3	2019	*Festuca arundinacea*	Reduces fluoranthene levels in the soil, multiplies the number of soil bacteria and also the activities of the enzyme dehydrogenase.	(Rostami and Rostami, 2019)
4	2018	*Brachiaria mutica*	Reduces oil content by 61% in oil-polluted soils.	(Fatima *et al.*, 2018)
5	2010	*Jatropha curcas*	Reduces up to 67.3% of the lubricating oil that pollutes the soil.	(Agamuthu *et al.,* 2010)
6	2014	*Poa Foliosa*	Very receptive towards Special Antarctic Blend (SAB) and reduces TPH levels up to 48% within two months.	(Bramley-Alves *et al.*, 2014)

Based on the literature review results, it is shown that *Chrysopogon zizanioides*, *Spartina Anglica*, *Festuca arundinacea*, *Brachiaria mutica*, *Jatropha curcas* and *Poa Foliosa* could grow to a certain extent in oil-polluted land and take and absorb pollutants. Each type of grass has different characteristics and this could be seen from the specific benefits generated and the time required to reduce petroleum content in oil-polluted land. Phytoremediation research utilizes grass plants. The selection of the appropriate type of plant proved to be promising for the decontamination of sediments contaminated by oil industry activities and indirectly contributing to minimize global warming through carbon sequestration (Agamuthu *et al.*, 2010). The implementation of phytoremediation by using endemic species in oil-contaminated areas is a very appropriate choice as the method is easy to be obtained and grown (Bramley-Alves *et al.*, 2014).

In addition to grasses, some plants could be used to reduce petroleum levels. Baoune *et al.* (2019) demonstrated that inoculation of corn plants with *Streptomyces* sp. could remove petroleum hydrocarbons up to 70% and increase plant growth in contaminated soil. There is a decrease of up to 100% for some aromatic Polycyclic Hydrocarbon Fractions (PAH) using *Medicago satuva* (Xiao *et al.*, 2015). According to Sarma (2011), the success of the phytoremediation system relies on the plant species and the climate.

Impact and Efforts to Oil Spills Management

This study examined the use of phytoremediation technology so that it could be carried out optimally with the coordination with local stakeholders. Petroleum pollution certainly becomes detrimental to

both the environment and the local community. As per the outcome of the interview with the Informant 1 explicates that the impact caused by oil pollution:

> *"The impact caused by this oil pollution is the inability to fish in the sea due to the polluted sea, emerging health-related problems such as headaches, eye strain, irritation and the soil pollution as seen from the number of oil spills reaching to the land. This incident also caused a decline in income due to the inability to work impacted from the oil spills."*

The impact of pollution that could be detrimental for the community should have gained the attention and assistance from the industries as well as the Government. As a result of this in-depth interview with the affected community the efforts of the industries and the Government to deal with the exposed area from the oil spill have been further elaborated below:

> *"The industry is seeking the community to work as 'ojek limbah', cleaning the sea and land by transporting the waste oil. Approximately around 3-4 months, we have assisted the industry to ship the crude oil but not all people have done this, so we have to replace it. Every day we are paid Rp. 150,000, but when compared to the income before the oil spill, this is certainly still not enough for our daily needs. The industry promises some money as compensation due to the impact of oil pollution, but until now there is still no compensation just like they said. Only a few households have received the compensation and the amount was not as promised. The condition has gotten quite well, but the oil still remains there though not as bad as before, the smell so bad, and it made me dizzy."*

In addition to the efforts to handle oil spills, thus the researcher asked Informant 1 about the use of phytoremediation as a technology to restore contaminated land conducted by both the industries and government. Informant 1 explicated that:

> *"Such technique has not been carried out, in which we have seen is only to ship the crude oil from the sea and land to the location. If such Method can help to remove oil, of course it's good, it could also be taught to the public, you know and also it's more natural to use plants to remove the oil."*

The researcher also conducted an in-depth interview with Informant 2, namely as the Chairperson of the Sedari's Community Development Committee who became the bridge between the community and the industry in developing community programs. The information from Informant 2 regarding the efforts made by the industry in oil spill management are as follows:

> *"The industry sent a team of experts to examine the situation in the field. Community-owned boats were rented to transport the waste. The industry also provided free emergency medical tent. The industry also asked the public to carry the applicable oil so that they could turn those into a source of income during the times in which the industry was not sailing. Regarding the compensation, some elements have been delivered and some have not been delivered and it is not managed by the industry but rather by the Fisheries Service. While this is more on the handling of oil from the industry, government institutions only serve to monitor the activities."*

In regard to the the management that has been carried out by the industry, the researcher further asked about the restoration carried out while using the biological method, namely phytoremediation, the response from Informant 2 are as follows:

> *"The actual restoration has not been implemented, right now the restoration that is being carried out is still just regular cleaning. The issues that we hear is that the land could recover in 1-2 years. Many researchers also visit this place to observe and take samples, but the industry has not implemented the technology mentioned thus far."*

Based on the results of the interview, there has not been any actions in any good faith conducted by the industries nor the Government to carry out biological remediation. The use of this green technology to restore polluted land requires the outreach and cooperation between stakeholders so in order for this technology to be beneficial.

Indonesian Government Regulation in Handling Petroleum Pollution Through Phytoremediation

Petroleum pollution has a detrimental effect especially towards the human health and ecosystem, soil productivity and social and economic aspects (Zhang *et al.*, 2015). According to Government Regulation of the Republic of Indonesia No. 101 of 2014 concerning Management of Non Hazardous and Toxic Wastes caused by the functions of the environment restoration which is conducted by limiting sources of pollution, remediation, rehabilitation, restoration as well as other means through the development of science and technology.

The remediation referred to in Article 203 is conducted by selecting the remediation technology, planning a plan and the implementation of the remediation as well as the preparing and submitting the remediation on the environmental pollution to the minister, governor, regent/mayor. According to da Silva and Maranho (2019), the appropriate choice of remediation determines the level of success for the environment restoration to its initial state. This regulation is in line with the Decree of the State Minister for the Environment No. 128 of 2003 that it requires the processing of petroleum waste as part of the recovery measures of the environment through biological approach, one of which is phytoremediation.

Implementing the recovery of polluted land with phytoremediation technology must meet the following the requirements of biologically-treated petroleum waste as follows (1) maximum initial TPH concentration amounting to <15%; (2) TPH concentration which was before the processing phase amounting > 15%, it is necessary to initially do the processing or utilization; and (3) TCLP test results of heavy metals were below the quality standard in reference to KEP 04/Bapedal/09/1995. After the processing phase meets the specified criteria, measures could be taken with the requirements as listed in Table 2.

Table 2: Handling of Processed Products After Treatment

Concentration	Handling activities	Note
>2%	The processing phase continues	Until meeting the criteria
1%-2%	Landfill	In accordance with Kepdal 04/1995
≤1%	a. Placement on exclusive and limited land b. Utilization	a. Growing plants not for consumption b. Mixing materials for road layers, building materials and others

(Source: Decree of the Minister of Environment No. 128 of 2003)

As per the Republic of Indonesia Government Regulation, the restoration of biologically-contaminated land could be conducted by following the applicable regulations. Land that has been successfully remediated through specified standards may be re-used by the community to grow plants not consumption and may be used for mixing road layers for building materials and other uses. Based on the aforementioned study, the researcher illustrates the concept of phytoremediation and its potential using grass plants to be applied and developed at the study site.

Figure 1: The Implementation of Phytoremediation Concept Using Grass Plants

Based on Figure 1, should there be a proper coordination between stakeholders, efforts to tackle oil could be optimally carried out using phytoremediation technology. In addition, phytoremediation could also be managed or developed by the community or local community through an outreach conducted by the Government and the industries. The use of this technique has not been widely carried out in oil-polluted areas making this paper to become a recommendation for companies or the government regarding this matter.

Conclusion

Phytoremediation by using grass plants could be utilized to handle the petroleum pollution. This is due to the nature of grass plants of being very receptive and adaptive towards oil-polluted land and the grass plants are able to absorb these pollutants. The use of biological remediation could be conducted but must take into account the terms and conditions of the local government. Based on the Government Regulation of the Republic Indonesia, several regulations have been made as a requirement in biological remediation. Biological treatment may be used if the initial TPH concentration is <15%. In its implementation, it is necessary to coordinate among stakeholders as an effort to optimize phytoremediation method in reducing petroleum content. The research also suggests that phytoremediation may also be managed by local communities for the restoration of oil-polluted land. The use of phytoremediation technology has not been widely applied in areas that are especially located close to oil industries. This research is expected to be a recommendation (for the government and other related stakeholders) in efforts to restore oil-polluted soils.

Acknowledgment

This research is funded by Penelitian Tesis Magister Kementerian Riset dan Teknologi/Badan Riset dan Inovasi Nasional (KEMENRISTEK/BRIN)- Universitas Indonesia with contract number 8/E/KP.PTNBH/2020 and 255/PKS/R/UI/2020

Abstract

Transnationalization is the most important component and at the same time the main mechanism of the General processes of globalization. It seems to be the most essential element and one of the main circuits-regulators that ensure the unity of the functioning of the world economy. Through TNCs (Transnational corporations) and related transnational banks pass the financial and commodity flows that determine the development of the world economy. They are the leading factor of globalization of economy, placing separate parts and stages of reproduction processes on territories of different countries. Transnational corporations not only affect the economic, political and social state of society, but also act as a leading factor in world development, so the importance of TNCs in mergers and acquisitions is very difficult to overestimate. With broad financial and organizational capabilities, TNCs are the main participants in the market for mergers and acquisitions, but it is worth noting that TNCs have come a long way from a simple business combination to a deep integration of capital.

Keywords: Systemic transformation of the economy, foreign economic activity, multinational companies.

Introduction

The modern economic world is gradually acquiring the properties of global, although so far limited in scale, self-regulation.

Global processes have evolutionarily created planetary feedback loops that allow to restore planetary equilibrium with relatively small external disturbances occurring at any point of the Earth. This is what indicates the emergence of a new situation in the world economy, which, since the last quarter of the twentieth century, is a single global economic system, self-regulating on the basis of feedback mechanisms.

TNCs perform important functions in the modern world economy, to a greater extent stimulating. They show the following advantages of TNCs: contribute to the development of scientific and technological progress; create a favorable basis for the globalization of the entire economy; favor the spread of international production; impose free competition in international trade; have free access to natural resources, investments and high-tech developments; set a relatively low price of their resources, which affects the investment attractiveness of the Corporation itself; effectively use the scale of the enterprise (ie, their dispersion in different countries); the ability to select specialized personnel and the best staff.

But TNCs also have their disadvantages, such as: the incentive to turn it into a monopoly in the host country; the risk that TNCs can influence not only their competitors, but also the entire state

economy; the emergence of such a phenomenon as the reduction of employment in TNC units in developed countries.

The purpose of the work is to consider current features of the activities of transnational corporations, identify problems and develop proposals for the formation of a global strategy for the activities of transnational corporations in international economic relations, and identify ways to increase the competitive advantages of Russian multinationals.

In the process of solving the set tasks, general scientific methods were used: dialectical, system-functional, structural-level, theoretical, monographic, and private-scientific methods: logical, analytical, comparative, forecasting, graphical and tabular interpretation of data.

Material and Methods

In order to overcome or minimize the negative consequences of the activities of TNCs, it is necessary to realize the emergence of new tasks that clarify the functions of the state in interaction with TNCs. TNCs have teams of specialists who are responsible for both tax minimization and analysis and creation of special schemes to optimize activities. Taking into account this fact, it is necessary to strengthen the position of state institutions as a set of structures regulating the financial and economic activities of TNCs in the specific conditions of the Russian Federation.

Methods of state regulation of TNCs: system of state guarantees and insurance of foreign private investments against risks; tax incentives; agreements on avoidance of double taxation; state credits; antitrust legislation; legislation on foreign investments; legislation on state control over prices; customs and preferential legislation.

Recent studies of domestic and foreign authors differ greatly in the role and assessment of Russia in the global oil market. They are distinguished primarily by the level of operating with statistical data, access to the completeness of information and the level of politicization of the research. Some authors (S.A. Basher, A.A. Haug and P. Sadorsky, 2018) provide objective information about Russia's place on the world oil market compared to the yield of crude oil reserves in Canada, Norway, Russia, Kuwait, Saudi Arabia and the United Arab Emirates. The authors argue that oil reserves affect stock returns in Canada, Russia, Kuwait and the United Arab Emirates. Oil supply shocks are important for the UK, Kuwait and the United Arab Emirates. Mexico is the only country where stock returns are not affected by shocks in the oil market.

Joint research of domestic and foreign researchers (Y. Tuzova & F. Qayum, 2016) showed the interconnection of Russia's positions on the world oil market in the context of the sanctions against Russia. The results showed a significant impact of oil prices on the Russian economy. Researchers predict that Russia's economic prospects are not very optimistic and real GDP for the quarter by quarter will decline by an average of 19 percent over the next two years.

Adnan Vatansever (A. Vatansever, 2017) touches another vector of Russia's position on the world oil market, associated with the construction of pipelines. The consequences of Russia's excess capacity can be significant for Europe and Asia. As for oil, the maneuvering space is wide enough to allow Russia to abandon the whole route of its choice.

Domestic researchers (A. Goppert, D. Ola and S. Prakash, 2015) reveal the importance of introducing innovative technologies in the extraction and development of oil fields, without which it will be difficult for Russia to find its niche in the modern oil market.

Stupin V.V. (2012) notes significant territorial-structural shifts in the oil industry of the world for Russia, and considers it necessary for Russia to take advantage of a favorable situation. A similar opinion is shared by Filimonova I.V. with fellow researchers (I.V. Filimonova, L.V. Eder, V.Yu. Nemov & I.A. Agile, 2017).

A. Bondar (2019) in his study notes that US sanctions have become a kind of catalyst for strengthening Russia's position on the world oil market. But R. Ivanov (2019) believes that not everything is so optimistic for our country and offers three scenarios for the development of world energy until 2050, in which Russia is far from leading positions on the world oil market.

Thus, the relevance of the study of this topic is obvious.

Results and Discussion

TNCs operate primarily for long-term investment. Therefore, TNCs often contribute to the stabilization of the economic environment, including the financial one. However, the purpose of TNCs is to make a profit, so sometimes entire markets and even countries can become victims of them on the way to achieving this goal. As a result, it is necessary to understand the pros and cons of TNC activities and to develop specific measures of state regulation of TNCs to protect the economy from possible negative consequences.

Economically, the processes of transnationalization are mainly conditioned by the possibility and necessity of capital transfer from countries with its relative surplus to countries with its deficit, where, however, there are other factors of production (labor, land, minerals) in excess, which cannot be rationally used in reproduction processes due to the lack of capital. In addition, these processes are stimulated by the need to reduce risks by placing capital in different countries, as well as the desire to bring production closer to promising markets and rationalize taxation and customs payments for the Corporation as a whole. Objectively, transnationalization leads to the equalization of economic conditions in different countries (I.V. Minakova, M.A. Parkhomchuk, A.A. Golovin and T.N. Bukreeva, 2018).

Fortune Global 500 – is the most famous and authoritative ranking of the largest companies in the world. It has been published by the American business magazine Fortune since 1955. The list is compiled annually and shows the largest corporate players, thus allowing you to assess the economic development and trends of the markets.

All companies in the rating are ranked according to the following indicators: total income; profit; assets; share capital; dynamics of income per share for the last 10 years; total annual income of all investors; average annual rate of total income of investors for the last 10 years.

Places on the Fortune Global 500 roster are determined according to the companies' earnings for the past year. The researchers include only U.S. companies that submit an annual report to the U.S. Securities and Exchange Commission (US Securities and Exchange Commission) on form 10-K, as well as private companies registered outside the United States and with open records.

American Walmart received for the year operating income of 514,4 billion dollars and occupies a leading position. The company's profit in 2018 amounted to 6,67 billion dollars. This is stated in the Fortune Global 500 ranking for 2019.

The total operating income of the 500 companies included in the rating reached 32,7 trillion. dollars, this is 8,9% more than last year. Their profits hit a new record high of 2,15 trillion. dollars'. These companies employ about 69,3 million people.

This year, 129 Chinese companies entered the ranking, making China the leader in the number of its representatives in the Fortune Global 500 for the first time in history. And Sinopec entered the top three and took the second place. In 2019, the ranking for the first time included the Chinese smartphone manufacturer Xiaomi (486 place) with an operating income of 26,44 billion dollars and a profit of 2 billion dollars.

There are 121 American companies in the ranking.

The fastest-growing are Amazon with operating income of 232.8 billion dollars, + 30,9% (13th place), Centene with revenue of 60,1 billion dollars, +23,8% (168th place) and Facebook with revenue of 55,8 billion dollars, +37,4% (184th place).

The best Russian company in the rating is "Gazprom". At the end of 2018, it rose from 49 to 42 place. LUKOIL moved from 63 to 50 position. Rosneft advanced from 115th to 86th place. Sberbank-dropped from 205 to 255 position.

In general, the global market is still dominated by American and Chinese corporations.

For a more complete analysis of the current trends in the activities of transnational corporations the Forbes 2000 rating is also considered – the list of 2000 largest public companies in the world according to Forbes magazine. The Forbes ranking of the world's largest companies is based on a combined assessment of revenues, profits, assets and market value.

The Top ten for the number of billionaire firms included the United States and China – the only countries on the list in which the number of giant companies has increased. Also in the top three of the list of countries with the largest number of large companies, what in general includes 61 countries, got and Japan too.

Top 10 largest companies according to Forbes:

1. ICBC is China's largest commercial Bank.

2. JPMorgan Chase-American financial holding company.

3. China Construction Bank – one of the largest Chinese banks.

4. Agricultural Bank of China – China's largest Bank.

5. Bank of America – American financial conglomerate.

6. Apple is an American technology Corporation.

7. Ping An Insurance Group – Chinese insurance group of companies.

8. Bank of China-Chinese financial group.

9. Royal Dutch Shell is a British-Dutch oil and gas company.

10. Wells Fargo is an American Bank holding company.

Four Russian corporations entered the top hundred of the Forbes Global 2000 ranking of the world's largest companies.

Gazprom is the highest in the ranking: it took the 40th place, Sberbank was placed on the 47th, Rosneft-on the 52nd, LUKOIL-on the 97th.

In total, there are 575 American companies in the 2019 ranking, that is 16 companies more than last year. It also included 309 Chinese companies, up 18 companies from a year earlier.

Forbes included 22 Russian companies in the rating in 2019 (there were 25 in 2018), among which Gazprom retains the leadership for the 4th year in a row. Compared to 2018, the Russian gas holding has risen from 43 to 40 places. Its market value, according to Forbes, was $59,9 billion. Assets are estimated at $305,9 billion. Us $ 18,9 billion in profit. USA.

In addition to Gazprom, 4 Russian companies - Sberbank (47th place), Rosneft (52nd) and LUKOIL (97th) – were in the top 100, as in 2018. The rating also includes Surgutneftegaz (330th place), Transneft (386), VTB Bank (471), NOVATEK (500), Tatneft (524), Norilsk Nickel (574), rosseti (767), Novolipetsk metallurgical plant (791), Severstal (925).

Moreover, among the Russian companies in the Forbes list in 2019 are INTER RAO (1189th place), Magnitogorsk iron and steel works (1237), ALROSA (1327), Magnit (1370), Sistema (1467), Moscow exchange (1704), Moscow credit Bank (1837), United aircraft Corporation (1895), RusHydro (1957).

Compared to 2018, the gold mining company Polyus, Aeroflot and Uralkali were eliminated from the rating, which occupied 1552, 1932 and 1993 places, respectively.

The analysis of the rating of Russian transnational corporations for 2018-2019 shows that the activities of domestic TNCs in the international market are mainly limited to the supply of fuel and energy raw materials.

In order to improve the development of transnational corporations, it is necessary to form a global strategy for their activities.

The main goal of the global strategy of transnational corporations is not so much to maximize profits through the globalization of the market of their products/services, but to achieve economically beneficial complementarity (adaptation) with the external environment of their activities.

The result of the formation of the global strategy is the creation of an integrated international trade and industrial system.

Economic hypergrowth management is based on the use of modern management models: value-oriented management (value Based Management, VBM), balanced scorecard and strategic maps (Balanced Scorecard, BSC and Strategy Map), value chain management, intra-firm economic calculation (BUM-Business Unit Management), etc.

Nowadays, successful organizations are rapidly bringing new products out, entering and exiting markets, and sometimes going out of business. In such circumstances, the essence of the global integration strategy is not in the structure of the organization's products and markets, but in the dynamics and time of its formation. The goal is to generate and modify operational routines and hard-to-replicate core competencies based on the generation, evaluation, and development of dynamic capabilities that distinguish an organization from competitors in the marketplace. This makes the use of dynamic capabilities the main tool for shaping the strategy of global integration of the organization in the framework of its development in the national, international and global markets.

To ensure sustainable demand for its products in a changing environment, an organization must be able to recognize new business opportunities and competitive "challenges". And then extracting economic benefits from them through the adoption of adaptive management decisions and organizational changes (transformation of competencies) on the basis of organizational development.

In shaping the strategy of global integration, special emphasis is placed on determining the benefits of targeted Hyper-growth of the organization to generate sustainable competitive advantage.

A TNC implementing a Hyper-growth strategy has the ability to (Strategic Report, 2017):

– to receive advantages, concentrating these or those productions in regions with cheap raw materials and low rates of a salary;

– plan and make profits in different countries depending on the level of income tax;

– adapt production and marketing schemes to the conditions of national markets of different countries;

– to implement the accounting policy of operations of subsidiaries and branches, beneficial to the Central organization;

– respond effectively to shifts in comparative advantage (e.g. commodity prices or exchange rates, changes in tax policy);

– to effectively allocate the education and training of professionals between countries;

– improve reputation in the eyes of mobile consumers who may encounter this firm in different countries;

– the ability to differentiate and more effectively serve multinational customers who simultaneously deal with several divisions of the company in different countries;

– respond to competitive threats using the most convenient and effective forms and methods of dealing with competitors.

These advantages of the strategy contribute to increasing operational efficiency, as well as strengthening the unique position of TNCs.

The issue of competitiveness is quite acute for the Russian economy, especially if it is in the context of the world market. Competitiveness can act as a factor of sustainability and development for Russian TNCs.

Russian TNCs demonstrate competitiveness only in such industries as fuel, metallurgical, military, that is, where there is a comparative advantage, but on the whole domestic companies they have low competitiveness in many areas of activity, because it is necessary to take stable positions in other industries, such as the market of fast-turning goods, information technology, etc. This circumstance explains the fact that a limited number of domestic companies enter the world markets.

Competitiveness is one of the most important factors in ensuring sustainable development of the enterprise economy. Sustainable economic development economic structure characterizes a complex system of indicators, reflecting the dynamics of economic growth, strengthen financial condition and increase of efficiency of use of the entire set and each type of resource, performance during the reporting period, obligations to employees, other businesses and government.

In order to increase the competitiveness of Russian TNCs it is necessary to implement the following stages of strategic analysis: analysis of strengths and weaknesses; compliance with market conjuncture; awareness of consumer desires and market trends; analysis of competitors; tracking trends in production, consumer environment, information, technology, management environment.

Conclusions

With constant and competent implementation of these stages, the Corporation will always meet the constantly changing external conditions, any fluctuations in market conditions, the changing state of the main competitors, as well as carry out internal innovative transformations that meet all modern challenges of the world and regional economies, and, consequently, achieve a certain level of competitiveness.

In a complex functionally integrated management mechanism of TNCs, the effective use of information support systems for business processes is important. The information and logistics system is based on a systematic approach that covers all activities related to planning and managing processes aimed at providing TNCs with the necessary information.

Information logistics is particularly in demand in the activities of corporations and, above all, TNCs, whose enterprises are scattered around the world and which are managed mainly at the level of information flows. Therefore, the solution of the main task of information logistics-ensuring and coordinating information flows at all horizontal and vertical levels of management-will ensure the effectiveness of management of transnational corporations and increase its competitiveness.

The solution of the main task of information logistics-provision and coordination of information flows at all horizontal and vertical levels of management, will ensure the effectiveness of management of transnational corporations and increase its competitiveness.

The priority measures to improve the activities of Russian TNCs in the global economy should be the formation of specialized innovation support institutions, improvement of the legal framework for investment activities and state support for innovations, the creation of organizational mechanisms for managing the innovation activity of corporations.

As for the internal aspects of the activities of Russian TNCs, the main goal can be defined as ensuring transparency of their activities. This can be achieved by improving the relevant legal acts and legislative initiatives to limit monopolistic activities and to protect the rights of investors.

Russia has enormous economic potential, which can be realized with careful planning of the activities of Russian TNCs. Implementation of the proposed measures could provide Russia with stable economic development and expansion of national TNCs. In turn, this would enable our state to take a higher position in modern international economic relations and to use the maximum benefit from the globalization process.

The publication has been implemented as part of the 2020 Government target (No. 0851-2020-0034).

Abstract

The article explains transformations that are taking place in indirect tax administration along with the digitalization of the Russian economy. The authors explore the evolution of indirect taxes at every stage of economic development. The forms of and trends in the transformations of indirect taxes under the influence of digital technology and amid the application of a risk-oriented approach. As a result of an analytical review, trends in the digitalization of tax administration of indirect taxation in Russia were highlighted. It is proved that these trends can with high probability be reproduced in other tax systems during the development of digital control services. The research concept is, therefore, to advocate the effectiveness of solutions for the transformation of the indirect tax administration system that would be adequate to the global challenges and development trends in the digital economy of Russia.

Keywords: Indirect Taxes, VAT, Tax Administration, Digitalization.

Introduction

The present stage of economic development in the world is characterized by the arrival of digital technology in all spheres of activity. The digitalization of the Russian economy is a source of long-term growth thanks to streamlined production and logistics, better labor and equipment productivity, a more efficient labor market, higher research efficiency, lower resource consumption and production losses. A legislative framework for the development of the digital industry is being created by the government. Russia's national program for the development of digital economy was approved on 6 July 2017. It has been estimated that as a result of the digitalization of the Russian economy the country's GDP could grow by 4.1–8.9 trillion rubles by 2025, which is from 19 to 34% of the total expected GDP growth. In 2018, the share of the digital economy in the country's GDP increased by 150% from 2.1% to 5.1%. Innovations that spread in the global information environment are an essential factor of sustainable economic development, the sphere of indirect tax administration being no exception. Indirect taxes make up a considerable share of total government revenue in Russia, varying from 25% to 30% a year over 2014-18. The share of indirect taxes has continued a steady upward trend over the past five years, with VAT revenue growing by 63.5%, excise duties by 49.5%. At the same time, there is a VAT tax gap in Russia that is the difference between the sales records of suppliers and the purchase records of buyers. According the head of the Federal Tax Service, Russia's VAT gap is the lowest in the world at 0.6%. In Europe, for example, it is 10% and upwards (FTS, 2020).

Methodology

The methodology and research methods were selected with consideration to the supposed long-term impact of digitalization of the economy on the transformation of indirect taxation. The methodology proposed for achieving the goals of the research includes successive phases and methods. At phase one, the scope of digitalization of indirect taxation is determined by means of the content analysis of

available literature on the subject. This made it possible to "scan the environment", i.e., to define current trends in the development of digitalization of indirect taxation and to highlight ideas and make guesses about the future scope of digitalization. Information on the aspects of the subject under research was retrieved by doing a content analysis of key words, abstracts and full-text article in Russian and English repositories of academic articles.

Research

1. Evolution of the system of indirect tax administration. The evolution of the tax system in a country is the result of a large number of minor changes and small-scale reforms along with major changes, such as the introduction of new taxes replacing old ones or an overhaul of the tax administration and collection system. The historical analysis of the transformations of indirect taxation amid a conceptual change of the economic model enables one to distinguish four historical tax systems. Table 1 presents the characteristics of these historical tax systems.

Table 1: Comparison of characteristics of historical tax systems

	Historic period	Economic attributes	Attributes of taxation
Tax system 1.0	Pre-industrial economy	- predominantly subsistence-based agricultural economy; - moneyless exchanges; - land-based economy; - main communication means - books, messengers, by word of mouth.	Self-sufficient economy meets internal needs of society. Economic conditions are created by the economy, are reproduced and recovered from gross domestic product. Up to 70% of gross product is redistributed. Indirect taxes: sales taxes, judicial fees, excise taxes on alcohol, tobacco, salt.
Tax system 2.0	Industrial economy	- man no longer dependent on nature thanks to development of tools and technology; - development of currency system; money as a measure of value; - legally protected and regulated trade; - capital is the key element; - communication means newspapers, magazines, books, later telephone, telegraph, radio and television.	Source of taxes –profits and wages (payroll taxes were viewed as shifted on entrepreneurs' profit). Taxation formula: all taxes are ultimately paid from the capitalist's profit and only some taxes are paid from land rent; the form of tax is irrelevant. Such theory of taxation justified the introduction of any tax, with some reservations about taxes that were directly imposed on entrepreneurs. VAT is a result of the development of the industrial economy; it is an all-pervading tax that has a socio-economic explanation.
Tax system 3.0	Neo-industrial economy	- development of non-manufacturing sector – that of services; - information is the key element; -computer networks; mobile phones, radio, television; - borders between nations are erased; - high money velocity.	- traditional taxation methods are difficult to apply because of a high share of profit-yielding intangible assets; anonymous purchases online; purchases can be made in any place on the planet, which serves as an argument in favor of indirect taxation.

Source: compiled by the authors based on Vishnevsky V. P., Chekina V. D. (2018)

The table leads one to a conclusion that economic conditions determine capacities for taxation. During the pre-industrial period, the complexity of tax administration was the deciding factor for the use of indirect taxes in the form of duties, charges and excise taxes. Indirect taxes are taxes that are paid as a surcharge to the price or tariff and that is collected when a product or a service is consumed by the end buyer, who pays the tax. Criticism of indirect taxes is mainly aimed at the complexity of administration, accounting and control. However, modern digital technology offers new opportunities for wider use

and development of indirect taxes. Indirect taxes in the Russian Federation are regulated by the Tax Code that establishes a system of indirect taxes and general principles of indirect taxation. The characteristics of indirect taxes in Russia are summarized in Table 2.

Table 2 allows the following conclusions to be drawn:

- indirect taxes in Russia are designed to regularly replenish the treasury (on a monthly, quarterly basis);
- legal entities are taxpayers of indirect taxes as they are easier to control; private individuals only pay indirect taxes in the case of importation of goods across the border;
- the object of indirect taxation in Russia is sales of goods and services;
- the tax base for indirect taxes in Russia is the value of goods or services of their volume (excisable goods).

Table 2: Indirect taxes as per Tax Code of Russia.

Attribute	VAT	Excise duties
Tax payers	- organizations; -private entrepreneurs; - persons who are deemed to be taxpayers of VAT in connection with the conveyance of goods across the customs border of the Customs Union;	- organizations; -private entrepreneurs; - persons who are deemed to be taxpayers of excise taxes in connection with the conveyance of goods across the customs border of the Customs Union;
Object of taxation	- the sale of goods (work and services) in the territory of the Russian Federation, , and the transfer of property rights. - the transfer of goods (performance of work, rendering of services) in the territory of the Russian Federation for own requirements, - the performance of construction and installation work for own consumption; - the importation of goods into the territory of the Russian Federation and other territories under its jurisdiction.	- the sale by persons in the territory of the Russian Federation of excisable goods produced by them, including the sale of pledged articles and the transfer of excisable goods under an indemnity or novation agreement.
Tax base	Where taxpayers apply different tax rates in selling (transferring, performing, rendering for own requirements) goods (work and services), the tax base shall be determined separately for each type of goods (work and services) assessable at different rates. Where the same rates of tax are applied the tax base shall be determined as an aggregate for all types of operations assessable at that rate.	- volume, quantity or other physical parameters of imported marked goods for which fixed (specific) rates of excise duties have been established; - value of imported excisable goods for which ad valorem rates of excise duties have been established;
Tax period	Quarter	Calendar month
Tax rate	0 %, 10 %, 20 % depending on the goods or services.	Depends on type of excisable goods

Source: Tax Code (2020)

The concept for the development of tax administration in Russia was designed a few years ago and is being implemented in a phased manner: a risk-oriented approach started to be applied in 2007; a major project to digitalize tax administration of VAT was launched in 2013. The application of the risk-oriented approach for control activities was formally described in the Concept of On-site Tax Audits (in force since 2007). The Concept is an open-source document that was produced with the purpose of creating a system of planning for on-site tax audits that would be universal, open, and clear to both

taxpayers and tax authorities. The concept contains 12 non-classified criteria for self-administered risk assessment; some of them are directly related to consumption taxes (Concept, 2007):

- the business's tax burden is lower than the sector-wide average;
- the tax reports show considerable tax deductions over a certain period. The amount of VAT the business may deduct is equal to or exceeds 89% of the amount of VAT due from that business over a 12- month period; ;
- the taxpayer builds its business and financial activities on contracts with middlemen or intermediaries ("chains of intermediaries") without any sensible economic or other reasons;
- the business runs a high risk of tax noncompliance.

Among the indicators of a high risk of tax noncompliance is the lack of:

- information on the sources of background information about the contract party contract (no TV advertising, no website etc.);
- personal contacts between the executives of the supplier and of the supplying company and the purchasing company in the course of contract negotiations;
- documents confirming the authority of the head of the company that is party to a contract; a copy of his or her ID;
- information on the actual location of the company that is party to the contract and its warehouses, production or sales facility;
- information on the company that is party to the contract in the Unified State Register of Legal Entities;

Additionally, the Concept identifies signs in the relationships between the taxpayer and its contract partners that increase the risk of tax noncompliance. For example, contracts might contain clauses that are different from the typical rules of business conduct (large batches of goods are delivered without any advance payment; transactions are made through third parties; payment with bills of exchange etc.); there are reasonable doubts about the contract partner's ability to fulfill their contractual obligations; the payer (or their contract partner) does not take any action to collect the debt; the contract partner issues, buys or sells bills of exchange etc.

The work to improve the VAT administration system started with the creation at phase one of a system for verification of VAT refund claims using a risk-oriented approach. The system applies practice-based criteria to divide taxpayers into three groups: high-risk, medium-risk and low-risk ones (RMS FTS, 2016).

The next step in the application of the risk-oriented approach was the introduction of automated VAT control system ASK NDS-2 in 2017. The system enables tax authorities to automatically control VAT refund claims and tax deductions. Tax authorities use the system to automatically monitor the entire supply chain, the emergence and size of value added as well as the amounts of VAT invoiced, and VAT refunds claimed. ASK NDS-2 analyses VAT returns of the taxpayer and his contract partners by comparing invoices, sales journals and purchases journals, and invoice journals of intermediaries with the similar data of the contractual partners. The system detects two types of deviations:

- a discrepancy between the VAT amounts (when the transaction is recorded in the returns of both contractual partners, but different VAT amounts are entered);
- a gap (when a transaction is not reported in the returns of one of the contractual partners or one of them is not registered in the Unified State Register of Legal Entities) (FTS, 2020).

Furthermore, the ASK NDS-2 software solution enables tax inspectors to build chains of contractual partners, to create "a tree of connections" and detect complex tax gaps – e.g. incidents of VAT non-payment by a second-tier or further contractor. Over 80 risk criteria are currently applied in Russia to analyze corporate data. The criteria address a company's overall business activity, registration data, track record of tax compliance; beneficiaries etc. The risk assessment algorithms are classified and are

constantly updated on the basis of internal and external information. The analysis results provide grounds for subjecting companies to simplified, regular or enhanced control.

2. Transformation of indirect tax administration. The automated VAT administration system that has been created by the Federal Tax Service of the Russian Federation incorporates:

- a central database that is fed by a network of federal data processing centers;
- a risk management system (RMS AKS NDS);
- a tool for comparison of transaction data that are recorded in VAT returns (ASK NDS-2.

Digital interaction between tax authorities and other government agencies and the expansion of the automated information system of tax authorities (AIS Nalog-3) offers a greater opportunity for detecting and preventing the taxation risks of a state. Under Article 93.1 of the Tax Code of the Russian Federation, a tax authority shall have the right to use data provided by a third party, including a contract partner of an audited taxpayer, for performing an in-house VAT audit (Tax Code, 2020). As of 1 January 2019, tax authorities can request audit firms and private auditors to provide such information should the head of the Federal Tax Service or his deputies decide so (FTS, 2020).

Similar measures are actively employed by tax services in various countries. Figure 1 presents the results of the analysis of data provided by third parties for tax administration in OECD member states (OECD, 2019).

Fig.1: Use of data from third parties in tax administration in OECD countries, 2017

As was stated above, the key advantage of ASK NDS-2 is the capability to automatically find discrepancies in VAT data: the system processes millions of electronic returns and about 15bn electronic invoices a year. Today, a pool of trusted operators of electronic document management software has been established that first appeared back in 2012. Tax administration of electronic accounts has been progressing in the OECD member states, too (Fig. 2).

Fig. 2: Electronic invoice systems: existence and selected features in OECD countries as of 2017.

Source: OECD (2019)

Online cash registers that the Federal Tax Service has been introducing since 2017 are a tool for reducing the risk of indirect tax noncompliance. By enforcing online cash registers, the FTS has been efficiently countering money laundering. The transition to online cash registers made it possible to increase VAT collection in retailing by 50%, while the number of active cash registers increased by 150% to over 3.2 million units in possession by 1.4m users. According to the FTS head, over 200m checks are issued. All of them are transmitted in real-time to the FTS servers, their total amount exceeding 125 billion roubles daily. The average check in November 2019 was 700 roubles, with a steady growth in VAT paid by retailers by 50%, or 124 billion roubles over two years (FTS, 2020).

As a positive side effect of the deployment of ASK NDS-2, the number of fly-by-night firms has more than halved from 1.7 million in 2011 to 300,000 in 2018, which is 7.3% of all legal entities in the country. As of January 2019, the share of untrustworthy companies dropped to 4.7% of all registered businesses and other organizations in Russia: the Unified State Register of Legal Entities contained data on 3.9 million entities, while the number of dubious firms was down to 186,900. As the efficiency of tax collection grows, the number of on-site tax audits goes down. The number of such audits decreased by 14% to 30,600 over the past year, while the efficiency of one on-site audit increased by 8% (to 9 million roubles). Thanks to that, the collection of additional amounts of tax due increased to 60% (FTS, 2020).

In additional to the deployment of ASK NDS, the Federal Tax Service of Russia has been working on digital technologies that improve the efficiency of indirect tax administration, including

- sweeping adoption by retailers of cash register equipment that transmits fiscal data online;
- creation of a goods tracking system from the moment of customs clearance to purchase by the end user (RFID tagging, EGAIS).

The goal of the introduction of online cash registers is real time transfer of data on transactions between organizations and private entrepreneurs and individuals to tax authorities. According to the latest reports by the FTS, over 1.5 million taxpayers in Russia have switched over to online cash registers, with the total number of online cash registers in use reaching 3.2 million.

Table 3: Outcomes of implementation of cash registers in Russia, 2017 – 2019

	February - March 2017	2017	2018.	Jan-Oct 2019.
Number of taxpayers	-	500,000.	865,000	1.5 mln
Number of cash registers	более 100,000	1.6 mln	2,3 млн.	3.2 mln
Number of issued receipts per day	-	120 mln	150 mln (for a total of 90bn roubles.)	-
Total number of issued receipts	220 mln.	28bn	-	-
Total worth of receipts	over 110bn roubles.	over 18,700bn roubles (including over 1,600 mln of VAT)	-	-

Source: compiled by the authors with data from FTS (2020).

The cash register reform made it possible to considerably reduce administrative burden on businesses: cash statements have been eliminated; the number of tax audits has decreased by a factor of four against 2016.

A pilot project to electronically tag fur clothing started in the Eurasian Economic Union (Russia, Belarus, Armenia, Kazakhstan, Kyrgyzstan) on 12 August 2016 following the ratification of the Agreement on the Implementation in 2015-16 of a Pilot Project to Tag Fur Clothing. According to the Federal Customs Service of the Russian Federation, the project proved highly effective economically. In 2017, a total of 2.3 million imported and domestically made garments were tagged, a total of 1.2 million garments worth 68.5 billion roubles were sold. The number of declared fur garments increased by 50% in 2017 against 2016 from 277,000 to 417,000. Their value increased by 80% from 129 million dollars to 232 million dollars. The weight of the declared goods increased by 70% - from 417 tons to 693 tons; customs duties paid increased by over 80% (from 38.7 million dollars in 2016 to 69.6 million dollars in 2017). (Table 4).

The labeling and tagging of goods increased excise revenue collected by 20 to 40% over a period of two years (2016-17). Additionally, the tagging of goods makes it possible to decrease the share of the shadow economy by 50 to 60% and increase integration within the Eurasian Economic Union. It has to be noted that one year into the introduction of the ASK NDS automated system, the number of VAT refund claims from businesses halved.

Table 4: Preliminary results of pilot project to tag fur products

	2016.	2017.
Number of declared garments (thousand.)	277	417
Weight (tonnes)	417	693
Value (million US dollars)	129	232
Customs duties (million US dollars)	38,7	69,6

Source: compiled by the authors with data from FCS (2020)

In general, the number of dubious VAT deductions has decreased since the launch of the automated system and is now less than 1%, which is the lowest level in the world. In Europe, for example, this figure varies between 3 and 7%.

3. *Tax risks associated with digital transformations of indirect taxation.* Amid the progress of digitalization, the transmission, storage and integration of data are getting easier to do thanks to new

methods and processes. At the same time, the volume of data that are accessible to tax authorities for the purposes of tax control is growing considerably. A system of tax risk management based on data and big data analysis that is being put into service by the Federal Tax Service of Russia requires taxpayers to make arrangements for effective tax risk management. Table 5 presents a classification of tax risks faced by taxpayers from consumption taxes by type of tax implications.

Table 5: Classification of tax risks for taxpayers associated with consumption taxes

Risk	Legal framework
Risk of audit by oversight authority and heavier tax burden	
Risks envisaged in the Concept of On-site Tax Audits (accessible in public domain)	Instruction of FTS of 30 May 2007 № MM-3-06/333@
Risks of incorrect usage of online cash registers	Article 122 of Tax Code, Article 14.5, of Code of Administrative Offences
Risks of consequences of ASK NDS-2 usage	Article 122 of Tax Code
Risks of tax base adjustment – correction of VAT deduction	Article 54.1 of Tax Code
Risks of VAT minimization through formal through the formal splitting of the business	Article 54.1 of Tax Code, Newsletter of FTS
Risks of criminal prosecution	
Establishment of fly-by-night firms for VAT evasion	Article 173.1 of Criminal Code
Major cases of indirect tax evasion	Article199 of Criminal Code
Reputational risks	
Risks of detection of false information about taxpayer (e.g. fictitious supplies)	Article 76 of Tax Code, Article 119 of Tax Code, Article 76 of Tax Code
Risk of being blacklisted as non-compliant taxpayer	Article 122 of Tax Code

Compiled by the authors based on Concept (2007) Tax Code (2020), Code of the Russian Federation on Administrative Offenses, The Criminal Code of the Russian Federation

Taxpayers should, therefore, independently independent constant monitoring and assessment of tax risks and avoid shady dealings, refuse to deal with dubious companies and keep track of changes to tax legislation. Table 6 presents explanations of digital risks stemming from the transformation of indirect taxation.

Table 6: Description of digital risks of indirect tax transformation

Risks	Description
Digital disconnection	One of the most common issues that shows either in users' unwillingness to embrace the new format of communication with tax authorities, or the lack of stable internet connection (e.g. in remote areas of Russia's north)
Cost and complexity	The introduction of new software is a costly project both for tax authorities and taxpayers. Knowledgeable professionals are scarce
Security and privacy	Electronic communication channels are vulnerable to hacking. There is a human factor problem.
Data conversion	Past period reports are stored in hardcopy or in a format that does not fit the new system. Additional information needs to be filed.
Incoherent legislation	The existing legal and regulatory framework was created in the pre-digital era and is not in line with the current practice

Source: Compiled by the authors

In general, the application of VAT/GST in a digital economy is fraught with a number of problems that governments will have to overcome. A lack of agreement between countries in the field of taxation results in double taxation or the non-imposition of tax. One of the key taxation problems in a digital economy is the complexity of establishing tax nexus, that is, the fact that a business has a physical

presence in a jurisdiction. Establishing tax nexus for a digital company without its physical presence is complicated because of the mobility of intangible assets. At present, the problem could be solved by assigning sales based on the location of the customer (Victorova, N. G., Yevstigneev, EN; Yablokov, DY, Dubolazova, YA., 2018).

Conclusion and Future Research

The analytical review enabled the authors to identify trends in the digitalization of indirect tax administration. As part of the historical analysis of indirect tax transformations that have happened alongside conceptual changes in economic models (tax system 1.0 – pre-industrial economy; tax system 2.0 – industrial economy; tax system 3.0 – neo-industrial economy) explanations have been proposed for transformations that occurred at each phase of economic development. The principles and structural elements of the system of indirect taxation amid conceptual changes to the economic model (Versions 1.0; 2.0; 3.0) are explained. The results are presented of an analysis of an expert survey of tax experts for the sake of verification and interpretation of data that were obtained by means of content analysis. As a result of an analytical review, trends in the digitalization of tax administration of indirect taxation in Russia were highlighted. It is proved that these trends can with high probability be reproduced in other tax systems during the development of digital control services. Tax risks have been identified that are associated with digital transformations of the indirect tax administration system.

Application of RFID in Storage Processes in the Supply Chain

Tomasz SZCZEPANIK

Politechnika Częstochowska, Częstochowa, Poland
tomasz.szczepanik@wz.pcz.pl

Abstract

The article addresses the warehouse characteristics and issues regarding the storage process. It focuses on the presentation of the RFID system in warehousing in the supply chain. The advantages and disadvantages of using this technology and problems associated with the implementation alongside the specification of sensitive areas are presented. An assessment of the state of the warehouse infrastructure and the application of RFID technology in warehousing processes and further prospects for implementation was carried out.

Keywords: Logistics, Warehousing, RFID, Supply Chain

Warehouse and storage process characteristics

A size and throughput are the factors that best characterise a warehouse. Its designing should be guided by the priority of providing it with adequate throughput, depending on the degree of mechanisation of warehouse works, handling, movement, storage and release. It implies that such means of transport and working methods should be selected that optimal flow of material goods through the warehouse is ensured in a way to match them to the needs of production or trade in goods [2]. A warehouse is a functional-organisational facility intended to store material goods in a separate space, i.e. a warehouse building. This building should be constructed in accordance with the established technology and equipped with appropriate devices and technical measures. A team of people should be responsible for its management and operation [18].

It is worth noting that warehouse parameters must above all declare the optimal size as well as throughput. These two fundamental values should be adjusted to the tasks resulting from the necessity to secure the needs of the production process in terms of availability of resources and materials. Due to the function of balancing supply and demand, warehouses are created as objects closely related to the environment, and they constitute a consolidation link both in regional and increasingly often in international supply chains, thus ensuring a smooth flow of material goods. Regardless of the need to maintain stocks, warehouse facilities also perform functions linked to the picking activity of specific assortment inventory groups, according to needs reported by customer. Warehouses in the food industry perform additional functions while being in a way an extension of production as the next stage of natural processes directly related and resulting from manufacture technology in the form of, e.g. ripening of fruit or cheese, or freezing of meat, and others. As can be seen, these are further arguments for the existence of warehouses. Given the fact that warehouses are the main link in the supply chain, it can be stated that one of their primary functions is to receive, temporarily store, as well as transfer goods to subsequent links [6]. The issue of the receipt, maintenance and release of stocks must be classified as the fundamental and underlying factor justifying the operation of warehouses.

Warehousing is a process which solves the problems of meeting changing market needs. For the proper functioning of warehouses, it is necessary to equip them with means, devices ensuring the possibility of effective implementation of storage processes. Both the storage infrastructure and the complementary handling infrastructure must contain the necessary equipment, which should be kept in good condition by carrying out the necessary repairs and services. The effectiveness and efficiency of logistics services depend on the condition and degree of adjustment of logistics infrastructure to

the needs of companies providing logistics services [14]. The storage process can be defined as a set of activities related to the temporary stocking of inventories and material goods, their storage in the appropriate conditions, and their transfer to consignees. Inventories are the appropriate amount of resources that are accumulated to ensure the smooth and undisturbed functioning of the organisation in all areas. In enterprises, inventories are all kinds of goods in a strictly defined quantity, which are not used at a given moment, but their presence allows the achievement of specific objectives, in the form of maintaining continuity of the production process and meeting customer needs [12].

Warehousing processes consist of groups of operational activities directly correlated with the receipt, storage, picking and delivery of goods in adapted places meeting certain organisational or technological conditions [10]. Warehouse processes include flows of both materials and information. Handling activities are defined as all types of activities which result in changing the form of the cargo. Not only can they be observed mainly in the phase of receiving and releasing goods, but they are also visible in the phase of storage and picking.

RFID Application in Storage Processes

RFID (Radio Frequency Identification) is a technology that allows non-contact automatic identification and readout of data using radio waves of different frequencies. This technology is a development of barcode technology, but uses low-power radio signals for wireless data exchange between the RFID label - called a transponder or tag - and the reader, i.e. decoder. The reader is used to communicate between the database and the tag and middleware, which condenses and filters the data to avoid inaccuracies and transmits enterprise resource planning (ERP) to the management of operations [15]. The advantage of RFID readers is their ability to read and process a large number of labels within their range. A miniature chip called a tag is placed as a label on various products, packaging, and it consists of a processor ("IC") and antennas. The antenna is usually sprayed on an insulator layer. The data is saved in the processor - IC - cache memory, and its transmission takes place using the antenna. The range, as well as transmission speed, is determined by the size of the antenna, frequency used, the occurrence of interference, and their degree, radiation power [9].

The use of RFID in the warehouse process gives the possibility to carry out the warehouse operations more efficiently, starting from the receipt of goods, through their proper placement and storage, picking, to the moment of release from the warehouse. Any object can be tagged with a label, which allows the control over its position using a reader communicating with the transponder by radio waves without the need to scan the label directly [4]. This method offers a significant advantage in gathering and filtering information. Thereby the activities and processes performed using RFID technology in the warehouse are much faster and more precise. The RFID technology infrastructure consists of IT solutions that process and read data, and radio-emitting readers that are made up of an antenna and a radio transmitter together with a decoder [17]. In connection with ERP, WMS class warehouse information systems, RFID enables accurate and available real-time information on where the tagged object is located or moved.

A specific limitation is the cost of radio tags, which is much higher in comparison to traditional barcodes. It makes that the implementation of RFID technology together with the infrastructure that is necessary for proper functioning generates specific expenses. The implemented and functioning system, in which tags are in constant use, results in a quick return on investment, thanks to the possibility of introducing changes to the information in the company's IT system for its reuse. Moreover, the RFID system is limited by the interference from specific substances, such as metals, which can cause substantial interference or completely suppress radio transmission [16]. In cases of interference, radio transmission can be corrected and adjusted by selecting the correct frequency. Figure 1 shows the RFID system characteristics.

Figure 1: RFID characteristics in the supply chain

Source: own study based on [3]

The main advantages of this technology are speed and the fact that it is relatively inexpensive; it provides autonomous dedicated coding. It is characterised by features such as positioning and position registration, high operational efficiency, data privacy, real-time tracking, transparency, extensive customisation possibilities, work standardisation, process visualisation, and mentoring [11]. Moreover, the use of RFID in the supply chain significantly contributes to the improvement of production control, delivery of customer orders, shortening of production process lead times, development of inventory processes [5]. The main factors that speak in favour of RFID technology include: [8]

- no need for direct visibility of the antenna of the reading element with the identifier utilizing the radio communication,
- RFID technology has the lowest reading error rate when considering all technologies for automatic identification,
- the use of radio tags allows identification in hard-to-reach places where optical methods do not perform their function, as the tags can operate in a wide temperature range and their susceptibility to environmental conditions is negligible,
- the plasticity of radio tags concerning the materials they can be made of and shapes corresponding to personalised needs is free and can be: a cuboid, a ring, a capsule, a button, or a card,
- radio tags give the possibility to write data multiple times - even up to 300 000 and modify parts of them, not only the reading in relation to an unlimited number of readings, which makes the object marked with a tag can carry information of variable content,
- radio tags are not counterfeit because they have a serial number that cannot be changed assigned by the manufacturer at the time of production, and a password assigned by the user can protect the information stored on the tag,
- high versatility and application possibilities in various industries.

In addition to the advantages, there are disadvantages, as the system has certain limitations and problems resulting from the implementation phase as well as subsequent operation. These include, among others: [13]

- technical difficulties at the implementation level as well as the lack of harmonised standards,
- still insufficient resources of qualified personnel familiar with RFID technology,
- some limitations due to the interaction of radio waves and the need to take this phenomenon into account when designing new systems,
- the possibility of a hacker attack forces the security issues to be considered when designing the system.

RFID technology will be particularly useful in warehouses, where great attention is paid to the transparency of goods flow through the warehouse and their accessible location. RFID can improve the flow of products and information, thus determining supply and demand, as well as the quality of customer service to increase revenue and innovation. Furthermore, it has a positive impact on value creation since it intends to reduce costs as well as create a company image and build a competitive advantage.

Implementation of RFID technology in the warehouse requires a set of widely accepted standards and regulations. The areas mentioned below play a vital role in the application of this technology: [1]

- standardisation,
- the cost of the system,
- business process re-engineering,
- integration,
- privacy,
- lack of RFID professionals,
- and sensitive storage problems.

The issue that comes to the fore is system standardisation, followed by privacy and security. The wireless nature of the technology generates potential threats to users' security, as it is possible to intercept the signal communicating tags with the reader. It can lead to data interception and put the wireless transmission and physical storage of data at risk.

The threats and obstacles that can be identified in the RFID technology implementation in warehouses can be listed in the areas: [7]

- technological risk,
- risk of standardization,
- cost-related risk,
- risks related to infrastructure,
- risk with return on investment (ROI) usage.

Although, warehouses deciding to employ RFID technology are aware of the risks and drawbacks of the system, the expected benefits in improving physical and information flows outweigh.

Warehouse Infrastructure Assessment

The condition and type of warehouse infrastructure is the main factor influencing the implementation of logistics services in warehouse facilities in the supply chain. A questionnaire survey was conducted among storage companies having their warehouses to assess the condition of the infrastructure and its adaptation to the needs of logistics services. The research hypothesis was to examine the impact of warehouse infrastructure and its condition and the application of the RFID system on storage processes in the supply chain. The research task was performed using a questionnaire from October 2019 to February 2020 in a group of 53 Polish companies allowing examination of the following aspects. The companies were asked to indicate the technological transport devices they use in their warehouses, as shown in Figure 2.

Figure 2: Possession of technological transport equipment in warehouses

Source: Own study based on the research conducted

The surveyed companies use a variety of technological transport devices for the implementation of storage processes. The most frequently used ones include transport trolleys (100% of the surveyed companies), followed by palletisers and depalletisers as well as conveyors (as declared by 66% and 39% of the respondents respectively). The companies (9%) use cranes to the least extent in their work. Then they were asked to assess the technical condition of technological transport equipment. Figure 3 presents the results.

Figure 3: Technical condition of technological transport equipment

Source: Own study based on the research conducted

Among the surveyed companies, 26 described the technical condition of technological transport devices as good, 19 warehouses assessed it as very good, only 7 entities stated that the technical condition of technological transport equipment is sufficient, and one respondent described it as bad. The respondent explained that the poor assessment stemmed from the fact that a few transport trolleys, which were being repaired or replaced with new ones, had broken down. Then the companies were to indicate the auxiliary equipment they use in their warehouses, which included the following: [14]

- cargo containers,
- cargo pallets,
- pallet collars,
- transport and storage containers,
- bridges and loading platforms,
- empty pallet feeders,
- cargo unit securing devices.

The results are shown in Figure 4.

Figure 4: Possession of warehouse ancillary equipment

Source: Own study based on the research conducted

The surveyed companies use a variety of technological transport devices for the implementation of storage processes. The most frequently used ones include transport trolleys (100% of the surveyed companies), followed by palletisers and depalletisers as well as conveyors (as declared by 66% and 39% of the respondents respectively). The companies (9%) use cranes to the least extent in their work. Then they were asked to assess the technical condition of technological transport equipment. Figure 5 displays the results.

Figure 5: Technical condition of ancillary equipment

Source: Own study based on the research conducted

Among the surveyed enterprises, 28 indicated that the technical condition of ancillary transport equipment as good, 17 warehouses assessed it as very good, only 8 entities described it as sufficient. The survey also allowed collecting information on the actions taken by the warehouses to modernise and upgrade their infrastructure. The data is presented in Figure 6.

Figure 6: Warehouse infrastructure modernisation and upgrading

Source: Own study based on the research conducted

Figure 6 presents the answer to the question of undertaking actions aimed at infrastructure modernisation, to which 44 warehouses responded in the affirmative and 9 surveyed entities denied taking such actions. Figure 6 displays an assessment of the general condition of warehouse infrastructure.

Figure 7: General condition of the warehouse infrastructure

Source: Own study based on the research conducted

The surveyed warehouses were asked to assess the overall condition of the infrastructure. Out of the 53 surveyed entities, 28 described the condition of the infrastructure as good, 17 as very good, and only 8 as sufficient. It can, therefore, be concluded that the high assessment of the overall condition of the warehouses' infrastructure is since upgrades and modernisation of warehouses significantly improve their condition. Next, it was examined whether and to what extent the warehouse infrastructure affects the efficiency of the performance of logistics services in warehouses. The developed data is presented in Figure 8.

Figure 8: The impact of warehouse infrastructure on the efficiency of warehouse operations

Source: Own study based on the research conducted

According to 41 respondents, the warehouse infrastructure has a very high impact on the efficiency of warehouse operations, for 9 respondents, this impact was high and for 3 medium. These results prove that the assessment of the state of the warehouse infrastructure is very high and the fact that more than 80% of the surveyed warehouses declare taking measures about warehouse modernisation and upgrading influences the efficiency of storage processes in the warehouses. A vast majority of the surveyed entities have a technically efficient infrastructure adjusted to the needs and realisation of storage processes.

Assessment of RFID technology application in storage processes and further prospects for its implementation

The functioning of warehouses and the implementation of storage processes requires an efficient and well-functioning warehouse infrastructure. Given the fact that companies are looking for opportunities to improve their processes, they increasingly decide to implement modern IT systems. The respondents were asked to indicate the class of systems used for warehouse management and assess the degree of impact of the systems applied on the efficiency of logistics services. Besides, the survey allowed checking whether companies use systems for automatic identification, such as RFID to improve the performance of logistics services in their warehouses. Figure 8 presents the class of IT systems used in the surveyed warehouses to manage them.

Figure 9: The class of IT systems used in warehouses

Source: Own study based on the research conducted

Figure 9 shows that 30 surveyed companies use WMS systems and 23 ERP systems. Next, it was examined whether the systems used meet the respondents' expectations and enable efficient execution of storage processes. The developed data is presented in Figure 10.

Figure 10: The extent to which the IT systems meet the expectations and enable efficient execution of storage processes

Source: Own study based on the research conducted

The surveyed companies highly evaluate the systems used and their impact on logistics services. 42 respondents believe that their IT systems meet the expectations and enable the efficient realisation of storage processes to a very significant extent, while 11 respondents assess this extent as significant. After that, the respondents were asked about using RFID technology in their warehouses. Figure 11 presents the results.

Figure 11: Application of RFID technology in warehouses

Source: Own study based on the research conducted

24 out of 53 respondents confirm the use of RFID technology, while in 29 companies surveyed it is not employed. Next, the occurrence of problems related to the RFID technology implementation was examined. The results are presented in Figure 12.

Figure 12: Problems related to RFID implementation

Source: Own study based on the research conducted

As can be seen, the surveyed companies indicate implementation costs as the most common problems related to RFID implementation - 100% of the companies, 75% mention the lack of qualified staff, for 67 of them the privacy and security issues proved to be crucial. Technical issues and integration into enterprise systems turned out to be the least problematic. Then, among enterprises declaring it was examined to what extent the possessed RFID technology affects the implementation of logistics services, as displayed in Figure 13.

Figure 13: The extent to which RFID technology affects the realisation of storage processes

Source: Own study based on the research conducted

Figure 13 shows that 21 surveyed companies determined that RFID technology has a very high impact on the implementation of logistics services, and for 3 surveyed companies, this impact is high. The respondents who do not use RFID technology were asked if they have plans for its implementation in the next 5 years. The results are presented in Figure 14.

Figure 14: RFID implementation plans for the next 5 years

Source: Own study based on the research conducted

Figure 14 shows that only 11 companies plan to implement RFID technology in the nearest future, while 28 of them do not. Figure 15 shows the factors which enterprises that do not plan to implement RFID technology in the next 5 years have listed as defects of this technology.

Figure 15: Identification of RFID technology defects

Source: Own study based on the research conducted

It is clear from the below Figure 15 that the surveyed companies (100%) indicate implementation costs as the main disadvantages and reasons why they did not implement RFID technology. It was followed by the lack of qualified staff and the issues of ensuring privacy and security, as indicated by 83% and 72% of respondents respectively. To the least extent, the surveyed enterprises are afraid of technical problems and integration into their systems, which was indicated by 39% and 44% of respondents, respectively.

Conclusion

Therefore, it can be concluded that RFID implementation is not standard among the surveyed companies (24 implementations out of 53 surveyed companies). Nonetheless, the implementation of RFID technology is evaluated positively, which can be concluded from the high assessment of the degree of its impact on the implementation of logistics services. It appears evident that the surveyed companies also identify the disadvantages of the applied technology in the form of high implementation costs or lack of qualified staff. What is more, among the companies that did not implement the technology due to its shortcomings, implementation costs and lack of qualified staff were mentioned. However, 11 out of 29 surveyed companies not using RFID are planning to implement it over the next 5 years. As far as the state of the infrastructure is concerned, 53% of the 53 entities surveyed described the condition of the infrastructure as good, 32% as very good, and only 15% of the entities stated that their infrastructure is in the sufficient condition. Besides, 83% of all surveyed entities confirmed that they are taking measures to upgrade and modernise their infrastructure. Moreover, all companies using RFID say that this technology has a very high (84%) or high (16%) impact on the implementation of storage processes. It is worth noting that the examined enterprises highly rated the use of ERP and WMS systems in terms of meeting and enabling the efficient implementation of storage processes.

It follows that a vast majority of the surveyed entities have a technically efficient infrastructure, tailored to the needs and implementation of storage processes, and the use of RFID system significantly impacts the execution of storage processes. The above confirms the research hypothesis that the warehouse infrastructure, its condition, and the application of RFID system affects the storage processes in the supply chain.

The Impact of Socio-Economic Issues on Families' Cultural Socialisation and Participation: The Case Study Research in Latvia

Ilze KACANE

Daugavpils University, Daugavpils, Latvia
ilze.kacane@du.lv

Abstract

The impact of families' lifestyle and cultural orientation on young people's cultural knowledge and interactions is determined by subjective and objective factors of well-being. In addition, cultural principles such as family attitudes, intergenerational dialogue, shared commitments, passing down values, traditions, customs, and patterns of cooperation are important for creating the conditions for economic success. The effect of culture on economic performance may be perceived on the fact that a family is the basic unit of the country's economy and each family is the economic mainstay of its members. The aim of the research is to carry out qualitative data analysis on the impact of socially and economically most pressing issues on families, their well-being and lifestyles, cultural socialisation and participation. The empirical data have been obtained from 10 family case studies and intergenerational semi-structured in-depth interviews in urban, semi-urban, and rural areas of Latvia. The research has been carried out in the framework of the project "Cultural Heritage and Identities of Europe's Future (CHIEF) supported by the EU Research and Innovation programme Horizon 2020 and conducted across nine countries.

Keywords: Family, Intergenerational Dialogue, Culture, Socio-Economic Impact.

Introduction

Culture is a complex phenomenon that traditionally is seen as a broad anthropological and sociological structure, i.e. as a set of attitudes and practices. Culture not only resides within an economic milieu, but it can be approached and defined as economy, "If culture can be thought of as a system of beliefs, values, customs, etc. shared by a group, then cultural interactions among members of the group or between them and members of other groups can be modelled as transactions or exchanges of symbolic or material goods within an economising framework." (Throsby, 2001, p. 10) Among diverse facets of culture there are virtuous and life-enhancing qualities. Being a social asset culture can provide important social and economic benefits: it enhances the quality of life and increases overall well-being for both individuals and countries.

According to Latvian policy documents, culture is not only preservation and management of tangible and intangible cultural heritage, but also a strategic means leading to the national stability and security, as well as to economic development of the country. In long-term policy documents, e.g. "Sustainable Development Strategy of Latvia until 2030" (VARAM, 2010), culture is defined as "an important national foundation without which the country's existence and successful development would not be possible." (Romanovska and Kacane, 2019, p. 98) Cultural conditions, in which economic activity occurs, are directly linked to economic outcomes and, vice versa, economic growth determines the development and preservation of culture, as well as cultural behaviours (socialisation and participation practices) of individuals and groups.

The study has been carried out in the framework of the project "Cultural Heritage and Identities of Europe's Future (CHIEF) supported by the EU Research and Innovation programme Horizon 2020 and conducted across nine countries: the United Kingdom, Latvia, Croatia, Georgia, Turkey, Spain, Slovakia, India and Germany. In each of the project countries within the "Research on Intergenerational Dynamics of Cultural Socialization" that explores family settings as one of the most

important sites of informal cultural socialisation, 10 families were selected to identify socially, economically and politically pressing issues and factors facilitating and/or hindering inter-cultural communication and cultural participation. Cultural identities and practices of the young people are being shaped by many various aspects: it is not only multiple interactions in the framework of the procedural model "family – school – society", but primarily economic conditions and socio-cultural environment of the country and region, as well as national and regional cultural policies. (Kacane, 2020)

Methodology

Twenty-six in-depth semi-structured face-to-face interviews were conducted with representatives of three (in exceptional cases – two) generations from 10 families from September 2019 until January 2020, covering 34 individual family members. They represented geographical differences (rural, semi-urban and urban; mostly located in south-eastern region of Latvia – Latgale), various degrees of openness to inter-group communication, and heterogeneous socio-demographic variability – 12 young people aged 14-25 (5 females and 7 males); 11 people from the middle generation representing parents or similar (9 females and 2 males); and 11 people from the older generation representing grandparents or similar (8 females and 3 males). The interviews, the average length of each being round 60 minutes, were conducted with each family member separately, however, in isolated cases, when it was impossible to do so, they ran as conversations with several family members. One interview with a young person took place via Skype video call. The families represent (or are related to) various ethno-religious groups (Latvians, Russians, Poles, Jews, Belarusians; Catholics, Lutherans, Old Believers, Orthodox). All the interviewees, but one, were the citizens of Latvia. Before conducting the interviews, permissions from interviewees to use audio recording devices were obtained. In addition to audio recording, detailed participant notes were taken to record the context of the interview, the key themes that emerged in the course of the interview, and the reflections on the process of interview. Due to data anonymization, the interviewees were asked to replace their first names and surnames with self-pseudonyms. The languages of the interviews were Latvian and Russian based on the preference of the interviewee.

Results

According to the majority of the interviewees, family is a space of relaxation and purposeful alienation from global and, in many cases, national and regional issues. In general, families prefer topics contributing to building a free and easy atmosphere in their family circle, nevertheless, the theme of current concerns and most pressing issues was most actively discussed during the interviews mostly aimed at gaining insights on intergenerational dynamics and young people's engagement with culture and cultural heritage. The impact of socially and economically most pressing issues on families, their lifestyles, cultural socialisation and participation were most deeply discussed by the representatives of the middle and older generations testifying to existing huge concerns that are not always shared with the younger generation.

Economic Conditions

The quality of life in Latvia varies between regions; expressed in per capita income, it remains very pronounced. Social protection is limited therefore housing conditions are unsatisfactory for a relatively large part of the population. The Latvian financial and governance crisis (2008–2010), affected by the global financial crisis, caused economic and political chaos in the country, entailing a radical consolidation of the general government budget, which continues to have an effect to this today. Although the economic crisis is not deeply rooted in young people's memory, they are aware of the impact of the dramatic events experienced at that time on the Latvian economy and family lifestyle. The interviewed younger generation representatives believe that their families are currently financially secured, nevertheless young people are aware of today's economic challenges; they provide their views on possible solutions to the problems; these solutions have emerged from discussions with their peers, "[…] sometimes my friends and me think that the Baltic States could

unite, since Latvian economy goes into recession; more people die than are born; more people go away than arrive, and therefore, in my opinion, these small countries should be united." (Migle Migla, male, 14, F4, urban)

The interviewed middle and older generation representatives are concerned about the disproportionality of wages and pensions relative to the increase in the total cost of living (e.g. fuel prices). According to the elderly interviewees, the economic conditions are the ones that distinguish a genuinely European country from Latvia and a true European from a resident of Latvia who wants to be a true European, but because of various restrictions it is not possible to satisfy this wish. Many elderly people consider they are not true Europeans because of poor economic conditions, "Why should they [people in Latvia] count every penny? There is nothing like this in the EU". (Krjostnaja Mihailova, female, 67, F4, urban)

Despite financial difficulties and limitation of their needs, parents support the younger generation and invest in children's development in the hope of a better life for them in the future. This gives a distorted impression that the family is not facing economic problems. The middle and older generations not always talk directly about their financial problems but, on the contrary, they tend to appreciate more what they have, not to aspire to material things and not to complain about something they do not have. Such attitudes towards life are rooted in their religiousness where patience, modesty and gratitude are among the most valuable human qualities. An older-generation faithful woman, who lives near a Catholic church, attends the Mass every Sunday and has also instilled church service in her grandson, stresses, "[…], we're grateful for having food on the table, something to wear and we can't cry that we don't have, I don't know, the latest make of car or one produced last year, or we can't fly or go somewhere". (Koshka Kafe, female, 68, F3, rural)

Individual social groups, e.g. large families, are hit particularly hard by economic difficulties. The interviewed widowed mother of five children, who lives in a rural territory of the Latgale region, explains that at a certain time of her life, when the situation had become critical, she officially gave up her children hoping that they would be entrusted to a boarding school which would provide regular meals and warm premises. (Ludviga Felikss, female, 42, F5, rural) Consequently, financial problems, responsibility for the maintenance of children, an excessive workload and busy schedules, as well as depression as a side-effect, are among the reasons why cultural activities, particularly high-quality paid cultural events, are considered secondary and large families refuse to attend them to save the family budget, "We don't go to theatres with a family so frequently. Not a single time have we been to the opera either. […] For five people it is quite an expensive entertainment." (Raičuks Zaraija5, male, 19, F1, rural) The interviewed young people from a large family acknowledged that they do not have such opportunities as children from single-child families and the preservation of culture is only possible if a person is free from financial and economic problems.

Instability

According to the interviewees, the lack of stability, constant changes and reforms, are considered a long-standing problem for Latvia since the beginning of the "Third Awakening" (the second half of the 1980s – the beginning of the 1990s) when the previous political and economic system collapsed. Living at times of constant changes in power, borders, money, etc. causes a sense of chaos and despair in human consciousness. Therefore, instability is one of the causes of burning out, emotional fatigue and depression of the interviewed middle and older generation representatives, and it does not contribute to their cultural participation.

Government decisions are often described as irrational and, in the interviewees' opinion, they are not improving but, on the contrary, destroying the infrastructure, which has been recently created or re-established. Heavy criticism has been expressed in relation to the Administrative and Territorial Reform Aimed at National Development and Ensuring Welfare of the Population. As part of the reform, the number of municipalities will be significantly reduced by 2021 and the "deepening rural-urban divide" will be addressed. (OECD) However, the interviewed middle-aged and elderly people

confirmed that they are exhausted of endless reforms. Parents confess that they also do not recommend their children to stay in the countryside or regions, but suggest them to receive education in cities. Due to population ageing and depopulation, the availability of services (health care, transport, education un culture centres, shops, etc.) to the population still living in the Latvian rural space is decreasing, the places of the provision of services have been moved to more distant locations and have become unavailable to many people due to financial and other reasons. Consequently, the rural-urban gap is not narrowing but, vice versa, expanding, contributing to depopulation of rural areas in favour of cities and to stratification.

In circumstances where the population density in many regional communities of Latvia is less than 10 people per 1 square kilometre, the socio-economic development, along with the reduction in jobs, clearly reveals pronounced depopulation trends in rural territories. Shrinking population leads to closure of schools, health and other institutions, most notably in rural areas and towns located in regions, "Here, as soon as primary school is finished, children go to a secondary school or vocational school. They all go to Riga mostly, and they study at universities there, and stay there. […] There's nothing to do here. There's a very large emptiness here. There are no jobs here, there are very few people left here. Everybody's gone." (Vika Daugaviņa, female, 74, F8, rural)

However, in addition to the general instability in the country as a macrospace, the interviewees of the middle generation mention the particularly pressing issue of instability in the working environment related to the microspace where, given the tensions in the labour market and reforms in certain areas (e.g. the education system), instability, labour volume and competitiveness are increasing, manifestations of mobbing and bossing become evident, people are afraid of losing their jobs; all this affects the emotional well-being of an individual and eventually also the family microspace. The interviewees highlight the burn-out syndrome and exhaustion, a gradual deterioration in human health.

The interviewed middle generation representatives are concerned about the fact that their own effectiveness and that of other employees working in public institutions is declining due to instability, excessive bureaucracy and irrational activities. As a result of the financial crisis, bureaucratization has significantly increased leaving significant impact not only on families but their life-style and cultural participation.

Depopulation and Emigration

According to UN statistics, in 2000, Latvia's population stood at 2.38 million. At the beginning of 2019, it was less than 1.95 million. (Eurydice, 2020) Since joining the EU (2004), Latvia has lost one-fifth of its population. However, economic migration is not the only reason for the country's declining population: a low fertility rate and high mortality rate are among contributing factors. Based on the statistical data, there is a big concern that in 5-6 decades, Latvia may cease to be a nation.

The interviewees are concerned about Latvia's future and they are aware of the fact that in the coming years Latvia will be even emptier, but they express the belief that nowadays people need to go wherever there are workplaces. A large majority of the interviewees regret depopulation of Latvia, but they do not condemn emigration since they understand the reasons why people decide to leave the country. Neither representatives of the middle nor older generation prevent children from emigration. In the first wave of emigration, it was mostly the middle-aged people affected by the crisis that emigrated in search of employment, but today it is young people that are leaving, often encouraged by their parents, with a view to acquiring competitive education and developing a successful career in the future. This nevertheless endangers the transfer of cultural values to younger generations oriented towards supranational and global, "I think that the old will still preserve what we have, but there will be nobody to hand it down to". (Marija Murāne, female, 83, F6, urban)

Some young people, after acquiring knowledge, competences and skills abroad, hope to use them in Latvia, since these young people have a sense of belonging to the country where they come from, "To my mind, it is better to make one's own country better than to go to some other country, which already is better. If I go to some other country, I am nobody, since I am a newcomer, which means that I am an immigrant". (Ārzemnieks Felikss, male, 18, F5, rural) In some interviewed young people's opinion, emigration means the break with ancestors and the lifestyle introduced by them.

Unemployment vs. workforce shortages

Unemployment in Latvia increased dramatically during the economic crisis, but the share of long-term unemployed remains high. The interviewees relate the long-term unemployment problem to individual personal qualities, pointing out that there is a certain group of people who do not want and are not ready to take up employment or to engage in social support programmes, because over the years, they have lost their job skills due to different dependencies (alcoholism, etc.) or other social problems. Consequently, employers, including the individual ones, face difficulties in finding permanent and seasonal workers and bear most of the burden of work on their own shoulders, rarely leaving the rural areas for a longer time, taking leave or attending important cultural events outside the territory of their residence. This points to stratification of Latvia's population, i.e. part of the active workforce suffers from overload, while others do not establish lasting employment relationships. In both cases, there is a decline in cultural participation and consumption.

Thus, culture is impacted by various economic factors and is threatened if people face many socio-economic issues. "People are able to think about culture only if they are provided with everything, and life is favourable". (Ārzemnieks Felikss, male, 18, F5, rural)

Conclusion

The qualitative data analysis allows concluding that in today's Latvia the relationship between socio-economic factors and culture, as well as the effects of economic, cultural, and political interdependence are clearly observed. Although families acknowledge they have aspirations for their children and they are striving to develop their cultural knowledge and cultural literacy by maintaining dynamic inter-generational communication based on specific inherited customs, traditions, cultural values or newly created patterns, they also face many hindrances. Among the most often discussed areas of concerns that have directly impacted the families, villages, towns or the country they live in, there are unfavourable economic conditions, instability, depopulation, long-term unemployment and, thus, impossibility to keep work and life (family) balance. These factors have a negative impact not only on intergenerational dynamics in informal cultural socialisation, but also on Latvia's socio-economic development establishing the threat for the existence of culture in the long term. Families revealed both depressive symptoms and hope for the better future for the younger generation and the nation, although they also expressed fear that the community, which all the time speaks and thinks only about economic problems, is a community where culture cannot develop. They also emphasized that perceiving culture as a marginal aspect regionally and nationally, where the priority focus is on economic challenges, threatens the sustainability of the family, country and nation. Based on the obtained data, culture is not a spiritual value only and it should be looked upon like upon the economy. In Latvia, the problems of survival are the ones that affect and will affect cultural development in the future; socio-economic issues may lead to the disruption of traditions and "the culture of poverty". Although all generations are united in the hope that the fundamentals and cornerstone Latvian culture will be preserved in the future, they assume that culture will change in the coming years and decades. The reasons for that, as seen by the interviewees, are economic issues, globalisation as a process of connecting and open borders, cultural fusion tendencies, emigration and immigration.

Acknowledgment

The project "Cultural Heritage and Identities of Europe's Future" has received funding from the European Union's Horizon 2020 Research and Innovation programme under the Grant Agreement No 770464.

Abstract
This ongoing multilateral study investigates the role of televised marketing communication in creating awareness and impacting women's health in a densely-populated semi-urban location in Lagos, Nigeria. Opinions and attitudes of housewives, single mothers and potential mothers are examined, using the Health Belief Model. The purposive sampling method of quantitative research was used to design a questionnaire operated on 130 respondents within the age bracket of 15-49 years. Descriptive items were structured in line with the research objectives to elicit responses from the participants. Both terrestrial and subscription television channels were studied for a balanced research finding. Findings indicate that televised marketing communication is useful in creating awareness on maternal healthcare and achieving maternal health behavioural change. However,the audience frequency of exposure to programmes and the level of impact are low among the respondents. Collaborations are invited to expand this continuing study globally.

Keywords: Marketing Communication, Impact assessment, maternal health, Television programme.

Introduction

Subject area	Commercial Health Communication
More specific subject areas	Health Communication, Television Broadcasting, Marketing Communication
Study execution	Survey
Study format	Quantitative methodology
Experimental factors	This is an experimental study using the questionnaire instrument. One hundred and thirty housewives, single mothers and potential mothers were experimental respondents of equal distribution. Respondents for this study were randomly selected on shared proximity and alternate (turn-by-turn) households of each of the three groups of participants.
Experimental features	Data on the impact of televised marketing communication programmes on women's health and wellbeing. Specific information is rendered on housewives, single mothers and potential mothers to: 1. Uncover their awareness on televised marketing communication programmes. 2. Examine their level of exposure to televised maternal healthcare programmes 3. Unveil their impact assessment of televised marketing communication programmes on maternal healthcare and behavioural change.
Preliminary study location	Ejigbo, a densely-populated semi-urban area on mainland Lagos, Nigeria
Data accessibility	Potential collaborators and explorers may request for original data to guide their study simulation.

Value of Study

1. This study is valuable to the achievement of the United Nations Sustainable Development Goal (SGD) three, namely Good Health and Wellbeing.
2. Similar studies on the same subject could borrow form the preliminary findings of this endeavour.
3. Increasing global attention to womanhood and the girl-child could use the result of this study partly or wholly for reference, socioeconomic and documentary purposes in the future.
4. The interlocking citations of this study consist of the following:

    a. Health Communication, Research and Theory. Sample in: Aluko-Arowolo and Ademiluyi (2015); Olawale et al., (2019); WHO (2017, 2019); Bello (2015); Okoro and Nwachukwu (2015); Okorie (2013); Babalola, Fatusi and Anyanti (2009); Omotoso (2009); Achary et al., (2015); Oyesomi et al., (2017); Oyesomi et al., (2020);Asmah, Twerefou and Smith (2013); Akakiti and Ojomo (2015); UNICEF (2017); Zamawe et al.,2016; WHO (2019); Akinrinola et al., (2009); Chiwuzie et al., (2009); Rural Health Information Hub (2017); Glanz (2010); Avedian (2014); Odiboh et al., (2018); Odiboh, Adeyeye & Ekanem (2018); Krejcie and Morgan (1970); Research Advisor (2006).

Experimental Design, Materials and Methods

This continuous study covers housewives, single mothers and potential mothers in a semi-urban community in Nigeria. It is restricted to those within ages 15-49. This age-group represents the average childbearing age, as revealed in WHO research findings on maternal health (WHO, 2017). Thematically, the study is restricted to televised marketing communications on maternal healthcare programmes on both terrestrial and subscription television channels.

Preliminary Study Results

Descriptive statistics using frequency distribution tables are adopted in rendering the report of this study.

Table 1 shows above-average awareness of commercially televised maternal health programmes.

Table 1: Awareness of commercially televised programmes on women's health

		Frequency	Per cent	Valid Percent	Cumulative Percent
Valid	Yes	71	54.6	54.6	54.6
	No	44	33.8	33.8	88.5
	Not Sure	15	11.5	11.5	100.0
	Total	130	100.0	100.0	

Table 2 indicates that half (50%) of the respondents get maternal health messages from television talk shows, 20.8% on entertainment shows, and 13.1% on news programmes. In comparison, 7.7% and 8.5% get it from paid public service announcements.

Table 2: Which of the following are you aware of on television healthcare programmes?

		Frequency	Percent	Valid Percent	Cumulative Percent
	Talk Shows	65	50.0	50.0	83.8
	Entertainment Programme	27	20.8	20.8	33.8
	News Programme	17	13.1	13.1	13.1
	Others	11	8..5	8.5	91.5
	Public Service Announcement	10	7.7	7.7	100
	Total	130	100.0	100.0	

Table 3 shows that 58.5% of the respondents opine that televised maternal healthcare programmes have created awareness on mothers' survival; 27.7 % are not sure it has created awareness. In comparison, 13.1% disagree with televised maternal health care programmes create awareness on maternal survival.

Table 3: Impact of marketed healthcare programmes on mothers' survival

	Frequency	Per cent	Valid Percent	Cumulative Percent
Yes	76	58.5	58.5	58.5
Not Sure	36	27.7	27.7	99.2
No	17	13.1	13.1	71.5
Total	130	100.0	100.0	100

Conclusion

The empirical findings of this study will be useful to health care agencies of the government and the non-governmental organizations (NGOs). It will help them in considering the media framework for engaging and sustaining healthy maternal habits amongst women. Televised healthcare programme producers and directors will also benefit from this study. They will be aware of the effectiveness of their programme on semi-urban women. Donor agencies and international maternal healthcare advocates will obtain a better understanding of semi-urban women and their healthcare habits. Families and society will gain more in-depth insight on issues on maternal healthcare.

Abstract

The paper examines the consumption of basic food products by the Russian population in the context of ensuring food security. Sufficient food consumption by the population is the ultimate goal of ensuring food security. The initial stage of the study is an assessment of changes in the volume of basic food products consumption by Russian households. As a result of this stage, it was determined that for one part of food groups there is a negative trend of decreasing consumption, and for the other a positive trend of growth. Then, a comparison of consumption volumes of urban and rural households was made. It was revealed that there was a large disparity in the consumption of rural and urban households at the beginning of the study period. On the positive side, these imbalances were either completely eliminated or minimized by the end of the study period. Then the actual consumption was compared with the standard consumption and it was found that there is a significant under-consumption of some food products and excess of the standard consumption of others. Comparing the cost of purchasing food products of plant and animal origin allowed to determine a significant difference in their size for rural and urban households. In addition, the rural population is forced to give preference to less expensive and high-quality food products with a low degree of processing. A comparative analysis of the prices at which food was purchased by urban and rural households made it possible to identify macroeconomic and climatic factors as the main reasons for their high volatility. A comparison of the prices paid for food by urban and rural households determined lower prices for the majority of food products purchased by the rural population. The overall result of this work was the conclusion that the main reason for the low level of satisfaction of food needs by the population of the country is their low income.

Keywords: Food security, food stuff, food consumption, food cost, food prices, urban population, rural population, Russia.

Introduction

Food security is closely linked to the national and economic security of the state. The link with national security is determined by the provision of food to the population, and the level of this provision determines the stability of the socio-economic and socio-political framework of the state. The shortage of food in Russia became one of the catalysts of discontent in the XX century, which eventually led to the revolution and the disastrous consequences that accompanied it. The incompetent policy of the country's leadership and climatic conditions led to starvation in the 30s of the XX century. Famine in Central Russia, the Volga region, Ukraine, and Kazakhstan led to significant mortality among the population and, as a result, irretrievable losses of labor resources.

Food security in conjunction with economic security is determined by the need to provide raw materials for processing industries, achieve the stability of the functioning of agricultural producers, create jobs in rural areas, and create conditions that determine an adequate standard of living for the population (A.I.Altukhov, 2017). Not the least role in the national economy is played by the activities of agro-industrial production entities. Of course, not all agricultural business sub-sectors are profitable, requiring significant subsidies, but a number of sub-sectors are quite competitive, including in the global market. Even such an instrument of state regulation as subsidizing has an additional effect, which is manifested in stimulating the development of domestic science and technology (A.A.Golovin, S.A.Starykh, O.I.Solodukhina and Z.A.Vasileva, 2019).

Providing food to the population is the ultimate goal of the food security process. The assessment of the level of satisfaction of the need for food products should be carried out in comparison with the standards established by official governmental and intergovernmental authorities and organizations. Only in this case the question can be answered - Does the amount of food consumed cover the scientifically justified need for it? The volume of food products consumption is closely dependent on the assortment on the shelves, sales prices and income of the population (D.I.Babin, 2016).

Thus, the assessment of the level of food security of the population and the factors that influence it is a very relevant task, which allows us to determine the satisfaction of the population and the reasons that have a negative impact on this state. The identification and assessment of the causes that affect the degree of satisfaction of food needs is the first step in the development of programmatic measures to ensure food security.

The purpose of the work is to study the volume of consumption of basic food products by the population of Russia in the context of ensuring food security, as well as to study the factors that determine them.

The need to achieve this goal required the following tasks:

– to assess changes in the consumption of basic food by Russian households;

– to conduct a comparative analysis of the volume of food consumption by rural and urban households in Russia;

– to compare the actual consumption of basic food products with the standards set by the Russian Ministry of Health;

– to compare the total cost of food consumed by rural and urban households in Russia;

– to compare the total cost of plant foods consumed by rural and urban households in Russia;

– to compare the total cost of animal products consumed by rural and urban households in Russia;

– to study the change in prices for basic food consumed by urban and rural households in Russia;

– to compare the prices of food consumed by rural and urban households in Russia.

The object of the study was the socio-economic processes that determine the level of consumption of basic food products in the context of ensuring the country food security.

The subject of the study is the level of food consumption and food security of the state.

The working hypothesis of the study is the scientific assumption that ensuring the normative consumption of basic food products is an integral element of food security of the state and that the level of income of the population has the greatest influence on the volume of consumption.

Material and Methods

The theoretical and methodological basis of the study are the theoretical provisions, methodological approaches and concepts, research results of domestic and foreign scientists in the field of food security, food accessibility and agribusiness economics.

The main Russian scientists and economists who paid attention to the problem of ensuring food security are A.I.Altukhov, I.N.Buzdalov, I.G.Ushachev, E.N.Antamoshkina, V.Yu.Baganov, A.Yu.Belugin, R.R.Gumerov, A.A.Kaygorodtsev, S.V.Kiselev, A.I.Kostyaev, E.N.Krylatykh, A.G.Paptsov, N.I.Shagayda, T.A.Strokova etc. Among foreign scientists-economists D.Grey, J.N.Schubert, K.A.Hubert, X.Liu, A.McBratney, A.Sen, W.Su, P.Aylwin, J.Beauvais, G.Bickel, E.Clay made a significant contribution to the theory and practice of food security.

The study used a complex of methods: empirical, abstract-logical, grouping, monographic, system analysis, economic-statistical, comparative analysis, vertical and horizontal analysis. For the purpose of visual presentation, systematization and scientifically based interpretation of empirical information, a tabular and graphical form of presentation of the material is used.

The information and empirical base of the study was made up of scientific publications on the studied problem, materials of the Food and Agriculture Organization of the United Nations (FAO), the Ministry of Agriculture of the Russian Federation (Ministry of Agriculture of the Russian Federation), the Ministry of Health of the Russian Federation (Ministry of Health of Russia), and the Ministry of Economic Development of the Russian Federation (Ministry of Economic Development of Russia) , Federal State Statistics Service of the Russian Federation (Rosstat), research results of scientific institutions of Russia, given monographic and collective research, periodicals and the Internet.

Results and Discussion

The Doctrine of Food Security of the Russian Federation provides the following definition: “Food security is a state of socio-economic development of the country in which the food independence of the Russian Federation is ensured, and physical and economic accessibility for each citizen of the country of food products that meet mandatory requirements is not less than rational norms of consumption of food products necessary for an active and healthy lifestyle." Thus, from the definition it follows that food security is not only the production of the necessary amount of food, but also the consumption of food at a level not lower than rational norms. The volume of production sufficient to cover the country's food needs characterizes food independence, and if the income of the population allows satisfying its scientifically substantiated food needs, this state will determine the food security of the country as a whole (V.V.Garkavy, 2015).

To achieve the goal of the study, the changes in the volume of consumption of basic foodstuffs by Russian households should be estimated (Figure 1).

Fig 1: Change in the volume of consumption by households of Russia of basic foodstuffs for 1980-2018, kg / year / person

Source: compiled by the authors using statistics from the Federal State Statistics Service (Rosstat)

The data in Figure 1 indicate a significant decrease in the average annual consumption of milk and dairy products. In 1980, one person consumed an average of 390 kg / year of milk and dairy products per year, and in 2018 only 266 kg / year. The largest decline in consumption occurred in 2000, when 199 kg were per person per year. The general assessment shows a decrease in the consumption of milk and dairy products in 1980-2000 and recovery dynamics until 2013, starting from which the consumption volume is quite stable.

Over the study period, egg consumption significantly decreased from 286 pcs / year / person in 1980, up to 231 pcs / year / person in 2018. The peak decline in consumption occurred in 1995, when there were 191 eggs per person per year, and since 1996 there has been a steady increase in consumption.

Vegetables and gourds are an essential element of a healthy diet. In Russia, from 1980 to 2000, there was a decrease in the consumption of vegetables and gourds from 92 kg / year/person to 82 kg / year/person. Then there was an increase and again a decrease from 2005 to 2009. The general situation with changes in the consumption of vegetables and gourds is its high volatility. A positive point is that in 2018 the consumption of 104 kg/year/person of vegetables and gourds is higher than in 1980 by 12 kg.

Fruit and berry consumption shows unstable dynamics. A positive aspect is the growth of fruit and berry consumption in 2018 in comparison with 1980 by more than 2 times. This situation is due to the weak growth in consumption observed in 2005-2018, and before this period there was a decrease in the volume consumed.

Consumption of meat and meat products was stable in 1980-1990, when it was 70 kg / year/person, and since the end of 1990, there is a strong decline. In 2005, 50 kg of meat and meat products were consumed per 1 person, which is 20 kg less than the level of 1980-1990 since 2005, a stable increase in the volume of consumption was recorded, which provided for consumption of 89 kg/year/person in 2018.

Thus, the analysis of the data shown in Figure 1 demonstrates that the consumption of milk, dairy products, eggs, bread products, potatoes and sugar in 2018 did not reach the level of 1980, and if in the case of sugar, potatoes and bread products this can be assessed on the positive side, then for milk and dairy products this is definitely a negative situation. Undoubtedly, there is a positive trend in the consumption of fruits, berries, vegetables, gourds, fish, fish products, meat and products from it. The volume of consumer consumption of the products of these food groups in 2018 exceeded the level of 1980.

In Russia, as in any other country in the world, there is a differentiation of the population into urban and rural, each of which has its own way of life and sphere of activity. The urban population mainly buys food in stores and has a higher level of income. The rural population to some extent covers the needs for food at the expense of their own natural production, only those food products that can not be produced independently are purchased. At the same time, the income level of the rural population is significantly lower than that of the urban population. In this connection, there is an objective need to give a comparative assessment of the volume of food consumption by urban and rural populations (Figure 2) (I.V.Minakova, M.A.Parkhomchuk, A.A.Golovin and T.N.Bukreeva, 2018).

Fig 2: Comparative assessment of the volume of food consumption in rural and urban households in Russia, kg / year / person

Source: calculated by the authors using statistical data from the Federal state statistics service (Rosstat)

Figure 2 shows that there is a significant gap in the consumption of basic foodstuffs by rural and urban households. By the end of 1980, the rural population consumed 38 kg/year/person more bread products than the urban population and 52 kg/year / person of potatoes. There is a slightly smaller gap in the consumption of eggs, sugar and confectionery. The rural population consumed eggs by 2 pcs/year/person more than the urban population, and sugar and confectionery by 4 kg/year/person. This situation is a consequence of the natural production of the rural population and the relative cheapness of goods. The main crop grown in rural households is potatoes, which has predetermined its predominance in the diet, and sugar is used in preparations and for the production of home-made alcohol. Bread products are significantly cheap, as is the egg production process.

Thus, a retrospective of differences in food consumption by the Russian population revealed a situation in which the rural population in the Soviet period had an extremely unbalanced diet with a predominance in the diet of potatoes and bread products and a lack of consumption of milk, dairy products, meat, meat products, fruits, berries, vegetables, melons, fish and fish products. With the beginning of the restructuring of the economic system of the USSR, there was a change in consumption – the rural population began to eat much better than the urban population. This situation is the result of the development of private production in rural areas, which allowed to cover their own needs and the consequence of the destruction of state production complexes and economic chains, which caused a shortage of food in the city.

Since the assessment of food consumption does not provide a complete picture of the balance of nutrition and food security, it is necessary to assess actual food consumption in comparison with the standards set by the Ministry of Health of the Russian Federation (Table 1).

Table 1: comparison of actual consumption of basic food products with the standard set by the Ministry of Health of Russia according to data for 2018

Product Name	Norm, kg / year / person	Fact, kg / year / person			Deviation of actual consumption from the standard (+,-)		
		Russia	Urban population	Rural population	Russia	Urban population	Rural population
Bread products (bread and pasta in terms of flour, flour, cereals and legumes)	96	95,7	89,9	112,9	-0,3	-6,1	16,9
Potatoes	90	58,7	55,9	66,7	-31,3	-34,1	-23,3
Vegetables and gourds	140	104,1	103,5	105,8	-35,9	-36,5	-34,2
Fruits and berries, including dried in terms of fresh	100	73,7	75,7	68	-26,3	-24,3	-32
Meat and meat products in terms of meat	73	89,1	91,3	82,7	16,1	18,3	9,7
Milk and dairy products in terms of milk	325	265,5	267,4	260,1	-59,5	-57,6	-64,9
Eggs, pcs	260	231	231	229	-29	-29	-31
Fish and fish products in terms of fish	22	21,7	21,5	22,4	-0,3	-0,5	0,4
Sugar, including confectionery in terms of sugar	24	31,3	29,7	35,7	7,3	5,7	11,7
Vegetable oil and other fats	12	10,7	10,3	12,1	-1,3	-1,7	0,1

Source: calculated by authors using statistical data of Federal state statistics service (Rosstat) and the Ministry of Health of the Russian Federation

Table 1 shows that in Russia as a whole, the consumption of bread products is below the level set by the Ministry of Health of Russia. This situation was made possible by the consumption of bread products by the urban population at a level below the standard by 6.1 kg / year/person. The rural population, on the contrary, in 2018 consumed 16.9 kg/year/person more than the standard level.

Russia has a low level of consumption of vegetables and gourds. With a standard of 140 kg / year / person, the average consumption in the country is 104.1 kg / year/person, which is 35.9 kg/year/person less than the established standard. The rural population consumes vegetables and gourds slightly more than the urban population. Under-consumption for the urban population is 36.5 kg / year / person, and for the rural population is 34.2 kg / year/person. This situation is the result of natural production of private farms of the rural population.

The standard of fruits and berries consumption established by the Ministry of health of Russia is 100 kg/year/person. The analysis shows that in Russia there is a lack of fruits and berries consumption by urban and rural populations.

Consumption of meat and meat products is at a high level, exceeding the established norm of 73 kg / year/person. The population of the country as a whole consumes 16.1 kg/year/person more than the norm, the urban population by 18.3 kg/year/person, and the rural population by 9.7 kg/year/person. It should be noted that exceeding the norm, as well as not achieving it, is a negative situation. The predominance of pork and meat products in consumption threatens the balance of nutrition and, consequently, the health of the population.

A negative situation has developed with the consumption of milk and dairy products. When the

standard of consumption of 325 kg/year/person, the population consumes only 265,5 kg/year/person. Urban population consumes 57.6 kg/year/person less than the norm, and rural 64.9 kg/year/person. This situation is the result of high prices for milk and dairy products, as well as a consequence of reducing the number of dairy cows in private farms.

Thus, the overall situation with the consumption of basic food products should be assessed as negative, since there is a lack of consumption of vegetables, gourds, fruits, berries, milk and dairy products. Consumption of more than the established standard of meat, meat products, sugar, and confectionery can also be assessed on the negative side. A positive situation has developed with the consumption of bread products, potatoes, eggs, fish, fish products, vegetable oils and other fats. Under-consumption of bread products, potatoes, vegetable oils and other fats is a positive point in the diet. Consumption of fish, fish products and eggs is at a level that can be adjusted without significant effort to achieve the standard.

Further research should be conducted on the basis of studying the financial component of consumption of the main product groups. The feasibility of this approach is determined by the different income levels of urban and rural populations, as well as the level of food prices. The initial step is to compare the total cost of food consumed by rural and urban households (Figure 3).

Fig. 3: Comparison of the total cost of food consumed by rural and urban households in Russia, rub / month / person

Source: calculated by the authors using statistical data from the Federal state statistics service (Rosstat)

Comparison of the total cost of food consumed by Russian households suggests that the growth rate of food costs consumed by the urban population is faster than the cost of food consumed by the rural population. This difference grew during 2006-2015, then stabilized and shows slight variability in the range of 776.5-808 rubles / month./person. In general, over 13 years, the rural population began to spend more on food products than the urban population by 776.5 rubles/month./person, and the total increase in the difference in consumption costs was 275.3%.

Look in detail at what caused this differentiation in the cost of food products for rural and urban populations. Comparison of expenditures of rural and urban population is shown in the context of food products of plant and animal origin (Figure 4, 5).

Fig. 4: Comparison of the cost of plant-based food consumed by rural and urban households in Russia, rub / month / person

Source: calculated by the authors using statistical data from the Federal state statistics service (Rosstat)

Figure 4 shows that at the end of 2006, the rural population spent less than the urban population on bread products, vegetables, gourds, potatoes, sugar, confectionery, vegetable oil and other fats. At the same time, the urban population spent less on fruits and berries. Considering the dynamics of the cost of food, it is clear that the difference in costs for fruits and berries was minimized and in 2018 does not exceed 18.9 rubles/month. Gradually, the costs of the urban population for bread products, vegetables and melons became significantly higher than the costs of the rural population for similar goods. In 2018, this difference was 53.6 rubles/month for vegetables and gourds per person, and for bread products 104.1 rubles/month.

Fig. 5: Comparison of the cost of animal food consumed by rural and urban households in Russia, rub / month / person

Source: calculated by the authors using statistical data from the Federal state statistics service (Rosstat)

The dynamics of comparing the costs of animal food consumed by rural and urban households, shown in Figure 5, shows that the urban population spends a lot on purchasing this category of food. An important feature is that the growth rate of urban population spending on food is significantly faster than the growth rate of rural population spending. This feature is typical for meat, meat products, milk, dairy products, fish and fish products. This feature is not observed in eggs. The considered situation is the result of exceeding the volume of consumption of these products by the urban population over the volume of consumption by the rural population.

The volume of consumption and the amount of food costs are affected by their price and the level of income of the population. Therefore, it is necessary to consider changes in prices for the main food groups consumed by urban and rural populations (Figure 6) (I.V.Minakova, M.A.Parkhomchuk, A.A.Golovin and T.N.Bukreeva, 2018).

Fig. 6: Changes in prices of basic foodstuffs consumed by urban and rural households in Russia, %

Source: calculated by the authors using statistical data from the Federal state statistics service (Rosstat)

The trends shown in figure 6 indicate high volatility of prices for food consumed by the country's population. Food prices show a high dependence on macroeconomic crises and the results of the state's foreign policy. Thus, during the 2008 crisis, the growth rate of food prices ranged from 20 to 40%. Then the growth rate decreased and from 2009 to 2013 it was from 0 to 20%. Price changes 2013-2015 this was due to the country's macroeconomic problems, international economic sanctions against Russia and the retaliatory food embargo (G.V.Makhanko and A.S.Volosatykh, 2016). Along with macroeconomic and foreign policy factors, the prices of food sales are influenced by natural and climatic conditions. The increase in food prices in 2010-2011 was associated with a decrease in crop yields caused by an abnormal drought.

The assessment of price changes does not give a complete picture of their differentiation by territorial distribution of the population. To complete the picture and assess the factors that affect the size of the difference in food consumption by urban and rural populations, a comparative analysis of food prices is necessary (Figure 7).

Fig. 7: Comparison of prices for food consumed by rural and urban households in Russia, rub / kg

Source: calculated by the authors using statistical data from the Federal state statistics service (Rosstat)

From the trends shown in Figure 7, it can be seen that the prices of food purchased by the rural population are lower than the prices of food purchased by the urban population. This situation is due to the quality of products and the level of their processing. As noted earlier, the urban population prefers seafood, while the rural population prefers river fish and the cheapest seafood. The situation is similar with bread products, the rural population mostly buys ordinary bread products and pasta, flour, and the urban population-pasta made from expensive varieties of grain crops, whole grain pastries, etc.

Thus, an assessment of changes in the total cost of food consumed and prices paid by urban and rural populations suggests that the reason for underconsumption of food is primarily due to low incomes, rather than high prices. This conclusion is supported by the fact that at lower prices for food consumed by the rural population, there is a significant underconsumption. Another conclusion is that the low prices of food for the rural population are primarily due to its low quality and degree of processing.

Conclusions

Thus, the study of the consumption of basic food products by the Russian population in the context of food security allowed to draw a number of conclusions:

1. The assessment of changes in the average per capita consumption of basic food products allowed us to determine the negative dynamics of reducing the consumption of milk, dairy products, eggs, bread products, potatoes and sugar. The level of consumption of these products in 2018 is below the level of 1980. Positive dynamics of growth in consumption volumes are shown by such food groups as fruits, berries, vegetables, gourds, fish, fish products, meat and meat products. The volume of consumption of these food groups in 2018 exceeded the level of 1980.

2. By the end of 1980, the rural population consumed significantly less meat, milk, fish, fruit, berries, and significantly more bread products and potatoes than the urban population. This situation was the result of the planned economic model of the USSR and the uneven distribution of social product. By the end of 2018, there was a minimization in the difference in consumption volumes between rural and urban populations, which can be assessed on the positive side.

3. As a result of comparing the actual and normative volume of consumption of basic food products, it was possible to identify a negative situation caused by underconsumption of vegetables, melons, fruits, berries, milk, dairy products and excess of the normative consumption of meat, meat products, sugar and confectionery. A positive situation has developed with the consumption of bread products, potatoes, eggs, fish, fish products, vegetable oils and other fats.

4. Comparison of expenditures on consumed food products of plant origin allowed us to conclude that the rural population spends less than the urban population on vegetables, melons, fruits, berries, bread products and more on other food groups. A similar comparison of food products of animal origin allowed us to determine that the urban population spends significantly more than the rural population on meat, meat products, milk, dairy products, fish, fish products, and almost equally on the purchase of eggs.

5. The assessment of changes in prices for the main food groups made it possible to determine that prices are strongly influenced by the macroeconomic state of the national economy, natural and climatic conditions, foreign policy and the exchange rate. The most stable food prices were in the period from 2010 to 2013, and the rest of the studied years were affected by the 2008 crisis, the 2010 drought, events in Ukraine and their consequences (sanctions, food embargo, devaluation of the national currency).

6. A comparison of the prices of food consumed by rural and urban households in Russia shows that the prices of food purchased by the rural population are significantly lower than the prices of food purchased by the urban population. This situation is typical for all food groups with the exception of

fruits and berries. The explanation for this situation is the higher quality and degree of processing of food products consumed by the urban population.

Summarizing the results of the study, we can conclude about the reason for under-consumption of food products by the population of Russia. This reason is the low level of income of the population. Despite the fact that food prices paid by the rural population are lower than those paid by the urban population, there is still a greater under-consumption of food by the rural population.

The publication has been implemented as part of the 2020 Government target (No. 0851-2020-0034).

Abstract

The article describes the features of formation and management of production costs at energy enterprises. The relevance of the research is determined by the fact that cost reduction leads to an increase in the company's profit and overall economic stability, which is a strategic advantage in a competitive environment. The study identified the following features of cost formation in the energy sector: the cost of energy takes into account the costs not only for production, but also for transmission and distribution of energy; the absence of work-in-progress leads to the fact that production costs can be fully attributed to the cost of energy produced; the cost of energy is affected by the cost of maintaining the capacity reserve at power plants; the level of energy costs can vary significantly for individual types of power plants and power systems; there is a dependence of the cost of energy source. The results of the research activities of the energy company – PJSC "IDGC of Center" – "Kurskenergo" determined that the percentage of the cost of transmission of electricity in total cost structure of company's sales is quite high, however, the share of gross profit of the activity in the general structure of gross profit of the enterprise is much less. Thus, it is necessary to reduce the cost of electricity transmission by optimizing the cost of this type of activity. In addition, the main areas of cost reduction and profit increase should include the following: measures to reduce borrowing; increase capacity utilization of power grid equipment; reduce the level of electricity losses; reduce unit investment costs; increase labor productivity and innovation efficiency; meet the deadlines for technological connection and achieve a level of reliability of provided services.

Keywords: Costs, Expenses, Energy, Energy Production, Energy Enterprise, Production Cost, Expenses, Production Cost Management.

Introduction

The effectiveness of the organization is largely determined by the quality of management activities, which, in turn, depends on the quality of the economic information provided, which is the basis for the development of a management decision. All enterprises pursue the goals of improving the efficiency of their activities and preventing the occurrence of crisis situations, so there is a need to create a system for generating information about costs, financial results of the organization's activities and a cost management system. The cost management process includes:

- the analysis of the size, location, time and purpose of expenditure of material, labor and financial resources;

- forecast of necessary additional volumes of various resources;

- identifying inefficient costs and ensuring the maximum possible increase in the level of return on resource use, that is, the company's costs should generate profit.

Costs related to produced products (performed works, rendered services) are expressed in the cost of production (works, services). The cost of production is the monetary cost of its production and sale. The cost of production (works, services) of an enterprise consists of the costs associated with the use of natural resources, raw materials, materials, fuel, energy, fixed assets, labor resources, and other costs in the production process.

Thus, at the present stage of development of market relations in Russia, such direction as cost management in production is of particular importance and thus it becomes relevant for the activities and development of economic entities. In a competitive environment, the issue of improving the efficiency of enterprises based on minimizing production costs is acute, so the problem of forming an effective cost management system is particularly relevant. It is extremely important to have a holistic view of the size and dynamics of production costs in order to make the right management decisions, thereby increasing the competitiveness of the enterprise through profitability, productivity and production efficiency (A.A.Golovin, S.A.Starykh, O.I.Solodukhina and Z.A.Vasileva, 2019).

The purpose of the work is to determine the features of formation and management of production costs at energy enterprises, as well as to analyze the costs of a specific energy enterprise and develop measures to reduce them.

The need to achieve this goal required the following tasks:

- to consider the theoretical basis for the formation and management of production costs at energy enterprises;

- to determine the features of formation and management of production costs at energy enterprises;

- to conduct a study of the production cost management system at an energy enterprise;

- to evaluate the results of managing production costs at an energy enterprise;

- to determine the main directions for reducing production costs at an energy enterprise.

The object of the research was economic processes that determine the size and structure of production costs of energy enterprises.

The subject of the study was the production costs of the enterprise.

The working hypothesis of the research consists in the scientific assumption that the processes of forming and managing the costs of an energy enterprise have their own characteristics due to the specifics of economic activity and the degree of state regulation.

Material and Methods

The theoretical basis of the research was the works of leading scientists in the field of energy production cost accounting, periodical publications, research reports and legal framework on the subject under study. The theoretical significance of the research is to generalize the basics of formation and ways to manage production costs at energy enterprises.

Accounting and control of production costs were studied by such Russian scientists as A.E.Suglobov, B.T.Zharylgasova, S.A.Khmelev, A.S.Karataev, V.Y.Savin, I.S.Kamaykina, I.A.Dontsov,

D.M.Manyshin, A.A.Podrezov, O.D.Kaverina and others. The specifics of managing production costs of energy enterprises were touched upon by such scientists as N.S.Kulakova, O.V.Tarasova, O.A.Petrova, O.A.Fil, T.V.Malinina, L.S.Kazarinov, T.A.Barbasova and others.

