic components based on silicon are extremely effective in processing and transmission of data obtained by sensors. Therefore, flexible sensors, combined with silicon based electronics with reduced power are a viable and effective approach for medical monitoring, according to Khan et. all (2016).

On the website of Zerintia (Spain), the manufacturer of this technology, proposes the introduction of new e-health bracelets that allow improvement technology regarding patient monitoring and biometric measurements; this is a discovery and opens a way to explore new possibilities in the medical world. These new devices also have SDKs that allow developers of medical platforms to integrate quickly and efficiently, exploiting the full potential and adapting them to the needs of each medical center. Zerintia has already started collaborating with partners like Angel Sensor, the Samsung platform or Apple HealthKit. It is desired to develop a device adapted to this environment and focused on medical solutions for the following scenarios:

- Monitoring of hospitalized patients: once configured to the user, if the heart rate,t he temperature, their movements involve agitation or anxiety, an alarm is sent to the medical staff. These bracelets could replace the current ones with barcodes.

- Outpatients: after a surgery or a period of convalescence, they are sent home and do not have the support or supervision of a relative, requiring monitoring in the first days to prevent cases of complications of the type.

All of this will also be improved with new platforms and media and use of Big Data that the leading technology brands offer:

- Microsoft Health Platform: A collection of best practices and guidelines to build fast, secure and efficient e-Health solutions.
- SAMSUNG - Digital Health Initiative: technological platform that combines bracelets with SIMBAND sensors, together with the cloud data storage platform: SAMI.
- Apple: HealthKit is a framework and an important part of iOS8 and is the first step to getting the one more potential from the Apple Watch. It provides centralized information on medical history, in a coordinated and safe way. HealthKit works with third-party applications and provides them to control users over the exchange of information. ResearchKit is an open source framework that allows researchers and developers to create applications for medical research. Its potential lay in its ease of use, real-time tasks, variety of customized surveys and sharing with the scientific community.
- Philips HealthSuite digital platform: a platform for connecting patients, doctors and medical providers. Bringing health beyond the walls of the hospital into our homes and in our daily routine it is a wish.

This new revolution could soon become effective, as well conventional bracelets do, will begin to be part of the scientific research of the health of the ecosystem, of medicine and science, supporting the improvement of measurements, more realistic, real-time and with minimum impactful on patients.

Another producer, Medieta (Finland), also proposes a variant of the e-health bracelets, information found on their website. ErrS bracelet is equipped with GPS and measures several different biosignals, such as blood pressure, cardiac rhythm, respiratory rate and oxygen saturation. The measurement data is transferred in real time to Medieta cloud platform, where the doctor or nurse can verify the measurement data. They are also warned if significant anomalies or changes are detected at the level of vital functions of the patient.

In addition to collecting data, the system analyzes the data collected in the early warning score tables, which are widely used in hospitals and predicts possible development of complications such as cardiac attack. Remote monitoring makes it possible to discharge patients from the hospital earlier and reduces unnecessary hospital visits. This not only improves the well-being of patients, but it also brings substantial cost savings when fewer days of hospitalization are needed, and resources can be allocated more efficiently. Moreover, the data can be used to determine the right medication and treatment needed or, in some cases, even to see if a patient remembered to take the medicine.

Although the bracelet is equipped with suitable features for the pursuit of vitality, the plans of Medieta does not include expansion in the consumer market. Instead, the company considers different bracelet versions, which may be prescribed by doctors not only to existing patients, but also people in high-risk groups.

Advantages and disadvantages in using monitoring devices of patients

The advantages of Introducing the Patient Monitoring System

From the patient's point of view, but also from the medical staff, we can identify a series of advantages:

- monitoring vital functions on a regular basis can create an extremely comprehensive image on the pathological values of blood pressure, pulse, oxygen saturation and / or temperature.
- in case of limit values on vital functions, the doctor and the nurse can be alerted in real time, thus reducing their reaction time.

- the system can provide important data on the effectiveness of a treatment scheme. For example, a patient with high blood pressure can be easily monitored for treatment change of his heart condition.
- in the intensive care units, the introduction of mobile function monitoring systems can be vital of real help in the limit situations, warning in real time the existence of a imminent danger, but also the pathological values of these functions.
- from the psychological point of view, the patient can feel a real comfort knowing that it is monitored in permanence both during the hospitalization period and subsequently at home.
- in addition to monitoring vital functions, the doctor may also have access to other information about patients: medical history of chronic and acute conditions, allergies, chronic treatments, etc.
- by recording the values of the vital functions, with the help of an application installed on a computer from the hospital network, a patient profile and a complete history can be created.
- the care staff, with the help of the mounting device, can find out at any time where it is located inside the hospital

The disadvantages of introducing the patient monitoring system

- any computer system is at risk of being accessed by unauthorized persons and of occurring errors in operation
- certain patients may experience a certain state of anxiety knowing that they are monitored in permanence
- a monitoring device, such as an electronic bracelet, can create some discomfort after long wear

Conclusions

As man adapts to changes and innovations of technology, and not only, in turn technology needs to adapt to the growing needs of humanity. If by the year 1800, the doctor was obliged to attach the ear to the patient's chest to assess its arterial tension, the 21st century brings innovation in technology, especially medical. So, e-health bracelets are a must, soon becoming devices as popular as bicycles or mobile phones. These increase the quality of the medical act, while lowering the costs for providing medical supervision and treatment.

Accounts for Future Events, which Characterize the Activities of a Company, i.e. a Methodo-Logical Approach

Olga S. EREMEEVA

Khakassian State University named after N.F. Katanov, Abakan, Republic of Khakassia, Russia
E-mail: eremeeva.ksu@bk.ru

Abstract

The reporting development in terms of including information about the future of the enterprise is dictated by the needs of reporting users. To improve the quality of reporting, a universal methodology for accounting for future events should be developed. The purpose of the article is to reveal the methodology developed by the author for future events accounting. The method-ology includes sections, i.e. accounting objects, accounting tools and accounting techniques. The article defines the information of current monitoring, with the help of which it is possible to form a predictive opinion on the future values of assets, liabilities, income and expenses. Accounts and tools for its accounting are selected for the specified information. The uniqueness of the method lies in methods of traditional accounting, adapted to the requirements of modern accounting standards and financial reporting, while at the same time it is aimed at reflecting forecasted and integrated information in the reporting.

Keywords: Accounting Methods, Accounting for Future Events, Financial Statements, Integrated Reporting.

Introduction

Financial reporting continues to be the most accessible and reliable source of information about an economic entity. According to a survey of Russian companies board members conducted by PricewaterhouseCoopers, such an issue as 'increasing transparency and reporting' is seen as 'very' and 'rather' important for 93% of respondents ('*Sustainable development under the attention of boards of directors. A survey of board members of Russian companies'*, 2019) recently, the need for reporting users is to see in reporting information about the future of enterprises. Therefore, the practice of integrated reporting is in demand, as well as the inclusion of additional strategic information in the financial report. At the same time, we agree that integrated reporting does not compete with financial reporting and reporting in the field of sustainable development, but is an integral part of it (de Villiers and Sharma, 2017), the task of accounting is to ensure prospects for decision-making (Mouritsen and Kreiner, 2016), and the value of financial statements is determined by its forecast component (Evstafieva and Bogaty, 2013). This determines the relevance of building a convenient, practically applicable methodology for accounting for future events and reflecting them in reports.

To create an accounting methodology, we studied publications in the field of using accounting methods that take into account the time factor (Rayman, 2007; Pope, 2010; Okamoto, 2014; Abdalova and Karelskaya, 2015; Chen and Gong, 2019). The study examined work in the field of accounting methodology (Haynes, 2010; Beattie, 2014), accounting in conditions of uncertainty (Casta and Lesage, 2001; Dulesov *et al.*, 2019).

Non-financial problems, including environmental and social, can have far-reaching strategic importance for a company (Figge *et al.*, 2003). Disclosure of social information is important for investors (Qiu, Shaukat and Tharyan, 2016). Therefore, to construct a methodology for accounting for future events is highly required (Bernardi and Stark, 2018; Stasiskiene, 2019).

The aim of our study is to develop a methodological approach to accounting for uncertain future information, providing a comprehensive presentation in reporting both financial and socially

significant non-financial information, as well as making it possible to draw up forecast integrated reports of enterprises based on the methods and techniques of traditional accounting.

The main goals of scientific research:

- distinguish the objects of accounting information and monitoring of which is necessary to form an assessment of accounting for future events;
- identify accounts that allow you to take into account information that is important for reporting future events;
- Identify accounting tools applicable to the accounting of future events.

This method uniqueness lies in traditional accounting, adapted to the requirements of modern accounting standards and financial reporting, while at the same time it aims to reflect forecasted and integrated information in the reports.

The study was carried out based on Russian accounting practices. The work uses international financial reporting standards. Therefore, the methodology disclosed in the article can be used in other countries whose national legislation entitles these international standards.

Main Part

The study result is the methodology of accounting for future events, developed with the aim of improving the reporting quality and reporting compliance with modern user requirements. The technique is based on the method of structural-functional modeling. The main value of the methodology is the ability to use it to prepare reports taking into account future events. Through the methodology, the accountant has convenient tools for conducting integrated accounting (Table 1).

Table 1: Structural and functional model of future events accounting (developed by the author)

Methodology sections (structure)	The main question being answered	Section Content
Accounting Objects	Things to be taken into account	Objects of current observation, which could be used to generate predictive information about future values of traditional accounting objects
Accounting	Accounts to take into consideration	Accounting for objects of current monitoring Risk accounts Analytical Accounts
Tools, accounting methods	Methods to be used	Traditional accounting methods applicable to specific information about future events

Accounting Objects

The following accounting objects are traditionally distinguished as economic life facts; assets; liabilities; income and costs. The author has identified objects of current monitoring and made possible to generate predictive information about the future values of traditional accounting objects (Table 2).

The ‘Accounting objects for future events’ column reflects accounting objects, the future value of which should be estimated.

The ‘Information of the current accounting observation’ column, information is reflected, which is necessary to form an assessment of accounting objects for future events.

The 'Purpose of monitoring the object' column, an explanation is given of the need to highlight the relevant information of the current accounting observation in solving the problem of accounting for future events.

Table 2: Accounting Objects of Future Events (developed by the author)

Accounting objects for future events	Current accounting surveillance information	Object observation purpose
Assets	Asset maturity	Division of assets into non-current and current
	Asset useful life	Future assets determination
	Current and projected asset value	Reserve determination for value reduction, asset revaluation
	Maturity dates for receivables	Allowance determination for doubtful debts, cash flow planning
	The likelihood of future assets	Information generation of future contingent assets
	Exchange rate	Assets value determination denominated in foreign currency
	Differences between accounting profit (loss) and taxable profit (loss): temporary differences	Definition of deferred tax assets
Liabilities	Deadline	Long-term and short-term obligations division
	Obligations fulfillment	Separation of liabilities into urgent and past due, planning expenses for penalties, cash flow planning
	Exchange rate	Liabilities value determination denominated in foreign currency
	Probability future commitments	Reporting information on estimated liabilities, future contingent liabilities
	The compensation paid to staff	Information on estimated liabilities
	Targeted funding	Target use control, remaining obligations size determination and the possibility of their fulfillment
	Termination likelihood	Reporting information on estimated liabilities, future contingent liabilities
	Differences between accounting profit (loss) and taxable profit (loss): temporary differences	Determination of deferred tax liability
Profit	Obtaining economic benefits confidence	Accrual determination of income, forecast of future cash flow
	Future assets likelihood	Reporting information on future contingent assets
	Contracts, which duration happens on different reporting periods	Reporting period separation (past and future). Planning for future income, expenses
Costs	Future commitments probability	Reporting information on estimated liabilities, future contingent liabilities
	Confidence that a particular operation will result in an economic decrease	Accrual expense determination, future cash flow forecast
	Asset useful life	Depreciation expense determination

Accounting objects for future events	Current accounting surveillance information	Object observation purpose
	Contracts, which duration happens on different reporting periods	Separation of contractual work by reporting periods (past and future). Planning for future income, expenses

Accounts

In relation to the selected information of the current accounting observation, we summarize the possibilities of using accounts (Table 3).