Among the foreign scientists-economists who have made significant contributions to the theory and practice of production cost management we can distinguish Edward J. Blocher, David E. Stout, Gary Cokins, John H. Shank, John K. Shank, Vijay Govindarajan, Shank Govindarajan, Don Hansen, Maryanne Mowen, Liming Guan, and others; and among those who have been engaged in production cost management at energy enterprises we can mark Italo Atzeni, Luis G. Ordóñez, Gesualdo Scutari, Daniel p. Palomar, Javier Rodríguez Fonollosa, Nils Weinert, Stylianos Chiotellis, Günther Seliger and others.

The methodological basis of the research is such general scientific methods as scientific abstraction, analysis, synthesis, methods of induction and deduction, modeling, comparison, as well as the method of the system approach.

The information and the empirical base of the research concluded the scientific publications on the problem under study, the materials of the Council on International financial reporting standards, the Ministry of natural resources and ecology of the Russian Federation, the Ministry of industry and trade of the Russian Federation, the Ministry of energy of the Russian Federation, the Ministry of economic development of the Russian Federation, results of the research scientific establishments of Russia, data of monographs and collective studies, periodicals and the Internet, as well as data from the annual accounting statements of PJSC “IDGC of Center”.

Results and Discussion

Theoretical bases and features of formation and management of production costs at energy enterprises

Production costs in industry and energy are referred to as either annual production costs, operating costs, or current costs. Cost is the most important qualitative indicator of the company's performance. It reflects all the main factors of production activity: the level of labor productivity, the degree of mechanization and automation of production processes, the level of use of fixed assets, the cost-effectiveness of fuel, raw materials, materials and energy, the quality of operation and organization of production. Cost reduction is the basis for improving the efficiency of public production and one of the ways to increase the profit and profitability of the enterprise.

The purpose of cost accounting is the timely, complete and reliable determination of actual costs associated with production and sales of products, calculation of the actual cost of individual types and all products, as well as control over the use of material resources and cash (A.E.Suglobov, B.T.Zharylgasova, S.A.Khmelev and others, 2017).

The costs of power generation by power plants, transmission of energy through networks and in general by power companies are calculated in two documents: in the cost estimate and in the cost calculation.

A cost estimate is a document that reflects the total costs associated with the production or transfer of goods (services) without dividing costs by product type. In the estimate, costs are grouped by economic elements:

1) material costs, including:

- costs of raw materials and basic materials (includes the cost of purchased raw materials and materials that form the basis of the product or are necessary components in its production);

- expenses for auxiliary materials (including the cost of purchased materials spent on production and economic needs);

- production-related services (these include the cost of paying for work and services of a production nature performed by third-party organizations or divisions of the company itself that are not related to the main type of activity);

- fuel costs (includes the cost of all types of fuel purchased by the company);

- energy purchase costs (includes the cost of purchased energy of all types, including those spent on production and economic needs of the company and losses in the electric networks);

2) remuneration of labor (accruals to employees at tariff rates, incentive payments and compensation allowances, expenses related to the maintenance of employees provided for in labor contracts and collective agreements);

3) insurance contributions to social funds (intended for raising funds necessary for medical care, state pension and social security of citizens);

4) depreciation (reflects the amount of depreciation deductions for the full restoration of fixed assets);

5) other expenses, including:

- costs for repair services in the contract method of repair (costs for maintaining fixed assets in working condition, costs for carrying out current, medium and capital repairs);

- advertising expenses (expenses of the company for purposeful informing of consumers and promotion of products on sales markets);

- representation expenses (expenses related to the company's commercial activities);

- expenses for business trips related to production activities;

- expenses for training and retraining of personnel (expenses related to training and retraining of personnel in accordance with agreements with educational institutions);

- environmental payments that do not exceed the maximum permissible concentration charged to natural users whose economic activities have a negative impact on the biosphere;

- lease payments (expenses related to the lease of fixed assets from other legal entities or individuals);

- payment for services of mobile operators (hereinafter MO) and automatic telephone exchanges (hereinafter ATE);

- amortization of intangible assets;

- expenses for compulsory and voluntary property insurance (includes insurance premiums for all types of compulsory insurance, as well as for some types of voluntary insurance);

- expenses for research and development (hereinafter referred to as R&D);

- expenses for the maintenance of official vehicles;

- expenses for legal, informational, consulting, and audit services;

- expenses for market research;

- the cost of serving the industries and farms;

- expenses for the maintenance of paramilitary, fire protection;

- expenses for labor protection;

- environmental measures at the expense of cost;

- water tax (expenses related to general or special water use in accordance with the legislation of the Russian Federation);

- land tax (expenses related to the use of land);

- deductions to trust funds (O.D.Kaverina, 2018).

The variety of classification features of costs, their composition and volume form several types of cost, the use of which affects the organization and methodology of the calculation process. Cost types by cost structure are shown in table 1.

Table 1: cost types by cost structure

Type of cost price	The contents of the total cost	Content of the individual cost of a product or process
The cost of technology (for direct costs)	Direct production costs in the area, in the team, for a separate unit, land area	Costs for raw materials, materials, purchased semi-finished products, technological energy, labor remuneration of production workers
Reduced production cost	Process cost + General production expenses	Technological cost per unit + Share of general production expenses
Input cost	Reduced production cost + General economic cost	Reduced production cost per unit + Share of General expenses
Total cost	Production cost + Commercial expenses	Production cost per unit + Share of business expenses

In accordance with International accounting and financial reporting standards and accounting practices abroad all costs are summarized in three areas of activity:

1) for calculating cost, estimating inventory and work-in-progress, and determining profit;

2) for making management decisions, planning, forecasting;

3) for control and regulation (M.V.Kosolapova, 2018).

The classification of costs in accordance with International accounting and financial reporting standards is presented in table 2.

Table 2: cost classification

Classification sign	Cost group
1. Classification of costs for the purpose of calculating the cost of inventory and determining profit	
According to the degree of homogeneity	Singleton
	Complex
For a correct assessment of profit and loss	Inbox
	Past
By the method of inclusion in the cost of a unit of production	Direct
	Indirect
On the relationship of costs to the technological process	Main
	Invoices (general production, general economic, commercial)
By area of origin	Industrial
	Non-industrial
Depending on the time of occurrence	Current
	Nonrecurrent
2. Classification of costs for purposes of managerial decision-making, planning and forecasting	
From the planning point of view	Planned
	Unplanned
By efficiency (expediency)	Industrial
	Non-industrial
In relation to the production volume	Variable
	Permanent
	Mixed
On materiality for decision making	Relevant
	Irrelevant
In the development of management decisions (If it is necessary)	Irrevocable
	Imputed
	Incremental and marginal
3. Cost classification for control and regulation	
According to the Manager's influence on costs (If it is necessary)	Controlled
	Uncontrolled
By accounting objects	Costs by place of origin
	Costs for responsibility centers

The data obtained for expenditure elements is necessary for developing business plans determining the volume of purchases of material resources, the payroll fund and the amount of depreciation, organizing expenditure control, calculating resource efficiency indicators (material intensity, labor intensity), and a number of other indicators.

The cost of production is one of the most important economic indicators of enterprises, which comprehensively reflects the impact on it of the organization and technical level of production, labor productivity, the degree of efficiency of spending raw materials, materials, fuel and energy, the level and use of production capacity and all other conditions of production and economic activity of this enterprise.

Cost accounting is due to the necessary reimbursement of production costs and profit by the enterprise at the expense of funds received from the sale of products. Cost accounting information is used to determine the performance of energy companies and analyze the performance of their

branches. All expenses of such enterprises for production and sale of products in monetary form are the cost of these products.

The cost of production at energy enterprises is determined by the monetary expression of material and labor costs for the production and sale of electric energy for the planned period. The cost of production is calculated by economic elements and calculation items (A.E.Suglobov, B.T.Zharylgasova, S.A.Khmelev and others, 2017).

Calculation is a way of grouping costs for production and sale of products, goods, works and services. In the process of manufacturing products, purchasing goods for resale, performing works, providing services in the course of economic activity, material, labor, and financial resources are used (M.V.Kosolapova, 2018).

In accordance with the technological features in energy production, when planning and accounting for annual production costs and calculating the cost of generated energy, the following grouping of costs by expenditure items is used, shown in figure 1.

Fig. 1: Calculation articles in the energy sector

The procedure for calculating the cost of production is influenced by the range of produced products. In the energy sector, some enterprises produce one type of product (electricity), while others produce

two (electric and thermal energy). In the first case, the cost is determined by the total amount of incurred expenses, and in the second - they must be distributed among individual types of energy.

The most important feature of energy production is that enterprises in this industry work directly for the consumer without creating inventory and accounting for work-in-progress, and the incurred expenses during the reporting period are completely written off to the cost of energy generated, so there is no need to distribute them between finished products and work-in-progress.

In the energy sector, there is no shop cost. At power plants, due to the lack of work in progress, the shop cost of energy is not calculated, except for power repair enterprises and some other types of auxiliary production.

Research of the system and results of production cost management at an energy enterprise

Consider the formation of production costs and production costs on the example of the leading power grid company in Russia - PJSC "Interregional Distribution Grid Company of the Center" (hereinafter – PJSC "IDGC of Center"), which was founded in 2004 in the process of reforming the Russian power industry and dividing power companies by type of activity, their subsequent regional integration. The main activities of PJSC "IDGC of Center" are: services for transmission and distribution of electric energy in networks with a voltage of 0.4-110 kV and services for technological connection to them.

Based on the results of the analysis of the production cost management system of PJSC "Interregional Distribution Network Company of the Center", we can say the following. In assessing the results of on-farm activities, an important role is given to methods and procedures for analyzing the costs of production (provision of services). Cost analysis is carried out in order to make the most efficient use of the company's resources and find potential opportunities to reduce costs. Cost analysis of products, works and services is of great importance in the cost management system.

In the structure of production costs of PJSC "IDGC of Center", the largest share is taken by material costs. In 2019, the share of material costs in the total structure of production costs was 61.05%. Based on the results of the cost analysis for 1 ruble of sold products of PJSC "IDGC of Center", it can be determined that the growth rate of the cost of sales is higher than the growth rate of revenue during the entire analyzed period. In 2019, commercial expenses decreased by 7.02%, but management expenses increased by 0.83% in 2019. Thus, in 2019 1 ruble of revenue accounted for 0.92 rubles of the total cost of sales (T.V.Dobrinova and K.V.Shipulina, 2018).

In the structure of revenue, cost and gross profit of PJSC "IDGC of Center", the largest share is taken by the main activity – electricity transmission. Thus, in 2019 revenue from electricity transmission amounted to 95.89%. The main reasons for the growth of revenue from electricity transmission are:

- increase the average fare;

- amendments to "the Rules for non-discriminatory access to electric power transmission services and the provision of these services in terms of load losses";

- reduction of useful output.

In 2019 the cost of electricity transmission in the total cost structure of the enterprise was 98.03%. Profit from electricity transmission in the total gross profit structure of PJSC "IDGC of Center" in 2019 was 77.85%.

According to these facts the following conclusions can be drawn. PJSC "IDGC of Center" is a Russian electric grid company with such main activities as transmission of electricity and technological connection of new consumers to electric networks. Building a unified corporate

information system for resource management allowed automating all the main processes of the enterprise and significantly improving the efficiency of managing the power grid complex. In 2018 PJSC “IDGC of Center” started implementation of the concept of “Digital transformation of the electric grid complex 2030”. The strategic objectives implemented by the company in the framework of the transformation of the electric grid complex 2030 are presented in the following areas:

- improving the reliability and quality of power supply;

- increasing security of supply;

- improving the efficiency of the electric grid complex;

- reducing the number of territorial grid organizations.

Regarding the main types of activities - services for transmission and distribution of electric energy in networks and services for technological connection to electric networks - PJSC “IDGC of Center” takes measures to reduce costs. One of the ways to improve the efficiency of the power grid complex and reduce the cost of electricity transmission through the networks is to reduce electricity losses. Due to the implementation of a set of measures to optimize (reduce) electric energy losses in 2019, the amount of savings amounted to 167.5 million kWh (433.8 million rubles) (T.V.Dobrinova and K.V.Shipulina, 2018).

It must be said that PJSC “IDGC of Center” takes measures to detect and prevent non-contractual and unaccounted-for consumption in order to reduce power losses. Effective technical measures that reduce losses include load reallocation and disconnection of unloaded transformers at substations, installation of a larger section of wire on overloaded power lines (hereinafter referred to as power lines), and installation of self-supporting insulated wire on lines.

PJSC “IDGC of Centre” also conducts energy saving and energy efficiency measures aimed at reducing costs. In accordance with “The energy saving and energy efficiency improvement program" of PJSC “IDGC of Center” for the period 2017-2022, the following activities are carried out:

- reduction of electric energy losses during transmission and distribution over electric networks;

- consumption of energy resources for household needs;

- equipped with modern electricity metering devices in the retail market;

- use of led lighting devices.

Technological connection of new consumers to electric networks is a fully regulated activity on the part of the state. In order to reduce the network organization's costs for technological connection and reduce the terms of execution of contracts for technological connection, PJSC “IDGC of Center” continued to increase the share of contracts for which activities are performed in an economic way.

In the field of production cost management, the following activities are applied and implemented at the enterprise:

1. Improving the efficiency of the process of managing maintenance and repairs of equipment, buildings and structures.

2. Improving the efficiency of working capital management.

3. Improving the efficiency of fixed assets management.

4. Improving the effectiveness of the procurement and supply chain management system.

5. Introduction of modern technologies and use of innovations:

- “Innovative development program”.

6. Optimization of the staff motivation and remuneration system.

7. Improving energy efficiency:

- “Energy saving and energy efficiency improvement program”;

- “The program of decrease in losses”.

As for the reserves of PJSC “IDGC of Center”, they include spare parts, fuel, and costs in work-in-progress. As a part of improving the operational efficiency of PJSC “IDGC of Center”, the concept “Improving the efficiency of working capital management” in terms of inventory optimization was implemented in 2018. The achieved economic effect amounted to 12.3 million rubles.

In addition, as a part of improving the operational efficiency of PJSC “IDGC of Center”, the following measures were implemented to reduce costs. Improving the efficiency of management of fixed assets, in part increasing the productivity of equipment as a result of technical re-equipment and reconstruction of existing and construction of new production facilities, as well as the use of power transformers 6(10)/0.4 kV with reduced energy consumption (energy-efficient). The achieved economic effect was 2.3 million rubles. Reducing the costs associated with the maintenance and management of non-core assets, including as a result of their alienation, provided an economic effect equal to 2.8 million rubles (T.V.Dobrinova and K.V.Shipulina, 2018). In addition, with respect to the valuation of property, plant and equipment and intangible assets, at the end of each reporting year, depreciation methods, useful lives and residual values are reviewed to determine whether they need to be revised and, if necessary, revised.

Improving the efficiency of the procurement and supply chain management system has produced an economic effect of 431.6 million rubles. This result is a consequence of conducting trade and purchasing procedures due to re-bidding.

As a result of optimizing the system of motivation and remuneration of the staff in the part of forming a unified policy in the field of remuneration of staff, we managed to get an economic effect equal to 426.5 million rubles, and the formation of a unified policy in the field of non-material incentives for employees gave an economic effect of 2.6 million rubles.

The introduction of modern technologies and the use of innovations as a result of the implementation of the “Program of innovative development” gave an economic effect of 99.1 million rubles.

The increase in energy efficiency as a result of “The energy saving and energy efficiency program” provided an economic effect of 4.1 million rubles, and the economic effect of “The loss reduction Program” was 108.8 million rubles.

Thus, on the basis of the mentioned above, and, in particular, the analysis of the activities of PJSC “IDGC of Center”, we can draw the following conclusions and give practical recommendations. Throughout the analyzed period, all activities of the enterprise bring in gross profit. Percentage of the cost of transmission of electricity in total cost structure of company's sales is relatively large, however, the share of gross profit of the activity in the general structure of gross profit of the enterprise is much less. The cost of production, respectively, and the costs included in it have a huge impact on the profit and profitability of the enterprise. Based on the marked above, it should be concluded that PJSC “IDGC of Center” should analyze in detail the costs included in the cost of electricity transmission, as well as find possible cost overruns according to the norms, or ways to reduce item-by-item costs. As mentioned earlier, PJSC “IDGC of Center” is a leading electric grid

company that provides services for the transmission and distribution of electric energy, as well as services for technological connection to electric networks. Based on this fact, the main directions of cost reduction at this enterprise are to reduce losses in the power grid, correct loading of lines taking into account losses, in particular, optimization of power equipment capacity utilization modes at power plants and in power systems, optimization of the composition of operating and backup power equipment, including the frequency of repairs and costs for their implementation, as well as reducing the number of maintenance personnel of electric networks.

PJSC "IDGC of Center" should develop such activities as technological connection services and the production of other products, goods, works, and services of an industrial nature, since at a relatively low cost, the share of gross profit from these activities is quite high and has been increasing throughout the period, reaching its maximum in 2019 (the share of gross profit from technical connection was 15.45%, and the share of gross profit from other industrial products was 5.72%).

If we consider the transmission of electricity through networks in the context of costs included in the formation of the cost of this type of activity, we can make the following suggestions. Most of the costs (67.58% in 2019) are non-controlled costs. The group of non-controlled expenses includes the following types of expenses: compensation for losses, payment for services of PJSC "FGC UES", payment for services of territorial network organizations, as well as depreciation of fixed assets and intangible assets. To manage these types of costs is extremely difficult, you should also consider the fact that PJSC "IDGC of Centre" is an entity of natural monopoly, the main business is transmission and distribution of electricity from the main networks of PJSC "FGC UES" to territorial grid companies, utilities and large consumers, and key consumers of PJSC "IDGC of Center" are enterprises that have an important regional significance. Accordingly, it is not possible to regulate the price of services of PJSC "FGC UES" and the price of TNO services. The cost of compensation for losses can be reduced, in particular, if you introduce new technologies, install self-supporting insulated wire on lines, redistribute loads and disconnect unloaded transformers at substations. In particular, it is possible to reduce depreciation of OS and IA by increasing the productivity of equipment as a result of technical re-equipment and reconstruction of existing facilities, as well as construction and commissioning of new production facilities. It is also necessary to review the feasibility of maintaining non-core assets and unused fixed assets, and if they are found, take measures to preserve the fixed assets, as well as to sell or lease them.

The largest share in the structure of expenses for technological connection services of PJSC "IDGC of Center" is made up of personnel costs (payroll fund, insurance payments, NPF). As mentioned earlier, reducing this component of costs is possible by increasing labor productivity, as well as reducing the cost of labor for employees sent to carry out emergency recovery operations, by preventing emergency situations and unscheduled repairs.

In the structure of funding sources, a significant share is taken by borrowed capital (52.3% in 2019). The company needs to review its lending policy by gradually reducing its leverage, either increasing the company's equity, or paying off its obligations as quickly as possible.

It should be noted that PJSC "IDGC of Center" uses measures to control and manage fixed assets, optimize the system of motivation and remuneration of staff, and control power losses in the networks.

As recommendations, as in the case of management expenses to reduce other costs, it is necessary to consider the expediency of incurred expenses in the context of this article, and to reduce labor costs, measures should be applied to increase labor productivity.

Conclusions

Based on the results of studying the basics of formation and ways to manage production costs at energy enterprises, it was determined that the formation of cost in the energy sector has a number of features:

1. The cost of energy takes into account the costs not only for production, but also for the transmission and distribution of energy (due to the inextricable link between production and transmission of energy).

2. The absence of work in progress leads to the fact that the production costs for a certain period of time can be fully attributed to the cost of energy produced.

3. The cost of energy is affected by the cost of maintaining the capacity reserve at power plants and in the power grid to ensure uninterrupted power supply to consumers.

4. The level of energy cost can vary significantly for individual types of power plants and power systems.

5. There is a dependence of the cost price on the type and quality of the fuel.

6. There is the impossibility of disconnection from energy sources of some users of social purpose.

In contrast to other industries, the electricity industry calculates the cost of a unit of production that is not produced, but released. Definition of the released cost but not a manufactured unit is due to the fact that for electricity production (heat) the generating units consume part of the energy produced for own needs, and the transport energy part of it is consumed in the form of losses when you transfer energy networks.

In order to determine the cost of certain types of products, the calculation classification of production costs by expenditure items (calculation items) is used.

An important factor affecting the value of the cost of transmission and distribution of electricity is the amount of capital investment (the cost of fixed assets) in the construction of network facilities, while the better technically equipped production, the less the share of live labor in operating costs and the higher the share of materialized labor, thus, in electric grid enterprises with an increase in network capacity, the share of wages decreases, and depreciation charges increases. Also, the cost of electric power transmission in distribution networks is affected by their length and load. At the same level of power consumption, the higher the cost value, the longer the network length and the lower the load.

Thus, it can be concluded that an increase in production volume leads to a reduction in cost and, as a result, to an increase in profit per unit of production, an increase in the profitability of energy production. To get a higher profit in the power system, it is advantageous to maximize the load of power plants with a high share of fixed costs and the lowest fuel costs.

Cost is the most important, and in its economic content, the most perfect indicator of production efficiency, since it comprehensively reflects the level of labor, material and financial costs. Thus, the definition of ways to reduce individual items of current costs can be traced by analyzing the unit cost of production, that is, the cost of production items.

Based on the results of the research and analysis of the activities of PJSC “IDGC of Center” – “Kurskenergo”, we can draw the following conclusions and give practical recommendations. Throughout the analyzed period, all activities of the enterprise bring in gross profit. Percentage of the cost of transmission of electricity in total cost structure of company's sales is quite high, however, the share of gross profit of the activity in the general structure of gross profit of the enterprise is much less. Thus, it is necessary to reduce the cost of electricity transmission by optimizing the cost of this type of activity.

As for the branch JSC “IDGC of Center” – “Kurskenergo”, it is especially necessary to develop the type of activity “technical connection” because at a relatively low cost to the cost of the activity (less than 1% in the cost structure of company's sales), the share of gross profit from connection rather

high and very close to the share of gross profit from electricity transmission. Also the branch of JSC “IDGC of Center” - "Kurskenergo" you should pay attention to other products, goods, works, services of industrial nature, as this type of activity at a relatively small fraction of the cost in the cost structure of the company's sales, bringing a significant portion of the gross profit of the PJSC “IDGC of Centre” – “Kurskenergo”, this is especially noticeable in 2017, when the cost of other products, goods, works, and services of an industrial nature in the total structure of the cost of sales of the enterprise was 0.39%, and the share of gross profit in the total structure of gross profit of the enterprise was 11.76% (T.V.Dobrinova and K.V.Shipulina, 2018).

Based on the mentioned above, it should be said that PJSC “FGC UES” and PJSC “IDGC of Center” are natural monopolies and tariffs for services of companies are set by Executive authorities. Thus, if we consider the contractual activities of companies whose sphere of activity does not belong to the monopoly sector as a recommendation for contractual obligations, in particular for the provision of services, we could recommend reviewing the terms of contracts with existing suppliers, or finding new suppliers. However, since in our case both companies belong to natural monopolies, it is not possible to revise the price for the services of PJSC “FGC UES” or find another service provider.

Thus, as the prospects of development of PJSC “IDGC of Center” in the management of production costs it is possible to define the following aspects: implementation of the schedule of input of objects into operation; increasing capacity of electric grid equipment; reduced specific operating expenses (costs); reduction of electricity losses; reduced specific investment costs; increase productivity; increase of efficiency of innovative activity; the deadlines for technological connection, and achieving the level of reliability of services.

The publication has been implemented as part of the 2020 Government target (No. 0851-2020-0034).

Abstract

This research aims to analyze the effect of pesantren (Islamic Boarding School) cooperatives toward economic growth compared to the number of informal workers, growth in interest rates, and growth in the inflation rate in East Java Province in 2013-2017. This research uses quantitative approach with panel data regression method in 38 districts/cities in East Java Province in 2013-2017. This research determines random effect model as he best model. The results shows that there were three variables with significant effects toward economic growth in East Java Province in 2013-2017, which were growth in the number of pesantren cooperatives, growth in interest rates, and growth in inflation rates. The growth in the number of pesantren cooperatives of 10% has a significant positive effect toward economic growth of 1.64118%. Interest rate growth and inflation rate growth of 10% had a significant negative effect toward economic growth respectively -10.22606% and -1.37082%. From the great potential of pesantren cooperatives in economic growth. The government needs to encourage the development of pesantren cooperatives through facilities of licensing and access for financial capital.

Keywords: Pesantren cooperatives, Economic growth, Panel data, Macro Indicator.

Background

Ratification of Pesantren (Islamic Boarding School) Draft Law (RUU) into Pesantren Law (UU) in House of Representatives Plenary (DPR) on Tuesday, September 24th, 2019 was an affirmation efforts made by the government to accommodate the existence of pesantren in Indonesia. If pesantren is usually only considered as non-formal educational institutions, then with the enactment of the Pesantren Law, pesantren will be able to develop into part of an important element in shaping character and increasing the capacity of education for the community. Based on Madjid (1997), is an institution which conduct fair processes in the development of the national education system. In terms of history, pesantren is not only identical with the meaning of Islam, but also contains the value of authenticity of Indonesia (indigenous). It means that the pesantren is present in the midst of the community as a pillar of education that contributes greatly in improving human resources. The role of pesantren as an educational institution in Indonesia existed long before Indonesia's independence.

According to Religion Ministry in 2019, there were 28.194 pesantren with total of 4,290,626 people spread throughout Indonesia. From the total, 82.34% or 23,175 boarding schools are located in Java, or only 17.66% or 4,971 boarding schools located outside of Java. Furthermore, the Ministry of Religion states that the large number of pesantren is expected to be a strategic potential for Indonesia in three ways which are religious institutions, educational institutions, and social institutions. This means that the existing pesantren is expected to be able to be an agent of development not only in the

closed aspects of religion and education as it currently exists, but also in social aspects of society especially in developing the economic potential of the community.

Fig. 1: Percentage of Pesantren Distribution in Indonesia (Source: kemenag.go.id)

Pesantren is the oldest education institution in Indonesia, which *brings out* scholars in Indonesia (Syafe'i, 2017). The distinctive education system is wrapped with the local wisdom of the archipelago. It makes pesantren easily accommodate the educational needs of people in Indonesia from various walks of life. Pesantren is not only one of the opponents in the education system in Indonesia, but is also able to become a pillar of the Indonesian economy. Pesantren has a long history of developing a populist economy in Indonesia because previously the source of pesantren's life came from agricultural products to hereditary (Ningsih, 2017). Furthermore, it forms the progress of pesantren to develop not only as an educational institution, but also a community economic institution which is expected to be able to contribute in increasing the economic activities of the community. Based on Marlina (2014), Pesantren is present as real practice laboratory to apply sharia/Islamic economic theory in current economic activities. Moreover, the pesantren is currently present as a symbol of the development of a economic democracy system in Indonesia. Mubyarto (2014) explains economic democracy system system is a family-based economic system, the sovereignty of the people, and Pancasila, and shows the partiality of the people's economic interests. It is relevant if the pesantren is considered as one of the forces in the economic driving force of society in Indonesia because of the considerable potential in quantity.

Based on the data of Religion Ministry in 2015/2016, as economic institution, there were 18,885 pesantren (65.15%). Pesantren which had economic potential, including: agricultural potential of 3,024 (16%), cooperatives or *Baitul Mal wa Tamwil* (BMT) of 1,498 (7.93%), entrepreneurship of 795 (4.21%), livestockof 587 (3.11%), and plantations of 579 (3.07%). Cooperatives or *Baitul Mal wa Tamwil* (BMT) owned by pesantren were established with the aim of improving the pesantren's economy, training the entrepreneurship of the santri, and being a catalyst for improving the economy of the villages around the pesantren.

Fig. 2: Number of Pesantren Cooperatives in East Java in 2013-2017 (Source: Ministry of cooperatives and SME)

The effort to improve people's economy through pesantren faces big challenge. According to Central Bureau of Statistics (BPS), the poverty rate in Indonesia in September 2018 was 9.66% and the open unemployment rate was 5.34% in August 2018. Research related to the contribution of pesantren in improving the community's economy has never been carried out so far. Previous research on pesantren in the community economy was conducted by Marlina (2014) and Ningsih (2017).

In a research entitled The Potential of Islamic Boarding Schools in Sharia Economic Development, Marlina concludes that Islamic boarding schools have the potential in developing Islamic economics in society, which includes the role of Islamic boarding schools as agents of social change in the field of Islamic economics, Islamic boarding schools as syllabic business blaborators, and Islamic boarding schools as centers of learning of Islamic/sharia economics (Marlina, 2014). Furthermore, Ningsih in her research entitled Pesantren Economic Empowerment through Local Resource Development (Study at Daarut Tauhid Islamic Boarding School) states that pesantren as a cultural institution has a strategic role which not only positions as an educational institution and religious institution, but is also able to address social and economic problems in Public (Ningsih, 2017).

Research specifically discussing pesantren cooperatives was previously conducted by Rahayu and Rusydiana (2018). It focused to measure the efficiency of pesantren cooperatives. In a research entitled Measuring The Efficiency of Pesantren Cooperatives: Evidence in Indonesia, Global Review of Islamic Economics and Business, Rahayu and Rusydiana measured the effectiveness of pesantren cooperatives in Pesantren Suryalaya by using Data Envelopment Analysis (DEA). However, this research did not directly measure the comparison between the effectiveness of pesantren cooperatives with the impact of economic improvement on the surrounding community.

In measuring economic performance in a region, There are three very important macroeconomic variables as follow; Gross Domestic Product (GDP), inflation rate, and interest rates (Mankiw, 2013). Improvement in the community's economy in this research can be seen from the economic growth based on Regency/City GRDP in East Java Province in 2013-2017. Economic growth is seen as a terminology in the expansion of economic production in a region. In the traditional neoclassical economic growth approach, economic growth is affected by community savings, labor capital, and per capita income (Todaro and Smith, 2011). In the growth theory initiated by Robert Solow (in Mankiw, 2013), economic growth seen through the GDP of a region (Y) is determined by the existence of physical capital (k) and labor force (l) with the following equation $Y = F(K, L)$.

The relation between investment (I) and capital stock (K) is explained in the Horrad-Domar growth model with the equation $I = \Delta K$. This means that net investment in an area is determined as a change in the capital stock (Todaro and Smith, 2011). Investment also has a correlation with interest rates. A

company will purchase investment goods (I) to increase capital stock and replace consumable capital. The amount of capital goods demanded depends on the interest rate (r) used to finance investment. Then, This is summarized in equation I = I (r). This means that when the interest rate rises, the amount of investment will fall (Mankiw, 2013).

When it comes to inflation, it is closely related to inflation theory explained by the Phillips Curve (Phillips Curve). The Phillips curve explains that the inflation rate is affected by three forces, as follow: a) expected inflation; b) deviation of unemployment from the natural rate or unemployment skills; c) bid shocks. This is illustrated by the equation of $\pi = \pi^e - \beta (u - u^n) + v$ (Mankiw, 2013). It means inflation = expected inflation - (β x unemployment skills) + supply shocks. High unemployment has a tendency to reduce inflation. Economically, unemployment does not only have an impact on inflation but is more broadly related to the economic growth of a region. Okun's Law explains that there is a negative relationship between unemployment and the economic growth of a region (Mankiw, 2013). The permanent unemployment rate will have an impact on increasing economic growth calculated through GDP of 3.5%.

Furthermore, Mankiw pointed out the relationship between interest rates and economic growth in a region. Companies and households will have a tendency to purchase investment goods to increase the capital stock. The amount of investment goods requested depends on the existing interest rate. Absolutely, it will fluctuate at any time according to existing conditions. If the interest rate rises, fewer investment projects are profitable, and the number of investment goods requested decreases. Thus, economic growth in a region will tend to weaken (Mankiw, 2013).

Based on theoretical references above, the improvement of The economy of the people in East Java Province in this research will be measured in one dependent variable such as the level of GRDP and four independent variables, as follow: boarding schools, interest rates, the number of informal workers, and inflation. Therefore, this research is conducted with the following objectives: 1) to observe the relationship between the number of pesantren cooperatives and economic growth in East Java Province in 2013-2017; 2) To see the relationship between the number of informal workers and economic growth in East Java Province in 2013-2017; 3) To observe the relationship between interest rates and economic growth in East Java Province in 2013-2017; and 4) To observe the relationship between inflation rates and economic growth in East Java Province in 2013-2017.

Research Method

This research is to measure pesantren contribution in economic growth in East Java Province using panel data. It is a combination of time series data and individual data or cross sections. Time series data are data in 2013-2017, while cross section data is represented by data per district/city in East Java Province for each variable, both dependent and independent variables. There are 38 regencies/cities in East Java for each variable, bringing the total panel data used in this research of 190 data. The data used in this research are secondary data per district/city in East Java Province, which consists of GRDP data as the dependent variable, as well as data on the number of pesantren cooperatives, the level of interest rates, the number of informal workers, and the inflation rate as an independent variable or variable which will be measured in relation to the dependent variable in this research. Panel data processing uses eviews software 9 , with the panel model equation as follows:

$$LOGY_{it} = \beta_0 + \beta_1 LOGX1_{it} + \beta_2 LOGX2_{it} + \beta_3 LOGX3_{it} + \beta_4 LOGX4_{it} + e_t$$

LOGY is Gross Regional Domestic Product (PDRB) of East Java in 2013-2017 based on business field (Rupiah); LOGX1 is the Growth in the Number of Pesantren Cooperatives per Regency in East Java in 2013-2017 (units); LOGX2 is Growth in the Number of Informal Workers (Units); LOGX3 is the Growth of Interest Rates in East Java in 2013-2017 (Percentage); LOGX4 is the Growth Rate of Inflation in East Java in 2013-2017 (Percentage)

Result and Analysis

Based on data of East Java Province economic level in 2013-2017 as seen through GRDP data based on business in the Province of East Java, in general GRDP in East Java Province experienced a good trend with a consistent increase from 2013 to 2017. Increased GRDP in Java Province East significantly occurred in 2013 and 2014, reaching 11.24%. It means that during 2013-2017, East Java Province experienced good economic growth with an upward trend every year.

Fig. 3: Gross Regional Domestic Product (PDRB) Based on East Java Province Business Field in 2013-2017 in Billion Rupiah (Source: https://jatim.bps.go.id/)

As the economic growth in East Java Province in 2013-2017, several variables assumed to have correlations are also closely watched for trends. Islamic boarding schools cooperatives as one of the variables measured in this research also had an increasing trend in 2013-2017. In Law Number 17 in 2012 concerning Cooperatives, article one paragraph one, cooperatives are defined as legal entities established by individuals or cooperative legal entities, with the separation of the members' wealth as capital to run a business. It fulfills common aspirations and needs in the economic, social and cultural fields in accordance with the values and principles of cooperatives. In addition, cooperatives are established with the aim of increasing the welfare of members in particular and society in general, as well as an inseparable part of the democratic and just national economic order.

If it refers to the data of The Ministry of Cooperatives and SMEs, the number of pesantren cooperatives is divided into two based on their status, such as the number of pesantren cooperatives which are still active and the number of pesantren cooperatives that are not active. Active pesantren cooperatives are pesantren cooperatives registered in the Ministry of Cooperatives and SMEs database and currently continuing economic activities. While the pesantren cooperatives which are not active are those which have been registered in the Ministry of Cooperatives and SMEs database, but are not currently carrying out economic activities. From the data,in the East Java Province, there is quite a large gap between the existing pesantren cooperatives and active pesantren cooperatives, which is between 815 units and 771 units.

Fig. 4: Number of Pesatren Cooperatives in East Java Province in 2013-2017 (Source: Ministry of Cooperatives and SMEs, processed)

The improvement of economic growth in East Java Province in 2013-2017 was inversely proportional to the trend in interest rates in East Java Province in the same period. In general, credit interest rates in East Java Province in 2013-2017 had fluctuated since 2014 with a declining trend.

Fig. 5: Interest Rates in East Java Province in 2013-2017 (Source: Bank Indonesia, processed)

The number of workers in East Java Province in 2013-2017 had increased every year insignificantly. In general, the workforce is divided into two categories which are formal and informal labor. Based on data on labor in East Java Province in 2013-2017, the number of informal workers still dominated when compared to formal workers. Informal labor is one of the alternative solutions in the industrial world along with the rapid influence of globalization in the economic process as a company response to all existing labor regulations (Hussmanns, 2004). Therefore, the high number of informal workers in Indonesia must be balanced with government efforts to improve the provision of social security and improve the quality of informal workers.

Fig. 6: Number of Labor in East Java Province in 2013-2017 (Source: Ministry of Manpower, Processed)

If it is seen from the data, Inflation in East Java Province in 2013-2017 experienced a fairly fluctuating trend. The peak in 2014, East Java Province had a large inflation which was equal to 7.77. The high level of inflation is influenced by rising subsidized fuel prices (BBM) as one of the government's policies in the economic field.

Fig. 7: Inflation Rate in East Java Province in 2013-2017 (Source: Bank Indonesia, Processed)

All variable will be measured by using panel data regression to find out the relationship between variables with one another. In this research, the first process undertaken is the process of transforming data and selecting the best panel data model in drawing conclusions in research. The data transformation process is carried out to equalize the unit scale in each variable. Therefore, in this research, all data on all variable is transformed into logarithms (log).

The panel model selection is conducted to obtain the best model from the three existing panel data models, namely: Common Effect Model, Fixed Effect Model, Random Effect Model using eviews software 9. In the process of selecting the best model is carried out with two test models which are the chow test and thirst test. A chow test is performed to choose the best model between the Common Effect Model and the Fixed Effect Model. If the Fixed Effect Model is the best model, then the next

test will be conducted with the hausman test to test the best model between the Fixed Effect Model and the Random Effect Model.

Table 1: Selecting The Best Panel Model

Model test	Result	Information
Common Effect Model vs *Fixed Effect Model*	F(588.400954) = Chi-square (924.609526) Value Prob 0.0000 < α 0,05 so H0 is rejected, H1is accepted. It means that *Fixed Effect Model* fits	Chow test H0 is *Common Effect Model* H1 is *Fixed Effect Model*
Fixed Effect Model vs *Random Effect Model*	Chi-square = 0.000000 Value Prob 1.0000 > α 0,05 so, H1 is rejected, H0 is accepted. It means that *Random Effect Model* fits	Uji Hausman H0 is *Random Effect Model* H1 is *Fixed Effect Model*

Source: Statistic output result of Eviews9

In chow test, it is obtained the result that a probability value of 0.0000 <α 0.05 then H0 is rejected and H1 is accepted. It means Fixed Effect Model is appropriate . Next, hausman test is performed and the results are obtained that the value of Prob 1.0000> α 0.05 then H1 is rejected and H0 is accepted. It means that Random Effect Model fits. After conducting the two tests, it is determined that the Random Effect Model is an appropriate model to be used in this research to see the contribution of each variable in the research. Furthermore, testing the classical assumptions of the selected model is needed to ensure that the existing model can be used as a reference to assess real conditions. The classic assumption test in the Random Effect Model is carried out through a multicollinearity test.

Table 2: Multicollinearity Test

	LOGKOPPESANTREN	LOGTKIINFORMAL	LOGSUKUBUNGA	LOGINFLASI
LOGKOPPESANTREN	1.000000	-0.068861	0.488919	-0.104069
LOGTKIINFORMAL	-0.068861	1.000000	-0.114780	0.577281
LOGSUKUBUNGA	0.488919	-0.114780	1.000000	-0.150988
LOGINFLASI	-0.104069	0.577281	-0.150988	1.000000

Source: Statistic output result of Eviews9

From the result of classic test above, it can be seen that there are no problems related to multicollinearity because the value of the correlation between independent variables <0.8. Thus, data can be concluded to represent the reality that occurs in the field and it can be continued in the process of further data analysis. After going through the results, the panel data regression equation with the Random Effect Model in this research are seen below:

LOGGDP = 11.36302 + 0.164118*LOGKOPPESANTREN + 0.092864*LOGTKIINFORMAL - 1.022606* LOGSUKUBUNGA - 0.137082*LOGINFLASI

Prob (F-Stat) 0.000000; t-stat (P-Value): LOGKOPPESANTREN (0.0518), LOGTKIINFORMAL (0.2246), LOGSUKUBUNGA (0.0000), LOGINFLASI (0.0000).

LOGGDP is East Java GRDP Growth in 2013-2017 based on business fields (Rupiah); LOGKOPPESANTREN is the Growth in the Number of Pesantren Cooperatives per Regency in East Java in 2013-2017 (units); LOGTKIINFORMAL is the Growth in the Number of Informal Workers (Units); LOGSUKUBUNGA is the Growth of Interest Rates in East Java in 2013-2017 (Percentage); LOGINFLATION is the Growth Rate of Inflation in East Java in 2013-2017 (Percentage).

Based on the p-value in the F-Stat of 0.000000 which indicates a value smaller than 0.05, all the independent variable has a significant effect on the dependent variable. Interpretation of the results of the calculation of statistical data is seen partially through the t test. Based on the results of these calculations, it is concluded that the number of pesantren cooperatives has a significant influence on economic growth in East Java Province of 0.0518 with a coefficient value of 0.164118. This means that every increase in the number of active pesantren cooperatives will positively contribute to improving the economy of East Java Province through increasing the amount of GRDP based on business. In addition, based on a p-value of 0.0000 for the variable interest rates and the inflation rate, it can be concluded that both of them also have a significant negative effect on economic growth in East Java Province. While the variable number of informal workers has an insignificant effect because the p-value is greater than 0.05 or equal to 0.2246.

Analysis of The Effect of Pesantren Cooperatives Number Growth toward Economic Growth in East Java Province

Pesantren has a great economic potential to support the economic improvement of the surrounding area which ends in the goal of improving the community welfare. A pesantren which successfully develops economic ventures and becomes a role model for pesantren economic development in Indonesia is the Pesantren Sidogiri in Pasuruan District, East Java Province. Sidogiri Islamic Boarding School is currently successfully developing an economic enterprise based on Pesantren cooperatives. This originated from the idea of developing a pesantren cooperative, with the Baitul Maal wa Tamwil (BMT) Syariah Muamalah Cooperative model Masholihul Ummah (MMU) with an initial capital of IDR 13,500,000, which was collected from 200 students (Mursyid, 2011). The Sidogiri Islamic Boarding School Cooperative can develop rapidly by utilizing students and alumni network spread across 11 provinces in Indonesia through the BMT Sidogiri Integrated Joint Business since 1997. Evidently, the current BMT turnover owned by the Sidogiri Islamic Boarding School is able to reach IDR. 19 Trillion with assets of IDR. 2.6 trillion.

Based on the results of panel data regression with the Random Effect Model, pesantren cooperatives are the most contributing variables compared to other variables in this research to improve the economy of East Java Province as measured by the value of district/city GRDP. This is indicated by the p-value of 0.0518. This means that there is a significant positive effect between economic growth and the number of pesantren cooperatives in East Java Province. The magnitude of the influence of the number of pesantren cooperatives on economic growth in East Java Province with a coefficient value of 0.164118. It means that the 10% increase in the number of pesantren cooperatives will have an impact on economic growth of 1.64118% in East Java Province.

Pesantren cooperation are able to perfect the role of SMEs as micro-institutions in the midst of the conditions and threat of the crisis in Asia. BMT Cooperative as a community-based strategic micro institution is able to take a position as an initiative of Islamic microfinance institutions in Indonesia, which is able to be an alternative source of finance for SMEs in obtaining credit (Antonio, 2011). With the growing popularity of the concept of Islamic economics in Indonesia, the Islamic financial scheme run by Pesantren will be able to fill a strong strategic position to support the development of the Islamic banking industry and strengthen the national economy.

Analysis of The Effect of Informal Labor Number Growth toward Economic Growth in East Java

Labor is an important component in the process of producing goods and services. However, along with the high economic demands of a region especially after the monetary crisis, the definition of labor also begin to develop in two categories which are formal labor and informal labor. The trend of the development of informal labor is currently increasing. The low demands on companies' obligations to fulfill labor rights make the informal labor category an alternative employment solution which is widely taken by companies.

Through the calculation result of panel data regression with Random Effect Model in this research, it shows that informal workers have a p-value of 0.2246. It is greater than the error tolerance level of 5%, the null hypothesis is accepted. This means that there is no significant effect between the number of informal workers and growth in East Java Province in 2013-2017. In addition, in this research, there is a negative correlation or relation between the number of informal workers on the economic growth of East Java Province. This is indicated by the coefficient value of 0.092864. This means that an increase in the growth of the informal labor of 10% will have an impact on economic growth of 0.92864% in East Java Province. This is also a labor problem which not only occurs in East Java Province but also employment problems nationally. On the one hand, the existence of informal workers is one alternative to reducing unemployment, but on the other hand, informal workers also do not have a contribution in the economy because they do not have the obligation to pay taxes even though the amount of income is included in the income tax category (PPh). Thus, the increase in the number of informal workers does not significantly affect the economic improvement of a region.

The research about informal worker in developing country had been conducted by Onwe with the Nigerian research locus as one of the developing countries in Africa. Informal workers constituted a percentage of 21% of the total workforce in Sub Saharan countries in Africa and 38% of GDP in Nigeria (Onwe, 2013). However,The Nigerian government has not responded positively to the existence of the informal sector in the existing employment structure, as evidenced to date Nigeria has not started a clear policy on efforts to encourage the growth of the informal sector to improve its national economy (Onwe, 2013).

Analysis of The effect of Interest Rate Growth on Economic Growth in East Java Province

Low lending interest rates will encourage people to take out loans to make investments. Investment will be able to create economic activity in the community and increase employment. An increase in employment will affect the increase in people's income which creates prosperity and good economic growth for an area.

Based on the calculation of panel data regression with the Random Effect Model in this research, the interest rate in East Java Province in 2013-2017 showed a p-value of 0.0000 smaller than the error tolerance level of 5%, the null hypothesis was rejected. This means that there is a significant negative effect between interest rates on economic growth in the province of East Java. In addition, the results of the calculation of panel data regression in this research indicate the value of correlation or negative relation between interest rates and economic growth in East Java Province. This is indicated by the coefficient value of -1.022606. This means that an increase in loan interest rate growth of 10% has an impact on the decline in economic growth of 10.22606% in East Java Province. This is in line with the findings of previous research conducted by Harswari and Hamza that interest rates had a significant negative impact on GRDP/PDRB in 20 Asian countries in 2006-2015 (Harswari and Hamzah, 2017). Besides, in this research, influence is also mentioned that interest rates will directly affect the increase or decrease in a country's GDP and inflation (Harswari and Hamzah, 2017).

Analysis of The Effect of Inflation Rate toward Economic Growth in East Java Province

In East Java Province, the inflation rate in 2013-2017 was quite volatile. This condition was then measured as one of the variables to see the effect on economic growth. In this research, based on the results of the calculation of panel data regression with the Random Effect Model shows that inflation has a p-value of 0.0000 greater than the error tolerance level of 5%. The null hypothesis is rejected. This means that there was a significant negative effect between the inflation rate on economic growth in East Java Province in 2013-2017. In addition, in this research, there is a negative correlation between inflation and economic growth in East Java Province. This is indicated by the coefficient value of -0.137082. This means that an increase in inflation of 10% has an impact on the decline in economic growth of 1.37082% in East Java Province. This condition is relatively more unique when compared to general conditions, in which the controlled inflation rate will contribute to economic growth.

Negative effect between inflation rate toward economic growth does not only occur in East Java Province, but also occurs in other regions and even in other countries. This condition is inline with previous research related to inflation. In a previous research by Kasidi and Mwakanemela related to inflation, it also mentioned that the inflation rate in Tanzania in 1990-2011 had a negative correlation and impact on economic growth in the region (Kasidi and Mwakanemela, 2013). This condition is affected by several things, one of them is because people tend to reduce spending as a form of caution against the risk of high price increases during inflation. Thus, it will obviously affect the decline in economic activity and then also affect economic growth. Besides, if reviewed from the supply side, inflation will cause wage increases and price increases for goods, especially imported goods. This has resulted in a decrease in people's purchasing power and reduced investor interest, which has a negative impact on the economic growth of a region because the economic wheels are sluggish and hamper development (Sutawijaya, Zulfahmi. 2012).

Conclusion and Recommendation

Based on the calculation result of statistic data with panel data regression method with Random Effect Model, it can be concluded that there are three independent variables whcih have a significant effect on the economic growth of East Java Province in 2013-2017 as follow; the growth variable in the number of pesantren cooperatives, the variable interest rate growth, and the inflation rate growth variable. The growth variable of pesantren cooperatives has a positive and significant effect toward economic growth in East Java Province as seen from the GRDP based on business, with a p-value of 0.0518 and a coefficient value of 0.164118. It means that the 10% increase in the number of pesantren cooperatives will have an impact on an economic increase of 1.64118% in East Java Province. The variable interest rate growth and inflation rate growth have a significant p-value of 0.0000 but contribute negatively to economic growth in East Java Province. The variable of interest rate growth and the growth of the interest rate inflation and the inflation rate have coefficients of -1.022606 and -0.13082, respectively. This means that the growth in interest rates and growth of the inflation rate of 10% has a significant negative effect on economic growth of -10.22606% and -1.37082%, respectively. While the variable number of informal workers has an insignificant effect with a p-value of 0.2246 with a coefficient of 0.092864. In addition, the p-value in the F-Stat in this study is 0.000000 or smaller than 0.05. It can be concluded that all independent variable has a significant influence toward the dependent variable.

Based on the result of the research, there are some recommendations as follow:

1) The optimization of cooperative development by providing licensing facilities in accordance with regulations and easy access to financial capital for pesantren cooperatives; 2) In the future, the government needs to increase the protection of informal workers, one of which is through social security for informal workers. In addition, to encourage the trend of increasing the formal workforce, the government needs to increase the amount of training and certification of the workforce: and 3) Government policies are needed in the form of lowering lending rates to increase investment and economic activity in society.

The Use of Controlling in Companies Operating in Poland

Joanna DYNOWSKA

University of Warmia and Mazury in Olsztyn, Olsztyn, Poland
E-mail: joannan@uwm.edu.pl

Abstract

Circumstances of the market economy have increased the importance of new tools of management, especially controlling, that are necessary to implement in most, if not all, organizations. The use of controlling systems by European enterprises has given them a competitive advantage in their respective markets. At the same time, a lack of controlling has led to a wide gap between Polish enterprises and other European enterprises that have used controlling systems with success. There are many definitions and concepts of what controlling is and what it entails. This study aims to (1) analyze the manifestation and the definition of controlling in the literature and practice as well as to (2) answer the question: What is the current state of controlling practices in Polish companies? Based on a review of literature and the research, controlling may be defined as a tool of management that enables managers to steer a company based on continuous monitoring of company metrics and results, that is aligned with the company objectives through a coordinated management system, and that bridges planning and supervisory functions with information-sharing systems. The results of the research indicate weak implementation of controlling in companies operating in Poland. Over 85% of those surveyed claimed that they knew about controlling, but only 34.9% of them implemented it. Most that used controlling were large, foreign-capitalized companies with high revenues.

Keywords: Concept of Controlling, Management Accounting, Implementation of Controlling

Introduction

There are many views on the best business management tools to adjust the activities of enterprises to the realities of a market economy. Nevertheless, both theorists and practitioners agree that management needs effective tools to ensure long-term viability of a company and to achieve planned objectives. One management tool that satisfies the above criteria is controlling. Properly applied, controlling allows companies to respond quickly to changes in the environment through comprehensive coordination of objectives, decisions, and actions.

Historically, the use of controlling has been most prevalent in Germany and other German speaking countries. The adoption of controlling occurred in Poland in the 1990s, mainly due to the increasing size of companies and the globalization of markets. Although in recent years controlling has been associated with management accounting, the term has not officially been promulgated in the literature and it is still defined differently by different authors. Attempts made to unequivocally define controlling have not produced the expected results. A concrete definition of controlling has even eluded the greatest experts in the field. P.R. Preißler notes that "everyone knows what controlling means and what it should be, but everyone thinks about this a little differently (Preißler, 1985)." A. Zünd confirms: "Other business environment, other definition of controlling" (Zünd, 1978). The myriad of definitions helps cloud the distinction between controlling as a function and controlling as a position in the organizational structure. Furthermore, in practice, there are even more facets and forms of controlling than those described in the literature.

The aim of this paper is twofold. First, it provides an answer to the question of what is (the core of) controlling from the point of view of research practice and corporate practice and if it has developed differently from international management accounting research. Second, it analyses the use of controlling in companies operating in Poland. The research of the concept and use of controlling is facilitated by two types of empirical material, a quantitative analysis of journal publications of

controlling scholars and qualitative questionnaire interviews with, mostly, board members of the surveyed companies.

The research tested the following two hypotheses:

Hypothesis 1: Controlling is ambiguously formulated and addressed in the subject literature, as well as in the practices of Polish enterprises.

Hypothesis 2: Controlling is utilized mainly in large companies with infusions of foreign capital.

Theory

The Genesis of Controlling

Controlling's roots are in the West. The first controllers appeared in England in the public sector in the XV century as part of the royal court (Weber, 1999). The term "controlling" appeared for the first time in the Constituency of USA in 1778 when Congress established the rules of appointing a comptroller, treasurer, and auditor (Wojtania, 1999). In private institutions, the term "comptroller" appeared in the Atchison, Topeka & Santa Fe Railway System Company in 1880 (Weber, 2001). Controlling was gradually adopted by other countries in the second half of the 20th century when American corporations set up branches in Europe. Perhaps the biggest influence on the development of controlling was the oil crisis in the 1970s. Controlling was adopted by companies to help them reduce their costs and improve their efficiency to remain viable.

Nowadays controlling is predominantly developed and applied in Germany and other German-spoken countries, where it is used not only by big corporations but also by medium and small enterprises. Poland was relatively late in adopting controlling. Enterprises in Poland began to implement controlling systems in the 1990s in response to corporate growth and market globalization, which considerably complicated management processes. At first controlling had the function of control and was used to provide oversight in corporate finance. Now controlling tasks are so diverse and dynamic that it is difficult to pinpoint a single interpretation of controlling in theory and practice.

Definitions and Interpretations of the Concept of Controlling

Controlling is an interdisciplinary concept, which uses not only the achievements of management, accounting, and financial analysis, but also other components of the broader disciplines of economics. Both in literature and in practice, this term has different economic meanings. The many diverse opinions on the concept of controlling have contributed to the large number of controlling definitions, and these definitions (opinions) are constantly evolving in concert with transformations within enterprises and markets. For the purpose of this research, only some of the many interpretations and approaches to the concept of controlling will be considered.

Table 1: The most common meanings of controlling appearing in the literature

Author	Meaning	Interpretation
Marciniak, 2004	**conception of management**	way management uses philosophy and ideas of controlling in decision-making processes
Hahn, 1987	**philosophy of management**	involves posing clearly defined objectives, marking out paths to achieve them, and supervising their implementation using the numerical tools of accounting and finance
Horvath, 1998, Brzezin, 2001, Grudzewski, 2001,	**system, subsystem,**	aimed at optimizing financial results and value of the company; creates and coordinates planning, control, and supply of information, thereby

Goliszewski, 1990, Pocztowski, 1994, Nowak, 2003, Chaberek, 2001, Zadora, 1996 , Sikorski, 1993	**or model of management**	facilitating adaptation and coordination of entire system from standpoint of achieving objectives
Krüger, 1979, Vollmuth, 1993, Mann and Mayer, 1998, Janik, 1999, Haus and Nowosielski, 1995	**system of steering or supporting management**	supports managers in steering a firm in terms of objectives and performance monitoring; compares actual results with planned objectives and takes corrective actions to prevent/mitigate/eliminate problems
Wierzbicki, 1995	**system of coordination**	integrates activities of planning and control, collects and processes information, and organizes, selects, and trains personnel; implements decisions and actions of managers at all levels
Günter, 1985	**system of management control**	ensures integrity of enterprise-wide objectives and efficient measurement and assessment of the results of operations by comparing the current state of desired (planned) with current state of existing
Dellmann, 1996, Kloock, 1997, Jarugowa, 1997, Sobańska, 2003, Dobija, 1997	**system of management accounting**	deals with steering an enterprise and solving coordination problems between management subsystems via management accounting tools
Preißler, 1992, Hülsenberg and Wróbel, 1995, Knop and Sawicki, 1994, Sierpińska, 2004	**tool of management**	supports process of decision-making and process of steering an enterprise's activities towards determined targets through coordination of planning processes (distribution and control) and development of reliable analytical information systems
Czubakowska, 2004, Penc, 1994, Dźwigni, 2003, Mielczarek, 1999	**method of supporting management**	facilitates information-sharing and coordination of business functions; involves creation and modification of planning systems; creates measurements of company's financial situation and prepares information for decision making
Komanderek, 2002, Weber, 1999	**function of management**	combines elements of planning, disposal, inspection, analysis, and information supply and provides corporate management rationality through efficient use of resources with set goals
Kerzner, 1989	**process of management**	includes measurement of economic values, assessing level of achieved objectives, identification of causes of deviations from targets; corrects unfavorable trends and sustains favorable trends
Wojtania, 1999	**technology of management**	allows control over process of generating a profit and of making company navigable (subject to will of managers)
Steinmann and Schreyögg, 1986, Schweitzer and Friedl, 1992	**managerial task**	provides access to information for coordination of company management to ensure achievement of corporate goals through shaping organizational structures/processes and through securing agreement on the roles of staff and supervisors

Kwiecień, 1993	**discipline of management science**	coordinates planning, controlling, and supplying of information and facilitates steering of enterprise's activities
Saunders, 1996	**management information system**	directs processes in an enterprise using mechanisms of management accounting, budgets, cost centers, and revenue, etc.
C. P. Zeithalm and T. P. Bateman, (Fjałkowska, 2003)	**style of communication between groups**	directs ideas and human behavior towards achieving goals
Source: own elaboration.		

Based on a study of published literature, controlling is a broad and ambiguous term. Individual authors draw attention to varying aspects of a controlling system. For some, controlling is a system of steering a company. For others it is a tool of management or a function supporting management. Controlling is also known as a system, subsystem, or "oversystem" of management. Other conceptions of controlling involve the establishment of the company's goals and/or supervision of achieving the company's goals, both short and long term. There are also definitions classifying controlling as a process of management.

Most definitions of controlling are results-focused and assign dominant importance to coordination and the steering process. Furthermore, its importance in decision-making processes and information-sharing across the enterprise is often emphasized. In some definitions, controlling's role in the creation, coordination, and management of enterprise information is underlined. Other definitions of the term emphasize the functional aspects of controlling. In many definitions, controlling represents the overall coordination of information for planning, execution, and control. There are also definitions of controlling categorizing it as a process, function, philosophy, model, or concept of management. In defining a controlling system, it is often referred to as "a system of control over the execution of tasks in isolated responsibility centers of the company".

Controlling and Management Accounting

Some authors relate controlling to accounting, financial accounting as well as managerial accounting. Others are of the opinion that controlling has a boarder meaning. Furthermore, more and more authors equate contemporary controlling with management accounting.

According to A. Jarugowa, controlling is a modification of management accounting (Jarugowa and Nowak, 1997). A. Jarugowa contends that the goals, tasks, methods, and techniques of accounting and controlling do not have any noticeable differences (Jarugowa, 1995). Because controlling has evolved concurrently with management accounting, these two systems have many common features. Contemporary controlling does not differ considerably from management accounting. Often the terms controlling and management accounting appear together or are treated as synonyms. I. Sobańska shares this opinion and believes that controlling is a modification of management accounting. She contends that controlling and management accounting differ only in the presentation of knowledge and in the nature of these disciplines. To paraphrase her, controlling has a more complex structure and is connected with functions realized in an organization, e.g., financial controlling, personnel controlling, and ecology controlling. Controlling usually involves creating new roles for and/or expanding the reach of traditional management accounting (Sobańska, 2003). This is also confirmed by the research conducted by J. Płóciennik-Napierałowa, who demonstrates that the implementation of controlling usually involves the creation or expansion of scope of management accounting (Płóciennik-Napierałowa, 2001). Also, information systems developers often describe controlling as a variation of management accounting with elements of steering, regulation, and strategic management.

The identification of operational controlling as being associated exclusively with accounting management is quite common and is also emphasized in foreign literature. K. Dellmann's conception of controlling is based on accounting, with key functionality related to the planning, controlling, and coordination processes through the use of accounting systems (Dellmann, 1996). Similarly, J. Kloock, who essentially equates controlling with accounting, describes controlling as a subsystem having an organizational independence and competence to solve the existing problems of coordination between the subsystems of management via tools of management accounting (Kloock, 1997). Conversely, D. Schneider believes that controlling can be fully replaced by "planning and controlling" cost accounting (Schneider, 1991).

A deep insight into management accounting in German-speaking countries was presented by A. Wagenhofer (2006). German researchers dealing with the question 'What is Controlling?' have pointed out that the notion of 'controlling' stands for what in the Anglo-Saxon world would be called management accounting, and it reflects cultural differences between Germanic and Anglo-Saxon management accounting practice (Messner et al., 2014). Thus, controlling is sometimes called a German version of management accounting, combined with elements of steering, regulatory oversight, and strategic management (Jarugowa, 1995).

Sharman emphasizes that in many German-spoken countries there is a distinct organizational division within organizations (Sharman, 2004). Companies generally have a department responsible for financial accounting and a department responsible for controlling (Sharman and Vikas, 2004). Also, K. Zehetner and S. Eschenbach (2017) admit that although the goals of management accounting and financial accounting are the same – to provide the public with a true and fair view of corporate performace and to support managers' decisions – the managerial as well as financial accounting programs within German-speaking countries are materially different as compared to their United States counterparts.

A research study conducted by K.R. Krumwiede shows that non-German companies pay more emphasis on financial accounting than the German ones. American companies are more interested in capital markets and in strengthening their financial accounting systems than in implementing advanced cost accounting systems. In Germany, the number of "management accountants" and "controllers" is higher than the number of accountants who deal with financial accounting reports. Recently, a tendency to imitate the American model in combining employees and data in one department and system has been observed in Germany and other countries (Krumwiede, 2005). German companies emphasize management accounting more, and U.S. companies emphasize financial reporting accounting practices (Krumwiede, Suessmair, 2007&2008).

Researchers examining the German-speaking literature on management accounting, as it pertains to academic legitimization and the establishment of the discipline of controlling, suggest being cautious when using the notion of a 'discipline'. The authors have argued that different social and institutional contexts may result in different trajectories of a particular discipline in different countries. However in this case, there is no need to regard Germanic controlling and U.S. management accounting as different disciplines (Messner et al., 2014). The differences between German and US management accounting were also outlined by Portz and Lere (2010) within the context of how culture impacts the organizational and methodical aspects of cost accounting system design.

On the other hand, a confluence of accounting systems can be observed in business practice. K. Zehetner and S. Eschenbach (2017) have identified three major catalysts for this process of convergence: (1) the development of ERP systems, (2) regulatory requirements, and (3) changes in management thinking. In the practice of large worldwide companies (based on German and Anglo-American capital, where the two concepts collide), there is no distinction between the titles and duties of controllers and management accountants. Typically, the terms "controllers" and "management accountants" are used interchangeably (Sobańska, 2003). Similarly, the terms "controlling" and "management accounting" are used interchangeably (Sobańska, 2002). Also the IFAC considers the functional area defined as "management accounting" in the English-speaking countries to be known in Continental Europe as controlling, analytical accounting, or internal accounting. All of the systems that

make up this area were developed on the basis of cost accounting system and realize similar tasks, but differ in scope and degree of integration (IFAC, 1998).

When relating the differences between management accounting and controlling, many authors point out the areas of expertise, tools, functions, tasks, and goals that do not coincide. As indicated by W. Brzezin, management accounting is a major instrument (subset) of controlling (Brzezin and Dziewiątkowski, 2001). Similarly, when describing his classification of instruments for controlling, D. Hahn lists financial accounting and management accounting as his primary tools (Hahn, 1994). The definition of controlling by W. Grudzewski also categorizes management accounting as one of the tools of controlling, along with management by objectives, economic forecasting techniques, and elements of computer science and praxeology (Grudzewski, 2001). Similarly, P. Olech provides a list of controlling tools, including management by objectives, planning, and management accounting (Deyhle and Olech, 1997).

A. Karmanska references only the ex-ante dimension of management accounting, but emphasizes both the retrospective (ex-post) and prospective (ex-ante) nature of controlling, thereby indicating a wider range of controlling functions compared to management accounting (Karmańska, 2006). An opponent of equating controlling with accounting management is also M. Sierpińska, who is of the opinion that accounting is (only) effectively the information system for controlling (Sierpińska, 2004). H. Błoch believes that equating controlling and management accounting results in too much focused attention on documenting past events, i.e., neglecting the future-oriented characteristics of controlling (Sierpińska, 2004).

The above mentioned definitions lead to the observation that initially controlling was a pure accounting concept, involving the functions: cadastral, revision, collaboration with external revision, tax, and interpretation (Horvath, 1979). By the end of the twentieth century, the literature distinguished the concepts of controlling and management accounting as separate areas of knowledge. As a management tool, controlling uses the same tools, methods, and techniques as management accounting, but/and realizes similar functions, tasks, and goals. In recent years, a holistic understanding of controlling as an approach to management has appeared. Similarly, controlling has been described as a management style. In this sense, controlling is not only one of the tools of management, but is also a business management concept.

Management functions included in controlling may create discrepancies in interpreting the scope of the impact of controlling, its functions, and the role it plays in the enterprise. It may also lead to an equalization of the concepts of controlling and enterprise management. According to S. Nowosielski, equating the two concepts is not appropriate because controlling does not have any functionality for governing, it only supports managerial functions (Nowosielski, 1998). M. Urbanowicz is also critical of the belief that controlling is an oversystem of the system of management (Urbanowicz, 1997). Differentiating controlling from management is not practical because controlling does not have any stand-alone functions, it only supports managerial functions (Kużdowicz and Kużdowicz, 2012). The belief that controlling oversees management is contrary to its intended function, i.e., a process and tool of management.

Based on a review of the literature and the theoretical aspects of controlling referenced therein, a new definition of controlling has been formulated by the author of this paper. *Controlling is a tool of management that enables managers to steer a company based on continuous monitoring of company metrics and results, that is aligned with the company objectives through a coordinated management system, and that bridges planning and supervisory functions with information-sharing systems.* As a decision support tool, controlling provides executives with the instruments and information necessary to perform the work of planning, monitoring, and control. The growing demand for information for management purposes in the modern market economy and the direction of change in accounting determined by the development of international accounting rules for financial reporting promote conditions conducive to, or even necessary for, the implementation of controlling (management accounting) in enterprises.

Empirical Research Results

The main source of empirical data for the research study was a company survey. The survey targeted firms with at least 50 employees in Poland. Questionnaires were sent to the 257 randomly chosen organizations, of which 173 answered the questionnaire. After the initial analysis, 169 firms were selected for further consideration.

The Implementation of Controlling

Most published literature touts the numerous advantages of controlling usage as described and confirmed by the results of companies in German-spoken countries; however, the situation in Polish organizations seems to be more complex. In more than half the surveyed companies, the term controlling was known but it was not used by these organizations (Table 2).

Table 2: Implementation of controlling systems in the analyzed firms

Is "controlling" known and used?	**n**	**%**
Known and used in a firm	59	34.9
Known and not used in a firm	86	50.9
Unknown	24	14.2
All analyzed firms	**169**	**100**
Source: own elaboration.		

To determine whether or not there was a correlation between familiarity and use of controlling with other company characteristic variables, the chi-square statistic was used. The results show that factors that condition controlling usage include: form of ownership, value of revenues, and value of assets. ($p<0.05$). Cramer's V coefficients indicate a weak strength of dependence (Table 3).

Table 3: Use of controlling systems vs. characteristics of the analyzed firms – the assessment of stochastic independence

Analyzed characteristics	**Is "controlling" known and used?**		
	χ^2	**P**	**V**
Legal-organizational form	17.470	0.064	-
Number of employees	9.383	0.058	-
Ownership form	**21.135**	**0.006**	**0.250**
Kind of business activity	5.819	0.213	-
Profitability	7.973	0.436	-
Revenues	**22,636**	**<0.001**	**0.262**
Value of Assets	**32,125**	**<0.001**	**0.307**
Number of offered products	3.350	0.764	-
Source: own elaboration.			

The conducted research shows that the presence of foreign capital is often a key factor in the use of controlling in a company. When foreign enterprises had a partial or whole stake in the analyzed firms, the parent firms generally imposed their modern tools of management on their subsidiaries. So foreign capital, in addition to privatization in medium and large enterprises, was shown to be positively correlated with controlling implementation in these companies (Fig. 1).

Fig. 1: Use of controlling systems vs. form of ownership

Source: own elaboration.

Cramer's V coefficient (V = 0.262) indicates a weak association between the use of controlling and the value of revenues. Nevertheless, there is a general tendency for companies with higher revenues to use controlling (Table 4). Only 22.2% of companies with revenues up to 800 thousand euro used controlling, while 55.6% of companies with revenues exceeding 5 million euro implemented some form of controlling.

Table 4: Use of controlling systems vs. revenues

Value of revenues [M euro]	Controlling known and used in a firm		Controlling known but not used in a firm		Controlling unknown		All analyzed firms	
	N	%	N	%	N	%	N	%
up to 0.8	6	22.2	14	51.8	7	25.9	27	100
0.8 - 2.5	12	23.1	30	57.7	10	19.3	52	100
2.5 -5	10	32.3	16	51.6	5	16.1	31	100
> 5	30	55.6	24	44.4	0	0	54	100
Source: own elaboration.								

There is also a weak association (V = 0.307) between the use of controlling and the value of assets. A higher interest in controlling was recorded among companies whose value of assets exceeded 5 million euro. Among this group, 70.3% of the surveyed companies used controlling (table 5).

Table 5: Use of controlling systems vs. value of assets

Value of assets [M euro]	Controlling known and used in a firm		Controlling known but not used in a firm		Controlling unknown		All analyzed firms	
	N	%	N	%	N	%	n	%
Up to 1.5	15	21.7	38	55.1	16	23.2	69	100
1.5 – 2.5	7	25.9	17	62.9	3	11.1	27	100
2.5 – 5	10	31.2	19	59.4	3	9.4	32	100
> 5	26	70.3	10	27.0	1	2.7	37	100
Source: own elaboration.								

Linking knowledge and application of controlling with number of employees showed no significant relationship (p = 0.058). Graphical representation of the results (Fig. 2) reveals that the greater the number of employees, the lesser the ignorance about the nature of controlling and the greater the application of controlling.

Fig. 2: Use of controlling systems vs. size of firm

Source: own elaboration.

Firms that use controlling are mainly large and medium enterprises. Although small companies indicate that they are familiar with controlling, they are not fully conscious of its usefulness in management (Fig. 2). In large, multi-plant companies, typically those operating on an international scale with a diversified manufacturing program, controlling allows the organization to function in a more integrated and coordinated manner, ensuring flexibility and an enhanced ability to prosper and grow.

As for the relationship between the use of controlling and ROE (Fig. 3), the ratio between the number of companies that use controlling and the number of firms that do not is similar in each income group (with the exception of the three companies with the highest profitability). However, in the group that did operate under a deficit, the smallest subgroup was companies that used controlling (31.8%).

Fig. 3: Use of controlling systems vs. ROE of the firms

Source: own elaboration.

The Interpretation of Controlling

Due to the disparate definitions of controlling, with discrepancies in the interpretation of the scope of impact of controlling, its tasks, and its role in an enterprise, how controlling is understood by business practice was investigated.

Table 6: Controlling in the understanding of the surveyed companies

CONTROLLING INTERPRETATION	N	%
A set of instruments helpful in management	44	30,3
Budgeting	28	19,3
Information system	23	15,9
Control tool	23	15,9
Position in the organizational hierarchy	4	2,7
Profit control system	4	2,7
Philosophy of management	2	1,4
Total surveyed companies familiar with the term „controlling"	**145***	**100**

Source: Own study
* The total does not match the sum due to the possibility of choosing several response options.

The description of various practical solutions used in enterprises in Poland shows that controlling is most often understood as a results-oriented management support system. The survey results show that only 2.7% of the surveyed companies equate controlling with a profit control system (table 6). Most often, enterprises view controlling as a set of instruments helpful in company management or budgeting system. Identifying controlling with budgeting results in focused attention on activities related to the processes of planning the enterprise's economic goals and the subsequent procedures used to assess the compliance of planning assumptions with actual results. However, this understanding of controlling leads to an oversimplified view that neglects other areas of activity under the purview of controlling. Controlling is relatively often associated with an information system or control tool. Rarely, companies identify controlling only with a position in the organizational hierarchy or treat it as an expression of the company's policy, philosophy, or culture.

The average results presented above differ when segmenting by the size of the enterprise. In the case of small companies, controlling tends to fulfill more of a planning and control function and less of a management function. Similarly, the significance of a controlling as a management function tends to increase in concert with the size of the enterprise. In terms of acheived results, companies that were more profitable or that had relatively high revenues were more likely to view controlling as a profit control system and/or a set of instruments helpful in management. Companies that were less profitable or had relatively low revenues were more likely to view controlling as a control tool.

Many enterprises have implemented a controlling system as a result of corporate financing by large Western companies and corporations. Therefore, the interpretation of controlling may depend on the origin of the enterprise's capitalization. As shown by the research, the increase in foreign capital causes a broader interpretation of the concept of "controlling." And so those surveyed enterprises that are completely owned by Western companies, which represent almost half of the sample, view controlling as a control tool, a set of instruments helpful in management, an information system, and a budgeting system. Further, the interpretation of controlling depends to a large extent on the particular Western country. German financed companies tend to observe a link between controlling and management accounting. French financed companies tend to view controlling as a tool for coordinating planning, management, and control processes, as well as a tool for providing information.

Results and Discussion

The research enables the author to verify the hypotheses.

Hypothesis No. 1, stating that controlling is ambiguously formulated and addressed in the subject literature as well as in the practices of Polish enterprises, was supported.

The cited views show that controlling is not univocally based on the structure of management. Although a contemporary understanding of controlling is very wide, it is commonly assumed that controlling is a tool of improving the efficiency of organizations. Erroneously associating controlling with other functions or subsystems of management can be the main reason that its role is misunderstood and that there is a perceived dichotomy between controlling and management.

The term controlling has many disjunctive interpretations. Controlling definitions continuously change and evolve in concert with changes in enterprises and their environment. The interpretation of controlling also depends on the country in which it is formulated and developed. In German practice, controlling is strongly connected with cost accounting systems and is used to coordinate different parts of enterprise activities. In the USA, controlling plays a big part in the preparation of financial reports for external audiences and focuses on the effective usage of resources to foster corporate growth. In French enterprises, controlling appears in the form of analytical accounting and deals with ways to steer company activities via budgets aligned with corporate objectives. In Poland, controlling supports management mainly through the use of accounting tools.

Hypothesis No. 2, stating that controlling is utilized mainly in large companies with infusions of foreign capital was also supported.

The increasing involvement of foreign capital in Polish enterprises, due mainly to the integration of the Polish economy with the European economy, increases the need to improve how Polish businesses are managed. The study shows that the use of controlling can be seen most often in companies that are funded with foreign capital. Most of these companies are also medium or large enterprises, with (relatively) high yields, high sales volumes, and high asset values (more than 5 million euros). Many companies have implemented controlling systems as a result of mergers or acquisitions. Large parent companies, especially foreign ones, will often impose their controlling systems on satellite offices.

Conclusion

The aim of the conducted reseach is to not only contribute to the understanding of the emergnce of the field of controlling but also to expand the knowledge of its usage in Polish companies. As shown in the literature, there are a variety of views regarding controlling and what it entails. Controlling is often referred to as a system of management, an instrument of management, a support function, or a management control system. Other definitions relate controlling to a process, function, philosophy, model, or management concept. Some authors equate controlling and management accounting.

Controlling is necessary in almost every organization because it is difficult to imagine the long-term viability of a company that does not know how to adequately establish its goals and assess its achievements. However, according to the study, only 34.9% of the analysed companies have implemented it. Most that used controlling were large, foreign-capitalized companies with high revenues. The weak implementation of controlling in Polish companies, relative to its high recognition (85% of surveyed representatives of firms claimed that they knew about controlling), indicates that controlling is not only possible but also increasingly necessary in Polish enterprises. Nevertheless, implementation requires a significant corporate effort including:

- Implementation of new cost accounting systems,
- Modification of applied procedures,
- Implementation of responsibility centers,

- Training of personnel.

Polish companies still have a long way to go in first implementing controlling systems and then developing them to a level consistent with good management practices. This requires an understanding and acceptance of the system as well as full engagement in its implementation and usage. Only then can companies generate long-term value creation.

Acknowledgments

The publication was written as a result of the author's internship, Joanna Dynowska in James Madison University co-financed by the European Union under the European Social Fund (Operational Program Knowledge Education Development), carried out in the project Development Program at the University of Warmia and Mazury in Olsztyn (POWR.03.05. 00-00-Z310/17).

The Analysis of Russian Enterprises Readiness to Introduce Industry 4.0 Projects

Yuliya ASATUROVA

Peter the Great St. Petersburg Polytechnic University
Saint-Petersburg, Russia
asaturova_yum@spbstu.ru

Abstract

At present the competitiveness of the Russian economy is largely due to the successful transition in the national industry to a new digital technological level. The implementation of industrial Internet projects is becoming the main driving force of the industrial revolution and is one of the main factors in increasing production efficiency. This study analyzes the features of the development of the industrial revolution in Russia and abroad. An analysis is made of the level of readiness of Russian enterprises for the implementation of Industry 4.0 projects. The factors hindering the implementation of industrial Internet projects in the Russian economy have been identified. The priority tasks and estimated prospects for the development of the industrial Internet in Russia are formulated.

Keywords: Industry 4.0; Industrial Internet; digitalization; Russia; enterprise.

Introduction

In recent decades, the global economy is at the stage of active development of the fourth industrial revolution. In the context of the countries rivalry that has begun in the implementation of the Industry 4.0 program, the issues of transferring national industry to a digital technology platform are becoming particularly relevant. The development of projects in the field of industrial Internet will lead to an increase in the level of industrial productivity, bringing a huge economic effect both for the global economy and for the country's economy [1]. According to the World Economic Forum in Davos, the development of the main technological areas underlying cyber-physical systems, such as the Internet of things, cloud and quantum computing, big data, biotechnology, autonomous robots, virtual and augmented reality, 3D modeling and 3D printing can bring more than 30 trillion US dollars for the global economy in the next 10 years [2].

In recent years, the industrial Internet, as an integral part and the most important direction of the development of the industrial revolution, has been effectively introduced into the activities of Russian industrial enterprises [3]. Many large projects have been launched and are successfully functioning; a platform for the development of the industrial Internet is being developed. However, along with obvious successes in the development of industrial Internet in Russia, there are also some difficulties on the way of its introduction into the industry [4]. And the main problem is the lack of willingness of Russian enterprises to digitalize production processes and introduce industrial Internet technologies. The aim of this work is to analyze the current state of the Industry 4.0 concept in Russia and develop priority tasks that contribute to the development of industrial Internet at Russian enterprises. Achieving the goal requires solving the following tasks:

1. Assessment of the current state of industrial Internet development at Russian enterprises.
2. Analysis of the factors hindering the implementation of industrial Internet projects in the Russian economy.
3. Analysis of the level of readiness of Russian enterprises for digitalization and implementation of industrial Internet projects
4. Identification of tasks conducive to the development of industrial Internet in Russia.

Data and Methods

The theoretical basis of this work is the research of leading Russian and foreign scientists in the field of methodology for the development of the industrial revolution and the practice of its implementation in the economy of various countries, including in Russia. In the works of modern scientists, the tasks of the formation of the industrial revolution, the search for development paths, the study of the consequences of the impact on the economy and social life of society are solved. The general problems of the new industrial revolution are highlighted in [5, 6, 7]. In [8, 9], the impact of the Internet of things on the transformation of industrial production is investigated. The issues of the direct implementation of the Internet of things in industrial enterprises are considered in [10]. The impact of the industrial Internet on the competitiveness of various industries is estimated [11, 12, 13]. The issues of working with big data using Internet technologies are considered in [14, 28]. Studies of the socio-psychological and economic consequences of the introduction of intelligent technologies are considered in [15]. However, it should be noted that insufficient attention is paid to the analysis of the features of the development of the industrial Internet in the conditions of the Russian economy in modern literature. Assessment of the current state and prospects for the development of the Industry 4.0 concept at Russian enterprises determines the scientific novelty of the work.

The methodological basis of the study is the work of leading domestic and foreign scientists on statistics, financial and economic analysis, modern information technologies for storing and processing data. Assessment of the current state of development of the "Industry 4.0" concept at Russian enterprises is based on a comprehensive economic and statistical analysis of the state of Russian industry and an assessment of current trends in its development using methods of mathematical statistics and expert estimates. Studies were conducted on the basis of state statistical reporting. The statistical tools of the study were the methods of analytical grouping, correlation analysis, methods of mathematical forecasting and trend analysis.

Analysis of the level of readiness of Russian enterprises to implement projects Industry 4.0. is carried out on the basis of the method of assessing the maturity index of Industry 4.0, developed by the Acatech German Academy of Science and Technology [16]. Using this method allows you to set the current level of readiness of production companies to "Industry 4.0", as well as to identify areas in which further action is required. The method involves a systematic determination of the weaknesses and capabilities of the enterprise, and serves as the basis for manufacturing companies to develop an individual plan for implementing the Industry 4.0 concept, corresponding to their business strategy. Acatech Industry 4.0 Maturity Index helps determine at what stage the enterprise is currently being transformed into a developing, flexible company. The method allows you to evaluate from a technological, organizational and cultural point of view with emphasis on the business processes of manufacturing companies [29, 31]. Using this method, each company must make a strategic decision regarding the specific advantages it wants to achieve, its priorities and the sequence of appropriate measures. As a result of applying this methodology, the main weaknesses and difficulties in implementing the concept of "Industry 4.0" are identified and an action plan is developed to develop a common digital transformation strategy for the enterprise as a whole.

This methodological analysis provides the possibility of a comprehensive analysis and defines a number of guidelines that allow companies to establish what characteristics they need to develop for implementing Industry 4.0 projects. The statistical tools of the study were the methods of correlation analysis and expert assessment methods.

Results

Let us consider the features of the introduction of industrial Internet in Russia. Based on a comprehensive analysis of state statistics of the Russian Federation using methods of mathematical statistics, we can conclude that the Russian market for the introduction of industrial Internet is at the initial stage of its development. However, the proportion of the industrial segment in the Russian Internet of things market prevails. In 2016, its share was 64%, while the cross-industrial segment

occupied 20%, and the state and consumer segments about 8% [17]. This indicates good prospects for the development of industrial Internet technologies in Russia. In addition, it should be noted that the introduction of industrial Internet technologies among Russian companies varies greatly depending on the region. An analysis of the Russian market of industrial Internet of things, based on a study of the trend line of its development, showed that in 2017 it amounted to 17.9 million devices and grew by 42% compared to 2016. By 2021, the total number of Internet of things devices will grow to 79.5 million, and by 2026 - 164.7 million. The widespread introduction of the industrial Internet will be able to increase the world GDP by 10-15 trillion dollars in 20 years [18, 26].

An analysis of the readiness level of Russian enterprises for the implementation of Industry 4.0 projects based on the Acatech maturity index assessment method showed that despite a clearly expressed desire to introduce digital technologies at their enterprises, there are objective difficulties that hinder their implementation at Russian enterprises. The results of a survey of heads of companies from various sectors of the economy as a whole across the Russian Federation, interviewed in mid-2018, showed [19]:

• 32% of companies confirmed their desire to implement Internet of things technologies in their production.
• 11% of companies have already implemented projects using the Internet of things in their company.
• 57% of companies do not use IoT technology.

The results of the analysis also showed that at the moment its use is more typical for systems of automated data collection from devices at industrial facilities [20]. For example, in mechanical engineering, energy, mining. The area of inter-machine interaction is primarily developing among transport companies that effectively use navigation systems. As a positive trend, we can note the increase in the proportion of organizations that use information management systems in production [21, 27]. From 2013 to 2018, their percentage increased from 25 to 30%. First of all, their implementation is noted in the communication sectors, chemical production, electrical equipment and metallurgy [22].

The methodological analysis of the readiness of enterprises for digital transformations in accordance with the methodology for analyzing the weaknesses and capabilities of the enterprise revealed the factors that impede the integration of industrial Internet projects into production in the Russian economy [23].
Among the internal factors can be identified:

• insufficient flexibility of companies, holding back the ability to implement changes in the company in real time;
• insufficient development of business models of the company;
• lack of qualified personnel capable of servicing new technologies;
• limited funding [24].
Among external factors can be identified:
• low degree of awareness and accessibility of technologies;
• insufficiency of the normative failure base in the field of IT-technologies;
• low degree of elaboration of security issues, information protection when working with data;
• psychology and bureaucracy.

Based on the results of the above study, we formulate the priority tasks that contribute to the development of industrial Internet in Russia [25]. Thus, the priority tasks for the development of industrial Internet in the Russian Federation are:

1. Development and ensuring the availability of IoT platforms for the collection, storage and processing of data.
2. Creation of information and telecommunication infrastructure providing technological possibility of using new Internet technologies.

3. Creation and development of enterprises whose business model allows the use of IIoT technologies.
4. Creating a domestic market for connected devices capable of interacting with the IoT platform.
5. Public or public-private financing for the implementation of industrial Internet projects. Support for pilot projects.
6. Support for domestic developers of high-tech products, research in the field of creating artificial intelligence, information management systems, networking.
7. Reconstruction of the education system and training in the field of IT-technologies.
8. Development of a regulatory framework conducive to the development of new technologies, ensuring their legal legality and protection of information [30].

Conclusions

An analysis of the level of readiness of Russian enterprises for the implementation of Industry 4.0 projects showed that despite a clearly expressed desire to introduce digital technologies at their enterprises, there are objective difficulties that hinder their implementation. In particular, it was established that the main factors hindering the integration of the industrial Internet into production in the Russian economy are the lack of flexibility of companies, the lack of developed digital business models of the company, the lack of qualified personnel, and limited funding. Among external factors, one can single out a low degree of awareness and accessibility of technologies, a lack of a normative-failure base in the field of IT technologies, and a low degree of elaboration of information security issues when working with data. The creation of a unified digital technology platform in Russia, the development of information and telecommunications infrastructure for the use of new Internet technologies, as well as the solution of the tasks posed in the final part of the study, will contribute to the successful implementation of projects in the field of the industrial Internet of things in the Russian economy.

Creating Enterprise Image Versus Non-Financial Reports – A Case of The Social Reports Competition

Melania BĄK

Wroclaw University of Economics and Business, Poland
melania.bak@ue.wroc.pl

Abstract

Enterprise image represents an invisible resource which creates opinions and ideas among stakeholders responsible for making strategic decisions. Creating enterprise image is possible owing to the properly composed set of both non-financial and financial information, provided to stakeholders in various types of non-financial reports (e.g. in an integrated report). From the perspective of modern accounting, it can be observed that non-financial reports are increasingly frequently perceived as a form of enterprise representation. The process of non-financial reporting, as a new trend in contemporary accounting, is characterized by a voluntary, creative and individual approach. The offered information does not originate directly from traditional accounting. The process of such reports preparation covers as follows: analysing the reasons underlying their development (considering both advantages and disadvantages), identifying the main stakeholder groups (addressees), highlighting important problems, defining goals and activities which address the disclosed issues, selecting and developing the respective measurement indicators, choosing the form of disclosure. One of the methods to present and create an image is the voluntary participation of an enterprise in the competitions of non-financial reporting dedicated to social responsibility purposes (e.g. Social Reports Competition organized in Poland). The competition contributes towards propagating the idea of non-financial reporting, increasing the transparency of business operations and engaging in the dialogue with stakeholders, which has a positive effect on enterprise image creation. Awareness in image development should be based on considering both benefits and threats resulting from the information presented in non-financial reports.

Keywords: Enterprise Image, Non-Financial Reports, Social Reports Competition.

Introduction

Enterprise image (representing one of the invisible resources in traditional accounting) has an essential impact on achieving competitive advantage from the strategic perspective. The characteristic features of an enterprise image include, among others, enterprise uniqueness, the source of future benefits, correlations with other invisible resources, e.g. (Itami and Roehl, 1987) identity, brand, relationships with stakeholders. Enterprises use various forms of either direct or indirect contact with their stakeholders to develop a positive image. Among the instruments creating such image the following can be listed: the Internet and radio broadcasts; press publications; participation in competitions, fairs, festivals, exhibitions; interviews; posters; published reports; sponsorship; charity actions.

Reporting, understood more extensively than financial reporting alone, is an important instrument allowing for enterprise image development. The information provided in non-financial reporting and disclosed to a wide range of stakeholders is primarily of non-financial nature. Constructing a positive image is also enhanced by enterprises' participation in the competitions promoting corporate social responsibility (CSR) based on these reports. Such competitions contribute to a dialogue with stakeholders. The analysis of websites and social rankings allows concluding that CSR has become an important factor supporting the formation of an enterprise positive perception. These enterprises which include social aspects in their activities gain numerous benefits that have impact on developing and maintaining a positive image as well as affect the other invisible resources (Branco and Rodrigues, 2008). These benefits include, e.g.: winning a strong market position, higher

competitiveness, developing financial market confidence, gaining the status of a widely respected employer, employee satisfaction, increasing the attractiveness of offered products, improving work efficiency, larger access to capital and stakeholders' attention.

Image, as one of the invisible resources related to a modern enterprise, influences the widening gap between balance sheet value and market value of an enterprise, as it is not presented and disclosed in the traditional accounting system. The disclosure of non-financial information about an enterprise image in non-financial reporting is the manifestation of accounting opening to an intangible dimension. In the long run, an image (and its capital) exerts impact on financial figures, such as, e.g., revenues, profits and financial liquidity. An enterprise image is created by both the economic and social dimension of the conducted business activity.

The purpose of the article is to present the correlations between creating an enterprise image and its non-financial reports from both scientific and practical perspective. The theoretical approach to the analysed problem is based on an overview of the subject literature, applying descriptive and deductive methods and the author's considerations. The example of Social Reports Competition (organized in Poland by the Responsible Business Forum and Deloitte) was used to analyse enterprises' participation in the Competition, types of non-financial reports and the information they provide, in particular the ones affecting the image of selected enterprises.

Enterprise image – an Important Invisible Resource

The research addressing the problem of image was initiated by P. Martineau (1958), who described an image as the sum of functional properties and psychological attributes of a product present in the consumer's mind. Initially, the term image referred to a product, however, it evolved along with the subsequent research on the overall concept of an image. D. Bernstein, using the network theory, proposed to expand this concept, approaching it as a network resulting from the interaction of experiences, feelings, knowledge and impressions presented by people about a given enterprise (Abratt and Mofokeng, 2001). Currently, an image refers to a product, a person, an enterprise, an industry, a region and a country. The object of an image has also been expanded and applies not only to customers but also to a wider range of stakeholders (e.g. investors, suppliers).

An image is most often presented as a picture being the sum of ideas, experiences, impressions and thoughts functioning in the minds of people who come across a given object. An image in the mind of an addressee is co-created by, e.g., his/her experiences, observations, impressions, information and opinions of others. An image is the result of data processing, visualising signals and collecting experiences (Nawrocka, 2013). An image stands for the public portrayal of a person or an enterprise, presented in a favourable manner, which aims at gaining social acceptance for its activities and attracting stakeholders (Altkorn, 2004). According to G.R. Dowling (1986) an image is "a set of meanings by which an object is known and through which people describe, remember and relate to it". In turn, J. Penc (1998) suggests defining the company image as a composition of an enterprise personality resulting from its philosophy, history, culture, strategy, management style, reputation as well as employees' and its other representatives' behaviour.

An image refers to the company personality, which people perceive, identify with, and about which they express their opinions and emotions. Image placement in the minds of stakeholders and also the perceptions and feelings about an enterprise have impact on its positioning, as compared to the competition. The decisions made by enterprises are influenced by the pursuit of an ideal (desired) self-image, which they often try to achieve as a result of additional activities preferred at a given moment. According to J. Altkorn (2004) "an image which positions an enterprise precisely enough in the minds of its target audience remains the significant source of competitive advantage". A strong image ensures greater profits, lower risk and better functioning stability. The value of a company image (image quality) affects the process of company value creation, thus stimulating the demand for its products/services, the achieved profits and its brand strength. An image stands for a self-presentation outside. An image is the way of an enterprise perception, the form of its characterization and presentation (Budzyński, 2002). Appropriate creation, conducted business operations and mission

are crucial to develop a positive image, which is the result of everyday activities and does not stand a chance of satisfying everyone. It should be based on the presentation of the most important assets and merits. Creating a positive image of an enterprise is possible if it features reliability, dependability, trust and confidence in the environment, recognition and sustainable socio-environmental policy.

Non-financial reports as the Instrument for An Enterprise Image Creation

Non-financial information in accounting (primarily in financial reporting) is approached in two ways. Firstly, as an element explaining and correcting the imperfections of financial information, and secondly as a long-term source of value and knowledge which indicates the directions of enterprise development. Non-financial information (e.g. referring to enterprise image) can be classified, among others, in terms of their:

- form (e.g. descriptive/narrative, presented as figures, amounts, percentages),
- scope (e.g. social, environmental),
- characteristics (e.g. time range – retrospective and/or prospective, nature of achievements – operational and/or strategic, availability, specificity, usefulness, confidentiality),
- place of disclosures.

The purpose of non-financial information is primarily to inform about the value creation and the achievements, develop a competitive advantage, support understanding the business model and inform about the key tangible and intangible/invisible resources that affect both strategic and operational activities performed by an enterprise (Morros, 2016).

The non-financial dimension of reporting is related to the reports containing non-financial information (Gazdar, 2007), supplemented by financial information being largely voluntary and creative, where the information disclosed extends and supplements the information presented in financial statements, e.g., referring to the enterprise market value. The first disclosures of non-financial information in corporate annual reports appeared at the beginning of the 20th century and covered the enterprise activities in the area of human resources (e.g. employee security) and social involvement (Nehme and Koon Ghee Wee, 2008). The increasingly frequent presentation of non-financial information was observed in the late 1960s, and was gradually expanding from employee, social, quality problems to environmental and sustainable development issues. Currently, 95% of the largest corporations worldwide (capital groups) publish social reports, and the international report database provides over 41,600 publications (www.globalreporting.org/standards). In the accounting practice, both an increase in the demand for non-financial information and a higher supply (disclosures) of such information by the interested enterprises can be observed (Arvidsson, 2011).

The process of disclosing non-financial information is characterized by the following features: voluntariness, creativity and individuality. These enterprises which are not required to disclose non-financial information can individually decide whether to provide such disclosures and, if so, what is their scope and form. The process of preparing reports is characterized, to a great extent, by individualization, which consists of the following activities:

- considering the premises for their creation (taking into account the advantages and disadvantages),
- identification of major stakeholder groups,
- highlighting important issues,
- defining goals and activities in the area of disclosed issues,
- selection and development of measurement indicators,
- choosing the form of disclosure and contact with the stakeholders.

The disclosure of non-financial information results in both benefits (e.g. developing company image and reputation) and threats for an enterprise (e.g. failure to comply with the ethics and good practice requirements) summarized in Table 1.

Table 1: Crucial advantages and disadvantages of disclosing non-financial information

Advantages	Disadvantages
Information availability for all stakeholders. Developing stakeholder confidence. Engaging in a dialogue and improving communication with various stakeholder groups. Achieving competitive advantage. Explaining the difference between enterprise balance sheet value and market value. Creating a product brand. Building enterprise image and reputation. Developing good relationships with customers. Informing about the compliance with the principles of ethics and corporate governance. Promoting enterprise activities through the participation in various competitions and rankings. Higher awareness of taking care about the natural environment. Educating employees and constructing relations with the company. Supporting the local community. Awareness of the enterprise participation in global operations and participation in market trends	Difficulties in verifying the disclosed information by stakeholders. Selective disclosure and no specificity. Risk of liability to stakeholders. Loss of competitiveness as a result of trade secrets' disclosure. Estimating the value of invisible resources without the support from an accounting system. Subjective selection of measures and methods for measuring invisible resources. Costs of generating, disclosing and disseminating information in non-financial reports. The absence of mechanisms allowing feedback on the opinions regarding the disclosed information. Preparing "on demand" reports for stakeholders

Source: author's compilation based on (Gazdar, 2007; Krasodomska, 2014).

The disclosure of non-financial information is exposed to manipulation of the so-called stakeholders' impressions. D. M. Merkl-Davies and N.M. Brennan (2011) introduce the phrase "impression management", used in the reporting narrative, which aims at developing an enterprise image and reputation.

The scope of the disclosed non-financial information is diverse (it is up to the individual decision of an enterprise). As a rule, it covers the prospective information, not subject to legal regulations and free from any obligation to disclose it (Radebaugh and Gray, 2002). In the reporting practice, however, there are examples of its mandatory presentation along with the disclosed information in the reporting of large public-interest entities (e.g. Directive 2014/95/EU). Thus, it can be concluded that non-financial reporting is subject to a certain evolution: from optional to obligatory (but only with reference to some entities), from the creative choices of international standards and the widespread practice (determining their preparation) to national regulations provided by balance sheet law or the recommended guidelines.

Since January 1, 2017, all the EU Member States should follow the national provisions implementing Directive 2014/95/EU, the main assumption of which is to increase the transparency of social and environmental information in the area of corporate social responsibility as well as its cohesion and comparability. In Poland, the obligation of extending non-financial reporting has been provided by the Accounting Act (The Accounting Act dated December 15, 2016). Article 49b of the aforementioned Act refers to the obligation of extended reporting covering non-financial information, which should be included in the statement on non-financial information (as part of the activity report) or in a separate report on non-financial information. The number of enterprises having this obligation is quite small, therefore the majority of entities are going to follow their internal decisions and needs in this matter. The disclosed mandatory non-financial information should cover economic, social, employee related, environmental aspects, respecting human rights as well as counteracting corruption and bribery. The obligation of extended non-financial reporting in Poland refers to public interest entities at the level of individual and consolidated statements, including, e.g., limited companies,

limited joint-stock partnerships if they exceeded the following values in the financial year and in the preceding year: 500 people (average annual employment), PLN 85 million total balance sheet assets or PLN 170 million net revenues from the sales of goods and products.

The Global Reporting Initiative (GRI) and the International Integrated Reporting Council (IIRC) are the main organizations promoting non-financial reporting worldwide, in particular integrated reporting, which, however, represent divergent concepts. The GRI guidelines focus on the identification of various groups of stakeholders and emphasize the importance of environmental, economic and social spheres, whereas the IIRC is primarily concentrated on improving the information addressed to investors and also on business models and the creation of value (GRI-G4, 2018; IIRC, 2013). The enterprises preparing non-financial reports follow various standards, guidelines and recommendations developed by many international organizations, including, e.g., Social Accountability 8000, AccountAbility AA1000, GRI G1-G4, ISO 26000, ISO 14001, OECD. Enterprises can make choices within the framework of creative (voluntary) accounting policy regarding the standards, norms or reporting guidelines they are going to apply (national, EU, international, their own principles or a combination of different standards), provided the information about their decision is included in the report. The most popular, out of many guidelines, are the standards developed by the GRI, which specify basic principles and measures to be used in measuring and developing performance information related to economic, environmental and social aspects. The GRI guidelines are used in social and integrated reporting (www.globalreporting.org/standards). Over 80% of all enterprises applying the GRI guidelines used the GRI-G4 version.

Social reports and integrated reports are considered the sources of non-financial information (Śnieżek et al., 2018). Additional information, as part of a financial statement, although containing a marginal component of non-financial information, definitely signals the need to expand financial information in the evolution process of reporting and constitutes the preform of non-financial reporting. More developed presentations of non-financial reporting (also referred to as social reporting) take the form of sustainability reports and corporate social responsibility reports, whereas an integrated report holds the status of the most comprehensive and complex form of non-financial information disclosure.

The scope of disclosed information should depend on the type and purpose of a non-financial report (Table 2). Social reporting covers the issues related to measuring social achievements (results) related to the expectations of investors and the society. They are primarily dedicated to the local and global community. The purpose of corporate social responsibility reporting is to develop relationships between an enterprise and stakeholders (including the society), which allows disclosing both credible and reliable information, on the one hand, and making informed and well-analysed decisions, on the other. Therefore, the “information providers” are obliged to present and disclose it with due diligence. Compliance with social responsibility has impact on, among others, positive changes in the immediate milieu and transformations in the quality of life. Sustainability reporting refers to the disclosure of non-financial information relating to economic, social and environmental issues (Herzig and Schaltegger, 2006), balancing which in the course of business activities contributes significantly to its development in respect of the external (e.g. natural environment) and internal (e.g. employees, ongoing processes) milieu.

Table 2: The scope of disclosed information in non-financial reports

Type of non-financial report	The scope of disclosed information
Social report, including: • corporate social responsibility report • sustainability report	The report subject structure is diverse, its main elements are: company characteristics, business description (business model: activities, stakeholders, products, supply chain, customers), strategy description and risk management (e.g. operational, financial). Important issues cover: employees, human rights, workplace practices, social issues (involvement in social development), natural environment, dialogue with various stakeholder groups, corporate and organizational governance. The disclosed information refers to the following areas: – economic and financial (e.g. capital, market share, profits, investments in research and development, cash flow), – social (e.g. labour practices, human rights, employee programmes, safety and working conditions, employee diversity, remuneration policy, employee training), – environmental (e.g. consumption of natural resources, air and water pollution, applying ecological regulations, greenhouse gas emissions, waste management, energy consumption, recycling, soil contamination and erosion)
Integrated report	Main elements (in accordance with the IIRC): – characteristics of an enterprise and its external milieu, – corporate governance, – business model, – opportunities and threats/risks, – strategy and location of resources, – achievements, – perspectives, – basics of information preparation and presentation. Elements of the business model: resources (e.g. human, intellectual), activities (e.g. implementation of quality policy), results (e.g. profit), effects (e.g. customer satisfaction)

Source: author's compilation based on (GRI-G4, 2018; IIRC, 2013).

In response to the imperfections of non-financial reporting the concept of an integrated report was developed, which should allow stakeholders to find out about the enterprise capacity to create value in the future and observe how financial and non-financial information affect each other (Eccles and Krzus, 2010). The combination of financial and non-financial, retrospective and prospective, as well as economic, environmental and social information aims at creating a comprehensive picture about the operations and results of an enterprise. Integrated reporting, despite continuous improvements in its structure (included in various proposals of standards and norms) is still recognized as a new form of enterprise reporting. In the first development phase, integrated reporting was considered an excellent method for information disclosure that is intended to integrate financial information with non-financial information to meet the stakeholders' needs and reduce the existing information gap between the book value and the market value of an enterprise (IIRC, 2013). However, the several years of experience in preparing integrated reports does not confirm this enthusiasm, and receives a lot of criticism instead (Flower, 2015). The predominantly voiced allegations refer to an extensive freedom in creating non-financial information and the absence of their correlation with financial information.

Having analysed the subject literature and the accounting practice, one can conclude that a certain conceptual chaos does occur in terms of terminology referring to different types of non-financial reports, e.g., the term social report is used interchangeably with the phrase sustainability report. In the author's opinion, the term used should result directly from the purpose and scope of the report, and a non-financial report should be identified with the general/universal concept referring to non-financial information reporting. The sustainability report and the corporate social responsibility report can be

identified with the broadly understood social report, which also includes environmental and ethical issues. The social report is mainly focused on economic, social and environmental aspects, whereas the integrated report offers a wider range of financial and non-financial information. All the listed reports represent non-financial reports. In the process of studying non-financial reports, it is important to analyse their content by means of which both systematic and objective identification of the specific characteristics, inherent in the provided information, becomes possible (Dyczkowska, 2019).

Enterprise image creation in Polish practice based on non-financial reports submitted to the Social Reports Competition

Voluntary participation of enterprises in various competitions, e.g. dedicated to corporate social responsibility, opens opportunities for their image presentation and strengthening. The Social Reports Competition has been held in Poland since 2007 and its organizers are: Responsible Business Forum and Deloitte (until 2014 the competition was co-organized by PricewaterhouseCoopers – PwC and CSR Consulting, and in 2015 by Société Générale de Surveillance – SGS). This initiative aims at disseminating the idea of CSR, sustainable development, natural environment protection and social involvement. It is addressed to enterprises and organizations which publish reports presenting their performance in the aforementioned areas. The main goal of the Competition is to attract attention to the importance of non-financial reporting and to identify good practices in this area (http://raportyspoleczne.pl). The Competition awards and distinguishes reports prepared by the enterprises which, taking into account social and environmental aspects in their core activity, are capable of presenting their achievements published in non-financial reports in a clear, transparent and reliable manner. The Competition contributes towards increasing the transparency of enterprise operations, creating its image and engaging in a dialogue with stakeholders. From the perspective of thirteen years of experience in organizing the Social Reports Competition, a significant interest of enterprises in this event can be observed, as evidenced by the growing number of the submitted reports (from 12 to 46). Three periods can be distinguished in the development of the Competition:

- origins (2007-2011),
- early youth (2012-2016),
- mature youth (2017-2019).

The number of submitted reports in the distinguished periods presents the following ranges: from 12 to 18, from 27 to 35, from 41 to 46.

The name of the Competition is not consistent with its subject matter, which results from the existing conceptual chaos observed with reference to various types of non-financial reports. The Competition covers non-financial reports and, in particular, corporate social responsibility reports, sustainability reports and integrated reports. The submitted reports, in their major part – over 90% are prepared in accordance with the GRI guidelines. Awards are granted for various types of non-financial reports: sustainability reports (e.g. Cemex Polska Sp. z o.o, in 2015 and 2017), corporate social responsibility reports (e.g. Santander Bank Polska, former Bank WBK, in 2015 and 2019) and integrated reports (e.g. Orlen Group in 2016).

Table 3 presents the participation of enterprises in the Social Reports Competition by the industry sector in 2007-2019. The dominant industries involved in the Social Reports Competition represent such sectors as: finance, energy, food industry, raw materials and fuels. In the finance sector, the Competition active participants are as follows: Bank Millennium S.A., Santander Bank Polska (former Bank Zachodni WBK), ING Bank Śląski S.A., mBank S.A. Energy industry is represented by: Grupa Energa, PGE Polska Grupa Energetyczna, Grupa Enea, Tauron Polska Energia S.A. Food industry is most often represented by: Kompania Piwowarska S.A., Carlsberg Polska, Nestlé Polska S.A., Coca-Cola HBC Polska Sp. z o.o., Grupa Żywiec S.A., Danone Sp. z o.o. The leading participants in the sector of raw materials and fuels are: PKN Orlen S.A., KGHM Polska Miedź S.A., Grupa Lotos S.A.

Source: author's compilation based on http://raportyspoleczne.pl.

The enterprises use non-financial reports to highlight the most important information from the perspective of their image creation (see Table 4), e.g., the enterprises operating in the raw materials and fuels sector emphasize their activities focused on natural environment protection (Dreegan et al., 2000). PKN Orlen often distinguishes its brand by referring to numerous rankings and brands owned (19 brands, including Orlen, Verva, Vitay Club, Benzina plus). Participation in the discussed Competition and communication with the stakeholders through non-financial reports offers an opportunity to restore a given enterprise image if there occurred any negative incidents in the past, directly related to its operations, e.g. related to environment pollution or accidents at workplace.

Enterprise image creation is possible, e.g., through disclosing non-financial information about invisible resources and their intellectual capital (Bąk, 2020), in particular related to product brand, customer relations, innovation, human resources, reputation and identity (recognition). Having analysed the selected non-financial reports of Orange Polska (former Telekomunikacja Polska), KGHM Polska Miedź S.A. and Kompania Piwowarska S.A. it is possible to trace the disclosure of

such issues as, e.g. (Table 4): company identity, product brand, relations with stakeholders (including customers), activities for innovation, human resources management respecting the rights and diversity. At the same time, the disclosed non-financial information refers to economic and financial (e.g. financial stability), environmental (e.g. environmentally friendly manufacturing processes) and social (e.g. dialogue with the local community) aspects.

Table 4: Examples of enterprise image creation based on the selected non-financial reports

Enterprise - characteristics including participation in the Competition	Enterprise image creation – examples
Orange Polska (former Telekomunikacja Polska) Participation in 9 editions in the years: 2007, 2011-2015, 2017-2019. Awards received: • 4 distinctions for the corporate social responsibility report, • 1 distinction for the integrated report, • 1 Grand Prix for the corporate social responsibility report. Types of non-financial reports: • 6 corporate social responsibility reports, • 3 integrated reports	**Integrated report (2018 edition)** A letter by the President of the Management Board to stakeholders. Orange on the telecommunications market in Poland. Key trends affecting the company operations, e.g. digitization. Presentation of network infrastructure and IT systems. Presentation of sales network and market knowledge. Customer relations: contact channels, customer service. Product brand. Investment areas, e.g., fibre-optic network extension. A friendly employer in the digital world: trainings and employee satisfaction. Employees involved in voluntary service. Donations to various institutions (participation in public life). Impact on natural environment: energy consumption, reduction of greenhouse gas emissions, recycling, waste management. Disclosure of indicators referring to occupational diseases and accidents at workplace. Respect for diversity (gender, age, education, religion, nationality). Financial aspects, e.g., equity, dividend per share. Management Board structure and photos of its members
KGHM Polska Miedź S.A. Participation in 7 editions in the years: 2012-2014, 2016-2019. Awards received: • 1 award for the corporate social responsibility report, • 1 distinction for the integrated report. Types of non-financial reports: • 2 corporate social responsibility reports, • 1 sustainability report, • 4 integrated reports	**Integrated report (2016 edition)** A letter by the President of the Management Board to stakeholders. Crucial figures in the operations of KGHM Polska Miedź S.A. Importance of metals in the national economy. Leading trends on the global market, market position. Activities of the Management Board and Supervisory Board. Financial stability. Business model: exploration and penetration, ore mining, ore enrichment, metallurgy and refinery, processing, sales and trade, reclamation. Presentation of customer relations. Innovation development. Cooperation of science and practice in research and development, projects within the framework of international cooperation. Cooperation with local communities as part of corporate social responsibility. Involvement in environment protection: implementation of

	pro-ecological investments, timely payment of environmental fees, energy consumption, reduction of CO_2 emissions. Human resources. Employee competences and safety. Selected items from a separate and consolidated financial statement. Management Board structure and photos of its members
Kompania Piwowarska S.A. Participation in 9 editions in the years: 2007, 2011-2015, 2017-2019. Awards received: • 4 distinctions for corporate social responsibility reports, • 1 distinction for the integrated report, • 1 Grand Prix for the corporate social responsibility report. Types of non-financial reports: • 6 corporate social responsibility reports, • 3 integrated reports	**Sustainability report (2019 edition)** A letter by the President of the Management Board to stakeholders. Presentation of brands, products and novelties. Awards received. Membership in organizations. Relations with stakeholders. Contribution towards achieving sustainable development goals. Focus on health care and life quality. Participation in programmes: career from scratch, good education. Respect for diversity (gender, age, education, religion, nationality). Actions promoting responsible alcohol consumption. Development of the alcohol-free beer segment. Responsible alcohol consumption. Employee training on refusing to sell alcohol to minors. “Check your alcohol level” program allowing to estimate the level of alcohol in one’s blood after drinking it. Responsible labelling of products, e.g., “Don't drink alcohol when pregnant”. Employee development: education and trainings. Employee safety and health. Activities aimed at natural environment protection: protection of bison in the Białowieża National Park, optimal water consumption in manufacturing, energy, sewage and waste management, sales of beer in returnable bottles, replacement of machines and equipment into energy-efficient ones, environmentally friendly technologies and production processes. Climate oriented actions. Promoting fair market competition. Partnership for cooperation. Management Board structure and photos of its members

Source: author’s compilation based on http://raportyspoleczne.pl.

Based on the analysis of non-financial reports, submitted to the Social Reports Competition, the following conclusions can be put forward:

- enterprises prepare various types of non-financial reports for the subsequent editions (e.g. Orange Polska – from a corporate social responsibility report to an integrated report),
- the scope and form of non-financial reports is diverse, which results from the voluntary, creative and individual nature of their preparation, allowing enterprise image creation,
- some components of non-financial reports are the same for all enterprises, e.g. a letter by the President of the Management Board to stakeholders, which purpose is, e.g., to improve and strengthen the image,
- the disclosed non-financial information aims at developing confidence in the enterprise for its responsible operations and its image improvement,

- some non-financial information is intended to make the prospective financial information more credible (e.g. good customer relations are manifested in the achieved sales revenues),
- absence of consistency and mutual relations between financial and non-financial information,
- prevalence of non-financial information over financial information,
- for the sake of positive reception of the provided information (i.e. to create a positive image of an enterprise), diverse forms of information disclosure are used, among which the following can be listed: pictures, photographs, drawings, diagrams (column, pie or area charts, bar or linear graphs, scatter plots), patterns, schemes, interviews and letters.

The author proposed the structure of an integrated report using a synthetic approach (Table 5), which according to its concept should allow integrating non-financial and financial information, as part of the business model and value creation (e.g., in terms of disclosed and undisclosed assets in accounting). Both identity and self-reflection are essential in enterprise image creation.

Table 5: An integrated report structure – synthetic approach

Section title	Issues in individual sections
Enterprise – **identity**	About us: type and scope of activity, organizational structure Development strategy for the given years Stakeholders Contribution to the industry sector, market and local community development Awards and distinctions Membership in associations and organizations Crucial events Enterprise creators and personalities The most valuable asset
Enterprise – **self-reflection**	A letter by the Chairman of the Supervisory Board, a letter by the President of the Management Board Strategy implementation in the given year Risks (e.g. financial risk, commercial risk) Opportunities and threats as well as challenges for an enterprise Retrospective and prospective business activities
Business model and value creation	Property disclosed in accounting – identification of components (assets, liabilities, equity, costs, revenues) – financial statement as the primary source of information – value creation: components – activities – results – effects
	Property undisclosed in accounting approached as invisible resource and intellectual capital – identification of components (e.g. brand, customer relations, reputation, image, innovation, organizational culture, employees) – measurement of the components of undisclosed assets – financial and non-financial measures – value creation: components – activities – results – effect – mutual relations between the components of undisclosed and disclosed assets

Source: author's compilation.

Including, in the enterprise *curiculum vitae* (an internal document supporting, e.g., the image), information about the participation in the Social Reports Competition may contribute to higher prestige and reputation.

Conclusion

The author's considerations present a voice in the debate on the existing correlations between creating enterprise image and its non-financial report. Due to the complex nature of this relationship,

only the most important issues have been addressed in the study based on the subject literature and practice (including the selected example). The analysed problem (correlations) consists of many aspects and dilemmas, e.g., adjustment of financial and non-financial measures characterizing the image, choice of the disclosed information scope and reporting forms, awareness and behaviour of the enterprise board/management.

The opening of modern accounting to non-financial information, disclosed in voluntary and diverse reports can contribute to better knowledge about invisible resources from an accounting perspective, which makes up a significant part of any knowledge-oriented enterprise property. One of such invisible resources is represented by enterprise image, the development of which is possible, e.g., as a result of properly arranged set of non-financial and financial information, provided to stakeholders in various types of non-financial reports (e.g. in an integrated report).

The practice of modern accounting proves that non-financial reports represent a valuable source of information about enterprise achievements and value for potential stakeholders. The presented non-financial information extends and supplements the financial information disclosed in traditional financial reporting. Non-financial reports constitute one of the instruments supporting enterprise image creation, and their characteristics – diversity and individual nature allow creating enterprise personality (impressions about it).

From the perspective of modern accounting, it can be stated that the increasingly frequently prepared non-financial reports are approached as a kind of enterprise business card. In the course of preparing these reports the following factors are taken into account, e.g.: reasons for their development (advantages and disadvantages), identification of the main groups of stakeholders (addressees), highlighting important problems, formulating objectives and activities in the area of the disclosed issues, selection and development of the respective measures, choice of the disclosure form.

One of the methods for image development is the voluntary participation of enterprises in non-financial report competitions dedicated to corporate social responsibility. Based on the example of the selected enterprises participating in the Social Reports Competition, which has been organized in Poland since 2007, the scope and types of non-financial reports were analysed. Examples of non-financial information influencing the enterprise image were identified and the enterprise board/management increasing awareness regarding the significance of these disclosures was observed.

Voluntary participation of enterprises in the competitions promoting the idea of non-financial reporting, including information on corporate social responsibility and sustainable development, as well as the information about invisible resources of an enterprise, contribute significantly towards image creation and its credibility in the opinions of various stakeholder groups and competitors.

Acknowledgment

Ministerstwo Nauki i Szkolnictwa Wyższego

The project is financed by the Ministry of Science and Higher Education in Poland under the programme "Regional Initiative of Excellence" 2019-2022 project number 015/RID/2018/19 total funding amount 10 721 040,00 PLN.

Nouveau Protocole De Sécurité Intégrant L'ECC et l'MQTT pour La Sécurité De L'environnement IOT-Cloud

[1]Ayoub Amrani, [2]Najat Rafalia and [3]Abouchabaka Jaafar

[1,2,3]Computer and Telecommunications Research Laboratory université ibn tofail, Kenitra, Maroc,
[1]amrani.ayoub@uit.ac.ma, [2]najat.rafalia@uit.ac.ma, [3]abouchabaka@uit.ac.ma

Résumé

Cloud Computing et Internet des objets (IoT), deux technologies très différentes, font déjà partie de notre vie. Leur adoption et utilisation massives devraient de plus en plus augmenter, qui fera d'eux l'avenir du futur internet. Le tsunami d'inter-connectivité entre objets et de la collecte de données, repose de plus en plus sur le Cloud Computing, où l'analyse des données et l'intelligence réside réellement. Un nouveau paradigme où le Cloud et l'IoT sont fusionnés qui créera un nouvel air dans le monde de la technologie, qui sera un déclencheur et le générateur de nombreux services et application utile à l'humanité. Cependant, malgré ses avantages significatifs, ce paradigme souffre encore de certaines limitations qui freinent son expansion, principalement dans le domaine de la sécurité. Afin de garantir la réussite de l'intégration de ces deux technologies, une sécurité efficace et fonctionnelle de l'IoT est nécessaire afin de garantir l'anonymat, la confidentialité, l'intégrité, l'authentification, le contrôle d'accès des données. Dans cet article, nous proposons un protocole d'authentification mutuelle léger qui implémente MQTT comme protocole de communication, et basé sur la cryptographie des courbe elliptique. Le protocole proposé a été testé avec l'outil Avispa et a montré des résultats très satisfaisants.

Mots-clés : Sécurité, ECC, internet des objets, MQTT.

Introduction

Aujourd'hui, la présence d'appareils intelligents offrant une connectivité au monde à chaque seconde est considérée comme une partie obligatoire de notre vie. Ainsi, le nombre d'appareils connectés augmente rapidement chaque année. Cela nécessite la création d'un dispositif de communication autonome. L'une des solutions prometteuses aujourd'hui est connue sous le nom d'Internet des objets (IoT) [1]. IoT est un réseau d'information qui permet à la recherche d'informations sur les objets du monde réel d'interagir directement les uns avec les autres au moyen d'un identifiant unique (ID). D'ici 2025, une centaine de millions d'objets à ressources limités seront connectés à Internet qui communiquent et partagent diverses données avec Internet afin de fournir des services pour les utilisateurs tels que les soins de santé, les maisons intelligentes et transports \& logistique. Cependant, cette grande masse de données générées par ces objets ne peuvent être exécutés par un environnement de serveur unique.

Cloud Computing [2] ou " informatique de nuage ", est un paradigme informatique connu qui est devenu très mature en terme de services à la demande qu'il propose, des services qui sont accessible n'importe où et n'importe quand. Le Cloud Computing a une capacité illimitée en termes de stockage, puissance de traitement et peut s'adapter facilement au besoin de l'utilisateur, chose qui va certainement résoudre les problèmes que rencontre l'IoT. Ainsi on peut dire qu'un nouveau paradigme informatique est né, dans lequel le Cloud et l'IoT sont deux technologies complémentaire qui converge afin de donner un nouveau sens à l'Internet d'aujourd'hui et du future.
Malgré les différents services et applications que peut apporter cette technologie IoT-Cloud [3] à l'humanité. Ce paradigme souffre de nombreux problèmes ou niveau de sécurité, et cela dû aux interactions et les communications spontanées des dispositifs IoT et le Cloud Computing. On parle d'un Billard de communication transportant des informations sensible vers le Cloud. Sécuriser les

Dispositifs IoT, le Cloud et la transaction de data échangé, demeure un vrai challenge qui entrave l'expansion de cette de technologie.

Dans cet article, nous avons proposé un schéma de sécurité basé sur l'intégration de l'ECC et MQTT pour sécuriser l'environnement IoT-Cloud. Le protocole proposé garantit l'authentification mutuelle ainsi toutes les exigences de sécurités. Le reste du document est organisé comme suit. Dans la section 2, nous discuterons les préliminaires de notre étude. Dans la section 3, nous discuterons quelques travaux de recherche dans la littérature. Dans la section 4, nous proposerons un nouveau schéma de sécurité ECC. Dans la section 5, une analyse des performances a été réalisée. Nous avons vérifié dans la section 6 le protocole proposé en utilisant l'outil de validation automatisée des protocoles de sécurité Internet et applications (AVISPA). Enfin, nous conclurons dans la section 7 articles.

Préliminaire

MQTT

Il existe plusieurs protocoles de communication pour gérer les échanges de communication dans L'environnement IoT-Cloud comme L' HTTP et L' MQTT. Le protocole HTTP est généralement utilisé pour l'échange de données Web, il peut être utilisé pour gérer des données IoT. Mais la capacité de l'HTTP est moins adaptée lorsqu'il est utilisé sur des applications IoT.

Le protocole HTTP utilise un modèle de demande / réponse (request/response), qui est actuellement le mode le plus courant. MQTT utilise un modèle de publication / abonnement (publish/subscribe) [4] Le protocole HTTP n'est pas conçu pour un réseau omniprésent et peut causer une baisse de performance, en particulier dans l'utilisation de la bande passante et la durabilité de la batterie. Les applications IoT nécessite moins de bande passante, une réponse en temps réel et une faible consommation d'énergie car elle est couramment utilisée pour les petits appareils.

Une étude menée par Vergara et.al a montré la supériorité de l'MQTT implémentée sur Android appareils, ce qui peut réduire la consommation d'énergie par rapport au protocole HTTP [5]. MQTT et HTTP fonctionnent tous les deux sur TCP. Cependant, l'MQTT offre certains avantages tels que l'économie de l'énergie, parmi tant d'autres [6]

TLS/SSL

Transport Layer Security (TLS) [7] est un protocole qui assure l'authentification, la confidentialité et l'intégrité des données entre deux applications communicantes. Il s'agit du protocole de sécurité le plus utilisé à ce jour et utilisé pour les navigateurs Web et d'autres applications qui nécessitent un échange sécurisé des données sur un réseau, telles que les sessions de navigation Web, les transferts de fichiers, les connexions VPN, les sessions de bureau à distance et la voix sur IP (VoIP).

TLS a évolué à partir du protocole SSL (Secure Sockets Layer) de Netscape et l'a largement remplacé, bien que les termes SSL ou SSL / TLS soient encore parfois utilisés. Les principales différences entre SSL et TLS qui font de TLS un protocole plus sûr et plus efficace sont l'authentification des messages, la génération de matériel clé et les suites de chiffrement prises en charge, TLS prenant en charge des algorithmes plus récents et plus sécurisés. TLS et SSL ne sont pas interopérables, bien que TLS offre actuellement une certaine compatibilité descendante afin de fonctionner avec les systèmes hérités.

Cryptographie à Courbe Elliptique

Dans cette sous-section, nous introduisons le concept d'ECC (cryptographie à courbe elliptique). Pour commencer, les clés RSA qui ont la taille recommandée, continuent d'augmenter pour maintenir une force de cryptage suffisante. De 1024 bits à 2048 bits, sont les plus utilisées pour les certificats SSL il y a quelques années. Une alternative aux clés RSA est les clés ECC. Ces deux types de clés

principales partagent la même propriété importante d'être des algorithmes asymétriques (une clé pour chiffrer et une clé pour déchiffrer). Cependant, ECC peut offrir le même niveau de puissance de cryptage pour des clés beaucoup plus courtes, offrant une meilleure sécurité tout en réduisant les exigences informatiques. L'utilisation de courtes clé ECC peut aider à économiser des coûts évidents. Cette taille de clé réduite nous permet également de mettre en œuvre et de concevoir un fonctionnement cryptographique plus rapide et puissant, ce qui fait de l'ECC une option très attrayante pour les appareils dont la puissance de stockage ou de traitement est limitée, ce qui devient de plus en plus courant à l'ère de l'Internet des objets.

An elliptic curve E defined on r is a smooth curve given by a Weierstrass equation:

$$E: y^2 + a_1xy + a_3 = x^3 + a_2x^2 + a_4x + a_6 \quad (1)$$

We will consider in what follows an elliptic curve, is a curve that is drawn by the points that will solve the following equation:

$$E: (x, y) |\ y^2 \equiv x^3 + ax + b \text{ with } a, b \in K \quad (2)$$

a and b will have to fulfil the following condition $4a^3 + 27b^2 \neq 0$ K can be in the following fields $\{\mathbb{R}, \mathbb{Q}, \mathbb{C}, \mathbb{Z}/p\mathbb{Z}\}$.

Soit E une courbe elliptique définie sur un ensemble K, et deux points P, Q ∈ E (K), L la ligne reliant P à Q (la tangente à E si P = Q) et R le troisième point d'intersection de L à E. Soit L la droite verticale passant par R. On définit P + Q sur E (K) comme le deuxième point d'intersection de L avec E. Avec la loi de composition (E (K), +) est un groupe abélien dont l'élément neutre est le point vers l'infini (O).
L'addition scalaire et la multiplication scalaires sont deux opérations courantes sur les courbes elliptiques. La multiplication scalaire nP sur une courbe elliptique E (a, b) est définie comme des ajouts répétés, comme indiqué dans l'équation. (3) ci-dessous:

n.p = P+P+P+...+P (n fois) (3)

Où n ∈ K* La sécurité d'ECC dépend de la complexité et de la difficulté de résoudre les problèmes suivants:

Problème 1 :
Nous supposons une courbe E($\mathbb{Z}/n\mathbb{Z}$), En donnant P,Q ∈ E($\mathbb{Z}/n\mathbb{Z}$), avec Q multiple de P. Nous devons trouver K qui résout l'équation suivante Q = KP. C'est un problème difficile à résoudre. C'est ce qu'on appelle le problème du logarithme discret ou (ECDLP).

Problème 2 :
Étant donné trois points P, u et v sur une courbe elliptique E (a, b), où u,v ∈ K*. Il est difficile de résoudre uvP sur E (a, b) .en temps polynomial.

Notion utilisé

Table 2: Notations utilisées

Notation	Description	Notation	Description
ID_i	Identité du dispositif i	N_1, N_2	Nombre aléatoire généré pour les paramètres ECC
ID_{Bro}	Identité du Broker	**H(.)**	Fonction de hachage cryptographique
$Topic_i$	Souscirption au Tpoic i	**K**	clé d'authentification mutuelle
K_i	Clé du dispositif i	**M / C**	Message/ Message crypté
R	Nombre aléatoire	G	Générateur de point ECC
P	Large nombre premier avec ordre 2^{160}	$\oplus$	Operateur XOR

Travaux connexe

En 2015, un nouveau protocole proposé par Kalra & Sood [8] est apparu, ils ont acquis de l'expérience des protocoles discuté dans le paragraphe précèdent. Ils ont proposé un schéma d'authentification mutuelle pour sécuriser les communications entre un dispositif connecté est le Cloud avec une clé de session en utilisant des cookies HTTP (Hypertext Transfer Protocol). Ce protocole est destiné uniquement au petit dispositif qui est des clients HTTP. Malheureusement en 2017 Kumari et al. [9] ont prouvé que l'algorithme proposé par Karla est vulnérable contre les deux attaques "offline password guessing" \& "insider attack". Par la suite, ils ont exploité cette faille et ont amélioré l'algorithme en proposant un schéma d'authentification mutuelle avec deux facteurs pour assurer l'anonymat.

Durant les dernières années, les chercheurs essayent de diminuer la complexité de leur algorithme, et d'exploiter au mieux l'avantage qu'offrent les Clés ECC. Pour ce faire ils se sont penché à étudier l'intégration des protocoles de communication léger adapté à l'IoT comme MQTT, afin de développer des protocoles de sécurité puissant et léger très adapté à l'environnement IoT-Cloud. En 2019, Ankur et al. [10] ont proposé un schéma d'authentification et d'autorisation basé sur MQTT et ECC, malheureusement, ce schéma n'expose pas le véritable rôle des Borker MQTT et comment la distribution des clés est effectuée.

Protocole Proposé

Dans cette section, nous proposons un ECC protocole d'authentification léger pour l'environnement IoT-Cloud qui est des Abonnés MQTT.

Dans une Communication MQTT, le Broker est un élément très essentiel pour la distribution rapide des messages d'un éditeur à un abonné selon un thème donné. Notre conception est basée sur la connexion de plusieurs abonnés enregistrés dans un thème au Cloud, selon la fonction ou la tâche que cet appareil intelligent occupe, via le Broker en charge de l'expédition des informations. Puis le Cloud prend des décisions et publie cette dernière a la abonné concerné et ainsi de suite.

Cette prise de décision doit être sécurisée en raison de l'importance de l'information qui circule. Dans notre Modèle, nous ne supposons que le Broker à suffisamment de capacité de stockage et de calcul pour générer et distribuer les clés.

Le Cloud Computing dans notre cas, doit tout d'abord être abonné à tous les thèmes avant d'avoir l'habilité d'être un éditeur (**Figure 1**).Notre système renforce l'intégrité et le contrôle d'accès aux messages suivant un thème donné en utilisant d'un côté l'autorisation et le cryptage pour l'éditeur et de l'autre côté une clés de déchiffrement pour les abonnés.

Notre modèle se compose de trois phases. La première est l'initialisation où le Broker initie les paramètres nécessaires à la génération et distribution des clés. Le second est l'abonnement entre les objets et le Broker est également composé de sous-section que nous détaillerons plus tard. Et enfin la troisième est la publication, c'est là où l'éditeur (Cloud) publie des informations aux abonnés via le Broker.

Figure 1 : Les entités impliquées dans notre modèle

Phase d'initialisation

Dans cette phase c'est le Broker qui est en charge de la génération et distribution de clés suivant les étapes suivante:

1. Génère aléatoirement deux grands nombres a,b $\in \mathbb{Z}$ après il choisit une courbe elliptique E ($\mathbb{Z}$) sur $\mathbb{Z}_p$.
2. Le Broker choisit sa clé secrète $K_m \in \mathbb{Z}_p$.
3. Le Broker génère le générateur de point G tel que $n \times G = O$. $n > 2^{160}$.
4. Le Broker calcule la clé publique $L = G.K_m$.
5. Finalement, il diffuse les paramètres publics $K_p \leftarrow (E_p, G, p, L)$.

Phase Souscription

Après cette phase une mutuelle authentification sera générée entre les abonnées et le Broker. Pour ce faire deux sous phases seront développé. La première qui est la phase d'enregistrement, qui permettra d'enregistrer les abonnés au Broker. La deuxième est la phase de login/authentification dans cette phase, le Broker s'assure des informations des abonnés puis génère une clé de session entre les deux parties.

<u>Phase d'enregistrement</u>

Etape 1 Afin que l'abonnée i s'enregistre auprès du Broker, il se présente auprès de ce dernier avec son identité I_i calculé comme suit:

1. $I_i \rightarrow h(ID_i \| Topic_i \| rG)$

Etape 2 Le Broker Génère pour chaque abonnée i les paramètres de sécurités suivant :

1. Le Broker calcule $A_i \rightarrow h(K_m \| K_i)$, avec $K_i = h(N \| I_i \| ID_{bro}) \oplus topic_i$, ensuite il enregistre $A_i' = A_i.G$.
2. Le Broker calcule $K_s = K_m \oplus K_i$, $B_i = h(K_s \oplus I_i \oplus A_i')$ et enregistre $B_i' = B_i.G$, K_i et $Topic_i$ correspondent à l'identité ID_i de l'abonnée.

Phase du Login/Authentification

Etape 1 Avant chaque connexion, l'Abonné sélectionne un nombre aléatoire N_1 et puis calcule et enregistre les points ECC P_1 , P_2.

1. $P_1 = N_1.G$.
2. $P_2 = h(N1.A_i')$.
3. Envoie P_1 , P_2. et K_i au Broker.

Etape 2 Une fois le Broker reçoit les paramètres envoyé par l'abonné commence à la calculer les paramètres suivant:

1. $A_i \rightarrow h(K_m \| K_i)$ en calculant $K_m = K_s \oplus K_i$.
2. Après il calcule $P_2^* = h(P_1.A_i)$. Le Broker vérifie ensuite si la valeur de P_2^* est égale à la valeur reçue P_2 afin de valider les paramètres envoyés par l'abonnée i.

Etape 3 Après la validation des paramètres envoyés par l'abonnée i, le Broker ensuite choisit un nombre aléatoire N_2 pour calculer ses Points ECC :

1. $P_3 = N_2.G$.
2. $P_4 = N_2.B_i'$.
3. Envoie P_3, P_4 , et K_s à l'abonnée i.

Etape 4 De même afin que l'abonnée vérifie les paramètres du Broker il calcule les valeurs suivantes **:**

1. $B_i = h(k_s \oplus I_i \oplus A_i')$.
2. Calcule $P_4^* = P3.B_i$ L'abonnée i vérifie ensuite si la valeur de P_4^* est égale à la valeur reçue P_4 afin de valider les paramètres envoyé par le Broker.

Etape 5 Après la validation des paramètres du Broker, l'abonnée i calcule la session K comme suit :

1. $K = N_1.P_3 = N_1 . N_2 .G.$
2. Calcule et envoi au Broker $V_i = h(P_2 \| K)$.

Etape 6 Encore une fois le Broker compare V_i^* avec la valeur reçu de l'abonnée V_i :

1. Le Broker Calcule $V_i^* = h((P_1.A_i) \| K^*)$ avec $K^* = N_2.P_1$ afin de valider le paramètre reçu.

Phase de publication

Après l'authentification mutuelle. On passe à la phase de publication, où l'éditeur envoie un message crypté aux abonnés via le Broker, Pour ce faire on doit suivre les étapes suivantes:

Etape 1 L'éditeur (Publisher) doit demander la publication en présentant son identité ID_{pub} .

1. $ID_{pub} = h(topic_i \| ID_i \| G.K)$.

Etape 2 Le Broker ensuite vérifie l'identité de l'éditeur en calculant ID^*_{pub}.

1. $ID^*_{pub} = h(topic^*_i \| ID^*_i \| G.K^*)$.
2. Puis envoi son identité à l'éditeur.

Etape 3 Afin que l'éditeur publie ses messages d'une manière chiffré à l'abonnées à travers le Broker il calcule C_{pub} et envoie au Broker {Pub}:

1. $C_{pub} = r.G.K_i \oplus M$.
2. Envoie au Broker $Pub = h(Topic_i \| ID_i \| rG \| C_{pub})$.

Etape 4 Finalement le Broker extrait le message et le publie à l'abonnée en calculant les valeurs suivante:

1. Calcule $C_b = r.G.K_s \oplus C_{pub} = rGK_s \oplus rG.K_i \oplus M$ d'où $C_b = K_m \oplus M$.
2. Le Broker Calcule le message crypté à envoyer au Abonnée
   $C_i = C_b \oplus rGK_s = K_m \oplus M \oplus rGK_s$ d'où le message à publier est
   $C_i = rGK_i \oplus M$

Analyse de performance

Un protocole d'authentification efficace doit tenir en compte des coûts de calcul et de communication lors du processus d'authentification. Avec ECC, notre protocole utilise des opérations XOR et des fonctions de hachage unidirectionnelles, ces deux opérations sont très coûteuses en cryptographie. Notre protocole est très sécurisé et efficace car il est basé sur des valeurs aléatoires nonce. Lors du calcul du coût du protocole, les valeurs nonce (N_1, N_2), le nombre aléatoire R et les paramètres de sécurité sont tous supposés avoir une longueur de 224 bits. De plus, la sortie d'une fonction de hachage unidirectionnelle est de 224 bits et le cryptosystème à courbe elliptique est ECC - 224 bits.

Notre protocole est composé de subscriber/publisher et le Broker en charge de l'envoi d'informations. Le protocole proposé pourrait être évalué en termes de divers coût généraux,
Paramètres de sécurité et évolutivité. La communication entre les éditeurs et les abonnés est généralement sécurisé avec SSL / TSL. Dans cette section, nous allons évaluer et comparer notre protocole avec SSL / TLS.

SSL / TSL a 13 Handshakes, et c'est la version de TLS la plus courante. Comme la taille du message de chaque Handshake varie (**voir Tableau 2**), nous avons essayé d'approximer la taille des messages SSL / TLS dans chaque connexion de prise de contact. Rappelons que l'en-tête d'enregistrement TLS pour chaque enregistrement est de 5 octets et l'en-tête du Handshake TLS est de 4 octets. Nous en avons 4 enregistrements échangés (20 octets). Chaque message à une entête Handshake, et nous en avons 7 d'où 28 octets. Le coût total d'une seule nouvelle connexion SSL / TLS converge vers 1789 Octets. (20 + 28 + 170 + 75 + 1500 + 130 + 2 + 24 = 1789 octets). Le coût total d'une connexion SSL / TLS existant est d'environ 332 octets. (15 +16 + 202 + 75 + 2 + 24 = 332 octets).

Table 2: MESSAGE SIZES OF SSL/TSL

Message type	Message size
ClientHello	160–170 bytes
Server Hello	70–75 bytes
Certificate	800–1500 bytes

ClientKeyExchange	130 bytes
ChangeCipherSpec	1 byte
Finished	12–36 bytes

Cout De Communication

Le coût de communication d'un protocole est le coût impliqué dans la transmission des paramètres de sécurité. Dans le protocole proposé, les paramètres de communication sont :

- Pour la phase de souscription : $P_1, P_2, P_3, P_4, K_i, V_i, K_s$ = [224 + 224 + 224 + 224 + 224 +224 +224] = [7*224]= 1568 bits = 196 Bytes.
- Pour la phase de publication : [2 ID_{pub} , Pub, ID_{Bro}, C_i] = [2*224+ 224 + 224 + 224] = [5*224] = 1120 bits = 140 Bytes.

Table 3 : Comparaison de performance entre notre protocole et SSL / TLS(Phase de souscription)

Type de paramètre	Notre protocole	SSL/TLS
Coût de calcul	*2 XOR+ 4* T_{ecm} *(Sub/pub)* *6 XOR + 4* T_{ecm} *(Broker)*	-
Coût de communication	140 bytes	>1789 bytes

Avec T_{ecm} Coût d'une opération de multiplication scalaire ECC

Table 4 : Comparaison de performance entre notre protocole et SSL / TLS(Phase de publication)

Type de paramètre	Notre protocole	SSL/TLS
Coût de calcul	*3 XOR (Sub/pub)* *4 XOR (Broker)*	-
Coût de communication	196 butes	>1789 bytes

Vérification formelle du schéma proposé à l'aide d'Avispa

Avispa (validation automatisée des protocoles d'Internet et d'applications de sécurité) c'est un outil pour la validation automatisée de la sécurité des protocoles et d'applications. Il fournit un langage formel modulaire et expressif pour spécifier les protocoles et leurs propriétés de sécurité, et intègre différents back-end qui mettent en œuvre une analyse automatique avec une variété de techniques

[11]. Avispa propose un langage appelé langage de spécification de protocole de haut niveau (hlpsl) [12] pour décrire les protocoles de sécurité et spécifier leurs propriétés de sécurité prévues, ainsi qu'un ensemble de d'outils pour les valider formellement.

Le schéma proposé est analysé en utilisant les Back-ends OFMC et CL-AtSe et les résultats de l'exécution sont montrés dans la **Fig.** 2 et la **Fig.** 3. Dans ce modèle, l'intrus a un contrôle total sur le réseau de telle manière que tous les messages envoyés par les agents correspondant aux rôles sont à la disposition de l'intrus. Ce dernier peut intercepter, analyser et / ou modifier les messages. Il peut agir comme n'importe quel agent et envoyer n'importe quel message à un autre agent participant la communication. Les résultats de la simulation montrent que le le protocole est sécurisé.

Conclusion

La convergence entre l'IoT et le Cloud présente clairement des avantages dans plusieurs domaines, transport et logistique, santé, domaine de l'environnement intelligent ainsi que le domaine social. Dans ce chapitre, nous avons proposé un protocole de sécurité léger basé sur MQTT et la complexité des ECC. L'idée d'intègre le protocole de communication MQTT avec l'ECC pour authentifier les appareils intelligent au Cloud, est nouveau et satisfait toutes les exigences essentielles de sécurité nécessaires pour la convergence IoT-Cloud. Une comparaison des performances de notre schéma avec le TLS / SSL a été faite et le résultat a été très satisfaisant. Une analyse de sécurité formelle basée sur le modèle d'attaque a été effectuée et qui prouve que notre protocole est robuste contre toutes les menaces connues. Enfin, nous avons vérifié la validité de notre modèle en utilisant la vérification automatisée via l'outil AVISPA. Les résultats ont montré que notre protocole est sûr.

Abstract

Decisions are an essential part of the life of every human. Every decision should be concerned with the goal, the resources available to achieve the purpose, and the restrictions. The decision-making process is complicated, and the multi-dimensional environment for all decisions has to be supported by a mathematical approach. Many scientific works are based on the decision-making process. The field of this research is concerned with Z-numbers proposed by Zadeh and its application in decision-making. The Z-numbers' arithmetic is a crucial aspect of the article. The proposed method combines Z-numbers and ranking of decisions by the expert. The approach is based on the expert's knowledge expressed in Z-number, where the reliability of the opinion, as a critical factor, is considered in the model of decision-making. A numerical example illustrates the proposed method. Also, case studies were carried out that confirm the usefulness of the technique in the decision-making process.

Keywords: Decision making, Z-Numbers, Ranking.

Introduction

Shakespeare's question from Hamlet," To be, or not to be ..." in Shakespeare (1603) is quite old but shows the necessity of decision-making. The famous sentence presents the two options about living in this case but also shows that decisions are in the human's life. Decision-making, to obtain pieces of information, is a strategical activity. It is based on sections of information obtained from the environment. Those decisions are connected not only with personal matters, but what is more critical with organizational issues. Those features are the essential aspect of environmental analysis in case of uncertainty and changes in the environment, which was shown in Dill (1953), Duncan (1972), Draft et al. (1988), Boyd and Fulk (1996), Elenkov (1997), May et al. (2000), McGee and Sawyerr (2003), Day and Schoemaker (2005). All cited sources indicate that the decision-making process is still fundamental and a critical factor in the managerial area.

Decision-making is nothing without information. Information can be defined as all that we can use to better the choice of acts for obtaining a goal in Kolmogorov (1968). The most critical aspects of information are in Stoner et al. (1995):

- Quality of information,
- Timeliness of information,

- Quantity of information,
- The function of information.

Those aspects show that the appropriate value of information is connected with the fullness of information and the possibility of a good understanding of it. The better the information is, the better decisions made on it are. We can also consider information as a part of the decision process where we can see: data (collected form environment), information (analyzed data), managerial information (selected for managers), and decision in Stoner et al. (1995). The flow of information from the source to the user requires the construction of a system for collecting, storing, and analyze information in an organization. Every information system has to have in Griffin (1995):

- Set of information,
- Means of storage of information,
- Analysis of information,
- Presentation of information.

The information system is based on the quality of information, and the quality of information is based on certainty. To ordinary human life, many pieces of information are based on uncertain environments, and that causes some problems. To cope with some mathematical approaches were presented. Especially connected with fuzzy sets in Zadeh (1965), Zadeh (1979), Bellman and Zadeh (1970), Gaines et al. (1984), and Z-numbers in Zadeh (2011), Yager (2012), Yaakob and Gegov (2016), and understanding of natural language in Zadeh (1999), Liu and Jin (2012), Tian et al. (2016). To cope with multi-dimensional data from the environment, the necessity to organize decision-making as a process and develop a system that can support them in Trieu (2017).

Decision-making is an essential process in a human's and manager's life. This article presents a new approach in supporting the decision-making process by using a ranking of decisions made by an expert based on Z-numbers. The proposed system uses simple calculations on Z-numbers, which, according to scientific publications, can be quite complicated. To all scientific works we have reached, there were no tries of that approach.

The article contains sections: Introduction, which provides the scope of the paper. Than related works, which show the scientific field of interest and the novelty of the article. Another part is Preliminaries, which reminds the grounds of decision-making and fuzzy and Z-numbers. Then the next part is the Method description followed by a Numerical Example, which contains a Case Study, and finally, Conclusions.

Related Works

As it was shown earlier, decision-making is an interesting topic for researchers who are deploying it in different areas. Its application is divided into decisions in an uncertain environment in Kang et al. (2012), Peng and Wang (2017), multi-criteria decisions in Xiao (2014), Peng and Wang (2018), using fuzzy numbers in group decision-making in Liu (2013), in decision-making in case of incomplete information in Wang et al. (2009), in finances in Afful-Dadzie et al. (2015), Ruan and Fedrizzi (2012), in fuzzy Delphi method in Bouzon et al. (2016), Hsu et al. (2010), Lawnik and Banasik (2020). All those application areas are concerned to provide as full as possible information

for people making decisions. The criteria are used for determining which option is better than the other; obtaining data from the uncertain environment is focused on completion of the information, and fuzzy numbers are a way to cope with incomplete or natural language data in decisions.

The specific field of interest for authors is Z-numbers. In the process of decision-making, we can find Z-numbers in use with TOPSIS group decision-making to provide ranking in Yaakob and Gegov (2016). The combination of fuzzy logic and the multi-criteria decision is shown, but the use of Z-numbers offers better accuracy of human language in Gardashova (2014). The reliability of knowledge in the use of Z-numbers delivers better results than the classical fuzzy approach in Aliev and Zeinalova (2014). The Z-number arithmetic is an essential part of the study, and the solutions for adding the Z-numbers is not widely recognized, so the solution of Zadeh and Aliev is a significant step to the proposed method in Zadeh (2011), Aliev et al. (2017). Besides decision-making, Z-numbers have their application, for example, in the area of choosing an appropriate group of users for UX implementation in Banasik and Lawnik (2019) or in the Delphi method using Z-numbers in Lawnik et al. (2019).

As has been shown, the decision supporting topics is very significant in the scientific world. That statement determines us to present our approach to decision support tools using Z-numbers in the ranking of decisions.

Preliminaries

Decision-Making Process

The decision-making is a process which contains four phases in Turban et al. (2005):

- Analysis - the phase dedicated to the identification of a problem and gathering knowledge for experts,
- Projects - phase of finding or creating problems' model, gathering knowledge of possible solutions, decomposition of a problem,
- Choice - phase of selecting an answer from a set of alternatives,
- Implementation - a period of realization of the chosen solution.

The phases can be quite complicated. That forces researchers to find solutions to the problems. One of the approaches is the decision support system. The decision support system is a program, which contains artificial intelligence methods that help to recognize the problem and make the decision in uncertainty, lack of data in Burke et al. (2005).

Decision support systems are often based on mathematical models or simulations. The optimization methods can be divided by Turban et al. (2005):

- Type of problem being solved;
- Restrictions of the optimization method;
- Number of variables;

- Criteria of optimization.

To provide an appropriate mathematical model, a goal (to be reached) should be declared, resources provided (involved in the process), and restrictions indicated. In the case of a multi-criteria approach, it is necessary to provide better visualization of the decision process - the solution is the decision matrix. A decision matrix is a series of values in columns and rows that allows you to visually compare possible solutions by weighing their variables based on importance in Kou et al. (2014). The array can not only help you select the best course of action for your business, but it can also aid you in prioritizing tasks, problem-solving, and crafting arguments to defend a decision you've already made.

Fuzzy and Z-numbers

The mathematical approach presented in this article is based on fuzzy sets. The fuzzy set A defined in space X is set of pairs in Zadeh (1965)

$$\mathrm{A} = \{(\mathrm{x}, \mu_{\mathrm{A}}(\mathrm{x})) : \mathrm{x} \in \mathrm{X}\}. \tag{1}$$

The most important function in case of fuzzy set is a membership function. Function $\mu_A : X \to [0,1]$ is named membership function and it defines the element's degree of belonging x to A.

There are many possible choices for membership functions. One of the simplest membership functions is trapezoidal membership function:

$$(a,b,c,d) = \begin{cases} 0, & x \leqslant a \\ \frac{x-a}{b-a}, & a < x \leqslant b \\ 1 & b < x \leqslant c \\ \frac{d-x}{d-c}, & c < x \leqslant d \\ 0, & x > d \end{cases}. \tag{2}$$

Fuzzy sets can be transformed to crisp values. One of the options of converting fuzzy set A into crisp value $\overline{x}$ is Center of Gravity method in Patel and Mohan (2002):

$$\overline{x} = \frac{\int x \mu_A(x) dx}{\int \mu_A(x) dx}. \tag{3}$$

Fuzzy sets can also be defined in the interval form with the help of their bandwidth. Bandwidth A^b of fuzzy number A is value in Singh and Lone (2020)

$$A^b = |x_1 - x_2|, \tag{4}$$

where $\mu_A(x_1) = \mu_A(x_2) = 0.5$. Using the bandwith of fuzzy set A, its interval form $[A^{b1}, A^{b2}]$ can be defined in Fuh et al. (2014) as:

$$\mu_{[A^{b1},A^{b2}]}(x) = \begin{cases} \frac{1}{2}, & A^{b1} \leq x \leq A^{b2} \\ 0, & \text{otherwise} \end{cases}. \tag{5}$$

Fuzzy number is a fuzzy set A (where $A \subseteq \mathbb{R}$), which membership function fulfill listed conditions in Michael (2005):

- $\sup_{x \in \mathbb{R}} \mu_A(x) = 1$ (fuzzy set A is normal),
- $\mu_A(\lambda x_1 + (1-\lambda)x_2) \geq \min\{\mu_A(x_1), \mu_A(x_2)\}$ (set A is convex),
- $\mu_A(x)$ is intervally continuous function.

Another approach connected with natural language data is Z-number. Z-number in Zadeh (2011) is the ordered pair of fuzzy numbers (A, R), where A is the fuzzy limit of a certain real variable x, while R is a measure of the reliability of the first component.

Arithmetic operations on Z-numbers are quite complicated. Their simple form can be found in Zadeh (2011), and Aliev et al. (2017). For two Z-numbers $Z_1 = (A_1, R_1)$ and $Z_2 = (A_2, R_2)$ basic arithmetic operations $\{+, -, *, /\}$ are:

$$Z_1 * Z_2 = (A_1^b * A_2^b, R_1 \times R_2), \tag{6}$$

where A_1^b, A_2^b means bandwidth of number A_1 and A_2, else $R_1 \times R_2$ is the product of the fuzzy numbers R_1 and R_2.

In order to sum $\sum_i Z_i$ formula (6) of Z-numbers in the form of trapezoidal components $Z_i = \left(\left[A_i^{b1}, A_i^{b2}\right], (a_i, b_i, c_i, d_i)\right)$ can be written as

$$\sum_{i=1}^{k} Z_i = \left(\left[\sum_{i=1}^{k} A_i^{b1}, \sum_{i=1}^{k} A_i^{b2}\right], \left(\prod_{i=1}^{k} a_i, \prod_{i=1}^{k} b_i, \prod_{i=1}^{k} c_i, \prod_{i=1}^{k} d_i\right)\right), \tag{7}$$

where $\left[A_i^{b1}, A_i^{b2}\right]$ is the interval representation of component A_i of Z-number Z_i^S.

Method

The method of assessment of given decision variants is based on the knowledge of an expert. The expert declares, in each criterion, his or her decision, giving the value of the Z-number. The values provided by the expert can be in a linguistic form, which will be translated into a distinct possibility of controlling the experiment by the contracting entity. The next steps of the method can be described as follows:

- The expert evaluates each of the $O_i (i = 1,2, \dots, n)$ decision variants by giving k criteria's as Z-numbers in linguistic form.
- All the linguistic variables are converted into numerical values in the form of fuzzy trapezoidal numbers (2). The support for the first component of Z-number (A) is in the range $[0,10]$, while for the second component (R) is in the range $[0,1]$.

- The first components of given Z-numbers are converted into fuzzy interval numbers using (5), and the sum Z_i^S is calculated according to the formula (7) in each decision variant O_i.
- The received sums of Z_i^S are converted to the crisp value according to the formula:

$$Score(Z_i^S) = \frac{A_i^{b1} + A_i^{b2}}{2} \cdot \overline{x}, \tag{8}$$

where A_i^{b1}, A_i^{b2} are the restrictions from the interval form of Z_i^S, and $\overline{x} = \frac{\int x \mu_{R_i^{prod}}(x) dx}{\int \mu_{R_i^{prod}}(x) dx}$, and $R_i^{prod} = \left(\prod_{j=1}^{k} a_j, \prod_{j=1}^{k} b_j, \prod_{j=1}^{k} c_j, \prod_{j=1}^{k} d_j\right)$.

- Decision variants O_i are ordered according to the value obtained from the previous point (8).

Example

An IT company wants to open a new branch. A hypothetical logistics expert evaluated three location suggestions in terms of time, cost, and attractiveness. Example assessments for each of the decision numbers in the form of Z-numbers (linguistic components) are provided in Table 1. In the next step, the linguistic variables are converted to numerical values, and the results for these are given in Table 2. In all tables Loc. means location. The final results (Table 3) show that the best location, according to the Expert, is location A.

Table 1: Expert assessments to three different company locations in the form of Z-numbers with linguistic variables components.

Loc.	Time	Cost	Attractiveness
A	(about 9, high)	(about 7.5, very high)	(about 8, high)
B	(about 8, medium)	(about 8.5, high)	(about 9, very high)
C	(about 8.5, high)	(about 7.5, high)	(about 7.5, medium)

Table 2: Expert ratings for three different company locations in the form of Z-numbers with fuzzy trapezoidal numbers as components.

Loc.	Time	Cost	Attractiveness
A	((8.25, 8.75, 9.25, 9.75), (0.8, 0.83, 0.87, 0.9))	((6.75, 7.25, 7.75, 8.25), (0.9, 0.93, 0.97, 1))	((7.25, 7.75, 8.25, 8.75), (0.8, 0.83, 0.87, 0.9))
B	((7.25, 7.75, 8.25, 8.75), (0.7, 0.73, 0.77, 0.8))	((7.75, 8.25, 8.75, 9.25), (0.8, 0.83, 0.87, 0.9))	((8.25, 8.75, 9.25, 9.75), (0.9, 0.93, 0.97, 1))
C	((7.75, 8.25, 8.75, 9.25), (0.8, 0.83, 0.87, 0.9))	((6.75, 7.25, 7.75, 8.25), (0.8, 0.83, 0.87, 0.9))	((6.75, 7.25, 7.75, 8.25), (0.7, 0.73, 0.77, 0.8))

Table 3: The sum of the expert grades and their final value calculated based on the formulas (7) and (8).

Loc.	Sum	Final assessment
A	([23.0, 26.0], (0.576, 0.641, 0.734, 0.81))	16.920
B	([24.0, 27.0], (0.504, 0.563, 0.649, 0.72))	15.547
C	([22.0, 25.0], (0.448, 0.503, 0.583, 0.648))	12.826

Case Study

Looking at the expert's assessment given in Table 1, it can be seen that location C is determined by location A. This is because the assessment and reliability in each criterion are lower. Intuitively, such a decision option should be rated lower. This is also confirmed by the results in Table 3. Also, it is worth showing the sensitivity of the algorithm to the adopted values. You can modify the value of the first variant in the third criterion (attractiveness) from (about 8, high) to (about 8.5, high). Then the sum of Z-numbers is ([23.5, 26.5], (0.576, 0.641, 0.734, 0.81)), and the final score is in turn equal to 17.265 (compare with Table 3). That means that the proposed method is susceptible to the values given. A similar sensitivity applies to the reliability of the assessment. Replacing the value in the first variant again in the third criterion (attractiveness) from (about 8, high) to (about 8, very high) we get the results ([23.0, 26.0], (0.648, 0.718, 0.818, 0.9)) for the sum of Z -numbers and 18.902 for the final grade (compare with Table 3). That means that a change in the reliability of the assessment has a significant impact on the final result.

Conclusions

The article presents the possibility of manage the decision-making process supported by expert's knowledge and by that provides additional information for the manager. It is essential to simplify the data provided for the top management level. The reason is self-evident - the manager has plenty of sources of information. A large number of sources indicates the necessity of simple value information for people responsible for making decisions. The solution to this issue is the use of Z-numbers in the process of decision making. Therefore this article presents a method of decision making with the use of mentioned Z-numbers and only arithmetic calculations with them.

The ranking of the decision method using Z-numbers provides possible solutions, their classification, and credibility. The most important advantage of the technique is that it is sensitive to values in the decision process. Another advantage is the simplicity of mathematical operations based on the sum of Z-numbers.

The proposed method is universal and can be used in different fields of application. The only restriction is based on intervals and their adding procedure.

The proposed method may be developed by choosing another defuzzification method.

Barriers in the Technological Innovation Implementation and Digital Entrepreneurship Development

Małgorzata OKRĘGLICKA

Czestochowa University of Technology, Częstochowa, Poland
m.okreglicka@wp.pl

Abstract

Nowadays, digitalization plays an increasingly important role for both the economy and society. The development of organizations without technological innovations is currently significantly limited. Despite of many advantages of digitalization, this process is limited by many internal and external barriers. The advantages and disadvantages of digitalization are analyzed mostly in large enterprises, and analogous studies in SMEs are insufficient. This creates difficulties in determining the causes and determinants for the development of digital entrepreneurship. In this paper, we try to identify and assess the impact of barriers in the implementation of technological innovations in the digitization of processes and activities in SMEs, which affects the development of digital entrepreneurship. To achieve the set goal, a survey research among Polish small and medium enterprises was carried out in 2019. As a result of the study, the intensification of barriers in the implementation of technological innovations in SMEs was assessed and their impact on the development of digital entrepreneurship was examined.

Keywords: Digital Entrepreneurship, Digitalization, Management, Smes, Technological Innovations

Introduction

The importance of digitalization for business entities and society is constantly growing. Digital technologies are described as ones with the most significant impact on how new business ventures are created and developed (Elia et al., 2020). They are giving rise to the 4th industrial revolution and digital transformation by unprecedented convergence of computing, communications, contents, and networking of humans. Jeschke et al. (2017) explained Industry 4.0 as a new industrial stage at which there is an integration between manufacturing operations systems and ICTs which has impact on the forms of competition, the industry structure and customers' expectations. Industry 4.0 combines the advantages of optimized industrial manufacturing with advanced Internet technologies to create competitive advantages for organizations (Hamada, 2019). This is why the 4th industrial revolution can not exist without digitalization.

Digitalization can be explained as implementation of digital technologies for business improving, business processes transformation, value added creation, and building business environment, whereby digital information is at the core (Parviainen et al., 2017). In general, digital technologies are platforms, infrastructures or artefacts that use the power of computing on an existing public network (Zaheer et al., 2019). Digitalization could be understood for enterprise as the process of using digital technologies to create and obtain value in new ways (Gobble 2019). Organizations increase not only their performance but also their competitiveness when digitalizing. However, digitalization demands a holistic approach in its management for navigating in this rapidly changing surrounding.

Digital transformation describes how existing organizations may need to transform themselves radically to succeed in the emerging digital world (Nambisan et al., 2019). In the last decade, technology trends such as mobile services, social media, cloud computing, Internet of things, big data and robotics developed new forms of collaborating, organizing resources, new product development, matching complex demand and supply, and creation of new standards and solutions for entrepreneurship (Markus, Loebecke, 2013). Such rapid development has redesigned the competitive

environment and reshaped traditional business strategies, models and processes (Bharadwaj et al., 2013).

Digital technologies enabled the creation of new business ventures and digital start-ups, which constantly implement technology innovations as a vital component of their business models and operations. In this sense, digital technologies are enablers of the entrepreneurial activity (von Briel et al., 2018). This constant convergence between enterprise and digital technologies creates a new category of entrepreneurs who use digital technologies and the Internet to create new business ventures and the constant renewal of their organizations (Giones, Brem, 2017). Wherefore, there is a visible transformation of entrepreneurship into digital entrepreneurship.

Despite of many advantages of digitalization, this process is connected with many obstacles as well. It is usually complex and expansive in implementation, and only because of that keeping up with the requirements of industry 4.0 becomes difficult for many entities, especially SMEs. As SMEs play a crucial role for each economy it is important to constantly analyze and reduce barriers in their digitalization to provide them with the opportunity to compete with larger entities (Havierniková et al., 2017). However, studies on digitization barriers in SMEs remain modest, which leaves a research gap for further analysis. With this in mind, the main objective of this paper is to diagnose and assess the influence of barriers to technological innovations implementation in digitalization of processes and activities in SMEs.

Literature Overview

Digitalization of enterprises is a process dependent on many factors and conditions. The literature on the subject is most often devoted to problems and challenges concerning large enterprises or public institutions, while the digitization of small business is often described casually.

Technological Innovations in Stimulating Digital Entrepreneurship

The impact of ICT and digital technologies on business innovation and entrepreneurship is multifaceted. Those technologies can play a role of a facilitator, mediator or outcome of entrepreneurial operations, or determine the whole business model (Steininger, 2018). The terms digital entrepreneurship and digital innovation are linked to the intersection of digital technologies with traditional entrepreneurship and innovation processes and results. Both domains are the source of transformational changes introduced by digital technologies (Berger et al., 2019).

The concept of digital entrepreneurship was introduced to describe the creation of new ventures and transformation of existing businesses by developing new digital technologies or experimenting their novel usage (Shen, et al., 2018). It is similar but not identical with the concept of cyber-entrepreneurship since it refers to the use of the Internet and technology platforms to manage and execute business operations with clients, agents or partners (Shabbir et al., 2016), or sell products or services across digital networks (Guthrie, 2014). Digital entrepreneurship is a fundamental element for digital economic development by seeking to exploit opportunities based on digital media and technologies (Elia et al., 2020). It supports the exchange, transfer and acquisition of knowledge and information, and introduces new ways of doing business (Geissinger et al., 2018). Digital entrepreneurship refers to how startups use digital technologies and human resources to implement the overall entrepreneurial process (Le Dinh et al., 2018).

An attention to digital entrepreneurship in scientific researches has increased as it allow to generated opportunities to combine resources, reach markets and create value in creative ways, thus ensuring contemporary social and technological development (Kraus et al., 2018). Innovation and entrepreneurship are often interrelated because many digital entrepreneurial ventures cannot exist without digital innovation (Bessant, Tidd, 2007). Digital entrepreneurship can be described as a stream of entrepreneurship, with the unique characteristics. According Davidson et al. (2010), it is a multi-faceted phenomenon, which consists of three interconnected types of entrepreneurship: business entrepreneurship, knowledge entrepreneurship and institutional entrepreneurship.

For many enterprises, innovation, especially technological one, is the key to survival. According to products, technological innovation can improve performance characteristics of the product to ensure its commercial success. In relation to organizational processes, technological innovation can include a new technology adoption or implementation of an improved production process. Moreover, technological innovation could involve change in organization structure, working processes or new and innovative ways of human resource management (Gupta, Barua, 2016). Since innovation leads to more innovation, businesses that invest in R&D and build technological and organizational capabilities are likely to induce further innovation (Yigitcanlar et al., 2019). It should not be forgotten that nowadays innovations usually coincide with digital transformations that give entrepreneurs the opportunity to access new markets and offer goods and services to as many consumers as possible. The introduction of innovations in connection with digital transformations allows generating above average profits that stimulate entrepreneurship (Galindo-Martín et al., 2019).

It is emphasized, that SMEs and start-ups level have enormous potential for technological innovation across different countries of the world (Gupta, Barua, 2016; Fiala, Hedija, 2019). For SMEs, pioneering technologies, new techniques and digitalization allow to immediate response to the contemporary market dynamics, while creative products allow SMEs to differentiate themselves among competitors, minimize the risks, and ensure successively growth and development (Bagheri et al., 2019).

Barriers in Technological Innovations Implementation in SMEs

Digitalization and digital transformation are even more challenging for manufacturing SMEs, who need to follow suit large firms or risk being left out of digital supply chains (Peillona, Dubruc, 2019). Even though digitalization can offer vast opportunities for SMEs to enter new markets, the digital transformation path is not obvious, and manufacturing SMEs face major barriers and obstacles to run business in digital world.

There are many internal and external barriers to technology change of enterprises. From legal constraints to workforce resistance, the higher the barriers to the adoption of new technologies, the more expenses companies must incur to implement those (Fatorachian, Kazemi, 2018). In addition, the complexity of adopting new technologies is even higher when considering small companies, which don't have the necessary skills, absorptive capacity or financial resources (Cohen, Levinthal, 2000).

On the barrier list of digitalization, the factors related to the workforce occupy usually the highest positions (Teixeira, Fortuna, 2010). They relate to employment disruptions and the need for enhanced skills in new digital reality. Technological transformation of enterprise requires completely new competencies, resources, and forms of cooperation and networking. Lack of digital skills may be even more important constrain for SMEs. Digitalization significantly increases the complexity, abstraction, and problem-solving skills needed by all employees. This reality requires employees to be more involved and open to new approaches, usually characterized by people with high education and qualifications, which are often missing in small business. Advanced digital competences, necessary to implement digital technology innovations effectively, can be regarded as a prerequisite for the enhancement of digitalization (Süße et al., 2018).

Moreover, digitalization contributes to the development of entirely new business models and technological innovations represent a radical change. People are the firm's most valuable asset, but only when they bring creativity, knowledge and innovation to the organization. Employee expression and demonstration of these values cause rapid and positive changes that can ensure the success and survival of the company. The condition is, however, that employees constantly and promptly respond to environmental challenges (Entezari 2014). Meanwhile, radical change connected with digitalization often causes resistance in organizational structures, because it brings organizational and process change. Each modification entails specific costs for employees due to the fact that it distorts their current behavior patterns and expectations; people's unwillingness to change, or their indifference to the need to change may be the most important cultural barrier and is often underestimated and usually not recognized by companies (von Leipzig et al., 2017).

Moreover, it is concluded that the lack of suitable education system is one of the main barriers to digitalization and it causes other barriers like the employee resistance to the technological transformation, difficulties in finding qualified workforce, aversion to innovation and poor ICT adoption.

It is noted, that organizational strategy, not technology, should drive digital transformation. The strengths and benefits of digital technologies do not result from the technology itself, but rather in how companies integrate it to transform their business and take advantage of its potential (Peillona, Dubruc, 2019). Technological transformation involves the use of digital technologies to change key business operations, products, processes, organizational structures and management concepts (Matt et al., 2015). In turn, Müller et al. (2018) indicated that strategic opportunities, like new business models based on digital solutions, are mainly suitable for large corporations. Whereas, operational opportunities like improvements in process efficiency are more suitable for SMEs. This study also marked that environmental and social opportunities are transversal for all company sizes.

Valmohammadi (2016) pointed, that, the significant barriers to these opportunities are integration challenges, such as the difficulty in finding the proper suppliers of digital solutions, high investment outlays particularly in comparison to small size of enterprise, reduced investment capacity, and privacy and security concerns. Barriers in technical innovation are also visible such as customers' experiencing unforeseen technical issues, interactions that are more personal required by customers, or privacy concerns (Marcon et al., 2019).

Many authors strongly recommended that companies should systematically analyze and modify their business models concerning the industry 4.0 transformation with new business logic, based on platforms and service-oriented business models. Top management involvement and the workforce value recognition are crucial to deal successfully in the industry 4.0 era assuming that the knowledge and competence gaps of employees will be supplemented, organizational resistance to changes that will be introduced throughout the entire supply chain will be overcome (Dalmarco et al., 2019; Betakova et al., 2018).

Technological innovations are the basis for digitalization, but they are varied, complex, most of all expensive since they encompass Internet o things, big data and analytics, cloud computing, cyber security, mixed and augmented reality, advanced manufacturing solutions, additive manufacturing, simulation of connected machines, and artificial intelligence (Paschou et al., 2018). SMEs are financially limited and have problems obtaining external financing and lack easily available technical resources to implement and update digital technologies (Mittal et al., 2018). Also point to macroeconomic barriers, especially unsatisfactory and unreliable technical infrastructure, which is necessary to effectively use the offer of digital services (Lerch, Gotsch, 2015).

Based on a given literature a main hypothesis can be formulated:

H1: Barriers on technical innovations implementation determine a level of tendency to digital entrepreneurship development.

Methods

The study aims to diagnose and assess the influence of barriers to technological innovations implementation in digitalization of processes and activities in SMEs. After in-depth literature review, a direct questionnaire survey was realized. The survey was conducted in 2019 among 160 Polish small and medium-sized enterprises.

Sampling was purposeful and non-probability. As part of targeted selection, the focus was only on small and medium-sized enterprises. The enterprise sample was selected in convenience way. This is why the conclusions from the research should not be generalized, and the study should be treated as a seed study. However, it may be a preliminary model for wider research in the future.

In total, 160 full questionnaires were obtained, which were subjected to further statistical analysis. For the opinion forming questions the 5-point Likert scale was adopted. After data collection, they were entered into statistical software. For evaluation, the descriptive statistics and correlations analysis using non-parametric test (the Kendall Tau coefficient was calculated for p-value = 0.01 and 0.05) were done as the basis for multiple regression model building.

The barriers in technical innovation implementation selected to analyze ware classified in two groups:

- Internal barriers:
    - B1. Lack of equity capital
    - B2. Lack of time for innovation implementation
    - B3. Lack of qualified employees within an enterprise
    - B4. No idea for innovation
    - B5. Low advantages of implementation innovative technological solutions in the company
    - B6. The reluctance of employees / managers to new solutions
    - B7. Impossibility / difficulty in combining new technological solutions with the existing machine park / existing methods of operation
- External barriers:
    - B8. Bureaucracy
    - B9. Difficulties in recruiting qualified employees from the labor market
    - B10. Lack of support from public institutions
    - B11. Non-supportive tax solutions
    - B12. Unfavorable legal provisions
    - B13. Limited access to grants from the European Union
    - B14. Problems with obtaining external financing

Digital entrepreneurship (DE) development was a dependent variable being tested in a present research. It was discover as an answer to the question “Do you undertake real efforts to digitization processes and activities at various levels of the company?”

Results

The assessment the 5-point Likert scale indicated the highest barriers in technical innovation implementation in SMEs. The mean of answers is presented in Table 1 and, in general, indicate, that external barriers are seen as stronger than internal barriers. Three barriers with the highest average rating are: Lack of equity capital; Unfavorable legal provisions; and Limited access to grants from the European Union.

Regression analysis was utilized for hypothesis 1 testing, and the descriptive statistics and correlations of the study’s variables are presented in Table 1.

Twelve of fourteen analysed barriers in technical innovation implementation are significantly and negatively correlated with digital entrepreneurship development, which is consistent with the proposed entrepreneurial orientation model. The highest correlation intensity is visible to the factors: Lack of time for innovation implementation; Lack of qualified employees within an enterprise; and Low advantages of implementation innovative technological solutions in the company. This suggests problems with innovation at the basic level in SMEs, which do not understand the advantages of new solutions and do not treat them as the basis for maintaining competitive advantage.

The next step was identifying the correlations between predictors. Correlations between barrier variables were mostly week to modest, ranging from r = .05 to r = .59 (the value of .05 is exceeded only in two cases), which allow to assumed that it would be no problem with regression analysis.

Table 1: Descriptive statistics and correlation analysis (n=160)

	Mean	S.D.	Range	DE	B1	B2	B3	B4	B5	B6	B7	B8	B9	B10	B11	B12	B13

[i] *p<0.05;* [ii] *p<0.01.*

The tendency digital entrepreneurship development effects of the barriers on technical innovations implementation were assessed by applying multiple regression analyses. The digital entrepreneurship development level was included as dependent variables in regression. Multiple regression model summary (Table 2) confirmed that the whole model is statistically significant (p<0.05). However, the whole model explained 8.2% of variation in the response, which is limited result.

Table 2: Multiple regression model summary

Model	R Square	Adjusted R Square	Sum of Squares SS	df	Mean Square MS	Change Statistics			F	p
						SS	df	MS		
DE	0,404	0,082	24,161	14	1,726	124,214	145,000	0,857	2,015	0,020

n=160	Parameters estimates Sigma-restricted parameterization			
	EI Param.	EI Std. Err.	t	p
Intercept	4,583	0,371	12,354	0,000
B1	-0,029	0,078	-0,371	0,711
B2	-0,077	0,074	-1,039	0,301
B3	-0,158	0,087	-1,818	0,041
B4	0,029	0,095	0,307	0,759
B5	-0,163	0,101	-1,622	0,046
B6	-0,032	0,086	-0,369	0,713
B7	0,015	0,081	0,183	0,855
B8	-0,032	0,072	-0,438	0,662
B9	0,090	0,088	1,022	0,038
B10	-0,119	0,106	-1,118	0,266
B11	0,123	0,103	1,193	0,235
B12	0,078	0,110	0,704	0,483
B13	-0,085	0,104	-0,822	0,412
B14	0,051	0,082	0,625	0,533

Within model three predictors: B2, B3, B9 seems to have the positive influence on the digital entrepreneurship development with statistical significance. For the remaining barriers, the level of $p>0.05$ does not allow for unambiguous inferences, which can be dictated by the fact that the research group was of relatively low numbers. Hence, there is a justification for expanding research in the future.

Conclusion

Digital technologies are seen as external enablers and facilitators of the start-up process (von Briel et al., 2018). On the one hand, the progressing digitization significantly reduces the various barriers to entry and can therefore be expected to lead to more entrepreneurial acts (Fossen, Sorgne, 2019; Lemanska-Majdzik, Sipa, 2015). On the other hand, digitization itself generates a number of barriers and new risks that are manifested in different types of enterprises with varying degrees of strength. Given the potential of digital technologies as enabling and facilitating entrepreneurship, the authors point out the need for in-depth research into the conditions and impact of digital transformation on entrepreneurship (Nambisan, 2017). This is due to the fact that technological innovation projects comprise decision uncertainty, complexity, multiple objectives, and dynamic interactions (Wu et al., 2010).

Digital transformation is very slow in SMEs (Sommer, 2015). Among the barriers to the development of digital entrepreneurship, the lack of digital competence is particularly highlighted. This is a common problem among SMEs that lack the knowledge and skills to apply new technologies in business operations (Marques et al., 2017). As a result, this causes a lack of positive attitudes, including motivation and setting appropriate priorities by entrepreneurs for the implementation of digital technologies (Kilimi et al., 2019; Havierniková et al., 2019).

The present research shows that there are many obstacles in implementation of technological innovations. They have their source in the enterprise's operations but result also from the influence of the company's environment. In general, it could be said, that these barriers influence negatively digital entrepreneurship development. Both the lack of opportunities for innovation and the willingness and commitment to implement them result in SMEs often lagging behind when it comes to absorbing the idea of industry 4.0. Meanwhile, the development of a modern enterprise is practically impossible without digital technology.

This study contributes to digital entrepreneurship research by presenting the intensity of selected barriers of technological innovations and their impact on building digital entrepreneurship in relation to a specific group of enterprises - SMEs, operating in a specific country – Poland. As digitalization of SMEs will became more and more important research problem, an interesting development of current research could be to verify and expand the list of determinants for the digital entrepreneurship development, while comparing dependencies for two or more countries.

The study involves some limitations. The main limitation seems to be the size and unrepresentativeness of the research group. In addition, if the model explained 8.2% of variation it seems necessary to verify the list of factors limiting the implementation of technological innovations in SMEs. Despite above limitations, we believe that this research helps deepening the theoretical understanding of barriers on technological innovations in digital entrepreneurship development in a unique context of SMEs.

Abstract

One of the most important issues discussed currently on economic growth is the similarity of development of groups of countries and regions. Studies in this area frequently use the concept of real convergence. The approach proposed in the research is based on the classification of objects and measures stability of the obtained divisions and the similarity of time series. The main objective of the research is to divide countries into homogeneous groups according to the dynamics of gross domestic product (GDP) and employment. Classification was carried out for Europe, Asia, Africa and Latin America. The research includes the temporal analysis of the stability of belongingness of countries to a given cluster using the Rand index, and assessment of the sensitivity of clusters on the global economic crisis which has started in 2007. The data come from the Total Economy Database and covers the period 1993-2017. The findings highlight the unbalanced and not sustainable growth of GDP and employment during last three decades. The dynamics of these variables were very different in Africa and Asia, and similar in Europe and Latin America. Europe was the only continent with the full recovery of GDP growth after last economic crisis, but together with Latin America they suffer from stagnation on the labour market. The lowest level of similarity of economic growth and labour market development paths was observed in Asia, while the highest homogeneity of countries according to dynamics of these two indicators was observed within particular clusters in Europe and Latin America.

Keywords: Economic Growth, World Economy, Classification, Similarity Index, Temporal Analysis

Introduction

The legitimacy of searching for factors influencing economic growth and, consequently, the level of development of countries is well reflected in the still valid statement of Polish econometrician Zbigniew Czerwiński from many years ago, "We are witnessing huge disproportions between the levels of economic development in different countries. In this situation, it is of paramount importance to detect certain regularities in the economic development of countries and to find ways of rapid and harmonious development (Czerwiński, 1977). The persistence of differentiation in the level of development of countries is mainly due to differing long-term growth rates: "If we want to understand what causes the significant differences in quality of life between countries, we need to explain the mechanism for differentiating their long-term growth rates" (Barro and Sala-i-Martin, 2004). This task is difficult not only because of the complexity of the problem and changes in growth factors, but also because of the choice of the proper research tool. Many of researchers pointed out that the inequality of growth in spatial and temporal terms is mostly the result of the diversity of sets of considered phenomena that determine the dynamics of growth. These include economic and non-economic phenomena characterising a given country, especially those specific to a given stage of its development (Pritchett, 2000). The limitations of the models used should also be taken into account, including, inter alia: high generalization and simplification of the applied growth models in relation to the complicated economic reality, difficulties in defining and measuring the variables used and

frequent lack of resilience of the results obtained to the assumed time and spatial range of the research sample. The discovery of regularity, and in particular the factors determining the rate of economic growth, is the basis for the creation of an effective economic policy aimed at ensuring sustainable growth, especially during economic crises. Bosworth and Collins found that a very large portion of the cross-country variation in economic growth experiences over forty years 1960-2000, can be related to differences in initial conditions (income level, life expectancy, population), the quality of governing institutions (law and order, corruption, protection of property rights) and other factors (geographical location, predisposition to trade (Bosworth and Collins, 2003). Initial identification of growth factors can be made by observing evolution and verifying existing economic theories in this area. They show how the set of factors considered decisive in the process of economic growth has historically changed. A broad discussion on the relationship between crucial micro and macroeconomic factors and types of economic growth can be found in the work of Batóg (2010).

In the growth literature there are opinions that only selected phenomena significantly influence the economic growth rate (Durlauf *et al.* 2004). However, there is no consensus on what these factors are in the studies so far. The rate of GDP growth in the European Union countries in 2010-2016 was determined mainly by consumption, investment, export and labour productivity. In periods of economic slowdown, the set of key determinants of growth was complemented by public debt. Enlargement of the EU and a drop in consumption resulted in an increase in the importance of export as key factor of growth. Some authors still underline the significant meaning of classic factors like employment for economic growth. Kaseeram and Mahadea investigated the marginal effects of employment with respect to real output and capital in South Africa, using annual data covering the period 1946-2015 and the VAR/VECM Johansen's framework. The results show that there exists a statistically significant long-run co-integrating relationship between employment and real GDP growth (Kaseeram and Mahadea, 2017). Other paper examined the contribution of employment, capital accumulation and total factor productivity to economic growth in African countries over the period 1986-2014. The methodology was based on the translog dynamic stochastic production frontier for a set of 49 African economies. The main finding was however that the level of employment contributions to GDP growth is smaller than contributions of capital (Amador and dos Santos, 2018). These observations, confirmed by many other studies, formed the basis for the choice of employment as an additional dimension in the classification of countries according to their economic growth rates. This classification and the assessment of its stability over time are the main objectives of this study. To obtain this goal we follow the view that „There is no single classification with precisely defined criteria that can be applied to each country in order to provide relevant information and reliable picture of development of countries in the world. That is the main reason that it is necessary to determine a relatively small number of well-chosen macroeconomic indicators" (Račić, 2018).

Identifying the necessary strength and areas of state intervention requires not only knowledge of the development of general changes in the economic activity of a country, but also the detection of similarities between these changes and other countries, especially those with strong economic ties. Previous research indicates that EU countries exhibit significant variation in the degree of convergence of economic fluctuations over time, making it very difficult to anticipate economic developments and assess economic risks (Batóg, 2013). The situation is further complicated by the occurrence of a significant difference in the social and economic structure between the old and the new Member States of the European Union, despite the fact that nominal and real convergence is taking place. Similar patterns can be observed in other continents, particularly in Asia and Africa, where significant differences in the dynamics of economic growth and changes in employment can be observed. It is therefore difficult to expect a high degree of similarity in terms of the factors considered across the set of countries analysed. Rather, separate groups of countries should be visible, constituting specific "growth clubs" similar to "convergence clubs" described by Quah (1997). In addition to identifying homogeneous groups of countries and specifying the differences between them, the stability of received classifications in time by means of Rand index will be considered. Robustness of particular group of countries to the last global economic crisis studying macro variables co-movements within the period 1993-2017 will be also assessed. Research highlighting the differential resilience of economies to shocks opens up the possibility that long-run

growth paths are associated with how regions cope with and recover from such shocks. Some results suggest that regions with greater employment shares in sectors that are less susceptible to demand fluctuations are likely to experience more stable growth rates and be more resilient to economic downturns. This has implications for understanding the importance of evolutionary trends and specifically the role of national contexts and industrial legacies in shaping regional resilience (Webber *et al*. 2018). Within developed countries in EU we can observe the different behaviour during and after last economic crisis between south Europe (Spain, Portugal, Italy and Greece) and north European countries. In the last one Germany seems to be the less affected by the current economic crisis. There is the main reason of a strong discussion about whether all countries should be considered equal and, so on, whether they should be treated in the same way (Duarte *et al*. 2018).

This research covers four continents: Europe, Asia, Africa and Latin America. The analysis did not include North America as well as Australia and Oceania because they were represented in the database only by two countries each. The statistical data were obtained from the Total Economy Database developed by The Conference Board, Inc. (TED November 2018). The rest of the paper is organized as follows. In the next part chosen current research related to the economic growth and employment are presented. Third part presents methodology used in classification of economies according to their economic growth and employment change, its stability and assessment of similarity of time series of these factors. Fourth section consists data characteristics and discussion on the results and findings of the study. The last section presents concluding remarks and potential directions of future research.

Current Research

According to the majority of studies the fundamental factor that determines both the income divergence as well as the GDP *per capita* levels in different countries are the discrepancies in long-term economic growth rates. The expected long-term growth rate is an important factor for societal planning, for example investment plans, as they indicate future potential tax revenues, savings and pensions. On a global level expected long-term growth rates, and differences in growth rates between countries, affect inter- national relations, trade and power balances (Alfredsson and Malmaeus, 2017). The past decade has been characterized by fragile growth, high investor uncertainty and periodic spikes in global financial market volatility. Nowadays, at the global level, world gross product is forecast to expand at a steady pace of 3.0 per cent in 2018 and 2019. However, stronger economic activity has not been shared evenly across countries and regions, with many parts of the world yet to regain a healthy rate of growth. It is expected that developing economies from East and South Asia will remain the main drivers of global growth. The longer-term potential of the global economy continues to bear a scar from the extended period of weak investment, low productivity growth, weakness in wage growth, high levels of debt and elevated levels of policy uncertainty (*World Economic*…, 2018).

Both the previous and the latest studies on economic growth do not provide clear premises for separating one and additionally limited set of its determinants. Some authors provide empirical evidence related to the significant impact of two factors: R&D spending and export. R&D expenditure are strongly related to the technological innovations as well as technological spillovers and diffusion, while relative level of export and consequently share in international trade seems to be one of the most important engine of modern economic growth. Chen and Dahlman (2004) found for 92 countries for the period 1960 to 2000 that the level of domestic innovation, technological adaptation, and the level of ICT infrastructure exert statistically significant positive effects on long-term economic growth. In terms of innovation, they discovered that a 20 percent increase in the annual number of USPTO patents granted is associated with an increase of 3.8 percentage points in annual economic growth (see also Batóg and Batóg, 2015; Fernandes, 2013). At the same time, we can find many studies, confirming significant impact of changes in employment on the level of economic activity and growth. Increase in the level of entrepreneurship and the related increase in employment has been identified as a key contributor to economic growth by the quantitative empirical study based on pooled panel analysis and using annual secondary data from 2001 to 2015 for the BRICS countries (Meyer and Meyer, 2017). The relevance of labour depends on its main

characteristics, including: share of labour in the national income, labour productivity and the number of hours worked. The share of labour in national income has been one of the most important issues in economics and remains the focal point of modern economic theories. However, we can observe a long-term downward trend for labour shares in the majority of countries. The study conducted by Bassanini and Manfredi (2012) for 25 OECD countries, 20 business-sector industries and covering up to 28 years, indicated that total factor productivity growth and capital deepening jointly account for as much as 80% of the within-industry contraction of the labour share. According to Sweeney (2012-2013) the decline in labour share in GDP has contributed to increased inequality in the distribution of national income. He also pointed out the main reasons of this phenomenon: technology and policy changes, globalization, increased domestic and international competition, growing financialization and sectoral shifts in employment. It is not only the level of employment itself that is an important factor in economic growth. In the long term, its sectoral structure is also important. Countries characterised by a permanent economic growth and relatively low unemployment have a low share of persons employed in agriculture and a high share of persons employed in services in total employment. In the process of creating employment growth and economic growth in the short term, it is of great importance that particular countries have sectors characterised by high dynamics of employment growth. Countries with a mature sectoral structure of employment, i.e. characterised by a high share of the service sector, achieve on this account above-average increases in the number of employees (Batóg and Batóg, 2007).

Research Method

The methods of the analysis of similarity of time series are widely discussed in the literature. Here the Authors mention only several examples of similarity measures applied. Basalto and De Carlo (2006) proposed Chaotic Map Clustering algorithm in order to recognize groups of stocks sharing synchronous time evolutions and the correlation coefficients between time series lied at the bottom of this method. The study of Bełej and Kulesza (2014) examined similarities between local real estate markets in Poland from 2006-2013 analysing changes in housing prices and using Chebyshev distance. De Benedictis and Tajoli (2007) analysed the similarity of the trade structures toward the European Union market between four Central and Eastern Europe Countries and the EU15. They considered different measures of similarity and distance and finally applied the Bray-Curtis semimetric.

Dorosiewicz and Michalski (2000) described the similarity measure which is based on the cosine of an angle between the tangent lines to the graphs of two functions – this measure could also be applied to time series. Gullo *et al*. (2009) proposed the *Derivative time series Segment Approximation* (DSA) representation model which enables to capture the main trends of time series and data compression. Liao (2005) presented the overview of the measures used to determine the similarity/dissimilarity between two time series being compared, either in the forms of raw data, extracted features, or some model parameters. Oregi *et al.* proposed the On-line Elastic Similarity Measure, an adaptation of conventional ESMs suited to measure the similarity between time series in on-line settings which allowed to compute measures of similarity incrementally, and incorporate a forgetting mechanism to adapt to changes in the streaming time series. Palomba *et al*. (2009) applied pair-wise similarity of short-run dynamics (countries i and j have similar short-run dynamics if they share the same forecast function) and multi-wise similarity of short-run dynamics (countries belonging to a set have similar short-run dynamics if all of them share the same forecast function) in order to analyse the similarity of short-run inflation dynamics across European Union Member States during the Euro period. Serrà and Arcos (2014) compared the results of classification 45 time series coming from a variety of scientific domains using 7 different similarity measures coming from alternative measure 'families' and did not find one universal measure which is the best for every time series. Batóg and Dmytrów (2016) analysed similarity of economic development of Polish regions using Dynamic Time Warping.

The approach presented in the paper is slightly different. As a measure of time series similarity, the correlation coefficient for the examined period was used. The similarity of time series for all

countries for both the GDP growth rate and employment growth rate was examined, as well as the similarity between the examined variables in each year. Then countries were divided into 4 groups in each year as follows:

Group 1 – countries with GDP growth rate greater or equal median and employment growth rate greater or equal median,
Group 2 – countries with GDP growth rate less than median and employment growth rate greater or equal median,
Group 3 – countries with GDP growth rate less than median and employment growth rate less than median,
Group 4 – countries with GDP growth rate greater or equal median and employment growth rate less than median.

In the next step two indices of concordance of classifications were computed. The first one allows to evaluate the percentage of countries which stayed in the same group in two consecutive years (propensity to stay in the same class of objects):

$$C_1 = \frac{\sum_{i=1}^{n} c_i}{n} \tag{1}$$

where:

i – number of object (country),
n – number of objects,
$c_i = 1$ when object i is in the same group in both years,
$c_{rs} = 0$ when object i is not in the same group in the first and in the second year.

The second measure of concordance of classifications was index presented by Rand (1971):

$$C_2 = \frac{\sum_{r,s;r<s} c_{rs}}{\frac{n(n-1)}{2}} \tag{2}$$

where:

r, s – number of object (country),
n – number of objects,
$c_{rs} = 1$ when objects r and s are in the same group in both years or objects r and s are not in the same group in both years,
$c_{rs} = 0$ when objects r and s are in the same group in one year and are not in the same group in the second year.

Index C_2 assesses the level of similarity of structure of groups of countries in two consecutive years.

At the end of the analysis the division into 4 groups on the base of average growth rates was conducted and differentiation in every group of countries was computed. As a measure of differentiation the mean Euclidian distance from centroid was applied (3).

$$D = \frac{1}{k}\sum_{j=1}^{k}\sqrt{\left(x_j - c_x\right)^2 + \left(y_j - c_y\right)^2} \tag{3}$$

where:

k – number of objects in the given group,
c_x, c_y – coordinates of centroid of the given group,
x_j, y_j – values of average growth rates for GDP and employment.

All measures were computed separately for each continent.

Data Characteristic and Results

Our data came from The Conference Board Total Economy Database™, November 2018, and concerns GDP growth rate and employment growth rate in 1993–2017 for 119 countries from four continents. The data set covers 25 countries from Africa, 37 countries from Asia, 40 countries from Europe and 17 countries from Latin America. Figures 1, 2, 3 and 4 present medians of GDP and employment growth rates in Africa, Asia, Europe and Latin America respectively.

Fig 1. Medians of GDP and employment growth rates in Africa in 1993-2017
Source: authors own study

Fig 2. Medians of GDP and employment growth rates in Asia in 1993-2017
Source: authors own study

Fig 3. Medians of GDP and employment growth rates in Europe in 1993-2017
Source: authors own study

Fig 4. Medians of GDP and employment growth rates in Latin America in 1993-2017
Source: authors own study

It is visible (Fig 1-4) that GDP growth rates are always higher than employment growth rates in all cases. All the groups of countries surveyed were affected by the crisis that started in the United States in 2007. The economies in Europe and Latin America reacted the most strongly to the global crisis.

It can also be seen that only in European countries, after a relatively fast end of the recession, several years of GDP and employment growth have been recorded. The strongest immediate relation between changes in GDP and employment was observed in countries in Europe and Latin America, while in African and Asian countries changes in employment were characterised by a one-year lag with respect to real production.

For all possible pairs of countries in every continent correlation coefficients for GDP growth rates as well as for employment growth rates were calculated for 1993-2017. The Table 1 presents these results in the synthetic way – it contains percentages of statistically significant coefficients of correlation for all possible pairs of countries (assuming significance level 0.05).

Table 1: Percentage of statistically significant coefficients of correlation for all possible pairs of countries

Continent	GDP	Employment
Africa	15.7	23.0
Asia	26.1	13.4
Europe	52.6	35.4
Latin America	30.9	7.4

Source: authors own study

The results obtained (Table 1) indicate that the strongest synchronization of both GDP and employment changes occurs in European countries. In the most of the examined countries, apart from Africa, changes in GDP are characterised by a higher level of dependence compared to dependence of employment.

For the same period analysis of correlation between the GDP growth rates and employment growth rates for every single country was conducted. The Table 2 contains percentages of statistically significant coefficients of correlation for countries in every continent (assuming significance level 0.05).

Table 2: Percentage of statistically significant country specific coefficients of correlation between GDP growth rate and employment growth rate

Continent	GDP and Employment
Africa	32.0
Asia	42.2
Europe	85.0
Latin America	58.8

Source: authors own study

Similarly as in the case of a separate analysis of time series of both variables, the study of correlation between changes in GDP and employment in individual countries showed the highest level of dependence in European countries and Latin America.

After temporal analysis the stability of classification of countries to a specific class were checked. During the first step all countries belonging to the particular continent were divided into 4 different classes according to the scheme described in the research method part above. Then for all period the year-to-year concordance index C_1 was computed for every continent. The results are presented in the Figure 5.

Fig. 5: The year-to-year concordance index C_1 for 4 continents in 1993-2017
Source: authors own study

As can be seen (Fig 5), the stability of class membership on all four continents was moderate and relatively varied, both in space and time. It ranged from 5.9% to 77.5%, with the highest values for European countries and the lowest for Latin American countries. In Europe the strong decline in stability of class membership over several years started at the beginning of the economic crisis in 2008 – C_1 dropped from 78% to 35%.

Table 3 presents concordance index C_2 for chosen sub-periods for every continent separately.

Table 3: Values of index C_2 in chosen subperiods (in %)

Subperiod	Africa	Asia	Europe	Latin America
1993/2017	63.3	63.7	61.3	64.7
2007/2008	69.0	71.6	67.2	64.7
2008/2009	68.3	70.0	62.8	64.7
2007/2009	66.0	70.4	61.0	67.6
1993/1998	61.3	63.7	62.8	61.8
1998/2003	62.3	61.3	70.8	59.6
2003/2008	64.0	62.5	63.1	58.8
2008/2013	66.0	67.9	58.2	66.9
2013/2017	68.3	64.3	59.2	64.7

Source: authors own study

In all analysed periods there was a higher than average similarity of the structures of the obtained classes of countries – pairs of countries which in the first and second year of a given period were characterized by similar levels of changes in GDP and employment or in both these years were in different groups dominated. However, the differences in this measure between the continents are quite small.

The last part of results concerns average growth rates in 1993-2007 and their division into four groups. Figures 6, 7, 8 and 9 present average growth rates of GDP and employment for individual countries in Africa, Asia, Europe and Latin America respectively.

Fig 6. Average growth rates of GDP and employment in 1993-2017 in Africa
Source: authors own study

Fig 7. Average growth rates of GDP and employment in 1993-2017 in Asia
Source: authors own study

Fig 8. Average growth rates of GDP and employment in 1993-2017 in Europe
Source: authors own study

Fig 9. Average growth rates of GDP and employment in 1993-2017 in Latin America
Source: authors own study

The centroids for each continent had the following coordinates of average GDP and employment growth rates: Africa (4.47; 3.13), Asia (4.85; 2.38), Europe (2.53; 0.38) and Latin America (3.06; 2.06). Hence, the fastest economic growth was observed in Asia, and Europe was experiencing stagnation on the labour market.

All African countries were characterised by positive average GDP and employment growth rates. Zimbabwe (ZWE) and South Africa (ZAF) had the worst situation in terms of both parameters considered, while Mozambique (MOZ) and Ethiopia (ETH) had strong GDP growth rate, with the former being accompanied by relatively low employment growth rate.

Among Asian countries, the worst macroeconomic situation was observed in Syria (SYR) and Japan (JPN) and the most favourable one in Qatar (QAT). The negative average employment growth rates occurred in two countries: Georgia (GEO) and Armenia (ARM).

In the group of European countries, the worst situation was in the case of Ukraine (UKR), and the most favourable situation in Ireland (IRL), Luxembourg (LUX) and Malta (MLT). Bosnia and Herzegovina (BIH), Romania (ROU) and Moldova (MDA) had negative average employment growth rates, with Moldova (MDA) also having a low GDP growth rate.

Latin American countries constituted the least diverse group. They were distinguished by the negative macroeconomic situation of Jamaica (JAM), Barbados (BRB) and St. Lucia (LCA). Venezuela (VEN) was characterised by stagnating GDP growth, and Uruguay (URY) by low

employment growth. The strongest GDP growth was in the Dominican Republic (DOM) and Peru (PER), but at the same time these countries had an average employment growth rate.

Table 4 presents values of the measure of differentiation *D* in every group of average growth rates separately.

Table 4: Values of the measure of differentiation *D*

Group	Africa	Asia	Europe	Latin America
1	0.99	1.90	1.05	0.58
2	0.59	1.61	0.33	1.36
3	1.09	1.51	0.98	0.81
4	0.94	1.55	0.96	0.47

Source: authors own study

Looking at the values of the measure of differentiation *D* in the columns of Table 4 it could be observed that taking into account both analysed variables the highest differences between individual countries were in Asia whereas the smallest ones were in Europe.

Conclusions

The study of the degree of similarity between countries in terms of the two most important macro-economic parameters, the GDP growth rate and the employment growth rate, allows to formulate several general conclusions. During almost last three decades we were witnesses of unbalanced and not sustainable growth of these two variables, and in general, medians of GDP growth rates were much smaller than medians of employment growth rates. The dynamics of medians of GDP and employment growth rates were very different in Africa and Asia, and quite similar in Europe and Latin America. After the last world economic crisis there was a big drop in GDP growth rates in case of all continents, whereas the declines of employment growth rate were much smaller. Europe was the only continent with the full recovery of GDP growth after 2010, but together with Latin America they suffer from stagnation on the labour market. The strongest synchronization of GDP and employment was observed within European countries, while for employment the smallest one was noticed in Latin America, which means that almost every country on this continent had its own pattern of development of labour market. Classification of all countries according to both kinds of growth rates was quite unstable, especially in Latin Amerika, as well as in Asia and Europe directly after the last economic crisis. The lowest level of similarity of economic growth and labour market development paths was observed in Asia, while the highest homogeneity of countries according to dynamics of these two indicators was observed within particular clusters in Europe and Latin America.

Received results can be considered as a basis to create and apply differentiated anticyclical financial, monetary and fiscal policy across groups of countries characterized by the same pattern of GDP and employment growth. Identifying the necessary strength and areas of government intervention requires not only knowledge of how a country's overall economic activity evolves, but also the ability to detect its relationship with fluctuations of economic activity in other countries.

Apart from dynamics of GDP its structure is also important (e.g. the share of advanced technologies, such as products and services or raw materials). The relevance of labour contribution to economic growth depends also on its main characteristics, including: share of labour in the national income, labour productivity and the number of hours worked.

In the further research more detailed analysis could be conducted for individual countries. Also the classification of countries could be performed by means of other classification method, for example the cluster analysis with using more variables such as export and investment.

Abstract

Student's perception of corporate communication units in universities is the focus of this short paper. It shows the extent of corporate communication unit's interaction and engagement of students within six selected universities in the southwest, Nigeria. The administration of questionnaire to 265 undergraduates of six universities in the country produced the data. Descriptive and inferential methods of analysis were uses to process the research data. This paper is for potential teamwork with investigators from other universities all over the world.

Keywords: Corporate communication, Corporate Communication Units, Public relations, Students, Universities

Introduction

The success of what university administrators do depend on effective corporate communication with stakeholders, particularly, the students (Ekanem *et al*., 2020). Communication provides ways of motivating, influencing and interacting with students as they are the main target of services offered by universities (Aririguzoh, 2016; Amodu *et al*., 2019). Corporate communication units manage communication within universities. They aim to create mutual understanding, attain organisational goals and serve the publics' interests (Odiboh, 2020; Fashiku, 2016; Olatunji, 2014). Since, corporate communication units manage information within universities and keep the university community up-to-date with management plans, policies, and decisions among others. Thus, the assumption is that every member of the university community knows and is well acquainted with the Unit and its tasks (Amodu *et al*., 2017; Ekanem, *et al*., 2018; Saha, 2014; Goodman, 2006). It would, therefore, be insightful to investigate the perception of students on the subject matter.

This study can help university administrators, public relations professionals, universities' corporate communication units, regulators of higher institutions to uncover students' knowledge of their university's communication offices and its activities.

Subject area	Public Relations
More specific subject area	Corporate Communication and New Media Studies
How the study was executed	Survey through the use of a questionnaire
Study format	Quantitative
Experimental factors	The data for the survey was obtained from two hundred and sixty-five students in six public and private universities in Lagos, Ogun and Oyo States, Nigeria. The researchers designed the questionnaire, and the data was analysed using the Statistical Package for the Social Sciences (SPSS 22).
Experimental features	Corporate communication is a branch of public relations which deals with information exchange and management within an organization. Universities engage corporate communication Units to keep the university community, particularly the students, informed about managements' decisions, plans, and policies. It is imperative to find out students' knowledge of their university's communication offices and their perception of the Unit's activities.
Preliminary study location	Nigeria
Data accessibility	Study is available for further collaborations

Value of this study

1. This preliminary study will reveal student's knowledge of their university's communication offices.
2. It will reveal students' perception of the activities of the corporate communication units.
3. It could serve for additional enquiry on improving unit-students interaction and engagement.

Experimental Design, Materials and Method

The data for the survey came from mass communication undergraduates of six selected universities in Nigeria. Berry and Lindgren's (1990) 10% rule was applied to determine the sample size of the students for the administration of the copies of the questionnaire. The reason for using the 10% rule was to have a normal distribution since the population was small. This helped the researchers to avoid bias and ending up with data that was not representative. An observation was that in an attempt to interact and engage with students actively, corporate communication units of universities now have new media platforms. However, most of these new media platforms have low student followership because the students do not like the design of the pages. This point could not be accommodated in the research considering that the subject stands on knowledge of corporate communication units. The data gathering instrument was designed by the researchers to elicit responses about the identified variables. The data were analysed using the Statistical Package for Social Science (SPSS 22).

Preliminary Study Results

This study highlights the age, gender, undergraduate's knowledge of the existence of corporate communication units of six selected universities in Nigeria. Three were private and three were public universities. Descriptive and inferential methods of analysis were used to present the data obtained as shown in Tables 1 to Table 5:

Table 1: Age Distribution								
Age		Universities						Total
		LASU	Caleb	FUNNAB	Babcock	UI	Lead City	
18 - 22 years	Units	53	29	1	55	17	8	**163**
	%	63.1	59.2	2.9	93.2	73.9	53.3	**61.5**
23- 27 years	Units	29	20	5	5	6	6	**70**
	%	34.5	40.8	14.3	6.8	26.1	40.0	**26.4**
28- 32 years	Units	1	-	11			1	**14**
	%	2.4	-	31.4	-	-	6.7	**5.3**
33 years & above	Units	-	-	18				**18**
	%	-	-	51.4	-	-	-	**6.8**
Total	**Units**	**83**	**49**	**35**	**60**	**23**	**15**	**265**
	%	**100**	**100**	**100**	**100**	**100**	**100**	**100**

Virtually all the universities had the majority of its students between the ages of 18years and 27years. The Federal University of Agriculture (FUNNAB) was the only university with more students between the age bracket of 28years and above.

Table 2: Gender Distribution									
			Universities						
			LASU	Caleb	FUNNAB	Babcock	UI	Lead City	**Total**
Gender	Male	Units	26	26	17	21	8	6	**104**
		%	31.0	53.1	48.6	35.6	34.6	40.0	**39.2**
	Female	Units	58	23	18	38	15	9	**161**
		%	26.8	46.9	51.4	64.4	65.2	60.0	**60.8**
Total		**Units**	**83**	**49**	**35**	**60**	**23**	**15**	**265**
		%	**100**	**100**	**100**	**100**	**100**	**100**	**100**

Though females were more than male students, the males were well represented in the survey.

Table 3: I know my University has a Communication Unit							
	Universities						**Total (%)**
	LASU	CALEB	FUNNAB	BABCOCK	UI	LEADCITY	
Strongly Agree	50.0	18.4	22.9	27.1	17.4	40.0	**30.9**
Agree	41.7	24.5	40.0	45.8	65.3	40.0	**41.1**
Undecided	7.1	36.7	25.7	16.9	13.0	13.3	**18.1**
Disagree	3.6	12.2	5.7	8.5	4.3	6.7	**6.8**
Strongly Disagree	1.2	8.2	5.7	1.7	-	-	**3.0**
Total	**100 n=83**	**100 n=49**	**100 n=35**	**100 n=60**	**100 n=23**	**100 n=15**	**100 n=265**

From Table 3, the majority of the respondents, 72%, agreed that they knew that their respective university has a corporate communication unit. Only Caleb University's students (57.1%) do not know about the existence of a corporate communication unit in their institution. Meaning that the Communication Unit of the institution does not sufficiently interaction and engage with the students.

Table 4: Knowledge of Students on the name of Corporate Communication Unit

Unit Name	Universities						Total (%)
	LASU	CALEB	FUNAAB	BABCOCK	UI	LEAD CITY	
Centre for Information, Press and PR	79.8	-	-	-	-	-	**25.3**
Directorate of Corporate and Students' Affair	-	-	-	-	-	20.0	**1.1**
Directorate of Public Relations	-	-	2.9	-	-	20.0	**1.5**
Media and Public Relations Unit	-	-	-	-	-	-	**0**
Department of Marketing and Communication	-	-	-	3.4	-	-	**0.8**
Directorate of Public Communication	-	-	-	-	4.3	-	**0.4**
No Idea	20.2	100	97.1	96.6	95.7	60.0	**70.9**
Total	**100 n=83**	**100 n=49**	**100 n=35**	**100 n=60**	**100 n=23**	**100 n=14**	**100 n=256**

Table 4 shows that although the students were aware of the existence of corporate communication units in their respective universities (See Table 3), very few know the name of the unit. Lagos State University (LASU) is the only university where, 79.8% of its students correctly identified the Unit as the *Centre for Information, Press and Public Relations* (CIPPR). This impeccable result could be as a result of the Centre's acronym CIPPR. It makes it easier for the students to remember as virtually all the respondents filled it that way in the instrument. Next to LASU is Lead City University; even after the University merged its Communication Unit with Students' Affairs' Department, giving the students more reasons to interact with the Unit, only 20% could recall its name. Meanwhile, majority of Caleb University's Students either left their instruments blank on this question or filled public relations unit.

Table 5: The Communication Unit keeps me informed about University Activities

	Universities						Total (%)
	LASU	CALEB	FUNNAB	BABCOCK	UI	LEAD CITY	
Strongly Agree	36.9	8.2	20.0	15.3	-	53.3	**20.0**
Agree	45.2	16.3	25.7	23.7	34.5	26.7	**23.4**
Undecided	11.9	40.8	42.9	40.7	43.8	6.7	**41.5**
Disagree	4.8	22.4	5.7	18.6	17.4	13.3	**11.7**
Strongly Disagree	1.2	12.3	5.7	1.7	4.3	-	**3.4**
Total	**100 n=83**	**100 n=49**	**100 n=35**	**100 n=60**	**100 n=23**	**100 n=15**	**100 n=265**

Table 5 shows that undergraduates, 56.6%, one of the essential publics of the university, do not know that one of the tasks of the corporate communication unit is to keep them informed. Less than half of the respondents, 43.4%, agreed that the communication unit keeps them informed. This is primarily as a result of Lead City University, 80%, which has its Communication Unit merged with its Student's Affairs Department.

Conclusion

There are signals in this preliminary study that undergraduates of the six universities surveyed are not in tune with the corporate communication units in their institutions. Notably, corporate communication is an instrument of management that harmonises all internal and external interactions. The overall objective is to create a favourable basis for relationships with the stakeholders of an institution. This study is a benchmark for examining same scenarios in any university anywhere in the world. It is for this reason, further studies through co-authoring collaborations are required to expand the scope, and multidisciplinary potential of this research.

The impact of COVID-19 pandemic on Financial Statements and Audit

Marek STEPIEN

Wroclaw University of Economics, Wroclaw, Poland
marek.stepien@ue.wroc.pl

Abstract

Undoubtedly pandemic has far reaching implications for each sphere of our lives and accountancy is no exception. Auditors must adapt to new circumstances. The aim of this paper is to evaluate the possible impact of current COVID-19 pandemic on financial statements and external audit to drive broader discussion about approach to audit procedures in the new circumstances. The aim was accomplished by researching and analyzing key impacted areas trying to find possible answers to newly recognized challenges.The natural next step for further research will be to conduct audits in new circumstances, gather practical experience, insights, data and based on that draw final conclusions which may change approach to audit in the future. This will include also recommendation for reasonable alternative and additional audit procedures.

Keywords: Audit, Assurance, COVID-19, Accounting, Going Concern

Introduction

In December 2019 the City of Wuhan (China) reported the coronavirus COVID-19 outbreak. Since then the number of cases in other cities and countries has spread to the point that World Health Organization (WHO) named COVID-19 disease as a pandemic. When writing this paper coronavirus is affecting 210 countries and territories around the world. There are over 2 million confirmed cases. Certain restrictions has been introduced in almost every country to limit the impact.

Among these restrictions the most popular are isolation of cities and countries, people movement restrictions, travel bans and school closure. Coronavirus has impact on human health but also significant economic effects on companies. Key business impacts are: supply chain disruptions (especially that China was the first one impacted), interruptions of production, unavailability of personnel, inability to raise financing, reduction in sales, delays in planned investments and increased volatility in financial instruments value. What is more – the pandemic is affecting global economy and major financial markets leading to unavoidable crisis.

These economic conditions have also significant implications on accounting, reporting and auditing financial statements. Challenges never before faced by auditors in performing audits are emerging. The key is remembering that, while the auditing standards outline the performance requirements for obtaining reasonable assurance the financial statements are free from material misstatement, the auditing standards do not set specific requirements on how auditors might obtain that assurance. Now, more than ever, auditors might rely on technology in performing audit procedures.

Each entity must carefully consider this unprecedented circumstances and risk exposure when analyzing the impact for their financial reporting. Auditors must also analyze and audit those accounting considerations and perform additional procedures. Additionally some standard procedures cannot be performed in the standard way which disrupt the way auditors work even further.

Key Accounting Considerations Impacting Financial Statements

The current situation means that special attention should be given to events occurring after the reporting period and possibly required disclosures and recognitions. For majority of entities in Europe with a 31 December 2019 year-end this will be a non-adjusting event, since it occurred in January 2020. In case of most companies this will be significant event therefore an estimate of its financial effect should be disclosed by way of note. It will obviously vary according to specific industry, facts and circumstances.

For entities with year-end after 2019 the impact on financial statement will be more significant and careful consideration is required especially if it comes to accounting estimates, fair value measurements, inventory valuation, onerous contract provisions, hedge accounting, breach of loan covenants, employment termination benefits, taxation. For example if it comes to inventory valuation – inventories are measured at the lower of cost and NRV (net realizable value). In a new difficult economic circumstances, the NRV calculation may need additional challenge and scrutiny at the reporting date. If it comes to onerous contract provision - such contract arises when the unavoidable costs of meeting the obligations under the contract exceed the benefits expected to be received. In the current circumstances it is quite likely that some of company's contracts become an onerous ones. Breach of covenants (even after the reporting date) may also lead to situation where lender has right to demand full repayment which in turn may affect going concern basis. Another issue may be taxation, in particular when assessing ability to recover deferred tax asset which now may not be possible in the new economic environment.

All of abovementioned areas are now very sensitive to new economic environment and almost each of these can impact going concern assumption which entities and auditors must consider now in particular as even in case of non-adjusting event after reporting period – it may have significant impact on going concern basis which in turn has impact on the whole financial statement [*Audyt finansowy w jednostkach gospodarczych, p. 253-286*]. For example companies from sector like travel, aviation or leisure & hospitality has very high likelihood of bankruptcy therefore going concern basis may not be appropriate in the light of new economic circumstances. They need to consider running several possible sensitivity analyses to determine whether there is any material uncertainty on its ability to continue as a going concern. Going concern assessment should be continuously updated to the date the financial statements are approved. In such uncertain environment going concern assessment is a very complex problem therefore it requires a lot of time and attention form the auditors.

New Challenges to Audit Procedures

Apart from key accounting considerations and additional audit procedures requirement, pandemic circumstances are impacting also more practically the way auditors are performing their standard procedures.

First of all, pandemic and isolation requirement is affecting normal communication with clients due to impossibility to access client's premises or sick leaves of client's key staff members. This in turn results in inability to obtain audit documentation or evidence which may in some extreme cases hold issuance of auditor's report (for example when it is not possible to get representation letters or collect sufficient audit evidences). Given such challenges and limitations auditors need to develop alternative audit procedures to gather sufficient audit evidence.

Access to client records is one of the challenging areas, especially if clients still maintain mainly paper records. Auditors may obtain client-prepared copies or scans of key records but proper professional skepticism and additional audit procedures needs to be applied to consider the authenticity, accuracy and completeness.

Another challenging area is audit plan which is usually based on proper understanding of the business and test of the internal controls. In the new circumstances performing walkthroughs and test of controls may be very limited. This may in turn result in not relying on control and increase substantive testing required but even then basic understanding of crucial internal controls is needed. It clearly has an impact on the planned procedures, risk assessment and so on and so forth. It is possible to perform test of controls during preliminary fieldwork which in most cases happened before COVID-19 outbreak

but follow up and inquire about internal controls changes is needed. And probably due to current pandemic circumstances the way entities works has changed significantly which means that most likely system of internal controls is now different as well.

Physical Inventory counting may also be a big challenge, especially that inventory is often a significant position. This will affect companies which were not able to conduct stock count before COVID-19 outbreak so the ones with later year-end date. It is crucial to obtain sufficient audit evidence for inventory existence and condition. This is usually achieved by attending physical counting, recounting sample and observation of company's procedures. Now some retails locations or warehouses may be closed. Even if stock count is happening auditor may not be able to attend due to travel restrictions or simply limited staff which create an obvious challenge. Possible solution is to reschedule stock count to later date when it is safe to perform. Auditor will then perform additional audit procedures to rollback. If the company is able to perform stock count but auditor is not able to be there – maybe auditors should consider usage of new technologies such as live video feeds. Of course procedures performed virtually may be limited so additional audit procedures should be in place. If audit risks cannot be reduced to an acceptable level, it may result in scope limitation.

Secondly, given the very serious impact on business and all the business continuity planning needed, issuance of historical financial statements may not be the highest priority right now. A lot of employees are on sick leaves or just transitioning to remote work model. They may not be able to prepare all the accounts and financial statement on time. Audit companies may need to rebuild their schedule not only due to client's inability to provide data on time but their own employees will be affected by the coronavirus as well. This creates additional complexity. For sure it will cause a lot of delays in issuing financial statements. Thankfully in some countries, like Poland, deadline for preparation and approval of the financial statements has already been extended which gives some relief and is absolutely crucial.

Conclusions

The COVID-19 pandemic is impacting everyone – accountancy and assurance included – and will have far reaching consequences. We can see how world is changing in front of our eyes and even after the pandemic is gone nothing will be the same anymore.

In case of auditing financial statements the pandemic is implicating two categories of challenges. Firstly it is impacting the entities' business performance very significantly which requires additional audit considerations and performing additional procedures to gain sufficient assurance. Key matter is a going concern assumption but evaluation is very complex and time-consuming. Secondly, auditors also experience COVID-19 impact and has limited staff members available while whole schedule is changing very dynamically. On top of that imposed restrictions cause additional challenges when carrying out even standard procedures.

In this case surely new alternative methods needs to be developed to be able to perform audits and obtain sufficient audit evidence, especially that we are not sure how long will it take to fight this pandemic. Perhaps it is time to move to more technologically advanced analytical procedures and usage of big data analytics which would allow auditors to deliver higher audit quality and gain additional audit evidences [*How New Technologies Can Change Our Approach to Audit*]. In the time where it looks like we need to be more creative and collect more evidences remotely it is crucial.

Looking ahead, the impact of COVID-19 on the global economy and business is expected to continue to evolve so ongoing considerations are required. In this uncertain times auditors needs to be flexible and look for new solutions, new alternative procedures to gain sufficient assurance and above all share insights with each other as this is a very unique situation in which we found ourselves.

Comparison of Regional Carbon Footprints of Multinational HSR Projects: the Case of the Rail Baltica Project

Olga PITERINA

The Baltic International Academy, Riga, Latvia
olga@ekoair.lv

Abstract

The project of the High Speed Railway construction in Baltic States is the largest joint infrastructure project in the post-Soviet era. Rail Baltica (RB) is considered as the most energy-efficient project having the lowest environmental impact. The aim of the current research is to determine the regional indicators of CO2 emissions intensity of Rail Baltica, based on the project's energy consumption and carbon intensity of each individual RB Member State. The approach applied by the author in the current study is based on the significant effects of import/export of electricity by RB Member States and grid losses, in contrast to the local-based method for calculating emissions based on CO2, emission factor of electricity production, recommended by the International Union of Railways.
The author's calculations demonstrate the substantial difference in the figures of CO2 emissions intensity between the Lithuanian, Latvian and Estonian sections of the project, which is related to the trainload rate, traffic intensity, CO2 emission factor of Member State. Using RB project as an example, author demonstrates that conclusions regarding the positive environmental effect of multinational European HSR projects should not be based on average projects 'indicators, but on the environmental impacts of the project's sections in each Member State in order to avoid conflict of interests between the project participants, as well as, the delay in the implementation of such project due to the fact that the asymmetric information received was identified late by the project's participants.

Keywords: Carbon Dioxide Emissions; Carbon Intensity; Environmental Impact; Multinational High-Speed Railway; Rail Baltica.

Introduction

In recent decades European structures have been promoting High Speed Railway (HSR) within the framework of ecological rhetoric of sustainable mobility.

However, if we look at the sequence of procedures regarding the construction of HSR, then a certain discrepancy appears - the assessment of the ecological repercussions of each HSR construction project is conducted extensively only after the decision regarding the construction itself has been made. In this respect, European statistical reports indicate that the carbon footprint of HSR is almost zero during the operational stage due to the fact that CO_2 emitted during electricity generation does not need to be taken into account (IEA and UIC, 2017).

Nevertheless, the carbon dioxide intensity of the electricity used to power the train is, in fact, the key factor behind the environmental impact of HSR.

The existing official practice of silencing the data regarding the HSR carbon dioxide intensity may mislead the decision-makers into believing in an indisputable advantage of the investments into the expensive HSR infrastructure over other measures available to minimize the CO_2 emissions in the transport industry.