Table 3: Accounts in order to keep track of future events (developed by the author)

Current accounting surveillance information	Accounts
Asset maturity	Synthetic accounts for grouping non-current assets (fixed assets, intangible assets and others) and current assets (materials, finished products, goods, cash and other)
Asset useful life	Analytical accounts (information of an analytical nature for each corresponding synthetic asset accounting account)
Current and projected asset value	Fair value is the inventory accounts of the corresponding asset. Forecasted value is regulatory accounts designed to clarify and adjust the valuation of inventory accounts, for example, 'Provisions for reducing the value of material assets' and 'Provisions for impairment of financial investments'.
Maturity dates for receivables	Sub-accounts for urgent and overdue receivables separation, doubtful debts account, off-balance sheet account for the written-off receivables, and analytical information on the maturity date.
Future assets likelihood	Introduction of additional accounts for the contingent assets accounting
Differences between accounting profit (loss) and taxable profit (loss): temporary differences	Deferred tax asset accounts
Deadline	Long-term and short-term liabilities synthetic accounts
Obligations fulfillment	Subaccounts for the separation of urgent and overdue liabilities
Future commitments probability	Reserves account
The compensation paid to staff	Reserves account
Use of targeted funding	Deferred income account
Termination likelihood	Reserves account
Confidence in obtaining economic benefits from the operation	Revenue account
Contracts, which duration happens on different reporting periods	Income account for work completed stages contractually
Confidence that a particular operation will reduce economic benefits	Expense OR cost account

The main tool for reflecting risk information in the accounting system is the creation of reserves in accounts. Modern standards provide various risk categories. The risk of loss is offset by the creation

of reserve capital with its accumulation in the corresponding account 'Reserve capital'. The risk of the assets value decrease is taken into account by reserving the amount of the reduction in the 'Provisions for reducing the value of material assets' and 'Provisions for impairment of financial investments' accounts. The risk of counterparty defaults is provided in the 'Reserve for doubtful debts' account. The 'Reserves for future expenses' account summarizes information on estimated liabilities.

In addition, it is necessary to note the great importance of analytical accounts in solving the problem of accounting for future events. Through analytical accounting, material information of a qualitative nature that is important for accounting for future events is introduced into the accounting system. For example, the duration of the contracts, the useful lives of the assets and the payment dates of debtors.

Tools and Methods of Accounting

The main tools that allow you to keep track of future events are planning, forecasting, reservation, depreciation, revaluation and accrual basis. Table 4 groups accounting tools and information that can be taken into account while using these tools.

Table 4: Future Event Accounting Tools (developed by the author)

Accounting tool	Current accounting surveillance information
Planning	Contracts, which duration happens on different reporting periods
	The compensation paid to staff
	Termination likelihood
	Asset maturity
	Asset useful life
	Differences between accounting profit (loss) and taxable profit (loss): temporary differences
	Deadline
	Obligations fulfillment
Forecasting	Exchange rate
	Maturity (repayment) period of assets (liabilities)
	Maturity dates for receivables
	Future assets likelihood
Reservation, revaluation	Current and projected value of an asset
Reservation	Future commitments probability
	Termination likelihood
Accrual basis	Economic benefits from the operation
	Confidence that a particular operation will reduce economic benefits

Conclusion

The reporting development regarding the future of the enterprise is dictated by the needs of reporting users. To improve the quality of reporting, a universal methodology for accounting for future events should be developed. The article presents the accounting methodology for future events, which provides reporting information of both financial and socially significant information of a non-financial nature, as well as making it possible to draw up forecast-integrated reports of enterprises based on the methods and techniques of traditional accounting.

The methodology is showed in the following sections, i.e. accounting objects, accounting, accounting tools and accounting techniques. Among accounting objects, such as assets, liabilities, income and expenses the information is highlighted, accounting and monitoring of which is necessary to form an

assessment of future events. Information from the current accounting observation is highlighted based on the purpose of the observation associated with the time factor.

For each type of information some current accounts are selected (both synthetic and analytical). It is especially necessary to note the role of risk accounting and analytical accounting to reflect temporal characteristics and non-financial information.

For the current accounting observation, accounting tools are selected and grouped in a table. Among the traditional methods of accounting the methods following are distinguished, i.e. planning, forecasting, reservation, depreciation, revaluation and accrual basis.

The methodology is developed in accordance with the current standards of financial accounting and reporting. The technique or its individual elements can be put into practice. This requires only their establishment in the accounting policies of the enterprise.

A Portfolio Optimization Model Based on Polynomial Goal Programing Including Higher Order Moments Skewness and Kurtosis – Bucharest Stock Exchange

Mircea BAHNA

Bucharest University of Economic Studies, Bucharest, Romania
mirceabahna[at]yahoo.com

Abstract

Portfolio optimization as method used in finance aims to identify the potential scenarios for satisfying conflicting/competing objectives like, for example, maximizing the return/profit and reducing the risk/loss. Thus, the motivation for choosing studying and applying this method arises from the potential scenarios that the portfolio managers or the individual investors have when applying this framework. The Modern Portfolio Theory, as we know it, considers only the first two moments of the probability distributions of the rates of return as opposed to the considerable number of papers highlighting the need of the higher moments (skewness and kurtosis) acknowledgement, analysis and optimization. In this paper, we intend to use the polynomial goal programing, as an optimization method, to understand the selection problem for Bucharest Stock Exchange (2014-2020) daily quotes and to propose a set of reusable preference parameters when investing in this market. We conclude that shares being preferred in the Markowitz/Sharpe/Treynor frameworks have less impact in the MVSK space.

Keywords*:* portfolio selection, optimization, higher moments, polynomial goal programming.

JEL: C44, C61, C63, G11

Introduction

As most of the portfolio theory selection problem is based on Markowitz's work, the current study is also focusing on the highly attractive goal of portfolio selection and management, overpassing the sole consideration of the average return and risk. Along with a brief analysis of the state of the current research in the area of polynomial goal programming (PGP) we are focusing on the possibilities that the Romanian investor has in adopting goal programing as a technique to select and manage its portfolio.

The paper is structured in three sections: historical analysis of portfolio optimization and PGP, database and methodology used, results and conclusions.

Historical evolution of the goal programing in the portfolio management context

In the financial domain, as part of the Multi Criteria Decision Analysis, goal programing is offering various portfolio management methods and methodologies both to investors and portfolio managers but also to researchers. In the context of portfolio theory, it solves problems related to either achieving results given a certain set of resources and constraints or determining the various resources needed to maximize results while minimizing resources by providing multiple optimal solutions/scenarios for achieving these results.

The works of Charnes et al. (1959), Charnes and Cooper (1961) are the most acknowledged ones in terms of the origin of goal programming usage in the context of the portfolio optimization while the origin of its need is recognized to be Simon's (1957) concept of "satisficing" goals of the decision-

makers, the need to have a set of strategies when it comes to choosing between several alternatives that appear sequentially and that are unknown ex ante. Simon creates the premises for using the optimization methods described here by identifying the need either to simplify the decision-making space in optimization problems or to identify satisfactory solutions (local optimum) in taking into account a greater number of parameters (preferences) in describing the optimization problem.

Romero (1991, 2004) first concludes that goal programming is among the most widely used decision-making methods, with a methodology that is easy to implement and understand, and later (2004) identifies that the vast majority of research papers use the lexicographic approach. Using this one, the weights of the preferences of investors/portfolio managers are not substitutable, the preferences being rather prioritized as importance (i.e. the first being the maximization of the return, the second being the minimization of variance, the third being the maximization of skewness etc.), thus, using this method risks to remain theoretical when the lexicographic function (of prioritizing the criteria to be optimized) is not well-founded.

Weighting programming objectives involves prioritizing constraints by importance, e.g. maximizing the return is always preferred to minimizing risk. The optimal scenarios offered must take into account certain tolerated/acceptable deviation limits from the optimal, in other words, investors will set a certain margin of freedom in which the results may vary in reaching the optimal, i.e. a deviation of x% from the optimum for each individual constraint included in the model.

Although mostly used theoretically in the research paper from the 80's, starting with 2000 the fuzzy programming, is more and more used when targeting uncertainty, yet often this methodology is being complemented by simulation methods for identifying the weights allocated to the optimization criteria.

Among the recent literature review papers focusing on portfolio optimization, Kalayci et al (2019) analize a set of 175 research papers, the ones focusing on multi-objective space with more than just mean and variance taking into account criteria such as: cardinality (the number of securities), transactional costs, industry capitalization and so on. Other research papers of Aouni et al (2014) and Colapinto et al (2017) highlight an increased usage of goal programing in the context of portfolio selection and management pointing out that the lexicographic (preemptive) and weighted (Archimedean) methods are the most common while also recognizing the increased usage of the polynomial goal programming method.

Introduced by Tayi and Leonard, (1988) and Lai (1991) PGP focusing on incorporating higher order moments (skewness and kurtosis) tries to capture investors' preferences for maximizing skewness and for minimizing kurtosis for a more robust selection and management of portfolios. The works of Chunhachinda et al (1997), Wang and Xia (2002), Sun and Yan (2003), Prakash et al. (2003), Davies and Kat (2009), Azmi (2010) are just some of the highlights when discussing about incorporating skewness and kurtosis along with mean and variance.

Recent studies on PGP usage conclude the following: Livingston (2019) highlights the flexibility given by the usage of this method and the diversification of the available optimal scenarios. Khan (2020) identifies a better efficient frontier and the possibility to better fundament the investment decision. Chen (2020) concludes that the advantages of this method is: stabilizing the cumulated return and a better reaction to the market downwards moves/changes, while admitting the downside of the method being the computation time relative to similar methodologies. Cizauskas and Haslifah (2019) highlight that in their particular work the usage of MVS moments outperforms other higher order models. Gupta et al (2019) concludes that the advantages of using the method with MVS-Entropy leads to more flexible decision options while the computation time is still being seen as a small disadvantage of the model. Other recent studies show that PGP usage helps reduce entropy and uncertainty versus risk.