The construction of HSR project in the Baltic States – Rail Baltica (RB), is considered to be strategically and economically important for number of regions such as Estonia, Latvia and Lithuania and their citizens.

Unlike many other European HSR, this project involves the organization of both passenger and freight traffic on the new high-speed corridor. This is reflected in Regulation (EU) No 913/2010 of the European Parliament (2010) and of the Council of 22 September 2010 concerning a European rail network for competitive freight (OJ L 276, 20.10.2010, p. 22) RFC8 North Sea–Baltic.

In this respect, it is important to note that up till now the official European structures have carried out the comparison of HSR services only for passenger service and not for freight.

It has to be said, that in the investment justification of the RB project around 38 % of monetized socio-economic benefits out of total of 16 226 million euros constitute ecological improvements: among them air pollution reduction amounts to 3 268 million euros, whereas climate change mitigation amounts to 3 024 million euros (Ernst & Young, 2017).

At the same time, the analysis of the investment justifications of the already implemented European HSR projects has revealed the fact that the assessment of environmental impacts of RB project is nine times different from the assessment of other ongoing HSR projects. This way, National Audit Office in 2001 determined that the environmental savings are 3.9 % of the total benefits from Channel Tunnel Rail Link (CTRL) project (NAO, 2001). Whereas, the study of the AVE Madrid-Barcelona along with the CBA has presented four sensitivity analyses in which the environmental savings are 4.3% of the total benefits (ADIF, 2009).

As the result of the abovementioned comparison a significant number of questions arise regarding the environmental performance of the RB project, which should bring mutual benefits to all the actors involved.

The RB project investment justification has not addressed properly such issues as the energy consumption and the indirect CO_2 emissions associated with the need for electricity generation required for the operation of the project.

This paper aims to evaluate and compare regional performances of CO_2 emissions intensity level of the new HSR infrastructure. The analysis conducted will indicate the existing differences in performance between Latvia, Lithuania and Estonia and examine the results of research calculations made on the basis of the efficiency analysis.

It should be noted that in this article, the author, in contrast to the methodologies adopted in the official sources, takes into account the influence of import-export of electricity by the Baltic States on the country index of CO_2 intensity, which determines, to a large extent, the regional environmental results of the RB project.

The article is structured as follows: Section 2 demonstrates different points of view on energy consumption and the environmental impact of HSR projects by various researchers. Section 3 highlights the methodology and other details of the research. Section 4 presents the assessment results of the carbon footprint of all sections of RB. The conclusions are drawn in Section 5.

Background

Following European Commission (2011 a,b,c) policy documents as “A Roadmap for Moving to a Competitive Low Carbon Economy in 2050”, “A Roadmap to a resource efficient Europe”, “Regulation of the European Parliament and of the council (on Union guidelines for the development of the trans-European transport network” consider HSR as the most energy-efficient mode of transport having the lowest environmental impact.

However, with the accumulation of data on the results of construction and operation of HSR in Europe, the findings of researchers on the environmental friendliness of HSR have become more and more ambiguous.

Gonzalez-Gonzalez E. *et al* (2010), along with the research already mentioned above, determined that the environmental benefits of HSR construction projects represent only a small part of the benefits. The environmental impact assessment of HSR projects, according to the researchers, mainly affects route alignment and route selection. Therefore, as a pro-environmental policy, the development of HSR has significant limitations.

Miyoshi and Givoni (2012) have investigated the potential for environmental benefit from the introduction of the High Speed Train (HST) on the London–Manchester route in the UK, focusing on carbon dioxide (CO_2) emissions. The importance of demand in determining the environmental performance of HST lines was defined clearly. Thus, they demonstrate the train energy consumption (21.45 kWh per km) in cases where the UK electricity carbon reaches intensity (0.45 kg CO_2 per kWh). Their analysis shows relatively limited potential of HSR for reduction in CO_2 emissions. In 2033, the overall CO_2 reduction due to HST operation on the London–Manchester route is estimated at 100,000 t CO_2 per annum, which is less than 0.1 per cent of the total UK domestic transport emissions in 2007.

The reason for difference in HSR CO_2 emissions among the countries is the variation in numbers of such parameters as occupancy levels and the sources of electricity supply for the trains ʼoperation. For example, the French HSR has low CO_2 emissions per passenger-km (pkm) mainly due to the high share of nuclear power in French electricity supply to rail operators (Seguret, 2014). Nevertheless, there is a chance that investments into the rail industry may end up with much less environmental benefits than was expected during the planning stage due to several factors. In the research conducted by Von Rozycki *et al.* (2003) the CO_2 emissions figures for German HSR network are much higher (69.4 g/pkm), which can be explained by the fact that the demand is relatively low whereas the level of CO_2 emissions is quite high.

Alternatively, number of researchers criticize the approach of the determination of the environmental consequences of HSR based only on the analysis of the operational phase of such projects (Chester & Horvath, 2009; Westin & Kageson, 2012; Bueno *et al.*, 2016; Akerman, 2011; Givoni and Banister, 2012). The point of view taken up in these studies is that significant amount of energy consumption and CO_2 emissions originate from non-operational aspects of HSR systems, such as construction of stations and infrastructure in general, manufacturing of the vehicles, its maintenance and fuel production.

Jehanno (2011) claimed that the emissions from the construction of the HSR lines were estimated "in the range of 58 t–176 t of CO_2 per km of line and year. Lines with a moderate space and relief constraints (for example in France) emits around 60t of CO_2. The construction, maintenance and disposal of the rolling stock lead to emissions of 0.8 CO_2 to 1.0 g CO_2 per pkm. The construction of an airplane (0.5g CO_2/pkm) is in the same magnitude as HSR."

All the studies mentioned above were devoted to HSR projects that have been already implemented and are operating within the framework of one state.

The works devoted to the study of carbon footprint of international European HSR and the impact of their regional differences on the state policy of individual participating States in relation to the project currently are not available in the academic literature.

Only Dʼ Alfonso et al. (2016) has modeled the environmental impacts of London-Paris HSR-air transport competition, capturing the effects of induced demand, schedule frequency, and HSR speed: the authors showed that the net environmental effects of HSR can be negative since there is a negative trade-off due to the substitution effect.

Report of the European Court of Auditors (2018) explicitly mentions the problems of international European HSR projects implementation related both to differences in the estimated level of line congestion in different sections of such projects, and to the significant amount of earthwork

operations in individual sections, which will lead to various environmental results lowering the interest of individual States in the speedy implementation of projects.

Considering the Rail Balica project, it is important to mention the lack of research works available that include analysis of the carbon footprints of the future project and their impact on the public policy of RB Member States regarding the project.

Only Humal *et al*. (2018) have noticed that the authors of the RB investment justification have ignored the requirement of 'Guide to Cost-Benefit Analysis' (EC, 2014) regarding the CO_2 emissions arising out of the project's new infrastructure construction.

As it was already mentioned, Rail Baltica project involves the organization of both passenger and freight trains along a new corridor. The problem is that according to the review of the European Parliament (2015), HSR freight transport is still a 'poor relation'.

However, no significant researches on the comparative analysis of environmental indicators of cargo HSR are available and accessible in the international academic databases at the current moment. Therefore, Prussi and Lonza (2018) in their paper on the comparison of emissions profiles between HSR and air transportation on some European routes make a final observation that HSR is not used for freight, hence no comparison can be made with airfreight segment.

Methodology

When developing investment justifications for international transport infrastructure projects that are co-financed from EU funds, an averaged approach is used, which is correct to address general EU policies, but which does not allow to optimize policies at national level.

It was previously mentioned (Rail Baltica, 2018), that State's strategic development programs of the RB Member States were not taken into account in the calculations for the project. But States participating in the projects such as Rail Baltica are interested in assessing the impact (ex-ante and ex-post) of their own environmental policies. Accordingly, in order to understand the environmental impact of the abovementioned project on each participating State, it is necessary to take into account, at least, the drastic differences in CO_2 emission intensity (CI) of each of the RB Member States, which has not been done yet.

Calculations of CO_2 emissions for passengers and cargo traffic most often are based on the location-based method of the GHG Protocol Scope 2 Guidance (UIC, 2012). One of the key indicators in this case is the CO_2 emission factor. International Union of Railways recommends the use of index of CO_2 intensity of electricity production. However, this approach does not take into account grid losses and artificially lowers the indirect CO_2 emissions associated with the consumption of HSR electricity.

Unlike recommended UIC index of CO_2 intensity of electricity production, in the current research, the author uses National and European Emission Factors for Electricity (NEEFE) to estimate indirect CO_2 (tCO_2/MWh) or GHG (in tCO_2-eq/MWh) emissions related to the project's electricity consumption, which is calculated by applying the LCA emission factors to the energy carriers consumed to produce electricity. The LCA default emission factors have been calculated by adding to the standard emission factors, emissions from the supply chain as estimated from the latest version (v3.2) of the European Life Cycle Database (JRC, 2017).

In the case of a "closed system" (without import or export of electricity), Electricity consumed equals Electricity produced minus the losses in the grid. But in case of net export of electricity, both the losses in the national grid and the emissions related to the exported electricity (even if consumed outside the country) are accounted for. Inversely, for countries with consumption of electricity higher than production, the derived NEEFE calculated is smaller than the NEEFE*p* factor, because it accounts for the imported electricity but not for the associated CO_2 emissions (which are emitted outside the country).

That is, in case of important import or export of electricity, the NEEFE that are significantly different to the NEEFE*p* factor. However, it is problematic to find any information on the amount of emissions related to the import or export of electricity in European countries, since such information is generally not available in the existing international energy datasets.

Having assessed the CO_2 emissions of the RB project, the author has come to the conclusion that the above mentioned difference is of great importance, since two out of three participants of the RB project have considerable differences between the index of electricity production and index of CO_2 intensity of electricity consumption (NEEFE).

So, for Estonia, the export of electricity plays an essential role, because the main share of electricity in Estonia is produced from oil shale. Lithuania, on the contrary, provides the demand for electricity with its own production only covering 1/3 of the demand, and, hence, is significantly dependent on its imports.

Therefore, from the methodological viewpoint, the current research emphasizes the importance of taking into account the abovementioned impacts of electricity import/export by the countries-participants of the RB project.

As it was already indicated in the introduction, the data used for the current research includes the results of passengers and freight flows scenario forecast (Ernst & Young Baltic, 2017) as well as the data obtained from the official statistics of International Union of Railways (UIC, 2016), Eurostat and International Energy Agency (Table 1; Table 2).

It should be pointed out that in 2019 a more intensive Operational Plan of traffic organization for the RB corridor was presented (Rail Baltica, 2018). Yet, the given Plan does not take into account the aforementioned changes, since the information about the load factor/occupancy rate of trains and cost performance of the new traffic organization were not put forward.

CO_2 emissions indicators for RB passengers and freight traffic are calculated using the following equations:

$$ACE_{p(f)} = AEU_{p(f)} \times TC_{p(f)} \times LL \times 365 \times NT \times CCEF / 10^3 \quad (1a)$$

$$CEI_p = ((AEU_p / OR) \times CCEF) / 10^3 \quad (1b)$$

$$CEI_f = ((AEU_f / LF) \times CCEF) / 10^3 \quad (1c)$$

Where:

$ACE_{p(f)}$ - Annual CO_2 Emissions [kt CO_{2eq}];

$CEI_{p(f)}$ - CO_2 Emissions Intensity [g CO_{2eq} /p (t) km];

LL – Length of Railway line by Section (kilometres);

NT – Number of train/day;

TC – Train capacity, determined as the number of seats in a train for the passenger train (402;228 for the section Riga-Airport) or the total weight of the train in cases of the train transporting freight (1098 tonnes);

OR – Occupancy rate, the relation between the number of places occupied and the maximum number of places offered;

LF – Load factor, is the ratio of the average load to total train freight capacity, in tons or volume. Since such data is not available for the whole EU for all modes (with exception for aviation), the load factor is defined as the number of tonnes-km divided by the number of train-km;

AEU_p (Average electricity use pass.) (kWh/seat-km) - is the required amount of energy to transfer one seat travelling for 1 km. This indicator was considered by Jehanno (2011), Jurado (2012) and IEA & UIC (2017) based on the electric consumption of an Alstom AGV (0.033 kWh/seat-km);

AEU_f (Average electricity use freight) (kWh/tonne-km) - is the required amount of energy to transfer one ton of goods travelling for 1 km. This indicator was taken by the author as being equal to 0,05 kWh/tonne-km according to the methodology proposed in García Álvarez *et al*. (2013), due to the lack of the following data in the statistics of the European Union;

CCEF (country CO_2 emission factor) (in t CO_2-eq/MWh) - this indicator is assumed to be equal to the NEEFE for each Mamber States of RB Project, due to the lack of data regarding the future electricity suppliers for the project.

Moreover, as it was mentioned above, a complete carbon impact analysis of a HSR system should include both embedded and operational emissions. The data on the distribution of carbon dioxide emissions by years of operation arising during the construction of the railway infrastructure was adopted by the author on the basis of the IFEU/Tuschchmid methodology (UIC, 2016). However, taking into account that according to this methodology, the emissions are distributed by linear depreciation, the author of the study has conducted a procedure for compounding the built-in CO_2 emissions at construction at a rate of 5%, similar to the socio-economic discount rate of 5%, which is adopted in the investment rationale for the project. It was also taken into account that greenhouse gas emissions emitted during the construction stage are measured in terms of kg (or tonnes or grams) of carbon dioxide equivalent, written CO_{2eq}.

The total amount of CO_2 emissions will be an amount of the required reduction of emissions from other modes of transport, cargo and passengers, which will have to switch to a new railway.

The evaluation of the carbon footprints was carried out on the basis of a cluster analysis of the environmental consequences of the RB project for each of the participating countries with a subsequent comparison of their share in the project's environmental benefits.

Results and Discussion

The results of CO_2 emissions intensity assessment segregated by the types of flows are shown in the Table 3 and on the Fig.1 and Fig. 2.

Figure 2: Carbon footprints of passenger flows on Rail Baltica.

The results of the calculations show that Estonia has exceptionally high level of carbon dioxide emissions associated with the country's CO_2 emission factor (NEEFE). The intensity of emissions for the Estonian part of the RB will change from 164 g CO_{2eq} /pkm in 2030 to 131,6 g CO_{2eq} /pkm in 2050 (in case of the baseline scenario) and from 206,07 g CO_{2eq} /pkm to 167,37 g CO_{2eq} /pkm in 2050 (in case of the low scenario).

If we compare the carbon dioxide intensity of the Estonian section of RB with the intensity of CO_2 emissions from air transport and passenger vehicles, then it becomes obvious that the comparison is not in favour of RB. In ATOC analysis for Greengauge 21(Davies and Thompson, 2009), made on the basis of the carbon reduction strategy for road, it is stated "that new car emissions per passenger km might fall from around 105 g CO_2 now to around 40 g CO_2 per passenger km by 2055. And aviation emissions per passenger/km could fall from around 120 g CO_2 today to around 50 g CO_2 by 2055."

This suggests that the CO_2 emissions intensity of the Estonian section of RB from passenger traffic may exceed even the current CO_2 emission intensity figures exhibited by those types of transport that RB railway aims to replace due to its "high environmental friendliness" as stated in the investment justification of the RB Project.

In respect to the freight traffic, it has to be said that due to the high NEEFE country-wide index CO_2 emission intensity indicators for the Estonian section in 2030 will be much higher than CO_2 emissions produced by trucks per tonne/km (EP, 2015): 155,15 g CO_{2eq} against 75 g CO_2..

By 2050 the Estonian section will see a slight decrease in the intensity of CO2 emissions amounting to 144,07 g CO_{2eq} /tkm. Yet, it is not a competitive value if we compare it with the forecast data for the road transport.

With respect to other project participants having a comparable level of NEEFE indexes – Lithuania and Latvia, the following situation may be observed in terms of the intensity of CO2 emissions. Under the baseline scenario passenger flows on the Lithuanian section will have two times lower emission rates per one pkm than on the Latvian section: 7,26 g CO_{2eq} against 15,19 g CO_{2eq}, in 2030, and 6,85 g CO_{2eq} against 13,54 g CO_{2eq}, in 2050.

Such a significant difference is due to a lower occupancy rate in the Latvian section. It should be noted that the Lithuanian section provides for the construction of three railway stations for passengers: Vilnius, Kaunas and Panevežis, whereas on the Latvian section passenger stations will only be located in Riga, connecting the city centre and the airport. The consequence of this will be the high agglomeration effect of the RB project in Lithuania, which will eventually entail an increase in the occupancy of passenger trains within the region, and respectively, an increase in energy efficiency per one passenger km and a subsequent decrease in the emission intensity.

In Latvia, however, the opposite effect will be observed as follows from the Ernst & Young scenario. Low occupancy of passenger trains leads to high energy intensity of transportation and this, in turn, will affect not only the environmental performance of the project but also the price aspects of passenger transportation. The baseline scenario of the investment justification of the RB project provides that in the averaged current expenditure of the project, 17% - is electricity costs. As follows from the above calculations, the component of these costs will vary considerably, depending on the section and, therefore, will affect the price of the ticket.

Regarding the intensity of CO_2 emissions of freight traffic of the Lithuanian and Latvian sections of RB, it is necessary to emphasize again that due to the similar level of energy efficiency in the range of differences, the difference in emission intensity depends only on the difference in the NEEFE indexes: 9,17 g CO_{2eq} /tkm in 2030 on the Lithuanian section against 13,52 g CO_{2eq} /tkm on the Latvian section (while maintaining this proportion throughout the life cycle of the project.)

The author's calculations demonstrate significant difference in the intensity of CO_2 emissions among the Latvian, Lithuanian and Estonian sections of the RB project in relation to the train load factor and CO_2 emissions factor, taking into account the significant import/export of electricity by the countries participating in the project.

It becomes obvious that the project does not carry the same social benefits for all the participants of the project but involves only a synthesis of some stable links between the Member States, connecting them into a certain community.

Table 4 presents the final calculations for the total volume of CO_2 emissions per one km of each section of Rail Baltica, with the inclusion of CO_2 emissions resulting from the construction of the project's infrastructure.

Table 4: Total CO_2 emissions level of Rail Baltica by section

Figure 3: Total carbon footprints level of Rail Baltica by section.

Source: author's compilation

The results of the study shows considerable disagreement between the stated aims and performance criteria of the RB project and the objective elements of the economic structure of the regions of the three participating countries, including the country-wide CO_2 emissions factor and the structure of power generation as well as significant volumes of electricity import/export. The magnitude of indirect CO_2 emissions on the Estonian section may lead to a crisis of the entire project.

The investment justification of the RB project averages the environmental performance and ignores the CO_2 emissions associated with it, whereas current research separates this whole mass into independent regional elements. In practice these elements will interact with each other while maintaining their own status quo.

Conclusions

For the success of international European HSR projects and their high environmental performance achievement, it is important that favorable conditions are created before the start of their operation. This is one of the prerequisites in order to attract shippers and passengers of the regions to use the railway transport more often than they are used to it. Experience has shown that either rail transport should significantly improve the service, relying on favorable conditions provided by the respective governments, and/or that governments should take decisive measures to force shippers or passengers

to use rail transport. But the governments of individual States solve the issues of their sections of similar projects on their own, since all the infrastructure associated with such projects, in any case, is not the common property of the project Member States.

The defining feature of the RB project is its multinational character. Clarifying the qualitative difference in the evaluation of CO_2 emissions by region is a necessary step towards the formation of a sustainable development policy for all Member States of the RB project.

In author's opinion, currently, the conduction of the adjustments to the investment justification of RB project is required, in which the following factors should be considered:

a) all national programs of the countries-participants in the project aimed at achieving sustainable mobility;
b) the interests of the main external actors involved in the transportation services market in the region of the RB project. To believe that they would remain indifferent to such a powerful competitor as the RB project is to adopt a short-sighted attitude towards this situation, since the questions of tariff maneuverings can also lead to the project's crisis.
c) the depreciation's period of railway assets is significantly longer than the lifecycle of automotive vehicles and, therefore, it leaves less chance for the railway to change rapidly along with the innovative requirements of the freight and passenger market;
d) to take into account the high level of seasonality of the tourism industry in the RB project's region in terms of passenger transportation;
e) to ensure the development of the "last mile" infrastructure with the inclusion of cost's calculation into the total investment costs of the project.

Apart from that, Project holders need to start concluding contracts of intent with potentially low- CO_2 emissions electricity suppliers for the RB project. It needs to be done since the potential project customers and taxpayers of the RB Member States should realize the environmental orientation of the project already at its design stage. This measure should also be reflected in the investment justification of the project.

Financial Reporting of Cryptocurrencies

Jana VODÁKOVÁ and Jiří FOLTÝN

Masaryk University, Faculty of Economics and Administration, Brno, Czech Republic
Jana.Vodakova@econ.muni.cz, Jiri.Foltyn econ.muni.cz

Abstract

This paper deals with cryptocurrencies and their financial reporting in selected European countries, i.e. the Czech Republic, the Slovak Republic, and the Federal Republic of Germany. Its main aim is to compare and discuss attitude to financial reporting of cryptocurrencies in three selected European countries. Firstly, interpretation and characteristics of cryptocurrencies is introduced. Further, main rules of their disclosure in financial statements are analysed and compared not only within three selected countries, but also in view of IAS/IFRS interpretation.

Obtained findings suggest that an attitude to cryptocurrencies financial reporting differs among selected countries. While the Czech Republic discloses cryptocurrencies as inventories in the statement of financial position, the Slovak Republic integrates them into short-term financial assets and the Federal Republic of Germany recommends to disclose them as the long-term intangible assets or other assets. Taking account also IAS/IFRS interpretation it can be stated that the Slovak Republic holds different post not only in relation to the rest selected countries, but also to IAS/IFRS that treat cryptocurrencies as intangible assets or inventories. The Czech treatment corresponds to IAS/IFRS interpretation and also the German treatment does not contradict it. The Slovak attitude differs but in some aspects it better corresponds to functioning of cryptocurrencies in practice. Disclosure of cryptocurrencies in the statement of financial position than influences also disclosure of related revenues and expenses in the statement of financial performance. In the case of the Slovak Republic they influence solely financial net income while in the rest two countries they influence mainly operational net income.

Keywords: Cryptocurrency, Bitcoin, Financial Reporting Of Cryptocurrencies, IAS/IFRS

Introduction

Cryptocurrencies that belong to a broader category of cryptoassets still represent a relatively new phenomenon and so their accounting treatment differs not only among EU countries. Bitcoin, probably the first cryptocurrency, was firstly used approx. in 2008 in order to accelerate peer-to-peer transactions worldwide with utilization of blockchain technology. From accounting point of view, some countries recognize cryptocurrencies as cash or financial assets, some integrate them into the long-term intangible assets or the current assets. Evidently, financial reporting of cryptocurrencies is not unanimous and so their reporting in financial statements may signify relatively important differences among countries and used regulations.

Also understanding of a cryptocurrency may differ in literature. For example, it may be defined as means of exchange, similar as US dollar, but digital and using cryptographic tools to control production of currency units and to confirm transfers of money (PricewaterhouseCoopers, 2017). Martinák (2015, p. 47) states that digital currencies are a new kind of currency, electronically created and deposited which also represents their main specific in comparison with classic national or international money that naturally exist in a form of cash. Also Lánský (2018, s. 1) for example considers cryptocurrency as a type of digital currencies that use cryptographic means to confirm transactions. Martinák (2015, s. 55) summarizes characteristics of cryptocurrencies as follows: full decentralization of currency, an absence of agent, worldwide territory, low transaction fees, and anonymity. Cryptocurrencies are regulated by no central authority, transactions take place directly without any agent across the whole world and anonymously. Moreover, virtual transactions are subject to low transaction fees in comparison with classic economic transactions. Lánský (2018, s. 19) supplements characteristics of

cryptocurrencies as follows: specific production of new cryptocurrency units, provability of ownership, elimination of duplicity, no possibility of changes. Production of new units is regulated only by system, ownerships can be proved only cryptographically, duplicate transactions are excluded and once realized transaction cannot be changed or cancelled.

At present, more than 2 000 types of cryptocurrencies operate on market. The most important cryptocurrency as for market capitalization is Bitcoin (about 65 % of the total market capitalization at present). The second and the third position occupy probably Ethereum (about 8 %) and Ripple (about 4 %) while the total market capitalization according to CoinMarketCap (2019) represents approx. 180 billion US dollars at present. The total market capitalization values show significant fluctuation when the highest vales fluctuated about 830 billion US dollar at the turn of 2017 and 2018. Among biggest cryptocurrency exchanges can be put Bitstamp, Binance, Bitfinex or Coinbase currently. There must exist sufficient offer and demand on a cryptocurrency exchange to realize a transaction. It means a substantial difference in comparison with a common exchange office that holds the post of seller or buyer. The less active and smaller cryptocurrency exchange, the less liquid; which is also one of disadvantages of cryptocurrencies that can be characterized by lower liquidity generally. Further drawback represents a question of safety. Cryptocurrency exchange crashes are not extraordinary events and verifying client's identity happens by personal data provided.

Financial reporting of cryptocurrencies differs depending on particular jurisdictions. It usually comes from interpretation of cryptocurrency established by local financial or other central authority and from characteristics of cryptocurrency. As it was indicated above, presenting of cryptocurrencies in financial statements varies significantly among countries and these differences may be material depending on a ratio of cryptocurrencies on the total assets. That is way we decided to analyse and compare attitudes to disclosure and reporting of cryptocurrencies in selected EU countries.

Methodology and Data

This paper deals with cryptocurrencies from accounting point of view. Its main aim is to analyse current accounting regulations concerning cryptocurrencies in the Czech Republic and to compare them with regulations in the Slovak Republic and the Federal Republic of Germany. Comparison of cryptocurrencies reporting will be discussed also with respect to IAS/IFRS interpretation. The paper concentrates on reporting of cryptocurrencies in financial statements, i.e. the statement of financial position and statement of financial performance. Firstly, we examine interpretation of cryptocurrency established by jurisdictional financial authorities because usually it creates a base for relating accounting treatment. We compare jurisdictional interpretation also with IAS/IFRS attitude. Further, we analyse and discuss a way of disclosure of cryptocurrency in the statement of financial position and the statement of financial performance.

As a research sample we used three neighbouring EU countries, i.e. the Czech Republic, the Slovak Republic and the Federal Republic of Germany that have similar accounting history, especially the Czech Republic and the Slovak Republic. In this paper we loosely follow our previous research and in the future we would like to enlarge a research sample by other European countries.

For purposes of the paper we used basic scientific methods, i.e. literary search, description of cryptocurrency utilization development, analysis of the current state of cryptocurrencies reporting in the Czech Republic, the Slovak Republic and the Federal Republic of Germany, and comparison of jurisdictional attitudes with IAS/IFRS. In the last part of the paper we used synthesis of findings and discussion.

As main data sources we used monographies, scientific papers, expert comments, and accounting regulations issued by the Czech, Slovak, and German authorities.

Main findings and Discussion

It can be stated, in the Czech Republic do not exist obligatory explication of a cryptocurrency at present. In practice it is possible to follow statements of the Ministry of Finance of the Czech Republic, the Czech National Bank and the Customs Administration of the Czech Republic. The legal characteristic of cryptocurrency is not unequivocal though it is essential for fair and true financial reporting.

According to the Czech National Bank (2014) Bitcoins cannot be regarded as money, resp. non-cash money because they do not even fulfil characteristics of electronic money, i.e. at least Bitcoins do not represent a claim to anybody who issued them. Similar stand on cryptocurrencies takes European Central Bank (2012, s. 43). The Czech National bank further supplements that Bitcoin is not also financial instrument because it embodies no right or claim. The Ministry of Finance of the Czech Republic (2018, s. 9) however opposes that virtual currencies may embody features of financial derivatives or investment instruments. But at the same time it adds that virtual currencies do not fulfil a definition of securities because they do not have a documentary form. As it is evident, the Czech National Bank does not define cryptocurrency explicitly but excludes it understanding as money and financial instruments. On the base of this characteristic the Ministry of Finance of the Czech Republic (2018) issued communication in which describes virtual currency as an intangible asset and recommends to report it as a "supply of its kind".

In fact, this attitude is also in compliance with IAS/IFRS when the Interpretation Committee published an agenda decision concerning holdings of cryptocurrencies at its meeting in June 2019 (IFRS, 2019). The Committee firstly characterized cryptocurrencies as: "a) a digital or virtual currency recorded on a distributed ledger that uses crypthography for security; b) not issued by a jurisdictional authority or other party; c) does not give rise to a contract between the holder and another party." As for nature of a cryptocurrency, the Committee stated holding of cryptocurrency meets the definition of intangible asset according to IAS 38 (non-monetary and non-physical substance, separable from the entity and sold). Further the Committee concluded that when cryptocurrencies are held for sale in the ordinary course of business IAS 2 Inventories applies to them. If IAS 2 is not applicable an entity should apply IAS 38 to holding cryptorurrencies. In accordance with its conclusion the Committee presented also recommendation for disclosure of additional information concerning of cryptocurrencies in financial statements.

As table 1 implies the Ministry of Finance of the Czech Republic (2018) recommends to disclose cryptocurrencies in the statement of financial position separately from other items as the current assets, specifically as goods in the case of trade activities or cryptocurrency exchange and as own product or work in process in the case of cryptocurrency mining. Some experts however question this recommendation and suggest to disclose cryptocurrencies as non-tangible assets, securities or even cash. But above described statements of the Czech National Bank and the Ministry of Finance of the Czech Republic impede recognition of a cryptocurrency as money or securities.

Tab. 1: Cryptocurrencies disclosure in the financial statements – international comparison

Interpretation and disclosure in financial statements		**The Czech Republic**	**The Slovak Republic**	**The Federal Republic of Germany**
Interpretation of cryptocurrency		Inventory of its kind	Play role of payment means	Private payment means in barter trade
Statement of financial	Trade and exchange activity	Inventories – goods	Short-term financial assets	Long-term intangible assets or Short-term assets (Other receivables)
	Cryptocurrency mining	Inventories – own products, work in process	Sub-ledger accounts until exchange or sale	

	Alternative	Intangible assets	-	-
Statement of financial performance		Sale and cost of cryptocurrencies sold disclosed in operational net income Fees and exchange differences in financial net income	Revenues and expenses relating to operations with cryptocurrencies disclosed in financial net income	Sale and cost of cryptocurrencies sold disclosed in operational net income
Further specifics or recommendations		Separated disclosure recommended	Analytical evidence according to individual cryptocurrencies	Disclosure as money or financial assets do not recommended

Source: author's own processing based on jurisdictional regulations

Interpretation of cryptocurrency in the Slovak Republic is similar as in the Czech Republic. As the Ministry of Finance of the Slovak Republic states (2018) cryptocurrency is not money, legal means of payment or currency. But, as the Ministry admits it can play a role of payment means. Probably for this reason Amendment to the Act on Accounting and its implementing regulations interpret cryptocurrency as short-term financial assets and distinguish between cryptocurrency acquired by purchase and by mining. If cryptocurrency is acquired by mining, it is recorded on sub-ledger account until the moment of its exchange or sale. In other cases, (purchase or exchange) cryptocurrency is recognized as short-term financial asset immediately at the moment of its obtaining. Disclose of cryptocurrencies as financial assets in the statement of financial position implies also recognition of related revenues and expenses in the statement of financial performance. They are disclosed in the financial area of the statement and so influence net income from financial activities.

In Germany cryptocurrencies are treated as “clearing unit” (BAFIN, 2013). BAFIN argue that cryptocurrencies are comparable with foreign currencies but they are not legal payment means. They serve as private payment means in the terms of barter trade. Simultaneously cryptocurrencies are not counted as electronic money because they have no issuer in the form of any central authority. As for cryptocurrency accounting there exists no official or compulsory procedure in Germany at present. German branch of Mazars (2019) however states that cryptocurrencies are treated as long-term intangible assets, more specifically purchased licences and rights or other receivables in short-term assets when period of their possession is not longer than one year. Mazars (2019) further recommends to disclose cryptocurrencies neither as financial assets because they do not obtain any right to property of a company, nor as money because they are not legal payment means. Disclosure of cryptocurrencies as intangible assets imply also recognition of relating revenues and expenses. They will be encompassed to operational net income.

As our analysis implies legal regulations of selected countries do not contain any precise definition of cryptocurrency at present. For purposes of accounting treatment however statements of local central authorities are decisive. In the Czech Republic cryptocurrency is considered as a supply of its kind, the Slovak Republic states that cryptocurrency is not a legal payment means however it plays this role in practice which further specify German experts that understand cryptocurrency as private payment means in barter trade. Rather than precise definition experts or local authorities enumerate how cryptocurrency should not be interpreted.

As for disclosure of cryptocurrencies in financial statements, the Czech Republic encompasses them into inventories, i.e. either goods (when they are purchased and determined to sale) or as own products or work in process (in the case of mining). Alternatively, they could be included into intangible assets. In the Slovak Republic cryptocurrencies are disclosed in short-term financial assets which is differing in comparison with the rest two countries however it reflects functioning of cryptocurrencies in practice. When cryptocurrency was acquired by mining it is recorded on sub-ledger account until its

exchange or sale. In Germany cryptocurrency is treated as intangible assets or other assets (when it is possessed one year at maximum). Compared with IAS/IFRS it can be concluded that the Czech and the German attitude to cryptocurrency disclosure in the statement of financial position is not in contradiction to them. IAS/IFRS apply to cryptocurrencies IAS 2 Inventories when they are held for sale and IAS 38 Intangible assets. Classification of cryptocurrencies into specific asset category determines also disclosure of relating revenues and expenses. While according to the Czech and the German treatment they influence financial net income mainly, according to the Slovak treatment they influence financial net income.

Conclusion

This paper is focused on comparison of interpretation and disclosure of cryptocurrencies in financial statements. As a research sample were chosen the Czech Republic, the Slovak Republic and the Federal Republic of Germany.

Our analysis confirmed varying attitudes to interpretation and disclosure of cryptocurrencies within the research sample. While the Czech Republic and the Germany treat cryptocurrency as either inventory or intangible asset which corresponds to IAS/IFRS recommendation, the Slovak Republic interpret cryptocurrency as the short-term financial asset. It seems that this treatment probably reflects characteristics of cryptocurrency better though it is in contradiction with the definition of securities or financial instruments. Disclosure of cryptocurrencies in the statement of financial position further implies disclosure of related revenues and expenses in the statement of financial performance when in the Czech Republic and Germany they will be recorded mainly to operational net income and in the Slovak Republic to financial net income. In our future research we would like to enlarge a research sample by other European countries and to compare more factors relating to cryptocurrencies accounting treatment.

An Overview of Decision Making, Entrepreneurship and Performance: A Bibliometric Mapping and Visualization

Ana Alexandra GORA

The Bucharest University of Economic Studies, Bucharest, Romania

anaalexandra.gora@gmail.com

Abstract

The concepts of decision making and entrepreneurship have attracted researchers' attention for their relevance to a firm's performance. The purpose of this article is to provide an overview of the academic research on decision making, entrepreneurship, and performance. To achieve this, a bibliometric analysis was performed, which involves the analysis of 378 articles published in Web of Science in the 2000-2019 period, concerning the analyzed subject and a keywords' mapping in this field. This analysis focuses on articles, journals, countries, institutions and number of citations retrieved by the analyzed articles. For this analysis, the information provided by the Web of Science database through the "Analyze Results" and "Create Citation Report" sections were used. Moreover, "VOSviewer" software was used to map the keywords, and the co-occurrence of keywords represented the basis of this analysis. The main results illustrate the most relevant articles, journals, countries, authors and institutions with contributions to decision making, entrepreneurship, and performance research. The findings illustrate that the proximity between the concepts entrepreneurship and performance describes a strong relatedness between them, while the distance between entrepreneurship and decision making is showing a weaker relatedness.

Keywords: Bibliometric Analysis, Decision Making; Entrepreneurship, Performance, Vosviewer.

Introduction

The concepts "decision making" and "performance" represent two topics that are increasingly interconnected in the academic research. The notion of decision making is closely linked to the efficiency of an organization, its long-term success and organizational performance. In this respect, the decision making process is a key factor in determining the performance of an organization. The existing link in the academic research regarding these two concepts was studied in detail through a bibliometric analysis in a previous research (Gora, 2019). On the other hand, another concept related to organizational performance, that has attracted attention in time for its relevance to a firm performance, belongs to the entrepreneurship field and it is represented by the entrepreneurial orientation (Andrade-Valbuena, Merigo-Lindahl and Olavarrieta, 2019).

In this concern, the purpose of this paper is to map and cluster the existing connection between the concepts of decision making, entrepreneurship and performance from the research literature. This will provide an overview of the influential relationships in the literature, for future research on the studied topic, through a bibliometric analysis. Firstly, this study is underlining the most active and influential articles, authors and journals with contributions related to the subject analyzed, as well as the impact of these articles from the perspective of the number of citations received. Secondly, by mapping and clustering a keywords analysis, this article aims to graphically highlight the keywords of this research and to emphasize the connection of these keywords with other concepts in the field. Also related to keyword analysis, the research aims to present a map that showing the links between keywords in time.

The bibliometric mapping and clustering techniques are tools that help in structuring and visualizing the research and academic literature. During time, the bibliometric analysis has been performed on different research topics, using various databases and data analysis software. Blanco-Mesa, Merigó and Gil-Lafuente (2017) carried out a bibliometric analysis on the subject of "fuzzy decision-making" to highlight the main contributions in this field. Their article is based on the analysis of 950 articles

related to the research topic, articles extracted from the Web of Science (WoS) database. The "VOSviewer" software was used for mapping the keywords analysis. Related to "the expatriates and their impact on business performance" topic, Dabic, González-Loureiro and Harvey (2014) performed a bibliometric analysis on the existing analysis in the academic literature on these concepts, using 438 articles from the WoS database and the "Wordstat" software for keyword analysis. Regarding the entrepreneurship education, Aparicio, Iturralde and Maseda (2019) use data extracted from the Web of Science (WoS) database on 325 articles and perform a bibliometric analysis using "SciMat" software. Also related to the subject of entrepreneurship education, starting from the data extracted from WoS, Fellnhofer (2019) analyzes 1773 peer-reviewed documents and performs a bibliometric mapping and visualization using "VOSviewer" software.

Furthermore, on the subject of entrepreneurship, other researches have been identified that carry out bibliometric analysis related to this field. For example, Andrade-Valbuena, Merigo-Lindahl and Olavarrieta (2019) perform a bibliometric analysis that aims to outline an overview of existing research in the academic literature on the topic of entrepreneurial orientation. Using data from Web of Science and VOSviewer software, through this article, these authors analyze articles published for over 20 years and highlight who are the main authors having contributions on this topic, the most relevant journals and the most important articles in entrepreneurial orientation research (Andrade-Valbuena, Merigo-Lindahl and Olavarrieta, 2019). Another bibliometric analysis in the field of entrepreneurship belongs to the author Dionisio (2019), who offers an overview of research on social entrepreneurship. This research is based on articles published in the "Social Enterprise Journal", a publication that explores the social entrepreneurship field, and uses for analysis the open-source software package "R". The main analyzes conducted through this article focus on identifying the key authors who publish in the field of social entrepreneurship, the most relevant institutions associated with this topic and their geographical areas (Dionisio, 2019).

Starting from the mentioned aspects, this paper aims to highlight, through a bibliometric analysis, the existing connection between the concepts of decision making, entrepreneurship and performance in research literature. The structure of this article it is presented below. The following section describes in detail the research methodology, the steps that have been taken to collect the data and the methods used for data analysis. This section is followed by the results' discussions on the analysis of the selected papers and the mapping analysis. The last section of this article outlines the findings, limitations and future directions of research.

Research Methodology

To carry out this bibliometric analysis, a keyword search process was performed in 2020 in the Web of Science Core Collection: Citation Indexes database. Starting from similar bibliometric articles of other researchers (Andrade-Valbuena, Merigo-Lindahl and Olavarrieta, 2019; Aparicio, Iturralde and Maseda, 2019; Blanco-Mesa, Merigó and Gil-Lafuente, 2017; Dabic, González-Loureiro and Harvey, 2014; Fellnhofer, 2019), a topic keyword search in Wos (includes searches in the following fields within a record: title, abstract, author keywords and Keywords plus) was used, with the words ""decision making"*", "entrepreneurship" and "performance", using the 'and' connector between them. Also, the wildcard `*` and the signs `""` were used to find all the combinations of the decision making notion (e.g. decision-making, decision making, etc.) and to extract records containing the exact phrase of "decision making". This search was limited to articles published in the Web of Science database from 2000-2019 and a total of 456 articles were obtained. Subsequently, a series of filters were made, for keeping into analysis only the articles written in English and falling under "Business", "Management", "Economics" or "Operations Research Management Science" WoS categories. Also, only articles containing the "Article", "Review" or "Proceedings Paper" types were included in the analysis, while the category "Book Chapter", "Early Access" or other document types were removed. In total, 378 articles fulfilled these characteristics, these being selected for analysis in this research.

Following the selection of the 378 articles, the objectives of this research were to carry out the following types of analyzes:

a) The analysis of 378 selected papers by referring to:

- Yearly distribution of articles published in the period 2000-2019.
- Distribution of articles by authors or co-authors' country of origin.
- Highlighting the authors with the most contributions related to the subject analyzed.
- Highlighting the institutions with the most contributions related to the subject analyzed.
- Paper distribution on conference volumes or journals.

b) The analysis of the received citations:

- Top 10 articles sorted by the received citations.
- Top 10 journals sorted by number of received citations.

c) The analysis of the keywords:

-The occurrence, co-occurrence and the links between keywords.
-The keywords map (grouped in clusters).
-The mapping links between keywords in time.

Different research methods were used to carry out the 3 types of analyzes. Thus, for the analysis of the 378 selected papers and of the citations received the information provided by the Web of Science database through the "Analyze Results" and "Create Citation Report" sections were used. To perform the co-occurrence of keywords analysis, the "VOSviewer" software developed by Nees Jan van Eck and Ludo Waltman (2011) was used. This tool is a powerful network analysis software (Vallaster et al., 2019; Van Eck and Waltman, 2010), that helps to examine the structures of the addressed research field and to visualize the dynamics of a science. "VOSviewer" software has been used over time to perform bibliometric analyzes in various fields (Andrade-Valbuena, Merigo-Lindahl and Olavarrieta, 2019; Blanco-Mesa, Merigó and Gil-Lafuente, 2017; Fellnhofer, 2019; Vallaster et al., 2019).

Results and Discussions

Within this section, 3 types of analyzes have been performed through this paper, namely: selected papers analysis, citations analysis and keywords analysis.

Selected papers analysis

A first objective of the present research was to analyze the 378 scientific papers available on the Web of Science database, having the decision making, entrepreneurship and performance topics. Thus, the distribution of the selected papers by years, countries, authors and institutions with contributions related to the subject, as well as the distribution of 378 articles on conference volumes or journals were analyzed.

The distribution of the papers published between 2000-2019 per years is presented in Table 1.

Table 1: Distribution of 378 selected articles per year

Year	Number of articles	Percentage	Cumulative percentage
2000	4	1.06%	1.06%
2001	3	0.79%	1.85%
2002	3	0.79%	2.65%
2003	4	1.06%	3.70%
2004	5	1.32%	5.03%
2005	4	1.06%	6.08%
2006	10	2.65%	8.73%

2007	13	3.44%	12.17%
2008	10	2.65%	14.81%
2009	11	2.91%	17.72%
2010	20	5.29%	23.02%
2011	14	3.70%	26.72%
2012	16	4.23%	30.95%
2013	16	4.23%	35.19%
2014	15	3.97%	39.15%
2015	36	9.52%	48.68%
2016	46	12.17%	60.85%
2017	52	13.76%	74.60%
2018	58	15.34%	89.95%
2019	38	10.05%	100.00%

Source: WoS (2020a)

By analyzing the information provided by Table 1, it can be observed that the number of scientific articles referring to the topic of decision making, entrepreneurship and performance was generally increasing between 2000-2019. The highest number of articles published in a year was 58 (15.34% of the total of 378 articles), in 2018 and the smallest number of articles published during the analyzed period was 3, registered in 2001 and 2002. Moreover, the cumulative percentages in Table 1 illustrate that over the last 4 years of the analyzed period, and more precisely in the period 2016-2019, more than half of the total number of selected articles were published (51.32%). This might suggest that lately the topics of decision making, entrepreneurship and performance, as well as the study of the links between these concepts, have attracted attention and have begun to represent an area of interest for researchers.

As far as the country of the authors is concerned, there are a total of 39 countries / regions to which at least one author of the 378 selected articles is affiliated. As shown in Figure 1, 5 countries accumulate 74.34% of the total selected articles, namely: USA, England, Germany, Italy and Peoples R China.

Figure 1: Distribution of articles by country

Source: WoS (2020a)

Thus, with a total number of 162 documents (42.86%), the USA is the country with the largest number of articles to which at least one of the authors of the selected papers is affiliated. In second place is England, with a total of 46 articles (12.17% of the total).

Table 2 lists the top 8 authors and institutions with contributions on the topics of decision making, entrepreneurship and performance ranked by the number of published articles and affiliated to those authors or institutions.

Table 2:Top 8 authors and institutions with contributions on the analyzed subject

Authors		Top 8	Institutions	
Author Name	**Contributions**		**Institution Name**	**Contributions**
Shepherd D.A	7	1	Indiana University System	18
Baron R.A	5	2	Indiana University Bloomington	17
Sarasvathy S.D.	5	3	State University System of Florida	14
Wincent J.	5	4	Indiana University Kelley School of Business	12
Busenitz Lw.	4	5	Syracuse University	10
Dimitratos P.	4	6	University Of North Carolina	10
Morris Mh.	4	7	University of Oklahoma Norman	9
Verheul I.	4	8	University of Oklahoma System	9

Source: WoS (2020a)

A total of 863 authors contributed to the writing and publication of the 378 articles analyzed through this research. Analyzing table 2, it can be observed that the most contributions on the studied subject belong to the author Shepherd D.A., who published a total of 7 documents out of the total of 378. As for the institution to which this author is affiliated, according to information from the Web of Science database, it appears that this author is affiliated with 4 institutions, two of them being in the top 8 institutions illustrated in Table 2, namely "Indiana University System" and "Indiana University Bloomington". The next authors, according to the number of articles published on the subject analyzed, are Baron R.A, Sarasvathy S.D. and Wincent J., having 5 articles. These authors are not affiliated with any institution listed in Table 2. On the other hand, by analyzing the institutions affiliated with the authors of the 378 selected and analyzed articles, from Table 2, it can be stated that the institution with the most contributions on the subject, namely 18 articles, is Indiana University System, followed by Indiana University Bloomington, which contributes with 17 articles related to the topic analyzed.

Papers` distribution on conference volumes or journals are presented in Table 3.

Table 3 : Papers` distribution on conference volumes or journals

Rank	Conference volume or journal	Articles
1	Journal of Business Venturing	29
2	Entrepreneurship Theory and Practice	14
3	Journal of Business Research	14
4	Small Business Economics	12
5	Journal of Business Ethics	10
6	Journal of Small Business Management	10
7	Journal of Management	9
8	Strategic Management Journal	9
9	International Small Business Journal Researching Entrepreneurship	8
10	International Business Review	7

Source: WoS (2020a)

In total, the 378 selected articles were published in 166 journals or conference volumes that are directly related to the topics of decision making, entrepreneurship and performance. Most papers written on the subject analyzed are published in the "Journal of Business Venturing" (29 articles), in the "Entrepreneurship Theory and Practice: (14 articles) and in the "Journal of Business Research" (14 articles).

Citations Analysis

The second objective of the present paper was to analyze which are the most cited paper related to the topic analyzed, namely decision making, entrepreneurship and performance and which are the journals in which the 378 selected papers cumulate the highest number of citations.

The 378 analyzed articles have received from the moment of publication until the moment of this analysis (March 10th, 2020) a total number of 14,837 citations. Table 4 presents the Top 10 most cited articles related to the topic analyzed.

Table 4: Top 10 most cited articles on the analyzed subject

No.	Authors	Total number of citations	Average citations per year
1	Sambamurthy, Bharadwaj and Grover (2003)	991	55.06
2	McMullen and Shepherd (2006)	879	58.60
3	Alvarez and Busenitz (2001)	746	37.30
4	Shane and Cable (2002)	653	34.37
5	Baron (2008)	487	37.46
6	Covin, Green and Slevin (2006)	465	31.00
7	George (2005)	430	26.88
8	Baum and Wally (2003)	376	20.89
9	Lepoutre and Heene (2006)	328	21.87
10	Shrader, Oviatt and McDougall (2000)	308	14.67

Source: WoS (2020b)

Analyzing Table 4, it can be observed that the most cited article related to the topic analyzed through this article is written by the authors Sambamurthy, Bharadwaj and Grover (2003). The total number of citations accumulated since the date of publication until the time of analysis (March 10th, 2020) was 991, which represents an average of 55.06 citations per year. The article in the second position of the Top 10 most cited articles belongs to the authors McMullen and Shepherd (2006) and has accumulated a total of 879 citations. An important aspect to be mentioned regarding this article that occupies the position 2 in the ranking of the most cited articles in the total of the 378 documents analyzed, refers to the fact that one of its authors, namely Shepherd, is the first one in the ranking of the authors with the most many contributions related to the topic analyzed - decision making, entrepreneurship and performance (according to the information provided in Table 2).

The oldest article in the Top 10 most cited articles was written in 2000, belonging to the authors Shrader, Oviatt and McDougall (2000) and it is 10th as rank, with a total number of 308 citations. On the other side, the most recent article in the analyzed top was published in 2008 and belongs to Baron (2008). This article has accumulated 487 citations, which represents an average of 37.46 citations per year. Moreover, based on the information provided by Table 2, it can be observed that the author of this article, Baron, is in the second position in the Top 8 authors with contributions related to the analyzed subject, having published a number of 5 articles on this topic. In conclusion, it can be stated that there are more recent papers that have received more citations than other articles which were indexed before. This finding illustrates that the high number of citations received by these articles is

due to the quality and relevance of the topics they are dealing with, but also due to the opportunity to be published in prestigious journals.

The top 10 journals, according to the number of citations accumulated from the publication of articles from the 378 selected and analyzed, it is presented in Table 5.

Table 5 : Top 10 journals ranked by number of citations of the analyzed papers

Rank	Journal name	Articles	Citations	Average citations per article	% of 14.837 citations
1	Journal of Business Venturing	29	1881	64.86	12.68%
2	Journal of Management	9	1516	168.44	10.22%
3	Academy of Management Review	4	1433	358.25	9.66%
4	Entrepreneurship Theory and Practice	13	1209	93.00	8.15%
5	Journal of Business Ethics	10	1104	110.40	7.44%
6	Strategic Management Journal	9	1036	115.11	6.98%
7	Mis Quarterly	2	992	496.00	6.69%
8	Management Science	4	920	230.00	6.20%
9	Academy of Management Journal	5	909	181.80	6.13%
10	Organization Science	7	433	61.86	2.92%
Total		**92**	**11,433**	**-**	**77.06%**

Source: Created by author with VOSviewer (Van Eck and Waltman, 2020)

By analyzing Table 5, it can be observed that the "Journal of Business Venturing", in which most articles with contributions on the decision making, entrepreneurship and performance topic were published (29 articles), it is also the journal that accumulates the largest number of citations through the 29 articles, namely 1881, which represents 12.68% of the total citations of the 378 articles during the analyzed period. The second place, according to the citations accumulated, is represented by the Journal of Management which totals a numbers of 1516 citations, with 9 published articles (10.22% out of the total of 14.837 citations).

On the other hand, a more relevant analysis of the top journals that accumulate the most citations can be highlighted based on the average citations per article. In this regard, it can be noted that "Mis Quarterly", which is not in the Top 10 conference volumes or journals with contributions related to the analyzed subject, accumulated, by the 2 published articles, a total of 992, which represents an average of 496 citations per article. The second place in the ranking, according to the average citations per article, is the "Academy of Management Review", which cumulates a number of 1.433 citations, with 4 articles out of the 378 articles analyzed, which represents an average of 358.25 citations per article.

Connections of keywords on decision making, entrepreneurship and performance research

The last objective of the present research was to analyze the keywords from the 378 selected articles and to perform the keywords map. For this analysis, both the keywords provided by the authors and the keywords in the "keywords plus" category were considered and the following steps were taken:

Step 1: Extracting various information regarding the 378 articles analyzed from the "Web of Science" database: article title, authors, abstract, year of publication, keywords mentioned for each article.

Step 2: Inserting information collected from the "WoS" database into "VOSviewer" software (Van Eck and Waltman, 2020) for creating a map based on bibliographic data. During this stage, the "VOSviewer" software counted a total of 1894 keywords found in the 378 articles published on the topic of decision making, entrepreneurship and performance.

Step 3: Choosing a minimum number of occurrences per keywords equal to 20. In this context, the "occurrence" term illustrates the number of documents in which a keyword appears. As a result of this filtering, 25 keywords were retained for analysis.

Step 4: Highlighting for the 25 keywords analyzed the number of occurrences, the links between them and the co-occurrence (or the total strength between them) (Table 6).

Step 5: Creating the keyword map and grouping them into clusters (Figure 2).

As mentioned above, Table 6 presents the 25 keywords retained to create the map, ranked after the number of occurrences.

Table 6 : The keywords` number of occurrences, number of co-occurrences and links

No.	Keyword	Number of Occurrences	Links	Number of Co-occurrences
1	Performance	201	24	579
2	Entrepreneurship	151	24	448
3	Decision-making	139	23	387
4	Corporate entrepreneurship	63	23	198
5	Innovation	62	24	208
6	Firm performance	61	23	174
7	Management	57	24	205
8	Firms	50	21	157
9	Model	40	24	140
10	Strategic decision-making	40	20	117
11	Entrepreneurial orientation	39	20	130
12	Organizations	36	23	126
13	Business	35	22	123
14	Strategy	33	20	110
15	Orientation	32	24	116
16	Growth	32	21	110
17	Behavior	30	22	103

19	Decision making	26	20	89
20	Risk-taking	24	20	88
21	Knowledge	24	19	82

22	Perspective	24	22	80
23	Uncertainty	23	23	80
24	Moderating role	23	16	77
25	Effectuation	23	20	76

Source: Created by author with VOSviewer (Van Eck and Waltman, 2020)

Analyzing the information provided by Table 6, it can be stated that it is relevant to explain that by searching the three words (decision making, entrepreneurship and performance) in "Web of Science" after the topic (including searches in the following fields within a record: title, abstract, author keywords and Keywords plus), the word "performance" was mentioned as a keyword in 201 articles out of the total number of 378, the word "entrepreneurship" was mentioned in 151 of articles and the word "decision making" appears as a keyword in 139 articles under the form of "decision-making" and in 26 articles under the form of "decision making".

The VOS clustering technique, developed by Waltman, Van Eck, and Noyons (2010) was used to map the keywords and to group them under the form of clusters. The 25 keywords were assigned by the "VOSviewer" software in three clusters marked with different colors in Figure 2. The red cluster and the green cluster are composed of nine keywords, while the blue cluster is the smallest and includes seven keywords.

As explained in previous articles (Gora, 2019; Popa and Gora, 2020), the VOS clustering technique uses the number of nodes, the links between them, the total number of links and the total strength between them (the number of. co-occurrence). Moreover, VOS clustering provides for each node the distance from others and each node is positioned in a two-dimensional space (a representation called mapping).

Figure 2 presents a map with 25 nodes (based on the number of keywords that appear in at least 20 documents out of the total 378, also present in Table 6). The size of a node is given by the number of articles in which the keyword is found. From Figure 2, it can be observed that the largest node is represented by the keyword "performance", followed by the node "entrepreneurship".

Figure 2 : Keywords map
Source: Created by author with "VOSviewer" (Van Eck and Waltman, 2020)

An important aspect to be discussed is concerning the connections between the nodes. From Figure 2, it can be observed that these links are represented by curved lines, having different thicknesses. The thickness of a line is given by co-occurrence (or the link strength between keywords). Thus, the thicker the line between two keywords, the stronger is the link between those keywords. In this sense, Figure 2 illustrates that the strongest co-occurrence keyword (or the total link strength) is formed between "performance" and "entrepreneurship". The next strongest co-occurrence is between keywords "performance" and "decision-making", followed by keywords "entrepreneurship" and "decision-making".

Furthermore, the relatedness of keywords (which refers to the distance between the nodes or keywords) is another aspect to be discussed. This aspect highlights that the closer the two keywords are on the map, the stronger is the relationship between them. In this respect, Figure 2 illustrates that the proximity between entrepreneurship and performance describes a strong relatedness, while the distance between entrepreneurship and decision-making shows a weaker relatedness.

Also, in terms of keyword analysis, a second map was performed, presented in Figure 3, that illustrates the mapping links between keywords in time.

Figure 3 : Mapping links between keywords in time.
Source: Created by author with "VOSviewer" (Van Eck and Waltman, 2020)

From Figure 3, it can be noticed that at the beginning of the analyzed period, and more specifically, in the period 2000-2005, the researches focused on "performance", "entrepreneurship", "decision-making", "innovation" and "management". Between 2005-2015 the academic research focused more on topics such as "organizations", "behavior", "knowledge" or "strategy". In the last analysis period, respectively 2015-2019, the keyword "corporate entrepreneurship" becomes a representative subject for researchers. Also, during this period, the research focused on other topics such as "firm performance", "entrepreneurial orientation" and "strategic decision-making".

Conclusions

Through this research, a general bibliometric analysis was conducted, which focused rather on the content of the analyzed documents than on the three types of analyses (the analysis of selected papers, the analysis of the received citations and the analysis of the keywords). The results of the

existing connection between the concepts decision making, entrepreneurship and performance highlighted which are the most active and influential articles, authors and journals.

Firstly, the general overview of decision making, entrepreneurship and performance research illustrated that the USA is the country with the most contributions in this subject. Shepherd DA is the author with the most articles published on this topic, in the "Journal of Business Venturing" being published 29 articles out of the 378 analyzed articles.

Secondly, the analysis of the most relevant articles and journals with contributions in the field, based on the number of citations accumulated, revealed that the 378 articles accumulate a total of 14,837 citations at the time of this analysis. The most cited article totals 991 citations and it was written by the authors Sambamurthy, Bharadwaj and Grover (2003). The journal with the highest number of citations by published articles on the subject analyzed was "Journal of Business Venturing" with 1881 citations (an average of 64.86 citations per article). However, if we refer to the average citations per article, the most relevant journal was "Mis Quarterly", having an average of 496 citations per article.

Lastly, the findings have shown that the proximity between the entrepreneurship and performance concepts describes a strong relatedness between them, while the distance between entrepreneurship and decision-making shows a weaker relatedness. Also, from mapping links between keywords in time, it was found that in the period 2000-2005, the articles related to the analyzed topic focused rather on concepts such as "performance", "entrepreneurship", "decision-making", "innovation" or "management". In comparison, in the period 2015-2019, the "corporate entrepreneurship" keyword became representative, along with other concepts such as "firm performance", "entrepreneurial orientation" and "strategic decision-making".

The implications of this study might be useful to researchers and practitioners interested in this topic because it highlights the links between the three concepts analyzed: decision making, entrepreneurship and performance. Also, the article illustrates the correlation between the studied concepts and some other relevant ones, underlining the importance of these topics in academic research over time. Furthermore, the presentation of the most relevant articles, journals, countries, authors and institutions, with contributions on the analyzed subject, highlights the current state of existing academic research and opens new perspectives to continue research in this field, starting from the bibliometric analysis of the academic literature in the field.

Moreover, this article provides value for entrepreneurs, as it illustrates that over time researchers have highlighted the importance of the decision-making process, for achieving organizational performance. In this concern, by taking into account the findings of this research, entrepreneurs could be more aware of the correlations between these concepts. Moreover, several methods and techniques could be identified for better underlining their decisions and for achieving more efficiently and effectively the objectives set, concerning the organizational performance.

Given that the aim of this article is to provide an overview of the academic research on decision making, entrepreneurship and performance, it is important to emphasize that there have been some limitations of the research. Thus, a first limitation of the research is that the articles and information analyzed through this paper were only extracted from the "Web of Science" database. This could exclude a few relevant articles with significant contributions on the analyzed topic, published in other databases such as Scopus, Science Direct, etc. A second limitation of the research could be the period analyzed (2000-2019), existing the possibility of excluding some important papers published before or after this selected period, or even papers published during the analyzed period, but which were not yet included in "WoS" database at the time of analysis. Another limitation of the research could be the fact that only the articles in the "Business", "Management", "Economics" or "Operations Research Management Science" WoS categories were analyzed. Finally, the use of "VOSviewer" software could represent a research limitation because it does not allow the analysis of articles and information extracted from different databases at the same time, and the results highlighted by this tool should be taken with caution.

As for future research, this could also include analysis of articles published in other databases on the topics of decision making, entrepreneurship and performance, in order to extend and generalize the findings. Moreover, other bibliometric analysis techniques such as bibliographic coupling, networks connected by co-authorship, co-citation links, etc. can be used on the subject analyzed by this research.

Acknowledgement

This study was conducted through the doctoral program, Management field, coordinator The Bucharest University of Economic Studies. This work was cofinanced from the European Social Fund through Operational Programme Human Capital 2014-2020, project number POCU/380/6/13/125015 "Development of entrepreneurial skills for doctoral students and postdoctoral researchers in the field of economic sciences".

Abstract

This study aims to determine the relations between particular factors affecting the young consumer behaviour, and to identify the models of consumption and preferences of generation Y, and consequently to indicate the importance of education a crucial instrument for young people's socialization. The scope of research comprises young consumers from generation Y in selected countries around the world, with particular focus on the students of economy faculties at the universities in Poland and Croatia. The cognitive evaluation of factors affecting the young consumer behaviour in the consumption processes made it possible to obtain original research results, allowing to select the most important factors and preferences affecting the purchasing decisions of generation Y. The empirical research conducted by the authors of this study proves that for many young people, price, quality and brand are still very important, but the environmental and social issues are more and more acknowledged. This indicates that the consumption among the young does not reveal only hedonistic aspects, but also features the economic and environmental aspects.

Keywords: Young Consumers, Taking Decisions, Education, Economic Socialization, Generation Y, Multiple Correspondence Analysis

Introduction

Over the past decades, the concept of consumption has significantly been developed. It was formed by concepts such as 'consumer society', namely the society with consumption in the centre, and 'consumerism' defined as overemphasis on acquiring material goods. The consumption and consumerism shall not be used as synonyms. It results from the fact that consumption as a feature refers to individuals and consumerism is attributed to the society (Bauman, 2009, p.36). Moreover, the difference involves the fact that consumerism occurs when the consumption becomes the main driving force of the society and takes the key role, e.g. becomes a stronger rationale than work (Bywalec, 2010, p.17).

In recent years, especially after the crisis which began at the turn of 2008, consumerism became the subject of severe criticism. More and more people, especially more educated part of the society, raise a growing objection to the attitude of people who purchase large volume of material goods and services unreasonably beyond their actual needs as well as the ecological, social and individual costs, and who perceive their increased consumption as a measure of the quality of life or the most important or alternatively the only value. The disapproval of consumerism may apparently seem as aberration since in general it is believed that the abundance of consumer goods used to satisfy various needs shall be treated as good. Meanwhile, as reality shows that uncontrolled and excessive consumption brings numerous threats and adverse consequences. The negative effects of consumerism include, first of all: waste of natural resources, human labour, goods and destructive impact on the spiritual side of human life, allowing the situation where the more you have, the greater the desire to possess even more, materialistic approach to life, tendency to consume for show, and increasing addiction to compulsive buying.

The phenomenon of consumerism was acknowledged the civilization disease and named affluenza. This extreme symptom of consumerism is a civilization disease caused by 'continuous search for satisfaction provided by things which cannot bring any satisfaction'. The symptoms of this disease include: nervous tension, rush, feeling of relentless fatigue and dissatisfaction, feeling of continuous lack of something, which leads to nearly obsessive buying. Whereas the implications include: permanent indebtedness in banks, workaholism, deteriorating relations with the society, excess of post-consumer waste[i].

Apart from the negative phenomena and implications, the consumption, consumers and consumption civilization are also defined by positive aspects and roles to play, e.g.: developing own interest through the consumption, consumption related to work is a factor leading to gaining better and better education, the development of needs drives the market, new forms of trade are developed and the economic structure is changed, technique and science develop (Słaby, 2007, p.16). On the one hand, the negative and positive aspects of consumption raise questions on the nature of needs and their finiteness; on the other, indicate that proper reduction in consumption is no threat, and the consumption civilization should be associated with its more and more reasonable depiction.

The optimal method leading to respect and the ability to accept good models of consumer behaviour among the young is education. Education is the key instrument that may be used to limit the impulsive consumption. It may contribute to preventing the atomization of social and family life as well as its consequences, such as: cult of individualism, hedonistic and utilitarian attitude to life, new lifestyles e.g. instant, fragmentation of identity, ubiquitous entertainment leading to infantilization of thought and behaviour, as well as addictions.

This study aims to determine the relations between particular factors affecting the young consumer behaviour, and to identify the models of consumption and preferences of generation Y, and consequently to indicate the importance of education as a crucial instrument for young people's socialization. The scope of research comprises young consumers from generation Y in selected countries around the world, with particular focus on the students of economy faculties at the universities in Poland and Croatia.

The article is structured as follows: the first part comprises introduction, the second presents the demographic profile of young consumers in the light of empirical research, the third presents the shopping preferences of young consumers from generation Y, the fourth analyses the research material and describes the method, the fifth comprises research results, whereas the sixth and the last one provide the conclusions.

The demographic profile of young consumers in the light of empirical research with particular focus on generation Y

The research on young consumer behaviour constitutes an important trend in the analyses of the quality of life among societies. So far, numerous theoretical frameworks have been developed, in relation to the impact of consumption on every person's life, on the general level shaping the lifestyle and on the level of particular choices. The review of reference literature confirms that the style of making shopping decisions (purchasing styles, consumer decision-making styles) may be categorized into three main attitudes emphasized by Sproles and Kendall: psychographic attitude (concentration on defining the lifestyle), descriptive attitude (consumer characteristics approach) and consumer typology attitude (defining recipient groups) (Lysonski et al. 1996;Sproles, Kendall, 1986). Therefore, we can determine that the shopping styles result from mental orientation towards making choices in the purchasing process and the result of using the skills acquired through own experience that are relatively permanent, both in time and in different conditions and education. The examples involve differences in the shopping decision-making styles in the third group of receivers, determined by Sproles and Kendall, featuring young people divided into generation X, Y, and Z.
Generation X includes people born between 1965 and 1979. The representatives of generation X appreciate values, such as: personal development, independence, diversity, diligence and professional stability. In general, people from generation X believe that promotion is gained through hard work

and everything in life must be earned individually. Generation Y, the so-called 'millennials', includes people born between 1980 and 1990. People from generation Y are multitasking employees open to new challenges. They are strongly engaged in their work – provided that they perceive the work as interesting. Furthermore, they value flexible working hours and are open to relocation. They look for work which is going to satisfy them financially and the new employer will ensure their professional development. The representatives of generation Z include people born after 2000. They do not know the world without new technologies which, for them, are the main instruments used to acquire knowledge. They can move around smoothly in the virtual world and quickly analyse the information. They are perceived as pragmatics since they are aware of changes arising from the future automation and lack of stability. They look for work that will ensure their development.
The consumers from generation Y constitute a specific group, regarding their characteristic approach to consumption. The people who recently entered the labour market have significant financial potential and are very active as consumers. It is confirmed by studies conducted by Bitette (2019), which indicate that the millennials (generation Y), as clients are becoming a group of clients most influential on the world market of goods and services. It is predicted that e.g. in the USA the consumers between 17 and 34 years of age will spend 200 billion USD on consumption annually, and throughout their whole life over 10 sextillion USD (Lobo 2014). According to the PEW Research Center (2010) Report on the American society, generation Y is also the most educated one in the American history. The young consumers from this generation are also open to new trends and eager to new experience. According to the Travelport Report (2018), 51% of the American millennials went travelling in 2018.

Because of their upbringing in the 'digital era', generation Y is used to enjoy technical novelties and quick methods of communication. The survey by IPSOS (2019) conducted in Great Britain in 2013 indicated that 77% of the generation Y representatives used the Internet several times a day, and 54% used mobile devices to this end. The trend refers not only to the developed countries but also to the developing ones. People between 18 and 24 and between 25 and 34 years of age frequently use the social media. According to the DataReportal Report (2019), 24% of women and 35% of men frequently use facebook.com. and generation Y is the largest generation to use this platform. Whereas, the Horowitz Group Report (2018) indicates that more than 60% of the surveyed between 18 and 24 years of age use three platforms on a daily basis: Facebook, Instagram and Snapchat. For comparison, within a group of people aged between 25 and 34 years old, 80% mainly use Facebook.
The above mentioned research results indicate that nowadays, the Internet is becoming the main information medium for the young. On the one hand, the Internet is a quick source of information on any sphere of life and on any topic, and on the other, it generates the 'information overload' which involves the overflow of information, where it is difficult to find real and essential information. As emphasized by Berg (2018) (see also: Batat, 2010; Singh, 2012), young people as a large group of Internet users, are particularly exposed to the digital commercial pressure, especially when we take into account easy access to personal data, often used by the suppliers of goods and services.

The previous analyses of the behaviour of young consumers, with particular focus on generation Y, concentrated mainly on the general typology of consumers and on defining the recipient groups. In this context, it is worth presenting the research results defining the attitude and models adopted by the young consumers from generation Y, which has been described in the next part of this article.

Shopping preferences of young consumers from generation Y

The prospective model of consumption is still under discussion. In principle, there are only general suggestions about the impact on its structure. It is a demanding task as the models of consumption change in time and are closely connected with the increase in the society living standards. In recent years, significant emphasis is put on the issues of sustainable development of consumption. The sustainable consumption involves the use of goods and services to fulfil the needs in a satisfactory manner, improving the living standards, and, at the same time, to make it also available for future generations. Certainly, as emphasised by H. Pondel (2013, p. 21), these issues shall be perceived on multiple levels and not perceived only as ecological issues.

It is worth combining the analysis of the behaviour of young consumers from generation Y and their attitude to sustainable consumption with the issue of collaborative consumption which can be defined as the highest level of ecological awareness. Recently, it significantly gained in importance since it provides people with benefits resulting from the title to ownership combined with lower individual burden and lower costs, as well as lower detrimental impact on the environment. The collaborative consumption among the young is becoming more and more convincing alternative to the traditional forms of purchasing and possessing goods and services. Within the collaborative consumption the goods that constitute private property can be shared or leased to other people. It seems that collaborative consumption will prove to be neither niche trend nor temporary fashion. It features the social and economic changes resulting from better care for the natural environment and the cooperation with local community.

Interesting research results were presented by Ordun (2015), where the behaviour and preferences of clients coming from various age groups were compared. The survey was conducted among 4000 clients of two fashion companies, operating on the world markets and having more than 100 international stores. The survey focused on 13 features of products and their impact on purchase, and consequently: price, trend, loyalty, prestige, brand, volume (size), quality, suggestions, advertisement, environment, availability, diversity and service. The explorations indicated that the analysed clients from generation Y opted more often for the price, trend, prestige, brand and service. Interestingly, they rarely relied on the suggestions of other people or advertisements. Moreover, the presented analyses make it possible to attribute the following features to the consumers from generation Y:

- they are characterised by special ethos of cooperation with companies and brands. they want to co-design a particular product and brand (see Lewis 2013);
- they have a lot of friends and colleagues, both in real life and online. they share their experiences, observations and desires with others via social media (see Horowitz 2018);
- they are not confrontational in relation to other generations;
- they expect that the technologies they use on a continuous and uninterrupted basis will be user-friendly;
- they value experience, discoveries and emotions (see Uptin, 2016).
- they follow their own values and desire authenticity (see Solomon, 2018).

The social and cultural changes seem inevitable. They are going to influence more significantly the changes in consumer behaviour. The cultural context is extremely important in developing the consumption models, especially of the young. Meanwhile, the market began to fill in the social vacuum resulting from rapid transformations in every sphere of social and economic life, to a larger and larger extent. The market became not only the most important sphere of social life, but also the model of social relations. It was clearly visible, first of all, in post-socialist countries, where after 1989, after years of shortage economy, they experienced the consumption boom and transformation in the models of consumer behaviour. We can say that generation Y is a generation where, on the one hand, their consumer choices are influenced by family and social identity (although the impact of these factors is decreasing), and on the other, by the Internet, including the promoted global trends. It was confirmed by the above mentioned results of studies conducted by researchers in various countries, as well as primary research conducted by the authors of this article, presented in the part entitled: statistical material and method, and results.

Statistical Material and Method

The analysis of factors taken into account upon doing shopping by the young between 18 and 25 years of age (generation Y) included questionnaires addressed to students of economy faculties in Poland and Croatia at the turn of 2019. The answers were obtained under their acceptance to participate in research. As many as 1340 correctly filled-in questionnaires were received, and among the respondents the dominant group included students from Poland, only every third student came from Croatia. Over 67% of the respondents were women. The questionnaire included nine factors that might be taken into account while doing shopping. They included: price, quality, brand, compound,

country of origin, advertisements, ecological markings, consumer awards and ecological packaging. The respondents were to assess the impact of these factors on their decisions. Moreover, the research included variables related to the country of origin and sex. The categories of variables received the following symbols:

- country: PL – Poland, HRV – Croatia,
- sex: K – women, M – man,
- level of the study: L1 – Bachelor's, L2 – Master's and PhD,
- price: P1 - always; P2 - usually; P3 – never,
- advertisement: A1 - always; A2 - usually; A3 – never,
- quality: Q1 - always; Q2 - usually; Q3 – never,
- brand: B1 - always; B2 - usually; B3 – never,
- compound: C1 - always; C2 - usually; C3 – never,
- country of origin: CR1 - always; CR2 - usually; CR3 – never,
- ecological marking : EM1 - always; EM2 - usually; EM3 – never,
- consumer awards: EP1 - always; EP2 - usually; EP3 – never,
- ecological packing : EP1 - always; EP2 - usually; EP3 – never,

The research was based on the Multiple Correspondence Analysis – MCA. The method enables to recognize accurately the coexistence of categories of variables (or objects) measured on a nominal scale. The algorithm for the application of Multiple Correspondence Analysis includes the following stages (Greenacre, 1984, 1993, 1994; Goodman 1986; Lebart, Morineau, Warwick, 1984; Stanimir 2005; Bąk 2009):

1. Computing the Burt matrix (B) to obtain the symmetric block matrix where apart from the main diagonal there are the contingency tables, corresponding to two different variables, containing the number of objects of fixed categories of these two features. Whereas, on the main diagonal there are diagonal matrices where non-zero values determine the count of occurrences of particular variable category.
2. Defining the volume of real co-existence area of variable category K under formula:

$$K = \sum_{q=1}^{Q} (J_q - 1) \tag{1}$$

   where: J_q – number of categories of variable q (q = 1, 2, …, Q), Q – the number of variables.
3. Verifying to what extent eigenvalues of lower dimension of space explain the total inertia[1] with the application of Greenacre criterion, indicating that research-significant are the principal inertias higher than $\frac{1}{Q}$.
4. Modifying the eigenvalues as per the Greenacre criterion to increase the quality of projection in *n*-dimensional space as follows:

$$\tilde{\lambda}_k = \left(\frac{Q}{Q-1}\right)^2 \cdot \left(\sqrt{\lambda_{B,k}} - \frac{1}{Q}\right)^2 \tag{2}$$

   where: Q – number of tested variables, $\lambda_{B,k}$ – k-th eigenvalue of matrix B (k = 1, 2, …, K), $\left(\sqrt{\lambda_{B,k}} = \gamma_{B,k}\right)$, $\gamma_{B,k}$ – k-th singular value of matrix B.
5. Presenting graphically the results of correspondence analysis in *n*-dimensional space, including the modification of eigenvalues. New values of coordinates are equal to:

$$\tilde{F} = F^* \cdot \Gamma^{-1} \cdot \tilde{\Lambda} \tag{3}$$

   where: $\tilde{F}$ – matrix of new coordinate values for the categories of variables, F* – matrix of primary coordinate values for the category of variables, Γ^{-1} – inverse of diagonal matrix of singular values, $\tilde{\Lambda}$ – diagonal matrix of modified eigenvalues.

[1]Total inertia λ is the K sum of eigenvalues, where K is the dimension of real space coexistence.

Results

The correspondence analysis was conducted under the Burt matrix sized 33×33 created from 21 variables of the above mentioned categories. The dimension of real space coexistence of answers to analysed questions determined under formula (1) totalled 21. During the subsequent stage it was verified to what extent the eigenvalues of space of lower dimension explain the total inertia (λ = 1.7500). To this end, the Greenacre criterion was applied, indicating that research-significant are the principal inertias higher than $\frac{1}{Q} = \frac{1}{12} = 0.0833$. Table 1 shows that these are inertias for K taking the values of max. 6. For these dimensions the value of measure τ_k was analysed. Moreover, the graph of eigenvalues was provided, and with the use of 'elbow' criterion it was possible to determine that the space of coexistence of various variables should be three-dimensional (fig. 1). The degree of explaining the inertia in this space amounts to 31.02% (tab. 1). In order to improve the quality of projection in three-dimensional space the modification of eigenvalues was implemented, under formula (2), which proved that after the modification the degree of explaining inertia increased to 67.76%.

Source: own calculations using the Statistica 13.0 package.

The in-depth analysis of the results obtained based on the correspondence analysis involved the use of the Ward method; it enabled to determine the relations between the variable categories. The result depicted as dendrogram was presented in fig. 2.

Fig. 2. Classification of categories of analysed variables using the Ward method

Source: own elaboration

The line of 'cut off' at the height of 1.426 was determined under Grabiński factor[ii]. On these grounds, four classes of categories were specified:

- Class I (P3, Q3), the smallest group (1% of the respondents) – consumers within the first group do not attach importance to price and quality of purchased products;
- Class II (B3, C3, CR3, A3, EM3, CP3, EP3), including ca. 3% of the respondents – young people within this group, in their purchasing decisions, do not attach importance to brand, compound, advertisements, country of origin, consumer awards and ecological issues.
- Class III (CP1, EP1, EM1, A1, CR1), including ca. 12% of the respondents – the representatives of this group in their consumer choices frequently or always take into account the advertisement of product, ecological issues (packaging and markings), as well as consumer awards and the product country of origin.
- Class IV (K, M, S1, S2, PL, HRV, P1, P2, Q1, Q2, C1, C2, B1, B2, A2, CR2, EP2, EM2), the largest group, ca. 84% of the respondents – the representatives of the fourth group include both women and men, living in Poland and Croatia, students of the first and second cycle studies, who take into account, first of all, the price, quality, compound and brand in their purchasing decisions. Whereas, they attach little importance to advertisements, country of origin and issues related to ecology.

In the analysis of consumption we can rely on two theoretical trends: hedonistic and eudemonistic. In the quantitative empirical analyses, based on experiments or statistical analysis of data from the surveys, in general the first one is applied. Following the assumptions included in the first trend, and analysing the data based on the conducted surveys it turns out that the contemporary generation Y is characterized, to a large extent, by the hedonistic approach. The results of conducted research also indicate that the economic and ecological awareness of the young Polish and Croatian consumers is increasing, although slowly. The economic awareness - since 84% included the respondents who, at their purchasing decisions, take into account, first of all, the price and quality. The ecological awareness – since 12% of young consumers, at their purchasing decisions, frequently or always take into account the ecological issues (packaging and markings), as well as the consumer awards and the product country of origin. It should be noted that among the respondents (within group IV) 84% emphasize that while purchasing goods they do pay attention to the compound, namely the materials used to make the goods. Therefore, the young people from this group of respondents take into account the ecological issues but do not give them priority. Under the conducted analyses we can also determine the shopping styles of the surveyed consumers and divide them into three groups: social (for show), utilitarian (decision-making based on quality and price) and pro-ecological. Summing up,

it can be concluded that the identified four classes of categories related to the buying preferences of consumers studying at the faculties of economy in Poland and Croatia prove that also in these countries (although rather slowly at present) we can observe the revision of social and economic awareness among young people.

Conclusions

The authors' guiding idea is to identify key issues of the changing economic life in the context of economic socialization of young consumers, strongly correlated with the economic culture of societies in particular countries. This is the basic consideration since as G. Krzyminiecka (2009) puts it, the economic culture as the achievement of historic development exerts significant impact on the environment of economic processes, on the standards of human behaviour and the quality of interpersonal relations in organizations. It also affects the conditions of dissemination of knowledge on economic processes in societies, and consequently, the development of human capital for economic purposes.

At present, the most current social issues include those related to social change, namely globalization, consumption and technological development. As emphasised by Korzeniecka-Bondar (2016) and Krajewska (2015), for many social researchers (Alan Aldridge, George Ritzer, Jean Baudrillard, Zygmunt Bauman, Grzegorz Adamczyk, Felicjan Bylok, Mateusz Marciniak, Małgorzata Bogunia-Borowska and others), the consumption category constitutes the starting point for discussion on the contemporary society (consumption), culture (consumption) and human (consumer). Although the related studies are usually sociological or anthropological in their nature, the issue is also analysed in the area of economy and widely defined education. It results in the following constatation, namely that in the new millennium, where the consumerism boom has reached a significant level, the socialization has become a crucial issue. Therefore, numerous discussions among the representatives of various fields of science emphasize the importance of socializing processes, including the economic aspect which makes it possible to understand the surrounding economic reality. Within the meaning of market mechanisms, the key importance shall be attributed to education. It results from the following premises:

- thanks to the economic socialization, the young consumers can do shopping more effectively, and first of all, better understand the mutual influence of market components and the surrounding economic reality,
- economic socialization is a process taking place in the context of cognitive and social development of young people,
- as socialization in general, the economic socialization is a lifelong process since in the early stages of life, the habits related e.g. to consumption, expenditure planning and saving are developed.

Certainly, the socialization of young people cannot only be focused on economic premises since it is basically interdisciplinary in its character. Moreover, it must include numerous institutions, both formal and informal. In the case of young people from generation Y (and also other generations), the key elements include: family, closest environment, schools, universities and the country. Many universities provide educational activities to that effect; however, as emphasised by K. Szelągowska-Rudzka (2018, p. 221), despite the observed positive changes related to the form and lines of education at the universities, we need further, more widely understood, coherent and effective educational system, connected with mission and vision as well as strategy and development of universities. Wide access to the Internet provides enormous possibilities for the producers of goods and services to advertise their products on a local, regional, national and global level. The resulting 'information overload' makes the consumers confused. Education constitutes the main instrument used to strengthen the standing of consumers on the market since better informed consumers take more rational decisions and become the aware citizens in the global world. It also provides possibilities for the increase in consumers' awareness and focus on social choices. In the case of young people it must be based on developing the new models of consumer behaviour and the awareness of sustainable consumption. However, the research conducted e.g. by the authors of this

article shows that generation Y attaches importance to ecological issues, mainly in their declarations. Practically all research results (primary and secondary presented in this article) indicate that price and brand are the priority. Therefore, the young people from generation Y are not truly aware of prospects and risks resulting from unsustainable consumption, on both individual and social level. Meanwhile, it seems that the intensified youth movements in 2019 aimed to protect the natural environment show entirely opposite tendencies.

Thus, education is a prerequisite for building such awareness among the youth. First of all, it makes the economic socialization of the young, necessary not only to protect their own interests, more real, but also makes it possible to pressure the economic entities to address the environmental and social issues. The inspiration for research in this area came from the social, cultural, political, technical and technological changers we observe in recent years. As a result of these conversions the consumer behaviour began to transform quite rapidly. However, practice revealed that some premises e.g. regarding rationality of consumer behaviour influenced by the changed and rapidly changing reality lose relevance. As a result of these circumstances more and more economists begin to emphasize the exceptional role played by the consumers, in particular young people, and their impact on the development of companies and countries. In such situation it seems that in-depth analysis of this area of economy is not only advised, but also necessary to make it possible for the producers to schedule the production of goods and services for young consumers, and consequently obtain better results, in the scale of an individual company as well as the economy. Moreover, this study will be equally significant for scientists, economists, sociologists, psychologists, anthropologists, as well as those engaged e.g. in engineering and medical sciences, since this research may become inspirational for many of them and make them continue more thorough analyses.

Intramural Expenditures On R&D by Types of Costs in Poland: Evidence From NUTS-2 Regions

Aleksandra ZYGMUNT

Opole University of Technology, Opole, Poland
a.zygmunt@po.edu.pl

Abstract

R&D activities play a significant role in firms' innovation activities and competitiveness of firms and regions. Within this context, the issues related to R&D expenditures are of particular importance. This paper aims to investigate how intramural expenditures on R&D by types of costs incurred by firms, universities and regional policy actors differ in Poland at NUTS-2 level. Special concern was put on current and capital expenditure on R&D. The empirical evidence was based on data from Statistics Poland, Local Bank Data for the period 2004–2018 (except of 2008, due to missing data). The zero unitarization method and multivariate analysis were employed to hypothesis testing. This paper provides a contribution to the discussion on R&D activities in Poland. The findings reveal relatively high diversity between regions at NUTS-2 level in Poland in terms of current and capital expenditures on R&D incurred by firms, universities and regional policy actors. The results indicate also perpetual changes in the level of intramural expenditures on R&D in the most of Polish regions at NUTS-2 level. A policy implication is that regional policy actors should strengthen R&D policy in order to stimulate R&D activities and enhance firms' and regions' competitiveness.

Keywords: Intramural Expenditures On R&D by Types of Costs, Current Expenditures On R&D, Capital Expenditures On R&D, Polish Regions At NUTS-2 Level.

Introduction

R&D activities are increasingly seen as a key factor for knowledge creation and are strongly associated with innovation activities of firms. While there is a strong interaction between firms' innovation activities and competitiveness of regions, R&D activities take on a particular significance. In this regard, a growing literature discusses and evaluates the capacity of R&D activities to increase innovation performance (Huggins & Williams, 2011). This topic is especially important in context of creation conditions for economic growth of firms and regions (Fritsch *et al.*, 2019). This is also related with supporting knowledge diffusion processes between, among others, firms, universities and regional policy actors for strengthen innovation performance (Grillitsch *et al.*, 2019). However, despite an extensive literature on R&D activities (Chybowska *et al.*, 2018), little attention has been paid to intramural expenditures on R&D incurred by firms, universities and regional policy actors in Poland at NUTS-2 level.

To fill this gap, this study aims at gaining a deeper empirical understanding of R&D activities by shedding light on how intramural expenditures on R&D by types of costs incurred by firms, universities and regional policy actors differ in Polish regions at NUTS-2 level. Special attention was attached to such types of costs as current and capital expenditures on R&D.

The empirical evidence is based on data from Statistics Poland, Local Bank Data. The research period was 2004–2018 (except of 2008, due to missing data). The zero unitarization method and multivariate analysis were employed for hypothesis testing.

This study contributes to the literature on R&D activities by providing insights about differentiation of current and capital expenditures on R&D between Polish regions at NUTS-2 level. Focusing on

NUTS-2 regions is relevant because of the role of regional policy actors to strengthen conditions for competitiveness of firms, research system and regions.

The structure of the paper is as follows: the first part presents the theoretical framework and hypothesis development. The second part describes the data and the methodology used to investigate how intramural expenditures on R&D by types of costs incurred by firms, universities and regional policy actors differ in Poland at NUTS-2 level. The next part focuses on providing the results. The last part contains the concluding remarks, including the implication of the study, limitations and future research directions.

Literature Review

A number of empirical studies show the relevance of innovation for economic growth of firms and regions (Fritsch *et al.*, 2019). The interest in innovation enhance due to abilities of innovation to shift competitive advantage. For this reason, a vast body of literature focuses on determinants of innovation performance (Zygmunt, A., 2020; Scandura, 2016). Most studies seem to suggest the significance of exogenous and endogenous determinants in increasing innovation performance (Zygmunt, J., 2018a; Zygmunt, J., 2018b; Klemens, 2018; Maj, 2017; Rokita-Poskart & Jończy, 2019). While recognizing determinants of innovation performance, pivotal emphasis is put on interactions between firms' innovation activities and competitiveness of regions (Zygmunt, A., 2018). In this way, innovation activities of firms affect firms' competitiveness and, consequently, economic growth of regions. On the other hand, regions play a significant role in creating conditions for increasing firms' innovation activities. Therefore, these interactions are crucially important in diffusing innovation. In line with these arguments, the existing evidence suggests the significance of the networks between, among others, firms, universities and regional policy actors (Grillitsch *et al.*, 2019). Special concern is put on knowledge diffusion processes as crucial for innovation (Huggins & Williams, 2011). These issues are particularly emphasised by knowledge spillover and endogenous growth theories, and place-based approach.

While interactions between firms' innovation activities and regions' growth and knowledge diffusion processes seem essential for competitive advantage, a set of studies focus on the linkage between R&D activities and innovation performance (Scandura, 2016). This set of studies show that R&D activities are seen as a key component of enhancing innovation and knowledge flow between firms, universities and regional policy actors (Huggins & Williams, 2011). Over the past years, a vast body of literature has argued that R&D activities are the principal part of knowledge flow especially between firms and universities (Isaksen *et al.*, 2018). Such cooperation may take various forms. For example, it has been observed the great interest in patents, publications and collaborative R&D projects (Fritsch *et al.*, 2019). As noted Tijssen and Winnink, patents and publications express "R&D excellence" (Tijssen & Winnink, 2017, p. 689) as an effectiveness of knowledge diffusion processes between universities and firms. This body of research stresses the role of co-patenting, co-publications between firms and universities to create new knowledge crucial for innovation processes (Fritsch *et al.*, 2019). Empirical evidence finds also a strong focus on collaborative R&D projects between firms and universities to strengthen firms' innovation activities (Scandura, 2016).

A wide body of empirical literature assesses also the role of regional policy actors in creation and strengthen conditions for R&D activities (Huggins & Williams, 2011). Facing the need for increasing competitiveness of firms, regional policy actors may offer a various set of support. Following this, the existing studies point to support knowledge diffusion processes as being crucial for firms' and universities' innovation (Isaksen *et al.*, 2018). Another line of research emphasises the role of public R&D as providing support for innovation performance (Grillitsch *et al.*, 2019). Such support is seen as an essential for enhancing competitive advantage of firms and, consequently, competitive advantage of regions.

When supporting R&D activities and knowledge diffusion processes, strong emphasis is put on intramural R&D expenditures. It has been suggested that such R&D expenditures can be seen as

knowledge ability to improve innovation performance. A number of studies assess the role of intramural R&D expenditures on the national level (Tijssen & Winnink, 2017). According to Tijssen and Winnink, size and components of intramural national R&D expenditures provide feedback about country's "R&D excellence" (Tijssen & Winnink, 2017). Another part of the literature is focused on intramural R&D expenditures incurred by firms as important for firms' innovation performance (Haus-Reve *et al.*, 2019). From an innovation point of view, also intramural R&D expenditures incurred by universities and incurred by regional policy actors are crucial for firms' innovation activities. Such R&D expenditures built conditions for knowledge diffusions processes and to increase competitiveness.

A recent research on R&D activities in Poland focus, among others, on issues related to the linkages of R&D activities with knowledge diffusion issues. For example, the studies emphasise the role of R&D activities in enhancing total factor productivity of NUTS-2 regions (Danska-Borsiak, 2018). In this sense, R&D activities are crucial "to create jobs in technology and knowledge-intensive sectors" (Danska-Borsiak, 2018, p. 48). Another part of the literature is focused on identifying the role of R&D activities to increase Poland competitiveness (Chybowska *et al.*, 2018) and to shift intellectual capital of Polish and Slovak NUTS-2 regions (Pachura *et al.*, 2018). These studies also refer to intramural expenditures on R&D as a part of set of the measures employed for the research. Particularly, to the study related to total factor productivity of Polish NUTS-2 regions, intramural R&D expenditures on the national level were employed (Danska-Borsiak, 2018). Intramural R&D expenditures on the national level were also applied as a one of the measures of study regarding intellectual capital of Polish and Slovak NUTS-2 regions (Pachura *et al.*, 2018). To the research concerning the role of R&D activities to increase Poland competitiveness, intramural R&D expenditures incurred by firms, universities and regional policy actors were used (Chybowska *et al.*, 2018).

Thus, while a number of studies investigating R&D activities in Poland, very few studies address the issues related to intramural expenditures on R&D in Poland. Hence, it is important to carry out research and investigate intramural expenditures on R&D at NUTS-2 level. Research attention was put on intramural expenditures on R&D incurred by firms, universities and regional policy actors. The emphasis was also put on intramural expenditures on R&D by the types of cost: current expenditures on R&D and capital expenditures on R&D, which represent expenditures for fixed assets connected with R&D activity. Therefore, the hypothesis to be tested is the following:

H: Intramural expenditures on R&D by types of costs incurred by firms, universities and regional policy actors differ in Poland at NUTS-2 level.

Materials and Methods

The empirical data used in the study was retrieved from Statistics Poland, Local Bank Data. This dataset includes, among others, information on innovation performance of Polish firms, universities and regional policy actors at NUTS-2 level. While this research focuses on intramural expenditures on R&D by types of costs, using data from Statistics Poland, Local Bank Data, allows analysis how expenditures in question differ between NUTS-2 regions in Poland. In the research, particular attention was put on such types of costs as current and capital expenditures on R&D incurred by firms, universities and regional policy actors. The time period was referring to 2004–2018. Due to missing data for 2008, this year was excluded from the study.

The research consists of two parts. The first part contains a comparative analysis of intramural expenditures on R&D by types of costs between NUTS-2 regions in Poland. The second part focuses on how intramural expenditures on R&D by types of costs incurred by firms, universities and regional policy actors differ in Poland at NUTS 2 level, employing the zero unitarization method and multivariate analysis. Table 1 summarises descriptions and descriptive statistics of variables used in the study.

Table 1: Description and descriptive statistics of variables

Variables		Description	Mean	St. Dev.	Min.	Max.
Current expenditures on R&D	X_1	Current expenditures on R&D (PLN) per inhabitant	192.84	175.77	42.64	766.45
Capital expenditures on R&D	X_2	Capital expenditures on R&D (PLN) per inhabitant	61.95	43.91	15.55	184.40

Source: own study based on: Statistics Poland, Local Bank Data (Statistics Poland, 2020).

Since Statistics Poland, Local Bank Data, gathers information on intramural expenditures on R&D by types of costs incurred by firms, universities and regional policy actors at NUTS-2 level, to research how these types of costs differ in Poland, a comparative analysis of diagnostic variables and the zero unitarization method and multivariate analysis were used. This combination of methods enables an understanding of the differences between NUTS-2 regions in Poland and 'enables comparing the values of synthetic index for all years' (Balcerzak, 2015, p. 191).

To the normalisation of variables, a constant reference point was used (on the ground of zero unitarization method) (Kukuła & Bogocz, 2014, p. 7):

$$R(X_{jt}) - \max_{it} x_{ijt} - \min_{it} x_{ijt} \qquad (1)$$

Because variables used in the study are stimulants, the normalisation was conducted employing the following formula (Kukuła & Bogocz, 2014, p. 7):

$$z_{ijt} = \frac{x_{ijt} - \min_{it} x_{ijt}}{\max_{it} x_{ijt} - \min_{it} x_{ijt}} \qquad (2)$$

where $z_{ijt} \in [0,1]$; $(i = 1,2,\dots,n)$; $(j = 1,2,\dots,m)$; $(t = 1,2,\dots,l)$

Finally, the synthetic measure was calculated on the basis of the following formula (Balcerzak, 2015, p. 196):

$$SM_{it} = \frac{1}{m}\sum_{j=1}^{m} z_{ijt} \qquad (3)$$

where $z_{ijt} \in [0,1]$; $SM_{it} \in [0,1]$; $(i = 1,2,\dots,n)$; $(j = 1,2,\dots,m)$; $(t = 1,2,\dots,l)$

This procedure enabled to analyse how intramural expenditures on R&D by types of costs incurred by firms, universities and regional policy actors differ in Poland at NUTS-2 level.

Findings

Comparative analysis of variables

Figures 1–2 provide the results of the comparative analysis of intramural expenditures on R&D by types of costs incurred by firms, universities and regional policy actors at NUTS-2 level in Poland in 2004–2018. The comparison of current expenditures on R&D incurred by firms, universities and regional policy actors at NUTS-2 level indicates substantial features (Figures 1).

*Legend: PL-DS – Lower Silesian Voivodship; PL-KP – Kuyavian-Pomeranian Voivodship; PL-LU – Lublin Voivodship; PL-LB – Lubusz Voivodship**; PL-LD – Łódź Voivodship; PL-MA – Lesser Poland Voivodship; PL-MZ – Masovian Voivodship; PL-OP – Opole Voivodship; PL-PK – Subcarpatian Voivodship; PL-PD – Podlaskie Voivodship; PL-PM – Pomeranian Voivodship*; PL-SL – Silesian Voivodship; PL-SK – Świętokrzyskie Voivodship*; PL-WN – Warmian-Masurian Voivodship; PL-WP – Greater Poland Voivodship; PL-ZP– West Pomeranian Voivodship**; * lack of data for 2011, ** lack of data for 2013.*

Figure 1: Current expenditures on R&D (PLN per inhabitant) in Poland in 2004–2018
Source: own calculations based on data from: Statistics Poland, Local Bank Data (Statistics Poland, 2020).

First, the notable increase of current expenditures on R&D incurred by firms, universities and regional policy actors can be seen at NUTS-2 level in Poland in 2004–2018. This trend imply that current expenditures on R&D play an increasing role in firms', universities and regional policy actors' performance and may result in enhancing innovation activities of firms and, consequently, to increase competitive advantage of firms and regions.

Second, an important feature that can be observed when comparing Polish NUTS-2 regions is the gap in the level of current expenditures on R&D incurred by firms, universities and regional policy actors. It may be noticed that in such Polish regions at NUTS-2 level as Masovian Voivodship, Lesser Poland Voivodship, Pomeranian Voivodship and Lower Silesian Voivodship, current expenditures on R&D incurred by firms, universities and regional policy actors are noticeably higher than in other NUTS-2 regions in Poland. This gap is persistent over the period 2004–2018 and may be the consequence of firms', universities' and regional policy actors' capabilities to stimulate R&D activities. This may have wider effect on knowledge diffusions between universities, firms and regional policy actors and may affect innovation activities of firms and regional development.

When considering capital expenditures on R&D incurred by firms, universities and regional policy actors in Polish regions at NUTS-2 level in 2004–2018 (Figures 2), much lower intensive engagement of these types of cost for intramural expenditures on R&D is found in comparison to current expenditures on R&D. This reflects that firms, universities and regional policy actors are likely to stimulate R&D activities through current expenditures on R&D.

Figure 2: Capital expenditures on R&D (PLN per inhabitant) in Poland in 2004–2018
Source: own calculations based on data from: Statistics Poland, Local Bank Data (Statistics Poland, 2020).

Legend: like in Figure 1.

The results also reveal perpetual changes in the level of capital expenditures on R&D incurred by firms, universities and regional policy actors in the most of Polish regions at NUTS-2 level in 2004–2018. This may result in hampering R&D activities and may affect competitiveness of firms and regions. The study shows such changes for, among others, Lublin Voivodship Podlaskie Voivodship and Subcarpatian Voivodship. However, since 2016, the vast majority of NUTS-2 regions in Poland have been distinguished by growth of capital expenditures on R&D incurred by firms, universities and regional policy actors. This should be treated positively as increasing capabilities to stimulate R&D activities. It may be also noticed that in comparison to others Polish regions at NUTS-2 level, Masovian Voivodship emphasises a relatively high level of of capital expenditures on R&D incurred by firms, universities and regional policy actors in 2004–2018. This finding suggests high potential of Masovian Voivodship to knowledge diffusions between universities, firms and regional policy actors and to economic growth of firms and region.

The Zero Unitarization Method and Multivariate Analysis Results

Tables 2–3 shows the results of the zero unitarization method and multivariate analysis of intramural expenditures on R&D by types of costs incurred by firms, universities and regional policy actors in Poland at NUTS 2 level in 2004–2018.

Legend: like in Figure 1.
Source: own calculations based on data from: Statistics Poland, Local Bank Data (Statistics Poland, 2020).

The results reveal relatively high diversity between Polish regions at NUTS-2 level in supporting R&D activities by current and capital expenditures incurred by firms, universities and regional policy actors in the period under the study. These findings are consistent with the stated hypothesis. Since R&D activities play an important role in firms' innovation performance, such diversity may affect competitive advantage of firms and regions. While intramural expenditures on R&D present lack of steady trend in the vast majority of NUTS-2 regions in Poland in 2004–2018, stated diversity may results also in limited capabilities to stimulate R&D activities.

According to the findings, the highest diversity in terms of current and capital expenditures on R&D incurred by firms, universities and regional policy actors can be seen between Masovian Voivodship, Lesser Poland Voivodship and Świętokrzyskie Voivodship, Opole Voivodship, Lubusz Voivodship. That findings suggest also that Masovian Voivodship and Lesser Poland Voivodship highlight relatively the highest level of current and capital expenditures on R&D incurred by firms, universities and regional policy actors in comparison to other Polish regions at NUTS-2 level. This suggests high potential of Voivodships in question to knowledge diffusions and supporting R&D activities. On the other hand, compared to other NUTS-2 regions in Poland, the results indicate relatively the lowest level of intramural expenditures on R&D incurred by firms, universities and regional policy actors in Świętokrzyskie Voivodship, Opole Voivodship and Lubusz Voivodship. These suggest that above Polish regions at NUTS-2 level may experience difficulties in stimulating R&D activities. This may affect innovation activities of firms and competitive advantage of regions. A relatively low level of current and capital expenditures on R&D incurred by firms, universities and regional policy actors can also be observed in such NUTS-2 regions in Poland as Warmian-Masurian Voivodship and West Pomeranian Voivodship and may result in limitations of economic growht of firms and regions.

Conclusions

This paper provides a contribution to the discussion on R&D activities in Poland. This research complements previous studies by shedding light on how intramural expenditures on R&D by types of costs incurred by firms, universities and regional policy actors differ in Polish regions at NUTS-2 level.

The study shows relatively high diversity between regions at NUTS-2 level in Poland in terms of current and capital expenditures on R&D incurred by firms, universities and regional policy actors in 2004–2018. In connection with constant changes of intramural expenditures on R&D level in the vast majority of Polish regions at NUTS-2 level, such feature may result in limited capabilities to knowledge diffusions between universities, firms and regional policy actors and to stimulate R&D activities. That may contribute to firms' innovation activities and to competitive advantage of firms and regions.

The findings call for policy implications. Since R&D activities are the important component of competitive advantage, there is a need to strengthen R&D policy to support firms and universities in improving innovation performance. The attention should be also paid to strengthen conditions for knowledge diffusion processes between firms, universities and regional policy actors in order to enhance competitiveness of firms, research system and regions.

This study is not without limitations. The results are limited to current and capital expenditures on R&D incurred by firms, universities and regional policy actors at NUTS-2 level expressed in overall value and some conclusions may not be observed. For future studies, intramural expenditures on R&D by types of costs should be dealt with separately in relation to firms, universities and regional policy actors. It would be also beneficial to investigate the causes of relatively high diversity between regions at NUTS-2 level in Poland in terms of current and capital expenditures on R&D incurred by firms, universities and regional policy actors.

Abstract

The development of local economic systems in modern Russia stimulates the interest of researchers in studying the historical experience of similar processes in the regulation of trade and market relations, development vectors of infrastructure elements, and economic practices. Aggravation of public and scientific discussion about the ways of modernization of the country and its results at the beginning of the XXI century increased the importance of studying regional and local markets in the all-Russian system.

Keywords*:* Trading Exchange, Trading Companies, Agricultural Production, Handicraft Production, Urban Social Classes, Merchants, Petty Bourgeois.

The case of Tula province, which combined typical features of the development of economic processes within the Central Industrial and Central Agricultural regions, allows us to come closer to understanding the versatility of capitalist modernization in the European part of the country during the period of the Great Reforms and their first results (Borodkin L.I. et al., 2007).

A research of the local markets of the Kursk province, due to the specifics of all-empire institutions, elements of local infrastructure, proximity to the capital, and specialization in commercial and industrial development, allows us to study the features of the spatial organization of market relations in Russia in the second half of the XIX century.

Kursk has long been a city with developed trade. In the last third of the XIX century, when railway construction greatly facilitated communication within the province and expanded the possibilities of relations outside it, new conditions appeared for the revitalization of trade. A large number of agricultural products were exported from the province, including grain, raw skin, fur, hemp, lard, and vegetable oils.

As shown, for example, by the governor's report for 1879, this year the bread trade was especially brisk and the bread was readily bought by visiting agents of foreign trading firms despite the high prices of all the grain crops in the provincial markets. Also, 1,497 patents for trade and crafts were issued for local merchants (Excerpts on the history of Kursk province, 1965).

With the growth in the number of people in trade, a need arose for a variety of information - about prices, demand, areas of most profitable sales, etc. The need for proper execution of transactions began to feel more acute.

One of the most common forms of capital organization in Russia was trading houses, the legal status of which was fixed in the 1807 Manifesto, “On new benefits granted to merchants, and new ways to

spread and strengthen trading enterprises". This act established two types of "merchant partnerships": full partnership and trust partnership (limited partnership), which existed unchanged until 1917.

A full partnership "was formed from two or many comrades who put together the common name of all." A trust partnership, which is a higher form of associating capital, was formed from one or many partners with the "involvement of one or many investors who first entrust the known amounts of their capital" (Code of laws of the Russian Empire, 1903) without directly participating in management.

The study of trading houses allows you to establish the organizational structure of capital and characterize the initial stage of its association.

Moreover, this makes it possible to determine the extent of the spread of new forms of entrepreneurial activity.

This problem was to some extent investigated by historians.

In the available papers, the general indicators (number, structure, composition of owners) of trading houses throughout the country as well as the work of individual large partnerships (Bokhanov A.N., 1930) are analyzed

However, the same parameters for individual regions, particularly the Central Agricultural Region, are poorly studied.

This article represents the first experience in the study of partnerships in the Kursk region based on a complex of archival and print sources.

In Kursk province, trading houses became common structures in 1890s. According to the data of local city administrations and public self-governments as of January 1, 1893, there were only 3 trading houses with a capital of 70 thousand rubles in the province. However, in 1897 there were already 9 different partnerships operating (the capitalization is unknown).

The numerical growth of trading houses was accompanied by territorial expansion. In 1892, all partnerships were registered in large cities of the Kursk province (Kursk and Belgorod), with 66.6% of trading houses operating in Belgorod, and 33.3% in Kursk. However, in terms of size, the largest partnerships, which accounted for 85.7% of the capital, functioned in the provincial center.

In 1896, 25 trading houses (89.2%) conducted their business in cities and only 3 (10.7%) - in villages. It should be noted that more than half of the trading houses (60.7%) operated in Kursk, which was the economic center of the province. 85.7% of all limited partnerships were also located here. By the way, the latter carried out their operations only in large cities.

All this shows us yet another correlation: the higher the level of development of trade and industry in a particular area, the more intensive process of association took place here.

Most trading houses carried out their activities within the place of registration. Few partnerships extended their activities to the nearest cities or rural settlements of the Kursk province. E.g., the trading house "A. N. Mikheeva and sons" was mainly engaged in wine trade both in the town of Shchigry, the location of the main office, and throughout the county.

Another example is the alcohol trading partnership "I.A. Morozov and P.I. Belyansky", registered in the city of Korocha, but having its branches in the city of Novy Oskol and adjacent counties.

Social indicators of owners of trading houses are of undoubted interest.

Table 1: Number and state of trading house owners in 1892 and 1915

	Number of full partners	State of full partners*					
		merchants	hereditary honorary citizens	petty bourgeois	peasants	foreigners	other**
1892	6	4/66.7					2/33.3
1915	65	12/18.4	2/3.0	29/44.6	16/24.6	1/1.5	5/7.6

** Numerator is the number of the owners; denominator is the percentage of the owners.*

*** This category included workshop and college secretaries, as well as those who did not determine their state affiliation (midwives, dentists, etc.).*

As you can see, in 1890s most full partners were the merchants, but there were practically peasants and bourgeois among these entrepreneurs. It resulted in a class homogeneity for the owners of trading houses, characteristic of the end of the 19th century. However, by 1915, as the table shows, there were strong changes in the contingent of full partners.

On the one hand, their number increased due to the influx of members of various social groups, which contributed to the destruction of class homogeneity of owners of trading houses. On the other hand, there was a significant increase in the proportion of peasants and bourgeois. They accounted for a total of 69.2% of full partners. Finally, there was a reduction in the share of merchants. By 1915, it decreased by 72.3% and amounted to only 13.4% (State Archives of Kursk Region).

Belonging to "urban social class", merchants concentrated mainly in cities. For example, in 1897, urban merchants accounted for 78.3% of all merchants in the Kursk province. This distribution, in turn, affected the geography of their trade activities, which were concentrated in cities. The state of merchant trade is shown in Table 2 using the provincial center and one county center as an example (the numerator is an absolute value; the denominator is percentage) (Zakharov V.V., 1994).

Table 2 : Merchant trade in the Kursk province

	Kursk		Lgov	
	1896	1914	1893	1916
Number of merchants' trading enterprises	80 29.8	49 14.0	37 31.0	13 10.8
Turnover (rubles)	3958100 73.2	3249217 41.0	816500 77.5	892800 35.8

As you can see, at the end of the last century in Kursk, merchants owned a third of all trading enterprises with 73.2% of the total monetary turnover. At the beginning of the XX century, the number of merchant shops and stores was almost halving, and their share was 14.0%. The turnover of merchants' trading enterprises decreased from 3,958,100 rubles to 3,249,217 rubles (by 17.9%).