Methodology and database

Following up on the concepts proposed by Henry Markowitz in 1952, given N assets (i=1, N), an observed period T, Pi(t) representing the price of asset i at time t, the return of asset i at the moment t is Ri(t) as shown in equation (1), its expected return is E[Ri] (2) while its variance (the measure of risk) is represented in equation (3):

$$R_i(t) = \ln\left(\frac{P_i(t)}{P_i(t-1)}\right) \quad (1)$$

$$E[R_i] = \frac{1}{T}\sum_{t=1}^{T} R_i(t) \quad (2)$$

$$\sigma_i^2 = E[R_i(t) - E(R_i)]^2 = \frac{1}{T}\sum_{t=1}^{T}[R_i(t) - E(R_i)]^2 \quad (3)$$

The covariance of a given pair of assets is represented in equation (4):

$$\operatorname{cov}(R_i, R_j) = E[(R_i(t) - E(R_i))(R_j(t) - E(R_j))] = \frac{1}{T}\sum_{t=1}^{T}[(R_i(t) - E(R_i))(R_j(t) - E(R_j))] \quad (4)$$

Given the above the expected return and risk of a portfolio are represented in equations (5) and (6) respectively, with wi representing the relative weight of asset i in the portfolio.

$$E[R_P] = \frac{1}{T}\sum_{i=1}^{I} w_i E(R_i) \quad (5)$$

$$\sigma_P^2 = \sum_{i=1}^{I} w_i^2 \sigma_i^2 + 2\sum_{\substack{i,j=1 \\ i \neq j}}^{I} w_i w_j \operatorname{cov}(R_i R_j) \quad (6)$$

Given Markowitz's portfolio theory, the optimum portfolio taking into account mean-variance is computed by using equation (7). We're choosing between the highest expected return on a given level of risk, or the other way around.

$$\max_{w_i} E(R_P) = \sum_{i=1}^{I} w_i E(R_i)$$

$$\begin{cases} \sigma_P^2 = \sum_{i=1}^{N}\sum_{j=1}^{N} w_i w_j \sigma_{ij} \leq c \\ \sum_{i=1}^{N} w_i = 1 \\ w_i \geq 0, \quad i = 1,2,\ldots,N \end{cases} \quad (7)$$

Starting with Mandelbrot (1963) și Fama (1965), the above optimization problem in equation (7) is rejected given the normal distribution of assets returns hypothesis is used.

Thus, we're focusing on taking into account empirical distribution of assets returns, obviously different than the normal distribution so this will impact the portfolio selection and management. To be more robust the weights that investors should choose are computed while selecting the portfolios. Given the hypotheses that investors' impact/weight into the daily traded volume is small they would take into account skewness and kurtosis as parameters/preferences of their optimization model, the assumption being that they consistent returns versus high returns.

The proposed optimization framework, based on PGP, allows identifying solutions using higher moments like skewness and kurtosis.

The component for this framework are given by the decisional space (subset of feasible solutions), the objectives space (the variables to be optimized per se), the parameters space (the parameters/preferences included in the optimization model) and the weights space (for each preference of the model).

We compute the objective functions based on system (8):

$$Mean = M(x) = X^T\overline{M} \quad (8.1)$$
$$Variance = V(x) = X^T VX \quad (8.2)$$
$$Skewness = S(x) = E\left(X^T\left(M - \overline{M}\right)\right)^3 (8.3)$$
$$Kurtosis = K(x) = E\left(X^T\left(M - \overline{M}\right)\right)^4 (8.4)$$

with M the mean return distribution, $\overline{M}$ their median, XT vector of weights (Xi,n) for the assets in the portfolio. V, S and K are variance-covariance, skewness-coskewness and kurtosis-cokurtosis respectively matrix of M.

To include all the parameters that form the multiple objective and maximize the expected return, including skewness while minimizing even order moments of the distribution, we divide the optimization problem into two steps, first computing the individual optimum for each of the 4 moments as follows (I is the vector of 1):

$$M^* = Max(X^T\overline{M})$$
$$V^* = Min(X^T VX)$$
$$S^* = Max(E\left(X^T\left(M - \overline{M}\right)\right)^3)$$
$$K^* = Min(E\left(X^T\left(M - \overline{M}\right)\right)^4)$$
$$\text{subject to:} \quad X^T I = 1$$
$$X \geq 0$$

then we need to compute a vector of weights using the result from the above step.

To aggregte all four optimization problems into one, based on the PGP framework, we define d_i the deviations of moment i of the return distribution from its optimal value (moment*).

The main computation step described below provides the optimal vector of weights for the given set of parameters with Ri the set of restrictions:

$$\begin{cases} Min\left(Z = \left(1+\frac{d_1}{M^*}\right)^{\lambda_1} + \left(1+\frac{d_2}{V^*}\right)^{\lambda_2} + \left(1+\frac{d_3}{S^*}\right)^{\lambda_3} + \left(1+\frac{d_4}{K^*}\right)^{\lambda_4}\right) \\ R1: X^T\overline{M} + d_1 = M^* \\ R2: X^T VX - d_2 = V^* \\ R3: E\left[X^T\left(M-\overline{M}\right)\right]^3 = S^* \\ R4: E\left[X^T\left(M-\overline{M}\right)\right]^4 = K^* \\ R5: X^T I = 1 \\ R6: X \geq 0 \\ R7: d_i \geq 0, \quad i = 1,\ldots,4 \end{cases}$$

All the shares listed at BSE between June 2014 – February 2020 in the standard and premium categories are taken into account before applying the selection based on: industry diversification, market capitalization, liquidity, return/risk. We've opted for daily closing prices to compute the shares returns, while restricting short selling. 25 shares are selected given previously mentioned restriction/criteria.

Results

The first set of results we are interested in is presented in Table 1, capturing the optimal (min/max) values for each of the 4 movements of the returns' distribution.

Table 1: Optimal results for the Moments* of the returns

M*	V*	S*	K*
0.0022	0.0061	1.637	1.51

The next optimization scenario follows the case where the investor is unable to compute its preference parameters (lambda), thus he/she is indifferent to these weights.

To get the high/medium/low preferences for each parameters we force the investor to be neutral to the weight of the parameter (=1) for the rest of the 3 moments of the return. We thus get the high preference value (lambda) for which each momentum when the distribution moment gets very close, almost equal to its optimum (moment*).

Next we compute the preferences for each(individual) moment, i.e. for mean return we try to capture every lambda that has a constent impact on the Z function to get the maximum (high) preference versus the opposite end where we say that the impact on Z is low. The average is in the middle of the improvement slope.

For more consistent preference parameters we've also added an extra constraint making the distances versus the individual optimum (di) not being too spread apart Variance(dij) less than 0.01 since previous computation on BSE data sets (before 2010) led to parameters of preferences varying from 2000 to 1,3 for mean and skewness respectively leading to discrepancies in interpretation and usage by the investor. Below we aggregate the results for (lambda).

Table 2: Moments preferences (lambda)

	M	V	S	K
Low	1	2	1	1.1
Medium	3.5	5	2.5	1.2
High	7	10	5	1.4

Taking into account above, we can say that an investor with high preference for both variance and skewness (minimize risk and have a highly positive asymmetry of the returns) would opt for 10 and 5 lambda parameters for variance and skewness respectively, keeping the other 2 preference parameters at 1.

The results are consistent with Davies and Kat (2009) work in terms of parameters range of values while standing aside for previous works where lambda value was randomly assigned to for example 1,2,3 for low/medium/high in the autor's respective optimization models: Aracioglu (2010), Giesecke (2010), Kemalbay (2011), Škrinjarić (2013).

As expected, from previous runs of the optimization model (2009-2010, 2010-2014) on BSE, the λ3 and λ4 parameters reflect the higher sensitivity of the investors to the changes in the higher order moments preferences.

Similar to Briec (2011) we tried to eliminate saddle points (local optimum points) through multiple distribution of shares (weights) inside the portfolio and increased weight/granularity of each of the 25 shares inside the portfolio, in order to increase the accuracy of the proposed weights.

With the preference parameters computed we can summarize the results for our selected objectives space, we can also describe the weights space and we try to understand and explain the results.

Table 3: Optimization of the portfolios results

M	Medium	High	Low	High	Low	*	High
V	Medium	High	Low	Low	High	*	Medium
S	Medium	Low	High	High	Low	*	Low
K	Medium	Low	High	Low	High	*	Low
TLV	3%	2%					4%
BRD	4%				8%		
TGN	3%				8%		
BIO	4%	2%	10%		15%		1%
SIF1	4%	1%	18%				
SIF2	3%	8%					12%
SIF3	3%						
SIF4	4%						
SIF5	2%	10%					
TBM	7%	35%		36%	4%	14%	16%
RRC	3%		18%				
SCD	7%	10%		32%	11%	19%	14%
OIL	10%		20%				5%
EBS	5%				4%	31%	
CMP	3%		10%		13%	36%	
FP	2%		23%		7%		1%
SNN	4%	3%			11%		5%
ALR	2%	4%					2%
COTE	4%	1%			9%		11%
TRP	5%	14%					12%
IMP	1%	1%					1%
IAR	4%	2%		31%			12%
ELGS	4%	6%			1%		5%
VNC	4%						
ROCE	4%				7%		4%
M	0.0009	0,0014	0,0009	0,0019	0,0007	0,0009	0,0011
V	0.0071	0,011	0,0093	0.0149	0.0069	0,011	0,0191
S	-0.4979	0,0433	0,367	0,794	-0.2444	0,1615	0,4553
K	8.972	5,7119	2,303	4.405	3.96	1.514	2,6767

Note that the (****) portfolio does not include the lambda preferences, the Z function only taking into account the absolute distances (di) vs the individual optimum of each moment. It clearly shows that Kurtosis optimization prevails in terms of the optimization, being very close to the K* result. Of course, the distances (di) need to be calibrated in order to get proportional preferences parameters.

Given at least one lambda gets stronger minimum one of the other three moments of the distribution is less optimum, decreasing in the investor's preference. SIF3 and SIF4 shares are being left out so we can conclude that these 2 securities are average in terms of performance when it comes to using higher order moments along with mean and variance. Although preferred for its higher return, IAR weight in the portfolio is smaller when other moments need to be optimized as well. SCD seems to be preferred the most in the given scenarios, this also being the most inelastic security towards the BSE composite index (BET-Plus).

When comparing to modern portfolio selection models (Markowitz, Sharpe, Treynor) we observe that securities such as IAR, TLV, SIF3 and SIF4 have a less impact in terms of weights in the MVSK portfolios.

It is obvious to say the least that a tradeoff mechanism needs to be identified when giving up on one moment of the return distribution versus the other.

Conclusions

The need to take into account higher order moments gets obvious in the highly uncertainty scenarios and helps the investors (be it individuals or portfolio managers) get to more robust results. Using the proposed PGP framework helps identify various scenarios when dealing with empirical securities returns which always seem not to respect the normal distribution hypothesis.

We managed to identify BSE set of preference parameters (as also confirmed with previous appliations of the model for the 2009-2010 and 2010-2014 time series). We also identified shares preferred through the modern portfolio theory frameworks Markowitz/Sharpe/Treynor fail to be selected in substantial weights inside the MVSK PGP framework.

As concluded by recent studies as well, further efforts are needed to identify the objectives trade-off and in order to ease the computation burden.