By 1916, the number of merchant shops decreased to 13, which amounted to 10.8% of the total number of trading enterprises. Their turnover increased slightly, but the proportion decreased to 35.8%.

Thus, a process of reducing merchant trade is clearly observed both in absolute and relative terms in the cities of the Kursk province in the second half of the XIX and early XX century.

In their commercial activities, members of the merchant class were not limited to cities and were active in rural areas. In the counties, the shops were kept not only by merchants who lived here permanently, but also by representatives of the "urban merchants" who traded through their clerks.

A general picture of the evolution of rural merchants' trade can be drawn from the verification materials district for 1896 and 1913.

According to verification journals of the Stary Oskol county in 1896, there were 77 stores that belonged to merchants, accounting for 25.2% of the total number of stores. Their turnover reached 291,350 rubles, or 61.9% of the turnover of county trade. In 1917, there were only 15 merchant trading enterprises (6.3%) with a turnover of 690 thousand rubles (21.8%). In other words, there was a decline in the merchant sector in rural trade (State Archives of Kursk Region).

Internal characteristics of merchants' rural trade is shown in Table 3 using verification journals of the Stary Oskol county (the numerator consists of absolute value and bracketed percentage, and the denominator is percentage relating to total count) (State Archives of Kursk Region).

Table 3 : Characteristics of rural trade in the Kursk province.

	1896		1917	
	Stores	Annual turnover	Stores	Annual turnover
Less than 5 thousand rubles	63 (81.8) 21.9	98850 (33.9) 39.1	1 (6.6) 0.5	4000 (0.5) 0.1
5-25 thousand rubles	12 (15.5) 75.0	112500 (68.6) 81.6	6 (40.0) 21.4	73000 (10.5) 23.4
More than 25 thousand rubles	2 (2.5) 100	80000 (27.4) 100	8 (53.3) 34.7	613000 (88.8) 23.6

As you can see, at the end of the last century, in the villages, merchants owned, as a rule, small shops. For example, in the Stary Oskol county in 1896, 81.8% of merchant shops were small, they accounted for 33.9% of all merchant turnover. The proportion of trade enterprises of this size was small and amounted to 21.9% (revenues - 39.1%).

At the end of the XIX century representatives of the merchant class concentrated in their hands most of the large and medium-sized trade in industrial goods and foodstuffs in the cities and villages of the Kursk province. However, the decrease in the number of merchants that began in early XX century entailed a reduction in merchant trade, which was carried out primarily due to the small and medium trading sectors.

At the same time, controlling up to half of local trade, merchants occupied prominent positions among traders of the Kursk province. The merchants used various organizational forms of trade. Along with traditional trade (stores), more modern types (shops, exchanges) also developed. This indicates that the merchants, modernizing their entrepreneurial activities, adequately responded to the "challenges of the time" (Zakharov V.V., 1996).

According to sources, in the late XIX - early XX centuries there was a numerical growth of partnerships. From 1892 to 1915, their number increased by 9.3 times, and the amount of capital - by 16.1 times.

It is noteworthy that the time of establishment of trading houses did not always coincide with periods of favorable economic conditions. They were created both during the crisis years and at the stage of economic recovery. One of the reasons for this was, presumably, the economic orientation of the province (its agricultural specialization), as a result of which the state of agriculture, which did not always fit into economic cycles, largely determined the local trade and industry, as well as their association. By the way, the two Gründer bursts coincide with the years when a good crop was harvested (Zakharov V.V., 1996).

In the period under review, the contingent of owners of trading houses significantly changed. Merchants lost their dominant position to people from the lower classes. This is evidence that local business have adapted to new economic conditions.

Abstract

The study of motivational activity is conducted primarily in order to understand to what extent it contributes to the effectiveness of the enterprise. The development of effective solutions in the field of motivational activity requires a detailed analysis, which is impossible without a competent choice of research methods. The article offers two scenarios for the study of motivational activity. Qualitative and quantitative indicators for evaluating the effectiveness of motivation are given.
It is proved that the application of the proposed approaches will ensure balance of the motivation system towards the goals of the organization, that is, the applied forms and methods of motivation will be linked to both the objectives of the enterprise and the expectations of employees

Keywords: Motivation, incentives, labor productivity, wages, staff turnover, types of motivation, effectiveness of motivational activity.

Introduction

Motivation is usually understood as an incentive to work, reflecting the employee's perception of their responsibilities, and the behavior of the employee during the work process. Motivation is based on the needs of employees, as well as on an understanding of which needs can be met at a given workplace now, and which needs can be met in the near future.

The system of personnel motivation in an enterprise is a combination of various measures that stimulate employees not only to work at a job that pays but also to the desire to work in this organization, ensuring high results in their activities.

The socio-economic significance of motivation is not in dispute. However, in many Russian enterprises, this issue is almost ignored. To some extent, only material motivation is used, which is reduced to the presentation of "insignificant" gifts or certificates, and it often has a negative effect.

Currently, there is already a negative experience of huge losses associated with the dismissal of key employees. As a result, the problem of developing an effective system of motivation and incentives for staff is urgent. And no less relevant is the work on analyzing the effectiveness of motivational activities of specific enterprises.

Meanwhile, the assessment of the motivational work of many Russian enterprises either is not carried out or is reduced to the analysis of one or two indicators. For example, the dynamics of the proportion of premiums in wages or to the analysis of wage differentiation, for which all of the staff

is grouped by level of regular income in three groups: low-wage(under 8 category), medium-wage(8 to 12 category) and high-wage (12 to 18 category). The analyst's opinion on what level of income in which region to recognize as high or medium becomes important in this issue. It is clear that the lack of evaluation of the effectiveness of motivational activities does not help to identify problems in the field of personnel motivation in the enterprise.

The development of effective solutions in the field of motivational activity requires a detailed analysis. The basis for analyzing the motivation system is a clear definition of goals and objectives that take into account the specifics of a particular organization (field of activity, the state of personnel, their professional specialization). Obtaining the required information is impossible without a competent choice of research methods.

The purpose of the article is to analyze the effectiveness of motivational activity at one of the industrial enterprises of the Republic of Tatarstan on the basis of the proposed methodology and to develop recommendations aimed at improving its effectiveness.

Research Methodology

The following methods were used in the research: analysis of normative documents, statistical research methods, questionnaire survey, systematization and generalization of facts and concepts.

Review of specialized literature

There is an extensive literature on staff motivation. Among foreign authors it is possible to emphasize Drucker P. F. (1977, 2003) Maslow A. (1943) McGregor D. (1960), McGregor D.(2005). Among the Russian are Kibanov, Gerchikov V., Rebrov, Svirina A. and others.

We shall consider which components of motivational schemes can be used in Russian enterprises.
Most researchers almost subconsciously associate motivation with Maslow's pyramid, who states that each person has five consecutive levels of needs to be satisfied, and until the lower-level needs are met, it makes no sense to motivate a person based on more complex needs [2]. A similar idea underlies MacGregor's theory of X and Y (i.e., the needs of people X are at the two bottom levels of the Maslow pyramid, and the needs of people Y are higher). The disadvantage of these classical theories is the premise that an employee who is not satisfied, for example, in terms of social needs, cannot be motivated by the need for respect or self-realization.

Also, under no circumstances can a person Y be motivated to work by simply promising stable earnings. From the modern point of view, it is obvious that these assumptions are not always correct: the presence of material needs does not completely exclude ambition. Similarly, even for a person whose main goal in work is achieving the best result (the need for self-realization is maximized, the person clearly belongs to the category Y), at least, there may be periods in life when stable earnings may be a priority for him, regardless of the type of work. At the same time, he will be satisfied with the work, since his self-realization in this case will be expressed in achieving stability. Thus, a person can be simultaneously characterized by the needs located at all levels of the Maslow pyramid.

This idea is reflected, although incomplete, in the two-factor theory of Herzberg, where the working person in terms of satisfaction can be at one of the stages of satisfaction (Dissatisfaction;
Lack of dissatisfaction; Lack of satisfaction; Contentment).

Modern theories of motivation based on setting goals, motivating work tasks, and fairness proceed from the premise that an employee is a reasonable and adequate being, capable of objective assessment of himself and reality. Therefore, the goal setting theory assumes that every employee strives for self-effectiveness, which is the confidence that they are able to perform the tasks they face. However, it is obvious that all types of result-oriented motivations do not work if employees do not adequately assess their abilities and contribution to the overall result, which indicates that classical motivational theories are not applicable in this case.

Researches on the most successful global business practices (the works of J. Collins, J. Lyker and K. Kobyel) clearly confirm that modern business organizations that have achieved the highest productivity indicators do not use any special incentive schemes, but they pay special attention to the selection of people with specific features of motivation pattern.

Therefore, it makes sense to consider the theory of motivation, which is most applicable to Russian conditions and is known as the typological theory of V. Gerchikov. After conducting thousands of interviews with employees at various levels, V. Gerchikov concluded that there are five types of work motivation – instrumental, professional, host, patriotic and lumpen.

For people of the instrumental type, work itself is not of any value: they are only interested in money [3]. Such a person will work with maximum efficiency in any job, as long as they are well paid. Most Russian managers believe that all or most of their employees are belong to the instrumental type, and base the motivation system only on material incentives.

A person with professional motivation, on the contrary, values not the material reward, but the content of the work itself.

An employee with a host's motivation takes full responsibility for the case. Such an employee may seem ideal, but he is difficult to manage.

An employee of the patriotic type first of all wants to feel needed by his organization. Most of all, he values the effectiveness of the common cause and the recognition of his achievements by the management. This category of employees is also known in foreign theories of motivation. But special attention is paid to the fifth type of motivation, discovered in the framework of V. Gerchikov's theory During the research was found that there is a category of people who do not want to work at all and do only what they will not be punished by the management. V. Gerchikov called this type avoidant, or lumpen. In Western theories, the existence of such a category of people is denied in principle, but in Russian practice they are quite common.

Despite the logic and clarity, the typological model of V. Gerchikov is not used by many companies. One of the reasons is the lack of willingness to spend resources to allocate different groups of employees and develop their own motivational schemes for each of them. The methods of motivation recommended by the author of the theory for various categories of employees are presented in table 1.

Table 1: Methods of stimulating employees with different types of motivation [1]

Types of incentives	Types of motivation				
	Instrumental	Professional	Patriotic	Host	Avoidant (lumpen)
Negative (punishments, threat of job loss, etc.)	Possible in monetary form	Prohibited	Possible in sign form	Prohibited	Basic
Money	Basic	Possible	Neutral	Possible	Neutral
Natural (buying or renting a home, providing a car, etc.)	Possible in monetary form	Possible for target-based agreements	Possible in sign form	Possible for target-based agreements	Basic
Moral	Prohibited	Possible	Basic	Neutral	Neutral
Paternalism (caring for the employee)	Prohibited	Prohibited	Possible	Prohibited	Basic
Organizational (content, conditions and organization of work)	Neutral	Basic	Neutral	Possible	Prohibited
Career and development	Possible	Basic	Neutral	Possible	Prohibited
Participation in co-ownership and management	Neutral	Possible	Possible	Basic	Prohibited

People with certain types of motivation are also more likely to have certain types of work, which was also considered by Vladimir Gerchikov [ibid].

According to estimates of Russian recruitment agencies, hiring an employee with inappropriate motivation leads to a loss of about 25% of their productivity and, consequently, to lost profits for the organization.

It is also necessary to pay attention to the possibility of studying the structure of employee motivation based on the Motype test developed by V. Gerchikov.

Further development of the idea of V. Gerchikov can be found in the works of Rebrov and Svirina A. In particular, A. Svirina suggests identifying qualitative and quantitative indicators that characterize the effectiveness of motivation.

According to Svirina A., the first qualitative indicator is the level of staff satisfaction (table 2).

Table 2: Evaluating the motivation process in an organization

Characterization of satisfaction	Motivation process evaluation
Most employees are satisfied with their job	High
Half of the employees are satisfied with their work, while others mostly describe their condition as unsatisfactory (lack of satisfaction, according to Herzberg)	Above average
Most employees describe their condition as unsatisfying (lack of satisfaction, according to Herzberg)	Average
Most employees describe their condition as normal (no dissatisfaction, according to Herzberg)	Below average
Most employees are unsatisfied with their job	Unacceptably low

The second indicator that characterizes the motivation process is the balance between the types of motivation and the work performed (table 3).

Table 3. Evaluating the quality of the motivation process

Percentage of people holding positions, not corresponding to the dominant motivation	Charachterization of the level of motivation
0-7	High
7-15	Average
15-25	Permissible
25-40	Low
More than 40	Unacceptable

As a quantitative indicator, A. Svirina suggests using an individual coefficient of motivational leverage (similar to the operating one), which characterizes how much percent the profit from sales of an enterprise will increase (decrease) when the number of employees satisfied with their work increases (decreases) by 1%:

$$ML = \frac{\sum_{i=1}^{n} \frac{\Delta \mathrm{Ps}}{\Delta \mathrm{Se}}}{n}$$

Where i is the number of analyzed periods from 1 to n;

ML - motivational lever;
ΔPs — change in profit from sales;
ΔSe - change in the number of employees who are satisfied with their work.

The level of motivational leverage increases with the increase in the number of unsatisfied employees, which leads to a decrease in profit from sales.

Research Result

The study of motivational activity is carried out primarily in order to understand to what extent it contributes to the efficiency of the enterprise, and is implemented in two directions:

- analysis of the company's regulatory documents aimed at determining compliance with legislative acts and summarizing official information about all elements of the motivation system;
- analysis of the labor output and personnel performance, which allows us to clearly define the boundaries and direction of the upcoming research. In fact, in the course of this analysis the need to improve the motivational activities is revealed.

Analysis of the first direction -- the documentation of the studied enterprise engaged in the production of radio devices - revealed the following:

- the regulation on remuneration of labor reveals the structure of the forms and systems of material reward used, as well as the conditions for obtaining it by employees;
- the regulation on certification defines the methods and procedure for determining the results and personnel performance;
- internal regulations contain a set of requirements (rules) for the behavior of employees, as well as a list of disciplinary penalties, etc.

Thus, the analysis of regulatory documents of the studied enterprise allowed us to give them a positive assessment and determine the prerequisites for motivational activity of the enterprise.
The following information was used for the implementation of the second direction - analysis of labor results and efficiency of the personnel of the studied enterprise:

- indicators that characterize the dynamics of labor productivity;

- indicators that reflect trends in staff turnover;
- enterprise plans that define requirements for the main results of work.

The analysis of enterprise plans is a necessary element in the structure of motivation system research. The plans reflect the requirements for the staff performance in a certain time period. Plans are implemented if the labor standards on the basis of which the plans are calculated are fully justified. Over-fulfillment of the plan can only be caused when employees apply excessive efforts. Therefore, if the plans are constantly implemented in excess of labor standards, this indicates either that the regulatory framework is lagging behind the conditions of a particular production, or that the methods of material incentives used do not correspond to the results achieved. Any consistently observed deviation of labor results from the planned indicators allows us to draw conclusions about the inefficient use of personnel [1].

So, to analyze the results of personnel performance, it is necessary, first of all, to evaluate the indicators that characterize the dynamics of labor productivity.

The initial data for analyzing the results of labor and efficiency of personnel are presented in table 4.

Table 4:The source data for the analysis of the results of work and efficiency of employees

№ p/p	Indicators	2017	2018	2019	2018 to 2017	2019 to 2018	2019 to 2017
1	Revenue, thousand rubles	2 621 108	2 463 046	2 524 963	0, 940	1.025	0.963
2	Average number of employees, people	539	481	436	0.892	0.906	0.809
3	Payroll, thousand rubles.	252,588	222,288	216,624	0.880	0.975	0.858

The evaluation of information should begin, as already noted, with an analysis of labor productivity. Workforce productivity is calculated using the following formula:

$$WP = \frac{R}{Avg}$$

Where WP is an indicator of workforce productivity at the enterprise, in rubles/person.

R is revenue for the accounting period, thousand rubles.
Avg is Average number of employees, people
The average salary is determined by dividing the payroll by the average number of employees for the same period.

The calculation results are shown in table 5.

Table 5: The indicators used for the analysis of the results of work and efficiency of employees

№ p/p	Indicators	2017	2018	2019	2018 to 2017	2019 to 2018
1	Labor productivity, thousand rubles/person	4 862,9	5 120,68	5 791,2	1.053	1.131
2	Average salary, rubles	39 052	40 674	41 404	1.042	1.018

The actual indicators of labor productivity at this enterprise slightly exceed the planned indicators, which corresponds to the requirements formulated above.

Next, we will determine the presence or absence of organizational problems in the field of personnel motivation in the enterprise. The following always indicates organizational problems:

- decreasing dynamics of labor productivity during the study period, if this trend is not related to the seasonal nature of the organization's activities;
- the turnover rate, if its indicators for a sufficiently long period (at least six months) exceed 7 - 10%.

As for the studied enterprise, according to the data presented in table 5, it can be seen that the rate of labor productivity increases over the analyzed period.

To formulate conclusions about the effectiveness of the applied system of motivation and incentives for staff, it is also necessary to analyze the ratio of the growth rate of labor productivity and the growth rate of average wages [3]. The coefficient of outpacing the growth rate of labor productivity over the growth rate of average wages is defined as the ratio of the labor productivity growth index to the average wage growth index. The advance rate of labor productivity growth over the growth rate of average wages in 2018 was 1.011 (1.053/1.042), in 2019 - 1.111 (1.131/1.018), which can be assessed positively.

The level of average wages at the enterprise outstrips the level of average wages in the Republic of Tatarstan as a whole.

Given the increasing dynamics of labor productivity during the study period, the faster growth rates of labor productivity in comparison with the growth rate of average wages, a fairly high level of average wages, it could be concluded that the forms and methods of incentives used are linked to both the objectives of the enterprise and the expectations of employees, and the applied system of motivation and incentive of personnel is balanced relative to the goals of the organization.

However, this conclusion is hasty, since staff turnover rates were not taken into account.

When formulating conclusions regarding balance of motivation system, it is necessary to consider the following generalization: if productivity is consistently kept at the target level, the turnover rate does not exceed 7-10% for six months, and there are no changes in the activities of the enterprise, further study does not make sense, because the incentive system is balanced relative to the goals of the organization, i.e., the forms and incentives used correspond to both the objectives of the enterprise and expectations of employees.

At the enterprise under study, productivity is maintained at the level of planned indicators. However, there is a high turnover of staff, the level of which in 2019 significantly exceeded 30%. Moreover, turnover over the last three years has been growing, and in the face of the falling average number of workers there is an increase in the number of dismissed. If an organization introduces new methods of organizing production, new technologies, and equipment that lead to an increase in labor productivity, this may be considered normal. Therefore, to avoid hasty conclusions, it is necessary to determine staff turnover indicators and study the reasons for dismissal.

The indicators of absolute turnover and their dynamics are presented in table 6.

Table 6: Analysis of employee turnover in the enterprise

№	Indicators	2017	2018	2019	2018 to 2017	2019 to 2018
1	Average number of employees, people. (Avg)	539	481	436	0.892	0.906
2	Dismissed, people (Dp)	129	125	157	0.969	1.226
3	Turnover, % (T)	24	26	36	1.083	1.385

The data presented in table 4 indicate the catastrophic scale of staff turnover at the enterprise and the inactivity of the enterprise's management to solve this problem. Turnover limits for enterprises in various fields of work differ [2]. For the production sector in Russia, the normal turnover is about 10 percent. In a rapidly growing business, especially at the mass hiring stage, the turnover rate can be higher, at about 20 percent. Turnover at the level of 36%, as already noted, is disastrously high for a

business that is not characterized by high activity, and leads to a decrease in the constancy of personnel.

For a more detailed analysis, along with the analysis of absolute turnover, it is necessary to determine the relative turnover for each division, within a certain age, gender, among employees with a particular experience, grounds for dismissal, etc.

Along with the turnover coefficient, the staff constancy coefficient is calculated.

It was revealed that in 2019, the number of people who worked for a full year was only 22, which can be estimated very unsatisfactorily. It is obvious that at this enterprise, the work on the analysis of turnover and the reasons for its appearance is carried out formally or not at all, and measures to reduce staff turnover are not implemented.

To develop measures aimed at reducing staff turnover, it is necessary to know the reasons for turnover. The reasons for the dismissal of employees, i.e. basis for termination of the employment contract according to the labour code are: the agreement of the parties, the expiration of contract, termination of the contract by the employee or the employer, the employee can be transferred to another employer, the refusal of the employee from continuing work in connection with the change of certain parties of the employment contract terms etc. It should be taken into account that dismissal of employees for some reasons does not affect the turnover rate. When calculating the turnover rate, only the reasons for dismissal are taken into account, which do not depend on industrial or state necessity. For example, layoffs for reasons of staff reduction, downsizing, reorganization of the company, personnel changes due to a change in management, retirement do not affect the turnover rate.

The most common reason for dismissal in the company under study is voluntary resignation. As it turned out, it is used even when the employee is dismissed at the initiative of the employer, due to the fact that none of the parties to the employment relationship is interested in conflict situations and legal proceedings.

In case of voluntary dismissal, the labor law does not oblige the employee to explain the reasons for dismissal, and for the employer, voluntary dismissal exempts from certain procedures, in particular, it is not necessary to pay increased compensation for dismissal, and there is no need to search for valid arguments to terminate the contract.

In this regard, there is a need to more deeply identify the actual reasons for dismissals. For this purpose, a survey is usually conducted in the form of a questionnaire in order to assess the level of satisfaction of employees with various motivating conditions. The survey applies to employees who leave the company and those who remain working at the company, but are thinking about leaving. Thus, the main causes of turnover are usually identified by the results of a "job satisfaction" survey.
At the enterprise under study, the main causes of turnover in 2019 were identified based on the results of a survey and are shown in figure 1.

Fig. 1: reasons for staff turnover as a percentage by type of reason

Summing up the interim results, we can note that the analysis of the company's regulatory documents carried out according to the first direction allowed us to give them a positive assessment and determine the prerequisites for motivational activity.

At the same time, when analyzing the second direction of research, it was found that the system of motivation and incentives for staff is not balanced with respect to the goals of the organization, and the forms and methods of incentives used do not fully meet the expectations of employees.

Motivational activity does not fully contribute to the effective operation of the enterprise and requires improvement, which involves identifying the causes of high labor intensity and a large number of hours of overtime, eliminating excessive differentiation of wages by category of personnel, as well as identifying the causes of wage delays.

At this point, the analysis of the motivational activity of the enterprise under study can be considered complete, since specific problems have been identified, and they require developing specific measures.

However, there may be other situations in an enterprise that involve using other approaches for the study of motivational activity. For example, if there was an increasing dynamics of labor productivity during the study period, and the level of turnover for a sufficiently long period (at least six months) did not exceed 7 - 10%, it would be necessary to move to the next stage (direction) - to conduct a more in-depth study, in particular, to study the motivational profile of each employee (for starters, key employees) on the basis of the Gerchikov test (Motype test). Identifying the motivational profile is necessary, in particular, in order to transfer employees with inappropriate motivation to other types of work. According to estimates of Russian recruitment agencies, hiring an employee with inappropriate motivation leads to a loss of about 25% of their productivity and, consequently, to lost profits for the organization.

In addition, the study of the motivational profile of each employee allows you to identify their short-term and long-term motivation and suggest appropriate measures. The fact is that short-term motivation influences only the dominant character traits. For example, an employee belongs to the instrumental type of motivation and, consequently, the incentive is provided exclusively by monetary payments (table 1).
Long-term motivation is based on taking into account the motivational profile of the employee's personality as a whole and allows you to develop measures aimed at changing this profile in the company's desired direction. Ideally, it is necessary to take into account and develop all the motivational components of the employee's personality.

The final stage of analysing motivational activity in the enterprise is calculation of indicators that allow you to assess the effectiveness of motivation. For this purpose, it is proposed to calculate both qualitative indicators (the degree of staff satisfaction (table 2) and the quality of the motivation process (table 3)), and quantitative. As a quantitative indicator for evaluating the effectiveness of motivation, it is proposed to use the motivational lever.

A decrease in the level of employee satisfaction, incorrect motivation, or lack of correspondence between the type of employee motivation and the work performed by them can lead to a deterioration in the company's performance indicators.

Conclusions and Recommendations

When evaluating motivational activities of personnel, it is not enough to rely only on analysing the company's documentation, assessing work results and performance of employees, as it is also needed to analyse the ratio of productivity growth rate and wage growth rate, to study turnover rate, identify their causes, to determine actions for their systematic elimination.

In that case, if during the study period there is a rising dynamics of labour productivity and the turnover rate does not exceed 7 - 10% for a sufficiently long period (at least six months), it is recommended to continue the analysis of motivational activity to conduct a study of motivational profile of key employees (ideally all employees) on the basis of test Motype to identify the type of motivation and to choose forms of incentives (table 1).

If necessary, measures should be developed to change motivational profile in the company's desired direction.

The final stage of the analysis is to evaluate the effectiveness of motivation, which is performed:

- evaluation of the motivation process based on the level of staff satisfaction (table 2);
- studying the balance of motivation types and work performed (table 3), which allows us to conclude about the quality of the motivation process;
- calculation of the motivational lever.

A decrease in the level of employee satisfaction, incorrect motivation, or lack of correspondence between the type of employee motivation and the work performed by them can lead to a deterioration in the company's performance indicators.

A constant monitoring of condition and movement of enterprise's personnel, a development and an implementation of measures aimed at achieving an optimal balance between labor productivity growth and wage growth, a reduction in staff turnover, an increase in employee satisfaction, a proper motivation, a match between the type of motivation and the job will provide a balanced system of incentives relative to the goals of the organization, that is, the applied forms and methods of stimulation will correspond to the objectives of the enterprise and the expectations of employees.
It is necessary to understand that any system of labor motivation does not show results immediately. Comprehensive measures should be carried out constantly considering specific characteristics of employees and with full respect and understanding of the needs of each employee.

Abstract

The paper presents indirect impacts of sharing economy platforms in tourism on functioning of cities as tourism destinations. The SALSA analytical framework (Search, AppraisaL, Synthesis and Analysis) as well as qualitative and quantitative content analysis of selected publications were applied in order to appoint areas of city functioning which are influenced by activity of sharing economy platforms. Five topics appeared to be the most commonly linked with the development of sharing economy in tourism. They are: entrepreneurship and innovativeness of citizens, real estate market, local transportation, citizens' quality of life and local budgets' incomes. As recognized the indirect impact includes both positive and negative consequences.

Keywords: Sharing Economy Platforms; Tourism Destination, Cities, Indirect Impacts

Introduction

The development of ICT-based exchange platforms is currently taking place in many sectors (e.g. financial, hotel, transport) and is affecting more and more people in the world who raise funds for innovative projects (e.g. on Kickstarter.com) and share their apartments (e.g. through HomeAway.com), or free space in the car (e.g. giving an announcement on BlaBlaCar.com). Many authors emphasize that the sharing economy is an emerging economic-technological phenomenon that is fuelled by developments in information and communications technology (Botsman & Rogers, 2010; Kaplan & Haenlein, 2010; Wang & Zhang, 2012).

Fast development of the *sharing economy* (hereinafter referred to as SE) can be seen in big cities, where the new business model finds many supporters and followers. This trend is in line with growing popularity of big cities as tourism destinations. Tourism remains one of the most important areas of development of SE. Sharing economy in tourism is a very big and diverse phenomenon, most of the research and press releases are connected with two biggest platforms that enhance peer-to-peer relations, i.e. Airbnb in the hospitality sector and Uber in the passenger transportation. Since the second decade of the 21st century, the effects of platform activities have been the subject of scientific research conducted in various disciplines – IT management, urban planning, sociology, economics, spatial management etc.). This is due to the fact that the size of their operations has direct and indirect impacts on cities. The direct impacts are understood as impacts on the tourism industry (e.g. hotel sector). The indirect impacts mean any impact on others areas of city functioning. The size of their operations and the scale of their influence as well as legal controversies makes them very interesting topic of scientific debate.

The purpose of the article is to identify the state of art of scientific research on indirect effects generated in cities by the sharing economy platforms functioning in tourism. The aim was achieved by application of SALSA analytical framework method (Search, AppraisaL, Synthesis and Analysis) as well as qualitative and quantitative content analysis of selected publications in order to appoint areas of city

functions which are influenced by sharing economy. The analysis embraced papers from two popular citation bases – EBSCOhost and Science Direct. Reaching presented findings required two steps. The first one was identification of the most important areas of SE's impact on cities development, while the second was selection of papers presenting that impact.

The paper is divided into five parts. The first one is devoted to presentation of theoretical foundation of sharing economy and sharing economy platforms. The second one described in detail methodology. The results presented in third part of the paper show that sharing economy in tourism has impact on cities, particularly on entrepreneurship and innovativeness of citizens, real estate market, local transportation, citizens' quality of life and local budgets' incomes. The article additionally presents discussion with findings other researchers. Conclusion, limitations and proposals of further research close this paper.

Defining the sharing economy and SE platforms

The lack of universal and clearly definition of the term "sharing economy" is noticed by many academics (Walsh, 2011; Koopman, Mitchell & Thierer, 2014; Cheng, 2016a; Oei & Ring, 2016; On & Moon, 2016; Zale, 2016; Curtis & Mont, 2019). As Frenken and Schor (2017) noticed the sharing economy refers to consumers' providing temporary access to their under-utilized physical assets and it is oriented probably for obtaining of monetary gains.

Many of researchers explain term of SE through the description of its dimensions and attributes, but it is not definition. Although the dimensions do not constitute a definition of the sharing economy (Curtis & Mont, 2019), but they discover the complicated nature of SE. The differences in understanding of the SE nature lead to existence the different terms of this new phenomenon, e.g.: "collaborative consumption" (Botsman & Rogers, 2010; Hamari *et al.*, 2016; Möhlmann, 2015), "access-based consumption" (Bardhi & Eckhardt, 2012; Barnes & Mattsson, 2016), "on-demand economy" (Cockayne, 2016) or "gig economy" (Greenwood *et al.*, 2017). Aloni (2016) proposed to use the "peer-to-peer" (P2P) economy term, what allows to avoid many misunderstandings and misconceptions about what sharing economy is. According to his concept the "peer-to-peer" economy model include for-profit web platforms or mobile apps facilitate peer-to-peer exchanges of goods, services, space, and money. The crucial role of "digital platforms", "ICT" (information-communication technology) or just "technology" in the sharing economy development was noted by many researchers (Tab. 1) and was proposed as a defining characteristic, separating the term "sharing economy" from traditional sharing (Oei & Ring, 2016; Sutherland & Jarrahi, 2018).

The development of information technologies alongside the growth of web 2.0 has enabled the development of online platforms that promote user-generated content, sharing, and collaboration (Kaplan & Haenlein, 2010). SE operates through technological platforms, such as a website or mobile app, facilitating the sharing of goods and services through information technology. The platforms also are referred to as e.g. peer-to-peer (P2P) platforms (Rodrigues & Druschel, 2010), online platforms or CC (collaborative consumption) platforms (Hamari Sjöklint & Ukkonen, 2016), network platforms (Oskam & Boswijk, 2016), IT platforms (Ho, 2015). This digital infrastructure empower the growth of model of production, distribution and consumption whereby people share their assets or other resources on an spare capacity basis. Internet-based platforms and applications create new ways for people to share goods and services with one another on a previously unimaginable scale, emphasizing that the platforms focus on collaboration (Kaplan & Nadler, 2015) between providers, and consumers of goods and services (Tab. 2). As Ranjibari *et al.* (2018) noticed the most frequent term in SE definitions is "online platforms" containing websites and mobile applications.

Table 1: Definitions of sharing economy focused on digital platforms/technology

Author	Definition	Internet/ online	Technology	ICT	Digital platforms
Lessig (2008)	*"The allocation of resources between the parties to the exchange, exploding due to the development of the Internet, based not on money but on interpersonal relations and motivated more by social than economic factors."*	•			
Wosskow (2014)	*„…sharing property, resources, time and skills across online platforms"*	•			•
Stephany (2015)	*"The sharing economy is the value in taking underutilized assets and making them accessible online to a community, leading to a reduced need for ownership of those assets"*	•			
Hamari Sjöklint, & Ukkonen, (2016)	*"The peer-to-peer-based activity of obtaining, giving, or sharing the access to goods and services, coordinated through community-based online services."*	•			
Aloni (2016)	*"An economic activity in which web platforms facilitate peer-to-peer exchanges of diverse types of goods and services; in detail: an economic model in which for-profit web platforms or mobile apps facilitate peer-to-peer exchanges of goods, services, space, and money."*	•			•
Cockayne (2016)	*"The on-demand or 'sharing' economy is a term that describes digital platforms that connect consumers to a service or commodity through the use of a mobile application or website"*	•			•
Hult & Bradley (2017)	*"The initiatives based on horizontal networks and participation of a community. It is built on distributed power and trust within communities, which often meet and interact on online networks and peer-to-peer platforms."*	•			
Laurell & Sandström (2017)	*„ICT-enabled platforms for exchanges of goods and services drawing on non-market logics such as sharing, lending, gifting and swapping as well as market logics such as renting and selling".*			•	•
Ranjbari, Morales-Alonso & Carrasco-Gallego (2018)	*„An economic system, whose intermediary companies utilize online platforms to facilitate and lower the cost of the for-profit transactions of giving temporary access– without the transfer of ownership – to idle resources of consumers in the peer-to-peer networks that it has created, because of the trust built among its members, who may be individuals or businesses.*	•			•
Curtis & Lehner (2019)	*"A socio-economic system that leverages technology to mediate two- or multi-sided markets, which facilitate temporary access to goods that are under-utilised, tangible, and rivalrous"*	•	•		•

Table 2: Definitions of Sharing economy platform

Author	Definition	Characteristics
Rodrigues & Druschel (2010)	*"a system in which content generation is highly distributed and decentralized as a result of the organic growth and strong user self-organization."*	content generation and distribution system, decentralized
Dervojeda *et al.* (2013)	*"a company to have an accessibility based business model for peer-to-peer markets when their value proposition consists of creating a match between a peer owning a certain resource and a peer in need of that resource, at the right time and against reasonable transaction costs."*	business model for peer-to-peer markets, connecting
Kaplan & Nadler (2015)	*"a sharing economy companies, like Airbnb, offering a variety of Internet-based solutions and applications that create new ways for people to share goods and services with one another on a previously unimaginable scale, emphasize that the platforms focus on collaboration"*	company, new way of collaboration based Internet
Demary (2015)	"that the business models of the Sharing Economy are usually platform-based to connect demand and supply and goods or services are shared between individuals"	business model, connecting demand and supply
Coyle (2016)	*"the hybrid entities using digital technology as an interface between the users or consumers of a product or service and its suppliers"*	digital technology, hybrid entity, interface
UNWTO (2017)	"the intermediaries, connecting providers with users through an online platform, and facilitating transactions between them"	intermediaries connecting providers with users
de Reuver, Sørensen, & Basole (2018)	*„the digital infrastructure, rules, and processes that enable resource exchange between external producers and consumers."*	digital infrastructure
Airbnb (https://news.airbnb.com/en-uk/about-us/)	defines itself as *"one of the world's largest marketplaces for unique, authentic places to stay and things to do, offering over 7 million accommodations and 40,000 handcrafted activities, all powered by local hosts. Airbnb promotes people-to-people connection, community and trust around the world."*	trusted market connecting people, a place of exchange

Source: Compiled on the basis of quoted literature.

Enabling the connection between spare capacity and demand (Gazzola, 2018), platforms decide about costs and scale of sharing and provide to increasing consumption of sharing economy services and the number of transaction. They makes the peer-to-peer transactions for the under-utilized assets viable (Ranjibari *et al.*, 2018). Due to this important role of Internet-based platforms in sharing, UNWTO (2017, p. 14) named the sharing economy as the platform economy and the exchanged goods as the platform tourism services. The new platform tourism services was defined as business models in which private individuals offer goods or services to visitors through digital platforms that match demand and supply.

Methodology

In order to investigate how the researchers perceive the problem of the impact of SE platforms activity on areas of city functioning as: entrepreneurship and innovativeness of citizens, real estate market, transportation, local budgets' incomes and quality of life/gentrification, we conducted a literature review followed by quantitative and qualitative content analysis method. This method increases the level of order and the level of detail of research, and is also the most relevant in the case of review study and has already been used in scientific articles on SE (Gössling, 2013; Glotz-Richter, 2016; del Romero Renau, 2018). The research procedure in the review process has been divided into four critical

steps: search, appraisal, synthesis and analysis that were the root for the SALSA abbreviation. By many authors (Bruce, 2001; Grant & Booth 2009; Major & Savin-Baden, 2010; Sadruddin *et al.*, 2017), SALSA is considered to be an appropriate research behaviour in a variety of types of reviews, including literature review. By organizing and structuring the research, SALSA makes it easier to find the most notable articles in this subject field and a sophisticated analysis (Edwards, Russell & Stott 1998; Booth, Sutton & Papaioannou, 2016).

Searching

Literature review-type scientific article requires searching and selecting articles that will undergo in-depth critical analysis. This stage involved selecting scientific databases which will be used to select articles about SE. The large number of databases and diverse approach of researchers to this issue should be noted. In the research process in the field of SE and SE platforms researchers usually review Web of Science, Scopus EBSCOHost and/or Science Direct databases. The EBSCOHost (EB) and Science Direct (SD) are selected in this article as those databases were regarded as the largest and the most popular (Görög, 2018; Cheng, 2016b; Buhalis & Law, 2008).

AppraisaL

The next stage consisted in selecting the articles, i.e. qualifying or rejecting the scientific article based on the analysis of the content of the whole article in terms of the content of terms specified in the categorization key. It is a set of words/categories needed to make the selection. Among many categories/terms related to SE, such as: collaborative consumption, collaborative economy, peer-to-peer consumption, digital economy, it was decided to use the most appropriate keywords considering the title and goal of the article: "sharing economy" and "tourism" as well as "cities or urban or city". Other criteria of selection strategy:

- *article part* – title and abstract and key words and main text,
- *availability* – full text document,
- *journal type* – science journal,
- *article category* – reviewed article,
- *period* – 2008-2019,
- *language* – English.

As a result, 161 articles were found in SD corresponding to the assumed selection criteria, in EB – 75 were found and chosen for further research.

Synthesis

At this stage, in this paper applied the traditional approach to synthesis that involved reading the content of all articles (236) selected at the previous stage and taking notes. This was related by the desire to ensure high quality of research resulting from the advantage of the human mind over IT programs. In this part of article has presented specific research topics undertaken by academics in these articles. 21.2% of articles irrelevant to the issues of this study were identified (these were articles that contained at least one of the keywords in the content, but they were not dedicated to the issue investigated), which were rejected from further research procedure. Thus, 186 articles (78.8%) were taken into account, including 122 from the SD database and 64 from the EB database. Then, they were subjected to the synthesis process in which the tabular method and narrative were adopted. There are articles that raise more than 1 subject. Therefore, the TAT index for each base is higher than the number of articles taken for the study. The table shows a quantitative indicator that measures the number of articles in individual databases and according to the subjects identified in the study, as well as a structural indicator that measures the share of individual articles by subject. Researchers examine many aspects of rapidly developing SE in tourism phenomenon. The most frequently discussed issue was "customer value/experiences/ motivations/preferences/choice" (14.4% of articles) (Tab. 3). Articles in lines 13 to 17 (Tab. 3) emphasize the relationship between SE in tourism and cities examining the impact of SE in tourism on particular areas of city functions, i.e. an entrepreneurship and innovativeness of citizens, real estate market in cities, city transportation system, quality of citizens' life/gentrification and city budgets' incomes. Eventually, there were 33 articles like these in two databases jointly (SD and EB)

and having eliminated the repetitions in them (Horn & Merente 2017; DiNatale, Lewis & Parker 2018; Wegmann & Jiao 2017), 30 of them were qualified in total for the next stage.

Table 3: Topics appearing in the literature review

No.	Topic	SD	EB	Total	%
1.	Customer value/experiences/motivations/preferences/choice	30	6	36	14,4
2.	Impact on hospitality	15	14	29	11,6
3.	Host-guest relation including trust and reputation	13	12	25	10,0
4.	Locality of short term rentals	9	11	20	8,0
5.	Governance and regulations	7	14	21	8,4
6.	The nature of SE in tourism	14	3	17	6,8
7.	Prices	8	5	13	5,2
8.	Impact on transportation	7	5	12	4,8
9.	Business model	5	9	14	5,6
10.	Impact on different forms of tourism	3	5	8	3,2
11.	Impact on environment and climate change	6	0	6	2,4
12.	Segmentation	3	0	3	1,2
13.	An entrepreneurship and innovativeness of citizens	3	1	4	1,6
14.	Real estate market in cities	4	11	15	6,0
15.	City transportation system	8	5	13	5,2
16.	Quality of citizens' life/gentrification	5	7	12	4,8
17.	City budgets' incomes	0	2	2	0,8
18.	Total articles by topics (TAT)	140	110	250	100

Source: own compilation.

Analysis

The stage involved an in-depth qualitative content analysis method of the selected articles. The purpose of the research at this stage was to identify the purpose, methods, results and subject scope of 30 articles Additionally, the use of the content analysis method allowed to structure a database of 30 articles according to the following criteria: type of research (desk and filed research), data sources (primary and secondary, scientific and non-scientific), the nature of the article (review, empirical and mixed) and the number of issues raised in one article (Tab. 4).

Table 4: Detailed Indicator Analysis

Criterion	Number of Articles (N=30/100%)		
Data Sources	Scientific (based solely on scientific articles by other authors)	Mixed: Scientific and Non- Scientific (25/83.3%)	
		Sources based on methodology or created by academics	Sources based on methodology or created by academics
	5/16.7%	22/73.0%	10/33.3%
	Primary	Secondary	Mixed: primary and secondary
	5/16.7%	21/70.0%	4/13.3%
Type of Research	Field research	Desk research	Mixed: desk and field research
	2/6.7%	24/80.0%	4/13.3%
Type of Article	Review	Empirical	Mixed: review-empirical
	5/16.7%	16/53.3%	9/30.0%

Findings

Development of SE platforms in tourism has impact on different aspects of cities' economies and societies. Analysis of scientific literature allowed to point five areas, these are: entrepreneurship and innovativeness of citizens, real estate market, city transportation system, quality of life and city budgets' incomes.

Development of SE platforms in tourism – impact on entrepreneurship and innovativeness of citizens

The relationship between the development of SE in tourism and local entrepreneurship and innovativeness is underlined. This relationship is complex, complicated and two-dimensional and includes positive and negative aspects (Tab. 5).

Table 5: Development of SE platforms in tourism – impact on entrepreneurship and innovativeness of citizens (positive and negative aspects)

Positive	Negative
• Diversification of services offered by microentrepreneurs • Upgrade to new entrepreneurial opportunities and ecosystems. • New employment opportunities through micro and part-time entrepreneurship • Establishing new types of companies • Increased opportunities for individuals to become micro-entrepreneurs • Enhanced innovations in the sector of microentrepreneurs • Alternative income streams for residents who become micro-entrepreneurs • Lowering unemployment rate	• Labor exploitation • Unfair competition • Ethical issues

Source: own elaboration based on: Wu & Zhi (2016); Alrawadieh & Alrawadieh (2018), Stabrowski (2017); Palgan, Zvolska & Mont (2017).

Both, positive and negative connected aspects with the impact of the SE platforms in tourism on entrepreneurship and innovativeness of citizens are difficult to be measured and finding convincing evidence. Especially, in case of impact on innovativeness and entrepreneurship, benefits are underlined and cities' representatives make efforts to maximize them. Those actions include financial support, space, individual advice and matchmaking for technological start-ups and creative entrepreneurs in collaboration with the private sector.

Development of SE platforms in tourism – impact on real estate market of cities

Majority of publications agree that this impact is only or almost only negative (Brauckmann, 2017). However Horn and Merante (2017) state that there is only limited evidence on whether and how home sharing affects the housing market, despite the obvious overlap between these two markets. The essence of that impact (negative) is related to big increase in the demand on the houses and apartments created by prospect runners of the P2P services (Lima, 2019) (Tab. 6).

Table 6: Development of SE platforms in tourism – impact on real estate market of cities (positive and negative aspects)

Positive	Negative
• More efficient use of existing properties to build the sharing economy offer	• Increased demand for properties, increased prices of properties • Transfer of many properties from the long term rental to tourism short-term rental • Deepening the existing housing affordability problems

Source: own elaboration based on: DiNatale, Lewis & Parker (2018), Wegmann & Jiao (2017), Palgan, Zvolska & Mont (2017), Horn & Merante (2017).

These negative effects on the real estate market can be contrasted only by a positive consequence resulting from the more effective use of available properties in the city area (Horn & Merante, 2017). The SE platforms in tourism accommodation industry has grown, in part, due to the natural tendency for capital to maximize return on investment. In many places, short-term tourism rental appeared to be more profitable to local residents than renting. As a result, investors, both big players and small local ones, in order to maximize their profits have been drawn to the P2P accommodation market where small investors with as little as one apartment to rent can access the global marketplace.

Development of SE platforms in tourism – impact on transportation system of cities

Innovative sharing companies are often perceived as the ones that bring a new solution for existing transportation problems in most of cities. Those problems involve congestion and traffic jams and CO_2 emission (Cohen & Kietzmann, 2014). Car sharing may improve effectiveness of use of assets (cars) while bike sharing is a strong support for probably the most ecological and demanded way of local transport. However, due to huge scale and pace of development of SE platforms, many additional problems arose here (Tab. 7).

Table 7: Development of SE platforms in tourism – impact on transportation system of cities (positive and negative aspects)

Positive	Negative
• New, innovative solution for city traffic problems • Greening of transport system due to more efficient use of modes of transport and lowering the number of cars possessed by citizens • More efficient operations of local taxi companies forced by competitive environment • Improvement of public transportation traffic in cities	• Unfair competition and tension between employees of traditional transportation companies and employees engaged in new sharing-ones, especially between taxi drivers and Uber drivers • Advancing unjust tendencies to privatize public space and services • Increasing congestion when car-sharing and hailing services compete with public transport

Source: own elaboration based on: del Romero Renau (2018); Cohen & Kietzmann (2014); Hall et al. (2018); Dudley et al. (2017); Kim et al. (2018); Mounce & Nelson (2019), de Chardon (2019); Pawlicz (2019); Gössling (2013).

The most commonly noticed problem are legal differences between taxi companies and their drivers and drivers of Uber who do a similar job. Because of the level of prices connected with fees paid by traditional taxi drivers and taxi corporations, Uber's position on the market is very strong and privileged and it is difficult to make market opportunities for traditional taxis and Uber-like platforms more equal without administrative and/or legal measures.

Development of SE platforms in tourism – impact on quality of life in cities

It is expected that the development of tourism sharing platforms should create additional incomes obtained by particular cities' inhabitants (Di Natale, Lewis & Parker 2018), thus improving their quality of life (Horn & Merante, 2017). This phenomenon undoubtedly takes place, however, recently, a new phenomenon, which is clearly a limitation to positive economic effects for ordinary urban residents, can also be seen (Tab. 8). This phenomenon is related to the purchasing of attractively located real estate mentioned above and is regarded as a capital investment, which is additionally supposed to pay off by bringing revenues by selling accommodation through SE platforms. In many cities apartment networks come into being. These new trends are the reason why real estate renting revenues from SE platforms are not distributed to a wide range of residents, but are transferred to a small group of investors, who sometimes are from outside.

Table 8: Development of SE platforms in tourism – impact on quality of citizens' life (positive and negative aspects)

Positive	Negative
• A source of additional incomes for inhabitants • SE platforms in tourism have implications for the cities' sustainability	• Introducing tourism into quarters that were so far reserved for inhabitants • Overcrowding the most attractive parts of the city and overcrowding local roads as well as means of local transportation • Uneven distribution of economic benefits • Increased cost of living • Unfavorable change in the character of a part of the city

Source: own elaboration based on: Postma & Schmuecker (2017), Wachsmuth & Weisler (2018), Garcia-Ayllon (2018), Frenken & Shor (2017); Palgan et al. (2017), Wu & Zhi (2016).

A significant increase in tourist traffic, for residents is often a problem. It is increasingly often referred to in literature by the concepts of overtourism and tourismophobia (Goodwin, 2017). Too many tourists is a cause of congestion in many, especially central, places in cities, as well as local roads, means of transport or even bicycle routes. Often, the inappropriate behaviour of tourists who feel too anonymous in the crowd, is also a problem.

Development of SE platforms in tourism – impact on city budgets' incomes

The impact of SE in tourism on local budgets' incomes is a subject of deeper interest of authors of as little as two articles (DiNatale, Lewis & Parker 2018; Wachsmuth & Weisler 2018), although the main purpose of these papers was to study the impact of SE platforms in tourism on the real estate market. A significant number of customers using SE platforms are not only guests 'taken' from the traditional accommodation business, but also, to a large extent, newly generated tourist arrivals. The increasing number of visitors contributes to the increasing development of entrepreneurship and employment growth also in other areas related to the operation of tourist traffic, such as gastronomy, tourist attractions, tour guide business. In recent years, these enterprises have faced a significant increase in turnover in many cities, which also increases revenues to local budgets (Tab. 9).

Table 9: Development of SE platforms in tourism – impact on city budgets' incomes (positive and negative aspects)

Positive	Negative
• Introducing the lodging taxes and license fees and generating increased tax revenue to areas with few traditional lodging types • Increasing number of hosts, the owners of short-term rental who are taxpayers • Growing number of tourists that pay local taxes	• Growth in grey economy • Difficulty with collecting taxes from short-term rental • Increasing police and city staff cost

Source: own elaboration based on DiNatale, Lewis & Parker (2018), Wachsmuth & Weisler (2018).

Discussion

Based on literature review, this study helps understand that the sharing economy in tourism impacts on areas of city's functioning. Researchers conducted works devoted to 5 areas (the real estate market, local transportation systems, quality of citizens' life, an entrepreneurship and innovativeness and local budgets' income) as we saw above.

Sharing economy platforms in tourism and the entrepreneurship and innovativeness of citizens

The authors of 4 articles on the impact of SE platforms in tourism on entrepreneurship and innovativeness of citizens emphasize that that this process has enhanced opportunities to open up new

markets and expand the existing markets. SE platform is often perceived as a typical niche business suitable for micro-businesses and innovative start-ups (Martin, 2016). To confirm those, Davidson and Infranca (2016) indicate that entry costs and innovation risk for new companies as the main factors of entrepreneurship and innovativeness development were reduced. Sharing economy brings many positive effects on local entrepreneurship and innovativeness, however, its development in tourism is not free from problems (Martin, 2016; Frenken & Schor, 2017).

Sharing economy platforms in tourism and the real estate market

Review of articles provides evidence that development in SE platforms in tourism brings more costs than benefits on real estate market causing many conflicts in the area of land use and land revenue. The following negative externalities are particularly highlighted: increasing prices of properties and rental, limiting the number of properties for long-term rental for residents which contributes to making the existing housing affordability problems even more serious. However, according to Davidson and Infranca (2016), the process of increasing prices of long-term rental of properties does not have to occur because it depends on the share of short-term rentals in the total rental. Miller's research (2016) conducted under a slightly different angle draws attention to additional aspects of the impact of development of SE platforms in tourism on the city real estate market. On the one hand, it contributes to the market growth, and on the other hand, to real estate market speculation. Some benefits of SE platforms in tourism to real estate market identified in this review of articles can be supplemented by the results of a study by Jefferson-Jones (2016) who noted that the revenues obtained from short-term rental can help owners defray mortgage and pay real estate tax costs.

Sharing economy platforms in tourism and the local transportation systems

Many articles (13) subjected to detailed analysis concern the impact of SE platforms in tourism on local transportation systems where the authors emphasize that car-sharing and bike-sharing services enrich urban transportation. They also indicate that they are more innovative, green and efficient modes of transportation and, as Davidson and Infranca (2016) add, they change patterns of mobility. On the other hand, the same authors (Davidson & Infranca, 2016) indicated the negative impact on public urban transportation, which may be related to a decline in demand for its services. And this, in turn, can make the existing problems with the efficiency of transportation systems in cities even more urgent. This may prompt to increase transportation tariffs - a process which is unfavorable for residents. Other costs are also recognized in the articles examined, such as: competition between employees of traditional transportation companies and employees involved in new sharing-ones, progressing tendencies to privatize public space and services, and competition between car-sharing services platforms and local public transportation increases congestion in cities. While, Standing, Standing and Biermann (2018) suggest a reverse effect: less traffic congestion and reducing the demand for parking.

Sharing economy platforms in tourism and the quality of citizens' life

Based on the literature review that we made, it can be concluded that many researchers emphasize mainly the benefits of renting Airbnb accommodation for non-commercial residents. DiNatale, Lewis and Parker (2018) identified the most Airbnb hosts that operate a single short term rental and most hosts list their unit as their entire home. However, the research by Horn and Merante (2017) conducted in Boston, indicates that only 18% of hosts had multiple properties listed simultaneously in Boston, but their properties represented almost half of those listed on Airbnb (46%). This suggests that a large part of Airbnb's properties in the city are leased by commercial operators. However, the quality of life of the inhabitants cannot be measured only by means of economic effects. Gurran and Phibbs (2017) and Garcia-Ayllon (2018) are of similar opinion emphasizing social externalities. Onete *et al*. (2018) supplement this view with cultural and moral perspectives on human coexistence (prosocial/altruistic behavior, collaborative symbiosis). However, other researchers also see the social costs of SE development in tourism for residents neighboring short-term rental accommodation. Jefferson-Jones (2016) claims that permanent residents may argue that short-term tenants do not have ties to the community and do not or cannot, therefore, reflect the values of the community. These arguments conflate how long they stay in a community with whether or not they are able (or more precisely the unable) to be a good neighbor.

Sharing Economy Platforms in Tourism and The Local Budgets' Income

When analyzing the impact of SE platforms in tourism on local budgets, the authors of two articles (DiNatale, Lewis & Parker 2018; Wachsmuth & Weisler 2018) drew readers' attention to three sources of local revenues, i.e.: tourist expenses, taxes and fees from service providers, as well as to citizens' expenses from additional income achieved from operations in SE. Nevertheless, Davidson and Infranca (2016) cools the enthusiasm of the researchers, indicating the risk of leakages of revenue from the local economy due to high commissions charged by the SE platforms (e.g. Uber commission ranges 5-20% of the fare).

Conclusion, Future Research and Limitations

Review of scientific papers indexed in two of leading international citation bases allowed to draw several conclusions.

The number of scientific publications devoted to SE in tourism and SE platforms is growing exponentially last years, but usually the research problem is connected with the general nature of SE and platform perceived as a new business model or with the impact of SE on tourism market or hotel sector. Topic of indirect impacts of the SE platforms operating in tourism on functions of the cities is researched rarely and almost only in a form of studying of particular forms of impact, never complex.

In papers where the authors study particular of SE platforms in tourism and their development in the cities, the most often studies are connected with impact on local real estate market or on local transportation systems. In the first case the studies are connected with accommodation-sharing and most often with Airbnb – the biggest global web platform linking peers. In the second case studies concentrate on car and bike sharing and car hailing companies like Uber. Those two bodies of literature are rarely interconnected. Due to of very different nature of the impact accommodation –sharing and car-sharing are usually researched separately.

Development of SE platforms in tourism creates both positive and negative effects for particular cities. Most of them are clearly identified but there are very few proves showing the scale of particular effects and their measurement is complicated as many of those are connected with qualitative changes and/or impact issues which are simultaneously influenced by others factors independent from SE in tourism.

Using SALSA research procedure found five areas of indirect impact of SE platforms functioning in tourism on the cities. Among them, three topics are researched relatively often, and the other two are researched rarely or very rarely (i.e., entrepreneurship and innovativeness of citizens and local budgets' incomes). Most commonly, the researchers are interested in the real estate market, the city transportation systems, and the quality of citizens' life.

The conclusions presented above allowed to point several gaps in our scientific knowledge as well as the most important directions of future research. The results of the literature review show that the number of publications dealing with the topic of indirect effects of the development of SE platforms in tourism is surprisingly low. It means that actually any empirical studies within this topic should be welcomed, however those researching the impact of SE in tourism on entrepreneurship and innovativeness and on local budgets are the most demanded. Even more necessary are studies presenting those effects as a total impact of SE in tourism on cities sustainable development or at least trying to compare the impact on two or more areas of functioning of cities. Such papers are extremely rare.

In the study area of the impact of SE platforms in tourism on entrepreneurship and innovation of residents, future research should enable the answer two important questions:

(1) What is the role of peer-to-peer platforms in raising entrepreneurship and self-employment of seniors, the unemployed, disabled city residents or people with low incomes and qualifications?
(2) What actions should city authorities take to make the distribution of benefits from the development of SE platforms more socially equal?

The impacts of SE platforms in tourism on local budget incomes remains the least explored field. Among the goals of future research should be: an estimation the city's income generated by SE in tourism and expenses related to limiting the negative consequences of activities of SE platforms.

Another important direction of future studies is connected with dealing with effects by practice. Contemporary literature presents only fragmented knowledge on effects observed in particular cities and on measures undertaken to deal with them. However, the most urgent issue seems to be estimation of effectiveness of those measures to establish some benchmarks for authorities of particular cities starting their efforts to maximize benefits and minimize cost of development of SE. It is also expected to get more evidence from cities from other continents than just Europe (mainly Western Europe) and North America.

Limitations of the study are the result of the disadvantages of the content analysis method used, which is weakly codified and the resulting fluctuation of the study structure itself. In addition, it is difficult for a researcher to remain objective because 'reading' the content is never free from his/her interpretation. Like in other review articles about new phenomena that do not have unambiguous names, the issue of searching and selecting the appropriate documents is the limitation of this research. Therefore, the authors are aware of the fact that in their analysis, they did not take account of all adequate publications placed in the databases selected. Different options to filter the resources of the scientific bases selected were an additional difficulty.

The Concept of Assessing Logistic Capabilities of Maritime Container Terminals – A Case Study in Poland

Bohdan PAC

WSB University in Gdansk / Wyzsza Szkola Bankowa, Gdansk, Poland
bpac@wsb.gda.pl

Abstract

The paper presents a concept of assessing logistic capabilities of maritime container terminals on the example of Poland, in which management and applied logistics methods have been used. The solution suggested in the paper comes as a model which offers a possibility of providing a parametric evaluation of the analysed facilities in terms of their logistic capabilities, with consideration of criteria related to the logistic interoperability levels and actual maximal annual cargo handling capacity of the discussed facilities. The results obtained during the research can be applied to configure land-sea logistic transport chains and to evaluate capability levels of handling potential customers by the discussed facilities. The study is of conceptual nature, however it has been verified based on the data provided by the Polish maritime container terminals for the years 2015-2016. It has been written under the individual project *Modelling Strategical Capabilities of Maritime Industry on the Example of Poland – an Economic and Defensive Area* , implemented by the Author at the Baltic Centre of Applied Logistics.

Keywords: a maritime container terminal, logistic interoperability, a conceptual model, management, logistic capabilities.

Introduction

Intermodal transport is the key service provided on the market of international and national cargo shipping . It results mainly from its universal nature based on some well-established logistics standards, among which intermodal transport units take a significant position along with technical and technological solutions related to transporting and cargo handling operations between the modes of transport engaged into these processes, without stripping load units. The applied standards make it possible for interested parties to achieve all their key logistic targets, including time of delivery / move time, logistic costs optimization and quality of services they provide (Cf.: Rushton, Croucher, Baker, 2006). The minimal cargo handling requirements related to the shortening of the lead time and the reducing of logistic costs and cargo safety and security on the way from its senders to its receivers come as the fundamental factors which affect the level of customer service influencing the competitiveness of supply chains.

One of the basic sub-systems which operate in the system of intermodal transport is the container transport system. The aim of this study is to present a model for parametric evaluation of logistic capabilities of maritime container terminals and its verification based on the data related to the discussed type of facilities operating in Polish maritime economy.

The research problem which must be solved in order to achieve the above-mentioned aim is to find an answer to the following question: in what way should the data and other information related to maritime container terminals be used in order to develop a tool for assessing capabilities of such facilities in the field of container transport handling?

A working hypothesis which should be proved in order to solve the above-mentioned problem has been formulated as follows:

If the proper structuring and decomposing of logistic capabilities of maritime container terminals are provided, based on the actual data given in specialist periodicals, it is possible to develop

a tool for assessing capabilities of such facilities in the discussed set and for providing their ranking list in the field of container transport handling.

In order to achieve the aim, to solve the research problem defined above and to prove the working hypothesis, the following research tasks must be carried out:

- defining a research scheme;
- identifying a set of maritime container terminals for the analysis;
- reviewing specialist literature and developing a model for assessing capabilities of the analysed facilities, according to the assumed assessment criteria;
- adopting and substantiating a particular method for assessing logistic capabilities of maritime container terminals;
- performing tasks related to the evaluation of the elements defined in the model and to the interdependencies observed among them;
- quantifying logistic capabilities of the container terminals in the defined set and providing their ranking list referring to the discussed field.

There have been the following limitations assumed in the study:

- the research refers to the maritime container terminals which operate at Polish sea ports;
- the analysed data on the discussed facilities refer to the years 2015-2016.

The research Scheme

The research procedures are divided into three stages (Figure 1):

1. ***Preliminary stage*** – is focused on a review of specialist literature and selection of publications referring to the system of maritime container transport, including data related to the analysed sector, obtained from the market. At this stage, relevant limitations have been assumed in relation to the scope of the research and time period of the required data. The research includes all the maritime container terminals operating at the Polish sea ports (Table 1 and Figure 2);

Figure 1: Scheme of the research stages

Source: Elaborated by the author

2. ***Analytical and research stage*** – includes development of a model of logistic capabilities of a maritime container terminal in the field of transport handling. There are two main assessment criteria identified, namely: actual maximal annual cargo handling capacity and logistic interoperability (Figure 3). Logistic interoperability is an equivalent of the quality of a maritime container terminal which affects its cargo handling capacity. For the requirements of the research, this value is described with the use of a relevant assessment sheet. The required data have been obtained from specialist periodicals referring to the years 2015-2016. In order to provide the assessment of logistic capabilities, a positive correlation between the identified assessment criteria and the logistic capabilities of a terminal has been determined.

Table 1: A set of the analysed maritime container terminals

No.	Maritime container terminal	Total area [ha]	Storage area [TEU]	Actual maximal annual cargo handling capacity [TEU]
1	Deepwater Container Terminal S.A. (DCT Gdansk).	49	29000	1500000
2	Baltic Container Terminal S.A. (BCT Gdynia)	66,2	20000	1200000
3	Gdynia Container Terminal (GCT) S.A.	19,6	8200	429000
4	Gdansk Container Terminal (GTK) S.A.	6,7	4000	70000
5	DB Port Szczecin S.A.	12,7	4000	120000
6	OT Port Świnoujście S.A.	20	2000	70000

Source: Elaborated by author based on Office of Rail Transport (2016)

Figure 2: Geographical location of the maritime container terminals analysed in the research
Source: Elaborated by the author based on LINK (2016)

Logistic interoperability is understood as capabilities of a logistic facility to provide logistic services to customers/contractors and customers'/contractors' abilities to accept such services (Cf.: NATO, 1997). Therefore, it is possible to identify the positive correlation between the logistic interoperability of a terminal and its maximal annual cargo handling capacity.

Figure 3: Logistic capabilities of a maritime container terminal

Source: Elaborated by the author based on Office of Rail Transport (2016).

In accordance with the model suggested in the study, logistic interoperability consists of six components (S_i) which include diagnostic features (C_{ij}), forming a sheet of logistic interoperability (Table 2). These components are:

- location of a terminal, including its location along the transport corridors and its location at the sea port, also the modes of transport handled at the terminal and the vicinity of an urban agglomeration and industrial zones;
- parameters and equipment of a terminal, including the total area of the analysed facility and TEU storage area, the number of container layers in stacks, cargo handling facilities (ship – to shore gantries, mobile harbour cranes, rail mounted gantries, rubber – tyred gantries, straddle carriers, reach-stackers, yard tractors, forklifts, road chassis and terminal chassis etc.), railway cranes, capacity of truck parking areas, the number of electrical connectors;
- maritime infrastructure: length of wharfs with cargo handling facilities, depth of berths for vessels, the number of cargo handling berths at the port, width of ramps for handling ro-ro vessels;
- transport accessibility from the sea and from the land, including the linear infrastructure of road transport (communication lines, in accordance with the AGR agreement) and of rail transport (communication lines, in accordance with the AGTC and AGC agreements), vicinity of airports and inland ports, regular vessel connection lines and regular ocean shipping services;
- terminal railway hub, including the number and the length of cargo handling railway tracks, the total length of railway tracks, the number of railway sidings, the number of regular national and international connection lines;
- services provided to handle vessels and block trains, basic services provided to handle containers (customs services, electronic reporting systems, storage of full and empty containers, services provided to handle RID, ADR and isothermal containers) and other services provided to handle containers (sealing and cleaning containers, emergency repair services). Additionally, the services also include cargo handling relations and services related to temporary storage.

Table 2: A sheet of logistic interoperability of a maritime container terminal

S_1	**Location**
C_{11}	Transport corridor (yes or no/which one?) and location at the port
C_{12}	Modes of transport handled
C_{13}	Vicinity of an agglomeration (yes or no/the size of the population)
C_{14}	Industrial zone (yes or no)

S_2	**Parameters and equipment of a terminal**
C_{21}	Total area
C_{22}	Storage area
C_{23}	Number of layers in a stack
C_{24}	Cargo handling facilities
C_{25}	Number of railway cranes
C_{26}	Capacity of truck parking areas
C_{27}	Electrical connectors

S_3	**Maritime infrastructure**
C_{31}	Length of cargo handling wharfs
C_{32}	Depth of vessel berths
C_{33}	Number of vessel berths at the port
C_{34}	Width of a ro-ro ramp

S_4	**Transport accessibility from the sea and from the land**
C_{41}	Linear infrastructure of road transport
C_{42}	Linear infrastructure of rail transport
C_{43}	Vicinity of airports
C_{44}	Vicinity of inland (river) ports
C_{45}	Regular vessel connection lines
C_{56}	Regular ocean shipping services

S_5	**Terminal railway hub**
C_{51}	Number of cargo handling railway tracks
C_{52}	Length of cargo handling railway tracks
C_{53}	Total length of railway tracks
C_{54}	Railway sidings
C_{55}	Number of regular national connections
C_{56}	Number of regular international railway connections

S_6	**Logistics services**
C_{61}	Vessel handling
C_{62}	Block train handling
C_{63}	Basic services provided to handle containers
C_{64}	Additional services provided to handle containers
C_{65}	Cargo handling relations
C_{66}	Temporary storage facilities

Source: Elaborated by the author

3. ***Final stage*** – includes relevant calculations, according to the method accepted for the research. In this method the values related to the logistic interoperability of a maritime container terminal are taken into consideration, along with the actual maximal annual cargo handling capacity and the relation between these parameters. Based on that, the relevant preference rates have been calculated, according to actual maximal annual cargo handling capacity, according to logistic interoperability along with an average decision-making rate which determines the position of a particular terminal in the analysed set, based on its logistic capabilities. The final stage is ended with the interpretation of the results.

Methodology assumed for the assessment of logistic capabilities of a maritime container terminal

In order to identify a logistic capabilities level for a maritime container terminal and to provide a ranking list of terminals, the following sequence of actions has been applied:

1. Calculating the value of logistic interoperability at the level of the diagnostic features, based on the arithmetic mean of evaluations obtained during the expert research survey (Table 3), with the use of the following equation:

$$PC_{ij} = W_{ij}\ x\ \overline{WC_{ij}} \quad (1)$$

where:

PC_{ij}– is the logistic interoperability value of the jth diagnostic feature in the ith component of logistic interoperability;

W_{ij} – is the weight coefficient of the jth diagnostic feature in the ith component of logistic interoperability; weight coefficients have been determined by the AHP (Analytic Hierarchy Process) method and verified by the consistency ratio CR (Saaty, 1980);

$\overline{WC_{ij}}$ – is the arithmetic mean of the logistic interoperability evaluation provided to the jth diagnostic feature in the ith component, identified on the basis of expert opinions;

WC_{ij} – is the expert evaluation of logistic interoperability of the jth diagnostic feature in the ith component; the scale of expert evaluation has been ranged from 0 to 10;

$\sum_{k=1}^{n} WC_{ijk}$ – is the sum of the expert evaluations of logistic interoperability of the jth diagnostic feature in the ith component, where n=10 – is the number of the experts. The experts have been recruited from the academic environment focused on research studies related to maritime economy.

The expert opinions referring to the particular features in the particular components of logistic interoperability have been analysed in terms of convergence, based on the classical coefficient of variation (Everit B.,1998), according to the following equation:

$$v_{ij} = \frac{\sigma_{ij}}{\overline{WC_{ij}}} \quad (2)$$

v_{ij} – is the classical coefficient of variation (calculated for the particular features);

σ_{ij} –is the average standard deviation for the particular analysed diagnostic feature.

Table 3: A table for evaluation of diagnostic features in terms of logistic interoperability components

| | | |

Table 4: The preference scale of the classical coefficients of variation

v_{ij}	Preference scale
$v_{ij} \leq 0{,}1$	Weak differentiation of the coefficient (a satisfactory level)
$0{,}1 < v_{ij} \leq 0{,}3$	Medium differentiation of the coefficient (an acceptable level)
$0{,}3 < v_{ij} \leq 0{,}5$	Strong differentiation of the coefficient (an unacceptable level)
$v_{ij} > 0{,}5$	Very strong differentiation of the coefficient (an unacceptable level)

Source: Elaborated by the author

2. Calculating the value of logistic interoperability at the level of the components, according to the following equation:

$$PS_i = W_i x \sum PC_{ij} \tag{3}$$

where:

W_i – is the weight coefficient of the ith component, determined by the AHP (Analytic Hierarchy Process) method (Saaty, 1980);

$\sum PC_{ij}$ – the sum of the value of logistic interoperability at the level of the diagnostic features forming the ith component of logistic interoperability.

3. Calculating the logistic interoperability rate of a maritime container terminal, according to the following equation:

$$\pi_z = \frac{\sum PS_i}{\sum PS_i^{Max}} \tag{4}$$

where:

π_z – is the logistic interoperability rate (the value expressed with a decimal fraction) of a maritime container terminal, where the z index indicates the subsequent terminal analysed in the identified set; in the research survey z= 1,2,3,4,5,6 (see: Table 1);

$\sum PS_i$- is the sum of the value of logistic interoperability at the level of the components in the analysed maritime container terminal;

$\sum PS_i^{Max}$ – is the benchmark value $\sum PS_i$ for which all the diagnostic features take the maximum value = 10.

4. Calculating the *cargo handling capacity - logistic interoperability* rate for the zth maritime container terminal (the relation of the cargo handling capacity of a terminal to the level of its logistic interoperability):

$$e_z = \frac{q_z}{\pi_z} \tag{5}$$

where:

e_z- is the *cargo handling capacity - logistic interoperability* rate of a maritime container terminal;

q_z- is the relative value of the cargo handling capacity of a maritime container terminal.

with consideration of:

$$q_z = \frac{Q_z - Q_{MIN}}{Q_{MAX} - Q_{MIN}} \quad (6)$$

where:

Q_z- is the actual maximal annual cargo handling capacity of an analysed terminal.

Q_{MAX}- is the highest value of the actual maximal annual cargo handling capacity of a terminal in the analysed set;

Q_{MIN}- the lowest value of the actual maximal annual cargo handling capacity of a terminal in the analysed set;

The q_z value indicates the relative status of the cargo handling capacity of the particular facility in the analysed set. This is a relation of the reduced absolute value of the actual maximal annual cargo handling capacity of the analysed terminal to the total analysed variation interval of that value in the discussed set of terminals (Figure 4).

Figure 4: Interpretation of the relative status of cargo handling capacity of a terminal
Source: Elaborated by author based on Kolman (2015)

where:

$Q_{MAX} - Q_{MIN}$- is the total analysed variation interval of the actual maximal annual cargo handling capacity in the analysed set of container terminals.

$Q_z - Q_{MIN}$ - is the reduced absolute value of the actual maximal annual cargo handling capability of the analysed terminal.

5. Calculating the decision interpretation rate for the analysed terminal:

$$d_{kz} = 0{,}5e_z \quad \text{for } e_z \in (0 \div 1\rangle \quad (7)$$

$$\text{and } d_{kz} = 0{,}5 + 0{,}5(1 - \frac{1}{e_z}) \text{ for } e_z > 1 \quad (8)$$

where:

$d_{kz} \in (0 \div 1\rangle$ – is the decision interpretation rate for the analysed terminal (see: Kolman, 2015). The rate enables the Author to establish a preliminary ranking list of terminals within the aspect of logistic

capabilities, taking into consideration the logistic interoperability and the actual maximal annual cargo handling capacity of the facilities under research.

6. Calculating the absolute rate of cargo handling capacity of a terminal:

$$C_z = \frac{Q_z}{\Pi_z} \quad \text{[thousands of TEU/ \%]} \tag{9}$$

where:

Q_z – is the actual maximal annual cargo handling capacity of the analysed terminal, expressed in thousands of TEU;

Π_z – is the logistic interoperability rate of the analysed terminal, expressed in %;

7. To calculate the preference rates for the assumed criteria and the average decision-making rate which determines the position of a terminal in terms of its logistic capabilities, the following factors related to the logistic interoperability level and the actual maximal annual cargo handling capacity of a terminal have been taken into account:

- d_{kz} - the decision interpretation rate for the analysed terminal;
- π_z - the logistic interoperability rate of the analysed terminal;
- c_{Qz} – the relative value of the absolute cargo handling capacity rate of the analysed terminal.

The c_{Qz} value indicates the relative status of the absolute cargo handling capacity rate of a particular facility in the analysed set of terminals. This is a relation of the reduced value of the absolute cargo handling capacity rate of the subsequent analysed terminal to the total analysed variation interval of that rate in the discussed set of terminals (Figure 5).

8. Calculating c_{Qz} value using the equitation:

$$c_{Qz} = \frac{C_z - C_{MIN}}{C_{MAX} - C_{MIN}} \tag{10}$$

where:

C_{MIN} – is the lowest value of the absolute cargo handling capacity rate recorded in the analysed set of terminals;

C_{MAX} – is the highest value of the absolute cargo handling capacity rate recorded in the analysed set of terminals;

$C_{MAX} - C_{MIN}$ – is the total range of variation of the absolute cargo handling capacity rate in the analysed set of container terminals;

$C_Z - C_{MIN}$ – is the reduced value of the absolute cargo handling capacity rate of a particular container terminal in the analysed set.

Figure 5: Interpretation of the relative status of the absolute cargo handling capacity rate of a terminal

Source: Elaborated by author based on Kolman (2015)

9. Calculating the preference rate of the logistic interoperability of a terminal with the use of the following equation (Cf.: Kolman, 2015):

$$WP_z = \frac{\alpha\pi_z + \beta d_{kz} + \gamma c_{Qz}}{\alpha + \beta + \gamma} \quad (11)$$

where:

$\alpha, \beta, \gamma,$ - are the significance coefficients for which the following proportion has been assumed, considering the requirements of the research survey: $\alpha : \beta : \gamma = 3 : 2 : 1$.

As a result, the following equation has been obtained:

$$WP_z = 0{,}167(3\pi_z + 2d_{kz} + 1c_{Qz}) \quad (12)$$

10. Calculating the preference rate of the actual maximal annual cargo handling capacity of a terminal with use of the following equation (Cf.: Kolman, 2015):

$$WQ_z = \frac{\alpha c_{Qz} + \beta d_{kz} + \gamma \pi_z}{\alpha + \beta + \gamma} \quad (13)$$

where:

$\alpha, \beta, \gamma,$ - are the significance coefficients for which the following proportion has been assumed, considering the requirements of the research survey: $\alpha : \beta : \gamma = 3 : 2 : 1$.

As a result, the following equation has been obtained:

$$WQ_z = 0{,}167(3c_{Qz} + 2d_{kz} + 1\pi_z) \quad (14)$$

11. Calculating the value of the average decision-making rate referring to the logistic capabilities of a maritime container terminal and defining its position on the ranking list (Cf.: Kolman, 2015):

$$W\Pi_z = 0{,}5(WP_z + WQ_z) \quad (15)$$

Calculations and verification of the Results

In Table 5 a synthetic presentation of the results obtained during the research is displayed. It refers to the logistic interoperability levels of the maritime container terminals analysed at the particular stages of the model decomposition. Table 5 presents the following data:

- $\overline{WC_{ij}}$ - the arithmetic mean of the logistic interoperability evaluation provided to diagnostic feature level determined on the basis of the expert evaluations, where the $v_{ij} = \frac{\sigma_{ij}}{\overline{WC_{ij}}} \leq 0{,}3$ condition has been met for each feature (see: Table 4);
- the weight coefficients at the level of the diagnostic features (W_{ij}) and the weight coefficients at the levels of the subsequent components of logistic interoperability (W_i). The weight coefficients at the level of the diagnostic features and the components of logistic interoperability have been determined by the AHP ((Analytic Hierarchy Process) method, for which the relevant Consistency Index (CI) and Consistency Ratio (CR) have been calculated, providing that the following condition has been met:

$$CR = \frac{CI}{RI} \leq 0{,}1 \tag{16}$$

  where:

  RI – is the random index (Saaty, 1980). In this case, it depends on the number of the compared elements, referring to the diagnostic features in a component of logistic interoperability or on the number of components of logistic interoperability of a maritime container terminal;

- the values of logistic interoperability at the level of the diagnostic features (PC_{ij}) at the particular terminals;
- the values of logistic interoperability at the level of the components (PS_i) at the particular terminals;
- the logistic interoperability rates of the analysed maritime container terminals (π_z).

The calculations referring to the preference rates at the logistic interoperability level, the actual maximal annual cargo handling capacity of the analysed terminals and the average decision-making rate of logistic capabilities for the analysed maritime container terminals are presented in Table 6. The graphic interpretation of Table 6 is presented in Figures 6,7 and 8.

The analysis of the results obtained during the research, based on the actual data referring to the maritime container terminals operating at the Polish sea ports allows the Author to draw the following conclusions:

- the values of the decision interpretation rates (d_{kz}) and the average decision-making rates ($W\Pi_z$), achieved by the terminals under research, place the facilities on the similar positions, both on the preliminary and final ranking lists;
- the largest group of maritime container terminals is situated in the Gulf of Gdańsk;
- the analysed maritime container terminals located there indicate 94.3% of their total annual cargo handling capacity during the analysed period of time;
- the highest average decision-making rate of logistic capabilities is indicated by the Deepwater Container Terminal which is the largest facility of this type on the Polish coast, both in terms of the actual maximal annual cargo handling capacity and of the TEU storage area;
- during the analysed period of time, DCT, BCT and GCT terminals indicate the highest levels of balance between the calculated preference rates referring to logistic interoperability and the actual maximal annual cargo handling capacity. It can be interpreted as proper adjustment of their current logistic interoperability to the tasks they perform, which are determined by their maximal annual cargo handling capacity;
- considering the largest installations, the levels of using their maximal annual cargo handling capacity during the analysed period of time are respectively: 79.2% for DCT, 39.5% for BCT. Hence, this fact indicates uneven distribution of workload among the facilities located in the same area, which provide services to the same port hinterland;
- the area of Western Pomerania (see: Figure 2) is still underinvested and underdeveloped in terms of services provided to handle container transport in land-sea supply chains, despite the fact that the shortest way connecting Scandinavia with Southern Europe runs through the sea ports in Szczecin and Świnoujście;
- the coast between the group of the sea ports of Szczecin-Świnoujście and the sea ports of Tricity (sea ports of Gdańsk and Gdynia) is a completely passive zone in terms of services provided to handle maritime transport of cargo, mainly because of the lack of advanced port infrastructure required to handle all categories of cargo shipping;
- important elements which affect logistic interoperability are the TEU storage area and total area of a terminal because these are the factors that strongly influence the growth of the maximal annual cargo handling capacity, especially when facilities indicating similar transport accessibility from the sea and from the land are considered.

Concluding Remarks

To sum up the research survey, it should be stated that the suggested model makes it possible for interested parties to compare maritime container terminals in three aspects, namely:

- logistic capabilities of a particular terminal in the field of container transport handling operations;
- logistic interoperability of a particular terminal, with consideration of actual maximal annual cargo handling capacity of that installation;
- actual maximal annual cargo handling capacity of a particular terminal, with consideration of the logistic interoperability level of a that installation.

The method applied in the research allows interested parties to analyse the relative status of the facilities in the discussed set of maritime container terminals, in terms of their cargo handling capacity and their logistic interoperability. The research has been limited to the area of Poland, nevertheless, more access to relevant data will make it possible to provide assessment of any terminal located in a particular water region.

Presented in the research study, the concept of assessing logistic capabilities of a maritime container terminal is verified on the basis of real data referring to the years 2015-2016. It has allowed the Author to draw some conclusions referring to further research on the development of maritime economy of the State in terms of the analysed facilities.

From the perspective of 2019, it is now obvious, that the DCT has been growing dynamically in terms of the TEU storage area; the terminal has significantly increased its maximal annual cargo handling capacity up to 3 250 000 TEU, which are used in 69% in practice.

Strong competition of German sea ports (e.g. Rostock) should result in significant investment into the maritime container terminals in Szczecin and Świnoujście. There has been a decision made about construction of a new deep-water container terminal in Świnoujście, whose annual cargo handling capacity is planned for 1.5 million TEU. An additional advantage will be the deepening of the fairway between the Port of Świnoujście and the Port of Szczecin to 12.5 m in order to allow vessels of the capacity of 2500 TEU to enter that sea port. This investment would increase the operability of the sea port in Szczecin in terms of handling land-sea container transport chains.

There is also a question related to the central coast. The Polish sea ports located in the Gulf of Gdańsk are situated in the immediate vicinity of the Kaliningrad Region and in a situation of a crisis or an international conflict they can be completely neutralised in terms of economic and military aspects. Hence, while analysing the volume of containers transported through the Polish coast to the region and in transit, a concept of "the third window" should be considered, that is namely: construction of an additional port facility on the central coast. It would complement the ports of Tricity and it could, at least partially, take over tasks performed by these sea ports. To sum up the research study, the fact of uneven development should be emphasized as well as the lack of even distribution of resources and facilities required to handle maritime container transport along the Polish coast.

Abstract

The paper provides an assessment and economic analysis of Nigeria's biofuels policy by considering the fiscal incentives therein and its effectiveness. It starts with an overview of biofuel industry in Nigeria, highlighting its growth and then describes the biofuels policy with a focus on its fiscal elements. Using available data in a two-scenario model, biofuels investment is appraised to capture basic financial and economic analytics. The study finds that biofuels investment with respect to the sole production of only ethanol is not efficient economically,given the available fiscal incentives. The outcome, however, changes when the number of products increases to include animal forage, processedsugar, and power generation for sale; with inherent risks. Furthermore, it reveals the potential implications of biofuels on government from a fiscal perspective. Following the several open issues for consumers and the environmental effects of petroleum combustion, this paper recommends their consideration to enhance the prospects of biodiesel, biorefinery and bioeconomy in Nigeria.

Keywords: Biodiesel, Biofuel policy, Ethanol, Fiscal incentives, Nigeria

JEL Code: Q2, H2, F1

Introduction

Biofuels are obtained from biological materials, particularly from plants, micro-organisms, animals and waste. They are gaseous fuels gotten from biogas that contain a high amount of sugar. Examples include starch from cassava and corn, oil from palms and soybeans, sorghum and sugarcane.They, therefore, emit zero Carbon dioxide (CO_2) unlike carbon-based fuels (Ejemeyovwi, Obindah and Tiena, 2018; United States Department of Agriculture-USDA, 2006). Basically, biofuel originates from the conversion of solar energy to chemical energy makes it different from fossil fuel. Some of the strengths of biofuel over fossil fuel include its easy extraction from biomass and its biodegradable properties that make it sustainable and environment friendly (Gaurav, Sivasankari, Kiran, Ninawe and Selvin, 2017).Consequently, with increasing CO_2 emissions and global population rise which has affected social and environmental well-being, energy demand rose suddenly (Gershon and Patricia, 2019; Gaurav et al., 2017).

Owing to the fact that fossil fuel is used majorly in the transportation sector around the world, enormous effort has been made to improve biofuel production, as well as, its management. Global biofuel production increased steadily from about 16 billion litres in the year 2000 to around 122 billion litres in 2015, accounting for about 3.5 percent of global road transport fuel. In this regard, Brazil has

succeeded in providing about 25 percent of the current demand for road transport fuel (Energypedia, 2018). Also, the United States as at 2017 had biofuels representing about 5% of their transport fuel demand (Energy Information Administration-EIA, 2018).The interest in biofuels has furthermore been motivated by the search for low carbon energy alternatives, the increasing global oil prices, and the pursuit of energy independence (Sivashankar, Weerahewa, Pushpakumara and Galagedara, 2016; Sorda, Banse and Kemfert, 2010). This interest in biofuels is stirred within the context of the emerging bioeconomy as well as the global energy transition from oil-based fuels to bio-products (Ceapraz, Kotbi, and Sauvee, 2016).

In biofuels production, African countries have lagged behind – neither manufacturing nor utilizing much conventional biofuels. However, power generation and heat heavily relies on available residue (Sielhorst, Molenaar and Offerman, 2008). Many of these African countries have technical production potential, however, liquid biofuels are manufactured and utilized on a mini scale, with no export. Although, some African countries have started investing in the plantation of jatropha oil seeds for biodiesel production, they are still faced with financial barriers, technical expertise as well as uncoordinated government policies (Sekoai and Yoro, 2016). Burkina Faso has successfully planted over 70000 jatropha oil seed trees and has even partnered with the European Union Biofuel Directive to improve the renewable energy sector. Ghana is not left out as they have put in place targets of 10 percent and 20 percent for the years 2020 and 2030 respectively, for an improved biofuels production. South Africa is among the leading African countries in biofuels production as it contributes about 14 percent of their renewable energy.

Nigeria on the other hand has produced up to 134 million litres of ethanol annually from its 5 primary commercial scale ethanol distillery plant. However, for Nigeria to be part of the African countries where the domestic demand for biofuel will be about 2 billion litres in 2030 as forecasted by the Energy Information Administration, the production of biofuels needs to be largely improved (Oniemola and Sanusi, 2009). To expand biofuels production and consumption, there is a need for supportive energy prices as well as policy interventions (Fundira and Henley, 2017). Cue is taken from advanced economies like USA, Japan, China, and the European Union, as well as, Brazil that have thriving renewable energy industries. The United States of America focuses on ethanol production as their cars are mostly powered by gasoline while Brazil focuses on sugarcane-based ethanol production with a production of about 21 billion litres annually (Sekoai and Yoro, 2016). As such, energy transition is driven by deliberate government policies which in turn mean that biofuels policy development arises out of a thoughtful process in attempt liquid fossil fuels (Ceapraz, Kotbi, and Sauvee, 2016).

In 2005, the Nigerian government releaseda mandate on Automotive Biomass Programme with objectives to encourage an environment suitable for the creation of the industry for local ethanol fuel.The set goal was to steadily move the country from its dependence on imported gasoline, reduce factors polluting the environment, put in placea commercially operational industry, and bring about sustainable jobs within Nigeria (Aliyu, Deba, Saidu, Muhammad and Usman, 2017). More so, in 2007, the Nigerian Biofuels policy was launched and incentives were added to it to reflect the intent and seriousness of the government to achieve the policy objectives. Government aimed to build a strong and successful fuel ethanol industry through the use of agricultural products which will in turn improve the quality of transport fuel, as well as, increase clean energy supply in the country (Ugwoke, Gershon, Becchio, Corgnati, and Leone, 2020; Oniemola and Sanusi, 2009).The expected gains from the Biofuel policy were increase in government's tax revenue, improvement in farming techniques, power generation for households and firms as well as environmental gains. As such, this paper assesses how tax attractiveNigeria's Policy on Biofuels is to the achievement ofits objectives.In other words, this study is investigating the extent to which the tax incentives in the biofuels policy is attractive enough for investments to deliver the set goals.

Insights from Extant Studies

Contemporary biofuels markets were created as a result of constant oil price volatility since 1970 as well as climate change concerns (Viaggi, 2016). Countries around the world, in seeking to achieve energy independence, formulated policies for alternative transportation fuels(Gershon, Gershon,

Ezenwa, and Osabohien, 2019; The Economist, 2013). Brazil and the United States were the first to create a productive market for ethanol through the use of sugarcane and corn respectively. They had policies like legal mandates, exemptions from taxes, subsidies as well as favourable credits.They were closely followed by the European Union (EU) whosebiofuel industry was aimed at achieving the Kyoto protocol targets through the use of tax exemptions and statutory mandates.So far, over 50 countries have adopted renewable energy sources, however, Brazil, the Unites States and The European Union produce about 91 percent of the global biofuels (HLPE, 2013).

In a survey carried out on biofuels among a group of countries, it was revealed that biofuels policies, like shared and contrasted fiscal instrument use, as well as, mandates to reduce Green House Gas (GHS) emissions from transport fuel, land use policies and excise exemptions. For instance, in 1975, Brazil initiated a National Alcohol Program with incentives and subsidies attached to it, which boosted the Brazilian ethanol production (Shikida, Finco, Cardoso, Galante, Rahmeier, Bentivoglio and Rasetti, 2014). The biofuels policy in the United States sees biofuels as a route to energy independence. To this end, they made use of tax exemptions, import duties on fuel ethanol (Naveen and Andrew, 2014; HLPE, 2013).

The South African biofuels policy is made up ofa fast depreciation scheme for the production of biodiesel facilities and also a 50 percent exemption from general fuel levy. Irrespective of this, the objectives of the South African biofuels policy were not created as a result of the need to gain energy independenceor to get rid of CO_2emissions. It was put in place to bring about rural development and alleviate poverty (South African Biofuels Regulatory Framework, 2014; HLPE, 2013). The Indian Biofuels policy on the other hand, is focused primarily on non-food foragewhich is to be obtained from wastelands regarded as not suitable for agriculture. This was aimed at ensuring food security is not given away to the search for good fuel. India's biofuels policy also gives room for appropriate periodic financial and fiscal schemes including support for feedstock prices and the promotion of the employment of biofuels in all sectors of the economy. It also contains an increase in the ethanol production target from 2 percent to 20 percent by 2030 (India National Policy on Biofuels, 2018; National Policy on Biofuels, 2009). However, there have been food insecurity issues with biofuels and agricultural land use in Malawi (Herrmann, Jumbe, Bruentrup, and Osabuohien, 2018)

The primary aim underlying the Nigerian biofuels policy is to improve the agricultural sector by connecting it to the lucrative and thriving energy sector. Though a good objective, a survey of the United States biofuel's policy revealed that there are negative economic impacts for linkages between the energy and agricultural sector (Naveen and Andrew, 2014). It has been argued that the Nigerian Biofuels policy may fail unless there is food security and effective regulatory standard for the environment. (Elliot, 2015; Oshewolo, 2010). This is because in Nigeria, using sugarcane to make ethanol has been estimated in the range of 55% to 65% of total cost of producing ethanol.(Dias, Cunha, Jesus, Scandiffio, Rossell, Filho, and Bonomi, 2010; Kojima, Mitchell and Ward, 2007).

It has been asserted that biofuels produced from waste oil takes care of the threat of food insecurity evident in the biofuels production of the first–generation. Though it has been successfully employed in Europe and has generated about 2 billion litres of biofuels (Kojima et al., 2007), the case could be different in Nigeria. Moreover, there is a need to determine its economic viability within the context of Nigeria's biofuel policy.This study, hereby contributes to existing literature as it investigates the effectiveness of the tax incentives in the Nigerian Biofuels policy.

Methods of Analysis

Methods and Techniques

To achieve the aforementioned research objective, first the policy's tax components are ascertained. This is followed by the estimations of Capital Expenditure (CAPEX) and Operating Expenditure (OPEX), as well as the consideration of different biofuel price scenarios. Based on the Discounted Cash Flow (DCF), a spreadsheet economic model from the policy implementation is created to explain the

fiscal gains to biofuels investors, the cost to the government as well asthe biofuels consumers. In this study, the fiscal cost to the government and consumers of biofuels is viewed using an industry-wide single integrated investment. In other words, the biofuel project is conceived comprehensively from the plantation to the distillery plant, with focus on the returns and fiscal gains to the biofuels investors.

Data Analysis

Reproduced succinctly in Table 1, are tax elements of the NigerianPolicy on biofuels production. It assumes the country needs 1.3billion litres of ethanol per year to be blended with gasoline at 10%. Furthermore, the policy uses daily gasoline consumption of 36.5million litres and estimates ethanol demand to reach 2billion litres per year in 12years.

Table 3.1: Nigerian Biofuels Policy Tax Incentives

S/N	Fiscal Incentive
1	Exemption from the 66.67% rule on the cap on allowable capital allowance deduction
2	Tax Holiday of 10 years which could be extended for 5 more years
3	10year Waiver of Import Duties
4	Exemption from Value Added Tax
5	With-holding Tax Exception on dividends and interests

Evaluation of the Nigerian Biofuels Industry – Impact on Government Receipts

Tax credits and/or tax holidays have implications for domestic resource mobilization (Adesuwa, Gershon, Blessing and Makwal, 2017). As such, the waivers and exemptions granted in the Nigerian biofuels policy are assessed in relation to their wider economic impact. A $22.27 billion Capital Expenditure estimated over a 10year period is needed for the achievement ofthe Ethanol blend mandate of 2 billion litres per annum. This will result in an estimated waiver of excise tax of $4.01Billion, Value Added Tax (VAT)of $2.33 billion and estimated ethanol import subsidies of $0.84 billion.

Figure 3.1: Profile of Tax Incentives to the Biofuels Industry – Excise Tax, Value Added Tax and Subsidies

Source: Authors' computation

Figure 3.1 presents a 20-year profile of tax incentives of$7.17 billion. The initially high customs duty reduces as a result of a decreasing Capital Expenditure (CAPEX), as capacity is being built. Value Added Tax (VAT) on the other hand, increases as feedstock consumption as well as the manufacturing of ethanol improves. Furthermore, it is worth noting that the subsidy incentives decreaseswith increase in domestic production to a pre-set level.

Figure 3.2: Percentage Distribution Profile of Tax Incentives/Waivers to the Biofuels Industry – Excise Tax, Value Added Tax and Subsidies

Source: Authors' computation

Relatively, Value Added Tax (VAT) increases and accounts for the most proportion of waivers (>90%) granted to the biofuels industry at the latter period as can be seen in Figure 3.2.During the latter period, post the twelfth year, the waivers on customs duty drop off to 0% of all the waivers issued as investment in meeting the targets.

Table 3.3: Economics of Biofuels Industry in Nigeria with Tax Incentives/Waivers

Viability Indices	**Unit**	**With Waivers**

Debt	$/Ltr	0.62
CapEx	$/Ltr	0.89
OpEx	$/Ltr	2.55
GT	$/Ltr	-
Ind. Profit	$/Ltr	(1.95)

Using the results in Table 3.3 in which the tax assumptions made in Table are maintained, the economic viability of the integrated biofuel project/industry is analyzed. It is revealed that the Nigerian biofuels Industry is not economically self-sustaining when ethanol is only produced from sugarcane. As such, with the incentives/waivers, it is unprofitable and unable to bear the burden of corporate income tax. To be profitable, this industry will need a 20-year subsidy of about $1.95l per litre. A long-range bioethanol price of $2.66/litre is required by the industry to breakeven on Net Present Value (NPV) basis. With the recent reduction in the cap pump-price of premium motor spirit (PMS), this subsidy will be more.

Evaluation of the Biofuels Industry – Impact on Consumer Prices

Table 3.4: Comparative Analysis or Ethanol and E10 blend Prices

	Units	**Symbols**	**Based on $0.67/LtrEthOH**	**Based on $2.66/LtrEthOH**
Pct Gasoline	%	**A**	90%	90%
Pct Ethanol	%	**B**	10%	10%

Difference from N145	N/Ltr	**L = J - K**	17.37	108.57

Source: *Authors' computation*

Where: EthOH is Ethanol; GEE is Gasoline Energy Equivalent

The impact on the retail price of E10 depicts that the biofuels consumer will pay ₦17.37/litre above the current gasoline retail price of ₦145.00/litre, given the currently estimated price of ethanol of $0.67/Litre. At this point, Net Present Value (NPV) is at $20.23 million; depicting a poor performanceof the industry. To achieve a 10 percent Internal Rate of Return (IRR), the industry long-range ethanol price will have to be $2.66/litre, which is four times the current estimated ethanol price of $0.67/Litre, and ten times the current Import parity price of gasoline generated based on energy equivalence. E10 retail prices is to be retailed at ₦108.57/litre, a price above the current gasoline retail price, for the achievement of the Ethanol impact of $2.66/Litre.

Figure 3.3: Ex-Depot Gasoline Price to Achieve E10 Gasoline Parity at N114/litre

Figure 3.3depicts the Ex-depot price of gasoline and ethanol for the achievement of the E10 price parity,given the present retail gasoline price of ₦145.00/litre. When Ethanol Price is kept at $0.67/Litre, Figure 3.3 reveals that the E10ex-depot price of gasoline is at parity of ₦114.00/Litre, which is smaller than the current Ex-depot gasoline price of ₦133.28/Litre.

Figure 3.4: Ex-Depot Ethanol Price to Achieve E10 Gasoline Parity at $0.29/litre

To keep the Ex-depot price gasoline price at N133.28/litre, the ethanol price for E10 parity with gasoline is $0.29/Litre. This observation means that ethanol price will have to be 57% less than present ethanol prices for the achievement of E10 gasoline parity. This will depreciate the economic performance of the biofuel industry as NPV10 will sink to **$24.09 million**from **$20.23 million** andimprove the industry's support required from the government from **$48.94 billion** to **$61.24 billion** over a 20year period.

According to Kojima et al. (2007), countries with negative taxes on petroleum fuels would find it hard to build a viable biofuel market on a commercial basis as biofuels require large reductions in tax to remain competitive with petroleum fuels. The Nigerian Biofuels Policy will therefore cost the government **$4.01 billion** in forgone duties, **$2.33 billion** in forgone Value Added Tax, **$0.84 billion**of import subsidies. This will lead to a yield of an estimated total of **$7.17 billion** over a 20year period. Additionally, in the same time period, it is important for the government to bear a subsidy burden of **$48.94 billion** to allow the biofuels industry make profit. From the biofuels consumers end, given the current prices of gasoline and ethanol, the E10 blend will cost the biofuels consumer **₦17.37/litre**more than the present gasoline price of ₦145.00/litre if it is not subsidized. There would be a translation to an annual consumer subsidy burden of **$739Million** per annumif the government is allowed to subsidize the biofuels consumer at the policy-assumed gasoline consumption level of 35.6Million litres/day,.

Evaluation of Integrated Biofuels Plant Project

In this section, the extent of the fiscal incentives contained in the biofuels policy is examined from the view of a biofuels plant integrated with a sugar cane plantation. Bearing in mind that one of the gains of the biofuels policy is to providespecific co-generation energy benefits where an ethanol distillery also produces electricity for sale to the power grid. Analysis will be conducted under the following production cases:

- Case 1: Production of Ethanol, Animal Feed, and CO_2
- Case 2: Production of Ethanol, Animal Feed, CO_2, Refined Sugar, and Electricity

Table 3.5: Detailed Production Cases for Integrated Projects

	Units	**Scenario No. 1**	**Scenario No. 2**		
Plantation CapEx	$ Million	130.99	130.99		
Plant CapEx	$ Million	151.75	203.51		
Products				**Quantity Produced**	**Units**

Source: *Authors' computation*

To evaluate the integrated project, the principles of Transfer Pricing Regulations is employed; where the production of sugarcane is combined with the biofuels plant on an arm's length basis with the recognition that the biofuels plant forage can be sourced from out growers as contained in the policy. Also, the out growers can also supply feedstock other Agro-Allied industry purposes.

Economic Viability Indices

To measure the extent of fiscal incentives granted by the biofuels policy, key economic viability indices are used. The impact of the integrated project performance to both investor and government is judged based on the following indices:

Net Present Value (NPV): It is the Present Value (PV) of future Net Cash Flows discounted at a given hurdle rate. A project is regarded as viable if the NPV discounted at the investor's hurdle rate, D%, is greater than zero that is, NPV at D% > 0). Generally, for a project to be regarded as viable, a higher NPV is the criteria. The NPV formula is as seen below:

$$\boldsymbol{NPV} = \sum_{t=0}^{N} \frac{\boldsymbol{NCF_t}}{(\boldsymbol{1} + \boldsymbol{D})^t} \qquad (\boldsymbol{1})$$

Internal Rate of Return (IRR): This is the discount rate which makes the NPV of all cash flows from a project equal to zero. IRR calculations rely on the same formula as NPV does.

$$\boldsymbol{IRR} = \{\boldsymbol{D} | \boldsymbol{NPV} = \boldsymbol{0}\} \qquad (\boldsymbol{2})$$

Government Take (GT): This is an important metric that measures government receipts from the integrated biofuels project. For this project, it is calculated as the sum of government inflows which consists Education Tax (ET), Corporate Income Tax (CIT), and WithHolding Tax (WHT) on interests. Value Added Tax (VAT) and Customs Duties (CD) are not added to this computation. The formula is as seen below:

$$\boldsymbol{GT} = \sum_{t=0}^{N} \boldsymbol{ET_t} + \boldsymbol{CIT_t} + \boldsymbol{WHT_t} \qquad (\boldsymbol{3})$$

Results

This section reportsthe integrated biofuels plant economics in Table 4.1 and Table 4.2 respectively,for both Case 1 and Case 2; given the impact of fiscal waivers.

Table 4.1: Economic Indices of Integrated Biofuels Projects (Equity)-Case 1

	Unit	With Waivers	Without Waivers

Source: *Authors' computation*

In Case 1, the NPV15 of the Integrated Project when waivers are in placeis **$190.18 million** and without waivers is **$193.66 million.** While Government Take (GT) on the other hand is **$1.70 million** with waivers and **$17.48 million**without waivers, reflecting a difference of about **$15.78 million.** In Case 1 where only Ethanol, Animal Feed, and $CO_2$are produced, this result implies that the project is not viable to equity investors, even with the waivers. This in turn shows the inadequacy of the government waivers to turn unviable projects into viable projects, at the given cost price structure of the project.

Table 4.2: Economic Indices of Integrated Biofuels Projects (Equity)-Case 2

	Unit	With Waivers	Without Waivers
CapEx	$ Mln	334.50	334.50

Source: *Authors' computation*

In Case 2, NPV15 when waivers are in place is **$247.30 million** while without waivers is **$164.71 million**. Government Takers with waivers in place is $380.14 million and when there are no waivers it isat $861.04 million. Recall that Case 2 comprises the production of Refined Sugar and Electricity in addition to Ethanol, Animal Feed, and CO_2. Dias etal.(2010) also reported the viable economics that results from the addition of refined sugar and electricity generated from biofuels plants. Thus, the sale of surplus electricity produced as a by-product of bio-ethanol from distillation has a positive impact on the economics.Note that in Case 2, the waivers only serve to enhance the project value to the equity investor which is already positive under the no-waivers scenario that is, NPV15 of $164.71 million and IRR of 25%.

Figure 4.1: Government's Receipt-Case 1 **Figure 4.2: Government's Receipt-Case 2**

Figure 4.1 and Figure 4.2 shows the comparison betweenthe Government Take (GT) profilesin Case 1 and Case 2. It provides a deeper revelation of the tax dollar received and the timing of receipts impact of waivers.From thesegiven profiles, it is seen that GT commencement is delayed by 10 years in both Case 1 and Case 2 with waivers, relative to the commencement of GT without waivers. When viewed from a present value angle, the delay in tax receipts caused by the waiver in both Case 1 and Case 2further reduces Government Take. In Case 2 GT with waivers is $480.90Million in undiscounted terms, while in discounted terms it amounts to $30.62Million, which is about 6% the value in undiscounted terms. In Case 1, GT is much lower with the waiver than without waiver, even after taxes begin to flow. This contrasts with Case 2, where once GT (with waivers) commences, the level rises to the level it would be without waivers. Additionally, in Case 1, GT without waiver reduces from 2024 to 2037.This is due to the Withholding Tax (WHT) imposed on the reduction of interests paid by the investors, thus, constituting most of the inflow to the government under this case. The lack of taxable incomeagainst what to charge the Company Income Tax (CIT) enables the bulk of tax receipt to be the WHT on interests. The spike at the end of the profile is due to the later stageavailability of taxable income on which the CIT rate is applied.

Table 4.3: Revenue Contribution of Products from Integrated Biofuels Plant

Revenue Source	Case 1	Case 2
Ethanol	57.89%	18.49%
Yeast	41.98%	13.41%
CO2	0.13%	0.04%
PW Sugar	0.00%	0.00%
Refined Sugar	0.00%	24.58%
Electricity	0.00%	43.48%

Source: *Authors' computation*

Table 4.3 gives a breakdown of the source of revenue to the integrated project under Case 1 and Case 2. Under Case 1, Ethanol contributes about 58 percent; Animal feed contributes about 42 percentwhile sales of CO_2contribute less than 1 percent to the revenue. However, under Case 2, sales from Electricity contribute about 44 percent; Refined Sugar contributes about 25 percent; Ethanol contributes about 19 percent, and Animal Forage contributes about 13 percent. For the economically viable Case 2, the revenue distribution shows that the viability of the integrated biofuels project is dependent on the sales of Electricity and Refined Sugar than it is on Ethanol. This therefore means that:

- Given the poor record of payments for electricity supplied in Nigeria a 44 percent revenue derived from electricity is a high risk to the project (Gershon&Ezurum);
- The biofuels project receives waivers to effectively refine sugar, an activity in accordance to the Nigerian Sugar Master Plan (National Sugar Development Council, 2011).

When focus is on ethanol in the integrated biofuels projects reflecting economic viability, attention is paid to ethanol price with respect to its impacts on the extent of Government Take sacrificed due to waivers (Forgone Government Take, or Government Waivers) where Forgone Government Take (FGT) is defined as:

$$\boldsymbol{FGT = GT_1 - GT_2} \qquad (\mathbf{4})$$

Where:
$\boldsymbol{GT_1}$: Government Take without waivers
$\boldsymbol{GT_2}$: Government Take with waivers

Figure 4.3: Impact of Ethanol prices on Forgone Government Take- Case 1 **Figure 4.4: Impact of Ethanol prices on Forgone Government Take- Case 2**

In Case 1, for ethanol prices up to $1/litre and beyond $1.30/litre the extent of government waivers remains constant at $15.77 million. The extent of waivers increases by $20.47 million for every $0.1/litre increase in ethanol prices. This profile showsthat a minimum ethanol price is needed for government waivers to increase as project profitability increases. However, over the price range considered in Case 2,due to the support provided by the other sources of project revenue, government waivers increase with the ethanol price. These profiles emphasize that government waivers are static below a certain profitability threshold.

Conclusion

Bio-economics has strong potential for innovation and is emerging in many developed countries as a new development model (Viaggi, 2016; Romano, 2012). The Nigerian biofuels policy attempts to strongly build a successful fuel ethanol industry by employing agricultural products. This will in turn, connectthe agricultural and the energy sectors, with the underlying goalto stimulate the development of the agricultural sector. To stimulate private sector involvement in the achievement of a thriving ethanol industry and bio-economy, fiscal incentives were contained in the Nigerian Biofuels policy. Most of the literature surveyed on the biofuels industry in Nigeria centred on food security and environmental impact. This paper, however, considered the fiscal perspective and their economic impacts. The following key findings were obtained:

1. The mandate of 2 billion litres per annum of ethanol blend needsa 10year estimated $22.27 billion Capital Expenditure. This means about **$7.17 billion of** waivers and subsidies are required over a twenty-year period;
2. The biofuels industry when only ethanol is produced is not economically self-sustaining and thus requires **$48.94Billion** (with the waivers in place). This will cause the industry to be profitable with subsidy over a 20years period. At the current ethanol price of $0.67/litre, the retail price of E10 will be **₦17.37/litre** above the current gasoline retail price of ₦145.00/litre and **₦108.57/litre** above the current gasoline price for the industry to achieve a 10% IRR;
3. The ethanol price for E10–gasoline parity is $0.29/litre, a price 57% less than current ethanol prices, which will worsen the biofuel industry economic performance;
4. This analysis also considersan integrated biofuels plant project when given the following production cases:
    a. Case 1: Production of Ethanol, Animal Feed, and CO2
    b. Case 2: Production of Ethanol, Animal Feed, CO2, Refined Sugar, and Electricity
5. Under Case 1, the project is unviable to equity investor even with the waivers thus showing the inadequacy of the Government waivers to improve the unviable project to one that is

viable. Government Take (GT) with waivers is $1.7 million and without waivers is $17.48 million;

6. Under Case 2, NPV15 with waivers is **$247.30 million** while when there are no waivers it is **$164.71 million**. GT with waivers in place is $380.14 million less than when it is without waivers at **$861.04 million**. The waivers in Case 2 only serve to enhance the project value to the equity investor which is already positive under the no-waivers scenario (NPV15 of $164.71Million and IRR of 25%);
7. 68% of revenue from electricity sales is derived for the economically viable projects.

This study highlighted the extent of the biofuels fiscal incentives as contained in the Nigerian Biofuelspolicy. It revealed the impact of implementing biofuels in the fuel mix on consumer spending and illustrates the inadequacy of fiscal waivers within the industry cost price structure and the possible errorsin the biofuels policy. Perhaps, if this policy is changed there could be better outcomes.

The Development of Instruments for Countering Insurance Fraud – Polish And International Solutions

Anna BERA

Institute of Economics and Finance, University of Szczecin, Poland

anna.bera@usz.edu.pl

ORCID 0000-0002-5916-5606

Abstract

The article addresses the issue of insurance fraud in the aspect of instruments used to limit this negative phenomenon on the market. This is a fairly complex economic problem that affects the entire insurance sector, both in terms of domestic and global market. The article indicates the scale of insurance fraud by referring to the figures concerning selected foreign markets as well as data relating to the Polish insurance market. Joint initiatives often adopting the nature of system solutions were illustrated using Poland as an example, but also in relation to the three largest insurance markets in Europe, i.e. the United Kingdom, Germany and France. The internal instruments used by insurers in countering insurance fraud were also presented. This is the result of research among key insurers on the financial market in Poland and trends in international markets based on information from insurance institutions. The article ends with conclusions on possible solutions to increase the efficiency of fraud detection, which may contribute to reducing this negative phenomenon on the insurance market.

Keywords: Insurance, Insurance fraud, Instruments for countering

Introduction

Insurance fraud is a growing socio-financial problem. It is understood as actions contrary to both the law and the interests of insured persons. Participants of the insurance market (insurers, insurance institutions, insured, etc.) are constantly exposed to the risk of insurance and benefit fraud as well as losses caused by various types of criminal acts (Maciążek 2014). The development of the insurance market is accompanied by the perpetual emergence of new ways and methods of fraud, with the constantly increasing range and number of perpetrators of insurance fraud. For a long time in Europe, criminal acts concerned primarily occasional fraud and were mainly related to settlement of motor claims. However, the dynamic development of the financial market caused a change in the approach to fraud mechanisms, as well as their number and the area of their occurrence increased significantly. In the developed European markets (i.e. the United Kingdom, Germany or France) already at the end of the 1990s, insurance fraud began to take the form of organized crime involving specialized criminal groups. Insurance fraud has become a negative phenomenon not only on individual domestic markets, but has also occurred at a meso-level, as the phenomenon of insurance crime is definitely global (cross-border).The research process required the use of the following methods and techniques: critical analysis of literature, desk research, observation, qualitative methods, and graphic presentation of research results.

Insurance fraud as the subject of research

Insurance fraud is the result of many factors: socio-cultural, economic, legal, or already associated with the very specificity of insurance activity. In the book by Bera, Kordela, Pauch and Bera definition of insurance fraud understood as *all crimes and offenses affecting directly and indirectly the interests of insurers, as well as other insurance market participants (insurers, insured, beneficiaries, financial institutions, etc.*) (2019, 2018). In a research study by Derring on the other hand, in a broad sense, insurance fraud means all unfavourable phenomena occurring on the

insurance market, which are identified, verified, and eventually combated and prevented from happening (2002).

Insurance fraud Köneke, Müller-Peters, Fetchenhauer are defining manifests itself, among others, in activities such as (2015):

- providing false or incomplete information in the insurance application;
- submitting a request for compensation based on untrue circumstances of the event in order to obtain benefits from the insurance agreement;
- submitting false documentation and evidence regarding specific damage;
- prohibited acts committed by the insured themselves or third parties;
- crime against the insurer related to individual or group claims as a result of fictitious injuries caused by a road accident;
- acts committed by highly specialized criminal groups aimed at extorting unjustified benefit or compensation.

According to *Insurance Europe*, the scope and scale of insurance fraud varies from country to country. The estimates of *Insurance Europe* indicate that detected and undetected fraud represents up to 10% of all compensations and benefits paid in Europe. According to this organization, the scale of fraud is much higher in countries where insurance supervision is weak for examples in the countries of Africa and some countries of Asia and South America. Furthermore, this number varies between countries and types of insurance due to several factors including the size of the insurance market or the obligation to purchase certain types of insurance.

Table 1 contains estimates of losses due to insurance fraud calculated by *Insurance Europe* in 2015-2016.

Table 1: Losses due to insurance fraud in selected countries

Country	Insurance type	Losses
Germany	All types of insurance	10% of claims
Australia	All types of insurance	10% of claims
Canada	All types of insurance	10-15% of claims
Spain	Motor insurance	22% of claims
The United Kingdom	Personal insurance	7% of claims
Scandinavian countries	All types of insurance	5-10% of claims
The USA	All types of insurance	10% of claims

Source: (Bera, Kordela, Pauch, 2019)

In a research study by Miksiewicz according to international and national institutions, among others the Polish Chamber of Insurance, fraud value may annually constitute 3% of the premiums collected by insurance companies (2015). On the other hand, according to the data obtained by the Polish Chamber of Insurance, the average annual losses from insurance fraud in 2011-2016 in Poland were: in Section I – PLN 9 731 678, in Section II – PLN 142 440 649. Whereas, the median over the period considered was as follows: Section I – 10 227 982 PLN, Section II – 135 730 128 PLN. The annual values of losses of insurance companies are presented in Figure 1.

Fig. 1: Value of fraud in Sections I and II in 2011-2016 (PLN)
Source: own work based on: (Majewski 2017)

The difference in the value of detected fraud between Sections I and II is partly due to the fact that the products of Section I are not equally subject to extortion. Classic life products, accident insurance, as well as group and sickness insurance can be used to generate fraudulent claims. In a research study by Polish Chamber of Insurance On the other hand, the group of products less subject to fraud include investment insurance, which, due to its structure, prevent obtaining compensation by false pretences (2017).

In addition to obtaining indemnities or benefits by false pretences, insurance companies also record insurance fraud outside the area of payment of compensations (Figure 2). In this case, the risk of crime concerns not the client, but mainly the insurance company. Dishonest employees and insurance intermediaries can be a serious source of financial loss.

Fig. 2: Insurance fraud outside the payment of compensations in Sections I and II in 2016 (PLN)
Source: own work based on: (Majewski 2017)

In the "other" category, insurance companies indicate, in particular, money laundering, cybercrime and social engineering. Criminals tend to impersonate the person entitled to receive payments on benefits and take over the payment by changing the bank account number.

Conclusions from the research in the light of Polish experience in the field of joint initiatives in counteracting insurance fraud

The scope of joint initiatives undertaken to counteract insurance fraud, as well as the group of entities involved in this process, is constantly growing. Apart from insurers in Poland, a key role is played by financial institutions (the Polish Financial Supervision Authority, Insurance Guarantee Fund (UFG), the Polish Chamber of Insurance, Financial Ombudsman, etc.), which through their activity and holistic solutions implement tools to improve detection in the field of insurance fraud. Furthermore, the entities involved in counteracting insurance crime include: the Ministry of Justice, Prosecutors, Courts, Police, motor vehicle surveyors, forensic laboratories, scientific and research institutes, and coroner's court, etc. Moreover, this group should include entities that are able to prepare useful expertise in identifying fraud in such fields as: automotive, mechanoscopic, physicochemical, document and writing examination, firefighting, accounting, medical, reconstruction of road accidents, or interdisciplinary.

The results of research conducted among all insurers operating in Poland (in 2018) show that among the joint initiatives first of all the following should be mentioned:

- improving the quality and speed of information exchange between insurers,
- inspiring legislative initiatives to help prevent and counter insurance fraud,
- cooperating with the Police and other institutions, as well as the very activity of these institutions,
- developing joint initiatives in the field of IT (information technologies) tools,
- educational and preventive activities.

An efficient and effective system of information exchange between insurers is one of the priorities of the institutions whose activities focus on improving the quality of preventive activities in the field of insurance fraud. Information plays an important role in the proper functioning of insurance companies. Without reliable, high-quality and timely information about suspected damage, the insurer's ability to make the right decision in the claim settlement process is at a significant risk of error. Information from various sources is used during claim settlement. Hence, an important factor in the proper investigation process of investigating a prohibited act is cooperation between insurance companies and public administration institutions, as well as law enforcement authorities and courts. In the exchange of information, the effectiveness of the system is determined by: the reliability of exchanged data, transmission speed, functioning of the system in accordance with applicable legal standards, and security of data transmission.

A special role in the Polish insurance market in terms of identifying insurance fraud will be played by a platform created as a part of the Integrated Platform for the Identification and Verification of Insurance Crime project launched on February 4, 2019. The platform's task, which is the basis for knowledge about insurance fraud, is to support all insurance market participants in disclosing and counteracting fraud. This platform enables (www.ufg.pl) primarily:

- identifying, verifying and sharing information on phenomena related to insurance fraud,
- formulating inquiries and conducting analyses of insurance fraud phenomena based on data held by UFG,
- sharing information in the field of multiple motor insurance,
- providing information on the results of verification of facilities submitted by insurance companies with public registers,
- sharing information about vehicles and material damage,

- secure communication as part of reported incidents of a criminal nature,
- access to the Knowledge Base for international institutions, insurance companies and citizens.

The aim of the platform is the typing of suspicious claims and payments, as well as criminal networks that simultaneously affect many insurance companies through the use of advanced analytical techniques (including predictive models and data mining tools). As consequence, the use of the new tool is to lead to effective reduction of the scale of insurance fraud in Poland. Although it is impossible to completely eliminate this negative phenomenon from the market, limiting it to a size that does not threaten the financial stability of insurers is already becoming a real and feasible goal for entities in the insurance sector.

Conclusions from the research in the scope of internal activities of insurers used in countering insurance fraud (regardless of the insurer's country of origin)

Insurance companies themselves should play an important role in the fight against insurance fraud. In addition to commonly used reports and inquiries within available information databases, scoring methods are one of the modern and increasingly common ways used to fight insurance fraud in the area of research on insurance extortion probability. The range of scoring models used is very extensive in terms of operational risk, as well as supports detection of insurance fraud. The aim of the predictive model is to minimize its effect on the entire claim settlement process in terms of time, costs and quality, while effectively isolating claims with the highest risk of fraud. The early warning system allows for analysis of the symptoms of extortion and, consequently, for actions leading to a reduction or temporary refusal to pay compensation. Statistical models and data mining is used to efficiently and quickly detect fraud regarding damage and are the basis for building a utility predictive model (Figure 3).

Figure 3: Suspected damage detection process

Source: own work.

In a research study by Leśniarek-Woźniak, Raubo in statistical models of the type – *data mining* – fraud modelling in the form of enhanced trees can be used (2012). Along with the increase of awareness and knowledge of insurance institutions about the risk related to offenses committed in the area of fraud insurance, risk management strategies have become an important factor in mitigating the risk. Strategies for managing fraud risk can influence its reduction as well as mitigation of negative consequences. For this purpose, risk maps and other supporting tools are used. They consist of four interdependent elements having a direct impact on the level of organization resistance through assessment, prevention, detection and reaction technique. In a research study by Flejterski the elements that make up the whole risk management strategy include (2013):

- threat assessment, which is the first step on the way to managing fraud risk; before implementing preventive strategies, risk factors should be identified, categorized and assessed, as well as identification regarding which of them requires restriction and what strategy to use for this purpose should be carried out;
- implementation of preventive strategies based on estimating risk factors; there are many such strategies – from promoting corporate ethics to control methods; preventive strategies aim to anticipate, counteract and discourage to commit offenses;
- selective implementation of fraud detection strategies; the scope and intensity of these activities may vary – from periodic audit to constant monitoring of transactions (random checking of selected transactions or checking all transactions in real time);
- preparation of logical scenarios for responding to detected fraud in order to minimize their negative impact on the company and to protect it against the consequences.

The constant emergence of new forms of fraudulent insurance claims on the market indicates that in order to combat insurance fraud, particular emphasis should be put on the development of innovative tools to counteract this phenomenon. To this end, IT tools used in insurance companies should be systematically developed in order to identify undesirable phenomena. The new tools are to help effectively identify fraud patterns of behaviour and anomalies, as well as indicate risks and threats. In a research study by Dudek it appears that a large amount of data available in insurance companies can be properly analysed only when using dedicated IT systems, which, thanks to advanced analytics, are able to properly combine and interpret it (2017). At the same time, another important element used in this process are networks of connections. The analysis of links between entities allows discovering hidden relationships and suspicious interdependencies between clients, accounts, vehicles, damage or other entities.

In a research study by Morley, Ball, Ormerod thus, two main approaches applied to combat fraud by technology can be identified (2016). The first and perhaps most common is the use of data mining methods, in which systems make it possible to access databases of information on customers and claims, and cross-check it with external data sources for identification. The other technology-based approach to combat fraud employs methods that aim at 'profiling' probable fraudsters, including techniques such as voice stress analysis. However, techniques such as voice stress analysis require direct contact of the insurance company with the insured. This is somewhat difficult, as more and more insurance products are sold through external entities, e.g. insurance intermediaries and via the Internet.

According to a survey conducted by Accenture (data from 2014), the most important initiatives taken by insurers to increase the detection of fraud include use of modelling techniques, improvement of data collection processes from both internal systems and external sources, increased support by the IT department. The research results indicate that in the next years insurers will focus mainly on organizational restructuring, training courses and process improvement in order to increase the level of fraud detection. The use of analytical methods (76 percent), providing better IT support and optimization of data collection processes are becoming a priority (Figure 4).

Fig. 4: Key initiatives implemented by insurance companies to improve fraud detection
Source: (Accenture, 2016)

Another important element is the development of analytical tools to identify fraud damage by assessing transactions in real time. This involves combating insurance fraud at the time of taking out insurance (and not, as before, only at the stage of claim settlement).

Countering Insurance Crime – Experience from Key European Insurance Markets

The scope and scale of fraud in individual countries varies. The diversity results from many factors related to the functioning of national financial markets. It is also the result of the state's financial policy and public-legal relations. Due to the differences in the offenses committed in the insurance sector, the approach and method of identification, as well as the selection of insurance crime prevention tools, differ. In some countries, the most important task in the fight against crime is to determine the number of revealed and undisclosed offenses and fraud in order to assess losses and select risk management instruments regarding insurance fraud. Whereas in other countries, crime prevention institutions focus on the ongoing detection of insurance fraud to limit the payment of fraudulent damage and benefits (www.insuranceeurope.eu 2019). Regardless of the approach, the aim – which is to define current and future activities and initiatives that will effectively and thus efficiently prevent fraud attempts – is the same. Selected initiatives and actions taken on foreign markets are quite diverse, which was presented in relation to the market in the United Kingdom, Germany and France.

The United Kingdom

Initiatives to reduce insurance fraud are common in the UK. An example is the activity of *the Insurance Fraud Enforcement Department* (IFDE), which is a specialized police unit dealing in combating insurance fraud (www.cityoflondon.police.uk 2019). Established in 2012, the IFED is funded by the Association of British Insurers (ABI) and members of Lloyds of London. It is a part of the City of London Police Economic Crime Directorate. The team of IFDE detectives, investigators and police employees operates independently, working closely with the insurance industry. The IFDE prevents established crime in the field of motor insurance, civil and commercial liability while

focusing on emerging threats such as illegal insurance advisers. The unit also actively fights organized crime groups that are responsible for the growing number of insurance fraud on the UK financial market. Also in the United Kingdom, a special institution named the *Insurance Fraud Bureau* was established, whose activity is focused on detecting and preventing organized insurance fraud. The IFB conducts and coordinates the work of the insurance sector in identifying fraud detectability and cooperates closely with the police and other law enforcement agencies.

The Insurance Fraud Register (IFR) is an important tool on the British market. It was launched in 2013 as the first industry cross-sectoral database of insurance fraudsters. Two-thirds of the insurance market (by market share) is currently registered and uses this service, which includes approximately 18 000 records about dishonest individuals, businesses and entities on various personal and commercial lines. In December 2017, the IFR Board decided to extend the rights to include members of the *Lloyd's Market Association*. The IFR software plays an important role as an information exchange system for insurers. The system can be used in the investigation of property and life crimes, as well as at any time during the life cycle of the insurance product. For security reasons, only insurance companies that meet certain requirements can use the system. Furthermore, the information contained in the programme must strictly fall under the definition of insurance fraud, whereas registered entities have the right to appeal against the decision in order to dismiss the allegation of committing insurance fraud. Although the IFR is not intended to generate an automatic result on the crime committed, it supports the entire decision-making process and the management of fraud risk in the area of insurance. The system allows a thorough analysis of the case being investigated – enables its assessment, scale and area of operation, and also supports in the process of selecting instruments for preventing insurance crime.

Germany

In Germany, among the many initiatives taken in this field, the Warning and Information System tool - HIS (Das Hinweis- und Informationssystem der Versicherungswirtschaft) occupies a particularly important place. The German Warning System is primarily used to counteract insurance crime and supports fraud risk assessment. This tool has been developed in close cooperation with the authorities dealing with the protection of personal data to maintain full security. The basic structure of the system was established in 1993. The current system is the result of evaluating warning files initially used only for motor insurance. Then, the system was gradually implemented in the scope of other types of insurance. The system is responsible for assessing the risk of an insurance claim in terms of an attempt to extort a compensation / benefit. A HIS message about a suspected attempt to extort an unjustified benefit does not completely reject the application, but it prompts the insurer to further investigate the case. HIS acts as a warning signal if irregularities are detected. As an information centre, it also collects data on the insurer (in terms of: the type of risk covered by the agreement, the general conditions of the agreement concluded, other information that may be useful in the course of the investigation of an insurance fraud).

The German Warning and Information System is an instrument designed to increase effectiveness in counteracting insurance fraud. Its fundamental feature is transparency, reliability and accuracy of information while maintaining full security of transmitted data. This system is the fundamental database for the German insurance market, which is currently used by the majority of active insurers on the market.

France

According to data published *by the French Insurance Federation* (Fédération Française de l'Assurance – FFA), a significant increase in insurance fraud in all areas of insurance has been recorded (/www.ffa-assurance.fr 2019). According to the organization's estimates, French insurers spend about EUR 20 million annually on combating this negative phenomenon. France is certainly a pioneer in the fight against insurance fraud, as the anti-fraud agency ALFA was created in 1989. ALFA is a specialized organization aimed at supporting the fight against crime, which creates new instruments to prevent fraud and supports activities aimed at combating insurance fraud. The agency

aims to raise public insurance awareness and train specialized experts to fight insurance fraud. Due to the dynamic development of new forms of insurance fraud, at the request of the employees of this organization in 2012, the country's political control against insurance fraud was increased. This was due to the fact that this phenomenon is becoming increasingly negative for individual, collective and economic interests of the country.

SAS is another tool in the fight against insurance fraud, dedicated to insurance companies in France. This application is a complete solution for the prevention, detection and management of fraud risk in the area of all available insurance. This solution includes detection, management, alarming, investigation, analysis, statistical research on unfair behaviour and monitoring of fraudulent behaviour (www.sas.com/ru 2019). Among the benefits of using the SAS system in countering insurance fraud, market experts state: reduction of losses caused by fraud, detection of similarities in acts committed, enriching the rules and instruments for combating insurance fraud, increasing detection of internal fraud and organized groups, the possibility of building complex detection models.

Conclusion

The development of innovative anti-fraud systems is the only possible way to increase efficiency in detecting crime and insurance fraud. The use of ICT solutions is a great opportunity to increase the transparency of the insurance market. These solutions allow for: early detection of fraud, increasing the efficiency of preliminary investigations, greater involvement of operational units in preventing fraud, and limiting expenses related to fraud. Nevertheless, it should be borne in mind that in the whole process of detecting insurance fraud, man still remains the key element. Even if the system correctly detects irregularities, the employee of the insurance company must properly analyse and address them as well as decide what to do with a given case.

The anti-fraud solutions adopted in Poland and other emerging countries are largely based on the system solutions presented in the article and used in the United Kingdom, Germany and France. An example is the implementation of an integrated platform for the identification and verification of criminal activities (which took into account the experience of the discussed markets). It should also be noted that a significant part of the initiatives undertaken in this area are joint projects, an example of which is the successfully completed endeavour of the Baltic countries. It was the Oslofjord project, whose creator was the Norwegian government, dedicated to coastal, organized crime in Norway and Scandinavia, and the Baltic States of Europe. It allowed breaking up of one of the largest organized criminal groups responsible for insurance fraud in Scandinavia.

In conclusion, it should be stated that it is important for insurance companies to be leaders in building and implementing modern solutions in detecting fraud and improving defence mechanisms in the technological, process and human areas. The role of state insurance institutions remains paramount and is significant above all in the context of financial security of the financial system of the state as a whole.

Abstract

In article the question of the beginning of a scientific discussion about the urgent need of development and introduction of a global objective system of assessment of a condition of sustainable development in Ukraine in modern conditions are updated, the present place of our state in the global world rankings is shown, the key conventional international rates (indicators) which can be used at assessment of the state of affairs in the state (society) are analysed. An innovative author's algorithm for the development and introduction of a global aggregated system for assessment the state of sustainable development with step-by-step detail, consistent with modern democratic principles of international cooperation, which is based on existing public available tools, does not require additional financial and material costs and can be implemented in the shortest possible time is proposed, based on the study of international experience.

Keywords: the aggregated system of assessment of a condition of sustainable development, sustainable development, state policy of regulation of a system of assessment of a condition of sustainable development, the aggregated rates (indicators).

Introduction

Like the vast majority of the developed countries of the world, Ukraine is in urgent need of professional scientific justification for the basic principles and practical ways of implementing state policy aimed at developing new approaches to the development and implementation of an aggregated system for assessing the sustainable development of the state in the current conditions of global transformation.

The assessment of the current state of sustainable development and its The assessment of the current state of sustainable development and its prospects in the various spheres of human activity is essential for any country in the world. This scientific and practical problem has become particularly urgent for Ukraine at the current stage of the state - after the annexation of the Crimean peninsula and the deployment of hybrid aggression by the Russian Federation in eastern Ukraine. Objective analysis of the development of the Ukrainian state and society in the sustainable development, constant monitoring of the domestic security of the environment are an integral part of the system of ensuring the sustainable development of Ukraine and require constant professional expert and predictive support.

The tasks to improve the state system of strategic planning, to create a unified system of monitoring, analysis, prediction and decision-making in the sustainable development were initiated as early as January 2015 in the Strategy for Sustainable Development "Ukraine-2020" (President of Ukraine, 2015),

However, despite the held organizational and administrative and scientific and communicative events, it is not possible to introduce more or less effective system of indicators (rates) of a condition of sustainable development of Ukraine for information and analytical support the leaders of the state of the estimated and expected data necessary for decision-making on questions ensuring sustainable development in peace time, the crisis periods and during the special period yet.

The works of such well-known scientists, as (N. Andreev, 2010; I. Bystriakov, 2012; O. Bilorus, 2006; B. Burkynskyi, 2011; V. Heiets, 2000; Z. Herasymchuk, 2004; B. Danylyshyn and O. Maslyukivska, 2008; M. Zhurovskyi, 2006; V. Kravtsiv and P. Zhuk, 2013; L. Melnyk and O. Kubatko, 2009; A. Mokii and M. Flaychuk, 2008; P. Nadolishnyi, 2002; M. Pashkevych, 2012; V. Potapenko, 2013; D. Stechenko, 2007; V. Trehobchuk, 2004; E. Khlobystov, 2008) and others are devoted to the study of various aspects of defining and understanding the essence of sustainable development, as well as the definition of its components at the present stage of development.

However, issues related to the methodology of development and introduction of the aggregated system of evaluation of sustainable development of Ukraine in the conditions of modern challenges and threats remain insufficiently developed in the domestic and foreign literature. Today, the need to study the mechanisms of implementation of the state policy aimed at forming new approaches to the development and introduction of an aggregated system of assessment of the state of sustainable development of the state, as well as to determine the methodology of its regulation is particularly relevant.

The main purpose is the author's theoretical and methodological justification of the basic principles and practical ways to implement the latest approaches to the state policy of regulating the processes of social and economic changes aimed at the development and introduction of an aggregated system of assessment of the state of sustainable development of Ukraine in the context of the latest geopolitical realities.

Research Methodology

In our study we proposed an author's vision of new approaches to the introduction of an aggregated system of assessment of the state of sustainable development, which determine the place of Ukraine among other states of the world almost in a hundred parameters and characterizes the situation in almost all spheres of life of Ukrainian society.

The analysis made it possible to propose an author's algorithm for the development and introduction of a global methodology for assessing the state of sustainable development not only of Ukraine, but also of other states in the field of sustainable development.

At the first stage. Not to develop (invent) own exclusive parameters or assessment indicators, but to borrow them in already existing recognized world methods and ratings. It is only necessary to determine which of them we need in order to fully characterize the state of sustainable development of a particular state. The use of any parameters (indicators) of the world global ratings is free subject to copyright, they are public available and regularly updated.

At the second stage. It is necessary to group borrowed parameters (indices) into areas of sustainable development. If necessary, on the basis of them, to develop integral (aggregated) indices in order to integrated assessment of the overall state of sustainability of a particular state and society in the field of sustainable development. Then determine the form and frequency of presentation of the obtained results (comparative table, charts, maps, etc.).

At the third. Develop and implement a targeted international PR strategy to advance our methodology (rating) for a global assessment of the sustainability of the world's states and societies in the field of sustainable development. At this stage, the mandatory participation of international organizations, the Ukrainian world diaspora and foreign foundations is expected. Such activities should become a strategic task in the near future for Ukrainian state institutions.

In the study we used methods of system approach and system analysis of rates (indices), which together allowed to reach a more or less objective assessment of the general state of sustainable development of the states of the world and to determine the place of Ukraine in this system in the first approach. This study was carried out on the following aggregates:

- The sustainable society index is determined by indicators (sufficient food, sufficient to drink, safe sanitation, education, healthy life, gender equality, income distribution, population growth, good governance, biodiversity forest area, biodiversity protected area, renewable water resources, ecological footprint, energy use, energy savings, greenhouse gases, renewable energy, organic farming, genuine savings, GDP, employment, public debt);

- Worldwide Governance Indicators (WGI) – the methodology, rates of which were used to measure the overall sustainable development status of each individual country in the world by key management ratings (indices) of administration (voice and accountability, political stability and lack of violence/terrorism, government effectiveness, regulatory quality, the rule of law, control of corruption).

Using the method of prediction, the effectiveness of state policy of Ukraine in the field of regulation and prediction of rates of sustainable development were assessed.

Research Results and Discussion

UN Millennium Development Goal, which was adopted in 2000, by 189 countries at the UN Millennium Summit, and which established a comprehensive framework of values, principles and key factors of development under the three core UN mandates: peace and security; development; human rights, is the modern guide to human development for the entire civilized world. The road map for the implementation of the Millennium Development Goal proposed a set of eight universal goals, with specific time frames and quantitative indicators, aimed at eliminating all major obstacles to the decent life of every human being in any society, namely, the eradication of hunger and extreme poverty; access to education; ensuring gender equality; reducing maternal and child mortality; reducing HIV/AIDS and other diseases; environmental sustainability and harmonization of external assistance for developing countries (Millennium Development Goals Ukraine: 2000 - 2015: National Report, 2015).

In September 2015, within the 70th session of the UN General Assembly, the world community defined new guidelines for the development of mankind for the next fifteen years (2015-2030), called Transforming our world: The 2030 Agenda for Sustainable Development and presented in the form of seventeen global Sustainable Development Goals.

Ukraine, by participating in the historic United Nations Summit for Sustainable Development in Rio de Janeiro (Rio+20), has clearly demonstrated its strategic freedom to shape its own future on the basis of the principles of sustainable development. Along with other countries, our country have worked hard to realize the Millennium Development Goals determined by the results of the UN Millennium Summit held in 2000. Thus, in January 2015 the Strategy of Sustainable Development "Ukraine - 2020" was approved by the Decree of the President of Ukraine P. Poroshenko, in which, in addition to general phrases about the transition to a new era of history and a unique chance to build a new Ukraine, a number of concrete practical measures were defined with the aim of introducing European standards of life in our state and reaching the leading positions in the world (President of Ukraine, 2015).

In September, 2019 the Global sustainable development goals till 2030 proclaimed the Resolution of the General Assembly of the United Nations of September 25, 2015 No. 70/1 were supported by the Decree of the President of Ukraine V. Zelenskyi and the results of their adaptation taking into account specifics of development of Ukraine stated in the National report of “a sustainable development goals of Ukraine” and also definite purposes of sustainable development of Ukraine until 2030 (Ministry of Economic Development and Trade of Ukraine, 2017); President of Ukraine, 2019).

According to the carried-out analysis, for two decades from the moment of the official introduction the concept "sustainable development" already left the plane of purely scientific term, and is rather widely used by the international community (in particular, in acts of the UN and the EU) and domestic political elite not only in standard and legal documents, but also in daily communications.

The introduction of the term "sustainable development" is the official Ukrainian equivalent of the English term "sustainable development", the literal translation of which, according to the context, can be "viable development" and, within the meaning of "self-sustaining development", can also be interpreted as a comprehensively balanced development. According to the United Nations Commission on Sustainable Development, its purpose is to meet the needs of modern society without compromising the ability of future generations to meet their needs.

Lee Endress & James A. Roumasset (1994) mentioned that the theory of sustainable development is an alternative to the paradigm of economic growth, which ignores the environmental danger from development according to an extensive model (Endress and Roumasset, 1994).

Today, in investigating new approaches to public policies of regulation in the field of sustainable development, we put special emphasis on operating an aggregated system of assessment of its provision.

According to recent data, Ukraine has strengthened its position in key international ratings, which provides an argument for certain stabilization of the situation in the country as a whole, a tangible improvement in the tax burden situation, economic freedom, competitiveness of domestic institutions, gender equality, etc. Analysis of the dynamics of rates of key international indices (Table 1) shows indirectly the continuous and gradual growth of the stability of the Ukrainian state and society in the sustainable development.

Table 1: Ukraine's positions in key international indices

Name of rating	Year	Place of Ukraine/total number of countries [a]	Dynamics [b]
The Global Innovation Index	2017	50/127	+ 6
Fraud Surveys: Corruption perception	2016	1/41	+ 1
Global Terrorism Index	2017	17/134	- 6
Global Peace Index	2017	154/163	+ 2
GCI - WEF	2017	53/137	+ 1
Rule of law index	2017	77/113	+ 1
The Global Gender Gap Index	2017	61/144	+ 8
Index of Globalization	2016	45/207	- 3
Democracy Index	2017	83/167	+ 3
The Global Wealth Report	2016	95/173	- 12
Environmental Performace Index	2017	109/180	N/A
Index of Economy Freedom	2017	150/180	+ 16
English Proficiency Index	2017	47/80	- 6
Bloomberg innovation index	2017	46/50	- 4
The Global Competitiveness Index	2017	81/137	+ 4

Name of rating	Year	Place of Ukraine/total number of countries [a]	Dynamics [b]
Higher Education	2017	35/137	- 2
Institutions (GCI-WEF)	2017	118/137	+ 11
Easy of Doing Business	2017	76/190	+ 4
Global Slavery Index	2016	25/167	N/A
Human Development Index (UNDP)	2016	84/187	without changes
Fragile States Index	2017	90/178	- 5
Global Firepower Military Ranks	2017	30/133	without changes
The legatum prosperity index	2017	112/149	without changes
Social Progress Index	2017	64/128	- 1
Corruption perception index	2017	130/180	+ 1
World Happiness Report	2017	138/156	- 15
Happy Planet Index	2016	70/140	N/A
Paying taxes ranking	2017	43/189	+ 41
WCY	2017	60/63	- 1
World Press Freedom Index	2017	102/180	+ 5
Freedom in the World (Freedom House)	2016	107/195	+ 1
The Human Capital Index	2017	24/130	+ 2

Source: Own elaboration with (Ukraine in global rankings, 2020)

The established world practice of assessment of the situation in a certain state is based on the methodology of using appropriate special indicators (indices), which allow to give the most objective assessment of the state or changes taking place in certain spheres of life of the country (society). The main purpose of such a methodology is to assess the current state of affairs (or events) in a separate sphere of life, to develop a prediction of the most probable development of the situation, as well as to develop a strategy (action plan) for its positive solution.

The analysis highlights two main approaches that are used in the leading countries of the world and include the use of special indicators (indices) to assess the situation in the state:

The first

Construction of a system of indicators (indices), by means of which it is possible to estimate certain aspects of the state and development of certain spheres of life of the state (society), for example:

- citizens' satisfaction with the degree of protection of their constitutional rights and freedoms, personal and property interests, in particular against criminal trespasses;
- weight of modern weapons, military and special equipment in the structures of the security and defence sector of the country;
- life expectancy;
- gross domestic product per capita;
- the decile ratio of income-consumption differentiation (the ratio of income of 10% of the richest population to income of 10% of the poorest, or per capita, consumption of goods and services);
- inflation and unemployment rates;
- share of expenses for the development of science, education, culture, health, etc. in gross domestic product;
- the proportion of the country's territory that does not meet recognized environmental standards.

The second

Development of integral (aggregative) indices for the purpose of comprehensive assessment of the overall state of affairs in the state (or region). The main disadvantage of this approach is that it is almost impossible to clearly determine the weight of the initial rates for assessing the general status of the state (society) without losing their importance and then avoiding subjectivity.

Currently, there is no conventional science-based quantitative rate (index) that measures the overall state of an individual state and society in the sustainable development objectively. However, many countries of the world and international organizations use quite widely various methods, which allow to make a general assessment of the state of sustainable development of both the individual country and the region as a whole, indirectly, through analysis of quantitative raates of certain aspects of social, political, economic, sociocultural, environmental and other life of the country.

Among such methods, the analysis of rates (indices) of which in conjunction allows to reach in the first approximation for a more or less objective assessment of the overall state of each individual state in the sustainable development, should be:

The Sustainable Society Index is a combined indicator of the Sustainable Society Foundation that measures countries' achievements in terms of sustainability of social development. Research direction: study of economic and social processes. The area of research is public administration. Started from 2006 to the present. The frequency of the study is regular, once every few years. Project leaders: Geurt van de Kerk and Arthur Manuel (SSF, 2020).

Indicators for determining the Sustainable Society Index for the countries of the world

The Sustainable Society Index is determined by such indicators for the countries of the world:

1. Sufficient Food: number of undernourished people in % of total population. The index is developed and regularly published by the Food and Agriculture Organization, FAO) (SSF, 2020);

2. Sufficient to Drink: number of people as % of the total population, with sustainable access to an improved water source. The index is developed and regularly published by FAO;

*3. **S**afe Sanitation*: number of people in % of total population, with sustainable access to improved sanitation. The index is developed and regularly published by FAO;

4. Education: combined gross enrolment ratio for primary, secondary and tertiary schools. The index is developed and regularly published by UNESCO (UNESCO Institute for Statistics, 2009);

5. Healthy Life: life expectancy in the country. The index is developed and regularly published by World Health Organization, WHO (World Health Organization, 2020);

6. Gender Equality: gender gap index is defined in the Annual Global Study of the World Economic Forum with the accompanying world ranking (Economic Discussion Club, 2017);

7. *Income Distribution*: ratio of income of the richest 10% to the poorest 10% of the people in a country. The index is defined by the World Bank for each certain country of the world (World Bank. 2018);

8. *Population Growth*: 5-years change in total population size (in %). Index is determined and published by WB;

9. Good Governance: sum of the values of the six Worldwide Governance. Index is determined and published by WB;

10A. Biodiversity forest area: 10-year change in the forest area of the country. The index is defined according to the program document of the UN Transforming our world: the 2030 Agenda for Sustainable Development and is also regularly published in the Protected Planet Report) (Protected Planet Report, 2016));

10B. Biodiversity protected area: protected land area in % of land area of the country. The index is defined in Protected Planet Report;

11. Renewable Water Resources: annual water withdrawals in m^3 per capita as % of renewable water resources. Index is developed and regularly published by FAO (FAO, 2016);

12. Ecological Footprint: degree of human impact on the natural environment, which makes it possible to calculate the necessary size of the surrounding area for restoration of consumed environmental resources and absorption of waste products. The index is determined and regularly published by Global Footprint Network, an international nonprofit organization (The Ecological Footprint, 2020);

13. Energy Use: energy use in tons oil equivalents (toe) per person. The index is determined and published by International Energy Agency, IEA (IEA, 2020);

14. Energy Savings: 4-year energy consumption change index in %. The index is determined and published by IEA;

15. Greenhouse Gases: CO_2 emissions per capita per year. The index is determined and published by IEA;

16. Renewable Energy: consumption of renewable energy as % of total energy consumption in the country. The index is determined and published by IEA;

17. Organic Farming: area for organic farming in % of total agricultural area of a country. The index is determined and published by Research Institute of Organic Agriculture, FiBL (FiBL & IFOAM – Organics International, 2016);

18. Genuine Savings: Adjusted Net Savings as % of Gross National Income. The index is determined and published by WB (Hamilton, 2020);

19. GDP: integrated index, which is regularly determined and published by the International Monetary Fund, IMF based on analysis of Gross Domestic Product per capita, PPP and current international $ for each country of the world (IMF, 2020);

20. Employment: unemployment as % of total labour force of the country. The index is determined and published by WB (World Bank, 2020);

21. Public Debt: the level of public debt of a country as % of GDP. Index, which is regularly determined and published by the International Monetary Fund, IMF for each country of the world (IMF, 2015).

Today the general data of the Sustainable Society Foundation (SSF) include information on the specified rates for 154 countries of the world for 2006-2016 period, as well as progress over the past 10 years. It made it possible for us to summarize the current data on the rating of Ukraine according to the Sustainable Society Index (SSI) of the world countries for the specified period, which is provided in free access and present them in the (Table 2 and Figure 1).

Table 2: Analysis of Rating of Ukraine on the Sustainable Society Index of the world countries for the period 2006 - 2016:

Human Wellbeing						
Year	**2006**	**2008**	**2010**	**2012**	**2014**	**2016**
Rate	33	31	27	31	30	36
Environmental Wellbeing						
Year	**2006**	**2008**	**2010**	**2012**	**2014**	**2016**
Rate	106	98	97	102	102	85
Economic Wellbeing						
Year	**2006**	**2008**	**2010**	**2012**	**2014**	**2016**
Rate	44	44	48	61	102	130

Figure 1: Rates of Ukraine on SSI Sustainable Development Indices
Source: elaboration with (SSF, 2020)

Information:

On the Fig.1 – the spiderweb shows the score of each of the 21 indicators of the country in green, on a scale of 1-10 (10=sustainable, 1=not sustainable). The red line is the weighted average score of all countries..

Worldwide Governance Indicators **(WGI) –** is another methodology that can be used to assess the overall sustainable development situation of each individual country in the world. A project initiated by the World Bank (WB) since 1996 presents aggregate and individual management success rates in selected countries across six key management ratings (indices):

- Voice & Accountability (*Note:* the Voice & Accountability rate records the extent to which citizens can participate in the election of their government, the state of freedom of speech, assembly and the media);
- Political Stability and Lack of Violence;

- Government Effectiveness;
- Regulatory Quality (*Note:* the Regulatory Quality indicator reflects the ability of the government to formulate and implement robust policies and procedures that enable and promote private sector development);
- Rule of Law;
- Control of Corruption.

The aggregative WGI rates combine the views of a large number of respondents with more than 30 organizations, institutions and experts, use more than 40 data sources relating to nearly 200 countries and are updated annually since 2002.

According to The Global Economy data, the average value of *the Voice & Accountability index* was – 0.03 points among the countries of the world for 2016. The largest value was in Norway: +1.58 points, and the lowest – in North Korea: – 2.13 points. Ukraine scored +0.02 points in this rating and took 100 place of 194 countries of the world.

The average value of *the Political Stability index* is 0.04 points. Singapore had the highest value: +1.53 points, and the lowest is in Syria: - 2.91 points. Ukraine scored - 1.89 points in this rating and took 183 place of 194 countries of the world.

The average value of *the Government Efficiency index* is 0.02 points. The largest value was in Singapore: +2.21 points, and the lowest – in Somalia: – 2.18 points. Ukraine scored – 0.58 points in this rating and took 131 place of 193 countries of the world.

The average value of *the Regulatory Quality index* is 0.03 points. Singapore had the highest value: +2.18 points, and the lowest is in North Korea: – 2.33 points. Ukraine scored – 0.43 points in this rating and took 120 place of 192 countries of the world.

The average value of *the Rule of Law index* is – 0.04 points. The largest value was in Sweden: +2.04 points, and the lowest – in Somalia: – 2.37 points. Ukraine scored – 0.77 points in this rating and took 147 place of 193 countries of the world.

The average value *of the Control of Corruption index* is – 0.04 points. The largest value was in New Zealand: + 1.3 points, and the lowest – in Guinea: –1.81 points. Ukraine scored – 0.84 points in this rating and took 153 place of 193 countries of the world (TheGlobalEconomy.com: Business and economic data for 200 countries, 2018).

Conclusions

Today, Ukraine is presented in more than three dozen various global world rankings which define our place among other countries of the world almost behind one hundred parameters characterizing a situation practically in all spheres of human activity. However, none of these generally recognized global ratings aims to carry out a comprehensive integrated ranking of the countries of the world according to the criteria of sustainable development, assessment of stability of the state and society, level of development of the security and defense sector, etc. There are no universal methods in the world that allow an objective comparative analysis of the place (rating) of Ukraine among other countries of the world in the context of realizing their own national interests and ensuring the sustainability of the state and society in the field of sustainable development.

In the context of the hybrid war launched by the Russian Federation not only against Ukraine, but against the rest of the civilized world (interference in the last election of the President of the United States, provoking a wave of illegal migration to the European Union, terrorist acts in Great Britain, etc.), our country and the international community demand urgently the development and introduction of a global comprehensive methodology for assessing the state of sustainability of states and societies in the sustainable development. The practical implementation of such a project undoubtedly will have a positive impact on the image of Ukraine on the world stage and will bring

our country to a qualitatively new level of international cooperation.

The existing experience of developing own (exclusive) methods of assessing the state of sustainable development in Ukraine shows that this process, despite a decade of history, does not have more or less logical completion, and then – practical implementation yet. At the same time, the main disadvantage is the lack of a unified approach to assessing the state of sustainable development, the subjectivity of the evaluation criteria, the lack of tools and financial support for constant monitoring. And even if we`ll ever be able to develop an exclusive system for assessing the state of sustainable development, the process of its recognition in the international arena seems rather problematic.

The proposed conceptual approach (scenario) for the development and introduction of a global integrated system for the assessment of the state of states in the sustainable development is consistent with the modern democratic principles of international cooperation, based on new public available tools, will not require additional financial costs and can be implemented as soon as possible. In addition, such an approach can be applied to the development of systems for assessing the national sustainability of the state, the capacity of the security and defence sector, etc.

Abstract

This paper proposes that urban agriculture (UA) enables urban farmers to cope with issues of food, economic, and social insecurity, as well as lack of urban green space; therefore, it contributes to the practical efforts made towards sustainable urban development. In Jakarta, some programs and policies have been developed to manage existing UA practice. However, some practical gaps and environmental challenges are left unaddressed, thus limiting their performance in supporting and sustaining UA development. This study considers urban farmers' motivation to farm and their experienced benefits from farming as critical success factors in sustaining UA activities. This study was done qualitatively by employing focus group discussions and questionnaire surveys to identify and analyze urban farmer's motivation to farm and their experienced benefits from farming in Central Jakarta—the centermost municipality of Jakarta. Results revealed gaps in urban farmers' motivations and experienced benefits from farming that had not been addressed by the currently implemented UA policies. From therein, some entry points for policy development were discussed. It was concluded that with no novel approach and policy intervention, it will be increasingly challenging for urban farmers to sustain UA activities; this will also hinder UA's contribution to sustainable urban development.

Keywords: Urban Agriculture; Urban Development; Motivation; Perceived Benefits.

Introduction

Urban agriculture (UA) is defined as the activity of planting, processing and distributing food products through the cultivation of plants and animal husbandry in and around urban areas (Mougeot, 2006; RUAF Foundation, 2018; Zezza & Tasciotti, 2010). The integration of agricultural system into the urban environment through UA is considered to be a strategy that enables urban farmers to cope with societal challenges or urbanization such as: food, economic, and social insecurity, as well as lack of urban green space (Artmann & Sartison, 2018; Pemprov DKI Jakarta, 2018). As such, UA contributes to sustainable urban development (Artmann & Sartison, 2018; Cahya, 2016; De Zeeuw, Van Veenhuizen, & Dubbeling, 2011; Kutiwa, Boon, & Devuyst, 2010), that is defined in this study as a process of integration and co-evolution among the economic, social, environmental, and physical aspects that make up a city, which results in non-decreasing level of wellbeing in the long term, without compromising the chance for development of surrounding areas by reducing the harmful effects of urban development on the biosphere (Capello, 2017). Ecologically, UA creates green spaces in urbanized landscape (Mougeot, 2005; Zasada, 2011), creates ecosystem services, and enhances microclimate qualities (Akinnifesi et al., 2010; Deelstra & Girardet, 2000). Socially, participation in community gardening has been studied to increase community cohesion (Chan, DuBois, & Tidball, 2015; Säumel, Reddy, & Wachtel, 2019) and resiliency during times of crisis (Chan, DuBois, &

Tidball, 2015). In addition, there is a growing number of literature that correlates leisure farming with increased quality of life and personal well-being (Zasada, 2011) and more positive outlook in life (Mourão, Moreira, Almeida, & Brito, 2019). Economically, UA has been documented to provide opportunities to obtain alternative income (Aubry et al., 2012; Indraprahasta & Agustina, 2012) and reduce the risk of food insecurity through food production (Altieri et al., 1999; Maxwell, 1995).

It is widely acknowledged that UA's potential in reducing urban poverty and food insecurity is often critically limited by urban development and the rise of value in urban land markets (Badami & Ramankutty, 2015; Redwood, 2009; Zezza & Tasciotti, 2010). This study is also aware that UA is not likely to replace the role of conventional agriculture (Redwood, 2009). Nevertheless, it finds UA's economic abilities to build a safety net and to secure access to nutritious foods in low-income populations (Duchemin, Wegmuller, & Legault, 2009; Zezza & Tasciotti, 2010) remain relevant in the study site.

This study focuses on UA that is practiced within the intra-urban environment of Central Jakarta—the centremost municipality of Jakarta—one of the highly urbanized city in Asia. Historically, UA has been documented to provide various socioeconomic supports in response to times of food crisis in Jakarta and the Jabodetabek Metropolitan Area (JMA), particularly through its provision of food and nutrition security for the urban poor (Pribadi & Pauleit, 2015, 2016). Some programs and policies have also been developed to manage existing UA practice; however, some practical gaps and environmental challenges are left unaddressed, thus limiting their performance in supporting and sustaining UA development. This study seeks to update the existing UA developmental strategies due the importance of understanding variations in urban farmers and existing urban farming practice to allow efficient tailoring of incentives and policies (Indraprahasta & Agustina, 2012). Few studies have been conducted on the topic of urban farmer's relationship and influence over UA, particularly regarding UA in cities outside of the Global North. Therefore, this study adds to the literature with insights on needs-based assessment to support UA's development.

As a collective urban food movement, this study considers urban farmer's motivation to farm and their experienced benefits from farming as critical success factors in sustaining UA activities. Therefore, this study seeks to analyse urban farmer's motivation and experienced benefits in Central Jakarta. Procedures on data acquisition and analyses that were used in this study are summarized in the following Methods section. Lastly, the study results and discussion of urban farming motivation and benefits experienced by urban farmers can also be found in the Results and Discussion section.

Methods

This study was performed using qualitative approach to provide a more comprehensive understanding of the multifaceted nature of UA and sustainability issues. Data acquisition took place in Central Jakarta, the centermost municipality of Jakarta, particularly on sites where UA activities were previously recorded by the Department of Food Security, Maritime Affairs and Agriculture (*Dinas Ketahanan Pangan, Kelautan dan Pertanian*; DKPKP), one of several government agencies that managed existing UA and its related programs in Jakarta (Fig.1). Two methodologies were mainly used for this step: focus group discussions (FGD) and questionnaire survey. FGD sessions were performed with key urban farmers and representatives from DKPKP. On the other hand, questionnaires were distributed to urban farmers in the community via snowball sampling, which yielded 221 respondents that were later analyzed.

Fig. 1: Distribution of UA sites that were studied in Central Jakarta

Questionnaires

Questionnaires were distributed to identify and measure two main variables: motivations to farm and experienced benefits from farming. Two sub-variables of motivation were identified and analyzed using descriptive statistics: urban farmer's reasons to start farming and frequency of farming in a week. On the other hand, three sub-variables of experienced benefits were measured using Likert scale and analyzed with descriptive statistics: economic, social, and environmental benefits from farming.

Analysis

Z-score (standard score) (Equation 1) was used to compare the values of all three sub-variables of experienced benefits from farming (i.e., the economic, social, and environmental aspect of the experienced benefits). This analysis described the position of each sub-variable in terms of its distance from the mean value of experienced benefits from farming. Therefore, positive z-score indicated that the value of said sub-variable lied above the mean and was interpreted as greater expression of experienced benefit from that aspect relative to the average.

$$z_i = \frac{x_i - \mu}{\sigma}$$

……

(Equation 1)

Where:

z_i : Z-score for sample i

x_i : Mean of sample i

μ : Population mean

σ : Standard deviation of population

Results and Discussion

The observed UA sites mainly existed in public or communal spaces such as roadsides in residential areas, riverbanks, vacant lots, or integrated as part of green space area in several public parks. Insecure land tenure and limited space for farming are some limiting factors that are identified in previous studies (Purnomohadi, 2000; Sampeliling, Sitorus, Nurisyah, & Pramudya, 2012) and were also evident in UA sites Central Jakarta. Furthermore, soil contamination, pest, and insufficient sunlight exposure for planting were also prominent concerns. Table 1 summarizes the most common farming activities, which were practiced in small scales with hardy plant and animal species as a mean of adaptation to the lack of space.

Table 1: Frequency distribution of identified farming activities

Identified activity	Total % of respondent
Planting crops	34.2
Planting herbs or medicinal plants	25.5
Planting fruits	18.6
Transplantation	8.6
Aquaculture	6.3
Post-harvest processing	6.1
Raising poultry	0.6
Others	0.2

In addition, urban farmers also developed adaptive measures such as optimizing the use of vertical spaces and above ground planting with alternative planting media to adjust to the non-accommodating planting conditions (Fig. 2).

Fig. 2: Optimization of vertical space: (a) Planting fruit trees above open sewers in Gambir Sub-District (SD); (b) aquaponics system in Johar Baru SD; (c) medicinal plants planted in pots above open sewer in Sawah Besar SD

More than half (57.3%) of sampled urban farmers were involved in both individual and community gardening in the neighborhood; 37% only participated in community gardening; and 11.3% only participated in individual farming within their private property. Lack of space for home garden in urban farmer's private property was reported to be the main reason why some of them participated solely in community gardening. Some socioeconomic patterns were observed on-site; the location of UA sites greatly overlap with high-density residential areas with predominant low to middle income households and 56.5% of the studied respondents received income below the provincial minimum wage in 2019 (Rp3,940,973 per month), thus indicating a condition of financial insecurity shared among urban farmers.

Motivations to Farm

Access to fresh food was the most common reason that motivated urban farmers to start farming (17.1%), followed by farming as a hobby (15.8%), and environmental beautification (14.6%) (Table 2). Food production being urban farmer's primary motivation is consistent with findings from Maxwell (1995) and Zezza and Tasciotti (2010), which hold UA's role in securing nonmarket source of food of particular importance in the context of financial insecurity.

Table 2: Frequency distribution of reasons to start farming

Reasons	Percentage (%)	Category
Access to fresh food	17.1	Economic
Hobby	15.8	Social
Environmental beautification	14.6	Environmental
Socializing	12.8	Social
Improvement of environmental quality	11.2	Environmental
Self/community enrichment	9.7	Social
Grocery savings	6.4	Economic
Community education	6.1	Social
Additional income	5.3	Economic
Household waste management	1.1	Environmental

A major proportion of the sample (38.4%) reported that they tend to their crops/livestock every day (7 days a week) (Table 3), which may indicate high motivation to keep maintaining and sustaining UA activities in more than one third of the sample.

Table 3: Distribution of frequency of farming

Frequency of farming in a week	Percentage (%)
Every day (7 days)	38.4
Once a week	26.5
2-6 days/week	21.5
Less than once a week	13.7

Further cross-analysis with an FGD session suggested that variation in farming frequency may be influenced by the implementation of UA program in the community and the type of farming activities urban farmers were involved in (i.e., individual, community, or both). Informant 1, who was a key urban farmer who actively coordinated and participated in community gardening sessions in Sawah

Besar Sub-District, informed that UA program that was being implemented by the DKPKP in the local community also encouraged urban farmers to actively participate in community gardening,

> "(Aside from) watering and transplanting which I do together with my husband, I and the community gardening members also participate in *jumantik* (*juru pemantau jentik*; *Aedes aegypti* mosquito larvae monitoring as a method of dengue fever prevention) and post-harvest processing activities once a week every Friday." (Informant 1)

This session also informed that community gardening were held once a week along with other communal activities that were relevant in the local community. Therefore, urban farmers who solely participated in community gardening due to their involvement in these communal activities had a tendency to farm less frequently (Table 4). On the other hand, those who participated in both individual and community gardening activities tend to farm more frequently and consistently (Table 4).

Table 4: Crosstab analysis between frequency of farming and types of UA activities

Frequency of farming	Types of UA activities			Total
	Individual	Community	Both	(Urban farmers)
Less than once a week	3	22	3	28
Once a week	5	20	30	55
2-6 days/week	1	14	30	45
Every day (7 days)	3	20	57	80

Informal interviews with DKPKP representatives and key urban farmers further confirmed that currently there was a lack of enthusiasm from the community gardening members to participate more actively and consistently. This may also explain the greater incidence of inconsistency in farming frequency (i.e., greater proportion of urban farmers that farm less than once a week) in urban farmers who solely participate in community gardening activities relative to the other two groups. Given that frequency of farming is considered as one of key sub-variables that express urban farmer's motivation to sustain farming, it can be concluded that high motivation to sustain UA is not expressed equally among urban farmers in the community.

The currently implemented UA program's integration to other communal activities has been functioning as an entry point strategy for extending farming opportunities in the community. However, alternative approach needs to be developed to increase community's enthusiasm and need for UA beyond the weekly communal activities. To do so, this study suggests further efforts to be made firsthand to address the underlying issues of insecure land tenure and lack of space for farming to make farming accessible for all.

Experienced Benefits from Farming

Analysis of perceived benefits from farming using Z-score analysis showed that urban farmers particularly experience the social aspect of farming the most and the economic aspect the least (Table 5). Further analysis confirmed that in exception of some success stories, the agricultural production of urban farmers was often minimal. This result deviates from previous studies by Kutiwa et al. (2010) and Mougeot (2006), which attribute UA's economic benefits to its potential to create jobs and generate additional income among urban farmers in developing countries.

Table 5: Comparison of values of economic, social, and ecological aspects of experienced benefits

Aspects of Experienced Benefits	Number of Response	Minimum Value	Maximum Value	Mean	SD	Z-Score
Social	208	14.00	25.00	20.13	2.46	1.07
Ecological	214	10.00	20.00	17.10	1.86	0.26
Economic	144	6.00	15.00	11.18	1.72	-1.33

Further cross-analysing with FGD results indicated few interest for farming and greater demand for non-agricultural land use in the community, which may indicate other sector's greater potential in supporting livelihood.

> "This used to be an empty lot…which was used by the neighbors to park their (peddling) carts, for peddling, and other means of self-interest. Then, with the help of both village and district chiefs, a garden was built (in the empty lot)… That time we managed to (get the place) tidied up, but now the neighbors have attempted (to use the space)… for drying clothes again… they view that space as an opportunity for (gaining) income, (considering) previously (that empty lot) used to be a food stall, a barber shop, and a parking space for peddling carts." (Informant 1)

This session informed that there were repeated attempts by some community members to reclaim the lot back as a functional aspect of their livelihoods. It is possible that aside from urban farmers, the community does not experience direct benefits from the existence of UA, hence the evident lack of interest and support. However, further study needs to be done to better understand non-practitioner's perception of UA and the resulting dynamics UA has on the non-practitioner side of the community.

This study finds that in order to bring forth UA's optimal benefits, it is imperative for UA to be adjusted to the biophysical and sociocultural needs of the community. Following previous study by Reuther and Dewar (2006), the evident lack of UA's role in poverty alleviation may indicate that UA is not economically feasible to be implemented in the studied sites. Urban development and the rise of value in urban land markets have been identified to limit UA's economic performance (Badami & Ramankutty, 2015; Redwood, 2009; Zezza & Tasciotti, 2010). Even so, this study wants to bring focus to UA's potential in providing safety net as evident in reported income shares from farming or contribution to savings on grocery. It can be concluded that increasing the economic aspect of UA's experienced benefits may positively influence UA's appeal and sustainability in the community.

Conclusion

This paper set out to analyse urban farmer's motivation to farm and their experienced benefits from farming. The study found that UA was mostly practiced in high-density residential areas with predominant low to middle income households. Access to fresh food was found to be the most common reason for urban farmers to start farming and this is of particular importance given the context of financial insecurity in the studied site. Variation in farming frequency may be influenced by the implementation of UA program in the community and the type of farming activities urban farmers partake in (i.e., individual, community, or both). The current UA program's approach needs to be developed to increase community's motivation to sustain UA program and activities; to do so, this study finds it imperative to primarily address the underlying issues of land tenure and space for farming. Z-score analysis showed that urban farmers particularly experience the social aspect of farming the most and the economic aspect the least, which may indicate UA's lack of economic feasibility in the studied sites. In order to optimize UA's benefits and ensure its sustainability, this paper suggests further adjustments to be made on UA practice to suit the biophysical and sociocultural needs of the community.

Abstract

A numerical study of the thermomechanical state of rods of variable cross section in the presence of local temperature, heat flux, thermal insulation, heat transfer, and axial forces is of interest for technology and technological processes related to the strengths of elements of partially insulated structures.The rapid development of the processing of natural wealth, which faced scientists with new problems in developing adequate mathematical models of universal computational algorithms and methods, allowing a comprehensive numerical study of the thermoelastic state of partially heat-insulated structural elements of variable cross-section working in a complex thermal and force field. The relevance of these problems is also motivated by the fact that many structural elements of variable cross section work under the simultaneous action of tensile (compressive) axial force, local temperature, heat flux, heat transfer and thermal insulation.

Keywords: Heat Flow, Heat Transfer, Thermal Expansion, Thermal Conductivity, Heat Transfer, Elastic Modulus, Thermal Insulation.

Introduction

Load-bearing elements of a modern gas power plants, nuclear and thermal power plants, hydrogen and jet engines, internal combustion engines, installations of deep processing of mineral raw materials and oils work in complex power and thermal field. Reliable operation of the above installations will depend on thermal strength characteristics of their load-bearing elements. As bearing elements was considered rods of limited length and of constant cross section [1][2]. In these problems, based on fundamental laws of thermal physics [3] defined the field of temperature distribution along the length of the rod of limited length, taking into account existing types of heat sources. Other similar problems are considered in works [4-6]. In these works, the authors limit the definition of the law of temperature distribution along the length of the rod depending on the types of specified sources. In contrast, in this paper as the load-bearing element of construction is considered a horizontal rod of limited length and a constant cross-section. Thus the lateral surface of the rod is completely thermally insulated. The cross-sectional area of the left end is supplied with heat flux of constant intensity. Through the cross sectional area of the right end occurs heat exchange with the

environment. In the simultaneous presence of diverse types of heat sources in the bearing elements of the strategic structures arise axial compressive stress: the field distribution of displacements, elastic, temperature and thermoelastic components of the deformations and corresponding stresses. In this regard, development of fundamental methods for deep exploration of complex thermo-physical conditions of load-bearing structural elements is an actual problem of applied physics.

In this task, using the fundamental laws of conservation of energy [1] are defined:

- the law of temperature distribution along the length of the considered rod;
- the value of thermal lengthening;
- the value of the axial compressive force;
- the laws of distribution of elastic, thermal and thermo elastic components of deformation and stress;
- the displacement field [2].

The output of allowing equations

Considered a horizontal rod of limited length L [cm], the cross-sectional area of which is F [cm2] constant along its length. The cross sectional profile of the rod can be round, rectangular, triangular, polygonal, etc. Thermophysical material properties of the rod are characterized by the coefficient of thermal expansion of the material of rod α [1/°C], thermal conductivity κx [$\frac{W}{cm*°C}$] and a modulus of elasticity E[$\frac{kg}{cm^2}$].

The cross-sectional area of the left end of the sample rod, supplied with heat flux q [$\frac{W}{cm^2}$]. In summing up the heat flow to the local surface, its value may be negative, i.e. q<0. Through the cross-sectional area of the right end of convective heat exchange with its environment. The heat transfer coefficient h [$\frac{W}{cm^2°C}$], and the surrounding temperature $T_{°C}$[°C]. It is required from the beginning to determine the law of temperature distribution along the length of the researched rod depending on the form of the existing heat sources, geometrical and thermo physical characteristics of the rod. To do this, first construct the local approximation quadratic spline function [3].

Calculation scheme of the considered problem is shown in figure 1.

Figure 1: The calculation scheme of tasks

Let us assume

$$T(\mathrm{x}=0)=T_i;\ T\left(x=\frac{L}{2}\right)=T_j;\ T(x=L)=T_k \tag{1}$$

The law of temperature distribution along the length of the researched rod we approximate full second-order polynomial spline functions [4]

$$T(x)=ax^2+bx+c=\varphi_i(x)\,T_i+\varphi_j(x)T_j+\varphi_k(x)T_k;\ 0\le x\le L \tag{2}$$

where

$$\varphi_i(x) = \frac{2x^2-3Lx+L^2}{L^2};\ \varphi_j(x) = \frac{4Lx-4x^2}{L^2};\ \varphi_k(x) = \frac{2x^2-Lx}{L^2};\ 0 \le x \le L \qquad (3)$$

Now for the investigated problem we write the functional which characterizes the law of conservation of energy [5].

$$J = \int_{S(x=0)} qTdS \int \quad + \int_V \frac{kxx}{2}\left(\frac{\partial T}{\partial x}\right)^2 dV + \int_{S(x=L)} \frac{h}{2}(T - T_{0C})^2 dS\ , \qquad (4)$$

It should be noted that the dimension of each member is [W°C]. This is the work done by temperature, by analogy, the work force [kg*cm]. Physical considerations are:

$$J_1 = \int_{S(x=0)} q * TdS = FqT_i \qquad (5)$$

$$J_3 = \int_{S(x=L)} \frac{h}{2}(T - T_{0C})^2 dS = \frac{Fh}{2}(T_k - T_{0C})^2 \qquad (6)$$

To calculate the volume integral in the expression (4), it is necessary to determine the temperature gradient

$$\frac{\partial T}{\partial x} = \frac{\partial \varphi_i}{\partial x}T_i + \frac{\partial \varphi_j}{\partial x}T_j + \frac{\partial \varphi_k}{\partial x}T_k = \frac{4x-3L}{L^2}T_i + \frac{4L-8x}{L^2}T_j + \frac{4x-L}{L^2}T_k,\ 0 \le x \le L \quad (7)$$

Next, substituting (7) in the expression J, and using the known formula

$\int_V f(x)dV = F\int_0^L f(x)dx$, we get

$$J_2 = \int_V \frac{k_x}{2}\left(\frac{\partial T}{\partial x}\right)^2 dV = \frac{Fk_x}{\partial x}(7\,T_i^2 - 16T_iT_j + 2T_iT_k - 16T_jT_k + 16T_j^2 + 7T_k^2) \qquad (8)$$

Then the functional of total thermal energy is:

$$J = J_1 + J_2 + J_3 == FqT_i + \frac{Fk_i}{\partial x}\left(7\,T_i^2 - 16T_iT_j + 2T_iT_k - 16T_jT_k + 16T_j^2 + +7T_k^2\right) + \frac{Fh}{2}(T_k - T_{0C})^2 \qquad (9)$$

It should be noted here that to determine the values of T_i, T_j и T_k we can obtain a system of linear algebraic equations, which takes into account all existing natural boundary conditions, varying J throughT_i, T_j and T_k.

$$\left.\begin{array}{ll} 1) & \frac{\partial J}{\partial T_i} = 0;\ \rightarrow Fq + \frac{Fk_x}{6L}(14T_i - 16T_j + 2T_k) = 0 \\ 2) & \frac{\partial J}{\partial T_j} = 0;\ \rightarrow \frac{Fk_x}{6L}(-16T_i + 32T_j - 16T_k) = 0 \\ 3) & \frac{\partial J}{\partial T_k} = 0;\ \rightarrow \frac{Fk_x}{6L}\left(2T_i - 16T_j + 14T_k\right) + FhT_k - FhT_{0C} = 0 \end{array}\right\} \qquad (10)$$

From where we receive

$$\left.\begin{array}{l} 7T_i - 8T_j + T_k = -\frac{3Lq}{k_x} \\ T_i - 2T_j + T_k = 0 \\ 7T_i - 8T_j + 7T_k + \dfrac{3Lh}{k_x}T_k = \dfrac{3LhT_{OC}}{k_x} \end{array}\right\} \qquad (11)$$

Solving the system (11), we define

$$T_i = T_{OC} - \frac{q}{h} - \frac{Lq}{k_x};\ T_j = T_{OC} - \frac{q}{h} - \frac{Lq}{2k_x};\ T_k = T_{OC} - \frac{q}{h} \quad (12)$$

Next, substituting (12) into (2-3), we define the law of distribution of temperature along the length of the researched rod taking into account the simultaneously presence of insulation, heat flow and heat transfer. It will have the following form:

$$T = T(x, T_{OC}, q, h, L, k_x) = \left(T_{OC} - \frac{q}{h} - \frac{qL}{k_x}\right) + \frac{q}{k_x}x;\ 0 \le x \le L \quad (13)$$

This shows that in our case the law of temperature distribution along the length of the rod is linear.

The definition of the thermal state of the rod

Now, we will solve the next task. Due to the presence of the temperature field, the test rod will be extended. Required to determine the amount of lengthening depending on the simultaneous presence of heterogeneous heat sources. For this, assume that the left end of rod rigidly clamped is and right - free. From the general laws of thermodynamics [5] it is known that the value of lengthening rod from field temperature is determined as follows:

$$\Delta l_T = \int_0^L \alpha T(x)dx \quad (14)$$

If we assume that α=const, we have

$$\Delta l_T = \int_0^L \alpha T(x)dx = \alpha L(T_{OC} - \frac{q}{h} - \frac{qL}{2k_x}) \quad (15)$$

We will consider a case where both end of the researched rod are rigidly fixed, it can neither be lengthened nor shortened. In this case there is axial compressive force R[kg]. We define it as the solution of statically indeterminate tasks and at the same time use compatibility conditions of deformation:

$$\frac{RL}{EF} + \Delta L_T = 0 \rightarrow R = -\frac{\Delta L_T EF}{L} = -\alpha EF(T_{OC} - \frac{q}{h} - \frac{qL}{2k_x}) \quad (16)$$

After, this is easily determined the following solution, the definition of the emerging field of thermo-elastic stresses $\sigma\left[\frac{\text{кГ}}{\text{см}^2}\right]$. It is determined according to the generalized Hooke's law: [9]

$$\sigma = \frac{R}{F} = -\alpha E(T_{OC} - \frac{q}{h} - \frac{qL}{2k_x}) \quad (17)$$

This shows that the field distribution of the thermo-elastic component of the stress σ will be straight line that is parallel to the axis of the rod and the ox axis.
Again applying the generalized Hooke's law, we find the solution of determining the field of thermo-elastic deformation of the component

$$\varepsilon = \frac{\sigma}{E} = -\alpha(T_{OC} - \frac{q}{h} - \frac{qL}{2k_x}) \quad (18)$$

From the solution it is clear that it is linear and parallel to the axis ox.

If we consider that q<0, then from (16-18) shows that R, σ and ε will only have compressive nature.

Then using the fundamental laws of thermodynamics, it is possible to solve the following problem of determining the field of temperature deformation of the component

$$\varepsilon_T(x) = -\alpha T(x) = -\alpha\left[\left(T_{OC} - \frac{q}{h} - \frac{qL}{k_x}\right) + \frac{q}{k_x}x\right], \quad 0 \le x \le L \qquad (19),$$

This shows that ε_T- will have a compressive nature, and the field distribution is linear.

Using the generalized Hooke's law, we will define the following, when the distribution of temperature field of the stress component has the following form:

$$\sigma_T(x) = E\varepsilon_T(x) = -\alpha E\left[\left(T_{OC} - \frac{q}{h} - \frac{qL}{k_x}\right) + \frac{q}{k_x}x\right], 0 \le x \le L \qquad (20)$$

it is clear that it is linear and contractive nature.

The field of elastic deformations we define the components of the fundamental law

$$\varepsilon_x(x) = \varepsilon - \varepsilon_T(x) = \frac{\alpha}{k_x}\left(-\frac{qL}{2} + qx\right) = \frac{q\alpha}{k_x}\left(-\frac{L}{2} + x\right), \qquad (21)$$

This shows that $\varepsilon_x(x)$ is linear. On the section $0 \le x \le \frac{L}{2}$, it has tensile nature. In the cross-section is x=$\frac{L}{2}$, $\varepsilon_x\left(\frac{L}{2}\right) = 0$. Further it has a compressive character.

Follows from Hooke's law

$$\sigma_x(x) = E\varepsilon_x(x) = \frac{q\alpha E}{k_x}\left(-\frac{L}{2} + x\right) \qquad (22)$$

His character is the same as for $\varepsilon_x(x)$.

Now, finally, we solve the tenth problem of determining the displacement field U(x). It is determined from the ratio of the Cauchy

$$\varepsilon_x = \frac{\partial U}{\partial x} = \rightarrow U(x) = \int \varepsilon_x(x)dx = \frac{q\alpha}{k_x}\left(-\frac{L}{2}x + \frac{x^2}{2}\right) + C, \text{ где C=const.}$$

The value of the constant will determine from the condition of clamped both ends, i.e. U(x=0)=U(x=L)=0. Then C=0 and the displacement field has the following form:

$$U(x) = \frac{q\alpha x}{k_x}\left(\frac{x}{2} - \frac{L}{2}\right), \quad 0 \le x \le L \qquad (23)$$

In this section, from the area $0 < x \le L$, moves in the direction of *Ox*.

Of course, clamped the ends do not move, i.e. U(x=0)=U(x=L)=0.

Conclusion

Based on fundamental laws of conservation of energy developed computational algorithm and method of the study established thermo-physical state of a thermally insulated rod of limited length in the simultaneous presence of heat flow and heat transfer. It is revealed that the distribution laws of the temperature, elastic and thermal components will be linear; the values of the thermo elastic component of strain and stress will be permanent. The distribution law of displacement will have a quadratic character, and all sections of the rod will move from left to right if q<=0.

Abstract

Great attention is being paid to the problems of the development of science and state support for the involvement of young people in the scientific activity in the Russian Federation. Science is one of the important mechanisms for the development of society and the state. Thus, the role of the higher education system in the training of highly qualified and competitive specialists who can make up the human resources of science in the country is growing. Among the urgent problems of modern Russian science are obsolescence of scientific personnel, violation of the continuity of generations of scientific traditions. It determines the special social significance and relevance of the scientific search in the field of psychological and pedagogical mechanisms for involving young people in research activities, their activation, the formation of positive motivation for research work in higher education. The paper focuses on the approaches to the consideration of research activities in psychological science; motivation of scientists and university students involved in research work; sources and mechanisms of interest formation, motivation of research activities among students. The analysis of scientific sources has revealed that the perception of science, scientific activity, and the image of a modern scientist can also become a significant factor inhibiting or activating the interest of young people in participating in scientific work. The aim of the study is to study the image of a scientist in the representations of students of a Russian university. 230 students involved in research activities of a regional Russian university have taken part in the empirical study. It has studied the ideas about modern problems of science, the image of a scientist and motivation for scientific activity of famous scientists of the country and region. A comparative analysis has been conducted between groups of university students, differing in the degree of activity and effectiveness of participation in research activities, involvement in the scientific environment. The work highlights the experience of a regional Russian university in popularizing science, enhancing the research activities of students, including raising the awareness of university students about modern scientists through organizing various meetings and master classes with scientists. It gives information about the achievements of science and higher school teachers as research scientists.

Keywords: The image of a scientist, the image of science, representations of the students, motivation for research activities, Russian regional university**.**

Introduction

Science is one of the important mechanisms for the development of society and the state, in connection with this, the role of the higher education system in training highly qualified and competitive specialists who can make up the human resources of the country's science is growing.

Great attention is being paid to the problems of the development of science and state support for the involvement of young people in the scientific activity in the Russian Federation. The measures taken in Russia over the past decade to attract and consolidate young people in the scientific field are yielding results: the age structure of researchers has become more balanced. According to statistics for 2017, the proportion of researchers under the age of 29 was 18.4%, from 30 to 39 years old - 25.4%, from 40 to 49 years old - 14.2%, 50 - 59 years old - 16.6%, 60 - 69 years 16%, 70 years and older - 9.3% (Indicators of science, 2019).

There was a quantitative and qualitative decline among the scientific staff; the number of scientific personnel was reduced with a deterioration in their age structure, age-related imbalances in the scientific staff caused by the difficult demographic situation, the aging of the scientific and pedagogical staff of the higher education system, and the violation of the continuity of scientific schools (Volodina, E. D., 2014; Allahverdyan A.G., 2014).

Scientists note that in the personnel structure of modern scientific institutes the middle-aged layer of scientific workers has been "lost", respectively, the continuity of scientific traditions and scientific thinking was interrupted. As a result, young researchers for the most part do not have the necessary knowledge, skills, methods of scientific thinking, and a value base for carrying out scientific activities as a professional (Razina T.V., 2014).

But the situation in this area is still complicated, which determines the special social significance and relevance of the scientific search in the field of psychological and pedagogical mechanisms for involving young people in research activities, their activation, the formation of positive motivation for research work in the higher education system.

D. Berlyne, C. Hutt, H. Keller, H.-G. Voss have studied the psychological problems of scientific activity abroad that are devoted to the problems of research behavior. The isssues of social factors of a scientific career are studied by G.J. Feist (Feist G.J., 2006), values and ethical-moral aspects of scientific activities are shown by L. Tondl (Tondl L., 2001), M. W. Martin (Martin M.W., 2006), the psychological phenomena of scientific thinking are observed by J.J. Clement (Clement J.J., 2008).

An analysis of foreign scientific sources shows that the perception of science, scientific activity, and the image of a modern scientist can also become a significant factor that inhibits or activates youth's interest in participating in scientific work.

One of the common areas of research in the field of studying science and scientific activity is research on the perception of scientists by different groups of the population, including differences depending on gender, culture and socio-economic status (Christidou V., 2011).

For this purpose, children's drawings are often used, including the Draw-a-scientist-test (DAST). It was found that children have stereotypical ideas about scientists. Since the 1950s the image of scientists as older men in white coats and glasses, working in the laboratory alone are shown in studies as the stereotypical concept of scientists, (Chambers, 1983; Fung, 2002; Newton & Newton, 1998; She 1995, 1998; Song, Pak & Jang, 1992). Over time the problem began to change in several countries. (Milford & Tippett, 2013; Fralick, Kearn, Thompson, & Lyons, 2009). For example, in a study in the United States and China, in which 1350 Elementary school children took part, about 35% of female scientists appeared in children's drawings (Farland-Smith, 2009). The same study also identified changes in stereotypical representations of Chinese schoolchildren associated with robots.

A number of researchers suggest that children's attitudes toward science are largely dependent on their perceptions of science. Studies show that most young children have a positive attitude towards science at the age of 10, but then this interest decreases sharply, and by the age of 14, their attitude and interest in studying science has largely changed (Archer, L., DeWitt, J., Osborne, J., Dillon, J., Willis, B., & Wong, B., 2010).

A study by Narayan R. et al. (Narayan R., Park S., Peker D., Suh J., 2013) compared the views of 1800 students from five different countries (China, India, South Korea, Turkey and the USA) about science and scientists reflected in their drawings using a modified version of the Drawing-A-Scientist-Test. In all countries, the results showed that lower levels of education have fewer stereotypical perceptions than higher ones. It was shown that in any country, participants' perceptions of scientists were not related to their choice of profession.

A study of Thomson MM, Zakaria Z., Radut-Taciu R. (2019) of the young school children from Romania enrolled in both rural and urban public schools showed that most children represented stereotypical characteristics of scientists in their drawings such as white male wearing lab coats using instruments that reflected a chemistry lab.

In a study (Buldu M., 2006) of the perception of scientists by children aged 5 to 8 years in Turkey it has been revealed that such perception differs depending on age and socio-economic status.

In a study by El Takach S., Yacoubian H.A. (El Takach, S. & Yacoubian, H.A., 2020), conducted in Lebanon using the Draw-a-scientist-test (DAST), teachers (middle school chemistry teachers) and their students were involved. The results showed that a stereotypical view of a male scientist working in the laboratory and conducting experiments mainly in chemistry is widespread. The participants had a positive attitude towards scientists, many students, as a rule, had a positive attitude towards a career in science and technology. Interestingly, elementary school students had more diverse images of scientists, and stereotyping of images increased among high school students, becoming more similar to the images of their teachers. Among the preferred names of the scientists presented by the students, there were no modern scientists and women scientists.

A study by Miller D. et al (Miller D., Eagly A., Linn MC, 2014) conducted in 66 countries among 350,000 participants showed that, despite the fact that over the past 40 years, the proportion of women in science has increased significantly in most countries, gender-scientific stereotypes, as before, associate science with men more than with women. The work revealed that gender stereotypes in the perception of science are still strong even in countries with small gender differences in participation in scientific activities.

In a study by Fralick B., Kearn J., Thompson S., et al. in the United States 1600 middle school students from urban and suburban schools in the southeastern United States took part. The results show that students participating in this study most often perceive scientists as working indoors and conducting experiments. It has been revealed that the ideas of young students about engineers and scientists often inhabit misconceptions and stereotypes (Fralick B., Kearn J., Thompson S., et al., 2009).

Scientists and university professors today are forced to think about how they perceive natural and technical sciences in society, in particular, about what kind of science dominates the minds of an educated and not very educated public (Sismondo S., 2010).

The scientific work of A.G. Allahverdyan (Allahverdyan A. G., 2014), A.V. Yurevich, M.G. Yaroshevsky (Allahverdyan A.G., Moshkova G.Yu., Yurevich A.V., Yaroshevsky M.G., 1998); Yurevich A.V., 2013; Yurevich A.V., Tsapenko I.P., 2010), T.V. Razina (2016), A.L. Mazaleckaya (2011), Yu. S. Medvedeva (Medvedeva Yu. S., 2015), T.V. Ogorodova (Ogorodova T.V., Medvedeva Yu.S., 2013), Bokhan T.G., Alekseeva L.F., Shabolovskaya M.V., Moreva S.A., Kuznetsova T. M. (2014), Boyarkina, S.I., Ivanov, E.A., Tucuman, B.G. (2015), Edronova V.N., Ovcharov A.O. (2013) is devoted to the study of the psychological characteristics of research activities in modern Russian psychology.

An analysis of scientific sources on the problem of psychological characteristics has showed that the research activities of university students are one of the most significant components of the training of a future specialist. This is due to the fact that this type of activity is one of the main in higher education and contributes to the development of students' competencies.

There are several approaches to the consideration of research activities in psychological science. Of particular interest is the personality of a student engaged in research work in the process of obtaining higher education, a system of motives and incentives, creative abilities. Searches for sources and mechanisms of interest formation, motivation of students' research activities, are being studied, relevant forms of participation in scientific work are studied.

However, it should be noted the lack of research on the psychological characteristics of the research activities of students in universities of the regions of the Russian Federation.

Earlier, we have already considered the problem of the relationship between the features of the research activities of university students with their motivation for studying at the university and personal creativity (Zakharova A.N. et al, 2020).

One of the least disclosed topics, in our opinion, is the problem of social ideas about the science and scientific activity of university students.

One of the least disclosed topics in Russian science, in our opinion, is the problem of social ideas about science and the scientific activity of university students.

Scientists have revealed the existence of vivid dynamics of the image of science, which can be associated with the continuous acceleration of the development of scientific thought, the rapid expansion of the scientific knowledge, changes in the social context of the functioning of the institute of science, the complexity of the forms of interaction between science and society, as well as the specifics of the practical request, which is important for theoretical understanding of socio-psychological problems in general (Razina T.V., Volodarskaya E.V., 2017; Volodarskaya E.V., Razina T.V., 2017; Tsvetkova N.A., Petrova E.A., Gorshkova V.V., 2017).

The image of the scientist is evolving in the European historical and cultural tradition. Scientists have shown that the public perception of the scientist's personality and the social role played by him have historically changed with the development of science and society (Matyash, Matyash, 2015).

Scientists prove the relevance of studying the image of the ideal scientist among modern young Russians to understand the formation of their professional preferences and the desire to engage in scientific activities in modern conditions of science.

In the article M. I. Mikeshin discusses the problem of the widespread everyday, "standard" idea of science and scientific activity, characteristic of people who receive education in Russia. This idea is based on the collective practices of everyday, educational, scientific and is not the result of only personal experience. A popular image has the property of normativity, i.e., serves to create a single space of principles and standards of the community (Mikeshin M.I., 2018).

Boyarkina S.I., Ivanova E.A., Tukumtsev B.G. came to the conclusion that the ideas of the young generation are dominated by idealized images of scientific activity and qualities that a scientist should possess. The authors suggest that these representations may be due to parental influence or stereotypes (Boyarkina S.I., Ivanova E.A., Tukumtsev B.G., 2010).

In the study of the image of science in the students' view, carried out using the method of incomplete sentences, the authors have revealed the degree of influence of various factors (training course, university specialty) on the formation of the image of science of modern students. Students of humanitarian specialties assign a dominant role in the development of science to a person, personality, specialist. Representatives of technical specialties pay more attention to the material and technical base when highlighting factors for the development of science. As a result of the study, 4 generalized categories were identified that make up the image of science and the scientist: the social

functions of science, the social factors of the development of science, the image of the scientist, the attitude of students to science. The most significant generalized categories turned out to be “Social Functions of Science” and “Attitude of Students to Science”, which are directly related to the concept of “science”. Such trends are observed in all categories of students regardless of the course or faculty (Razinskaya V.D., Zhiryakova E.S., Kuzminova N.V., 2013).

The structurally meaningful special features of the scientist's image among students and working youth, and the factors that determine it (Razina T.V., Volodarskaya E. A., 2017) were established. The image of an ideal scientist is characterized by cognitive (ability to formulate a problem, express one’s thoughts, resistance to uncertainty, discipline of thinking) and personal (determination, determination, principle, focus on results, high efficiency, versatility, originality, rich imagination) qualities. The conclusion is drawn about the substantial similarity of the images of the ideal scientist among working and studying youth, and the differences in its image-forming basis.

The purpose of the study was the study of ideas about science and scientific activity, the image of a scientist, among students of a Russian university involved in research activities.

Research Methods

Research methods are analysis of scientific sources, questionnaires, methods of mathematical and statistical data processing.

Based on the analysis of scientific sources, a questionnaire was compiled to determine the attitude of university students to research activities, their personal interest in scientific work, the image of a scientist, opinions on modern problems of science, knowledge of famous scientists of their country and region.

To process the obtained results, a mathematical-statistical method was used, including descriptive statistics, a T-test for the significance of student differences.

The study involved students from a university in Cheboksary, Russian Federation, engaged in research activities. The total number of respondents is 230 people aged 18 to 24 years.

Based on the survey, all participants have been divided into two groups. The criteria for dividing into groups has been the answers to questions devoted to identifying the degree of student participation in research activities (NID), the effectiveness of NID, the experience of using scientific knowledge.

The first group - “Active members of the NID” (N = 150) are participants of the Student Scientific Society of the university who make presentations at conferences, participate in olympiads and competitions, have publications in collections of scientific papers, become laureates, winners and prize-winners at various conferences, olympiads and competitions.

The second group has received the name - “Less active participants in the NID” (N = 80) - these are university students who have taken part in scientific student events less effectively, less often became winners and winners until they published the results of their research activities.

Results

According to the question "Why do people engage in scientific activity, become scientists?" (Tab. 1) it turned out that the ideas of university students about the image of a scientist is curiosity, readiness to engage in creative, innovative, creative activity, which is of high importance at the state level.

Table 1: Answers of university students - participants of the NID to the question "Why do people engage in scientific activity, become scientists?",%

Answer Options	General	Active participants in the NID (N = 150)	Less active participants in the NID (N = 80)
I like it, it is interesting	70	68.7	72.5
Desire to invent / learn new	13.5	10.7	18.8
Develop our country / science	15.2	19.3	7.5
Material benefit	0.9	0.7	1.3
Prestige, fame	0.4	0.7	0

Material incentives and motives of public recognition are less significant than the scientific activity itself. It can be noted that the choice of "desire to invent or learn new things" and "development of the country / science" has been made by university students who are actively involved in scientific research.

Based on the answers to the question "What are the main problems of modern science, you can name?" (Tab. 2) it has been revealed that most university students note a combination of internal and external factors. According to students, people these days lack personal interest, involvement, perhaps curiosity, and confidence in personal material well-being to engage in research work. This assumption is relevant in the midst of the younger generation, university students, since at this age stage, professional self-determination and entry into an independent adult life take place. So, individuals who decided to build a scientific career, according to the respondents, leave their homes in search of a more paid and technologically comfortable place of work, including abroad.

Table 2: Answers of university students - participants of the NID to the question "What are the main problems of modern science you can name?",%

Answer Options	General	Active participants in the NID (N = 150)	Less active participants in the NID (N = 80)
Lack of funding	50.9	49.3	53.8
People are not interested in scientific work	11.7	12.0	11.3
Lack of personnel	10.9	14.7	3.8
Brain drain to other countries	8.7	6.0	13.8
Outdated equipment	6.5	7.3	5.0
Low level of education	3.5	2.7	5.0
Excessive commercialization of science	3.5	4.0	2.5

Not enough youth (qualified personnel) in science	1.7	2.7	0.0
Unclaimedness of scientists in the labor market	1.3	0.0	3.8
Lack of information	1.3	1.3	1.3

We would like to note the difference in the number of responses of active and less active participants in the NID regarding the position of personal interest in doing science. It is possible that, at the time of the study, less active students lack an element of fascination for more active participation in research activities at the university.

In answers to the questions “What scientists of Russia do you know?” and “What scientists of Chuvashia can you name?” (table 3) the answers have been distributed as follows. Students named mainly prominent people of domestic science of past centuries (Russian scientists - 57% and scientists of the Chuvash region - 52%). Students are less aware of the state of science at the regional level (65% are scientists of the Chechen Republic versus 89% are scientists of Russia).

Most students named the following prominent scientists and educators of Russia 18-19 centuries: the first Russian natural scientist Lomonosov M.V., a famous scientist-encyclopedist, chemist, physicist Mendeleev D.I., fzik, electrical engineer and inventor Popov A.I. , surgeon, creator of the anatomical atlas Pirogov N.I., first researchers of higher nervous activity, physiologists Sechenov I.M. and Pavlov I.P.

Representatives of the Chuvash region that have been named: the linguist, author of the Chuvash dictionary Ashmarin NI, orientalist, one of the founders of Russian Sinology Bichurin N. Ya., mathematician, founder of the Russian school of shipbuilding Krylov A. N., teacher, leading Chuvash educator Yakovlev I. Ya.

Among the modern scientists of Russian science of the 20th century were named: designer-rocket engineer Korolev S. P., Nobel laureate, physicist Sakharov A. D.

Modern scientists of the Chuvash region: the teacher, founder of ethnopedagogy Volkov G. N., chemist Abakumov G. A., historian, archaeologist, leading researcher of the medieval history of the Volga and Volga peoples V. D. Dimitriev, physicist, doctor of physical and mathematical sciences, creator of the first NI laboratory in physics in Chuvashia Abrukov S. A., scientist in the field of theoretical mechanics, teacher-organizer of higher school Saykin S. F.

From our point of view, it is significant that very few women scientists have been named. In the views of students, the image of a scientist is male. Of the Russian scientists of the past centuries, the following were named: the mathematician, mechanic, the first woman in the world - professor of mathematics S. Kovalevskaya and psychologist, founder of domestic pathopsychology Zeigarnik B. V. Of the modern scientists of Chuvashia, only 2 women were named, the representatives of the university in which the study was conducted.

It should be noted that students very rarely indicated their own teachers as modern scientists. Almost all of them conduct serious scientific activity and have a scientific degree. This fact indicates that students need to cover the achievements of university science as broadly and vividly as possible, to acquaint with outstanding scientists working in the university, women scientists, which will contribute to a wider involvement of student youth in science.

Table 3: Answers to the questions "What scientists of Russia do you know?" and "What scientists of Chuvashia can you name?", man/% (N = 230)

Answer Options	Scientists of Russia	Scientists of Chuvashia
Modern scientists	74 (32%)	30 (14%)
Figures of science 17 - 19 centuries	132 (57%)	121 (52%)
Difficulties to answer	26 (11%)	79 (34%)

The question has been asked about the ideas about the features of motivation of scientific research activities of scientists for a more detailed study of the ideas about the science of university students,. The motives of the research activity were taken from the research of Yu.S. Medvedeva, T.V. Ogorodova (Ogorodova T.V., Medvedeva Yu.S., 2013) and were evaluated on a five-point scale. The results were distributed as follows (Tab. 4).

Table 4: Motivation of the research activities of scientists in the views of university students

NID motivation	General indicator	Active NID participants (N=150)	Less active NID participants (N=80)	Significance of differences	
				t	p
Professional level	4.24 ± 0.81	4.23 ± 0.82	4.26 ± 0.81	-0.317	0.751
Comfort	4.17 ± 0.84	4.11 ± 0.87	4.28 ± 0.78	-1.450	0.148
Social Utility usefulness	4.14 ± 0.83	4.15 ± 0.83	4.11 ± 0.84	0.355	0.723
Communication	4.06 ± 0.94	4.10 ± 0.94	3.98 ± 0.95	0.956	0.340
Creativity	3.97 ± 0.96	3.97 ± 0.99	3.95 ± 0.90	0.176	0.861
Career	3.30 ± 1.06	3.31 ± 1.08	3.28 ± 1.04	0. 260	0.795
* Material well-being	3.12 ± 1.09	3.28 ± 1.09	2.81 ± 1.02	3.160	0.002

*Note: * - differences significant at $p \leq 0.01$.*

Students see the "Professional level" as the most dominant motive for doing science, interest directly in the field of science and the desire to deepen their professional theoretical knowledge, the desire to become a strong specialist in their field, the development of new technologies and theories not only in their field, but also related ones.

In second place is the attributed motive "Comfort," which in this classification of NID motives is understood as the desire for convenience and freedom of action, the preference for some independence, the absence of pressure. Interest in the activity itself is associated with the conditions for the implementation of the activity, while the activity will become unattractive if there are conditions that do not satisfy the person and vice versa.

The third rank is the motive "Social Utility". This type of motivation for NID is characteristic of people seeking to interact with society and the ability to influence it, while such people need not only to be useful, but to feel their importance in doing so.

Further on the representation is the motive “Creativity” which is associated with the need for the possibility of self-realization and self-development in scientific activity in a creative context, implementation in a topic of interest, creating a new, previously unknown, unique.

The motives “Career” and “Material well-being” are turned out to be the lowest in the study.

Most students involved in research activities have not appreciated the importance of Career motivation related to rapid career advancement, ensuring respect and acceptance by society or the team, when the interest in the activity is not related to its subject, but to the possibility of promotion in service.

Such a motive for pursuing science as “material well-being” is expressed in the desire for prosperity and financial independence, realized through research activities, has been rated the lowest. This type of motivation has given the opportunity to identify significant differences ($p \leq 0.01$). Students who are effectively engaged in scientific work within the walls of the university have rated higher this type of motivation. Perhaps this is due to the fact that they know more about the possibility of obtaining grant support, other forms of material support and encouragement of scientific activity.

Conclusion

Based on the results, we can offer the following recommendations for activating the NID of students at a university:

It is necessary to consider the personal interest of students as one of the main elements for the development of their research activities, to identify and help them use their emotional attitude to various forms of scientific work. To conduct trainings in order to disclose and develop the interests, inclinations, motives of students. To develop the motivation and creative activity for research activities through participanion practical conferences, Olympiads, in scientific competitions and forums (Alexandrov A.Yu., et al, 2018).

To create conditions for increasing the motivation of learning by taking into account individual aspirations, inclinations and interests of students, taking into account their wishes regarding the organization of forms of scientific and educational activities, providing the opportunity to independently choose some disciplines, conducting special courses. It is necessary that the content of training be practice-oriented and consistent with the direction of future professional activity of a university student (Zakharova A., Talanova T., et al, 2018; Morova N.S., et al, 2017).

To develop the scientific potential of university students with the inclusion of active and interactive teaching methods in research activities to enhance the process of learning new things, ways to stimulate independent and creative search in solving educational and research problems .

To conduct psychological training in order to disclose and develop scientific, creative interests, inclinations, and enhance the motives of students' research activities.

To increase the forms of students' personal and emotionally involved participation in the development of new material through business games, round tables (discussions, debates), quests, intellectual games, project activities, the BarCamp method, when students themselves are the ideological organizers of conferences.

To give university students the opportunity to learn about the scientists of their time. So that university students have information about the achievements of teachers of higher education, about scientific researchers of our time. To do this, you can conduct master classes and various meetings with scientists and teachers of higher education.

Considerable experience has been accumulated in the direction of popularizing science, enhancing the research activities of students, including raising the awareness of university students about modern scientists through organizing various meetings and master classes with scientists, modern

scientists, informing about achievements of science and teachers of higher education as a research scientist in the Chuvash State University.

Abstract

Purpose: Aim of the present study is to examine the influence of Psychological Capital (PsyCap) and Work Engagement (WE) in predicting Employees Well-Being (EWB) who work in Jakarta as the capital city of Indonesia. Variables of PsyCap consist of self-efficacy, hope, optimist and resiliency. WE determine by employee's vigor, dedication and absorption, while employee's subjective well-being explained as the employee's overall satisfaction in the three aspects including work, life and psychologically. **Design/methodology, approach:** Quantitative research design is used in the present study. 400 employees who work at Jakarta were participated in this study. PsyCap measured by a scale developed by Luthans et al. WE measured by *Utrecht Work Engagement Scale* (UWES) and EWB measured by Scale developed by Zheng et al 2015. Two step Structural Equation modelling was used to analyze data. Confirmatory Factors Analysis (CFA) showed that, the measurement model of each variables are valid and reliable. **Result:** Result in the present study found that, PsyCap and WE significantly predict EWB with R Square 63.5 %. PsyCap show higher coefficient correlation with EWB ($r= 0.587$, $p <0.01$) in compare to the relationship between WE with EWB ($r=0.260$, $p<0.01$). Therefore, to ensure employee well-being, it is important to promote self-efficacy, hope, optimist and resilience among employees who work in Jakarta. Not only that, employee's dedication, vigor and absorption toward their job also can predict employee's well-being.

Keywords: Employee well-being, Psychological capital, Work Engagement

Introduction

Chartered Institute of Personnel and Development research (CIPD, 2007) shows that health and well-being in the workplace increase business productivity. Employee well-being (EWB) is actually the quality of employee life and psychological status at work (Siegrist et al., 2006 in Zheng, Zhu et al, 2015). This involve satisfaction with job and the absent of emotional exhaustion at work. Although it is sound promising for a quality job, however, maintaining the well-being among the urban employees is not an easy task.

Various problems faced by the urban employees every day, it is not only due to time consuming during the traffic jump, a very competitive working environment, demanding superior at work and juggling with work life balance. Therefore, urban employees need to ensure their well-being for a better job performance.

Past study shown that, psychological capital as one of the variables related to individual internal characteristic, significantly enhance employee well-being. Psychological capital is a positive psychological state of an individual that is characterized by having self-efficacy, hope, optimism and resiliency (Luthans, 2007 as cited in Chen & Lim, 2012).

Other variable that also can enhance employeee well-being, which related to job aspect, is the work engagement. Schaufeli and Bakker (2004), stated that, employees who engaged with their job show,

absortion,vigor and dedication toward their job. However, still lack of study focusing on the empirically test, the relationship between these two variables, especially in the context of urban employees in the Asian countries.

Therefore the present study aim to examine the roles of psychological capital and work engament in predicting well-being among the urban employees who work in Jakarta. Jakarta is one of the biggest cities in Indonesia. Which consist of 304,397 worker who work in this city as per year 2011 (www.bps.go.id). The work demand and stressful work and life problems commonly experience by employees in Jakarta nowadays. As Nafiri (2015) found in his study, there is the impact of stress on work and the well-being of the employees in Jakarta. Further, study also found that, the engagement level among the employees in Jakarta also not high. Therefore, the present study will shed a light on promoting well-being of the urban employees, by designing a proper intervention in enhancing psychological capital as well as the work engagement among the urban employees in Jakarta.

Literature Review

Employee Well-being

There are two main philosophical perspectives on well-being, the first being happiness-oriented e.g. hedonism and subjective experience of happiness. Other perspectives are aware of potential human strengths, for example eudemonism results from personal achievement, self-actualization, or self-position. Most recent welfare studies accept these two different perspectives (Ryan & Deci, 2001 in Zheng, Zhu et al, 2015). In the present study, employee well-being involves three basic aspects namely life, work, and psychological (Zheng, Zhu et al, 2015).

Work Engagement

According to Schaufeli and Bakker (2004), work engagement consist of; vigor, dedication and absorption. Vigor is characterized by high levels of energy and mental endurance at work. Dedication is characterized by a sense of importance, enthusiasm, inspiration, pride, and challenges, while, absorption is characterized by being fully concentrated and happy at work, where time passes quickly and one has difficulty separating from work (Burke, 2006).

Psychological Capital

Luthans (2007 as cited in Chen & Lim, 2012) stated that, there are four dimension of psychological capital including the; self efficacy, hope, resilience and optimism. Self efficacy which reflect, ones'confidence to carry out tasks or achieve goals. Hope, refers to an individual's perceived ability to obtain pathways to achieve desired goals and to motivate oneself through thinking agents to use pathways. Optimism refer to those who make internal and stable attributions regarding positive events and negative event attributes (for example, job loss) to external, temporary, and situation specific factors. Resiliency refers to the capacity to recover from adversity, conflict, failure, or even positive events.

Relationship between Psychological Well-being, Work Engagement and Employee Well-being

Past studies examine several factor that related with employee well-being. Katie Davis (2016) examines the roles of Corporate Psychopathy and The Influence of Negative Leadership Behaviors on Organizational Performance and Employee Well-Being" . This study found that the more the leader shows psychopahty characteristic, the more likely that the employees will not have a good well-being. Further, Abbas and Usman Raja (2015), indicated that, psychological capital also related with innovative performance and job stress in Pakistan.The result of this study stated that, the employees who are innovative and less stress are the one who have psychological capital.

Oi Ling Siu (2013) examine the relationship between "Psychological Capital, Work Well-Being, and Work-Life Balance Among Chinese Employees. Result indicated that, psychological capital significantly related with work well-being.

Previous study, also found that work engament is related with good organizational culture. The more enganged the employees, the more likely that, organizational culture create a better job outome and happy workplace (Akbar, 2013). Carolyn Timms, Paula Brough, Michael O'Driscoll, (2014) conducted study on the flexible work arrangements, work engagement, turnover intentions and psychological health. This study found that, employee engagement is related with the psychological health of the employees.

Based on the literature, the hypothesis of the present study are:

- Psychological Capital and work engagement predict well-being among urban employees in Jakarta.

Method

Quantitative research design is used in the present study. 400 employees who work at Jakarta were participated in this study. PsyCap measured by a scale developed by Luthans et al. WE measured by *Utrecht Work Engagement Scale* (UWES) and EWB measured by Scale developed by Zheng et al 2015. Two step Structural Equation modelling was used to analyze data. Confirmatory Factors Analysis (CFA) showed that, the measurement model of each variables are valid and reliable.

Result and Discussion

Results of the confirmatory factor analysis shows all dimensions are valid and reflecting their respective variables in which, all dimensions of each variable have a loading factor> 0.5. From the psychological capital variable on the dimensions of self-efficacy of 0.708, hope of 0.773, resiliency of 0.664 and optimism of 0.631. In the work engagement variable on the vigor dimension of 0.846, dedication of 0.836 and absorption of 0.761. Employee well-being on the LWB dimension of 0.618, WWB of 0.759 and on the PWB dimension of 0.695.

In addition, all the measures used in the present study also indicated that a reliable measure with Critical ratio greater than 0.5.

Result of structural model of the analysis after conducting some modification to fit the model, found that, there is significant contribution between psychological capital ad work engagement with employee well-being. In which PsyCap and WE significantly predict EWB with R Square 63.5 %. PsyCap show higher coefficient correlation with EWB ($r= 0.587$, $p <0.01$) in compare to the relationship between WE with EWB ($r=0.260$, $p<0.01$).

This finding is line with the previous study done by Oi Ling Siu (2013) who found that the more the employees show Psycap the more likely that that will have the well-being. In addition, result in the present study also inline with the previous finding on the role of work engament in enhancing well being. Carolyn et al (2014) indicated that, employees who show well being will perform better at work and more happy at the work place. In addition, Oktaviana Sasmita and Mardhatillah (2019), also stated that, a better well being can be achieved through individual efficacy in balancing about work life and see the enhancement between different roles. This efficacy is inline with the aspect of psychological well being, in which the more individu believed that, they are capable in doing the task the more likely that they will have a better well being.

The contribution of Psycap are greater than work engagement in the present study. This result lead to the important intervenstiom in enhancing Psycap among employees in Jakarta. Several interventions can be done to enhance self efficacy, hope, resilience and optimism. Resilien at work program can be design by the organization, in away to enhance individual coping strategies in dealing with difficult situation as well as promoting the self love. Several self help training can be implemeted at the workpalce to enhance Psycap. Not, only that, office policies and culture can be realligned in way to promote better wellbeing among the employees.

Further, with regard to the employee engagement, several work crafting activities, in term of task crafting, relational crafting and the variation in doing the job, might enhance employees dedication, absortion as well as vigor in conductin their job. By ensuring the work engagement consistently improved as well as continuously enhance the Psycap skill among the employees, the wellbeing among employees in Jakarta might be come better and lead to a better performance at work.

Conclusion

In conlusion, the present study , found significant relationship between Psycap and work engagment with employee well being in Jakarta. Therefore, to ensure employee well-being, it is important to promote self-efficacy, hope, optimist and resilience among employees who work in Jakarta. Not only that, employee's dedication, vigor and absorption toward their job also can predict employee's well-being.

Abstract

The organization flexibility is one of the key determinants of increasing efficiency and effectiveness, and as a result increasing the chance for success in project management. It is most often defined as an organization's ability to make changes under the external and internal factors, and the degree of adaptability to changes within the project environment. Modern conditions of the companies' operations put new challenges to project teams, and higher flexibility of the organization is now a very desirable attribute. Changes in the area of project teams' flexibility are inherently related to the flexibility of the parent organization structure in which the teams operate. The aim of this Paper is to present the results of a pilot case study to identify the intensity of the basic structural dimensions occurrence to determine the flexibility of project teams' organization. The research techniques used are: analysis of the organizational documentation content and an in-depth semi-structured interview within the method of multiple exploratory case studies, aiming to formulate further research directions. The article presents the results of a study conducted in the second half of 2019 for two companies (A and B) with foreign capital, operating in Poland. The findings showed that company B, as a result of the transformation, began to show higher flexibility in the organization of project teams and consequently better adapted to the conditions of its external and internal environment.

Keywords: Organization Flexibility, Project Teams, Structural Dimensions, Production Companies

Introduction

In today's world, project management, the organization of flexible project teams and the continuous improvement process to meet the various customer expectations for new and innovative products are becoming ever more important (Thompson, 2018; Trocki, 2014).

There are many terms for project teams in the literature: task forces, work teams or problem teams. Most often they are defined as a temporary group of people appointed to solve a specific task. Project structures ensure the integration and coordination of the individual team members work and significantly increase the flexibility of a particular organization (Lichtarski, 2018; Kerzner, 2017; Lock, 2014).

Large and medium-sized companies face increasing intra-organizational obstacles to their adaptation to dynamic environmental conditions (Bełz and Cyfert, 2017; Basol and Dogerliogliu, 2014). The literature studies conducted have shown the presence of many concepts relating to the issue of project management success factors, increasing the efficiency and effectiveness of project teams (Ika, 2009). It has been noted that a significant contribution to organizational efficiency has the shape of an organizational structure, as it helps to cope the problems related to management, enables the innovation capability and employee relationships improvement while reducing costs.

The basic attributes of a flexible organization are: active adaptation to change in the company, the ability of employees to participate in many projects simultaneously and to set priorities quickly,

integration (a sense of being a team member with the company and a willingness to change roles) in addition to commitment and readiness to changes (Galbraith, Downey and Kates, 2002).

The most influential concept has been the proposal of the Aston group (Pugh et al., 1976), who have empirically confirmed the existence of five basic dimensions of the organizational structure, that is: specialization, standardization, formalization, centralization and configuration. The intensity of structural features determines the organic nature of the examined structure, i.e., the lower the intensity of features, the more organic (less mechanistic) the structure and vice versa (Burns and Stalker, 1961). To the basic structural features need to be added the networkability, defined as the durability of the network configuration and its complexity, that is the result of increasingly intense inter-organizational cooperation, as well as the shifting of organizational boundaries. The extreme states of these dimensions make it possible to distinguish two types of structures with different flexibility: mechanistic (inflexible) and organic (perfectly flexible) structures and an infinite number of intermediate states (Burton, 2011).

The reason for undertaking the subject of the study are certain gaps in empirical research and theoretical analysis in management-related sciences. The theoretical gap identified by the Authors is insufficient recognition of project teams' organizational structures in manufacturing companies in the context of their flexibility evaluation. On the other hand, the empirical gap results from the deficiencies of research studies, which focus mainly on quantitative rather than qualitative researches - without considering the context of the examined reality. The use of the case study method, allows to examine and understand today's phenomena in an in-depth and multifaceted way. The aim of the article is to present the results of the pilot case study, which is to identify the intensity of occurrence of basic structural dimensions to determine the flexibility of project teams' organization.

Research Methods

The pilot study, conducted in the first half of 2019, covered two companies from Lower Silesia focusing on the production of electrical machinery and equipment for the power sector with an international range. A purpose selection was used here, based on the following criteria: type of activity - production, the need to execute orders through project management with the involvement of project teams, the size of companies classifying them as large and, most importantly, the companies affected by the acquisition (an important external factor of the environment, allowing to verify the degree of flexibility of the organization). The companies examined, coded in the article as "A" and "B", are multinational companies with foreign capital, of which company "A" was acquired by "B". The research methods consist of two parts. In the theoretical part the analysis of Polish and foreign literature on the subject was used, in the empirical part the Authors used the measurement process of multiple case studies, the questionnaire of a semi-structured in-depth interview addressed to respondents - representatives of senior management, actively participating in project teams for at least several years. The questions concerned issues allowing to determine the occurrence intensity of particular structural dimensions in order to determine the flexibility of project teams' organization. The Authors of this study, to maintain the context of the examined reality, used the qualitative characteristics of the examined phenomena, supplementing it with the quantitative presentation of structural features. The range of the measurement scale for determining the occurrence intensity of structural indicators is in the range from 0 to 1. The use of a unified and coherent measurement scale allows to precisely measure the current state and changes in the occurrence intensity of individual features and to compare them with each other. A thorough analysis of the organizational documentation content was done: charts of organizational structures, regulations, procedures and instructions for project execution as well as roles and responsibilities of team members. The reason for the use of multiple/comparative case studies was the repeatability of the research procedure and the possibility of comparing the results from different cases with each other (Yin, 2009).

In order to achieve the objective of this Article, the following research questions have been formulated:

- RQ 1. What is the occurrence intensity of particular structural dimensions in both examined companies?

- RQ 2. Which of the examined companies A and B shows higher flexibility of project teams' organization?

The Authors have attempted to determine for the companies examined the intensity of occurrence of the basic structural dimensions of flexibility, i. e. indicators: configuration, centralization, specialization, formalization and networking, using modified concepts of Pugh et al. (1976). The Authors took into account the dimension of networkability and applied formalization in the context of details and rigorousness, omitting standardization. In order to determine the degree of flexibility in the organization of project teams, the direction of influence of individual dimensions on higher flexibility (dependent variable) had to be unified to correspond to the orientation of influence on specialization and networking. Accordingly, the flatness of the structure, which is the inverse of the configuration's slenderness, decentralization instead of centralization, and a move away from bureaucraticity as the inverse of formalization were used to show greater flexibility. To determine the occurrence of structural dimensions, the Authors used the following formulas.

$$W_S = \frac{S}{(Rp + S)}$$

S - number of levels of structure in the most vertically expanded unit

Rp - arithmetic mean of typical control spans for all levels
Rpi - arithmetic mean of typical control spans at i-th level

The total centralization index Cp was determined using the following ranks for decisions: w = 1 execution; w = 2 allocation; w = 3 methodical; w = 4 directional most relevant for the organization development. To this purpose, the respondents were asked a question: what affects the distribution of decisions within the organization and what levels of organization hierarchy of making a particular decision. The formula was used to determine it:

$$C_p = \frac{\sum_n^{i=1} C_i}{f_o}$$

Ci - an indicator of centralization of decisions within individual functions
fo - number of functions implemented in the company (12 were taken)
In order to determine the specialization indicator (Si), the respondents were asked to clarify the division of responsibilities in their company (how many positions have been defined for a specific function) using the following ranks: r = 1 position; r = 2 section; r = 3 department; r = 4 division.

$$S_i = \frac{r_i}{r_{max}}$$

Si - degree of specialization i-th function

ri - ranks of the degree of specialization i-th function
r max - highest possible rank value (rated as 4)

Total specialization indicator (for the entire company) – So

$$S_o = \frac{\sum_n^{i=1} S_i}{f_o}$$

So - total specialization degree indicator

Si - specialization indicator i-th function
fo - number of organizationally identified functions (12)
The rate of formalization was determined for individual document Fd and the entire company Fp using the following rank values: r = 1 activity is not included in the organization's documentation at all; r = 2 activities are included in general; r = 3 activities of the members of the organization are defined in more detail; r = 4 existing regulations almost completely limit the employees' behaviour in a respective area.