Modelling the Rationality in Residential Investor Decision Making

Anita MAKOWSKA

Wroclaw University of Economics and Business, Wroclaw, Poland
anita.makowska@ue.wroc.pl

Abstract

The article presents a way of choosing an investment strategy by an individual investor on the residential market. It shows in particular that the investor, apart from financial factors (price), makes a decision also based on social and psychological factors. This leads to a new interpretation of the concept of a rational investor, basing the investment strategy on individual preferences, deviating from typical capital market's behavior.

Keywords: Real Estate Market, Rationality, Residential, Investing

Introduction

Among many investment options, the real estate market has always served as a safe and tangible capital investment. Hence, despite the high capital intensity, it is still popular among individuals.

Interest from foreign investment funds has been increasing significantly in recent years. However according to the Evaluer Index Report ("Evaluer Index", 2019), individual investors are still dominating the rental market in the largest Polish agglomerations. In turn, in the report "Emerging Trends in Real Estate. Creating an Impact" ("Emerging Trends in Real Estate", 2019), the authors also point out the steady increase in the inflow of investment capital in the real estate market among private investors. The reason is in low yield on investment in the equity and bond markets, which no longer offer return as is finding at a real estate market (Benjamin, Chinloy & Jud, 2004).

The high rating of a real estate as an investment subject comes from, among others the following premises (Kucharska-Stasiak, 2016):

- real estate is a source of income – this income is most often the result of rents or sale of the property while maintaining its increase in value;

- real estate is an investment protecting against inflation – this is connected with maintaining the real value of the property or even its increase, which is particularly an evident in the phase of increase in construction costs or loan interest;

- real estate is a basis for obtaining tax benefits - income tax is reduced by the costs of taking out a mortgage; hence the decrease in the effective cost of credit;

- real estate is a basis for defrosting capital - in the investor's opinion, this is one of the most important premises encouraging to invest in the real estate market; capital defrosting can take place through the sale of real estate, sale and leaseback and, in particular, the possibility of taking out a loan secured by a mortgage on the real estate;

- real estate is a basis for stimulating consumer demand - the real estate market through consumer spending can act as an accelerator of business cycles;

- real estate is an indivisible investment - the funds invested are usually indivisible, which means that it is difficult to recover their value partially;

- real estate is an investment with moderate investment risk - real estate is usually perceived as an investment with medium risk, between bonds and shares, which is perfectly confirmed by the rates of return obtained from investing in these three types of assets;

- real estate is an active investment that requires management - proper management of the value of the property may result in increasing this value; on the legal side, it protects the owner against failure in renting caused by incorrect selection of tenants.

Investor's Decision Model

Given the above premises, it seems reasonable that an individual investor sees investment benefits on the real estate market difficult to identify on other financial markets. Nevertheless, he faces a choice of investment based on knowledge and available resources. On the financial markets, we are talking about a rational man's paradigm. Economics assumes that when making investment choices a person behaves rationally, correctly analyzes the market environment and on this basis makes the best decision. Meanwhile, due to the tangibility of the subject of investment in real estate, it is impossible not to pay attention to the sociological and psychological factors supporting the decision-making process. On a decision-making basis, we are therefore dealing with a collision of the rational man paradigm (*homo oeconomicus*) with the emotional man paradigm (*homo sapiens oeconomicus*) and the paradigm of a man who is part of a social group (*homo sociologicus*) (Kirchgessner, 2008).

Figure no. 1 presents the investor's decision model, taking into account all of the above factors.

Fig. 1: Real estate investor's decision model

Source: Own study

The range of options to choose (the compilation of economical, sociological and psychological factors), in particular depends on both: the nature of decisions and the conditions under which they are made.

The nature of decisions depends on the investor's experience. We can distinguish here:

- absolute binary decisions (invest / not invest),

- relative decisions based on the most economically viable option,

- portfolio decisions based on the construction of an optimal portfolio, enabling the benefits from diversification,

- time decisions taken with the optimization of the moment of their beginning or ending.

The conditions under which the decision is made is related to the investor's attitude to risk and his ability to assess individual options, in the background of other investors' behavior. These conditions include certainty (rarely) or uncertainty as to the level of project efficiency with the possibility or inability to assess the probability of occurrence of a given state.

Investment Strategy

The above-mentioned criteria are included in the whole spectrum of available investment strategies. Table no. 1 presents profiles that should be considered to create the final investment strategy, tailored to the preferences of the individual investor directly interested in the residential market. When building a portfolio of this type of investment, the strategy selection should be taken x-times, making different choices in individual profiles and thus diversifying the risk of a single strategy.

Table 1: Profiles to create a final investment strategy on the real estate residential market

Profile	Category	Concept / variant
Business model profile	financing	cash
		loan and cash
	profit	use and manage
		buy and earn
		buy and sell
		buy, add value and sell
	risk	conservative concept
		moderate risk concept
		defensive concept
Subject profile	segment	apartments
		premium
		popular
	building	new (development status) - primary or secondary market
		an older block of flats built in traditional technology or prefabricated
		tenement house

	dwelling	micro apartment
		studio
		2-room room flat or bigger
	standard	finished
		for minor refurbishment
		for general renovation
		development standard
Location profile	city	the largest agglomerations in the country
		dynamically developing smaller agglomerations
		small cities
	detailed location	city center
		downtown
		the periphery
		neighborhoods with problems

Source: Own study

The business model profile should be considered one-way, for all the categories listed in the block together. The profit category shows how to obtain the expected benefits from the market. The "use and manage" option means the use of real estate for own needs as a capital investment (increase in value with proper management). The "buy and earn" option is based on regular cash flow income from rents, or is based on a long-term increase in invested capital (passive management) resulting from market trends. The "buy and sell" option is a speculative option to achieve a profit on the difference in transaction prices, resulting from factors other than the price changes over time. Ultimately, the "buy, add value and sell" or in other words quasi-developer variant provides value from active management of property in order to increase it. It includes investment behavior such as flipping, home staging or even transformation of the property layout into one that will positively affect its value (e.g. conversion of a 5-room flat into 5 studio apartments). There is also a variation of this strategy in which the last component 'sell' can be replaced by the component “rent” if the previous actions will result in a higher return on rent instead of sale.

The risk category is not only under the criterion of the conditions in which the decision is made, but it is also a derivative of the investor's individual preferences. The sources of risk considered in the context of this paper include the market, policy, technical and random conditions. These sources allow defining the types of risk that a direct investor faces, ranging from the risk of strategy accuracy, through price change risk, legal risk and ultimately the catastrophic risk. This catalog is very rich, and appropriate mathematical tools with a certain probability allow to estimate the expected return on risky investment (Seay, Anderson, Carswell & Nielsen, 2018). Nevertheless, from the perspective of the rationality of the investor, a man with a certain temperament and at the same time acting in a certain social group, behaving in a way defined by imposed norms, not necessarily legal, can accept different level of risk and what goes with it – different level of yield (Kahneman & Tversky, 1979). Hence, the use of mathematical tools in economic calculations can show (as demonstrated by the study carried out in the

article) that rationalism expressed by the number (e.g. standard deviation) deviates from the final choices of investors.

The subject profile refers to the investment object. The investor must decide in which segment the apartment will be selected, whether the purchase will take place (on the primary or secondary market), what will be the layout, area and standard. At this stage, some categories overlap, and the choice of variant in one of them often determines the other choices. It is therefore important that the investment strategy after the revision of the subject should be consistent.

Location profile, includes categories indicating literally the place of investment. The city category is a broader view on the location and takes into account the selection from the largest cities (with a slightly lower rate of return due to the high capital intensity of investments, but also with a lower risk of vacancies), smaller but dynamically developing cities, and satellite agglomerations. The detailed location category narrows the selection to central and downtown areas, as well as the periphery and neighborhoods with "problems" such as, for example, poor neighborhood reputation or unattractive buildings.

The Rationality Model

The compilation of individual profiles, where the selection is supported by available resources, market knowledge and non-economic factors, ultimately should give the final investment strategy. This model is a function of costs and benefits and takes into account the investor rationality based on logical reasoning, but also emotions and individual motivations. Rationality understood in such a way is a difficult object to modeling investment behavior on the real estate market, but it is certainly an excellent background for the interpretation of atypical behaviors, resulting in accumulation in imbalance of the market condition. This model can take the following form:

$$I_t = f(y, s_f, p_f, \sigma),$$

$$y = f\left(r_f, r_i, r_l, r_m, \sigma_{P,M}\right) = f(P, C, g_1, g_2, \sigma_{P,M})$$

where:

y – yield understood as the expected profit from investment

s_f – social factors

p_f – psychological factors

σ – total uncertainty with respect to built-asset return

r_f – risk-free interest rate

r_i – inflation rate

r_l – liquidity premium

r_m – maturity premium

$\sigma_{P,M}$ – systematic risk

P – price of the asset

C – total additional costs of the investment

g_1 – the expected rent growth

g_2 – the expected growth in asset value

Modeling the rationality of choosing an investment strategy is therefore a function of economic, social and psychological factors taking into account the risk of the project as a whole. Economic factors are represented by the rate of return on investment, which can be reflected by market factors (e.g. risk-free rate, inflation level, risk premium), or the function of factors directly related to the project, taking into account the price of the property, additional costs associated with investment and the expected level of rent and property value. The rate of return also includes market risk.

In each of the profiles / variants, the investor's choice should be based on economic analysis, however, investors are unable to break up with the psychological and social factors mentioned above.

Market Research

To prove that price is not the only factor contributing to the rationality of decisions taken by investors, four large housing estates on the primary market, currently on sale, located in the city with over 600,000 inhabitants were analyzed. Each of these housing estates differ in location (from the city center to the periphery) as well as standard (from the apartment building to popular). The sales curves for each of the individual housing estate, with relation of average prices over time are presented in Figures nos. 2-5.

Fig 1-5: Average prices vs percentage of sale in each of the analyzed hosing estates

Source: Own study

In each of the above cases, the correlation coefficient between the change in the average price of flats and the change in the number of flats sold in comparison to the previous period, was additionally analyzed. This ratio for each of the housing estates was respectively: 0.007%, (-24.01%), (-43.93%), (-44.53%). This shows that in three out of four analyzed cases, as the price increases, the number of apartments purchased decreases. However, this relationship is not strong, which may indicate that the change in prices affects the volume of sales, but it is not the only factor shaping it. In the case of the first housing estate, it can even be said that the changes in prices does not matter at all (positive correlation, close to zero). The reason is that the order of presented estates is adequate to the decrease in their prestige. Housing estate no. I is therefore the most prestigious among the others analyzed. The correlation coefficient achieved here is therefore also a confirmation of the Veblen paradox, saying that an increase in price in the case of luxury goods may cause an increase in demand for a given good.

Figures nos. 6-9, for the same housing estates as previously, presents how the sale has changed regardless of time, with price movement between particular periods.

Fig. 6-9: Percentage of changes in prices vs no. of sold apartments in each of the analyzed hosing estates

Source: Own study

In case of housing estates nos. I and II, the largest of the price increases caused a sharp increase in sales. These are apartment and premium class housing estates. In the case of housing estate no. IV, of a popular standard, a price increase above 4% caused only decrease in sales. Nevertheless, in each of the analyzed settlements, it is difficult to look for rationality in the behavior of buyers, associated with increases and decreases in demand with a corresponding decrease and increase in prices.

A rational investor, deciding whether it is on the stock or bond market, rejects sentiments and follows simple mathematical principles. In case of the real estate market, in particular investors buying their "first second apartment", apart from prices, are guided by emotions as they are associated with the subject of investment for years. In addition, they identify it with wealth and prosperity. They boast about their portfolio. And the greater the need for prestige, the greater emotions play a role. Therefore, the investment value on the development market is not only the low price, but the packaging of the sales object with eye-catching marketing tools that also affect psychological and social factors. Hence, the ability to work with a rational customer, understood in the way presented in the article, is the strength of development of the real estate market.

Acknowledgment

The project is financed by the Ministry of Science and Higher Education in Poland under the programme "Regional Initiative of Excellence" 2019 - 2022 project number 015/RID/2018/19 total funding amount 10 721 040,00 PLN.

Renewal and Buiding Social Ties in The Face of The Safety Threat Posed by the SARS-Cov-2 Pandemic - Overview of The Problem

Luiza TRZCIŃSKA

Military University of Technology in Warsaw, Warsaw, Poland
luiza.trzcinska@wat.edu.pl

Abstract

This text outlines the problem of renewing and building social ties in the face of the safety threat posed by the SARS-CoV-2 pandemic. The article presents examples of initiatives taken by society to help people who are in a difficult situation as a result of the pandemic. This article is an introduction to the studies planned.

Keywords: Threat, Pandemic, SARS-Cov-2, Safety, Security, The Feeling of Security

Introduction

It could be expected that in the face of the safety threat that the SARS-CoV-2 pandemic is undoubtedly posing, society will not be willing to help those in need. But it turned out to be the opposite. Every day new initiatives emerge to help others survive this difficult time. In both large and small towns there are groups of people who want to help those most affected by the pandemic. The groups targeted are: the elderly, chronically ill, with reduced immunity, disabled, under official quarantine, and those who have lost their source of income as a result of the pandemic outbreak. The aid provided comes in various forms. It is a financial, material and psychological aid, among others. Just a few days after the announcement of restrictions on the prevention of the spread of the virus in Poland, appeals for help appeared in social media. Many people have been made destitute overnight. The panic that was spreading among the society was also not insignificant. Many people in hysteria rushed to the shops to make supplies. This resulted in a shortage of goods on the shelves, so that the elderly, for example, were unable to make basic purchases. The uniting of society in a state of epidemics is a subject worth considering. What caused the so far indifferent people to help? What is their purpose in this? Will they continue with the projects they started after returning to the pre-pandemic state? These are questions to consider in future studies. The following text will focus on presenting the initiatives taken. At present, the solidarity and commitment, with which strangers help others, is admirable. The current situation is undermining our safety on many levels. It's not something we know and we know how to fight it. Paradoxically, it turns out that an invisible enemy unites strangers.

The next stage, taken after the threat of the coronavirus pandemic has subsided, will be to carry out research indicating the intentions of those who, in the face of the threat, have decided to engage in activities aimed at helping others.

The Need to Feel Safe in The Face of Threat

The SARS-CoV-2 pandemic has undoubtedly shaken the sense of safety around the world. This applies not only to entities such as states, but also, and perhaps above all, their citizens. Zbigniew Ciekanowski defines safety as follows: Safety is an important existential need, resulting from the objective living conditions of people and different social groups and their mutual relations, requiring care for its satisfaction (Ciekanowski, 2010). It should not be forgotten that safety is understood in a variety of ways by many researchers, also as a specific human need, becoming the highest value that he or she seeks in life (Fałdowski, 2018). When looking for reasons for people who have not been involved in any form of volunteering so far, it is necessary to reach for basic human needs. According to the hierarchy of the Maslow Pyramid, immediately after physiological needs the most important need is the need for safety (Maslow, 1943). Perhaps the willingness to help is due to everyone's inner needs. When you are in a situation of danger, which is certainly SARS-CoV-2 pandemic, you realise that one

day you may find yourself in a situation where your need for safety is not satisfied. That is why one tries to help others, because one would not want to get himself in a similar situation - the situation of lack of safety. So, what is a sense of safety and what does it mean to satisfy it? Ryszard Klamut describes the sense of safety as follows: If safety needs are satisfied and the individual realizes the values of safety, he or she experiences a state of satisfaction, happiness, understood as a sense of safety (Klamut, 2012). So maybe satisfaction is the key element that makes people so willing to get involved in helping others. This is an issue that will certainly be investigated. The current state of insecurity is paradoxically conducive to the merging of people. It is possible that this is due to isolation and the impossibility of contact with loved ones.

Initiatives to renew and build social ties as a result of the pandemic

Companies, Polish brands and celebrities are involved in the fight against the pandemic. However, it is worthwhile to raise the issue of involvement of small communities and groups of people, often not known to each other before. One of the first signs of willingness to help were advertisements hung on staircases in multi-family buildings. These advertisements proposes help in everyday grocery or pharmacy shopping to people who, due to their age or health condition, were afraid to leave their homes. After some time, the initiative moved to the Internet, to social networking sites such as Facebook and Instagram. At the same time, it resulted in the expansion of the scope of activities. Both in terms of forms of assistance and addressees. It turned out that there are not only elderly people in need, but also people who for various reasons are afraid for their health. These are often susceptible to infection, chronically ill people or people who are in a difficult financial situation.

One example of groups offering help is the Visible Hand group, which has been operating on Facebook since 11 March 2020. In the first stage of the announcement, mainly people who offered their help were adding. After some time only did the members of the group become active, who needed this help. The response of those determined to help is enormous. At the very beginning of the project there was only one all-Poland group. With increasing interest, regional groups have emerged, which at present cover almost the entire country. The Visible Hand Initiative was initially the initiative of a small group of friends, currently the main group has 108.7 thousand members (Widzialnareka, 2020) The initiative has expanded and there are now over a hundred regional groups of the Visible Hand. The vast majority operate in Poland, but there are exceptions and some of the groups operate in the UK, Berlin, Paris or Vienna.

As already mentioned above, the first proposals to help were mainly aimed at the elderly. Ads appeared on local community groups or notice boards. The advertisements were addressed to people who, for various reasons, cannot leave the flats and need help with shopping or taking care of the animals. A much greater range of help has begun to be offered by people who want to help remotely. There have been advertisements for, among other things, tutoring aids in subjects such as mathematics. Over time, other proposals have begun to emerge, among them: remote teaching of children's activities, storytelling, reading books, free language lessons conducted through platforms such as Skype, fitness classes conducted at a distance, free grocery shopping (mainly for those who have lost their source of income), taking in animals for the owners' quarantine period, conversation or emotional support. Psychologists and psychotherapists offer psychological support at a distance and lawyers offer legal advice. Physiotherapists also do not leave their patients and broadcast live exercises. In response to the high demand, there are also groups offering temporary contract work to support people who have lost their jobs.

It is also becoming increasingly popular to support local and small businesses by ordering and buying goods that are not essential. Such purchases will allow small companies, one-man businesses and self-employed to survive. There is also a growing number of people who are ordering hairdressing or beauty services for the future. Such orders are paid for, but the deadline for their completion will be determined individually after the threat has passed.

Another initiative worth mentioning is the sewing of protective masks by both professional sewers and volunteers. The masks are distributed or sold for symbolic amounts. The initiative of sewing the masks was also joined by, among others, beauticians, circles of rural housewives, pensioners and even

foundations. A related action is also the action of people with 3D printers. The owners of printers wanting to help in a difficult situation of danger decided to print and hand over visors (faceplates) free of charge for doctors working in hospitals. The people who can offer the purchase of semi-finished products were also involved in obtaining the materials necessary for sewing masks and folding visors. In the face of the coronavirus threat, many restaurants have decided to support doctors and rescuers who are on constant alert. Restaurants and bars all over the country provide meals free of charge to Hospital Emergency Wards, infectious disease wards or emergency medical centres. In order to provide products for prepared meals, there are organized collections on the Internet, which can be supported by anyone willing. An example of such a collection is the Meal for the Doctor action, thanks to which it was possible to offer help to 500 restaurants that serve meals to doctors. There are also advertisements on the Internet which provide doctors with free accommodation or offer free rest in resorts after the pandemic.

It is also noteworthy that some investors reduce or remit the fees for renting apartments or commercial premises. This is an expression of solidarity with people who have lost their jobs or are in a difficult situation. It is also popular to organize the collection of basic products such as: water, food, chemistry and cosmetics and to transfer them both to hospitals and individuals.

It is also noteworthy that assistance is not only provided by citizens of a given country, but also by persons temporarily residing within its borders. An example of such activity is sewing masks by Chechen women refugees.

The groups and initiatives that have been created also have another, very important factor - education. Education on how to safely deliver shopping, how to safely bring dogs out, how to react to violence and how to comply with quarantine. People pass on knowledge, develop common methods, face emerging problems.

Conclusion

It turns out that in the face of such a great tragedy as the SARS-CoV-2 pandemic, people can unite and help each other without expecting anything in return. I'm sure it's something to be proud of. It is also to be hoped that the assistance offered will not only be a temporary trend, but an incentive to engage even more in helping those in need.

We are witnessing how, in an emergency, ordinary and extraordinary people are able to unite and help those in need. Often people who need help are family or our closest neighbours, but also strangers whom we may never meet. It is also to be hoped that the solidarity that is emerging in society is not a temporary trend.

It is worth examining not only the types of assistance provided, but also the reasons that drove those providing it. Among a few of the alleged ones one can mention: own satisfaction, willingness to help the weaker ones, involvement of friends, sense of unity with people in a difficult situation, an attempt to temporarily forget about the prevailing situation, willingness to test oneself, compassion, religious motives, patriotism. The planned research will determine the type of assistance, the motives behind the volunteers and the impact of disinterested assistance on their sense of security.

The whole world has stopped, and a new reality may be created before our eyes. It's good that this reality is somehow better. Perhaps the actions taken by society will increase our sense of security.

A New Approach to Performance Budgeting Based on System Analysis

Nikita Olegovich BONDARENKO

Financial University under the Government of the Russian Federation,

Moscow, Russian Federation, suhov_32@bk.ru

Abstract

Despite an extensive experience of performance budgeting, Russia is still at the initial stage of introducing project approach. Hence, there is much room to increase state management effectiveness through the use of system analysis elements when planning budget spending. The goal of our research is assessment of relation between the targets of state programmers, national projects, the performance budgeting tools and the measures they encompass as well as the use of econometric modelling to establish relation between the goals of state policy and necessary financial resources. The results of our work can be used both when planning spending for new programmers and by way of improving the current programmers.

Keywords: performance budgeting, national projects, state programmers, healthcare, life expectancy, econometric models

Introduction

The current programmers of the Russian Federation, state-led and others, as well as the national projects are manifestation of a new wide-scale approach to public finance management, namely program-oriented management of budget expenditures within the framework of performance budgeting. These measures, according to Deyneli (2019), aimed at implementation of a state economic policy assume clear targets and key indicators of state agencies' activities, the ways of achievement and resource allocation (financial, labor, information and others) solely for the purpose of attaining the results.

Although the planned deadlines of budget spending on a significant number of state programmers and national projects are yet to be reached, it is already clear that the bulk of interim targets was not attained pointing to several drawbacks of the measures. Hence, according to Jeffrey (1998) compilation of lists of the planned measures under national, state and agencies' programmers as well as federal projects, etc., and the target systems used to evaluate effectiveness of the measures, is now often based on fragmented research, does not use systemic analysis for the projects. Measures with no direct influence on attaining the targets may be chosen.