Formalization degree indicator for a particular document – Fd

$$F_d = \frac{r_d}{r_{max}}$$

rd - the rank value of formalization for a given document resulting from its content and strictness of information
r max - highest rank value (rank 4 was taken)
Total degree of formalization indicator (for the entire company) – Fp

$$F_p = \frac{\sum_{d=1}^{n} F_d}{n}$$

Fd - the degree of document formalization
n - number of all organizational documents
Networkability intensity indicator - N was determined by the Authors of this study using the proposed formula below:

$$N = \frac{m}{M}$$

m - number of positions of project team members from outside the organization of the examined company, i.e. all members of the project team from outside the local company organization
M - total number of positions in project teams in a particular company

Empirical results and Discussion

According to the research, the configuration indicator (Ws) in company A is Ws=0.28, and in B: Ws=0.25. The flatness of structures was determined from the difference 1-Ws (company A: 0.72, and company B: 0.75). The proportion of administrative positions to all positions in each company is about 1/4 of the staff (Table 1).

Table 1: Indicator of the configuration and span (range) of control for the examined companies

Company:	**A**	**B**
Ws	**0.28**	**0.25**
1-Ws	**0.72**	**0.75**
S	5.00	4.00
Rp	12.93	11.69
Rp: level 1	6.00	14.00
Rp: level 2	2.83	17.75
Rp: level 3	2.67	3.00
Rp: level 4	3.17	12.00
Rp: level 5	50.00	-

According to the research, in the most vertically expanded unit of company A the number of levels is S=5 which is 1 level higher than in the company B. On the other hand, the arithmetical mean of the typical spans of control (Rp) on particular levels is similar for both examined companies (respectively in A: Rp=12.93, and in B: Rp=11.69). However, it is important to point out that the range of control is significantly different for both companies at the highest level (A: Rp=6, and B: Rp=14) and at the second level (A: Rp=2.83, B: Rp=17.75), which shows the reason for reducing the number of management levels of company B while maintaining a similar number of employees. The total centralization indicator Cp is similar (respectively in company A: Cp=0.55 and in company B: Cp=0.56), and consequently decentralization intensity of structures was determined from the difference 1-Cp (company A: 0.45 and B: 0.44). In company B the senior management wants to have more often its significant contribution to the decision-making.

The Si specialization indicator in company B is 0.70, while in company A it was only 0.58. The higher by 20% index of company B is the result of a large grouping of specialized jobs due to competence and combining them into specialized larger teams.

The formalization indicator Fp in company A is 0.82 and in the company B it was significantly lower, 0.65. So in company B the formalization indicator is lower by 21%. The lower the formalization degree, the higher the flexibility is, so the Authors determined the inverse indicator for the bureaucraticity of the organization from the difference 1-Fp (Table 2).

Table 2: Formalization indicator for the examined companies

Company:	**A**	**B**
Fp	**0.82**	**0.65**
1- Fp	**0.18**	**0.35**
Fd	29.50	23.25
n	36.00	36.00

This indicates a certain freedom of acting, it does not limit the B company's staff to rigidly adhere to the written rules, it allows for a certain individualization in the approach to their interpretation. With the acquisition of company A by company B, many of the previously existing organizational documents have lost their validity or have been replaced by new ones, valid only in company B.

The last of the examined dimensions was the network intensity indicator N, which in enterprise B was considerably higher than in A and was 0.33 (Table 3).

Table 3: Networkability indicator for the examined companies

Company:	**A**	**B**
N	0.12	0.33
m	2.00	7.00
M	17.00	21.00

This is due to the different number of external business partners in the inter-organizational networks of the examined companies: in B it is 7 people out of 21 team members, while in A, 2 people out of 17. To illustrate better the differences in the degree of flexibility between companies A and B examined, a figure showing these differences is given below.

Fig. 1: Comparison of the intensity of structural dimensions of the examined companies A and B

Conclusion

The research on the flexibility of organizational structures was carried out through the perspective of their specific features, such as specialization, configuration, centralization, formalization and networkability, which taken together determine the degree of flexibility of the organization.

With regard to the first research question, the self-conducted research shows that the particular structural dimensions of the two companies are significantly different. In the company B, due to the larger number of project team members and their higher geographical dispersion, coordinating the work of the team requires more effort from the project coordinator. The project teams operate in a more multicultural organization with dominant forms of communication being rather virtual.

Referring to the second research question, company B is much more flexible than A. The organizational structure of both companies is mixed, showing at the same time the attributes of functional and matrix structure at different levels of management. The companies examined use the PMI project management methodology and the projects lifecycle is relatively long (from 9 to 48 months). Company A has been incorporated into the global supply chain of company B, with stronger market rules and competing inside the organization and with external companies also. This was an important exogenous factor for the transformation and increased flexibility of the organizational structure.

In the future, the Authors plan to expand the scope of research in terms of sample size and examined objects. Due to the limitation of the research sample size to only two companies (pilot studies), the Authors are aware the generalization of research results should be done carefully. The Authors recommend further research, including quantitative approach on a larger sample size, in order to increase the certainty of inductive deductions for formulating generalizations, and also propose the following research question: Which are the key factors for the flexibility of project team organization in manufacturing companies?

Abstract

This article is devoted to the analysis of issues regarding the problems and prospects of legal regulation of digital economy in a modern state. It is noted that in the current legal system of the Russian Federation relations related to the development of digital processes are not regulated in a comprehensive and systematic manner. In particular, at both the legislative and by-law levels, such institutions of the digital economy as "block chain," crypto currency" , "startup," "smart-contact", "ICO" (primary placement of obligations in the market of crypto currency) and some others are still not properly regulated. Within the framework of this work, the authors have attempted to define the peculiarities of the legal regulation of the digital economy in Russia and in the world, to highlight some discussion and problematic points on this problem and to express their own position for their solution. At the end of the study, the authors propose how to use foreign positive experience in this direction and determine the directions of its refraction in the Russian legal system.

Keywords: Legal Regulation, Digitalization, Digital Economy, Digital Economy Institutions, Information Society, Innovations, National Program.

Introduction

It should be noted that currently in the Russian Federation and in the world there is a digitalization of various spheres of society, connected with the active application of information technologies in the development of the information society. One of the segments of general digitalization is the digital economy, the effective functioning of which as a whole and its individual institutions seems impossible without a qualitative (arbitrary and non-competitive) legal regulation of the relevant sphere of social relations. Meanwhile, it should be noted that in the current legal system of the Russian Federation, relations related to the development of digital processes are not sufficiently regulated in an integrated and systematic manner. In particular, at both the legislative and by-law levels, such institutions of the digital economy as "block chain," crypto currency", "startup", "smart-contact", "ICO" (primary placement of obligations in the market of crypto currency) and some others are still not properly regulated. This situation, as confirmed by a number of scientists [1], causes gaps in the legal regulation of the digital economy, as well as various legal conflicts that actually lead to the displacement of a number of digital transactions, carried out primarily by small and medium-sized businesses, into an illegal financial and economic field. Moreover, resources attracted by domestic business entities in virtual world capital markets, for example, as a result of the issue of crypto

currencies are qualified by the law enforcement agencies of the Russian Federation as "operations for the illegal import of capital," which is the basis for administrative and criminal liability.

In foreign countries, too, the legal vacuum in the regulation of the digital economy causes serious problems in the social sphere. Thus, N. Jones, as an example of such a situation, cites the introduction of such innovative technology as Uber in the sphere of services provision, as a result of which the traditional model of legal regulation of transport services provision was not applicable in a number of countries, in particular in India [2]. Moreover, some Western scientists believe that the development of the digital economy can significantly change the established goals, tasks and functions of public authorities and even influence national sovereignty [3].

In this regard within the framework of this article, it seems appropriate to refer to the definition of peculiarities of the legal regulation of the digital economy in Russia and in the world, to highlight some discussion and problematic points on this problem and to express the authors' view on their solution.

Methodology

The methodological basis of the study is based on the application of various popular scientific techniques and methods of scientific knowledge (analysis, synthesis, derivation, induction, system-structural, formal-logical approaches), as well as private scientific methods - formal-legal, comparative-legal and interpretative.

Discussion and Results

Before considering the peculiarities of the legal regulation of the digital economy, it seems logical, from our point of view, to turn to the concept of legal regulation as a whole. Note that "regulation" (from lat. regulare - to put in order) in social, political, psychological, and economic domains can take many forms: legal restrictions promoted by a government authority, contractual agreements (for example, contracts between regulations and regulations 4 norms), co-regulation, third-party regulation, certification, accreditation or market regulation [5].

This approach makes it possible to speak of legal regulation as a whole as a dynamic system (process), including the formation of legal norms; their effect which results in legal relations arising or changing; realization of subjective rights and obligations through which the objectives of legal regulation are achieved [6; 7, 8; 9].

As for the concept of "digital economy," the emergence of the corresponding concept in the 1990s is related to the name N. Negroponte, who, using the metaphor about "the transition from atom processing to bit processing", noted the lack of classic goods in their "physical" embodiment such as weight, raw materials, transport, and declared advantages of a new economy based on lack of goods weight, virtuality, lack of demand for raw materials, instant global movement [10]. In the legal literature, in parallel with the concept of "digital economy," the term "intellectual economy" is also found. The authors of this term associate the functioning of this economy type with the wide use of innovation, including artificial intelligence [11].

As the Competition Committee of the Finance and Business Office of the Organization for Economic Co-operation and Development (OECD) notes the concept of "digital economy" is the basis for referring to markets focused on digital technologies that are generally involved in the trade of information goods or services through electronic commerce. The digital economy operates on a multilevel basis with separate segments related to data transmission [12].

It should be noted that the specific characteristics of the digital economy, which differ from the post-industrial model of recent times [13], require a qualitatively different model of legal regulation, to the peculiarities of which we propose to refer in more detail.

First, let us draw attention to the fact that the digital economy is more globalized than traditional models of economic relations. Due to that certain regularities and universal principles of its legal regulation at the international and national levels in different countries can be found, so that the ways of solving emerging problems in legal regulation found in different countries will also be identical. Thus, in Russia and in the world, there is uncertainty and fragmentation in the legal regulation of the digital economy institutions, which cause problems at the international level.

The main difficulty in this matter is the specificity of the subject matter of the legal regulation. The fact is that the digital economy cannot be described as a single structured system, and therefore cannot be regulated by a "package" of laws or by public administration reform in this area. This system is complex, includes a wide variety of institutions and activities and does not cover all sectors of economic activity.

The specifics of the legal regulation in this field can be described in the following example. Thus, in 2009, the report of the Australia Government Department of Broadband, Communications and Digital Economy, setting out a strategy for the development of the digital economy in the country, noted that the development of the sector required concerted action by society, industry and the State, whose role was to fill market gaps, avoid social inequality and ensure the legitimate and efficient functioning of markets. The main task of the State is to provide opportunities for all subjects to take advantage of digital opportunities through the creation of appropriate infrastructure, the promotion of innovation and the consolidation of a favourable legal regime. [14]

The main idea of this report is a perfectly fair indication that "digital" regulation and "digital" development based on it in all spheres of social relations is possible only on the basis of clear strategic conceptual planning. This principle of legal regulation of the digital economy in the Russian Federation has been embodied in the relevant strategic documents.

The main strategic document that established the legal definition of the digital economy in the Russian Federation, is the Decree of the President of the Russian Federation No. 203 of 09.05.217 "On the Strategy for the Development of the Information Society in the Russian Federation from 2017 to 2030," which established the purposes, tasks and measures for implementation of domestic and foreign policy of the Russian Federation in scope of information and communication technologies, aimed at the development of the information society, the formation of the national digital economy, the promotion of national interests and the implementation of strategic national priorities. According to this regulation, the digital economy is economic activity, the production key factor of which is digital data, processing of large volumes and use of the results of analysis. If to compare with the traditional forms of economic management they allow to increase significantly the efficiency of various types of production, technologies, equipment, storage, sale, delivery of goods and services [15].

The document specifying the Strategy, in terms of the digital economy, is Resolution of the Government of the Russian Federation No. 234 of 02.03.2019 "On the System of Management of the Implementation of the National Program "Digital Economy of the Russian Federation"[16], which established the functional structure of the management system; procedure for development, monitoring and control of federal projects implementation; responsible authorities and organizations. This document "replaced" the previous program of the same name, but retained most of its shortcomings, namely, the lack of a definition of the concept of the digital economy and its structure; incomplete quantitative indicators of the future development of its national sector; poor development of issues of integration of domestic subjects of economic relations in the virtual segment (lack of an indication of the institute "block chain"); pretentiousness, non-availability with specific legal requirements [1, p. 70].

Foreign experience in the legal regulation of the problem is of interest in this study. In particular, since 2016, the United States has developed and implemented a comprehensive program for the development of the digital economy "Digital Economy Agenda" [17, p. 51], which regulates simultaneously the access liberalization and information security of citizens on the Internet, as well as

a number of issues to support the activities of ICT producers and sellers in the North-American and world industry markets. The analysis of the main provisions of this document shows that it is, to some extent, protectionist towards digital producers. At the same time, the program is aimed at (a) improving the efficiency of antitrust legislation in the field of digital technologies and virtual economy sectors; (b) stimulating economic actors operating in these markets; (c) improving the legal status of entities of the virtual sector of the digital economy, such as virtual corporations, financial and credit institutions (internet banks and investment funds, etc.; (d) development of legal regulation of financial and economic transactions carried out using crypto currency; (e) optimization of complex regulatory and legal support of smart-contracting institution.

Accordingly, the positive experience of such legal regulation can also be accepted by the domestic system of legal regulation of the ICT market in such areas as ensuring competitiveness and openness of production and sale of ICT for state and municipal needs; full introduction of antitrust compliance in the activities of economic actors; systemic and integrated public-private partnership in ICT; promotion of domestic technologies in developing ICT markets of "friendly" states within the framework of economic blocks such as the EAEU and BRICS.

In order to implement the directions mentioned above, it is proposed to solve the following main issues.

First, while modernizing the legal regulation of the digital economy, it is necessary to make a thorough analysis and assessment of the relevance of existing legal models, as well as the existence of conflicts and gaps in existing legislation [18].

There is a view that in the sphere of the digital economy there is a greater demand not for forward-looking (forecast-based) legal regulation, but for an approach aimed at streamlining already existing social relations after their emergence on the basis of the information available at that time [2, p. 24]. This approach can hardly be considered absolutely justified for our legal system, as it is suggested by the representative of Western civilization, where the main regulator is precedent. As for the analytical component of the law-making process in the development of the relevant legal and regulatory framework, its feasibility is beyond doubt.

Second, administrative barriers to the functioning of the digital economy institutions need to be reviewed and, if possible, eliminated (this is, inter alia, the example given at the beginning of this article on business in virtual world markets).

Third, to create unified approaches for all member states of the Eurasian Economic Union in the field of legal regulation of the digital economy, which contribute to the development of the digital economy in the corresponding legal space;

Fourth, to develop and approve the necessary methodological documents (regulations) aimed at forming appropriate competences in the field of digital economy for lawyers, public servants and other persons directly involved in the drafting process, adoption and implementation of regulatory legal acts in the sphere of regulation of the digital economy in the territory of the Russian Federation, and undertake the necessary measures to develop these competencies (professional retraining, advanced training, conferences, etc.).

Conclusion

As a result of the study carried out on the problems and prospects of legal regulation of the digital economy in the Russian Federation, the following conclusions can be drawn:

- The digital economy, as a subject of legal regulation, is characterized by its global nature, and therefore, at the international and national levels, there are certain patterns and universal principles for its regulation in various countries;

- The digital economy does not have a unified, homogeneous structure and cannot be regulated by a "package" of laws or by public administration reform in this area; it is an integrated system that brings together diverse ICT-based institutions and activities;
- "Digital" legal regulation and "digital" development based on it is possible only on the basis of clear strategic conceptual planning, which is reflected in the relevant strategic documents named and briefly analysed in our work;
- The use of foreign experience in modernizing the system of legal regulation of the digital economy is of some interest[18, p 3850].

Thus, basing on the analysis of various approaches to the study of optimizing the legal regulation of the digital economy, it can be concluded that in this area it is necessary to create a legal regime that would ensure, on the one hand, the smooth development of innovation and, on the other, minimize the possible risks associated with the inability to predict the development of institutions of the digital economy for a long period of time.

Abstract

There are many pension solutions in Poland such as the general system, the provision system and the agricultural system. In each of these pension systems there are privileges for selected groups. The objective of this paper was to assess the pension systems in Poland in terms of their adequacy which can be considered in three dimensions: the consumption smoothing, protecting against poverty and differences between the genders. The analysis indicates the occurrence of significant differences between individual systems, which result from the extensive pension privileges for selected groups. The conducted assessment shows that only the provision pension system is fully adequate. Other analyzed systems firstly, are not fully adequate, and secondly, the adequacy is not equal. Significant inequalities in the adequacy or its complete absence indicate that building one, uniform, coherent pension system in Poland requires the introduction of many systemic actions.

Keywords: Pension Privileges, Social Security, Generosity, Adequacy, Income, Old Age.

Introduction

There are many pension solutions in Poland - the general system (including miners), the provision system and the agricultural system. Pension privileges are an integral part of each pension system, mainly in post-Soviet states. In Poland, the numerous pension privileges fall into the following three groups: privileges in the general pension system, privileges in the provision pension system, and privileges in the agricultural pension system (Walczak, 2019). Maintaining the current pension privileges in Poland results from several reasons. One of them is rent seeking (Tullock, 2003; Krueger, 1974). Some professional groups maintain privileges in exchange for their support given to politicians in elections. But most privileges are a result of past decisions and upholding the acquired rights (Walczak, 2019). Another reason for pension privileges, which is frequently presented in Poland, is the supposed inability to work in certain professions long enough to reach the general retirement age. Subject literature often considers the particular nature of a given profession as an argument for maintaining the existing privileges (Jarmołowicz, Sikora, 2016).

In turn, when examining Poland's pension system, one should refer to the characteristics that every pension system should have, which also applies to privileged systems. These characteristics were formulated by The World Bank (Holzman, Hinz, Dorfman, 2008) and comprise adequacy, affordability, sustainability, equity, predictability, and robustness. Similar objectives of the pension system were defined by the European Commission (European Commission, 2012) which points out to

the fact that a pension system should deliver adequate, sustainable and safe retirement incomes. The European Commission also emphasizes that the proposed solutions within retirement incomes must be based on fiscal sustainability (debt reduction) and ensure increasing employment, mainly for women and older workers.

The objective of this paper is to assess the pension systems in Poland in terms of their adequacy. Thus, the following hypothesis was assumed:

H1: Pension systems in Poland are characterized by equal adequacy.

The Adequacy as One of The Features of Pension Systems

The qualities which can be explored within the pension systems include equity, adequacy, sustainability, and affordability (Holzman, Hinz, Dorfman, 2008).

An equitable pension system should provide the same benefit for the same contribution. This principle in relation to privileged solutions is not observed by definition. Being privileged or covered by any special pension system ultimately comes down to receiving benefits that exceed the amount of contributions paid. In addition, for similar reasons, the privileged system could not be actuarially fair (Vidal-Melia et al., 2009).

When it comes to adequacy, the first dimension of an adequate pension is protecting against poverty (Holzman, Hinz, Dorfman, 2008). Saunders and Wong (2011) provided a similar description, when presenting adequacy in relation to the income level. An adequate pension should allow avoiding or alleviating poverty and should be adequate for one person. The second dimension, consumption smoothing (Attias et al., 2016; Verbič et al., 2006), means that a pension is to be considered adequate if (besides preventing social exclusion) it allows one to maintain their lifestyle and consumption level unchanged after retirement. The third dimension of an adequate pension according to Chybalski and Marcinkiewicz (2016) is the difference between genders. The target of adequacy is to prevent discrimination of women and men in terms of pension benefits. A sustainable system is one that is financially sound and can be maintained over a foreseeable future under a broad set of reasonable assumptions.

An affordable system, in turn, is one that is within the financing capacity of individuals and society and does not unduly displace other social or economic imperatives or have untenable fiscal consequences (Holzman, Hinz, Dorfman, 2008). Each of the privileged systems in Poland requires co-financing by the state. Privileged pension schemes are a PAYG (Pay-As-You-Go) scheme (see more in the following sections). This ultimately results in the financing of retirement benefits from pension contributions or taxes paid by non-privileged persons. Because of their structure, these systems are based on intergroup solidarity, or solidarity of the entire community (Baldwin, 1989; Mesa-Lago, Bertranou, 2016). Solidarity is based on the individual's responsibility for the community and the community's responsibility for the individual, when it comes to activities of common interest (Walczak, 2015; Houtepen, Ter Meulen, 2000). In the case of pension benefits, we can talk about one-way solidarity. Due to financial and social issues, privileged systems are subject to a continuous political debate on potential changes (Armeanu, 2010; Inglot, 2016). For those reasons, privileged pensions systems are not sustainable or affordable.

Pension Systems in Poland – The General and Privileged Groups

Exactly as it was indicated in the introduction, in Poland the "tri-system" of old-age pensions is functioning, which consists of (Walczak, 2019):

- the general system,
- the provision system,
- the agricultural system.

In Poland employed persons as well as private entrepreneurs belong to the general pension system (for more about Polish pension system, cf. Kompa, Witkowska, 2015, European Commission, 2017). However, many social and professional groups are covered by separate systems – the provision pension system and the agricultural pension system (Czarzasty, 2016). Some people also make use of the different provisions existing within the general pension system, which contains numerous pension privileges (cf. the Act of 1998). The following can be considered as privileges (for more information on pension privileges in Poland, cf. Walczak, 2019):

- miners' pensions,
- bridging pensions of persons performing work in particularly difficult,
- compensation benefits for teachers,
- financing social security contributions for clergymen by the Church Fund.

The general pension system is operated by a specially designed institution, ZUS (Zakład Ubezpieczeń Społecznych, Eng. Social Insurance Institution, SII). It is the third largest employer in Poland with about 45,000 employees.

The provision pension scheme offers the following privileges:

- retirement provisions for military personnel,
- retirement provisions for former officers of the police, the Internal Security Agency, the Intelligence Agency, The Military Counterintelligence Service, The Military Intelligence Service, The Central Anticorruption Bureau, The Border Guards, The Marshal's Guard, The State Protection Service, The Government Protection Bureau, The State Fire Service, The Customs and Treasury Service, and The Prison Service, and for their families,
- retirement provisions for judges and prosecutors.

As this is a non-contributory, fully tax-financed pension scheme, the calculation and payment of benefits, for the first two groups, are being handled by the relevant ministries (The Ministry of Defence, The Ministry of Internal Affairs, or The Ministry of Justice). As for judges and prosecutors, those activities are performed by the bodies in which the judge or prosecutor received the last remuneration before the end of their professional career.

The last of the existing pension systems is the agricultural pension system, which is subjected to a separate institution – KRUS (Kasa Rolniczego Ubezpieczenia Społecznego, Eng. The Agricultural Social Insurance Fund, ASIF) (The Act of 1990). In Poland, this system includes not only farmers, but also other persons related to agriculture, such as spouses, members of the household, persons handling a special agricultural production unit, or even relatives helping the farmer (Pawłowska-Tyszko et al., 2013; Walczak, 2019).

Characteristics and Assessment of Pension Systems in Poland

The assessment of the adequacy of pension systems functioning in Poland can be carried out based on the following three dimensions (Chybalski, 2012):

- consumption smoothing,
- protecting against poverty,
- lack of differences between the genders (in the original version Chybalski uses the phrase 'differences between the gender' but for the sake of clarity, the authors of this article reformulate it into 'lack of differences between the genders').

When we are considering consumption smoothing, we should take into account the average pension's value in each type of system. Table 1 shows the amount of pension benefits received by different professional groups. The average monthly pension represents only about 50% of the pension of the miners and military personnel. The lowest payments are received by farmers who, however, also pay the lowest pension contributions (see Table 2). Judges and prosecutors receive the highest benefits.

They do not pay social insurance contributions, and, at least theoretically, do not retire but proceed to the so-called 'non-active status' (decommissioning). The rule is that the benefit constitutes 75% of the total basic salary and seniority allowance received at the last position held (The Act of 2001).

We cannot analyse the pension benefits without taking into consideration their co-financing by the state budget. The total subsidy from the state budget to the general pension system amounted to approximately 44 billion PLN, out of which almost 10 billion PLN was spent on subsidising miners' pensions. The payment of bridging benefits generates an expense of 658.9 million PLN, while compensation benefits for teachers cost 208.2 million PLN. State subsidies for uniformed services pensions paid out by three different ministries amounted in total to approximately 16.1 billion PLN in 2017 (including 6.4 billion paid by The Ministry of Defence, 8.3 billion paid by The Ministry of Internal Affairs and 1.4 billion paid by The Ministry of Justice). Due to the multiplicity of entities obliged to pay benefits (i.e., each Court and each Prosecutors Office in Poland), the most difficult to determine is the value of the co-financing for decommissioned judges and prosecutors, which was estimated at 600 million PLN. The subsidy for the agricultural pension system (including both disability and pension benefits), in turn, amounted to 16.7 billion PLN in 2017, which constituted approximately 90% of the expenditure on these benefits. The subsidy to the church fund from which the contributions for the priests are financed, amounted to 143.8 million PLN (CSO, 2018; SII, 2018a; SII, 2018 b, Council of Ministers, 2018; Walczak, 2019; SAO, 2018).

Table 1: Average pension value in 2017 (in PLN)

Type of system	Paying institution	Type of benefit	Average pension
The general pension system	SII	Average monthly pension	2,085.60
		Miners	4,215.82
		Bridging benefits	2,514.00
		Compensation benefits for teachers	2,073.98
The provision pension system	The Ministry of Defence	Soldiers and military intelligence and counterintelligence officers	3,481.61
	The Ministry of Internal Affairs	Officers of the Police, Internal Security Agency, Intelligence Agency, Central Anticorruption Bureau, Border Guards, Marshal's Guard, State Protection Service, State Fire Service, Customs and Treasury Service and State Protection Bureau	3,574.60
	The Ministry of Justice	Prison Service Officers	3,775.99
	Last employer (relevant court or prosecutor's office)	Judges[1] Prosecutors[1]	8,189.00 9,273.00
The agricultural pension system	ASIF	Farmers	1,221.69

[1]data from 2016.
Source: own study based on (CSO, 2018; SII, 2018a; SII, 2018 b; Walczak, 2019).

The existing pension privileges were shaped in the years 1945-1990, i.e., during the years of Communist control in Poland. Then, authorities used the system as an instrument allowing them to attain their political goals (Golinowska, 2009). At present, these privileged groups are large enough to exert political influence, which provides them with political support (Saunders, Wong, 2011). The original reason for creating each of the privileges was quite different. However, it is important to note

that they have all remained to this day in an almost unchanged form. Below, we present a short explanation for each of these privileges. Let us note that we listed only potential reasons, as these were probably not the only factors which influenced the decision to adopt the indicated solutions in the times of communism in Poland (Walczak, 2019). However, it is easy to observe the following facts:

- miners, as representatives of 'the working people', enjoyed the privileges of producing coal, the most important raw material of the Polish People's Republic (1952-1990) (Riley, Tkocz, 1998),
- the Polish state after World War II confiscated properties belonging to the Catholic Church. In return, a Church Fund was created, paying social security contributions to priests, which was intended to constitute a partial compensation for the confiscation (Bilska-Wodecka, 2006),
- officers of the uniformed services, as persons closely supporting the communist state, enjoyed numerous privileges, including retirement benefits (Bernhard, 1990),
- farmers received their privileges in 1982 (the privileges have been in force until now, this time under the Act of 1990), i.e., during the period of martial law that was introduced in Poland at that time (Wierzbicki, 2016).

Each of these groups also benefits from other privileges, which, in fact, come down to the financial aspect. Miners, the uniformed services, and judges and prosecutors receive an extra bonus salary (one month's extra pay). Retired miners are entitled to a coal allowance (the cash equivalent of three tons of coal paid in PLN), and soldiers leaving the military (e.g., retiring officers) are entitled to the so-called 'housing allowance' (amounting even to several hundred thousand PLN). In turn, farmers benefit from subsidised crop insurance premiums, subsidised interest rate payments paid on investment loans, and, what is more, they do not pay income tax (Walczak, 2017).

Pensions privileges in each of these solutions, in fact, come down to the following three aspects: 'age', 'contribution', and 'benefit'. The age privilege is the possibility of retiring earlier than the generally applicable retirement age in Poland (60/65). Table 2 contains the retirement age of 60 for women and 65 for men. This age was valid until December 31, 2013 and was introduced again starting from October 1, 2017. In the time period of January 01, 2014 to September 30, 2017, the retirement age was being gradually increased and was supposed to attain 67 years for both men (starting from 2020) and women (starting from 2040). However, this reform was never fully introduced. Miners and uniformed services are entitled to benefit from the retirement age privilege. Privileges regarding the possibility of paying lower pension contributions cover the uniformed services (who do not pay at all) and farmers. Miners and uniformed services can benefit from retirement age preferences.

Table 2: Main features of the pension systems in Poland and privileged solutions

Privileged solutions	General pension system	Miners	Provision pension system	Agricultural pension system
Contributions payer	employee/ employer	employee/ employer	without	farmer
Contribution rate	100%	100%	-	Much lower than in general pension system
Benefit (value)	-	Higher than average	Higher than average	Lower than average
Retirement age	60/65	55 years (in case of a sufficiently long service in the mine it is 50 years)	● no requirements – the uniformed services[1] ● 60/65 years - judges and prosecutors	60/65

Minimum employment period	20 years for women and 25 years for men	20 years for women and 25 years for men (Including at least 10 years of mining work)	● 15/25 years – the uniformed services[1] ● Without requirements for judges and prosecutors	25 years
DC/DB	DC	DB	DB	DB
PAYG (not-funded)/funded	PAYG/(partially funded)	PAYG	- (without contributions)	PAYG

[1] The length of service required to qualify for a retirement pension is 15 years, regardless of age, for people who started their work prior to January 01, 2013. For people who started work after December 31, 2012 the required length of service is 25 years.
Source: own study based on (Walczak, 2019).

Miners pay pension contributions in accordance with similar regulations binding all citizens belonging to the general pension system. Some of them also pay contributions to the second funded pension pillar. However, pension amounts do not depend on the value of the accumulated funds. They are calculated on completely different terms, which are dependent on the years of service and are more advantageous for miners. In order to benefit from an earlier pension, based on the defined benefit pension scheme, miners have to transfer funds accumulated on an account in the second pillar to the Treasury.

The way of calculating contributions and benefits for farmers differs significantly from other systems. As much as 99% of farmers (their spouses and household members) pay the same social security contributions. Merely 1% of persons have farms with an area of over 50 hectares and, therefore, they pay higher contributions that are still much lower than those in the general pension system (Pawłowska-Tyszko et al., 2015). Paying increased contributions does not, however, impact the amount of the future benefit. Moreover, pension benefits for farmers are differentiated theoretically only by the number of years of insurance. For a person that has been insured for 25 years, the pension amounts to 118% of the basic pension. However, for a person who pays insurance for as long as 50 years, the pension is 130% of the basic pension. Therefore, it can be stated that this system has more features beneficial to the insured under the defined benefit pension scheme than to those under the defined contribution pension system.

The reform of the pension system in Poland was introduced in 1999. It changed the rules of financing and functioning of the pension system. At present, pension benefits in the general pension system are calculated based on the value of the accumulated capital (Chłoń-Domińczak, Strzelecki, 2013; Kurach, Papla, 2016). As a result of this change, the level of benefits is decreasing dynamically (Jarocinska, Ruzik, 2016).

In general, 'protection against poverty' (one of pension adequacy dimensions) in the Polish pension system is provided by guaranteeing a minimum pension (Chłoń-Domińczak, Strzelecki, 2013). However, the possible elimination of this rule in the future may result in the payment of benefits which, in fact, will not guarantee proper protection against poverty. It will concern women in particular. In Poland, women earn less than men, especially if they are employed in the private sector (Regulska, Grabowska, 2008; Eurostat, 2017). They are also entitled to a lower retirement age and they tend to save on their own for old age (Bajtelsmit et al., 1999). Due to parental responsibilities, they also have more frequent breaks in the employment period. As a result of calculating the future pension based on the value of the accumulated capital, the value of their benefits will be lower.

One of the advantages of the privileged pensions in Poland is the lack of gender pension gap. Their legal structure resulted in the lack of significant differences on the grounds of gender. The privileged systems in Poland can be defined as gender-neutral pension systems (Frericks, Knijn, Maier, 2009). This results from several factors. Firstly, the public sector in Poland has one of the lowest gender pay gaps in Europe – 3.9% (e.g., Germany 13.4%) (Eurostat, 2017). Thus, women working as soldiers,

policemen, judges, or prosecutors earn as much as men do. In addition, for these professions the chances of advancement for women, (which means better earnings) are similar (or even better than in the past) to the chances that men have (Kozerawski, 2017). For example, a woman is the First President of the Supreme Court, however, a man is the President of the Supreme Administrative Court (as of April 22, 2020). Considering the way pension benefits are calculated in the provision pension system, they are of a similar value for both genders. In the case of farmers, due to the lower retirement age, women retire earlier. However, as indicated in the description contained in Table 2, in this system the benefits are slightly differentiated and, practically, they do not depend on the number of years of insurance. In principle, it should not be stated that benefits in the agricultural pension system are gender-differentiated because of the lower retirement age of women.

Due to the method of calculating contributions and benefits, the agricultural pension system does not ensure income equalization after retirement. Farmers' pensions are slightly higher than the minimum wage (see Table 1). Meanwhile, farmers in Poland are getting richer. Many farms are in fact well-run production companies. At the same time, the absence of any link between the farm income, the pension contribution and the benefit received results in a significant inadequacy of retirement benefits. Analysing the retirement situation of women and men in the case of miners is groundless, since mainly men work underground in mines.

Conclusions

In the case of pensions in Poland, there is no single coherent retirement system. The pension privileges introduced years ago contributed to the widening of differences in the functioning of several fragmented pension systems intended for various groups. Pension systems should have different characteristics, one of them is adequacy expressed in three dimensions.
The aim of the work was to assess the adequacy of the presented pension systems. A summary of the comparison of individual dimensions of adequacy for pension systems in Poland is presented in Table 3.

Table 3: Pension adequacy and the pension systems in Poland

Adequacy dimensions	General pension system	Miners	Provision pension system	Agricultural pension system
Consumption smoothing	NO	YES	YES	NO
Protecting against poverty	YES	YES	YES	YES
Lack of differences between the genders	NO	-	YES	YES

Source: see also (Walczak, 2019).

As can be seen in Table 3, only the provision pension system is fully adequate. Other analyzed systems firstly, are not fully adequate, and secondly, the adequacy is not equal. Therefore, the hypothesis that the analyzed pension systems are characterized of equal adequacy cannot be confirmed. There are significant differences between the general pension system (including the different solutions for miners), the provision pension system and the agricultural pension system. The first dimension – the consumption smoothing – is visible only in the pension system for miners and in the provision pension system. The second dimension – protection against poverty – theoretically, is filled by guaranteeing a minimum pension in Poland. In this case, there is a risk of abolishing this principle of the future, the effects of which may be particularly unfavorable for women. Whereas the third dimension of adequacy – lack of differences between the genders – is fulfilled in the case of the provision and agricultural pension systems only. Significant inequalities in adequacy or its complete absence indicate that building one uniform, coherent retirement system in Poland requires the introduction of many systemic actions.

Abstract

The advent of the web and its evolution have brought to an enormous production of data. Different forms of content such as textual, visual and audio-visual can be posted online but tourism is a sector particularly linked to imaging. Photos have several roles in documenting and shaping the tourist's experience and this is the reason why in the tourism sector photo-based social media use is constantly growing. Following this trend, this research would like to adopt a content analysis to the photos of small destinations uploaded on Instagram, to categorize the different image contents. In the literature this analysis was applied referring to big and famous cities mainly, but since small destinations have different features, more studies about this topic are needed. The objective is to shed light on which contents are uploaded as pictures related to small destinations. A framework for analysing contents can help destination management organizations to obtain useful insights for better answering to tourists' needs and wants and to exploit user generated images to provide both an economic and a social contribution to the tourism industry.

Keywords: User Generated Content, Tourism, Image Categories, Small Destinations

Introduction

Today social media are becoming a relevant marketing and communication tool for many industries. Looking at the tourism sector, competition is increasing, and this leads to the need of innovative tools to properly manage destinations. Destination management organizations (DMOs) have to start analyzing and understanding users-generated contents posted online (Kim et al., 2017). Many research are actually focused on the use of social media, but literature on the visual contents shared by tourists is still limited and mainly related to large cities or famous destinations (Galí and Donaire, 2015, Mukhina et al., 2017).

Image contents can represent small destinations and thus what is shared by tourists on Instagram can offer social, cultural and political insights. For these reasons we want to understand 1) which photos' contents are shared by tourists about small destinations and 2) whether the photo categories previously used in literature to study big cities can be useful for smaller tourist destinations too.

Literature Review

Social Media and Visual Contents in Tourism

Tourism has always played an important role in the development of social media (Minazzi, 2015), with a lot of contents linked to travel experiences.

Among the different forms of content such as textual, visual and audio-visual shared online, tourism is deeply related to visual media (Negri, 2018). Since photography can both build and transform an

intangible experience into something tangible, photo-based social media use is constantly growing in tourism (Mukhina et al., 2017).

More specifically, Instagram has become an effective place to find travel inspiration (Tenbarge, 2019) portraying the most "instagrammable" spots. Several places that have their own uniqueness became a tourism destination due to a post in Instagram (Mariani and Amir, 2016).

DMOs are aware of these ongoing trends and thus they try to explore the opportunities to produce online contents and use tourist-generated ones for their destinations, by developing and implementing new communication strategies (Zeng and Gerritsen, 2014, Kim et al., 2017).

Tourism in Small Destinations

Different analyses have been carried out to shed light on the potential of small cities and rural communities to position themselves more effectively in the tourism market (OECD, 2014, Brouder, 2012, Pierce et al., 2011).

On the one hand, we can see the growing power of a number of major urban centres, on the other, nowadays with the advent of a networked society smaller communities have found new opportunities to effectively compete with larger places in attracting visitors (Richards, 2019).

In fact, tourism has gone through enormous changes, with small unknown destinations that take a leading role in many countries, as they are able to combine the beauty of the landscape with history, culture, and traditions that are frequently missing in large mass destinations (Cracolici et al., 2008, Papatheodorou, 2002).

Using a quantitative research approach, Pabel & Prideaux (2016) have analysed how tourists who visit small destinations use social media - focusing on the pre-trip information search - and have considered how DMOs can use this knowledge to develop more effective social media strategies. They have demonstrated that social media have the potential to boost the online visibility of small destinations.

The Research Questions

Before Internet and social media diffusion, small destinations remained largely unknown, especially for international tourists. Now the situation has changed and these destinations already account in many countries for a sizable share of the total tourist flows (Istat, 2019, Sharpley, 2012, Jordan, 2000) but there is scarce research on how these destinations are portrayed online and how to analyse contents devoted to them.

Therefore, our research questions are:

RQ1: Which are the photo contents that are mostly shared about small destinations?
RQ2: Are the photo categories previously used in literature to study big cities representative of smaller tourist destinations too?

Design and Methodology

The research is carried out in three main phases:

- Phase 1 – Context selection: among different classification of small destination and a great numbers of small destination in most countries, we selected Italian *borghi* (typical small towns) as research setting. Italy is one of the world's major destinations, and according to the Association "*I Borghi più Belli d'Italia*", a *borgo* represents a prestigious assembly of territories with: (1) a population less than 2,000 inhabitants in the historical centre, and less than 15,000 inhabitants in the whole

municipality; (2) a remarkable urban and architectural heritage, certified by the Superintendence of Fine Arts.

- Phase 2 - Data collection: due to its explorative purpose, photos on Instagram about a sample of Italian *Borghi* were downloaded through the name of the town hashtag.
- Phase 3 - Content Analysis was applied to downloaded photos. Visual content analysis is an unobtrusive and nonreactive method specifically selected for the analysis of photographs (Negri, 2018; Galí and Donaire, 2015). A deductive content analysis using categories adopted in previous research and an inductive one are combined based on the image analysis. First, the items selected for content analysis are classified into categories, in accordance with suggestions by Bernkopf and Nixon (2019), then, some adjustments to the previously identified categories are made in order to better fit the territorial context. A final list of categories and subcategories are then defined. The inter-coder reliability for categories is tested on a 35 images subset (10% of the sample) using Krippendorff's alpha coefficient (Hayes and Krippendorff, 2007).

Results: categories and Sub-Categories Definition

The sample

The analyses are made on a limited sample of Italian *borghi* (small destinations) in order to test and define the image categories and sub-categories. These small destinations are selected among the northern part of Italy ones. Considering just the *borghi* that have an official Instagram account because of homogeneity (official accounts can increase the spread of specific hashtags). Only 5 *borghi* match these criteria. Images are downloaded from Instagram using the hashtag of the small destination name. The photos posted between 15 and 18 of August 2019 are considered. Sample is composed by 341 pictures (Table 1).

Table 1: Sample analysis

Destination Name	#Bienno	#Etroubles	#Sabbioneta	#Venzone	#Volpedo
Number of photos	60	34	86	156	5

Main Findings

Starting from the existing literature (Bernkopf and Nixon, 2019, Sonne and Erickson, 2018, Ferwerda et al., 2016), main photos features and content categories are identified and tested in our sample. Main findings related to RQ1 are summarized in table 2 and table 3.

Table 2: Human presence relevance in photos

	Relative frequencies %	**Relative frequencies for sub-categories %**	**SUB-CATEGORIES**
Human presence as main element *(Adapted from Sonne & Erickson, 2018 and Hausmann, Toivonen et*	19.65%	19.40%	With people posing alone (not selfie)
		7.46%	With people posing with others (not selfie)

al. 2018)		9.00%	With people taking a selfie alone
		14.93%	With people taking a selfie with others
		26.87%	With people doing something specific (for example a craft job)
		22.39%	Other

Despite of the context in which human presence appears, we found out that in 19.65% of the sample people are portrayed (Table 2). To classify this content, we adapted the sub-categories from Sonne & Erickson and Hausmann, Toivonen et al. (Hausmann et al., 2018, Sonne and Erickson, 2018) by focusing on both the way the photo is taken (selfie or not) and if it includes the tourists or general people doing some specific activity. Human presence is a cross-section category since it also appears in other sub-categories in an explicit (i.e. in leisure and recreation) or implicit way (i.e. pictures with a person and parts of a building as main subjects).

Table 3: Main findings of the photo categories

CATEGORY	**Category relative frequencies %**	**Relative frequencies for sub-categories %**	**SUB-CATEGORIES**
Culture history and art *(Bernkopf & Nixon, 2019)*	52.79%	29.61%	Quarters of the *borgo [new]*
		14.53%	Food (both dishes or typical products such as fruit or mushrooms) *[modified]*
		13.97%	Buildings *[modified]*
		11.17%	Parts of a building *[new]*
		7.63%	Sculptures and monuments *[modified]*
		6.70%	Details such as frescos *[new]*
		5.59%	Churches *[modified]*
		1.12%	Folklore
		9.68%	Other
Additional *(Bernkopf &Nixon, 2019)*	14.37%	46.94%	A specific object (as a bike wheel, a GPS device etc) *[new]*
		42.86%	Urban details (most of them are architectural ones framing especially windows and doors) *[new]*
		10.20%	Other

Natural resources *(Bernkopf & Nixon, 2019)*	11.14%	89.47%	Landscapes
		1.47%	Partial views *[new]*
		0.59%	Plants and animals *[modified]*
		8.47%	Other
Tourist infrastructure *(Bernkopf & Nixon, 2019)*	5.28%	77.78%	Store windows or store products *[modified]*
		22.22%	Restaurants, bars and ice-cream shops *[modified]*
Leisure and recreation *(Bernkopf & Nixon, 2019)*	5.51%	75%	People doing sport (mostly riding a bike or a motorbike) *[modified]*
		25%	People enjoying dinner out *[new]*
General infrastructure *(Bernkopf & Nixon, 2019)*	2.35%	100%	Urban centre street view *[modified]*
People *(added by authors)*	8,56%	100%	People as unique subject *[new]*

Table 3 shows the main results in applying Bernkopf and Nixon (2019) categories to the *borghi* territorial realities. It is important to underline that considering small territories as Borghi, two out of eight categories do not appear and one new category (people) was added. The category list was adapted by deleting "political and economic factors" which refers to elements such as parliament, safety, terrorism, and "natural environment" which refers to factors such as crowds, smog, traffic. Also looking at sub-categories, we detect that some of them are not applicable, some need to be modified while others need to be added in an inductive way. Results show that the most relevant sub-categories (higher number of recurrences) are part of "culture, history and art". In this category, some adjustments were needed. For example, we found that considering only buildings was not enough in order to explain the photo contents and we added the "parts of a building" dimension. The same happened for the "landscapes" sub-category, since a lot of shots did not show a full landscape, the "partial views or quarters" sub-category was introduced. Also in the "additional" category, we included a new sub-category which considers the photos that focus on any "urban detail". Moving to "natural resources" the "sky" is added. Furthermore, elements such as "fruit" and "other local products" are selected for the "food" sub-category. While, by evaluating photos about stores, we realized that "typical food shops" are so relevant that they could even represent a separated sub-category (RQ2).

Conclusions and Managerial Implications

This research focuses on images shared on Instagram about Italian small towns called *borghi* and has an explorative purpose. Results identify the most shared contents in small destinations and demonstrate that the existing content categories proposed in literature in order to represent a territory and mainly adopted for big and crowded cities do not perfectly fit these realities. Since a *borgo* is a small village made of high cultural values and ancient traditions, several elements representing big cities cannot be applied, and other new elements emerge.

We found that the most portrayed elements of a *borgo* are the ones that deal with architecture, moving from photos of entire buildings, to small architectural details such as a window, a column, a

door peephole. Instead, due to the nature of the considered territories, there is almost a total absence of portrayed infrastructures (RQ1).

Starting from the photo categories previously used in literature to study big cities, we found out that some readjustments are needed. In fact, categories such as "political and economic factors" and "natural environment" are not applicable and also some adjustments to sub-categories are found to be required. Furthermore, the need of considering the human presence in the picture, normally considered in social media analysis, arises in this specific tourism perspective (RQ2).

Listening and monitoring images posted online by users can benefit both the public government and companies involved in the tourism industry. This paper provides a categorization that fits small destinations, adapting previous classification and thus filling the gap found in the literature and providing new knowledge about online visual contents. Further analysis considering a larger sample is needed to confirm our findings. Analysing data through this framework can offer new opportunities for small destination managers. In fact, DMOs will have a detailed understanding of what is the projected image of the destination and tourists desire in relation to their time spent in small locations. Moreover, they will learn how to develop their social media strategy correctly to better face the actual increasing competition.

Furthermore, two future studies could be implemented. First study could relate the analyzed pictures of this research with its metadata such as likes, comments and hashtags in order to understand the photos which are perceived as highly engaging according also to the different categories of contents. A second study could be aimed at analyzing the effect of photo categories on tourists' response adopting a quantitative approach based on a questionnaire distributed to a sample of tourists to confirm results of the first study that are based on insights data. Representative images from each category identified in this research could be selected in order to test the effects on respondents in terms of cognitive, affective and conative response.

Smartwatch Adoption: A Conceptual Model for Older Adults

Irina CRISTESCU[1], Alexandru BALOG[1]and Lidia BAJENARU[1]

[1]National Institute for Research and Development in Informatics, Bucharest, Romania

e-mail address: {irina.cristescu, alexandru.bolog, lidia.bajenaru}@ici.ro

Abstract

In the context of a fast aging population, the usage of smart wearables responds to the increasing needs for healthcare and assistance in the case of older adults. The purpose of this study is to propose a conceptual model for adopting smartwatches by older adults. The proposed model includes factors that have been highlighted in prior studies, but have never been used altogether in a TAM model. The identified factors are defined and the corresponding hypotheses concerning the relationship between the factors that contribute to the adoption of smartwatches among older adults are formulated. Also, the analytical procedures that will be used to test the conceptual model are presented.

Keywords: smart wearables, smartwatch adoption, technology acceptance model, TAM.

Introduction

The need for monitoring older adults in order to increase their Quality of life (QoL) and wellbeing led to the development of specific systems to solve these problems (Dobre, Băjenaru, Marinescu, Tomescu, 2019). Nowadays, the IoT-based smart wearable devices became very popular and can be used for various tasks in the daily life. Older adults are able to obtain immediate feedback on their vital signs (e.g. heart rate, blood pressure), and thus real-time healthcare by transmitting physical condition data to a medical center through wireless sensor networks. The smart wearables have numerous advantages, such as reducing the cost of physical checkpup and decreasing the risk of hospital admission, thus facilitating the healthcare delivery process for older adult (Li et al., 2019).

Although the concepts of technology adoption have been widely used to measure user perception and social impact for a number of new technologies, in the case of adopting wearable devices (e.g. smartwatches) among older adults the research is limited to a small number of studies. The aim of this article is to propose a conceptual model for the adoption of smartwatches by older adults. The present study identifies and describes potential factors that may contribute to the adoption of smartwatches by older adults.

The paper is structured as follows. The next section focuses on the literature review concerning the technology adoption and the adoption of wearable technology. Section 3 presents the proposed research model, while section 4 describes the analytical procedures that will be used to test the proposed model. Conclusions and future work are provided in section 5.

Literature Review

Technology adoption

With regard to technology adoption, Davis (1989) proposed the technology acceptance model (TAM). TAM is one of the most commonly used models to understand the individual adoption of emerging information and communication technologies. TAM has been applied and validated for a wide range of new technologies and information systems, such as e-health systems (Martinez-Caro et al., 2018) and smartphones (Roy, 2017).

TAM postulates that perceived usefulness (PU) and perceived ease of use (PEOU) are two cognitive

belief dimensions that shape the users' attitude, which then determines behavioral intention to use and actual use. Additionally, TAM proposes that technologies are perceived as more useful when they are easier to use, and that usefulness also directly influences the behavioral intention to use (BI). PU is defined as "the extent to which a person believes that using particular technology will enhance his/her job performance" (Davis, 1989). PEOU describes "the degree to which a person believes that using a technology will be free from effort" (Davis, 1989).

Adoption of wearable technology

Smartwatches serve mostly for collecting useful data from a paired smartphone via wireless Bluetooth connection and providing more convenient, faster, and substitutable access to information, since its information processing is less demanding. This characteristic of smartwatches distinguishes them from other mobile devices, making them technologically and psychologically unique communication tools that deserve further investigation (Kim & Shin, 2015).

Scholars extended, adopted and applied TAM to different wearable contexts (Pal et al., 2018; Choi & Kim, 2016). Dutot et al. (2019) explored the differences of adoption of smartwatches in China, France, and Thailand. Overall, the results show that perceived affective quality, mobility, and trust are positively related to perceived usefulness (PU) and perceived ease of use (PEOU) and that PEOU, PU and attitude influence the intention to use smartwatches.

Dehghani, Kim, Dangelico (2018) investigated the factors contributing to the intention to keep using smartwatches. Complementary goods, healthology, aesthetic appeal and hedonic motivation were identified as key factors that play an important role in user behavior of smartwaches. Hong, Lin & Hsieh (2017) found that customer innovativeness was positively related to continuance intention of smartwatches, which was mediated by both hedonic and utilitarian value. Usefulness was found to be more satisfying for consumers than enjoyment/joy. Chuah et al. (2016) found that the key factors of smartwatch adoption are visibility and usefulness. Also, smartwatches are perceived by consumers as fashnology (fashion and/or technology).

Proposed Research Model

The proposed conceptual model is presented in Figure 1. By using TAM as the basic framework for the adoption of smartwatches by older adults, the proposed model witholds the influence relations between PEOU, PU, and BI from the original model by Davis (1989), as follows: *H1. PEOU has a positive influence on PU; H2. PEOU has a positive influence on BI; H3. PU has a positive influence on BI.*

The following section presents the factors and corresponding hypotheses linked to smartwatch adoption.

Ubiquity

Ubiquity represents the characteristic of IoT-based wearable devices to be operational and accessible anytime and anywhere when required for use (Balog, Băjenaru, Cristescu, 2019). Ubiquity includes *mobility (MB)* (the degree to which users believe that they can move to different locations and use their devices in transit (Shin, 2012)) and a*vailability (AV)* (the degree to which users believe that their devices offer real-time connectedness to information and services (Shin, 2012)). Therefore, the following hypotheses: *H9. MB has a positive influence on PEOU of smartwatches; H10. AV has a positive influence on PEOU of smartwatches.*

Figure 1: Smartwatch adoption model for older adults (source: authors)

Trust

In the present study, trust was defined taking into consideration the "willingness to rely" on the smartwatch. The correlation between trust and PU has previously been defined as positive (Gefen, Karahanna, Straub, 2003), similar to the correlation between trust and PEOU. Thus, the following hypotheses are presented: *H8a-8b. Trust has a positive influence on the PU and PEOU of smartwatches.*

Social influence

Social influence (SI) refers to the degree to which family members or important peers believe that the user should accept a technology (Venkatesh et al., 2003). Also, SI was identified as a strong antecedent for intention to use of Internet and perceived usefulness of consumer health information technology (Chen and Chan, 2014). Therefore, the following hypotheses are proposed: *H4a–H4c: SI has a positive influence on older adults PEOU, PU, and BI.*

Self-Reported Health Conditions

Self-reported health conditions reflects the current health status and biophysical characteristics of respondents. Significant influence of health conditions on adoption and usage of smart wearables was reported in previous studies (Chen and Chan, 2014). In the future empirical studies that the authors are going develop, the participants will be older adults aged 60 years or above, whose health status may at some point influence the adoption of smartwatches. Thus, hypotheses related to self-reported health status are as follows: *H7a–H7c.: Health has a negative influence on older adults PEOU, PU, and BI.*

Perceived Risks

Perceived risks can have a negative effect on how people perceive a new technology, which may act as a serious barrier in adopting it. The perceived risks that we have taken into account in our model are listed below.

Since the smartwatches have not been widely accepted by older adults, such systems may lead to potential risks, such as perceived social risk (PSR) and performance risk (PR) (Chan et al., 2012). PSR measures the degree to which health monitoring device users perceive stigmatization and humiliation by adopting smartwatches. PR refers to the degree to which users believe the technology may bring unanticipated risks (e.g. functionality risk and privacy violation) (Chatterjee, Price, 2009).

Therefore, PSR and PR are considered possible determinants that affect BI among older adults. Thus, the following hypotheses: *H5a–H5c. PSR has a negative influence on older adults PEOU, PU, and*

BI; H6a–H6c. PR has a negative influence on older adults PEOU, PU, and BI.

Analytical Procedures

The next phase of our research will deal with operationalization of constructs (definition and description of items) and the data will be gathered by means of a questionnaire. Data analysis will been carried out using the statistical package SPSS 23.0 for Windows. Structural Equation Modelling (SEM) with AMOS 23 software will be used to test the model. This technique is chosen for its ability to examine a series of dependence relationships simultaneously, especially where there are direct and indirect effects among constructs within model.

The data normality will be analyzed using the following tests: univariate outliers, multivariate outliers, skewness and kurtosis. The goodness of fit of the measurement model, the convergent validity and the discriminant validity will be analyzed taking into consideration the methodological recommendations concerning the evaluation criteria and the specific thresholds (Hair et al. 2014; Bagozzi & Yi, 2012; MacKenzie et al., 2011). The structural model will be examined in order to identify the links between variables and to test the hypotheses. The obtained results will be compared with findings from other studies.

Conclusion and Future Work

Recently, smartwatches have gained mass public awareness, but the actual adoption of these devices is not as high as expected. Understanding the factors that drive older adults to accept and adopt new technologies is one of the biggest challenges. Most studies on user perceptions are based on the technology acceptance theory. In addition, intentions to buy, use and continue to use new technologies are closely associated with the factors that influence and motivate users or potential users in adopting or continuing such behaviors.

The present study proposed a conceptual model for adopting smartwatches by older adults. The proposed model includes factors that have been highlighted in prior studies, but have never been used altogether in a TAM model. In the conceptual model, factors concerning the uniqueness of smart wearables including perceived social and performance risk, and health status, were considered to specifically predict the adoption of smartwatches by older adults. Moreover, the hypotheses were developed.

As the next step of this study, the measurement instrument will be developed and its reliability and validity will be examined. A survey among older adults will be carried out to examine the proposed conceptual model. The study will analyze the relationship between constructs, and will test the hypotheses concerning the relationship between the factors that contribute to the adoption of smartwatches.

Modern Machine Park Management in The Era of Industry 4.0 Concept

Katarzyna RADECKA

Faculty of Management, UTP University of Science and Technology, Bydgoszcz, Poland, katarzyna.woznicka@utp.edu.pl

Abstract

The Internet of Things and Technologies Industry 4.0 today uses machine manufacturers and applications that are far more effective than previously maintaining their performance, ensuring high performance and plant safety. The development of the Polish economy largely depends on innovation and the ability of new solutions. In the coming years, the industry will become one of the sectors that use modern technologies, including IoT. The article assumes research attempts to identify the main problems that link the condition of the machines with the quality of products in the company. In addition to the important issue of the functioning of a knowledge-based company and innovative methods used in the assessment of production quality, issues in the area of rational use of machines in terms of use and handling were distinguished, with the distinction of machine diagnostics. Machine diagnostics play an increasingly important role as a control element in the operation process, as it is an integral part of the operation strategy according to the state that effectively displaces the previously used plan and preventive strategy. The main problem is to improve the maintenance of machines in airworthiness by extending the possibility of vibration diagnostics of the main machines of the technological process, which translates into the quality of the plant's products. Recognition of the structure and tasks as well as the technological process of the plant gives reasons for the locations (facilities, machines) of the applications of the diagnostic procedures developed. The article presents the research goals, theses and scope of planned research.

Keywords : Maintenance, Product Quality, Industry 4.0 In Poland, Innovations.

Introduction

The contemporary, highly competitive productive environment offers enterprises the challenge of dealing with extensive data function, dynamic control of decision movement or flexibility of processing processes. Particularly the aspect of production flexibility is a key element here because, at present, the nature of production is shaped by changes in the model from mass production to production on demand, directed at customer needs (Gerwin 1994). These activities result in a shorter product life cycle, an increased product range, as well as a change of processes to those with high efficiency and the change of equipment and machinery to more flexible.

The effect of developing the technological process is the increase in complexity in all areas of the company's operations. This leads to increased demand for innovation in new materials and technologies, innovative production processes, but also an innovative approach to maintenance.

Traditional industrial maintenance strategies usually consist of two elements. The first is a schedule-based preventive approach. This solution assumes that machines are inspected and repaired at certain times. The time between subsequent inspections may be based on a calendar or mileage, and the supplement is servicing as part of fault repairs. Maintenance is another option after the plant is shut down, but most companies try to avoid it because of the cost of doing so.

However, this approach is not very effective. Most of the equipment that needs to be replaced because of the schedule could work smoothly for a long time. This is the main place where losses occur. And

while too frequent servicing generates excessive, unnecessary costs, extending the intervals in the schedule can result in increased defects and reduced product quality. The above strategy is less and less effective in modern industry, where equipment is complicated and requirements for reliability are increasingly high. Therefore, more accurate real-time insight into machine operating conditions is needed to ensure that service actions are appropriate (Fig.1.).

To meet the expected complexity of modern systems, a new concept based on knowledge, technology and tools, simulation, optimization and monitoring of existing production systems was created - Industry 4.0. However, Polish companies are not yet fully ready for this revolution.

Fig. 1: What is Condition Monitoring?

Industry Concept

The concept of Industry 4.0 was first presented at the Hanover Fair in 2014 as a report with synthetic research results (Abele, Reinhart 2011). From 2011 it was assumed that in the area of Industry 4.0, the company's production system will consist of an information system and numerically controlled machines that will be operating autonomously and display elements of artificial intelligence. Reality has verified this approach because due to the specificity of production systems in various industries, the term Industry 4.0 cannot be generalized in principle (Lasi , Fettke, Kemper, Feld, Hoffmann 2014, Schmidt, Möhring, Härting, Reichstein, Neumaier, Jozinovi 2015). Therefore, the scope of the definition of Industry 4.0 should be considered individually, depending on the needs of a given enterprise. The naming of the new concept is also changing. Nevertheless, generalizations and definitions of Industry 4.0 have been undertaken.

The first industrial revolution brought mechanization into production, the second is related to the electricity introduction. In the 70s of the last century, there was a third revolution, which further developed production processes with the introduction of information technologies. The term Industry 4.0 means the fourth industrial revolution, which assumes the functioning of intelligent factories built from intelligent cyber-physical systems. The implementation of this idea should allow the implementation of intelligent production systems that, in addition to the autonomy mentioned above, will have self-configuration, self-control or self-repairing properties. Under the model, science, technology and society are in a cyclical relationship and influence each other. In the future, it is expected that technologies that automate part of our human intellect and feelings will become the basis for future development.

Currently, Industry 4.0 is one of the most frequently discussed topics among practitioners and scientists, thus becoming paramount for many research centres and companies. The Industry 4.0 concept covers areas that include many technologies and related models. As the Industry 4.0 concept develops, every enterprise is perceived as offering an intelligent module to use in the production process and delivering the product to the customer, the size of the enterprise ceases to matter. Meanwhile, the level of technology used, the level of highly qualified staff employed and openness to unrestricted communication are becoming more important.

According to prof. Mariusz Bednarek, vice president of the Industry 4.0 Institute, Polish companies are very diverse when it comes to preparation for entering the era of the digital economy and it is difficult to clearly define their digital sophistication. At the request of PSI Polska by the PMR research agency, in the first quarter of 2019, the study "Readiness of production companies to implement Industry 4.0 solutions" was carried out. It covered large and medium production companies using ERP IT systems operating in Poland and with a turnover of over PLN 20 million. It showed that over half of the companies (52 per cent) met the term Industry 4.0. Big producers (62%) were more familiar with this concept than medium (41%).

The goals of Industry 4.0 announce new production systems. As the analyzes show, some have already been implemented or are being developed. For smaller factories, implementing the concept of 'Industry 4.0' is currently very difficult or still impossible. The planned research assumes the analysis of more advanced service and maintenance strategies and reference to how IoT and various components allow such activities to be carried out.

Goals and theses of Planned Research

The following objectives were set for carrying out the planned study:

- Literature analysis aimed at identifying the current state of the knowledge-based enterprise, its productivity, creative and innovative activities using virtual techniques.
- Identification of the currently used Support System for Maintenance and Maintenance Management in the selected company.
- Isolation of differences between the currently used model supporting the management of the machine park and the diagnostic model extended by the OPTIMUM, SVD, SIBI methods, and diagnostic modelling.

The main thesis of the planned research:
The functioning of a modern knowledge-based enterprise in a free market economy is possible with the use of creative and innovative activities in the area of productivity and quality, capturing the possibilities of information techniques for the needs of the wide application of modern methods in maintaining the condition of machines

Scope of Planned Research

Based on the literature analysis carried out so far, it can be said that computer-aided maintenance systems provide the opportunity to collect information about damage to objects, about their operation and allow the development of schedules for both periodic and preventive inspections. However, these systems do not have typical diagnostic functions in their structure, which should be supplemented with available software.

It will be necessary to study the changes in the state of machinery in the company using the proposed methodology of vibration diagnostics (experiments, results, statistical study).
It will be advisable to present the concept and develop recommendations supporting operation and maintenance management for the selected enterprise.

Therefore, the work necessary to achieve the research objectives will include:

- literature analysis on the subject of maintaining the fitness of machines,

- analysis of regulations and literature on modern methods of maintaining the fitness of machines in the era of Industry 4.0,
- study of changes in the state of machines of the enterprise using the vibration diagnostics methodology.

Abstract

The article describes the method and results of quantitative assessment of the impact of innovative economic development on the competitiveness of the region. The competitive position of the region was estimated using the author's method of determining the level of regional competitiveness, taking into consideration factors such as the level of economic potential and efficiency of its use, the region's attractiveness for people and for business, innovativeness of the regional economy

Keywords: Region, Competitiveness, Innovation.

Introduction

Competitiveness is one of the important aspects of social and economic development of regions. In this way the competitiveness of regions mainly defines by the level their innovative development. Moreover on the modern economy actually innovative component mostly determined and predetermined the achievement competitive advantages of the regions. Consequently to define the degree of importance this factor on the formation of competitive position of region is too significant.

As research has shown the competitiveness of the region correctly to define as the ability of region to formation, maintain, improve and use own competitive advantages on the relationships and interactions with other players on the market. And the aims of this action are the provision of sustainable social and economic development of the region and growth of welfare of population of this region. A large number of created or just inherited from nature the competitive advantages of region and high level their implementation describes the big competitiveness of the region. At the same time, just the mere presence of certain competitive advantages does not in itself mean that the system is competitive, since they still need to be implemented.

Competitiveness can be viewed and evaluated from two approaches quantitative and qualitative. If we talk about the first, the level or degree of competitiveness is usually assessed using a special system of indicators and appropriate methods, which are currently very numerous, but the most popular and applicable in recent years is the rating system.

As a rule, several groups of indicators are taken, for example:

– Standard of living of the population;
– The level of investment attractiveness;
– The level of efficiency of resource use.

The impact of innovations on the competitiveness of the region is carried out through the creation of a new type of competitive advantages innovative, which, unlike many others, for example, natural resources, which are ultimately inexhaustible, are not limited either by the possible impact potential or time frame. They are able to ensure continuous and sustainable economic growth and progressive development of the region both in the current period and in the strategic plan in any future.

Thus, the relationship between innovation and competitiveness indicates the unity of the quantitative and qualitative sides of the latter and actually means a new quality of competitiveness.

As for the analysis of the qualitative side of the category under study, it makes sense to use the approach of M. Porter, who, as we know, identifies “four interrelated stages in the development of competitiveness: factors of production, investment, innovation and wealth”.

In the first stage, competitiveness is achieved through competitive advantages related to the availability and use of human and financial resources. At this stage, the economic system is most sensitive to such phenomena as economic crises, currency fluctuations, etc., which, by the way, is very typical for the economy of modern Kazakhstan as a whole and its regions.

At the second stage of investment, competitiveness is ensured by an effective and even “aggressive” investment policy aimed at developing and implementing improved technologies and expanding the scale of production and sales, increasing investment in knowledge-intensive industries, and creating an effective scientific, technical and economic infrastructure.

For the formation of regional investment policy, it is important to identify and evaluate the investment potential of the region. Investment potential is an integral element of the investment climate, a characteristic of objective prerequisites for accepting investments, objects for investment in a region or country. It is calculated on the basis of macroeconomic indicators that take into account factors of production, consumer demand of the population, etc. Among the variety of indicators that reflect the state of economic and investment potential, it is necessary to highlight the main ones for the purposes of forming investment policy. These include a set of internal investment resources of the region (regional budget funds, funds of enterprises and financial institutions, funds of accumulation of the population, the value of collateral objects in the region).

The investment potential of the region is a complex indicator that reflects the state of investment resources, both actual and potential. It takes into account the main macroeconomic indicators, the saturation of the territory with factors of production, consumer demand of the population and other characteristics. The investment potential of the region consists of eight private potentials (each of which, in turn, is characterized by a whole group of indicators): resource and raw materials, labor, production, innovation, institutional, infrastructure, financial, and consumer potentials.

In such a vast country as Kazakhstan, the regional factor plays a key role in the overall economic development and investment of innovations. Today's priorities include: preventing further decline in the role of scientific and innovative and productive potential in the economy of regions, reducing the number of depressed cities and regions, overcoming the crisis situation in small cities and their

revival on an innovative basis by ensuring the influx of scientific and technological achievements and other innovations.

The set of actions listed above represents the practical implementation of regional investment and innovation policy. As a scientific category, the term "policy" means a set of goals and objectives of a strategic and tactical nature, which the subject of management seeks to achieve, and the mechanism for achieving them in any sphere of social development".

Based on this, the essence of regional investment and innovation policy can be defined as a purposeful, scientifically based activity of regional authorities and management to attract and effectively use investment resources to solve problems of socio-economic development of the region and improve the quality of life of the population based on scientific and technological progress.

The process of implementation of regional investment and innovation policy can be represented as a sequence of works performed by regional public authorities, in accordance with figure 1.

At the first stage, social, environmental and economic problems of the region are identified, the solution of which requires innovation and investment. When solving problems of regional development, strategic and tactical goals and priority directions of innovative development and investment are selected.

At the second stage, innovative development is determined which areas of the region's economy will have the greatest impact on solving social, environmental and economic problems in the region. At the third stage, priority directions of innovative development of the region's economy are determined. At the fourth stage, the regional investment strategy is determined. At the same time, a number of conditions are defined that must be met by investment projects implemented in the region.

Figure 1: Formation and implementation of investment and innovation policy
Note – Complied by the authors

The main ones are:

1) Investments should be innovation-oriented, ensuring the modernization of the region's industry, increasing labor productivity and employment;
2) Investments should be regionally oriented and ensure that the interests of the region's population are given priority when making investment decisions;
3) As one of the main investment criteria, the principle of "no degradation" of the region's population's habitat should be used, which implies taking into account environmental factors when calculating the projected results and consequences of investments. Compliance with this condition can be ensured by the introduction of mandatory expertise of investment projects and proposals.

At the fifth stage, the regional innovation and investment program has been formed.

Let's look at how the scheme of the regional investment and innovation policy model might look, in accordance with figure 2.

Based on the characteristics of the regional investment and innovation policy, two key blocks can be identified in the above diagram. The first block is criteria and methods for selecting objects and projects for regional development. The second block is mechanisms for attracting investment resources.

In accordance with figure 2, the central role in the scheme is occupied by the block of the regional investment and innovation program, which reflects the type of regional investment and innovation policy and determines its effectiveness. The main factor is the availability of a block for attracting resources.

Figure 2: Regional investment and innovation policy

Note – Complied by the authors

Under a centralized management system, state investment and innovation policy was based only on state resources that were concentrated in the hands of the state. Therefore, the problem itself and the technology for attracting investment were absent, and investment policy consisted mainly in the distribution of resources. Thus, the components is the economic potential of the territory, the development strategy and the economic self sufficiency of the region are prerequisites for the formation of a regional investment and innovation policy, as shown in figure 3.

Investment activity reflects the level of use of innovative potential in production and social relations. Innovation activity determines the ability of the region to perceive innovations in production. And this indicator should be required a special importance when forming investment and innovation policy in the region.

Figure 3: Methodological tools for evaluating investment and innovation activities
Note – Complied by the authors

The third stage has a particular importance innovative stage, when competitive advantages are actively formed by economic entities themselves, and domestic enterprises not only improve foreign technologies, but also create their own. This stage is characterized by the wide use of innovations in all spheres of economy and management, the creation of incentives for the introduction of new equipment and technologies, the growth of the number of scientific institutions and organizations focused directly on the needs of firms and industries, etc.

The analysis of works devoted to the assessment of the impact of the level of innovation of the regional economy on its competitiveness in various regions of the country allowed us to identify and systematize the key indicators of the level of innovation of the regional economy (Table 1).

Table 1: Indicators for assessing the impact of the level of innovation in the economy on the competitiveness of the region

Element of regional innovation system	Advantages of indicator	Disadvantages of indicator
1	2	3
Number of organizations doing R&D	Scientific and innovation potential of region assessment	Does not allow evaluating the structure of scientific organizations
Number of R&D personnel employed per 1,000 residents of the region	Assesses the human resources potential of knowledge generation and dissemination institutions	There is no information about performance and employment structure
Graduation of doctoral students with dissertation	Assesses the potential of the economy in the field of new	It does not allow you to assess the level of involvement of specialists

defense for 1 thousand residents of the region	personnel	in the process of creating knowledge
Technological innovation costs, as a % of GRP	Assesses the amount of investment in the final result of innovation activity	It does not allow evaluating the contribution of individual RIS entities to innovation financing
Volume of innovative goods, works, and services as a % of the total volume of goods, works, and services	Assessment of the degree of demand for scientific and technical achievements	Does not allow you to evaluate the degree of improvement of goods, works, services
Level of business innovation activity	Comprehensive assessment of business innovation activity	Evaluating the activity of industrial organizations only
Number of institutes for the development of scientific and technological potential in the region	Assessment of the development of the innovation infrastructure sector	It does not allow evaluating the activity of development institutions in supporting R&D
The number of registered subscriber stations of cellular communication	Assessment of the level of development of the information and communication environment in the region	Shows only an approximate degree of integration of elements RIS
Note – complied by the authors		

Based on the comparative analysis of the advantages and disadvantages of the RIS assessment methods, it can be concluded that the most effective method for a comprehensive assessment of the impact of the level of innovation of the regional economy on its competitiveness is the construction of integral indices.

The construction of a complex assessment in the form of an integral index consists of several consecutive stages:

1. Select a set of indicators.
2. Processing of primary data according to the selected processing method.
3. Normalization of calculated indicators, i.e. bringing them into a comparable form in the range [0,1].
4. Determining the relative importance of influence factors, i.e. weight coefficients.
5. Calculating the values of the integral index.

Testing of the results obtained on real data.

In our model, for each indicator, its normalized (index) value is defined as the ratio of the deviation from the minimum sample value to the sample size:

$$Ij = Xj - Xmin / Xmax - Xmin, \quad (1)$$

I_j – index value of the object's j-th characteristic
X_j – the observed value of the indicator for the object's j-th characteristic
X_{min} – minimum value of the indicator in the sample
X_{max} – maximum value of the indicator in the sample.

Since indexes can be heterogeneous in composition, i.e. contain "positive" and "negative" indicators, the resulting normalized values should be converted so that the dependence of the index values and the corresponding indicator corresponds to its conditional "positivity, or "negativity". This means that the greater the value of a positive indicator, the greater the index value should be, and in contrast the greater the value of a negative indicator, the smaller the index should be.

Therefore, if the indicator is conditionally positive, we leave it unchanged. Otherwise, the indicator value should be replaced with its complement to the unit.

$$Ij = 1 - I\Pi j; \quad (2)$$

I_j - the final value of the "negative" indicator for the object's j characteristic;
I^{Π}_j - index value of the "negative" indicator for the j characteristic of the object, calculated using the formula (2).

The proposed indicators for assessing the impact of the level of innovation in the economy on the competitiveness of the region allow us to evaluate and commercialize the results of R&D, and can be used to test various hypotheses (Table 2).

Table 2: Indicators for assessing the impact of the level of innovation in the economy on the competitiveness of the Kyzylorda region

Element RIS	2015	2016	2017	2018	2019	Growth rate of 2019 to 2015, %
Number of organizations doing R&D	7	6	6	8	10	42,8
Number of R&D personnel employed per 1,000 residents of the region	192/0,26	205/0,27	253/0,33	236/0,30	228/0,29	11,5
Graduation of doctoral students with dissertation defense for 1 thousand residents of the region	51/0,07	18/0,02	26/0,03	24/0,03	27/0,03	-13,3
Technological innovation costs, as a % of GRP	7 133,1/0,56	16 011,1/1,1	27 065,2/1,96	4 088,5/0,35	34 565,9/27,7	48,4
Volume of innovative goods, works, and services as a % of the total volume of goods, works, and services	3 645,0/0,28	6 641,7/0,45	4 761,2/0,34	6 930,3/0,59	6 295,2/5,06	17
Level of business innovation activity	12,8	12,0	10,1	11,7	11,2	-12,5
Note-calculated by the authors						

According to the table, in 2019, there was a decline in indicators such as the graduation of doctoral students with a thesis defense per 1 thousand residents of the region by 13.3%, the level of business innovation activity by 12.5% and therefore, there was a slowdown in innovation processes in the Kyzylorda region.

Conclusion

With the development of regionalization and local self-government processes, there is a division of powers, functions and responsibilities between the Government, regions and local self-government bodies. This includes investment and innovation policy, where regions have the opportunity to develop and implement their own investment and innovation policy by identifying priority investment and innovation facilities, developing and adopting regional legislation that promotes investment and innovation, and forming innovation and investment infrastructure in the region.

The model of regional investment and innovation policy at the stage of transition to a new industrial and innovative economy has a number of fundamental features that distinguish it from the models of investment policy of previous periods. The General strategy of socio-economic development of the region is a prerequisite for the formation of regional investment and innovation policy. In relation to it, the investment and innovation policy is a tool and should be agreed on the goals and deadlines for the implementation of individual projects, taking into account their synergistic impact. One of the features of the development of regional investment and innovation policy of the transition period is the limited overall period of its formation.

ul. Narbutta 85, 02-524 Warsaw, Poland
tadeusz.grzeszczyk@pw.edu.pl

Abstract

Evaluation processes should focus on estimating the outcomes of social projects and interventions because good intentions and positive looking goals do not always lead to the achievement of assumed and intended social benefits. There are many finance-economics evaluation methods and models. Against this background, the achievements in the field of social aspects evaluation are much more modest. Expanding the set of available solutions, it is worth looking for sources of inspiration related to the digital era, new business analytics methods and machine learning approaches. The main purpose of this paper is to explore the possibilities of using Support Vector Machine (SVM) data mining for social project evaluation. The proposed method can be a significant complement to the solutions used so far in this field. Properly conducted evaluation of social projects is one of the most important conditions for their proper implementation and success. The method allows conducting research using large collections of various data, it can be a real support in reducing the subjectivity of evaluation processes regarding social aspects of interventions from public funds by obtaining reliable research results and relatively easy identification of calculation errors. The paper presents theoretical considerations as well as an example implementation of the system supporting the evaluation of innovative social projects and the results of empirical research related to the verification process of the proposed method. Possible directions of further research in the field of development of the presented solutions are also indicated.

Keywords: Social Project Evaluation, Project Management, Support Vector Machine, SVM Data Mining.

Introduction

The United Nations' 2030 Agenda includes seventeen Sustainable Development Goals (SDG), which are a source of valuable inspiration related to the functioning of commercial and public institutions, as well as planning and implementation of commercial and non-commercial projects. They concern key sustainability problems concerning humanity and the entire planet, which include, for example, poverty, good health and well-being, inequalities reduction, quality of education, climate change, natural environment protection, decent work and economic growth as well as global and local partnership for achieving the goals (UN, 2015). SDG indicators serve as the basis for measuring and evaluating the sustainability of enterprises (Drobyazko et al., 2019) and various types of projects.

The guidelines contained in the documents related to SDG are associated with significant new challenges regarding corporate sustainability reporting (Tsalis et al., 2020) and conducting evaluations of various types of activities and projects. The issues of evaluation carried out in accordance with the SDG are of increasing importance and its proper implementation can provide significant difficulties, as projects are becoming more complex and the objectives to be achieved (observed from the perspective of various groups of stakeholders) are multifaceted, often inconsistent and contradictory. There is also usually considerable variation in the perception of project success by diverse groups of stakeholders and the need to develop modern methods and models for project evaluation that take into account dynamic changes of perspective within many time frames and many research perspectives occurs (Davis, 2017; Turner and Zolin, 2012). It is therefore necessary to carry out methodological studies taking into account the multifaceted nature of the social project outcomes evaluation.

On the part of policy makers, practicing managers and academics, there is considerable interest in the issues of multifaceted analyzes of social projects outcomes and social innovations carried out in the context of sustainable economic development in the digitalization era. Digitalization affects sustainable development and it is necessary to search for appropriate methods and measurement models for both micro and macro aspects related to sustainability dimensions (Jovanović, Dlacic and Okanovic, 2018). The key drivers for sustainable development are various types of innovations and it is necessary to conduct multidisciplinary research and discussion related to, i.e., with new technologies for sustainable development and challenges regarding social innovations (Silvestre and Tirca, 2019). Literature research on creating a clear picture of the academic discussion on the link between SDG and social innovation shows that it is a constantly growing field (Eichler and Schwarz, 2019).

Social projects (which are often based on the power of data) can solve societal problems, improve human development, be a source of valuable innovations, create social sustainability and desired changes (Howaldt and Schwarz, 2017). Until now, research related to the use of analytical modeling, machine learning and various numerical analysis has been mainly focused on solving technical and business problems. Therefore, there are challenges regarding the use of big data and data mining potential in solving social problems as well as taking data-driven decisions regarding the creation of new paths of social innovations and evaluation of sustainable development projects (Pappas et al., 2017). Social innovation projects are playing an increasingly important role in the development of modern societies and it is necessary to develop approaches and methods that support their multifaceted evaluation, including inspired by business analytics solutions.

The development of new research methods that can potentially meet the challenges of multifaceted evaluation of social projects can be based on conducting research work under the following two streams: improving methods known from social sciences or interdisciplinary research using achievements related to progress in the field of machine learning, AI and intelligent systems - single and mixed (Grzeszczyk, 2018). The achievements in the field of project evaluation related to the second stream are much more modest. Therefore, when conducting methodological research concern expanding the set of available methods for evaluating social projects, it is worth using sources of inspiration related to the digital era, new business analytics methods and machine learning approaches. Thus, a significant supplement to the solutions used so far in social project evaluation may be the method based on Support Vector Machine (SVM) data mining.

The main purpose of this paper is to explore the possibilities of using SVM data mining for social project evaluation. In addition to presenting theoretical issues, an example implementation of the system supporting the evaluation of social projects and verification studies based on empirical data were carried out. Empirical research was conducted using data on innovative social projects planned for implementation with financial support from the European Social Fund in Poland. Finally, possible directions of further research in the field of development of the proposed method were signaled.

Social Project Evaluation

Many contemporary projects are non-commercial and their goal is to achieve various social outcomes related to SDG, such as combating poverty, improving health and well-being, inequalities reduction, ensuring access to high quality education, reducing adverse climate change, protection of natural environment, decent work and economic growth as well as providing partnership for these goals. An overview of research concerning sustainable development and project management is provided in (Farias de Toledo et al., 2019).

In the programming period (2014-2020) of the EU Cohesion Policy, programs supporting economic and social cohesion, are implemented. Social projects implemented under these types of programs are used to involve organizations and local communities in activities related to the achievement of the objectives of the Europe 2020 Strategy for Smart, Sustainable and Inclusive Growth (Saracu and Trif, 2019). Among previously undertaken similar programs related to innovative activities were, among

others Community initiatives under the European Social Fund and among them several EQUAL themes promoting innovative social projects and social economy.

The implementation of mechanisms for equalizing employment opportunities for social groups experiencing inequalities resulting from a lack of qualifications and a low level of education, and ensuring their participation in the development of the information society requires the use of specific approaches focused on local conditions related to specific geographical locations of implemented social projects. In particular regions and countries there are differences in levels of digitalization specific problems related to social sustainable development in the digitalization era. For example, the first program in Poland aimed at implementing innovative projects tailored to local social problems is EQUAL Community Initiative. Many projects implemented under this program were innovative and set future standards for action in subsequent local programs and projects supported by the European Social Fund (Klimczuk 2015).

The issues of innovative social projects evaluation are not well researched. In the case of evaluation of such contemporary projects, methods based on cash flows and simple financial indicators are not useful. The evaluation methods used for sustainable projects should consider their diversity, complexity and be consistent with the following concepts: Corporate Social Responsibility (CSR), Triple Bottom Line (TBL) and Sustainable Project Management (Sabini, Muzio and Alderman, 2019). Approaches to CSR are discussed in more detail in publications such as e.g. (Jankalov and Jankal, 2017) and (Krajnakova et al., 2018).

There is a considerable variety of project evaluation methods (Gertler et al., 2016; Linfield and Posavac, 2019). However, it is worth paying attention to one more specific feature of social outcomes and social efficiency notion. In contrast to the measurements based on universal economic values, social measures are characterized by a significant diversity resulting, for example, from differently and subjectively understood social values, expectations and customs that can occur in societies and communities located in different regions of the world (Grzeszczyk and Pelszynski, 2020). Significant differences can be noticed even among people from one country who speak different languages and profess different religions (Crafa, Liu and Brodeur, 2019). Social projects usually involve a large number of stakeholders, often with significant cultural, linguistic differences and attitudes towards official responsibilities (Diallo and Thuillier, 2005). Social Impact Assessment is one of the approaches to support the resolution of this type of multifaceted problems related to mainly long-term social and environmental impacts of public projects and programs (Wong and Ho, 2015).

As part of evaluation studies concerning social projects, predictions or measurements of multifaceted outcomes are made. The proposed evaluation method should, first of all, take into account aspects of the hard to quantify and measure, sustainable and responsible socio-economic development - in accordance with the SDG criteria. Evaluation research can be related to many aspects, i.e. economic, ecological, technical, research, organizational, cultural, political, legal, etc. However, the key aspects are those related to social outcomes. Evaluation criteria of individual projects may differ significantly and depend on the regulations occurring in the programming documents of entities financing the evaluated projects. The criteria regarding socio-economic efficiency are of fundamental importance. The literature recommends focusing on assessing of social interventions, projects and programs, as well as according to the classical definition, evaluation of programs is their systematic assessment that includes improvement of social conditions and individual and collective well-being (Rossi et al., 2019).

It is necessary to harmoniously develop research on multicriteria evaluation of social projects in accordance with the SDG. The development of this type of research requires a new look at current achievements in evaluation theory and practice and going beyond the methods used so far towards approaches and solutions inspired by the digital era, new business analytics methods and machine learning approaches. Such inspirations may contribute to proposing new methods of evaluation of social projects that are a significant complement to the solutions used so far in this field.

The results of literature studies show that there is still not enough research on the applications of artificial intelligence and machine learning methods that are used in social project evaluation processes. The problem of evaluating this kind of projects can be considered complicated and complex and its resolution takes place in conditions of considerable uncertainty. It is justified to further explore new methods that are useful in processes of social projects evaluation and would take into account key achievements in the field of artificial intelligence methods. Significant potential which can be exploited in this field is associated with machine learning methods - including SVM.

The Potential of Using SVM Models in Project Evaluation

SVM is one of the most valued machine learning models as evidenced by the dynamically growing number of papers on its applications (Yu et al., 2020). The increase in interest is due to the relatively simple mathematical description and ease of use. Despite its simplicity, it has significant potential that can and should be used in various fields (Ma and Guo, 2014). For solving complex and nonlinear problems (concerning regression and classification), kernel methods are used, which are based on transferring the learning set to high-dimensional space using the appropriate mapping function. The use of such methods and models is also necessary when solving the problem of project evaluation.

The operation of SVM models is based on the use of the approach referred to as supervised learning - principle of searching for the most appropriate answers on the output of the model in response to the input data. The model learns based on sets of learning examples that contain pairs of input data and their corresponding output data. In this way, the learned model is informed about the belonging of objects to defined classes. A useful feature of machine learning models is their ability to generalize knowledge, i.e. to generalize the experience gained in learning processes. This involves the possibility of obtaining correct model responses to input data not previously found in the train set.

Classified objects can be characterized by the values of many features (attributes, criteria). The significant potential for applications in the field of evaluation of various types of projects results from the basic feature of the assessment process, which is systematic examination using the adopted evaluation criteria. Estimating the quality and value of public intervention, in the form of projects, cannot be carried out without using specific criteria. The necessity of basing the evaluation process on several evaluation criteria and the use of multi-criteria evaluation results from the multifaceted and comprehensive nature of the social projects evaluation problem.

The criteria for evaluating social projects that can be applied in calculations using SVM models are often complex, multidimensional and interdisciplinary. In addition to the quantitative financial-economic criteria (typical for commercial projects), there are also other types of criteria that take into account the qualitative and hard-measurable aspects of sustainable development compatible with the SDG. They are related to social aspects, but often also economic, technical, organizational, legal, ecological, cultural, political and other attributes describing the conditions of implementation and the evaluated project environment.

Models and methods based on SVM work well in carrying out research processes based on significantly differentiated and large data sets. In addition to the undoubted advantages, they also have some disadvantages typical for machine learning methods. Among them, there are some difficulties in assessing built models and estimating ex-ante errors. In practice, in the case of solving regression problems related to e.g. forecasting, accurate error estimation is possible ex post, as a result of comparing actual values with forecasts. However, the advantages of SVM methods outweigh their disadvantages. They are usually effective in accuracy and in many cases ensure obtaining correct calculation results at relatively low computation power.

SVM-based methods and models have huge and untapped research potential in the evaluation. Against the background of current achievements and considerations regarding the potential of SVM applications, there is a clearly visible gap in the application of such models in evaluation of various types of projects. This is an inspiration to develop research in this area.

Methodology

The research question - '*Is there a need and possibility to use SVM Data Mining in supporting social projects evaluation processes?*' - is the basis for the selection of appropriate research methods that allow the collection and analysis of empirical quantitative and qualitative data. In these studies, the following research methods and techniques were used: literature research and analysis of documents related to the evaluation processes of innovative social projects, which were evaluated in terms of possible funding from the ESF - European Social Fund in Poland (within EQUAL Community Initiative). The most important documents that were analyzed were the forms filled in by experts conducting the evaluation of social projects. In addition, simulation and computer experiments based on SVM data mining algorithm available in TIBCO Statistica 13.3 software were used. To facilitate these simulations and calculations, the collected empirical data was recorded in a spreadsheet.

Projects evaluated by experts were primarily an innovative complement and development of standard activities supported by the ESF and the state budget. They concerned activities related to the development, implementation and promotion of new, innovative methods of combating inequalities and discrimination that may occur on the labor market. The scope of these projects included experimental and innovative concepts, as well as transnationality activities that were planned to be implemented not by individual institutions, but through partnerships of many organizations with significant diversity, e.g. national, regional and local state authorities units as well as organizations supporting discriminated groups , private enterprises, universities and research centers and others (EQUAL, 2007).

The scope of document analysis was limited to priority Theme A, whose basic priorities were associated with supporting equalization of opportunities on the labor market for social groups with low qualifications and level of education, and therefore experiencing inequalities as well as including these groups to participate in the development of the information society. As part of this Theme (in 2004), 425 project proposals were submitted. This accounted for over half (around 57%) of all proposals. Other themes were less frequently represented (from one to several percent). 88% of project proposals (375) successfully passed the formal assessment phase. These projects were then sent to the second phase of substantive evaluation. After the second stage of evaluation carried out by a panel of experts appointed by the government institution, 248 projects were positive evaluation results and 127 were negative. Projects intended for financial support and implementation were selected from a set of projects evaluated positively.

Two sets of positive and negative evaluated projects were designated for computational experiments. The large amount of quantitative and qualitative empirical data justifies the use of SVM Data Mining for these calculations. The collected set of empirical project data was analyzed in terms of their acceptance (possible coverage with public funds) or rejection. Two decision classes have been identified: projects evaluated positive or negative (coded 1 and 0 respectively). Projects from these decision classes were divided into two random subsets: training (75%) and testing (25%). A model of SVM was built by using the training set. Then data saved in the testing set was applied in the process of verifying the suitability of SVM data mining for social project evaluation.

Results and Discussion

The presented results and discussion mainly focus on issues related to seeking answers to a research question regarding the need and possibility of using SVM Data Mining in supporting innovative social projects evaluation processes. The analysis of documents related to the evaluation of innovative social projects mainly concerned the forms filled in by the evaluators. Based on this analysis, the evaluation criteria, that were used by expert evaluators during the substantive evaluation phase, were identified. Analogous criteria have been applied in calculations based on SVM data mining, i.e.:

- The purpose of the partnership established to implement the evaluated project and connection with the program documents,

- Justification of the need to support the proposed activities of the partnership,
- Planned work and activities of the partnership,
- Ensuring partnership,
- Approach related to empowerment,
- Innovative approach,
- Approach to the dissemination and inclusion of results in accordance with the principle of mainstreaming,
- The objectives in the field of transnational cooperation.

Multicriteria analysis parameters and results obtained using SVM data mining (a multiclass, non-linear binary SVM classifier) are presented in Table 1. The obtained value of overall classification accuracy can be considered satisfactory and a good basis for further development of research on proposing practically useful tools not only for the needs of conducting scientific experiments, but also for supporting project evaluation processes.

Table 1: Multicriteria analysis parameters and results

Analysis parameters		SVM results	
Kernel type – RBF (Radial Basis Function), Gamma	0.125	Number of SV	62
Size of training sample (random sampling)	75%	Training classification accuracy	94.66%
Maximum number of iterations	1000	Test classification accuracy	91.49%
Stop training at error	0.001	Overall classification accuracy	93.87%

Source: own calculations

The basic concept associated with the classification based on the available SVM algorithm is support vector (SV). As a result of the calculations, 62 number of SV and 53 bounded support vectors (BSV) are detected. The number of SV proves the relatively good suitability of the built model for classifying projects from the analyzed data set. There are relatively few of them in relation to the number of evaluated projects. Future computational experiments related to the use of other types of algorithms may lead to a decrease in this number and an improvement in the functioning of the classifier from the point of view of the ability to generalize knowledge acquired in the learning process.

The correlations between the number of criteria and the numbers SV and BSV are opposite, i.e. as the number of criteria increases, the number of SV moves higher (positive relationship), while BSV decreases (negative correlation). Achieving similar and relatively small SV and BSV numbers in this case is a compromise solution because this means achieving a balance between two differently correlated parameters. The use of visual methods can be helpful in better understanding this kind of dependency (Caragea et al., 2008).

The confusion matrix for the innovative social project classification can be seen in Table 2. It includes two decision classes used in calculations. The form of the matrix proves the good properties of the built SVM model from the point of view of the ability to readily separate from each other the established decision classes. The number of cases from the learning set turned out to be enough to create a model that is a very powerful tool with significant practical utility in supporting project evaluation processes. When building supervised learning models (to which SVM belongs), requirements for too large learning collections are sometimes blocking many practical applications.

Table 2: Confusion matrix for social project classification

Class observed	0	1
0	27	3
1	5	59

Source: own calculations

The classification results obtained with the use of SVM data mining can be considered as quite satisfactory. These results of empirical research are only preliminary, but they make it possible to draw a conclusion about the practical usefulness of the proposed solution. These calculations show the possibility of using this method for social project evaluation. In the future, it is worth comparing the results with other classifiers.

Conclusions

Literature studies have shown that existing approaches, methods and research tools for the evaluation of social projects are often insufficient and it is worth paying attention to the possibilities of extending the set of available solutions to reduce the subjectivity of the assessments carried out (especially in the case of qualitative criteria). Therefore, there is a need to look for new research methods that could be applied in this field. An interesting source of inspiration for conducting methodological research are achievements in the field of AI and machine learning. One of the models known in machine learning is SVM, which enables analyzing large empirical data sets and solving classification and regression problems related to the evaluation of social projects. The paper synthetically indicates the significant potential of models and methods based on SVM Data Mining in this field.

Theoretical considerations and results of empirical research show that the proposed solution can be an interesting and major complement to other methods and models used so far. Its usefulness has been demonstrated in supporting multicriteria evaluation of innovative social projects whose goals refer to the SDG. The results of the conducted research allow confirming the need and possibilities of using the proposed method in supporting the evaluation processes of this kind of projects. The following advantages of this method have been demonstrated: SVM models are built relatively easily, it is not difficult to conduct analyzes using large data sets on multicriteria evaluation of social projects, the results obtained can be considered reliable and it is possible to assess computational errors using objectively verifiable indicators.

The presented research is only of a preliminary nature and there is a need to continue it in the direction of further improving the SVM data mining-based methods proposed in this paper. The obtained research results justify the need for further development of interdisciplinary research in this field. It is possible, for example, to supplement the developed solution with procedures for including in the ex-ante evaluation processes also data from ex-post evaluation concerning the results obtained after the completion of social projects. It is also possible to improve the quality assessment principles for the built evaluation models based on SVM data mining by increasing the number of parameters describing such models. The development of the proposed solution may also involve conducting research concerning the possibilities of using it to support the evaluation of other types of projects related to sustainable development, e.g. ecological. It is also interesting to consider modifying the mathematical and IT tools used. In particular, one can perform computational experiments with various computer algorithms and perform a comparative analysis to select a model with lowest computational errors.

The paper proposes a solution characterized by practical utility. The presented concept of using SVM data mining for social project evaluation can be useful in designing various types of systems supporting the processes of planning and evaluation of projects, as well as supporting decision

making by experts (evaluators), politicians, officials from different (state, regional and local) levels of public administration, contractors and other project stakeholders.

Application of RFID Technology to Model Transport of Dangerous Goods

Tomasz Remigiusz WASNIEWSKI

Military University of Technology, Warsaw, Poland
tomasz.wasniewski@wat.edu.pl

Abstract
The article discusses the problem of hazardous loads transported by roads. Possibility to use RFID technology for tracking and at the same time to model travel routes based on data sent to central databases. Locating the data in one place would allow for the tracking of vehicles with hazardous loads in a centralised manner.

Keywords: RFID, hazardous loads, transportation.
ORCID Identifier: 0000-0002-9424-377X

Introduction

The main factor influencing economic development is the transportation of people and loads. Transportation has influenced the evolution of many branches of economy and social life. Nowadays, in order to compete effectively on a difficult transportation market, it is necessary to respond flexibly to customers' needs and offer them services meeting their requirements. One of the ways to achieve this goal is to collect “historical” information, necessary to analyse and forecast market and customer needs. In recent years road transportation has become the main mode of transportation with an increasing trend [19,20] (0).

Fig. 1:The statistics by the European Union Eurostat on transportation structure
Source: compiled on the basis of [□,□].

Poland is the second country in Europe, after Germany, in terms of the amount of loads transported by roads. The volume of loads transported in the European Union by Poland in 2016-2017 is shown in Figure 2. 2017 was a record year in this respect.

Fig. 2: Volume of loads transported by road in Europe between 2016 and 2017
Source: compiled on the basis of Eurostat [□].

Figure 3 presents data that show an upward trend in the transportation of hazardous loads at the Polish carriers and the largest European carriers between 2012 and 2017. It is estimated that the volume of dangerous loads transported in Poland will increase every year from 2% to 4% [□].

The transportation of hazardous loads by road in Poland accounts for about 15% of all loads transported. The quality structure of the transportation of hazardous loads is at the following levels [□]:

- liquid fuels about 72%,
- liquefied gases about 19%,
- other toxic substances about 9%.

Fig. 3: Volume of hazardous loads transported by road in the EU
Source: in-house elaboration compiled on the basis of [□, □].

The increasing demand for the transportation of hazardous loads each year results in an increased flow of cargo between senders and recipients. This increases the risk caused by more vehicles on the roads. Tankers with various chemical compounds and other combustible materials are increasingly moving at the same time and in the same direction. Often, hazardous loads are carried on the same road at small distances and at high speeds, posing a threat to other road users and the environment. Such an example is the situation that took place on August 6, 2018 on the bypass of Bologna in Italy, where a tanker of LPG raided a heavy goods vehicle with solvents [□].

The transport of hazardous loads should therefore be monitored by the government services responsible. Voivodes and voivodeship marshals are responsible for the supervision of hazardous loads transported by road within the voivodeships. Unfortunately, they do not have enough tools (both legal and physical) to do so.

Action 2. RFID technology for hazardous loads tracking and route planning - the author's own proposal

In the age of the widespread internet and information circulation around the globe in a fraction of a second, the alternative to tracking hazardous loads is to use radio identification of products with a transponder containing the information. The possibilities of using this technology are still being discovered and thus increasingly common. It can be used on small, medium and long distances. Thanks to its diverse interface, it can be combined with other solutions using IT networks or used, for example, as a tool for data collection and transmission.

The most common solution is to place RFID transponders on parcels, electronic devices, car parts, expensive clothing or other products that can move near RFID concentrators with antennas. RFID concentrators, as devices for reading and transmitting information to the database, are usually stationary objects. The mobile part of the technology are transponders. The proposal to mount RFID concentrators on vehicles carrying hazardous loads would change the current utilization of this technology. Figure 4 shows the elements of a system that can monitor the process of transporting hazardous loads by roads. RFID transponders would be deployed along the roads. Vehicles equipped with RFID concentrators, based on read-out transponders placed along the road, could transmit their location. Such a solution would indicate how many vehicles carrying hazardous loads are on the roads equipped with transponders. Drivers with a dangerous load would be informed how far ahead of them another ADR transportation is located.

Fig. 4: Proposal to apply RFID technology to the transportation of hazardous loads
Source: the in-house elaboration.

An important part of the vehicle's equipment would be a transponder identification device (0). The RFID concentrator will be integrated with a device equipped with a GSM card for data transmission in a mobile network via UMTS.

Fig. 5: A vehicle with RFID concentrator

Source: the in-house elaboration.

RFID transponders will be located at the entrance and exit of the road links. If the road is located at the border of administrative areas such as voivodeships / districts / communities, the border areas transponder will be mounted here. Vehicles carrying the hazardous loads when leaving the sender's location will register the first transponder thereby recording the start time. This information will be sent by means of data transmission via GSM telephone to the Monitoring Centre for the Transportation of Hazardous Loads (MCTHL) and will be stored in a database under the load authorisation number. The database will contain information about: quantity, class of load, type of packaging and a driver with the number of the certificate for transporting this type of load. Each successive transponder is information for the centre where the vehicle with the load is located. The arrival of the vehicle at the recipient's premises and the loading of the last transponder will complete the process of tracking the loaded vehicle and sending the information to MCTHL.

The application of such a solution integrating a global Internet network with packet transmission and recording in a database of information on the location and movement of vehicles will allow authorized inspection authorities to better control the implementation of the process of transporting hazardous loads. On the other hand, the State Fire Service in its area of operation will be able to more efficiently remove the causes of chemical disasters (0).

Fig. 6: Network control system

Source: the in-house elaboration.

Control authorities such as: Inspectorate of Road Transport, Police, Customs Service, Border Guard, State Fire Service and Military Gendarmerie (only for loads transported for military purposes) will be able to track the vehicle moving with hazardous loads in their area via a web link and a web browser.

This way, the transponder information collected would be recorded as database records (0).

Fig. 7: The example of route record

Source: the in-house elaboration.

The driver of the vehicle will only enter the authorisation number, the system will automatically connect to the MCTHL database to download the following data:

- authorisation number issued by General Inspectorate of Road Transport (GIRT),
- number of class of material,
- packing group,
- identification number (UN) of the material and quantity of a load,
- the name of the sender with its exact location,
- name of the recipient with his location,
- planned place and time to start a route,
- the number of crew members and their documents,
- ADR approval certificate number.

On the basis of this data, the system will determine the shortest route, which will consist of the appropriate transponder numbers (0). An important element will be the time of departure, which may be decisive in determining the route. Assuming that the planned time of departure will be consistent with the actual one, the system will send a route information to the driver's device and load into the device's memory all relevant transponder numbers on that route. This route planned this way will be the shortest and safest one for the moment.

In 0Figure 8 shows the situation when the driver changes the route and interferes with the readings of transponders by the device. The disturbance will be reported to the MCTHL operator and will inform him which vehicle changed the route. There may be a situation where the RFID concentrator may have been damaged or the transponders are unreadable. To eliminate such situations, the number of the first transponder will be duplicated in the same direction at a distance of 0.1 and 0.2 of the entire section. Duplication of transponders with the same number is allowed in RFID technology. This increases reading reliability and eliminates errors. If the vehicle is registered at the entrance of the node and is not registered at the exit of the node and no transponder is read, then the MCTHL operator will receive information, on which node there was interruption. This type of situation will allow the controlling services to start up to locate the vehicle or try to contact the driver.

By analysing such situations and other disturbances, it is possible to take action in relation to equipment problems or to consider whether this is not an intentional action by a carrier or a driver. This will allow you to see what could have caused this type of disturbance.

Fig. 8: The exampled illustration of a faulty route

Source: the in-house elaboration.

This type of solution would assist carriers in planning routes for the transport of hazardous loads and at the same time would automatically collect data on the directions of flow of such loads. It would also make it possible to analyse the work time of ADR drivers in view of the very high responsibility that lies with them. The transportation process can be carried out by many vehicles in the same time frame. The definition of the time frame is the same day and the same time of departure from different senders to the same recipient.

In 0Figure 9 illustrates the situation when a recipient receives hazardous loads from different suppliers within the same time frame. A delivery time may be approximate due to various external factors that may occur during loading. Carriers are present at the premises of the senders n and n' in order to load the transport. Once the loading procedure is completed and the drivers enter the authorisation number, the system will determine the routes for the vehicles *st1* and *st2* that are intended to move in a given moment.

Fig. 9: Image of the travel and comparison of two transportation routes

Source: the in-house elaboration.

The travel routes for vehicles *st1* and *st2* will be compared. Repeated transponder numbers will be highlighted to check the approximate time of travel through these transponders. If times vary, the system will not change a plan of transportation route. However, if there is a possibility that vehicles *st1* and *st2* meet at the same transponder, the system will decide to change the route or will make a change during the departure of one of the vehicles.

At present, route planning by carriers is based on experience and knowledge of ADR issues. Efficient routing does not guarantee the successful delivery of a load to the recipient. The carriage of dangerous goods should be treated the same way as flight controllers treat aircraft during their flight. The flight controller is to determine the flight path so that the aircraft reaches its destination without approaching other aircrafts. Planning the transportation of hazardous loads by roads is the utilization of a single dimension, which is the length of the road section between the nodes from sender to recipient.

Transportation of hazardous loads by roads should be carried out with the participation of the system and organizational units located at the Voivodeship Commands of the State Fire Service. The system should track and exchange information between regions such as voivodeships. Vehicles with hazardous loads leaving one region would be taken over by the next region. In each of the regions there would be a organizational cell for tracking hazardous loads, placed at the Provincial Headquarters of the State Fire Service functioning as the end of the MCTHL monitoring centre.

Action 3. The method to optimise the transportation of hazardous loads with using RFID technology

Studying the process of transporting hazardous loads by roads is a complicated activity and requires taking into account a wide range of parameters and variables. The essence of the process of transporting hazardous loads is safe loading, carriage and unloading. In addition, the route must be planned in the shortest possible time, on the roads designated for this purpose, taking into account safety of road traffic. Hazardous loads are carried by different carriers who monitor their transportation on the roads but know nothing about other participants carrying dangerous goods in the same direction or on the same roads. Chaotic transportation of cargo carries a high ecological risk for the property and the environment.

For research purposes, the 3D spatial model was built to track the transportation of hazardous loads (0). In the model, the movement takes place in one direction from sender to recipient.

Fig. 10: Imaging the 3D model

Source: the in-house elaboration.

The model consists of 4 senders designated as *n1, n2, n3, n4* and one recipient designated as *o1*. The model contains 7 intermediate nodes *v1, v2, v3, v4, v5, v6, v7* connected by 12 arches (*v1v2, v1v3, v1v4, v2v4, v2v5, v3v4, v3v6, v4v5, v4v5, v4v6, v4v7, v5v7, v6v7*), on which the transports with hazardous loads will move. In the model there are 4 access arches connecting the senders n1, n3, n4 with intermediate node v1 and the sender n2 with the node v6. Node v7 is connected with the access arch to the recipient o1. For the purposes of the research, the following length of arches are adopted: 10 and 15 km, while the access arches from the senders to the intermediate nodes are between 500 and 1000 meters long. The travel time amounts to 10 seconds to go through the intermediate nodes. At the beginning and the end of the arches, RFID transponders were placed in the form of gateways (0).

Fig. 11: Exampled visualisation of RFID transponders in the model

Source: the in-house elaboration.

The transponders record vehicles entering and leaving the nodes. The average speed can be determined from the readings of the transponders within the arch. The algorithm controlling the node, based on the transponder readings, directs the vehicle to the arch, which is the safest and guarantees the fastest travel. It has been assumed that the average speed of the vehicles in a loaded vehicle model will be between 5

m/s and 20 m/s (from 18 km/h to 72 km/h) with a 0.1 m/s increments. It has also been assumed that the vehicles with a hazardous load should keep the distances between themselves in the range from 75 m to 2500 m in 1 m increments. The increment parameter for speed and distance has been determined in order to examine precisely at which speed and distance the best route can be determined for vehicles carrying hazardous loads. The model simulates vehicle traffic based on an exponential function where the departure time of the loads is the average time for each sender. The time of study was assumed to be 24 hours.

Discussion

The method developed for the research conducted in the thesis is characterized by phasedness and repeatability. It is necessary to distinguish the individual steps identifying the decisions to be taken on each of them, as well as their specific types of data and results. To this end, appropriate proprietary algorithms have been developed, ranking the activities and decisions for each of the above mentioned steps, thus putting the process of carrying hazardous loads in order.

The transportation of hazardous loads is divided into three stages:

- stage I - loading,
- stage II - carriage,
- stage III - unloading.

Using the algorithms, Stage II was tested. Thus, a single algorithm marked FA was used, which simulates conditions similar to the actual carriage of hazardous loads. Three basic algorithms marked RAP-TR, RbP-TR, RRiA-TR have been created. A combination of six algorithms marked RAPRbP-TR, RAPRRiA-TR, RbPRAP-TR, RbPRRiA-TR, RRiARAP-TR, RRiARbP-TR was built on the basis of these basic algorithms (Table 1).