Therefore, the aim of this work is econometric analysis of relation between budget financing and the key targets to assess correctness of passports of the national projects and state programmers. The analysis is done for life expectancy, which is very important now, when the demographic situation is negative, and includes consideration of spending on the key directions for systemic approach keeping in mind similar interrelations in other countries.

Literature Review

There is a general view that Russia's performance budgeting dates back to the 1920-1930s. Hence, the 1922 State Electrification Plan contained a common goal – to ensure comprehensive electrification – and the measures necessary to attain it thus becoming the first official economic document complying

with the principles of performance budgeting. Introduction by Robert McNamara of a project approach based on corporate management principles and systemic analysis in the 1960s was a significant step forward in the development of result-oriented budgeting. It was a significant contribution to the U.S.A. defense industry development. However, the systemic approach is not wide-spread in state management (Kosov, 2017; Bondarenko, 2019).

Research by modern scientists, who use some systemic analysis elements to assess effectiveness of performance budgeting are also of interest. Marti (2018) in his article analyzes the role of management by objectives in making budget decisions. He built econometric models linking budget system development, the index of management by objectives and other economic and political factors (Akhmadeev, 2018). The results of modelling, according to Raizberg (2017) demonstrated viability of the method for budget financing, when targets are used not only as a form of reporting to parliament and public, but as the basis for budget funds distribution.

Lavrov (2016) and Buzdalina (2020) built on the idea of using targets for budget decisions. In a research, he used econometric modelling to analyze the interrelations between performance budgeting, mid-term spending ceilings and flexibility of budget indicators. Although performance budgeting was introduced in all OECD states' government management, its results are only used for information about programmer implementation, not to establish future budget allocations (Kosov, 2016).

These researches are an example of how systemic analysis elements can be used to assess effectiveness of the result-oriented approach.

Theoretical Background

We selected the following 25 states for analysis: Australia, Austria, Belgium, the Czech Republic, Finland, France, Germany, Greece, Hungary, Ireland, Israel, Italy, Japan, Korea, the Netherlands, Norway, Poland, Portugal, Slovakia, Slovenia, Spain, Sweden, Switzerland, Great Britain, the U.S.A. The choice was predetermined by the presence of the Organization of Economic Cooperation and Development statistics on life expectancy at birth and consolidated budget spending by individual directions as well as exclusion of such states as Luxemburg, Estonia and others because of the small size of their economies and less typical other conditions. Spending was analyzed by its functional classification, which breaks down spending into general state expenditure, national defense, national security, national economy, environment, housing and utilities, healthcare, culture, education and social policy, according to the official OECD website. The period under analysis, 1995-2017, was chosen to maximize the period, when the data and the break down are available.

When considering life expectancy at birth in different countries one can notice that despite a general positive trend, fluctuations of the indicator are not the same in different states and are mostly

characterized by their chaotic nature. Thereby, we can conclude that the internal factors are at play here, making the interrelation between life expectancy and spending relevant (fig. 1).

Figure 1: International dynamics of life expectancy at birth

Compiled by the researchers with the help of the Organization of Economic Cooperation and Development data

We calculated the Pearson product-moment correlation coefficient for each of the 250 data series (in this case each data series represents life expectancy at birth and spending by article in each country in 1995-2017) to analyze the interrelation between life expectancy and spending. We observed a strong relation between life expectancy and spending and the type of relation persists from country to country (Table 1).

Table 1: Examples of the strongest relation of the indicators under consideration (product-moment correlation coefficient)

Country /Spending	General state spending	Defense	National security	National economy	Environment	Housing and public utilities	Healthcare	Culture	Education	Social policies
Austria	-0,94	-0,90	-0,91	0,41	-0,54	-0,79	0,93	-0,80	-0,80	-0,27
Belgium	-0,93	-0,97	0,81	0,80	0,65	-0,22	0,94	0,80	0,73	0,78
France	-0,94	-0,81	0,81	0,25	0,96	0,72	0,92	0,90	-0,74	0,88
The Netherlands	-0,91	-0,91	0,92	-0,57	-0,27	-0,34	0,98	0,11	0,73	0,08

Calculated by the authors with the use of the Organization for Economic Development and Cooperation data

However, data averaging for the 25 states produced less typical results of relations due to a large number of multidirectional deviations (Table 2).

Table 2: Average values of linear correlation coefficients in general for the countries under consideration

Indicators	General state spending	Defense	National security	National economy	Environment	Housing and public utilities	Healthcare	Culture	Education	Social policies
Average values	-0,47	-0,54	0,19	-0,11	0,06	-0,37	0,68	0,11	-0,08	0,31

However, the data helps us to conclude that internationally the following spending has a relatively significant impact on life expectancy:

- General state spending (-), Defense (-);
- Housing and public utilities (-);
- Healthcare (+), Social policies (+).

At that, the negative contribution of general state spending, defense and housing and public utilities is not direct, but through redistribution, where this spending is reduced raising spending with a direct stimulating effect on life expectancy, which resulted in positive growth of the dependent factor. We also did vertical analysis of the 2017 interrelations in the countries, where the factorial feature was not the year of observation, but a country. We undertook to build an econometric multifactorial model, where spending on each of the directions under consideration were individual factors. We paid much attention to the removal of multicollinearity, which means ensuring independence of the factorial features. Hence, we discovered explicative variables, which are very closely related when considering pair correlation. These are the factors; whose r-value exceeds conditionally selected value of 0.8 (Fig. 2).

	Y	*X1*	*X2*	*X3*	*X4*	*X5*	*X6*	*X7*	*X8*	*X9*	*X10*	*X11*
Y	1,00											
X1	0,06	1,00										
X2	-0,13	0,67	1,00									
X3	0,00	0,00	-0,07	1,00								
X4	-0,65	-0,02	0,27	0,20	1,00							
X5	-0,35	0,58	0,35	-0,34	0,20	1,00						
X6	0,35	0,15	-0,06	-0,06	0,15	0,03	1,00					
X7	-0,14	0,26	-0,04	-0,26	-0,06	0,37	-0,01	1,00				
X8	0,00	0,41	-0,01	0,03	-0,23	0,14	0,06	0,38	1,00			
X9	-0,43	0,38	0,28	-0,03	0,25	0,65	-0,10	0,19	-0,17	1,00		
X10	0,01	0,34	0,10	0,47	-0,05	0,24	-0,36	-0,09	0,07	0,29	1,00	
X11	0,33	0,86	0,54	-0,25	-0,25	0,35	0,25	0,20	0,23	0,15	0,04	1,00

Figure 2: Multicollinearity removal in analysis of the correlation matrix

It is noteworthy that when considering the economic meaning of the model this value can be both increased and decreased and it was done in this analysis (Bykanova, 2017; Dorofeyev, 2018; Frumina, 2020). Hence, we removed several factors from the model. Besides, we analyzed coefficients for explicative values and compared them with the r-values (Babeshko, 2018).

As a result, we eliminated the factors with opposing values of the indicators (the mismatching of values here violates the economic meaning of the relationship). Later we also eliminated the factors, for which the actual (observed) Student's t-criterion was below the critical (table) level. The factors were chosen simultaneously with the analysis of the F-test for the mode. As a result, we discovered that national security, environment, healthcare, culture and education spending was most important:

$$Y = -4{,}16X_4 + 3{,}26X_6 - 0{,}36X_8 - 1{,}13X_9 + 0{,}58X_{10} + 86{,}80,$$

where Y – life expectancy at birth;

X_4 – national security spending;

X_6 – environmental spending;

X_8 – healthcare;

X_9 – culture;

X_{10} – education.

The negative coefficient of the national security is explained by the aforementioned redistribution, while the negative coefficients of healthcare, which from an economic point of view should have direct relation with the variable, may be explained by higher spending due to the problems arising in the spheres, which result in a negative deviation of life expectancy. Let's consider similar relations in Russia. We have partially regrouped spending to ensure homogeneity in the period under consideration despite significant changes in budget classification carried out in 2011. Similar measures were taken when building a model to eliminate multicollinearity of two criteria. Having removed statistically irrelevant factors, accounting for Student's t-test and provision of economic grounds we developed the following model:

$$Y = 2500{,}92X_6 - 1294{,}99X_8 - 65{,}21X_{10} + 69{,}52,$$

where Y – life expectancy at birth;

X_6 – environmental spending;

X_8 – culture, cinema and mass media spending;

X_{10} – social spending.

The same calculations with a year-long lag demonstrated that environmental and social spending as well as general state spending and debt servicing are the significant explanatory factors. Discovery of the same significant factorial features (excluding spending on culture, cinema and mass media in the first case and on general state needs and state debt servicing in the second, which are of a negative effect on the result due to the aforementioned effects of redistribution and financing on the back of widening social problems) points to a stable nature of relation between life expectancy at birth on the Russian Federation's consolidated budget environment and social spending. It is noteworthy that we

observed no significant relation between the factor under discussion and healthcare spending in both cases (Sigarev, 2018).

Discussion

Hence, our results can be used in project management of state financing. The choice of measures to attain the targets of state programmers or national projects should be done with the help of econometric research on the impact of budget spending on the indicators (Gryzunova, 2018; Kosov, 2019). When considering national projects' passports, we can observe that national project Demography, which aims at increasing expectancy of healthy life until 67, has no ecology reform measures (Smirnov, 2016).

At the same time state programmer Environment, on the contrary, includes measures to improve the ecological situation in the country (Bloshenko, 2017), but its passport has no life expectancy targets (Osipov, 2017; Umerova, 2018).

Conclusion

Hence, our research helps us make the following conclusions. The key international budget policy factors with a positive effect on life expectancy are state healthcare, social and education spending. But in Russia higher life expectancy can be ensured through greater environmental and social spending. At present, the government does not take into consideration the econometric models and the relations they analyze when planning programmer and target budget spending. The results should be used when compiling state programmers and national projects to ensure a targeted impact of the measures on the state economic policy targets.

Abstract

In article, we present results of information technologies development for managerial decision support within maritime activities in Arctic within environmental economics while climate change. While studies, we used methods of data bases constructing within digital platforms, web-technologies and virtual reality tools. We make statement that maritime activities in Arctic is to be carried out in the environmental economics paradigm as related set of large natural-industrial projects within common space area and time period. We present a block model that combines the investment objectives of such project set with cost of adequate managerial support, including natural risks management goals and tasks. We suggest to use geo-information distributed online platforms as the main technological tools in the tasks of managerial decision support within maritime activities in Arctic. Platform https://www.researchgate.net/profile/Valery_Abramov2/ was used for data exchange and preliminary discussion while study.

Keywords: Information Technologies, Maritime Activity, Arctic, Managerial Decision Support, Environmental Economics

Introduction

Last time, digital transformation, named Industry 4.0, extends in the global economy, during which a lot of enterprises plan to implement wide spectrum of information technologies (Baikov, 2019), (Bidenko, 2019), (Drabenko, 2019), (Grachev, 2017), (Frolova, 2019), (Lukyanov, 2019). This leads to serious information technological changes in managerial support within geo-information management (Kirsanov, 2014), especially in natural risk management (Berboushi, 2014), (Ershova, 2018), (Garcia, 2018), (Isaev, 2015), (Istomin, 2018), (Shilin, 2019).

In paper, we conceder the results of information technologies development for managerial decision support within maritime activities in Arctic, as part of geo-information management area (Burlov, 2018), (Fokicheva, 2016), (Fokicheva, 2015), (Istomin, 2015), (Kirsanov, 2014), (Lednova, 2014), (Malakhova, 2014) in large environmental projects (Mandryka, 2019), (Popov, 2014), (Popova, 2019), (Rumyantseva, 2017), (Zhigulsky, 2018) within environmental economics (Chusov, 2019), (Golosovskaya, 2014), (Karlin, 2014), (Karlin, 2009), (Popov, 2016). Significant attention should be paid to geo-information support of natural risk management (Fokicheva, 2018) in the context of climate change (Mikheev, 2019), (Bournashov, 2014), (Gogoberidze, 2014), including the issues of information collection and processing (Fokicheva, 2019), (Khaimina, 2014), (Popova, 2019).

Methods and data

In study, we used: methods of data bases constructing in case of digital online platforms, web-technologies, big data technologies (Novikov, 2019), (Sokolov, 2019), geo-information technologies (Veretennikov, 2019), (Yaily, 2019) and virtual reality tools. Also, we used Foresight technologies, theory of decision making under uncertainties (Palkin, 2019), risk management approach for maritime activity. From the point of view of geo-information management, we structured geo-space to allocate the interconnected components of the solution space (Istomin, 2015).

Results

Currently, maritime activity in the Arctic (MAA) is a hot spot in the global environmental economy, and there are many ways to approach this problem. From the point of view of geo-information management (GIM), we put forward a statement, that MAA in recent stage is to be carried out in the environmental economics paradigm as related set of large natural-industrial projects (NIPs) within common space area and time period.

In figure1, we present a block model of investment structure while MAA, that combines the investment objectives of such NIPs (blocks 1-5) with cost of adequate managerial support (blocks 6-8), including natural risks management goals and tasks (block 7). Our analysis shows that the largest part of the cost of managerial support is the environmental monitoring (block 8), the essence of which is determined by the content of block 7. Significant part of the cost in block 8 is hardware and software, the cost of which varies significantly.

On basement of above mentioned model, we proposed to develop the managerial support system (MSS) with combined structure for access, storage and analysis of information from open geo-spatial data sources, including archives and operative mode web tools. As a result of the research performed using foresight technologies, we suggest to use geo-information distributed online platforms (GIDOP) as the main technological solutions for MSS while MAA. We give preference to open platforms like Google Earth. Also, we recommend to use GIDOP EOS eos.com, which allows to operate with space images from the Landsat-8 and Sentinel-2 satellite systems with limited open access.

Figure 1 : Block model for investment structure while MAA: 1 – block of distribution of resources; 2 – block of formation of resources; 3 - block of formation of private income; 4 - block of formation of total income; 5 – block of formation of the investment share of resources; 6 - block of comparison with the permissible level of risk; 7-block of formation changing in time set of natural risks, including climate risks; 8 – block of environmental monitoring

In our research, essential was block of environmental monitoring while MAA.

An important direction of MAA development is the usage of the Arctic sea space as a transport corridor between the main cargo ports of Europe and South-East Asia (SEA). One of possible way to solve problem is to use Northern Sea Route (NSR). Reducing the cost of MSS is an important question for MAA within NSR area. We propose to use GIDOP EOS eos.com as basement for low-cost MSS while MAA within NSR area. In figure 2, we post image space of Kara Gate Striate area for 28/02/2020, which we took from GIDOP EOS eos.com in agriculture color combination.

Note, Kara Gate Striate is one of critically important point of NSR, which have to be monitored constantly. GIDOP EOS allows to solve this problem. In figure 3, we present a space image of the Kara Gate Strait area for 27/03/2020 from GIDOP EOS with the natural color combination. Obviously, agriculture color combination gives more detailed information about the state of the ice cover and allows to distinguish between snow, ice and clouds.

Recently, there is intensive maritime infrastructure development in NSR area, including port Sabetta for liquid natural gas (LNG) loading. In figure 4, we present a space image of port Sabetta area on 29/03/2020 from GIDOP EOS with agriculture color combination. Reddish colors in centrum highlight the areas of artificial structures.

Figure 2: Space image of Kara Gate Strait area on 28/02/2020 with agriculture color combination

Figure 3: Space image of Kara Gate Strait area 27/03/2020 with natural color combination

Figure 4: Space image of Port Sabetta on 29/03/2020 with agriculture color combination

As essential result, we propose to use GIDOP EOS eos.com as basement for low-cost MSS while MAA.

Discussion

We propose to use GIDOP EOS for long-period ecological monitoring for important maritime infrastructure area. For example, in figures 5 and 6, we post space images of Neva dumb from GIDOP EOS for 02/05/17 and 02/05/17 with roughly two years' gap. In those figures, we used agriculture combination.

Figure 5 : Space image of Neva dumb on 02/05/17 with agriculture color combination

Figure 6: Space image of Neva dumb on 07/04/19 with agriculture color combination

As basement for low-cost MSS while MAA, GIDOP EOS can be used in educational and training purposes. The essential task of university practical learning (UPL) in the field of MAA is to teach students the practical aspects of work with GIDOP EOS tools, which requires a developed learning base within special geo-information systems (GIS) laboratory. In some cases, real practical work in special GIS laboratory can be undergoes with virtual reality (VR) technologies (Popov, 2019), that can reduce total cost of learning process. The presented in the article results of the research have a significant scientific novelty and can be used in the preparation of master's programs in environmental economics.

Conclusion

In the article, we consider results of information technologies development for managerial decision support within maritime activities in Arctic within environmental economics while climate change. While studies, we used methods of data bases constructing within digital platforms, web-technologies and virtual reality tools. We make statement that maritime activities in Arctic is to be carried out in the environmental economics paradigm as related set of large natural-industrial projects within common space area and time period. We present a block model that combines the investment objectives of such project set with cost of adequate managerial support, including natural risks management goals and tasks. We suggest to use geo-information distributed online platforms as the main technological tools in the tasks of managerial decision support within maritime activities in Arctic. We show that satellite images from the databases of Sentinel-2, Landsat-7, Landsat-8 systems can be used while MAA. The presented in the article results of the research have a significant scientific novelty and can be used in can be used in educational and training purposes, including the preparation of master's programs in environmental economics.

Acknowledgment

Associate professor Nikolay Popov, head of geo-information systems laboratory in Arctic and Subarctic Institute at the Russian State Hydrometeorological University, gave us very useful consulting while study. The platform https://www.researchgate.net/profile/Valery_Abramov2/ gave us excellent opportunities for preliminary discussion and data exchange while this research.

How to Understand, Formulate and Take Decisions when Managing Wicked Problems

Malgorzata PIETA-KANURSKA

Abstract

The unpredictability and variability of socio-economic processes resulting from the nature of the world makes it necessary to constantly solve problems. Some of them qualify as wicked problems. Although these problems cannot be completely resolved (at least with the current level of science and knowledge), they require proper reactions and managing. This article analyses the essence of wicked problems and the criteria for their qualification. Key areas in the management of wicked problems are indicated, and a research mode for approaching decision making regarding this group of problems is proposed.

Keywords: Wicked Problems, Decision-Making Process, Black Swan

Introduction

The term *wicked problem* was introduced into research literature at the same time by Simon (1973) and Rittel and Webber (1973). In the article *The Structure of ill structured problems*, Simon (1973) categorised problems into "well-structed" problems and "ill-structed" problems, i.e. those badly, improperly formulated, having a chronic nature (*like an illness*). Regardless of Simon's research, at the same time Rittel and Webber (1973) published an article entitled *Dilemmas in general planning theory*, in which they searched for scientific foundations to confront the problems of social policy planning. They concluded that it was not possible to find these foundations due to the nature of social problems. They identified these problems for the first time in the literature as "wicked problems." They used the term "wicked" to relate to pernicious, harmful, deceitful, aggressive and also when referring to *vicious circle*. In addition, they stated that science can only cope with "tame problems," or "regular" problems, in which the cause of their formation can be clearly defined and a systemic approach (such as those used by engineers), can be used to provide a final solution. It consists of successive stages: understanding the problem, gathering information, analysing, synthesising information and waiting for the so-called *creative leap* and working out a solution.

Wicked problems are those problems that are extremely complex and multidimensional. The system operation described above does not work when trying to solve them. They cannot be described definitively. *Wicked problems* are of a social nature. For example, Rittel and Webber (1973) pointed out that in a pluralistic society there is no such thing as an undisputed public good, there is no objective definition of equity and policies that respond to social problems cannot be significantly correct or false. According to their concept, there is no point in talking about optimal solutions to social problems, unless strict criteria for assessing their solutions are set first. They believe that in the case of social problems there are no solutions in the sense of definitive and objective answers (Rittel and Webber, 1973). They emphasised that this is not a special category of problems that are more complex than others, but "wicked problems" are problems that require a different approach when it comes to solving them.

A very interesting approach to wicked problems was presented by Coyne (2005) in his article entitled *Wicked problems revisited*. He reviewed the original article by Rittel and Webber and applied it to more current theories about rationality and professionalism. As a result of these analyses, he came to

the conclusion that "wickedness,, is not abnormal. According to Coyne, professionalism that pays homage to formal principles, setting goals and norms of rationality is a "deviation."

Over three decades after Rittel and Weber, Lucky (2009) indicated that some problems have such complex social, economic or organisational interactions that they cannot be fully solved. Despite the rapid development of science and technological revolution, the issue of a "wicked problem" still remains valid.

Definition and criteria for qualifying problems as „wicked"

According to Collins Thesaurus of the English Language (2002), "wicked" means: vile, evil, despicable, mean, indecent, disgraceful, shameful, sinful, godless, bad, nasty, malicious, terrible, unbearable, hideous, mischievous, malicious, threatening. There are, therefore, several synonyms for the word "wicked". In Polish literature on the subject, the concept is related to problems that are complicated, terrible, pathological, chronic or despicable. The genesis of this concept and a few contemporary definitions of "wicked problems" are worth analysing to explain what their essence is.

Wicked problems are a class of problems characterised by enormous complexity and high uncertainty. These aspects make them resistant to resolution through a traditional problem-solving process. *Wicked problems* are inherently difficult to define and divide into individual elements, because they are the result of multiple and inextricably entangled (intricate, complicated) causes. In addition, they affect multiple stakeholders whose priorities and goals may differ. Moreover, the perception of the nature of the problem is influenced by the possible solutions considered (Camillus, 2018).

Rittel and Webber formulated ten criteria to verify whether a given problem is a wicked problem. It is not a question of automatically qualifying a problem as wicked, but of insight into its essence, which will help to determine what kind of a problem is dealt with. The criteria, which can also be considered as typical properties of wicked problems, are:

1. The term "wicked problem" cannot be clearly defined.
2. Wicked problems can never be completely solved.
3. Solutions to wicked problems cannot be classified as true/false or good/bad.
4. Wicked problems do not have immediate or definitive solution tests.
5. Each wicked problem solution is a one-time operation.
6. Wicked problems do not have a quantifiable number of potential solutions;
7. Each wicked problem is unique.
8. Each wicked problem can be considered a symptom of a different problem.
9. Existing discrepancies that characterise a wicked problem can be explained in many ways.
10. "The planner has no right to be mistaken."

In their considerations, Rittel and Webber (1973) came to the conclusion that the first fundamental challenge is to formulate the problem. The phrase „wicked problem" is in itself a problem, there will always be some doubts and possibilities to rephrase it. While finding a problem would often mean finding a solution to it, however the problem cannot be defined until a solution is found. The difficulty is to know "what" differs the observed conditions from the desired conditions. Moreover, it is difficult to locate the problem, to find "where" in complex networks of connections the "problem" actually lies. Determining "how" to act, which could effectively narrow the gap between "what is" and "what should be", is equally difficult. A solution exists only in relation to established criteria; if the criteria for assessing the extent to which the problem is solved are changed, it may be that the problem is still unresolved.

Wicked problems are chronic problems with a long history, their nature changes but they are never completely solved. The assessment of the degree of their resolution depends on the adopted criteria, stakeholder value systems, ideological beliefs, considered time and space scale.

Every solution to wicked problems is a one-time operation, because every solution to wicked problems

leaves a trace, every attempt counts, because there is no opportunity to learn by "trial and error". Each action has certain and unknown consequences. When deciding on a solution, it is practically impossible to predict all the consequences. Attempts to solve wicked problems always change the reality. Moreover, not taking any action is also a decision and has consequences. This can lead to chaos, confusion. Therefore, on the one hand there is no opportunity to solve wicked problems, and on the other hand they should not be left unmanaged.

Wicked problems do not have a quantifiable number of potential solutions; there are no criteria to prove that all solutions to wicked problems have been identified and considered. Each wicked problem is unique and can be considered a symptom of another problem. Existing discrepancies that characterise a wicked problem can be explained in many ways. The choice of the explanation determines the nature of the solution.

"The planner has no right to be mistaken", no solution to the problem can be tested beforehand, knowledge is gained only during the implementation of the proposed solutions and their consequences (e.g. a motorway cannot be built for trial purposes, only during its use all the aspects of its functioning can be tested). It is also worth adding that given the megatrends such as globalisation, dematerialisation of production and democratisation of societies of the late 20th century and their continuation into the first twenty years of the 21st century, both the configuration of facts and the configuration of values must be taken into account in the approach to chronic problems. To deal with *wicked problems* it is essential to learn from stakeholders and the many groups with important "local knowledge". This means taking social participation into account in the planning process and solving social problems, the dialogue between policy makers and their audience plays a special role here (Paquet 1999).

Camillus (2018) points out that environmental degradation, terrorism and poverty are classic examples of wicked problems. They stand in contrast to difficult but ordinary problems which people can completely solve at a certain time using standard operating techniques. Moreover, the conventional process of action in the case of wicked problems can exacerbate the situation by generating undesirable consequences. The greatest difficulty is determining the current condition of the organisation and the desired conditions.

Wicked problems always have a social context. In the case of an organisation, wicked problems can occur when it is facing constant changes and unprecedented challenges. The greater the disagreement between the shareholders in the company, the more the problem can be described as wicked. Not all problems are wicked; however, confusion, strife, and lack of progress may indicate the threat of a chronic problem (Camillus, 2018).

Wicked problems are a class of chronic social problems. There are significant difficulties in determining the source of their occurrence. Rather, there is the interdependence and interpenetration of the causes of these problems, which come from many complex systems. It should be emphasised that they do not show any tendency to stabilise, but without corrective actions they plunge into chaos.

Key Areas in Managing Wicked Problems

Given the entire complexity of social problems considered to be chronic and unsolvable today, there is a growing call for an approach aimed at 'good governance' rather than solving them quickly. It is more about dealing with the problem, "addressing" it, and taking into account all its complex nature and different value systems of stakeholders. It is by no means a matter of dividing the "wicked" problem into smaller projects, as this will not result in a progress (Head, 2019). The answer may be actions aimed at seeking innovative, previously unknown solutions. What is needed here is creative thinking and integrated management, sometimes a reversal of the value hierarchy, and organisational changes in the system of shaping development policy. An important role is also played by such elements as: a new formulation (design) of the problem, study of *policy design studies*, capacity building of urban management policies and implementation context.

Problem design is a way of choosing, organising, interpreting and giving meaning to a complex reality

in order to provide signposts for knowledge, analysis, conviction and action. It is a particularly important stage of proceeding, because the way of defining a problem is very often imposes the type of solution. For example, poverty is already a chronic social problem that has served as an example many times. If it is perceived as a problem the source of which lies in the individual: in the deficit of their personal skills and motivation, then the proposed solutions will be oriented towards encouraging individual people to improve their skills and work efficiency. On the other hand, if we consider that poverty results from the social structure generated by the economic system and the market, the solution will be to seek better social security, employment programmes and income security. In fact, the best approach would be to work out a new, previously non-existent solution, assuming that to some extent socio-economic disparities are a natural feature of the modern world.

As indicated above, the fundamental challenge is the correct formulation of the problem. Difficulties result both from an in-depth diagnosis of the current situation and the establishment of the desired conditions which are being pursued. For example, in urban policy, which is a particular type of social policy in the context of planning the development of urbanised areas, a particular difficulty in determining the desired final effect can be observed. However, in the context of strategic planning, five features can be distinguished, which can be adapted to the planning of chronic urban problems:

1. Problems of strategic importance are influenced by many diverse groups of urban actors, who may have different objectives and value systems. The most populated group of city stakeholders are residents. However, city authorities do not always prioritize their interests in urban policy. This can be reflected in conflicts of interest resulting from gentrification.
2. Urban problems usually result from a number of reasons that are strongly linked. It is also difficult to unambiguously separate what the source of the problems is and what its consequences are, the dependencies are inseparably intertwined and multi-directional.
3. A chronic urban problem should be treated as a new problem every time. For this reason, the thoughtless use of previous solutions, patterns and even so-called good practices may not improve the situation. At the same time, it may generate time losses and unnecessary costs (e.g. hasty implementation of “off the point” projects). There is no single recipe for solving a problem. Therefore, it is necessary to diagnose chronic problems every time and use unconventional methods when solving them.
4. In the classical approach, city management can be understood as rational, effective and economically efficient coordination of various activities in the multi-level and multi-criteria structure of urban reality (Maciejewski, Redzik 2012). Whereas integrated city management means creating a new model of spatial organisation, ecological integration and functional integration of the city.
5. In response to the need of managing wicked problems, an approach based on inclusive growth, integrated city management and the combination of smart city multilevel governance is proposed.

Where is the error in the approach to wicked problems?

There is a number of possible causes and scenarios. In the context of managing wicked problems, attention should be paid to the decision-making process, because decision-making errors are costly (Milkman, Chugh and Bazerman, 2009). It is believed that the most significant errors in the management of wicked problems are generated at the very beginning of this decision-making process regarding managing the problem.

There are many different decision-making theoretical approaches in the literature, some of them are regarded as classical (Slovic, Fischhoff and Lichtenstein, 1977, Kahneman and Lovallo, 1993, Bazerman and Moore, 2009). But there is still need to improve the decision-making process (Milkman, Chugh and Bazerman, 2009). According to the approach proposed by Motyl (2015), in his book *Labyrinth. The art of decision making*, decisions are made in three modes: routine, confirmatory mode and research mode. In the table below each of these approaches is characterised (tab. 1).

Table 1: Decision making

Routine	Confirmation mode	Test mode
– unconscious, automated decisions – decisions undertaken on the basis of well-learned and repeatedly used mechanisms, there are applied to situation that occur often	– deliberate decisions – based on rational considerations	– decision making requires the analysis of all available data; – the problem should be looked at from every possible angle, involvement of people with different views is needed

Source: own study based on Motyl, P. (2015), Labyrinth. The art of decision making, ICAN.

Routine decisions are repetitive actions, taking place under conditions of certainty, that is, when we know exactly what the effect of the action will be. They can be also called as *programmed decisions* (Obi, 2018). The main advantage of routine decisions is the time and energy saved by our brains. This helps to develop the desired habits. For example, these decisions concern everyday activities (drinking coffee, driving a car, etc.).

If we encounter any problem, new unknown circumstances appear, and decisions are made in a confirmatory mode or *advocacy procedure* (Greitemeyer, Schulz-Hardt, Brodbeck and Frey 2006). In this mode, in the decision-making process we rely on our experience, knowledge and perception of the situation, which suggests the right solution. We look for so-called "hooking point", and then we look for data confirming that it is a good solution, and once we get it, the decision is made and implemented. There are some advantages to making decisions in this way. These are:

1. It works in a situation in which the so-called classic risk management is involved, i.e. when we know what the consequences of decisions taken will be and with what probability they may occur.
2. In this mode, decision-makers and teams act quickly and efficiently, searching for the key information for their decision.
3. This decision-making mode saves time – one of the most valuable resources in the organisation.

There are also some disadvantages of such an approach, the most frequent of which are:

1. Too superficial and insufficient analysis of data, i.e. available information. This disadvantage often occurs when acting "under time pressure".
2. In some cases, information may even be filtered out in such a way as not to prolong the decision-making process (e.g. not to prolong discussions at a meeting, to obtain confirmation of the correctness of the decision made).

This type of decision making under new circumstances not previously known usually leads to a significant decision error. In particular, one should be careful not act as in "black swan" case. In 2008, Nassim N. Taleb published a book titled *Black Swan: The Impact of the Highly Improbable*, in which he described the case of researchers who persistently created elaborate scientific studies proving why swans can only be white. One can imagine what a huge surprise and shock the discovery of a swan that was black was for those scientists. The black swan is an unpredictable event that goes beyond what is usually expected and has potentially serious consequences. Black swan events are characterised by their unusual rarity, strong impact and widespread persistence, which was visible in retrospect.

Therefore, when dealing with a situation that is a black swan, one should enter into research mode, especially it can be used the design thinking method (Buchanan, 1992). What the decision-maker's intuition and previous experiences suggest may be a mistake. Decision making requires analysis of all available data. One needs to look at the problem from every possible angle, involving people with different views. Decisions should be made by creating teams that are composed of people with different functions and different types of experience. The more diverse the team is, the deeper, more multi-faceted decisions are.

The disadvantage of this approach is that it takes a lot of time to act in this mode. However, its important advantage is that it allows to make decisions that are closest to the optimum, based on complete data analysis and evaluation of different scenarios.

It is considered that the implementation of the research mode in practice, with regard to wicked problems, should bring the best results. However, there are some risks that undermine the quality of the method. These include two aspects. First, the collection and incorporation of information necessary to make decisions. Second, the limitations resulting from the attitude of the decision-maker (one person or a whole group of rulers). Moreover, the two aspects are often inseparable.

In the first case, the success of management of wicked problems is largely determined by the first stage of data collection and analysis. The question arises: what information should be collected and analysed, and which can be omitted and considered irrelevant. It turns out that the selection of data determines the whole analysis process. In addition, there is a psychological phenomenon of omitting (consciously or unconsciously) the information that is inconvenient for the decision-maker, as it is considered "insignificant". Unfortunately, ignoring this information often results in a failure to manage problems that are then easier to be qualified as unsolvable.