The developed and applied algorithms are designed to determine the best method for planning routes for the carriage of hazardous loads with the support of RFID technology.

Table 1: Functions of Algorithms

No.	Algorithm	Description
1.	FA	The first any arch
2.	RAP-TR	Randomly accessible arch with RFID transponders
3.	RbP-TR	Randomly available arch with percentage distribution with RFID transponders
4.	RRiA-TR	Randomly available cyclically if the arch is free with RFID transponders
5.	RAPRbP-TR	Linking RAP and RbP algorithms with RFID transponders
6.	RAPRRiA-TR	Linking RAP and RRiA algorithms with RFID transponders
7.	RbPRAP-TR	Linking RbP and RAP algorithms with RFID transponders
8.	RbPRRiA-TR	Linking RbP and RRiA algorithms with RFID transponders
9.	RRiARAP-TR	Linking RRiA and RAP algorithms with RFID transponders
10.	RRiARbP-TR	Linking RRiA and RbP algorithms with RFID transponders

Source: the in-house elaboration.

Three basic algorithms RAP-TR, RbP-TR, RRiA-TR have been tested and applied to all nodes having a minimum of two output arches. The next six algorithms RAPRbP-TR, RAPRRiA-TR, RbPRAP-TR, RbPRRiA-TR, RRiARAP-TR, RRiARbP-TR are used on nodes where the first algorithm in a pair controls nodes that have at least three output arches, while the second algorithm in a pair is designed to control nodes that have two output arches.

All algorithms have been tested for speed and distance between the vehicles carrying hazardous loads. After testing the algorithms, the best algorithm is RRiARbP-TR (0), in which there are 28 optimization solutions, we have 6 repetitive speeds which gives us 19 variants. The speed range of the carried loads ranges from 12.6m/s (45km/h) to 15.6m/s (56km/h) ensuring that the transportation task is completed within a reasonable time. Rapid faults between the intervals take place at points of speed change. This type of solution will allow flexible adjustment of speed and distance between vehicles carrying hazardous loads.

Fig. 12:The optimal solution for RRiARbP-TR algorithm

Source: the in-house elaboration.

Conclusions

The transport of dangerous goods is an industry that is developing very dynamically. Unfortunately, the inability to model routes with hazardous loads becomes dangerous for the environment we live in. The use of IT tools, RFID technology, computer simulation systems and combining them into a single system will create a new tool to assist in tracking hazardous loads. Centralised routing would increase safety for traffic participants and the driver would be able to complete the task.

Preventive Measures to Increase the Safety of The Logistics Operations of a Production Enterprise

Małgorzata OZIĘBŁO

Military University of Technology, Warsaw, Poland
e-mail: malgorzata.ozieblo@wat.edu.pl

Abstract

The article presents one of the functioning production companies in which the analysis and assessment of the safety of logistic activities was conducted. The main part of the study are preventive actions increasing the safety of logistic activity in this entity. The final part presents the results of the research conducted. The summary refers to the degree of achievement of the agreed objective and draws conclusions.

Keywords: safety, logistics activity of an enterprise

Introduction

The main reason for developing the topic of the article is the author's interest in management of safety of logistics systems.

The objective set by the author of the article is to emphasize the role of preventive actions in increasing the safety of logistics activity in production enterprises.

The research problem was formulated as the question: What actions should be given special attention to increase the safety of a logistics activity of an enterprise?

Research hypothesis adopted: The lack of appropriate preventive measures in the logistics activity of the production enterprise is associated with a decrease in the level of safety, which directly transforms into a reduction in competitiveness by the examined entity.

The subject of the research is the analysis of the level of logistics safety and the assessment of effectiveness to manage logistics processes in the examined entity.

The examined entity is one of the operating business entities, in which the main field of activity is production.

The scope of the location covered the area of Poland.
The time span was from 2015 to 2019.
The research methods and the tools used in the article are: literature analysis, indicator analysis, 5-stage analysis.

Sources used in the content of the article are domestic and foreign literature and data obtained from the owner of the analyzed production enterprise.

Safety in theory

Safety is the interdisciplinary term. It is a very broad concept in terms of meaning and definitions. Safety issue has a multidisciplinary dimension. The safety term is referred to by many sciences, e.g. politics, economics, finance, ecology, political science, international relations, international law, culture. The diversity and definition of safety indicates the absoluteness when is studied from a scientific point of view.

In the context of logistics, given the size of the entity as a basis for division, the scope of safety can be categorised as:

- personal safety - the scope of individual safety e.g. recipient, customer, consumer;
- microeconomic safety - the scope of microeconomic safety e.g. businesses, farms;
- macroeconomic safety - the scope of state safety e.g. products, economy condition, unemployment;
- safety of local economy - the scope of local safety, e.g. safety of municipalities, safety of cities.

The field of interest in case of safety related to logistics is very broad. The number of areas of safety concerns contributes to this fact. Given the essence of logistics, which ensures the usefulness of place and time, safety can involve a variety of processes and actors. According to A. Szymonik, such an approach makes it possible to divide safety into three groups according to (Table 1): field of interest, relationship with the field of activity, the domain in which safety occurs.

Table 1: Safety categorisation taking into account the essence of logistics

GROUP	SUB-GROUP	EXAMPLES
FIELD OF INTEREST	Global safety	• global supply chains
	International safety	• international logistics networks
	National security	• military logistics
	Local safety	• urban logistics • hospital logistics
RELATIONSHIP TO THE FIELD OF ACTIVITY	External safety	• supplier market • customer market
	Internal safety	• manufacturing processes • warehousing processes • transportation processes • customer service processes
DOMAIN OF SAFETY	Industrial safety	• logistics of enterprises
	Economic safety	• logistics of business systems
	Environmental safety	• recycling logistics
	Security of energy supply	• gas supply system • energy supply system • water supply system
	Security of IT systems	• IT systems • Internet • Intranet • traceability in the supply chain • upstream
	Structural safety	• links in the supply chain
	Personal safety	• recipient • customer • consumer

Source: (Szymonik 2014, p. 594)

Safety in logistics is a specific feature that gives the enterprise a competitive advantage on the market, because enterprises that care about guaranteeing the safety of their products and services are highly valued by customers. According to I. Horzel, this is "the multidimensional phenomenon, relating to entities, tangible and intangible goods and processes, according to this definition, indicates the need to ensure the usefulness of place, time and condition" (Horzela 2018, Jałowiec 2018, p.232).

According to A. Szymonik, the safety of logistics is a theory and a practice that ensures the flow of material streams and accompanying information for the benefit of the safety entity, primarily by taking advantage of opportunities, taking up challenges, reducing risks and preventing and counteracting various types of threats to logistics activities (Szymonik 2016, p.14)

According to M. Pawlisiak, "(...) Every time the key to ensuring logistics safety is a person. He is the animator of all activities related to ensuring his own flow of supply of goods and services enabling continuity and rhythm of functioning. The quality of the logistics system depends on the work of a single employee, regardless of his or her position." (Pawlisiak 2016, p.54)

When considering safety, the approach of enterprise to occupational safety management cannot be overlooked. According to Karczewski and Karczewska, the modern approach in this respect is to build the image of enterprise based on the following points (Karczewski, Karczewska 2012; Bąk, Kapusta 2015, p.15):

- safety is an investment (economic approach);
- a key safety objective - prevention first and foremost;
- safety is an integral part of daily business management (system approach);
- the system is supposed to help, not interfere with everyday operation;
- without a correct and complete professional risk assessment there is no effective and at the same time efficient occupational safety management;
- all employees are responsible for safety of work;
- safety culture is the key to success.

Identification of the logistics system of the production enterprise X

The safety state is not stable and is not a good given once and for all. All activities in the logistics systems of enterprises should be oriented towards any changes in the environment, both internal and external, and managers should also take care of the possibility of cooperation with other entities as part of safety.

The tasks carried out in an enterprise's logistics system determine its logistics needs, which include:

- demand forecasting;
- production planning;
- purchases;
- movement and transportation of goods;
- warehousing and storage;
- industrial packaging;
- controlling the inventories;
- customer service at the appropriate level;
- waste collection and disposal.

When analysing the safety management activities in the logistics system of the examined enterprise, it can be seen that they are related to the safety of all its subsystems and the relations and links between them.

The assessment of the activity of the enterprise logistics system is carried out, among others, within the framework of logistics controlling, by using both short-term and long-term tools (S. Bartosiewicz, 2017, p. 52).

J. Pionta and T. Chenskowsky distinguished the following functions of the indicator system in logistics controlling (Pionek, Chenskowsky 2007, p.212-213; Dobroszek 2011, p.60-61):

- optimisation function - with the help of logistical indicators, you can measure and optimise the performance of your logistics activities, your logistical objectives and assess whether your objectives have been achieved;
- steering, controlling function - the system of indicators is closely linked to the management system (managing, planning, steering and controlling processes);
- information function - a system of indicators can positively influence the quality of the information provided and provides necessary information for current management;
- coordination function - allows, through a selected system of indicators, to combine many decentralised logistics areas into one whole and to indicate the relationships between them and other areas of economic activity;
- cognitive, decision-making function - the use of indicators makes it possible to get to know the current situation, identify the strengths and weaknesses of the logistics activity and, on this basis, make further decisions that would enhance and improve the current situation and activity of the entire enterprise. This function also allows for the analysis of deviations between planned and actual reports, for their assessment and for making appropriate decisions in this respect;
- responsibility function - a system of indicators used to steer and control specific fields of logistic activity, which also allows for the assessment of persons responsible for the fields analyzed and results obtained.

The system of logistics indicators plays an important role in assessing the proper functioning of this enterprise. If there is a conflict between the logistics objectives, they can be used to assess opportunities, risks and to identify possible deviations in a short time. The system of logistics indicators also makes it possible to initially detect weaknesses in logistics operations and, on this basis, to adjust and implement improvement measures. “Furthermore, the system of indicators, compared to other logistical controlling instruments, is easy to apply and allows the most important aspects of logistical activities to be presented in a short time” (Dobroszek 2011, p.61). When assessing the logistics system, its identification and analysis of its activities should be carried out and, on this basis, procedures for its assessment should be proposed.

Analysis and evaluation of the enterprise logistics system by using the indicator method

The small production enterprise X was analysed. It is a legally and economically separate business unit operating on its own account, producing reusable bags and rucksacks in order to achieve material benefits by satisfying customers' needs. The owner's intention is to achieve a high level of productivity and development, and a low level of the own enterprise costs. The enterprise has no extensive departments. In the examined enterprise, a great deal of emphasis is placed on:

- development of enterprise,
- identification of employees with the enterprise activities,
- planning the production,
- executing the production,
- controlling the production.

The whole activity of the production enterprise can be divided into four spheres of activity:

- the sphere of supplying;
- the sphere of production;

- the sphere of sales;
- the sphere of management.

Each of them constitutes one separate centre of responsibility. The spheres of supplying, production and sales function as result centres. Organisational units performing management functions have the form of cost centres.

The production department is supervised by the production manager, who receives directly from the owner of the enterprise guidelines on the models and quantities to be produced at a given time.

The owner of the enterprise was asked to take part in the evaluation of the functions of the indicator system used in logistics controlling, on a five-point scale. It includes five quality levels, in which:

- score 5 - means very good performance of the function being evaluated
- score 4 - means good performance of the function being evaluated,
- score 3 - means sufficient performance of the function being evaluated,
- score 2 - means insufficient performance of the function under assessment,
- score 1 - means poor performance of the function under assessment.

Table 2: Evaluation of the function of the indicator system in the logistics controlling according to the owner of the analyzed production enterprise

No.	Functions analyzed	Scores	Severity coefficient	Assessment
1	optimisation function	4	0.20	0.80
2	steering, controlling function	4	0.20	0.60
3	information function	5	0.15	0.75
4	coordination function	4	0.15	0.60
5	cognitive, decision-making function	5	0.15	0.75
6	responsibilities	4	0.15	0.60
Total			**1**	**4.1**

Source: own study

The resulting score was good. The owner of the analyzed enterprise rated the optimization function highest.

The conclusions of the study:

- in the enterprise, particular attention is paid in the first instance to the performance of the logistics activity and the assessment of the achievement of the objectives set;
- the owner pays equal attention to the quality of information provided for management purposes, as well as to the improvement of logistics activity and verification of any deviations;
- thirdly, the owner focuses on the steering, controlling function, even though he has previously stated that the production planning, production execution and production controlling are particularly important in the enterprise. It treats this function on an equal footing with the coordination function and the responsibility function, which makes it possible to assess those responsible for the fields analyzed and results obtained.

The assessment of the safety level of logistics activity was made on the basis of an analysis of five logistic indicators, which the author of the article considered the most important in the context of this assessment.

Table 3: The value of logistics indicators in a enterprise X in the years 2015-2019

Type of indicators	2015	2016	2017	2018	2019
COVERAGE INDICATOR [days]	27	27	28	28	28
NON-REVOLVING INVENTORY INDICATOR [%]	-	15.87	16.15	16.19	16.42
DELIVERY TIMELINESS INDICATOR [%]	87.64	86.57	92.24	90.54	88.13
ORDER FULFILMENT INDICATOR [%]	95.8	94.5	94.6	94.7	95.0
COMPLAINT INDICATOR [%]	3.75	3.27	2.14	2.17	2.13

Source: the in-house elaboration.

The coverage indicator (CovI), determines how much a given inventory item is sufficient for average daily consumption. This indicator can be calculated by using the formula:

$$CovI = \frac{\text{average inventories within the period studied}}{\text{sales within the period studied}} \times \text{number of days in the period studied} \quad [1]$$

This indicator stayed at 27 days between 2015 and 2016 and at 28 days between 2017 and 2019. It's not the positive phenomenon. This could have been influenced, for example, by the fall in GDP (gross domestic product) dynamics in Poland, with simultaneous optimistic forecasts for the growth of this indicator. Entrepreneurs often see the expected increase in inflation as an incentive to increase inventories in order to later sell products at higher prices.

Non-revolving inventory (NRII) is the part of the inventories that are not regularly used for sale. This inventories are intended to be the safety inventories. However, in practice, it often turns out that only a certain part of it is the safety inventory, which is necessary to maintain the assumed level of customer service, and the rest is excessive inventory, the maintenance of which is unjustified and brings only costs, mainly variable costs of inventory maintenance, and besides that it does not bring any value to the whole process. Each non-revolving goods are a cost in the form of unsold goods and occupied space in the warehouse. The lower the inventory indicator, the better the inventory utilisation and the warehouse generates less losses. This indicator is calculated according to the following formula:

$$NRII = \frac{\text{non-revolving inventory value within the period studied}}{\text{total inventory value within the period studied}} \times 100\% \quad [2]$$

In the studied enterprise in the years 2015-2019, this indicator remained at the level of about 16%. This shows that 4/25 of the finished products in the inventories of the enterprise were not sold. This shows the inefficiency of production planning processes with regard to reducing costs frozen in inventories. The owner should pay more attention to this indicator and monitor it periodically.

The delivery timeliness indicator (DTI) is calculated according to the formula:

$$DTI = \frac{\text{number of deliveries made on time within the period studied}}{\text{the sum of deliveries within the period studied}} \times 100\% \quad [3]$$

The delivery timeless indicator within the period studied was 89% on average. The business owner should answer the question: How to improve the timeliness of deliveries? Maybe the supply chain

should be reorganised. The competitiveness of companies increases every day. Customers want to receive delivery well, cheaply and on time.

The order fulfilment indicator (OCI) is very important. In the case of low value of this indicator, the business owner knows that there is insufficient inventories in the enterprise, and this may result in the loss of dissatisfied customers who will leave to another competing enterprise.

$$OCI = \frac{\text{number of order units delivered to customers within the period studied}}{\text{number of order units within the period studied}} \times 100\% \quad [4]$$

This indicator was around 95% during the period studied in the manufacturing enterprise, i.e. inventories in the enterprise are sufficient.

The complaint indicator (ComI) indicates how many of the total orders have not been fulfilled as expected by the customers, and which enterprise received the complaint. This indicator should be as low as possible. The high level of this indicator indicates the number of defective goods and the unreliability of employees. This indicator covers quantitative and/or qualitative complaints, but does not take into account price complaints. This indicator is calculated according to the following formula:

$$ComI = \frac{\text{number of complained orders in the period studied}}{\text{number of orders picked up by customers within the period studied}} \times 100\% \quad [5]$$

The complaint rate decreased from 3.75% in 2015 to 2.13% in 2019. It can be stated that in the analyzed enterprise the goods are taken care of. However, it should be noted that this indicator in 2017-2019 was comparable to 2017 - 2.14%, 2018 - 2.17%, 2019 - 2.13%.

Analyzing the last three indicators (the delivery timeliness indicator, the order fulfilment indicator, the complaint indicator), it can be concluded that in the analyzed production enterprise there is a relatively high efficiency of logistics process management in the field of transportation and order fulfilment.

Summary

The conducted indicator analysis of the security level of logistics activity of a manufacturing enterprise X is the example of using quantitative data to evaluate it.

The enterprise belongs to the group of economic entities whose main objective is to continuously improve the quality of manufactured products and productivity.

On the basis of the conducted in-house research, the following final conclusions were drawn:

1. The owner conducts control of individual departments only on the basis of the results obtained from the analysis of the value of quantitative parameters, while he does not conduct control based on indicator analysis:
   - in the first instance the business owner pays particular attention to the performance of the logistics activity and the assessment of the achievement of the objectives set;
   - secondarily, his attention is paid to the quality of the information provided for management purposes and the improvement of logistics activity and verification of any deviations;
   - only in the third place he focusses his attention on the controlling/steering function, despite the fact that he had previously declared a particular emphasis on production planning, production execution and production controlling, treating this function on an equal footing with the functions of: coordination and responsibility, which allows for the assessment of persons responsible for individual areas of activity and the results obtained.

2. In a production enterprise, it is the safety management of its logistic activity and employees (process participants), who should maximize the limitation of any threats that might disturb them, influence the continuity of the realized logistic processes.
3. In future, the owner of the analyzed production enterprise X should in practice focus more attention on the steering/controlling function of the logistics system processes.
4. The assessment of the security level of logistics activity in production enterprise X was made on the basis of the value of five logistic indicators, which the author of the article considered to be the most important in the context of this assessment: coverage indicator, non-revolving inventory indicator, delivery timeliness indicator, order fulfilment indicator, and complaint indicator.
   In the analyzed five-year period of operation of this enterprise (years 2015 - 2019) there is a relatively high efficiency of management of logistics processes in the area of transportation and order fulfilment, but in the near future the owner of this enterprise should pay more attention to controlling the supplying and production subsystems.

Product Life Cycle in Relation to The Issue of Recycling and Reuse of Waste from The Manufacture of Airbags

Tomasz STACHOWIAK

Częstochowa University of Technology, Faculty of Mechanical Engineering and Computer Science, Polymer Processing Department, Częstochowa 42-200, ul. J.H. Dąbrowskiego 69, Poland, stachowiak@ipp.pcz.pl

Abstract

The article presents the analysis of the life cycle of the product obtained from the automotive industry as well as the process of its recycling in order to manufacture the secondary raw material. The analyzed example is the reprocessing and management of waste from materials used for the manufacture of airbags and airbags themselves which have not positively passed the quality control. The conducted research was to analyze the state of this branch of industry and determine the impact of recycling on the processability of regranulates and thus the ability to manufacture new products and the effect on their selected properties. The scope of the study included the determination of technological factors (Melt Mass Flow Rate (MFR) and Melt Volume Flow Rate (MVR)) and the impact of impurities and the regranulation process on these indicators. The conducted analysis indicated significant changes in the value of the key indices responsible for the correct processing and thus the need to adapt the technological process to the properties of the material as well as the need to verify the properties of the regranulate itself.

Keywords: Polymers, Recycling, Product Life Cycle, Melt Flow Rate

Introduction

At present, 360 million tons of thermoplastics are manufactured and processed all over the world every year. These figures relate only and exclusively to the use of the so-called original materials which have not been processed yet (Fig. 1).

Fig. 1: The global and European market of the plastic processing [31]

Thera are many times more plastics traded in the so-called secondary market. It should also be pinpointed that a significant amount of worn plastic parts and polymeric waste is stored (the most often at the landfill) and is not managed in any way thus contributing to the destruction of the natural environment [48,49,50, 51].

In recent years, more and more activities have been undertaken on an international scale to increase the awareness of consumers and processors in terms of segregation of waste, recycling and reuse of polymeric materials which have already been possessed. In recent years (the research conducted since 2006), in the area of the EU, recycling and reuse of plastics have doubled (Fig. 2) [46].

Fig. 2: An increase in the significance of recycling in recent years [31]

However, this is still not enough. Subsequent steps include new industries. This also applies to the automotive industry and the possibilities of managing the production waste of the industry. It is a difficult challenge due to polymeric materials used in this industry, which often, in addition to their very good mechanical and thermal properties (hampering reprocessing), contain a number of excipients and fillers (glass fibers, carbon fibers) which additionally hinder recycling. The companies dealing with recycling on a large scale are often reluctant to reach for technical materials obtained from the automotive industry. The reprocessing of these materials frequently requires specific machinery and equipment but also relevant knowledge and the so-called “know-how” [47, 52]. The objective of the conducted research was to determine the product life cycle in relation to airbags placed in motor vehicles and waste generated in the process of their manufacture as well as the possibilities of managing this waste. Moreover, the aim of the conducted research was to determine technological indicators, such as Melt Mass Flow Rate (MFR) and Melt Volume Flow Rate (MVR) resulting from the process of the reprocessing of regranulates and the impact of impurities (polypropylene, silicone) on these indices.

Literature Review

Fig. 3: The diagram of the circular economy [31]

The current legislation and European directives are to introduce sustainable economy and circular economy where the manufactured goods (mostly products made of plastics) will not get to the landfill but will be reused (Fig. 3). One of the possibilities is still energy recovery (in many cases, it becomes the only alternative for storage; where the polymeric material is not suitable for reprocessing or is excessively degraded, this solution is also used in the case of dangerous polymers or the ones containing compounds hazardous for the natural environment).

Fig. 4: The diagram of the process of the collection of waste and its reuse in the recycling process [31]

In Figure 4, the diagram of waste management is presented. Nowadays, the aspirations of the EU and international organizations are to make the stream of waste for storage and energy recovery as small as possible with a clear focus to significantly reduce (of these two) the storage of plastic waste at landfills [48,49, 52].

Level of circularity / Application sector	Resource Efficiency						Impact on marine litter	Life time of products
	Material Efficiency	Energy Efficiency	CO_2 Reduction	Recyclability	Durability	Bio-degradability		
Packed goods	✓✓✓	✓✓✓	✓✓✓	✓	✓	✓	High	Short/ Medium
Building & Construction	✓✓	✓✓✓	✓✓✓	✓	✓✓✓		Very low	Very long
Automotive	✓✓	✓✓✓	✓✓✓	✓	✓✓		Low	Long

Fig. 5: The goods manufactured, taking into account the sectors of the economy and the product life cycle [31]

Products, semi-finished products and waste from the automotive industry are mostly characterized by the use of high-quality plastic, with very good mechanical, thermal and utility properties (Fig. 5). These materials are also characterized by a high content of mineral or fibrous fillers additionally modifying their properties. From the point of view of the final customer, these actions affect the quality and the manner and length of their use. On the other hand, from the point of view of their reuse, they are often the factors hampering recycling and leading to an increase in energy and economic input [53].

For many years, as mentioned in the introduction above, some works aimed at better use of waste polymeric materials have been carried out. The automotive industry is also inclined towards the introduction of technological solutions enabling reuse of polymers. In the studies [1-32, 39,42, 43], the authors mainly focus on the mechanical recycling of highly filled plastics from the group of polyamides [40] (the main substances modifying mechanical properties are glass fibers and just in terms of those the studies are being prepared and the research is being conducted; the use of glass fibers is connected primarily with their price and availability and the conducted research is to determine the impact of the recycling and shortening of glass fibers and polymer chains on the properties of the material itself and the finished product). Sólya J., Miskolczi N. [33] analyzed the impact of reprocessing on the properties of reinforced and non-reinforced polyamide while considering the issues of energy recovery. In addition, the subject of the analysis was also the amount of CO2 and NOx generated in the case of subjecting airbags to the process of utilization. The authors also focused on the issues of the consumption of energy and water during the production of the polymer itself as well as in relation to its reprocessing. Singh R., Kumar R., Ranjan N., Penna R., Fraternali F., in the work entitled "On the recyclability of polyamide for sustainable composite structures in civil engineering, Composite Structures", conducted the analysis of changes in mass melt flow index of the non-filled polyamide 6, subjected to the multiple processing process in relation to the possibility of its reuse in civil engineering. Similar research was carried out by Hassan M.M., Badway N.A., Gamal A.M., Elnaggar M.Y., Hegazy E.A. [37,38] and they analyzed the impact of the addition of shredded elastomers on the properties of the reprocessed polyamides. In this case, the filler was intentionally introduced into the polymer. The changes in the properties of the polyamide 6 contaminated with polypropylene was analyzed, among others, by Ghasemi H., Mirzadeh A., Bates P.J., Kamal M.R., in the publication entitled "Characterization of recycled polyamide 6: Effect of polypropylene and inorganic contaminants on mechanical properties". The authors focused on the effect of impurities on the mechanical properties of the obtained standardized moldings made of PA 6 contaminated with polypropylene and other inorganic impurities. The conducted research focused on impurities and fibrous fillers and their impact on selected mechanical properties. In the selected studies, the authors analyzed rheological properties or melt flow rate itself, however, there is no clear indication of the impact of these factors on the processability and technological nature of reuse of polyamide regranulates [53-56].

The issue discussed is to determine the impact of impurities in the form of silicones and interlayer foils on selected rheological and technological properties in relation to the product life cycle and the general possibility of reuse of the polymeric waste of this type. The works of this type have not been carried out so far and the issue of the effect of impurities on technological indicators have not been discussed. The literature review revealed that technological references in the process of recycling thermoplastic polymeric materials are marginalized and they are to determine the possibility of reuse of the material

and allow its classification in the appropriate processing technology. There are currently no studies clearly indicating how different types of impurities affect technological properties and thus the processability of selected material groups, which is crucial from the utilitarian point of view.

The analysis of the process of receiving waste and reprocessing materials from the automotive industry

Research Methodology

The objective of the conducted study was to determine the manner of reuse of airbags being a piece of equipment of all passenger cars and trucks moving on the roads all around the world as well as the waste from their production in terms of the product life cycle and the issue of recycling and the possibility of their reuse. The conducted research consisted in the determination of the stream of the waste flow and the possibility of its reuse. The process took into account the identification of the type of the processed polymeric material and possible impurities (in that case it was polypropylene interlayer foils and the silicone layer). The conducted study also indicates the possibility of changing the way of thinking and the course of conduct with the waste received (eliminating the need for the storage of waste of this type or its combustion for energy recovery). Another stage of the research was to carry out the process of recycling of the waste received and to manufacture high-quality regranulates which could be reused. The regranulates acquired were subjected to the analysis of their technological properties in relation to the pure material containing no impurities. The measurements of technological indicators were made using the plastometer Zwick. There were estimated: Melt Mass Flow Rate (MFR) and Melt Volume Flow Rate (MVR) for three types of materials: pure polyamide, polyamide contaminated with polypropylene and polyamide contaminated with silicone.

Fig. 6: Waste acquisition diagram (Own study)

The analysis of the stream of the material flow and waste acquisition

The presented case study is based on the process of reprocessing and reuse of production waste from the manufacture of airbags (waste received after the completion of the cutting process as well as finished products which do not meet the quality requirements, after removal of pyrotechnic charges, are subjected to reprocessing).

The input material for the process of airbag manufacture is mainly two groups of polymeric materials, i.e. polyamide (PA) and poly (ethylene terephthalate) (PET). These materials, in the form of fabric, are provided in bales, which are placed on the laser tables (in order to increase performance, many layers are often cut in this process; the number of layers depends on the type of material, its thickness, type of the applied interlayer foil or other type of coating, e.g. silicone and the power of the laser itself). For the purposes of the optimization of the cutting process, specialized software is used, which allows maximum use of the fabric surface (as little waste as possible – the reason is the costs and difficulties associated with transport, reprocessing and waste management and, obviously, the price of the fabric itself) (Fig. 6) [45].

As already mentioned, the difficulties with management are due to numerous factors, however, the main one is the presence of other polymeric materials in the fabric, these are mostly foils (manufactured from different polymers) as well as protective coatings made of silicone. While the foils can be mechanically separated, the silicone protective coating cannot be removed using mechanical methods (in the case of PET fabrics, there is the possibility of chemical separation and depolymerization of the material to the form of monomers, however, this process is costly and burdensome for the natural environment).

Scraps obtained after the cutting process are transferred as waste to the plant reprocessing this type of materials (the requirement is to possess appropriate machinery and equipment and "know-how" enabling the adequate processing of technical materials with foils or protective coatings).

The solutions in which polyamide fabric/PET fabric is coated with silicone are used to protect the fabric against high temperatures during firing the pyrotechnic charge of the airbag and thus to prevent the possibility of its damage and malfunction. However, the introduction of an additional material in the case of reprocessing gives rise to a number of technological problems and may significantly influence the properties of the finished product. The objective of the article is to determine the impact of undesirable additives (foils, silicone) on the properties of the regranulate itself and the finished product.

The analysis of the process of reprocessing the waste collected

Fig. 7: The diagram of reprocessing the waste collected (Own study)

The advantage of this waste is the fact that it does not need to be subjected to the washing process (its cutting takes place in enclosed spaces using discharging systems for impurities and gases produced during the cutting process). Its transport, both in the company dealing with the manufacture of airbags and transport to the reprocessing plant takes place in containers with no contact with environmental conditions that may affect the properties of the material (temperature, humidity).

The waste collected just after the completion of the process of cutting the fabric for airbags is not suitable for reprocessing. Due to the size of the fraction, it is necessary to use the process of mechanical grinding. Only the material prepared in this manner can be fed to the extruder and reprocessed to obtain regranulates (Fig. 7).

The analysis of technological properties of regranulates manufactured

The subject of the analysis was three types of polymeric materials belonging to the group of polyamides 6.6.
All the analyzed materials come from the reprocessing of technological waste of the airbag manufacture

process. They were the fabrics which the three types of regranulates were made of: pure material (PA 6.6) which, prior to the processing process, polyethylene foil was separated from (polyamide fabric was not coated with silicone), the second group is PA 6.6 regranulates, processed along with polypropylene foil (in the case of these fabrics, the material was also not coated with silicone) and the third group of materials was PA 6.6 regranulates contaminated with silicone (airbag fabric was coated with the silicone layer that was impossible to remove using mechanical methods, in that case, there was no interlayer foil).

The subject of the analysis was three types of materials coming from technological waste acquired in the process of the manufacture of airbags. The stream of material in the form of straps from the technological process (Fig. 8) was divided into three groups: pure material subjected to the process of sorting and physical separation of impurities marked as polyamide 66, the second group was polyamide 66 contaminated with polyethylene (there was no physical separation of the sealing polypropylene foil which polyamide was coated with) and the third group was polyamide 66 coated with silicone which was impossible to remove.

Fig. 8: Division of waste acquired for the research (Own study)

For all the three material groups, the reprocessing scheme was implemented according to the following assumptions. The material in the form of polyamide fabric trimmings was automatically transported to the crushing system (the crushing system is made of a roller equipped with a range of blades allowing the fragmentation of the material fed). Subsequently, the pre-ground material was fed to the compaction system seen in Figure 7. After the concentration, the material was transported to the system plasticizing the single-screw extruders of the STARLINGER company (Fig. 7). The device is equipped with the double degassing zone and the "wet" granulating head (the items of equipment are also visible in the picture). Another step was to dry the regranulate and its packaging. The analyzed regranulates were manufactured in the above technological cycle.

The assessment of the impact of impurities on selected rheological properties and utility properties of the finished product

For the purposes of the assessment of the impact of impurities in the form of unseparated polypropylene foil or a protective silicone coating on the properties of the reprocessed polyamide fabrics, the research into Melt Mass Flow Rate (MFR) and Melt Volume Flow Rate (MVR) was carried out. The measurements allow the assessment of usefulness of technologically acquired regranulates.

In relation to the analysis of the properties of the previously examined regranulates, the analysis of Melt Flow Rate was carried out according to the standard PN-EN ISO 1133 Plastics, Determination of Melt Mass Flow Rate (MFR) and Melt Volume Flow Rate (MVR) of thermoplastics. The plastometer of the ZWICK MFLOW company was used for the purposes of the research.

In order to calculate the indicators received, the following equation was carried out:

$$MFR(T, m_{nom}) = \frac{600m}{t}$$

where : T – test temperature [expressed in degrees Celsius], m_{nom} – nominal load [in kilograms], m – average weight of extruded profiles [in grams], t – cut-off interval [in seconds], 600 – coefficient to convert grams per second to grams per 10 minutes (600 s).

Melt Volume Flow Rate:

$$MVR(T, m_{nom}) = \frac{A600l}{t}$$

where: T – test temperature [expressed in degrees Celsius], m_{nom} – nominal load [in kilograms], A – arithmetic mean of the cross-section of the cylinder and the piston head [in square centimeters], predeterminated measurement time or arithmetic mean of individual time measurements [in seconds], l – predeterminated distance of the piston displacement or arithmetic mean of the results of individual distance measurements [in centimeters].

Before the measurement, all the material groups were properly prepared for the process, each of the materials was subjected to the drying process using the shelf drier SHINI; the drying process lasted for 4 hours and the drying temperature was 80°C. The measurement was carried out at 280°C at nominal load of 5 kg.

The obtained results of measurement of Melt Flow Rate are presented in Table 1.

Table 1. The results of measurement of Melt Mass Flow Rate (MFR) and Melt Volume Flow Rate (MVR) for the materials tested

Polymer tested	MFR [g/10min]	MVR [cm^3/10min]
PA6.6	96.64	91.20
PA6.6 + PP	115.80	110.15
PA6.6 + silicone	46.87	44.60

The obtained results indicate different effects of impurities on the material liquidity received. The uncontaminated polyamide 6.6 regranulate is characterized by a relatively high Melt Flow Rate, which indicates low melt viscosity at elevated temperatures and may affect the manner of filling the form of a mold cavity during the injection process. The Melt Flow Rate of polyamide 6.6 with no impurities was regarded as the reference point; the other results obtained were assessed in relation to this value. This measurement is one of the main factors to assess the technological and processing properties of the plastic. This value is one of the primary indicators and given in the first place (the so-called technical data sheet (TDS)). The value of this indicator and its repeatability determines the quality of production and repeatability of the properties of the finished product. This parameter is critical and affects the processability of the polymer. From the technological point of view, it is determined how fast the polymer flows and it is directly correlated with its viscosity and the manner of filling mold cavities of the injection mold. The changes in its value due to the presence of undesirable substances may affect the properties of the polymer melt, formation of defects in the form of incomplete filling of mold cavities or their overfilling and formation of outflows (both situations are undesirable from the economic point of view and have a negative impact on the condition of the tools used – injection molds). During the determination of Melt Flow Rate, both Melt Mass Flow Rate (MFR) and Melt Volume Flow Rate (MVR) were estimated by calculating both the mass and volume of the polymer flowing through the capillary, received during the measurement, which provided an opportunity for a comprehensive assessment of the behavior of the materials tested and evaluation of the impact of impurities on their further processing.

The determination of Melt Flow Rate is also required in terms of the application of subsequent processing technologies. The excessively significant reduction or increase in the value of this parameter may exclude the regranulate from use (processing technology) and affect the destabilization of the process and formation of defects of molded pieces and reduction in the quality of production.

In the case of the manufacture of regranulates contaminated with polypropylene, the obtained indicator and the viscosity of the polymer undergo further changes. The viscosity of the melt is reduced further.

The opposite effect can be observed in the case of polyamide 6.6 contaminated with silicone, for this material, a significant decline in Melt Flow Rate was obtained and thus an increase in the viscosity of the material tested. A significant reduction in the Melt Flow Rate of polyamide 6.6 contaminated with silicone can be related to the formation of silicone agglomerates impeding the flow of the polymer.

Conclusions

The conducted research indicated that the intentional introduction of impurities in the form of polypropylene and silicone has an impact on selected properties of the acquired regranulate. The introduction of these additives significantly affects the viscosity and thus the processability of the regranulates tested. In the case of adding polypropylene to polyamide, there is a sharp decline in viscosity and an increase in both Melt Mass Flow Rate (MFR) and Melt Volume Flow Rate (MVR). In the case of the polyamide regranulate with silicone, there is a significant increase in viscosity and a double decline in the value of Melt Mass Flow Rate. From the technological point of view, this knowledge enables better control of the process and thus improves the quality of molded pieces obtained from these regranulates.

The obtained results allow for the statement that the plastic reprocessing industry is a growing industry requiring support and greater knowledge in terms of the analysis of the properties of reprocessed polymeric materials. In addition, in view of increasing consumption of polymeric materials but also the amount of waste generated, it is necessary to find an optimal alternative which could relieve the natural environment and, at the same time, lead to reuse of once recycled plastics.

The presented results clearly indicated how the reprocessing of polyamides used for the manufacture of airbags, contaminated with polypropylene or silicone, affects the indicators of processability. The research allowed for the indication of significant changes in the values of Melt Flow Rate and thus the possibilities of processing the regranulates acquired. It seems necessary to search for the solutions which will enable the introduction of materials which are significantly different from the original in the market.

In the context of production management and the product life cycle definition, it is also required to change the approach to the way of management of regranulates required. It becomes impossible to reuse these materials for the manufacture of airbags. The factors affecting this are impurities and changes in basic technological indicators (MFI changes). However, it does not rule out the possibilities of their management since there are many processing technologies and applications using the modified processability of regranulates under consideration in the market.

Further work focuses on determining the impact of technological factors and the processability of the regranulates of polyamide 6.6 contaminated with polypropylene or silicone on thermal and mechanical properties which are directly linked to the properties of the finished product.

Abstract

In order to ensure sustainable socio-economic development of the republic, strengthen the economy, develop the social sphere and identify areas of priority development a Strategy for the Long-Term Socio-Economic Development of the Republic of Mari El until 2030 was developed. The main goal of the development of the Strategy is to identify ways and means to ensure sustainable improvement of the welfare of the residents of the Mari El Republic, the dynamic development of economy of the Republic in the long term. Being one of the fundamental documents of the strategic planning system of the Mari El Republic that defines long-term socio-economic policy, the Strategy is formed on the basis of a bunch of principles analyzed in this work. This study examines the main principles of the Strategy for socio-economic development of the Republic of Mari El for the period until 2030, analyzes the priorities, targets, tasks and areas of socio-economic development of the Republic of Mari El (RME). It considers a set of system decisions of the Government of the RME for the long-term period ensuring that the Republic of Mari El will become one of the most dynamically developing regions of the Volga Federal District in 2020-2030.

Keywords: strategies for socio-economic development of the Mari El Republic for the period until 2030, targets and priorities for socio-economic development, areas of the Strategy implementation, structural diversification of industries.

Introduction

In order to ensure sustainable socio-economic development of the Mari El Republic, strengthen its economy, develop its social sphere and identify areas of priority development a Strategy for the Long-Term Socio-Economic Development of the Mari El Republic was developed.
The Strategy for the Long-Term Socio-Economic Development of the Republic of Mari El defines the targets and development tasks of the Republic of Mari El, the main purpose which is to improve the quality of life and well-being of the population based on sustainable economic growth in the Republic of Mari El.

The key tasks of the socio-economic development of the Republic of Mari El until 2030 are determined by:

1) improving the standard of living of the population;
2) ensuring sustainable economic growth, doubling the gross regional product of the Mari El Republic over a ten-year period, developing a regional investment and innovation system;
3) implementation of priority national projects;
4) creation of conditions for the most effective management of public finances in accordance with the development priorities of the republic.

The strategy implements the main principles of dynamic socio-economic development of the Republic, the most significant of which are:

the principle of effectiveness of strategic planning, which means that the choice of methods of achieving the goals of socio-economic development of the Republic is based on the need to achieve the desired results;

the principle of efficiency, which requires the validity of the choice of strategic goals and mechanisms from the standpoint of minimizing costs;

the principle of realism, which assumes that in determining goals and objectives of socio-economic development we were guided by the possibility of achieving goals and solving tasks in a timely manner, taking into account resource limitations and risks;

the principle of resource provision, which means that when developing and approving strategic planning documents developed as part of planning and programming, the sources of support for the development are identified;

the principle of measurability of goals, which requires an assessment of the goals of socio-economic development of the republic set in the Strategy using quantitative and (or) qualitative targets, criteria and methods for their assessment;

the principle of compliance of indicators with goals that determines that the quantitative and qualitative indicators reflected in the Strategy correspond to the goals of socio-economic development of the republic and the Russian Federation.

Materials and Methods

The object of the study is the Strategy of socio-economic development of the Mari El Republic for the period up to 2030 as the fundamental document of the strategic planning system of the Republic, which determines the long-term socio-economic policy of the region.

The subject of the study is the priorities, targets, tasks and directions of socio-economic development of the Republic of Mari El for the long term period as well as systemic solutions designed to implement the target indicators of the developed Strategy.

Despite a large number of translated monographs and publications on the theory of strategic planning and management of regional economy a lack of uniformity in the explanation of the same terms is observed, which leads to the complexity and inaccessibility of their use, vagueness and ambiguity which creates a distorted semantic meaning. When developing strategies an unsystematic automatic listing of all the basic approaches and techniques used in foreign practice is often observed [7]. This

situation is explained by the complexity of perception and adaptation of control methods. The effective functioning of Russian regional economies, the smoothing out of excessive territorial imbalances in the level of their socio-economic and balanced development are becoming priority aspects of Russian economy modernization and its sustainable growth. Strategic planning is a tool by which a system of goals for the functioning of the economic system is formed, approaches to achieve specified performance indicators are determined and the efforts of all management entities are combined. The main goal of planning is primarily to provide optimal opportunities for efficient business activity, profitability, competitiveness, as well as control and operational management of financial resources. Strategic planning simultaneously solves proactive (anticipatory) and reactive (adaptive) tasks. The main methodological instruments of the theory of strategic planning were developed in the works by F. Abram, I. Ansoff, M. Porter, G. Hamel, R. Kaplan and D. Norton, G. Steiner, A. Thompson, V.N. Burkov, V A. Irikov, B.Z. Milner, S.P. Nikanorov and others.

The analysis of regional development and regional economy is widely reflected in domestic science in the works by L.I. Abalkin, V.L. Baburin and E.M. Bukhwald, L.B. Vardomsky, O.V. Kuznetsova, V.I.Suslov, A.N. Shvetsov, V.E. Shuvalov, etc.

Practical research of state and municipal strategic planning in the Russian Federation is carried out by such scientists as S.L. Baidakov, M.E.Dmitriev, I.N. Ilyina, I.A. Nikolayev, O.O. Smirnova, etc.

The methodological basis is the methods of working with statistical information (economic and statistical analysis, comparative analysis), legal analysis, forecasting, scenario method, system analysis as well as quantitative and qualitative methods, including text analysis.

Research Results and Discussion

The analysis of socio-economic development of the Mari El Republic allows to single out a number of regional strengths, threats and opportunities that can be effectively used for the progressive social and economic development of the Republic on the basis of which the authors conducted a SWAT analysis and built a matrix, Table .1.*

Table 1: The Matrix of the SWAT analysis of the assessment of socio-economic development of the Republic of Mari El in the long term period

Strengths	Weaknesses
Favorable economic and geographical position; Rich historical and cultural heritage; Rich recreational resources (ethnographic, ecological and rural tourism); Favorable environmental situation which allows environmentally friendly products release; High scientific, technical and personnel potential; The diversified nature of the industrial complex, which has a number of high technologies; Open economy to investment and innovation	Llimited raw material resources of the region; Available mineral resources are not fully utilized; Uneven spatial development of the Region; Significant differences in the socio-economic development of municipalities; Significant differentiation of the average monthly wage of workers in municipalities; Differentiation of municipalities for economic development; Unequal increment (accumulation) of the existing resources in both quantitative and qualitative terms
Opportunities	**Threats**
Doubling the gross regional product (GRP) of the Republic of Mari El over a ten-year period; Improving the standard of living of the population; Ensuring sustainable economic growth; Development of a regional investment and innovation system; Implementation of priority national projects (14); Creating conditions for the most effective management of public finances in accordance with the development priorities of the Republic	The deterioration of the demographic situation; Natural population decline; Aging of the population and growing burden on the able-bodied population; The presence of strong neighboring competing regions; Migration loss of population; Low level of average monthly wages of employees and average cash income per capita; Insufficient pace of development of high-tech industries;

	Problems in scaling up the introduction of innovations in business processes aimed at improving the competitiveness of enterprises; Lack of qualified personnel with a high level of knowledge, skills and mastery meeting the demands of the innovative development of the economy.

* Developed by the authors.

The weaknesses and threats to the long-term socio-economic development of the Republic of Mari El limit the opportunities for economic growth and social development of the Republic, nevertheless, they are not insurmountable obstacles to achieving the goals set in the Strategy.

Based on the results of the analysis of the competitive advantages of the Mari El Republic, long-term development trends of Russian and the world economies the mission, priorities, goals and objectives of the socio-economic development of the Mari El Republic until 2030 are determined.

The main strategic goal is the development of human capital as a condition for the formation of a dynamically developing region of the Russian Federation with comfortable conditions and high quality of life.

The main tasks of socio-economic development of the Mari El Republic in the long run are:

ensuring a high standard of living for the population of the Republic, the availability of quality education, health care, culture, sports, personal security infrastructure development; improving economy of the Republic through the development of an innovative economy open to new technologies; creation of conditions for investments and development of entrepreneurship; a balanced system of public, private and public-private institutions ensures the sustainable development of small and medium-sized businesses; ensuring balanced spatial development of the Republic; the effectiveness of the system of state and municipal administration; realization of the natural potential of the Republic; ensuring environmental safety and security of the life of the population.

The choice of strategic priorities is based on highlighting the key factors of sustainable economic growth and transformations in the social sphere which should cause the development of various types of activities, raising the living standards of the population of the Republic.

A list of the main areas of strategic development of the Mari El Republic until 2030 is defined:

1. Health.
2. Education.
3. Mortgages and rental housing.
4. Housing and public utilities and urban environment.
5. International cooperation and export.
6. Labor productivity.
7. Small business and support of individual entrepreneurial initiative.
8. Reform of control and supervisory activities.
9. Safe and quality roads.
10. Ecology.
11. Agro-industrial complex and agriculture.
12. Tourism.

The choice of priorities determine the main goals and objectives of the strategic development of the Republic of Mari El which are presented in Table 2.

Table 2 : Strategic goals and objectives of the development of the Republic of Mari El

Strategic goal	Strategic objective
The development of human capital	Demographic development; Educational development; Health system development; Culture and media development; The development of physical education and sports; Development of labor market and employment; Improving the standard of living of the population; Modernization of social services; Improving the system of social support for the population; Improving the availability and quality of provided state and municipal services; Creating a comfortable living environment; Providing affordable and comfortable housing to the population of the Republic; Ensuring a guaranteed level of protection of the population and territories from emergency situations within the limits of acceptable risk indicators;
Development of structural diversification of priority sectors of economy	Development of priority manufacturing industries; Development of the agro-industrial complex; Consumer market development; Service sector development;
Victory in the competition for the investor	Formation of a favorable investment climate; Development of public-private partnerships;
Development of small and medium enterprises	Improving the competitiveness of small and medium enterprises;
Infrastructure development	Development of transport infrastructure; Development of telecommunication infrastructure (industry); Development of energy infrastructure and increase in energy efficiency;
Development of tourist and recreational system of the Republic	Effective use of historical and cultural resources; Formation of the system of recreational, sports and entertainment zones on the basis of natural and recreational potential of the Republic;
Development of interregional and foreign economic relations	The development of foreign trade and international relations, ensuring the supply and demand of local producers and the needs of residents of the region;
Financial Development	Ensuring high efficiency of the financial system

The implementation of the Strategy is aimed at maintaining and improving the achieved positions by the main macroeconomic indicators in comparison with other regions of the Volga Federal District. As a result of the implementation of the Strategy it is supposed to improve the quality of the life of the population and the structure of economy.

The implementation of the Strategy of socio-economic development of the Mari El Republic until 2030 will allow the Rrepublic to accelerate socio-economic development, create new industries and modernize existing ones, increase the competitiveness of economy and the standard of living of the population.

It is expected that in 2030 the volume of gross regional product of the Republic will increase 2.2 times (1.2 times in comparable prices) by 2015.

The main indicators of the results of the implementation of the Strategy are presented in Table 3.

Table 3: Indicators of the results of the implementation of the Strategy of socio-economic development of the Republic of Mari El until 2030

Indicators	Indicator values		
	2016	2020	2030
1	2	3	4
Goal 1. "Development of human capital"			
The average annual population, thousand people	685,3	680,0	667,0
Birth rate	13,9	13,8	12,3
Total birth rate	1,980	1,88	1,88
Life expectancy at birth, years	70,8	73,4	74,6
Mortality from all causes (per 1000 population), people	13,2	13,2	12,6
Mortality rate for working age population, per 100 thousand people of working age	589,3	580,0	560,0
Dynamics of real cash incomes of the population (cumulative in relation to 2011), in%	107,6	113,2	140,1
Growth rate of real average monthly wage compared to 2011, in%	111,7	119,0	141,8
The population with cash incomes below the cost of living, in% of the total population	23,2*	21,0	16,2
Unemployment rate (according to the methodology of the International Labor Organization), in%	6,0	5,8	5,4
The number of pupils of preschool educational institutions, people	38269	38308	38628
The number of students in secondary schools, people	72667	82800	96226
The number of students in vocational educational institutions, people	13576	13851	14121
The share of employed population aged 25 to 65 years, trained in the continuing education programs and (or) the professional retraining programs, in the total number of people of this age group employed in the economic sector	39,0	39,0	45,0
The share of culture expenses in the volume of expenses of the consolidated budget of the subject of the Russian Federation, in%	4,9	6,0	6,1
Goal 2. “Development of structural diversification of priority sectors of economy”			
Labor productivity index relative to the level of 2011,%	123,1	131,3	165,1
The average annual number of people employed in the economy, thousand people	301,8	297,8	291,5
The number of high-performance jobs, thousands.	58,2	68,7	81,8
The ratio of the number of highly productive jobs to the average annual number of people employed in the economy,%	19,3	23,1	28,1
Volume index of gross regional product,% by 2011	114,5	119,2	147,2
Industrial production index,% of 2011	132,2	142,5	199,6
Agricultural production index,% of 2011	202,2	240,2	304,2
Retail turnover per capita, thousand rubles	114,5	140,5	251,4
Depreciation of fixed assets at the end of the year,%	55,2	55,4	52,0
Goal 3. “Development of an innovative system in the Republic»			
The share of high-tech and knowledge-intensive industries in the gross regional product relative to the level of 2011, in%	109,3	130	160
The volume of shipped innovative products, million rubles	10 323,2	14 500,5	18 900,0
Share of shipped innovative products in gross regional product,%	6,4	5,9	5,1
Goal 4. “Victory in the competition for the investor”			
The volume of investment in fixed assets per one person employed in the economy, thousand rubles	90,1	95,7	178,4
Index of physical volume of investments in fixed assets, in% by 2011	81,2	79,3	112,3

1	2	3	4

The share of households with broadband Internet access, in the total number of households,%	65	67	70

** Preliminary data of the Federal State Statistics Service*

The analysis of indicators of the results of the implementation of the Strategy shows a deterioration in demographic indicators for the long-term 10-year period associated with objective demographic problems of the Russian Federation which coincide with global trends. For the remaining blocks of goals a steady increase in the qualitative and quantitative indicators is predicted, which allows achieving the set goal of increasing the GRP by 2.2 times.

The stages of the Strategy implementation and terms are presented in Table 4.

Table 4: Dates and stages of implementation of the Strategy

Stage name	Time limits	Stage Content
Stage I of the Strategy	2017 - 2020	Implementation of anti-crisis measures, restoration of economic growth rates achieved in 2014 and consolidation of macroeconomic stability in 2020
Stage II of the Strategy	2021 - 2025	Formation of conditions for a new model of economic growth of the region
Stage III of the Strategy	2026 - 2030	Structural diversification of the economy of the Republic, increasing its competitiveness

Taking into consideration the SWAT analysis it seems possible to propose the use of a scenario approach to forecasting socio-economic development of the Rrepublic. It is assumed that it is advisable to use a moderate and innovatively active scenario for the implementation of the Strategy, Table 5.

Table 5: Scenarios for forecasting socio-economic development of the Mari El Republic

Scenario	Content
Moderate	It assumes moderate economic growth under the prevailing trends in the development of Russian economy, restrained investment policy and the dynamics of consumer demand. The implementation of this scenario will help maintain the average annual GRP growth rate of 102% per year, its volume will increase by 1.3 times by 2030.
Innovatively Active	It provides for a higher pace of development of the Republic, intensification of investment and innovation activities of enterprises, reduction of negative consequences associated with geopolitical tensions and creation of conditions for solving strategic planning tasks. It is supposed to change orientation of economy towards an investment development model and growth in consumption expenditures and social obligations of the state and business in the first year. GRP growth by 2030 will amount to about 103.0% per year, investments in fixed assets will increase by an average of 5.0% per year.

The choice of the optimal, balanced scenario for the socio-economic development of the Mari El Republic will be associated with the assessment of the necessary resources for the implementation of the scenarios and budget forecasts.

Conclusion

The implementation of the Strategy requires attraction of significant financial resources. Their sources will be budgetary (federal budget, republican budget, local budgets) and extra-budgetary funds (funds of enterprises-investors, etc.).

It is planned to raise funds from the federal budget for the implementation of the Strategy in accordance with the current procedure for financing state programs of the Russian Federation, federal target programs, the federal targeted investment program, the rules for the provision of budgetary appropriations of the Investment Fund of the Russian Federation within the total budget appropriations approved by the federal budget for the corresponding year.

According to the forecast of the socio-economic development of the Mari El Republic until 2030 at least 170 billion rubles of investment over a ten-year period must be attracted to the region to achieve strategic goals and achieve the planned growth indicators.

The implementation of the Strategy will allow the region to take its rightful place in the Volga Federal District and in the Russian Federation in terms of the quality of life of the population, the development of human capital and the level of socio-economic indicators.

Abstract

The topic of bank mergers and acquisitions is given great attention both in the Russian Federation and abroad. The mergers and acquisitions market is cyclical, unstable, however, it does not lose its relevance. Many large modern banks are the result of completed merger or acquisition transactions.
Currently, in the Russian Federation the topic of bank mergers and acquisitions is very relevant, since in the period of economic instability bank mergers and acquisitions are a survival tool for small and medium-sized banks. The changes that are currently taking place in Russian banking sector create all conditions for bank mergers and acquisitions. The number of credit organizations is decreasing, the number of mergers and acquisitions, which is caused by the need of banks to comply with regulatory requirements, is increasing. One of the most effective ways to increase a bank's capital is through mergers and acquisitions. For small players a merger and acquisition deal can be a lifeline. For large players new opportunities appear for rehabilitating problem banks and acquiring competitors at the lowest possible prices.

Keywords: Banks, Mergers, Acquisitions, Consolidation, Reorganization, M&A Transactions, Bank Of Russia, Financial Sector Of Economy

Introduction

Bank mergers and acquisitions to some extent reflect the state of a country's economy. According to the Bank of Russia`s data of 01.01.2020 the number of operating credit organizations in Russia is 442, including 402 banks , 24 banks had their licenses revoked in 2019, 57 banks - in 2018. The downward trend in commercial banks in the Russian Federation is slowing down but still continues, since in 2016 82 banks had their licenses revoked, in 2017 - 74 banks and in total 575 banks had their licenses revoked since the beginning of 2008. The dynamics of a decrease in the number of banks can be clearly seen in Figure 1, which shows the data of the Central Bank of the Russian Federation on the number of credit organizations (COs) that are eligible for banking operations. The data are shown from 2009 to 2019**.**

Fig. 1: The number of banks in Russia from 2009 to 2019

Source: Compiled by the author based on data from the Bank of Russia.

New banking organizations practically do not open. In recent years, one bank opened in 2019. The reason for this is mainly mergers and acquisitions in the banking sector.

Bank mergers and acquisitions allow credit organizations to open up new opportunities for increasing a bank's overall capitalization and competitiveness, improving the quality of banking services provided, expanding the customer base and reducing financial risks and costs. All this will help banks become more successful and in the future enter the international market.

Materials and Research Methods

The object of the study is bank mergers and acquisitions over the past 10 years from 2009 to 2019.

The subject of the research is Russian practice and foreign experience of bank mergers and acquisitions.

The theoretical basis of the study is the scientific development of Russian practice and foreign experience of bank mergers and acquisitions, problems of transactions of this type and recommendations for solving problems related to bank mergers and acquisitions. The concentration of bank capital is of interest to financiers studying the country's financial system. The phenomenon characteristic of the 20th century i.e. the concentration of banking capital has been studied in many scientific papers. Of great interest to both theorists and practitioners is consolidation of banks and concentration of bank capital in the form of mergers and acquisitions.

The economic model has been studied that describes relationship between an increase in the number of M&A processes in the Russian banking sector and the factors affecting these processes in Russia. When writing this work the scientific works of O.I. Lavrushin, M.A. Eskindaro etc. were used. Mergers and acquisitions, including banking, were studied by such domestic scientists and practitioners as Babenko I.A., Vladimirova I.G., Ignatishin Yu.V., Molotnikov A.E., Smelyansky I.E., Chernova E.G. as well as by such foreign authors as R. Braille, S. Reed, R. Lajou, T. Koch and S. MacDonald, T. Cowland and J. Weston, J. K. Van Horne and others.

The methodological basis was historical and logical, formal and substantive, unit and general approaches, deductive and inductive research methods.

Research Results and Discussion

The modern economy in the XXI century shows rapid dynamics causing adjustments to macroeconomic proportions, industry models that have existed for many years. All new changes relate in part to each industry. The banking sector is considered the most flexible to all changes. It was it which first was affected by all innovations that arose in the external and internal environment. Business financial models are highly dependent on any changes and cannot be inert. The external environment affects the systemic relationships of the banking system and its elements. Since 2008 the classical forms of conducting business have changed significantly throughout the world. For 2014-2019 a trend towards consolidation of the banking sector took place in the Russian Federation.

The causes of this trend are natural within each industry. The interest of banks in consolidation, the presence of state directives aimed at implementing anti-crisis measures and the existing policy of the Bank of Russia in the sphere of consolidation of the banking system contributed to this process. In addition, the market for bank mergers and acquisitions began to develop very actively. The Bank of Russia acts as the main regulator in carrying out this procedure. It receives its powers according to Russian law. The Bank of Russia has the right to establish mandatory standards for credit firms, including the liquidity standards of a credit institution, the adequacy of its own funds and the minimum reserves of a credit company. If a credit institution has completely exhausted its resources, then in order to fulfill the compiled standards it will most likely have to start the process of reorganization (mergers / acquisitions).

At the end of the 20th century an important part of history of mergers of Russian banks is the merger of commercial banking organizations with Rosselkhozbank. In the future mergers and acquisitions in the Russian market were not significant. All of them were carried out within the state and pursued the following goal: increasing influence, scale of action.

In the "Main Directions of the Unified State Monetary and Credit Policy for the Period of 2018–2019", the Central Bank of the Russian Federation makes a forecast that the internal financial conditions "will remain moderately harsh for a long time and the potential for reducing nominal interest rates in the economy will be limited taking into account the Bank's Russian monetary policy. " These factors became the reason for banks beginning reorganization of their own business (caring out M&A transactions).

Since 2014 the market for bank mergers and acquisitions in Russia experiences a crisis. According to the National Rating Agency (NRA), the Russian banking sector in 2016 should show the worst result in the last 10 years in the number of classic M&A transactions (mergers and acquisitions). According to the NRA forecasts, the number of acquisitions carried out using the financial recovery mechanism is similar to one of the previous years. It was planned that the number of transactions of traditional M&A could significantly increase and will increase the demand for the assets of private commercial banking organizations that managed to survive the financial crisis and achieve good results. In addition, market regulation will be tightened. According to the research by the Russian banking market of M&A, the results of which the NRA declared at the conference "Banking Mergers and Acquisitions" in 2005-2014 185 M&A transactions worth $ 17.4 billion were concluded in the Russian market.

Information on transactions in the financial sector (banks and insurance companies) is given in table 1.

Table 1: Information on the value and number of transactions on bank consolidation

Indicators	2014	2015	2016	2017	2018
Total cost, billion dollars	3,8	2,1	1,1	9,1	3,3
Amount of transactions	59	51	44	31	48
Average transaction value, billion dollars	0,064	0,041	0,025	0,045	0,028

** Developed by the authors.*

As our analysis of the industry value of a transaction is limited, it should be noted that it is impossible to take into account all debt portfolio restructuring transactions that are gradually gaining growth

in the Russian banking sector and have become the most popular after 2018. An obvious example of such transactions is the purchase of Financial Corporation by the Central Bank (2017, valued at $ 7.7 billion) and the purchase of Promsvyazbank by Deposit Insurance Agency Group of Companies (2018, for $ 1.967 billion). Both transactions were excluded by us in calculating the average transaction value in the financial sector.

The obtained values may indicate that there is a tendency to reduce the value of a transaction both in the economy as a whole and in the financial industry. This fact can be considered as a positive trend in the Russian market of mergers and acquisitions - a transition to transactions among not so large companies.

An important event in the practice of restructuring is the creation in the second half of 2018 of the Bank of Non-core Assets (BNA), which included various debts and shares of borrowers of large rehabilitated banks. At the moment BNA has received an unprecedented number of troubled assets formed by Otkritie (Discovery), Trust, BIN and ROST banks. The year 2018 was not a year of borrower restructuring but a year of bank restructuring in the context of measures taken by the government to improve the banking sector. An interesting trend from the point of view of M&A in 2018 is that banks increasingly sought to become quasi-shareholders of their borrowers, moreover, the main ones. We also observe that banks, having gained de facto (less often - de jure) control over the business begin, regardless of the will of the shareholder, to seek a buyer for this business - and it is here that we see a strong connection between the debt restructuring market and M&A market.

The largest banking services transactions completed in 2018 are shown in table 2.

Table 2: Largest banking services transactions completed in 2018.

Transaction object	Buyer	Seller	Acquired share, %	Amount of transaction, mln.dol.
«Promsvyazbank»	GC «Deposit Insurance Agency»	Private shareholders	99,9%	1967
«Invest project»	«SAFMAR Financial Investments»	Mikhail Gutseriev, Said Gutseriev	100%	210
«SAFMAR Financial Investments»	Institutional investors	«SAFMAR Financial Investments»»	15%	163
NPF «Blagosostojanie» (Welfare)	«Gazprombank»	RGD (Russian Railways)	50%	160
Nu Pagamento SA (Nubank)	DST Global	Existing shareholders	45,9%	150

The results of 2018 on mergers and acquisitions allow us to draw the following conclusions:

- the total value of transactions amounted to 3.3 billion dollars, which is 64.1% less than in 2017;
- the number of transactions amounted to 48, which is 45.5% more;
- transactions for the purchase of Russian assets amounted to 0.2 billion dollars, which is 40.5% less;
- transactions on the purchase of foreign assets - $ 0.3 billion, which is 1075% more;
- domestic transactions - 2, 8 billion dollars, which is less by 67, 5%.

Thus, the volume of transactions in the market of mergers and acquisitions in the banking sector is significantly reduced, the total share of this market is 6.3%.

In 2018 the value of transactions in monetary terms as a whole across the market decreased by 7% compared to the previous year, amounting to $ 51.7 billion, which is mainly due to the absence of

major transactions during this period. At the same time, the number of transactions increased significantly - from 552 transactions in 2018 to 652 transactions in 2018.

The growth in the amount of transactions compared to the previous year was recorded only in two key sectors of economy - oil and gas (by 96.8%) and consumer sector (by 55.6%). The most significant decrease in the total amount of transactions is observed in the sector of banking services, metallurgy and mining and in the real estate sector.

At the end of 2019 financial institutions with three transactions with a total volume of $ 7.54 billion (17.8% of the total value of TOP-30) were in the second place in the all-Russian ranking of M&A transactions (Table 3).

Table 3: Industry analysis of TOP M&A transactions in 2019

Industries	Volume of transaction, mln.dollars	Share in total volume	Number of transactions	Share in total amount
Fuel and energy complex	11514	27,2%	5	16,7%
Financial institutions	7539,3	17,8%	3	10%
IT	5970	14,1%	4	13,3%
Transport	3468,7	8,2%	6	20%
Communication	2774,4	6,6%	2	6,7%
Trade	2671,2	6,3%	2	6,7%
Sport	2350	5,6%	1	3,3%
Engineering	2242,3	5,3%	2	6,7%
Construction and developmentment	1910,4	4,5%	2	6,7%
Metallurgy	1209	2,9%	1	3,3%
Power industry	332,9	0,8%	1	3,3%
Agriculture	330	0,8%	1	3,3%
Total	42312,2	100%	30	100%

** Developed by the authors.*

The largest transaction of the year in the financial sector and the second largest in a year was the sale by Sberbank of Russia of its subsidiary in Turkey Denizbank to Emirates NBD for $ 5 billion. In addition, a major bank in the industry was reorganized and made it into the top ten largest transactions of the year: in July the Central Bank of Russia, within the framework of the bankruptcy prevention participation plan, acquired a 99.99% stake of Moscow Industrial Bank PJSC for $ 2.03 billion. On the whole, the number of reorganizations decreased markedly compared to 2018: MInBank - the first transaction of that kind since January 2019.

Next we consider the TOP 10 M&A market participants in 2019 (Table 4).

Table 4: TOP 10 M&A Market Participants in 2019

Market Participant	Acquisition	Sale	Total number of transactions
PJSC VTB Bank	10	8	18
PJSC Rostelecom	10	2	12
PJSC Gazprom	6	5	11
Alfa Group Holding	7	2	9
PIK Group	6	-	6
PJSC Sberbank of Russia	3	3	6

JSC IKS Holding	4	2	6
Safmar Group	5	1	6
PJSC National Bank Trust	-	6	6
GC Rostec	2	3	5

In the ranking of active market participants in terms of the number of M&A transactions completed in 2019, the first three lines are occupied by state-owned companies. The leader in the number of transactions VTB Bank PJSC, which made 18 M&A transactions during the year, is particularly notable. The Bank has set itself the task of creating a vertically integrated United Grain Holding, which will combine a number of grain production, storage and transportation companies.

Of the TOP 10 participants in the M&A market in 2019, out of 10 companies 4 were held in the financial sector: VTB Bank PJSC, Alfa Group Holding, Sberbank of Russia PJSC, National Trust Bank PJSC.

By the number of transactions, the financial industry is only in 4th place, after the transport, fuel and energy and IT.

Fig. 2: Industry Analysis: Number of M&A Transactions in 2019.

According to expert forecasts conducted in 2014-2017, the number of M&A transactions in 2018-2019 was to grow. However, they did not come true. Sanctions yielded negative results and aroused caution among investors.

In addition, among the largest 30 transactions in 2019 the share of cross-border transactions remains, as in the market as a whole, extremely high. So, in the total volume of TOP-30 transactions ($ 42.3 billion) of the acquisition of Russian assets by foreign investors (out-in) they occupy a share of 61.4% - their value is $ 25.99 billion and the number is 11 transactions. In general, this trend should be seen as a continuation of the sale of Russian assets abroad. The main reason is anti-Russian sanctions that complicate the work of subsidiaries of Russian entrepreneurs and therefore large players are forced to get rid of these assets.

At the same time, out-in deals occupy the first five lines of the rating. So, in the first place among foreign investors' acquisitions of Russian assets is the largest transaction in 2019: the merger of oil and gas companies Wintershall owned by the German concern BASF and Dea Deutsche Erdoel of

Russian businessman Mikhail Fridman for an estimated $ 7.18 billion. The second place out of cross-border out-in transactions (as in the overall rating) holds the sale of Sberbank of Russia`s subsidiary bank in Turkey Denizbank to Emirates NBD for $ 5 billion. In the third place there is the November acquisition by the American investment fund Blackstone of 99% of MagicLa from Andrei Andreyev and Finam estimated at $ 3 billion.

The fourth place among out-in deals was occupied by the sale of Brooklyn Nets basketball club, which was purchased by Joseph Tsai, vice president and co-founder of Alibaba Group, from Mikhail Prokhorov for $ 2.35 billion and the fifth was the acquisition by Sokar Energoresurs (Azerbaijani SOCAR owns 60%, Sberbank - 40%) 80% of the shares of Antipinsky Oil Refinery, estimated at $ 2.32 billion.

However, with regard to the acquisition of Russian investors abroad (in-out), the situation is exactly the opposite. Among all the TOP-30 transactions, only two belong to this category and their total value is $ 800 million (1.9%). The largest of the two in-out transactions was the March purchase by Michael Friedman` DEA of Mexican oil and gas Sierra Oil & Gas for approximately $ 500 million. It also became the largest in oil production in Mexico, since in 2013 the country's oil sector was open to foreign investors. In the second place there was the last in the rating, the 30th deal: in April, the Max-iPost group of companies acquired a controlling stake in the Chinese logistics platform Guangzhou Hanxuan International Freight Forwarding Co for an estimated value of $ 300 million.

At the same time, one of the major in-out transactions, the completion of which was expected in 2019 and which could enter the TOP-30, did not take place. So, Mikhail Fridman and his investment fund LetterOne faced difficulties associated with further repurchase of shares of the retailer Dia. Recall that in early 2019 the company announced its intention to acquire the majority share of the Spanish retailer (before that it owned 3% of its shares). In March the investment fund became the owner of 70% of Dia and received permission for a full buyout of the company. However, over the summer Dia stocks plummeted and Mikhail Fridman was accused of artificially lowering the company's value. In Italy an investigation was launched into an anonymous complaint, but the businessman denied the conspiracy. He emphasized that he had already invested 1.6 billion euros in the company and more than others suffered from a drop in quotations. We continue to monitor the developments.

The general trend remains negative. The activity of Russian companies in foreign markets is hindered by the deterioration of political climate - in particular, the imposition of US sanctions against a number of Russian companies and entrepreneurs.

Fig.3: The share of domestic and cross-border transactions by amount in 2019.

Companies where the state is the controlling shareholder completed 11 business acquisition transactions totaling $ 15.25 billion, which were included in the TOP-30 transactions for 2019. The most active transactions with large enterprises were state-owned companies such as VTB Bank PJSC, Sberbank of Russia PJSC, Russian Railways PJSC and Rostelecom.

The largest transaction involving a state-owned company was the sale by Sberbank of Russia of its subsidiary Denizbank in Turkey to Emirates NBD for $ 5 billion. Rostelecom consolidated 100% of T2 RTK Holding LLC (Tele2) with an estimated value of $ 2.04 billion. The third place among transactions with state participation was also taken by a transaction in the financial sector: in July, the Central Bank of Russia, as part of implementation of its participation plan to prevent bankruptcy, acquired a 99.99% stake in Moscow Industrial Bank for $ 2.03 billion.

It is worth noting that Russia is not only involved in mergers and acquisitions through its companies, but also remains an indirect driver of M&A activity in a number of industries. In some sectors legislative innovations encourage state-owned companies to sell their foreign business (for example, in the financial sector, fuel and energy sector and trade), or, conversely, to buy Russian companies to consolidate assets in sectors necessary for self-sufficiency of resources (IT, telecommunications and others). In addition, in the financial sector legislative changes in the order of reorganization of troubled banks can significantly increase the state's share in this market, even taking into account the subsequent privatization of part of these assets.

In addition to transactions recorded statistically, transactions are conducted which methodologically do not meet the requirements of M&A transactions, but are inherently very close to them. So in 2019 MTS PJSC bought 99.7% of MTS-Bank PJSC from the parent Sistema JSFC, however, the transfer of ownership did not take place, therefore, the transaction was not included in the statistics. And in July VTB Bank acquired from Sergey Gordeev a 15.48% stake in PIK Group for 38.6 billion rubles. ($ 609 million). After that VTB's share in the group increased to 23.05% and Gordeev's share fell to 59.15% - that is, there was no change in the controlling shareholder. In November Yandex announced a change in the management structure of the company and created the Public Interest Fund with which it will coordinate the consolidation of more than 10% of shares, the transfer of personal data and other issues. The restructuring process has just begun, but Sberbank has already returned to the company a "golden share", which has been owned for 10 years.

As for forecasts for the future, it can be said that M&A transactions in the financial sector will certainly take place, but most likely they will also concern the bank reorganization procedure. The pace of economic recovery was still slower than expected by the government. The main reason for this can be still existing uncertainty around the sanctions. Russian economy has already been able to adapt well to the sanctions that were introduced in 2014. And investors have learned to work under existing restrictions.

In recent years, merger and acquisition activity of domestic organizations markedly decreases. The main players in the market are foreign investors from France, the USA, Norway and Cyprus. Mass departure of foreign banking organizations from Russian market began in 2009. The main reasons for this were the effective cost reduction to zero and general political situation.

Until this year foreign investors were considered the main players in the domestic banking market of M&A. And banks with state participation in capital belonged to the second most important group. From 2005 to 2017 they managed to conclude 14 transactions worth more than $ 3.2 billion. The largest transactions include:

- Sberbank's purchase of the Troika Dialog investment bank, which allowed Sberbank to expand its investment services market;
- VTB Bank (PJSC) purchase of Transcreditbank OJSC, the transaction amount is $ 1.7 billion [8].

The peak of transactions, both in quantitative and in monetary terms, the peak came in 2006–2008, as this was the period when cheap loans were available to banks and the purchase brought a fairly quick financial effect. To the tops of the Russian market of banking M&A services 2005–2017 they include: Otkritie banking group - 3 transactions, BIN group - 6 transactions, Promsvyazbank group - 6 transactions and Gazprom-Bank group - 5 transactions.

In each sector, the M&A market completely depends on the degree of economic activity in the state, the investment climate, the national currency, the political situation and Russia's ability to quickly survive the crisis. According to experts of the banking business, the cleansing conducted by the Central Bank will help to maintain a position only for large financial institutions, high-tech medium-sized banks that have managed to adapt to new conditions. Large banking organizations have already built federal networks. They do not need new acquisitions. A large number of small and medium-sized banks are inclined to carry out a merger, which will help them to strengthen and withstand constantly increasing competition, to win the struggle for resources.

Today, a new type of transaction has emerged in the domestic banking market of M&A. When a credit institution loses its license, a deal may be concluded to transfer property rights and obligations. The right to approve a participation plan, transfer of all obligations is obtained by the CBR. For example, the right of the first stage is transferred from the "recalled" bank to the functioning one. The Deposit Insurance Agency (DIA) does not use funds from its own fund, since the “receiving” bank receives deposits worth more than the amount of insurance compensation. The assets of the bank are transferred in the amount of such liabilities and the buyer is given the right to choose the bank's asset for the amount of liabilities. There were two transactions of that kind on the market: PJSC Binbank, therefore, bought assets from Probusinessbank OJSC and the bank of Russian Capital JSCB (PJSC) - from OJSC Nota Bank. The essence of such transactions is the purchase of assets, but instead of paying a functioning bank assumes obligations of depositors. The interest of a functioning bank lies in the client base of borrowers and depositors.

According to experts, in recent years a healthy consolidation of assets could not be noticed in the domestic financial market. A bank was reorganized by the Central Bank or merged with another financial organization. Transactions of insurance companies and NPFs are not comparable in volume with the banking sector. It is probably wrong to take into account reorganized banks in M&A data. These are not deals concluded on the market, but only a necessary measure of a regulator. This opinion is shared by many financial market analysts. To activate real transactions in the financial segment of the Russian Central Bank you need to announce the completion of banking clearing, to convince everyone that there are no complaints against the remaining banking institutions.

Conclusion

The study of merger and acquisition practice of Russian banks allows us to conclude that they are carried out mainly for the purpose of consolidating indicators of a credit company to improve its financial stability. The Central Bank's policy is aimed at stimulating transactions between banks. It can be considered as a way to strengthen the pooling of bank capital. A large number of small and medium-sized banks, due to an increase in the reviews of licenses of financial organizations, are ready to merge aiming at enlargement.

Experts believe that in Russia there is almost no pure bank merger that allows each participant in the transaction to obtain a synergistic effect. Most often a major player "eats" small. There are virtually no takeovers on a voluntary basis.

If there are noticeable signs of economic recovery, the number of transactions in traditional M&A may again increase significantly. The demand for the assets of private sector players who were able to survive the financial crisis will increase.

But there is potential for growth, even if investors do not really believe in it. Now Chinese, Korean, Indonesian and Kazakhstani investors are already showing more interest in Russia than in 2015-2017. Inside the country there is a tendency to consolidate medium-sized IT companies around banking and telecommunication groups. Banks are also most interested in the high-tech industry.
Summing up, we can name the following current trends in the Russian market of mergers and acquisitions:

- merging credit organizations into banking groups / bank holdings;

- capitalization and consolidation of banks;
- decrease in the dynamics of mergers and acquisitions in the banking sector.

Strengthening requirements for financial institutions, the introduction of world standards have led to the fact that Russia has to keep only trusted and reliable players in the banking sector. This process allows to motivate banking institutions to consolidate. To meet modern requirements banks will already need to bear the costs, to analyze the possibility of future development and carry out activities in such a way that it is profitable.

Abstract

Socio-economic development and related issues are an extremely important issue raised at both theoretical and practical levels. The diversity of countries in terms of the level of socio-economic development is one of the most important global problems faced by both researchers and politicians. Central and South Asia stands out economically due to its high level of industrialisation, which, however, does not translate into quality of life and prosperity. Historical histories, including those of the colonial period, play an important role in the contemporary development path of many countries in the region. This article will attempt to answer the question about the impact of development aid on the socio-economic development of selected countries in Central and South Asia. The grey incidence analysis method will be used for this purpose.

Keywords: development assistance, Asian countries, development, GIA

Introduction

The problem of developing countries arise primarily from the eternal question: why are some regions developing much faster than others? These reflections go back to ancient times, where already the world's ancient state of knowledge and consciousness divided countries and geographical areas into rich and poor, which was mainly related to the availability of raw materials and favourable conditions for agricultural development. With the diverse development of individual countries, much poorer regions than others began to emerge. Examples include Sub-Saharan Africa and Central and South Asia. It is the latter that seems to be extremely interesting because there is no denying that Asian countries have chosen their path of development, different from that of the West. While Taiwan, Singapore, Japan and South Korea have developed and continue to develop rapidly, countries like India, Afghanistan and Bangladesh are still underdeveloped in terms of economic and social development.

The improvement of the situation of these countries was to be influenced by their support by foreign capital. Most transfers were made based on development assistance, which can be provided as money transfers, provision of consumer and investment goods or expertise and advice. Although it has been provided for decades, it is worthwhile, in the face of a growing wave of criticism (especially its effectiveness and efficiency), to check whether countries recorded economic and social development thanks to official development assistance. To this end, a study on the impact of development assistance on social and economic development was conducted in a group of the 5 largest recipients of British development assistance in Central and South Asia (India, Afghanistan, Bangladesh, Pakistan, Nepal) using the *grey incidence analysis* method.

Development and growth in Economic Theory

For many centuries, development was understood only in an economic context. It must be assumed, therefore, that great researchers like Ricardo, Mill or even Marx in the field of economics have partly dealt with the issues of economic development. The early theories of development economics did not distinguish between development and growth. It was assumed from the top down that growth and modernisation lead to solving problems faced by developing countries. It was also assumed that other aspects of economic and social life would improve with the growth of gross domestic product (GDP). It can, therefore, be seen that the overarching objective of that period was for countries to achieve growth that was synonymous with an overall improvement in the situation in developing countries. This is not entirely true, because even Smith in his greatest work distinguished between material wealth and prosperity. There can be no prosperity without material wealth, but material wealth does not mean prosperity.

Economic growth includes quantitative changes in aggregate GDP growth. Research on economic growth has for years been conducted by many prominent economists such as Schumpeter, Solow, Ramsey, Diamond, Romer, Lucas, Rebelo, Aghion and Howitt. They distinguished different growth paths within their models depending on the economic approach they represented. Generally speaking, economic growth has been characterised by an increase in the volumes such as national income, production and consumption over a given period. The calendar year is usually taken as the period in which comparisons are made more easily.

Many researchers have indicated that economic growth has a direct impact on national development. It is certainly a desirable element in society because it is connected with the improvement of living standards, development of civilization, but above all with the increase of income. However, the definition of development itself includes not only quantitative changes but above all certain aspects of a qualitative nature that directly affect, among others, the standard of living. Economic prosperity alone, without a corresponding increase in social welfare, is not enough to break through the barrier of a developing country.

Rapid sustainable economic growth is a relatively young phenomenon. So far, the average GDP per capita growth rate in Western Europe (1500-1820) was only 0.05%, which is an extremely unsatisfactory result. The impulse to accelerate growth was provided by the industrial revolution of the mid-18th century, which began in England at the time. It contributed to the rapid development of the railways, mining, shipbuilding, mechanical industry, textiles, as well as the arms and energy sectors. The newly created sectors required an inflow of money, creating a huge demand that could not be met by traditional goldsmiths' banks. Continuous technological innovation and industrial development on an unprecedented scale brought with it an increase in labour productivity and an increase in income. As a result, the overall level of GDP per capita has increased.

Economic development, in turn, is a process of structural change characterised by constant technological innovation and industrial progress. Modern economic growth is based on labour productivity growth and is therefore essentially a process of continuous structural change in terms of technology, economic sectors and infrastructure. These phenomena are conducive to raising labour productivity and accompany improvements in infrastructure and institutions which in turn reduce transaction costs in the economy. Transaction costs are the costs of concluding financial transactions and their existence leads people to use money more efficiently.

The procedures for explaining economic backwardness create a certain problem area that can be effectively addressed by the researchers' theory of growth or development. This problem area also contains colloquial ideas about difficult living conditions, poverty, disease, archaic social structures or depravity. According to the "dynamic model", the situation of developed countries is seen as a norm which has been temporarily prevented from being repeated by other countries by internal, external factors or a combination of these. It is implicitly assumed in the literature that the transformation of the economy of a backward country into a developed one is impossible without elements of coercion by the state and other subjects of modernization, which does not mean that it is completely acceptable to

use it. The high degree of the indifference of economists to violence results from the utilitarian treatment of coercion as not necessarily a noble but acceptable tool to push the system to a higher level, the evaluation of which is directly dependent on the results of systems. When thinking about violence against economically lagging countries, one can think of the most direct forms of its manifestation, e.g. the forced nature of employment, irreversible ecological damage, segmentation of social groups, monopolization of political choice or discrimination in terms of ethnic, religious or worldview.

The economic successes of the Asian economies were in line with the American slogan "trade not aid", which further stressed that money flows from rich to poor countries alone will not help them overcome their economic difficulties. Opening up to the global economy and liberalising flows of goods and services was supposed to foster growth in developing countries. Trade instead of aid was pushed through by P. Bauer, pointing out that a poor country in which there are incentives to invest does not need development assistance, while one that does not have such incentives will not use development flows for investment but rather for current consumption.

The societies of developing countries have their specificities. Therefore, techniques that correspond to the level of knowledge and skills should be used in their context. This is why Schumacher believed that one of the most important factors in development is education, as it directly influences work efficiency and the system of its organisation. The imposition of top-down more advanced production techniques on traditional society will not contribute to productivity growth but will even be seen as an attack on the internal social structure. Myrdal at the time argued that growth in developing countries could be achieved by levelling income and social inequalities. For this to happen, a wide-ranging institutional reform would have to be carried out, which would introduce rational ownership relations in the economy, as well as eliminate market defects such as corruption and nepotism. Theories have also emerged in those years to include the influence of cultural and institutional factors in the analysis of growth and development issues.

The theory shows that the trajectory of development is from agricultural production (African countries dominate at the lowest level of the economic ladder, reflecting the lowest income per capita), followed by industry (currently dominated by Asian countries) going from services to high value-added industry and research and development respectively. All countries should strive through the different stages of development to the highest because they have the highest GDP per capita. However, this is not the rule. For example, most Asian countries have moved from exporting goods to the powerhouse of production, leaving aside, for example, the stage of agricultural development.

Definition of developing countries

The countries have adopted to be divided into the developed and developing ones, with the vast majority of the countries in the world being classified as the latter, and therefore sufficient attention must be paid to them. The disparities between the two categories of countries concern not only economic aspects such as gross domestic product, inflation or trade balance, but above all social aspects such as different levels of education or access to medical care. Due to the differences, these countries cannot take advantage of the opportunities offered by the modern economic reality to the same extent. The literature of the subject indicates multiple approaches to the definition of a developing country. Various authors point to different classification criteria. There is no single universal and universally applicable definition. This is because under the common name of a developing country we will find countries that:

- have many natural resources (Venezuela, Democratic Republic of Congo) and countries without raw materials (Chad, Somalia),
- countries with a high GDP *per capita ratio* (Qatar, United Arab Emirates) and countries with the lowest values (Ethiopia, Afghanistan),
- with a relatively high level of social development (South Korea, Singapore) and those with a very low level (Yemen or Niger),
- with a huge territory such as Brazil and Mongolia, as well as micro-states in the Pacific Ocean,

- with high population density like India or China and low population density like Argentina or Ecuador,
- independent for over 100 years like Liberia and those that have gained independence quite recently like South Sudan,
- Catholic in Latin America and Muslim in Africa and Asia,
- the most indebted to their GDP (Rwanda, Lebanon) and rich thanks to the export of raw materials (Saudi Arabia).

However, economists often assume that this classification should be based on economic measures. The use of an economic measure alone was justified in the mid-20th century, but since the 1970s there have been many other aspects that also determine a country's actual level of development. The biggest weaknesses of the above approach include:

- lack of fully reliable statistical data due to different census traditions,
- not taking into account the costs of environmental degradation in GDP, but taking into account military goods and armaments spending,
- to ignore the standard of living of the inhabitants and economic potential in the future,
- the existence of a significant size of the 'grey economy' and a natural economy that produces subsistence goods,
- diversification of the population's income, making it useless to convert economic figures *per capita*.

It is much easier to determine which country deserves to be called a developed country, and then to say that a country which does not have such qualities is a developing country. To qualify a country as a highly developed country, political and social pluralism, as well as individual freedoms in the broadest sense, should be respected alongside economic freedoms.

The role of Asian countries in the global economy

Today we are witnessing a situation where the points of view of the people of Asia and Africa, the two most colonized continents, are beginning to spread. The undoubted economic and political success of Asia, including many former colonies (e.g. India, Hong Kong, Singapore, Malaysia, South Korea or Taiwan), makes us see the old dependencies on Europe or Japan differently. This is particularly evident in the context of Afghanistan or Nepal, which have never been anyone's colony.

In East Asia, many years ago, a model for their own was invented, combining market and state interventionism. This model was called the "development state" and can be applied to the whole of Asia because it takes into account its specific regional circumstances. The whole concept of a development state has been fulfilled by the work of Chalmers Johnson, who published his work in 1982. Initially, these were opposed and controversial, but over the years they have been considered the classic paper for Asian development. Johnson admitted from the beginning that the issue of linking democracy and development is important, but the state can develop in both democratic and autocratic conditions. This thesis was to be proved by his research on a long time series (1925-1975) when both types of political systems were present in the countries studied. In his opinion, the state is not just a "dictatorship of development", as it has legitimacy in two areas. Firstly, it is based on clear and transparent modernisation objectives for both the state and society and secondly, it is effective in its actions. The defence of this thesis is Japan's economic success in the second half of the 20th century. This approach quickly found its followers in the region in the form of Hong Kong, South Korea or Singapore. All these countries had common features:

- methodical planning of development to move towards modernity and modernisation,
- an export-oriented and open to the world economy,
- the vast resources of cheap labour resulting from demography,
- forced social discipline, enforced even at the cost of temporary oppression.

Thanks to these factors, the system was highly dynamic and flexible, and when necessary (or more precise: when the state considered it necessary) absolute. However, these countries were similar but

had different internal conditions, so they adapted the model developed by Japan well to their capabilities, resulting with success.

Methodology and results of empirical research

The diversity of the level of socio-economic development of countries and its causes is a field of interest for more and more researchers. International institutions as the UN, OECD and the World Bank, are also researching this area. The following set of variables was chosen to characterise socio-economic development:

- Gross Domestic Product per capita (in current prices, USD),
- Mortality per 1000 live births,
- Unemployment rate (%),
- Industrial added value per capita.

The following countries were selected for analysis: India, Afghanistan, Bangladesh, Pakistan and Nepal, which are the largest recipients of British development aid. Tables 1 to 5 show the evolution of development assistance per capita and previously presented socio-economic development indicators.

Table 1: Differences in the volume of development assistance per capita and selected socio-economic development indicators in India 2011-2017

	2011	2012	2013	2014	2015	2016	2017
UK development assistance per capita value	0,36	0,37	0,33	0,35	0,22	0,09	0,09
GDP per capita (in $, current prices)	1458,10	1443,88	1449,61	1573,88	1605,61	1729,27	1981,27

Variables that are presented in Tables 1 to 5 were the basis for further calculations. The *grey incidence analysis* (GIA) method was used to examine the impact of British development assistance (measured per capita) on selected indicators of socio-economic development of selected Central and South Asian

countries. It allows examining the similarities that exist between sets of variables. The most important advantage of this method is the possibility to analyze short time series, additionally, it is also possible to study not only quantitative but also qualitative variables. Due to the availability of data and reliability of the GIA method, it was decided to use it to study the impact of British development assistance on socio-economic development in selected South and Central Asian countries.

The test procedure was conducted in the following stages:

1. Formulating a set of time series that are subject to grey analysis together with linear unitization of the variables subject to grey relation analysis together with linear unitization of the variables. The general form of a time series that has been scaled may be presented as follows:

$$Xij = (xi(1), xi(2), xi(3),..., xi(n)), \qquad (1)$$

where:

i = 1.2..., 5 - indicates the country number

j = 1,2,...,4 - indicates the number of the variable under investigation

n - number of elements in a time series

How each country is marked is shown in Table 6.

Table 6: Country designations

i	Country
1	India
2	Afghanistan
3	Bangladesh
4	Pakistan
5	Nepal

Source: Own study.

The method of determining individual variables is presented in Table 7.

Table 7: Indications of variables used in the test

j	Variable
1	GDP per capita (in $, current prices)
2	Mortality per 1000 live births
3	Unemployment rate (%)
4	Industrial added value per capita

Source: Own study.

The reference vector, due to the purpose of the study (*Xr*), is the time series that characterises the value of development assistance per capita. The time series covered the period 2011-2017. The next part of the procedure will be presented on the example of India. The first step of the method for India resulted in the following time series:

X_1 = (0,03 0,00 0,01 0,24 0,30 0,53 1,00)
X_2= (0,03 0,00 0,01 0,24 0,30 0,53 1,00)
X_3= (0,56 1,00 0,24 0,00 0,37 0,44 0,53)
X_4= (0,00 0,06 0,14 0,31 0,59 0,82 1,00)
X_r= (0,99 1,00 0,86 0,96 0,46 0,03 0,00)

2. Subtraction of the individual values of the time series from the corresponding values of the reference vector gave the following form of vectors

X_1 =(0,00 -0,03 -0,02 0,22 0,27 0,50 0,97)

X_2 =(0,00 -0,24 -0,45 -0,63 -0,78 -0,90 -1,00)
X_3 =(0,00 0,44 -0,31 -0,56 -0,19 -0,12 -0,03)
X_4 =(0,00 0,06 0,14 0,31 0,59 0,82 1,00)

3. Calculation of vector behaviour measures by determining *si*, *sj* and *si-sj* indicator modules according to the following formulas:

$$|s_i| = \left|\sum_{k=2}^{n-1} x_i^0(k) + \frac{1}{2} x_i^0(n)\right| \quad (2)$$

$$|s_j| = \left|\sum_{k=2}^{n-1} x_j^0(k) + \frac{1}{2} x_j^0(n)\right| \quad (3)$$

$$|s_i - s_j| = \left|\sum_{k=2}^{n-1} [x_i^0(k) - x_j^0(k)] + \frac{1}{2} [x_i^0(n) - x_j^0(n)]\right| \quad (4)$$

The results of these activities are presented in Table 8.

Table 8: Measures of vector behaviour

εij	*si*	*sj*	*si-sj*
X11	1,439	**-2,134**	-3,560
X12	-3,483		1,362
X13	-0,744		-1,377
X14	2,414		-4,535

4. Calculate the absolute similarity index according to the following formula:

$$\varepsilon_{ij} = \frac{1+|s_i|+|s_j|}{1+|s_i|+|s_j|+|s_i - s_j|} \quad (5)$$

Table 9 shows the results of the absolute similarity index for all countries. The lowest values for a given country are highlighted and the highest values are marked in bold.

Table 9: Results of the absolute similarity index for countries

Country/Variable	GDP per capita	Mortality per 1000 live births	Unemployment rate	Industrial added value per capita
INDIA	0,56	**0,83**	0,74	0,55
AFGANISTAN	0,57	**0,94**	0,55	0,54
BANGLADESZ	0,58	**0,91**	0,53	0,55
PAKISTAN	**0,93**	0,53	0,90	0,81
NEPAL	0,83	0,54	0,87	**0,95**

Source: Own study.

The value of the absolute similarity index reflects the strength of relations between individual vectors (time series of variables). In a situation when there is a higher value of the indicator, the more strongly one variable affects the other variable. Based on the results obtained, development assistance (UK) had the greatest impact on the mortality rate per 1000 live births. The least impact was on industrial value-added per capita and mortality per 1000 live births.

Conclusions

The article aimed to examine the impact of development assistance on socio-economic development in a group of the 5 largest recipients of British official development assistance in Central and South Asia (India, Afghanistan, Bangladesh, Pakistan, Nepal). The characteristics of the level of socioeconomic development were reflected in the following indicators: GDP per capita (in current prices, USD), mortality per 1000 live births, unemployment rate and industrial value-added per capita. The *grey incidence analysis* method was used to carry out the impact analysis, which is extremely useful for short time series.

The results of the study indicate that the least impact UK development assistance has on industrial added value per capita and mortality per 1000 live births. In contrast, mortality per 1000 live births is also most affected. Such results may indicate that development assistance results in development areas related to social rather than economic aspects.

In the future, research may be extended to other countries that also benefit from UK development assistance. A wider set of indicators that are related to socio-economic development could also be considered.

Abstract

The importance of this issue has increased nowadays because in future today's generation actually faces real consequences of current socioeconomic activity, and it is exceedingly much as never before requires new technology-based approaches and methods in acquiring knowledge, skills and norms needed for all jobs, from the simplest to the most complex. The *purpose* of this study is to explore and substantiate the possibilities of the development of digital competence according to labour market trends in Latvia. The *research methodology* applied in this research study involves examining, analysing and summarizing relevant theoretical concepts, literature and Internet sources as well as statistical data. To achieve this goal, an interview was carried out as the key method of the research. In total, 25 (twenty-five) experts were addressed and in total 6 (six) field experts from business, education policymakers in Latvia and universities were interviewed by sorting them in 3 (three) groups. For each group, questions were prepared differently. The Analytic Hierarchy Process (AHP) method was used to analyse the development scenarios of the possible development of digital competence in the higher education system in line with labour market requirements. *The results indicate* that despite the widespread availability of technology, almost everywhere in the education system, there is still a large gap between educational technology adaptation in education organizations and the demand of the labour market and trends in building competencies. This requires maintaining the holistic approach to targeted digital education management.

Keywords: Analytic Hierarchy Process (AHP), Digital competence/skills, Education system, Labour market trends.

Introduction

The current period describes the digital revolution due to the growing use of information and communications technologies (ICTs). As a result, digital transformation is taking place in almost all areas. It means that digital technologies are used in many sectors such as farming, healthcare, transport, education, retail, automatics, energy, shipping, logistics, teaching and the information and communications technology industry. Careers such as engineering, accountancy, nursing, medicine, art, architecture, and many more require increasing levels of digital skills (European Commission, 2017a). Therefore, significant structural changes in the labour market and the nature of work, which could have significant impacts on employment. The demand for information and communications technology specialists is growing fast.

According to the McKinsey Global Institute, the highest demand will be observed for advanced IT and programming skills, as well as for basic digital skills, which could grow as much as 90 and 70 percent between 2016 and 2030. The demand for other skills that constitute this category will also grow, but not as strongly (Skill shift: Automation and the future of the workforce, 2018). In order to adapt to the change caused by digital transformation, and digital competence/skills are needed for all jobs, from the simplest to the most complex. Therefore, higher education institutions must have to equip graduates with relevant and up-to-date skills (Eteris, 2018). This will encompass a range of skills, from technical, academic, sectoral and digital skills to softer skills like problem solving, creative and design thinking, communication, emotional intelligence, multicultural openness, leadership, managerial and interaction skills (European Commission, 2018a). It means that the digital economy will require for all people to build up a range of new knowledge, abilities and different digital skills needed not only in traditional STEM occupations and ICT professionals but also in nearly for all job sectors where ICT complements existing tasks (Carnevale, Smith, & Melton, 2011).

It has to be mentioned that currently the EU has a significant and systemic gap between market needs and what is offered in terms of skills related to advanced digital technologies. For example, 44% of European citizens between 16 and 74 years of age do not have basic digital skills (European Commission, 2017b). According to the Digital Agenda Scoreboard 2018, 59.2% of European companies in the food industry and 62.5% in the construction industry state that they have the necessary skills to harness a digital transformation. This observation shows that more than one in three companies in these two industries in Europe struggle to find the human resources needed to exploit the opportunities offered by the digital economy. As well as 37% of people in the labour force – farmers, bank employees, and factory workers alike – also lack sufficient digital skills, despite the increasing need for such skills in all jobs. Europe also lacks skilled ICT specialists to fill the growing number of job vacancies in all sectors of the economy. For example, there are more than 350,000 vacancies in Europe for highly skilled technical experts in areas such as artificial intelligence, data analytics and cybersecurity (European Commission, 2018b).

As for Latvia, there is quite impressive progress in using computers in public services: the country ranks 8th in e-government performance, according to the EU's e-Government Benchmark-2017 analysis, which is higher than the EU average level. Latvia is among a top-ten group of advanced countries in e-government score, together with Malta, Denmark, Sweden, Estonia, Norway, Austria, the Netherlands, Latvia, Lithuania and Portugal. Besides, Latvia is among top EU Member States with the main public services online reach for citizens and businesses (Eteris, 2018). Despite progress, the most *essential problem* of developing digital competence, is educational system of Latvia, that is not sufficiently flexible in responding to the needs of the labour market. Latvian employers have difficulty finding people with the digital skills they need to grow and innovate. Therefore, the *purpose* of this study is to explore and substantiate the possibilities of the development of digital competence according to labour market trends in Latvia.

Taking into account that digital competence/skills shortage is likely to reduce the competitiveness of businesses in Europe and Latvia as well, there is necessary to invest not only in new technologies, but also in education, rooted not just in learning but in learning how to learn, and transforming teaching and learning of digital competence in lifelong learning in providing access to learning opportunities for all, including the training of teachers. In this context, the European Commission has created a new *Digital Europe Programme 2021–2027* with an overall budget of €9.2 billion to shape and support the digital transformation of Europe's societies and economies. The programme will boost frontline investments in supercomputing and five key digital sectors: high performance computing, artificial intelligence, cybersecurity and trust and advanced digital skills, thereby ensuring the wide use and deployment of digital technologies across the economy and society in order to strengthen European industrial technological leadership.

The new *Digital Europe Programme 2021–2027* with a budget of €700 million will expand the digital talent pool with around 256,000 people who will be able to deploy the latest technology in business throughout Europe. It will focus on three types of actions:

1) Master programmes in cutting-edge digital technologies developed together with EU excellence centres in artificial intelligence, cyber and high-performance computing. The aim is to offer 160 new master programmes training 80,000 digital specialists.

2) Short-term specialized training courses in advanced digital technologies for around 150,000 job seekers and employed people, especially for SMEs. The aim is to equip them with the competences that will enable the deployment of digital technologies across all sectors of the economy.

3) 35,000 job placements in companies or research centres where advanced digital technologies are developed or used. The aim is to give people the opportunity to learn specialists' skills working with the latest available technologies (European Commission, 2018c; d).

The theoretical basis of the study

In recent years, the concept of *digital competence* is increasingly used together with another concept – *digital skills*. It has to be noted that these terms are often used as synonyms. In this context, we should take a look at what is the relation between digital competence and digital skills. It makes us seek answers to the questions on how to explain these concepts from the theoretical aspect, what competences and personal traits have to be developed to prepare new professionals according to the challenges of the labour market.

The concept of digital competence

The present-day attitude towards the individual, to his/her development and to their values system has changed substantially, as, by putting a competent personality in front, apart from professional activities, this person has to ensure the social role/position in society no less. Each individual person has to become the subject of social changes, and must be able to understand the complicated processes of societal development, and, to influence them. All of this in turn serves to determine new requirements for the further development of the individual's competences of a human being. (Bikse, Riemere, 2013). Therefore, the European Commission developed a framework of 8 key competences (communication in a mother tongue and in a foreign language; mathematical, scientific and technological; digital; learn to learn; social and civic; entrepreneurship; and cultural awareness) as part of their lifelong learning strategies that have to be developed by everyone, beginning from childhood and throughout the entire life. These competences are considered equally important for life and work in a knowledge-based society (European Commission, 2006). In this respect, the OECD suggests that governments should make effort to identify and conceptualise the required set of skills and competences, and then incorporate them into the educational standards (OECD, 2010).

According to the European Commission (2017b), digital competence is one of the eight key competences and refers to the confident and critical usage of the full range of digital technologies for information, communication and basic problem-solving in all aspects of life. Within the context of using digital technologies in policy documents, in the academic literature, and in teaching, learning and certification practices, several terms have been used to describe the skills and competence, such as ICT skills, technology skills, 21st century skills, e-skills, computer literacy, media literacy, digital literacy, and digital skills. Differences were found between concepts by several authors (Ilomäki, et al., 2011, 2016; Gallardo-Echenique, et al., 2015). This paper does not intend to examine all these terms. A recent study aimed to identify the different approaches associated with digital competence and its connection to digital skills.

In specialized literature, policy-related papers and reports, a number of different definitions characterizing the concept of *digital competence* can be found. Having studied them, the conclusion is that, excepting a few differences, all the authors focus more or less on the same issue. For example, Caravello, et al. (2020) described digital competence as the ability to keep abreast with the rapid changes of technology; it includes the relevant knowledge and skills people need to use information and communications technology (ICT) in an appropriate way for their own purposes, both personal and professional.

A widest description of the concept of *a digital competence* is given by other authors, where digital competence consists not only of knowledge and digital skills but also include soft skills. For example, Justenhoven (2018) has defined digital competence as a set of knowledge, skills, attitudes, abilities, strategies, and awareness that are required when using ICT and digital media to perform tasks; solve problems; communicate; manage information; collaborate; create and share content; and build knowledge effectively, efficiently, appropriately, critically, creatively, flexibly, ethically, reflectively for work, leisure, participation, learning, and socializing. Moreover, OECD (2016) documents stress that the concept of digital competence, has to be focused on a broader approach, as in the digital economy era, ICT skills will not be enough and other complementary skills will be needed. Digital competence is ranging from good literacy and numeracy skills through to the right socio-emotional skills to work collaboratively and flexibly (OECD, 2016). Within the context of this other authors concludes that digital competence can be considered as digital literacy and requires the presence of four literacies: a) *information literacy* for managing digital information; b) *computer literacy* for treating data in different formats; c) *media literacy* for analysing and creating multimedia messages; and d) *communication literacy* for participating in a safe, ethical and civic manner from a digital identity (Gallardo-Echenique, et al., 2015).

So, according to these definitions, the digital competence is a very broad concept, including much more than basic skills in the use of ICT. It is about being competent to use technology in different situations (e.g. work, leisure) and for different purposes (e.g. learning, communicating, solving problems, online collaboration, building knowledge, creating and sharing). In a broader sense, digital competence can be defined using a wide range (21) of key components, which have to be developed to prepare new professionals according to the challenges of the labour market. To understand the nature of digital competence better, the European Commission has developed the *European Digital Competence Framework for Citizens* (DigComp) which is divided into five competence areas: information and data literacy; communication and collaboration; digital content creation; safety; and problem solving (European Commission, 2011; 2014; 2017b; 2017c). From the above, it is important to maintain the acquired knowledge and skills to such a level that they are useful in the global labour market which is constantly changing.

Digital competence and its connection to digital skills

As it was said before, the concept of digital competence includes a combination of knowledge, skills and attitudes such as being confident and critical. It means that digital competence and digital skills are closely related but not identical. Digital skills are the important component of digital competence. Within the context of this, the concept of digital competence may be explained in a much broader sense than that of skills. The relation between *competence* and *skills* is defined in an OECD project as follows: "A competency is more than just knowledge and skills. It involves the ability to meet complex demands, by drawing on and mobilizing psychosocial resources (including skills and attitudes) in a particular context" (OECD, 2005, p. 4).

Consequently, the concept of *digital competence* may be explained in a much broader – socio-economic – sense than that of digital skills. It means that along with professional training, the overall development of an individual as a personality, as well as the development of the individual's key competences, including digital competence, has to be ensured. It is built

through a process of acquiring knowledge, skills, and experience, i.e. in the digital education process. To our knowledge, digital education may be viewed in two senses: *in a broader sense,* it is oriented towards developing a certain set of personal traits and soft skills, which are important in any field of activity and in life, without directly associating it with how to use of ICT, while *in a narrow sense*, any particular stage of the educational system involves developing specific digital skills and acquiring knowledge of and experience in how to use of ICT. In this regard, the process of studies has to be oriented towards developing competences and integrating the elements of digital education into all study programmes in order to develop digital competence not only in those who plan to connect their professional life with ICT but everyone – future engineers, biologists, physicists, chemists, mathematicians, and many more. Besides, digital competences have to be developed in everyone from their childhood through implementing various digital education programmes at all levels of the education system, as well as through lifelong learning.

European Commission (2018) documents stress that the elements of digital education should be integrated in all study programmes (courses) or taught as a separate subject focused on building digital competences to give all students and teachers the opportunity to use digital tools and materials in their teaching and learning activities. This requires a complex approach not only to tackling organisational problems in the learning/training process, placing the main focus on the formation of personality and creating opportunities for self-realisation, but also to targeted digital education management. Success depends on the commitment, collaboration and expertise of many players, such as national governments, regions, local authorities, industry, academia, foundations, professional bodies, workers and civil society, and people themselves, seizing opportunities to make the best of their talents (European Commission, 2018b).

Research Methodology and Participants

Digital education is a dynamic and complex system. Equally complicated methods should be used for its research. Due to a complex character of the digital education, the interdisciplinary approach should be used which, in turn, means including both the qualitative and quantitative indicators in the analysis. To evaluate the possibilities of development of digital competence in the education process, an interview and an analysis of opinions were carried out as the key method of the research. In total, 25 (twenty-five) experts were addressed and in total 6 (six) field experts from business, education policymakers in Latvia and universities were interviewed by sorting them in 3 (three) groups. For each group, questions were prepared differently. Experts were selected on the basis of evaluating the competence level performed earlier. Experts whose field of action, experience, and position were sufficiently significant were selected for the survey to assess the offered priorities in the development of digital education. (Table 1) The interviews took nine months, from January 2019 to December 2019. In order to organize the experts' work scientifically and correctly and to process the results of the experts' assessment, the authors used the Analytic Hierarchy Process (AHP) and the key principles of the expert method (Saaty, 2008; 2012).

The data mathematical processing was performed with the computer programme Ms Excel. The criteria comparison results were illustrated in a graphic figure as a minimal, maximal and average coordinate of each factor's priority vector. A differentiated approach was used for scenario building and evaluation. The scenarios were created by the author of the research, while a scenario evaluation was carried out by experts from Latvia.

Evaluation of the development of digital competence in the education system by using the AHP method

The Analytic Hierarchy Process (AHP) method was used to analyse the development scenarios for the possible development of digital competence in the higher education system in line with

labour market requirements. The differentiated approach was used for working out and assessing the scenarios: the scenarios were worked out by the authors but they were assessed by experts. The criteria hierarchy for determining the priorities was developed during the research. The hierarchical pyramid of the research was divided into four levels as it is shown in Figure 1.

Figure 1: Structure of the Analytic Hierarchy Process in the research. Source: Author's figure.

As shown in Figure 1, the ***highest goal (first level)***– "Higher education system that meets labour market requirements" was chosen.

At the ***second level,*** four groups of criteria have been defined. These criteria groups were formulated according to the main tasks set in the strategy "Sustainable Development Strategy of Latvia until 2030" adopted by the Saeima of the Republic of Latvia (2010). The proposed structural reform challenges are grouped according to the main objective of structural reforms: higher education system development scenarios in line with labour market requirements: 1) *Industry bound.* Collaboration between students and organisations - after completing necessary theory courses, training is performed in companies in accordance with the knowledge obtained during the studies. 2) *Digitalisation and information technologies.* Use of information and communication technologies in teaching and learning processes and accessibility of massive online open course (MOOC) services. 3) *Retraining and qualification upgrading.* Recognition of non-formal knowledge, skills and competencies to provide a person with the opportunity to receive a formal education document and adults without specific pedagogical education to be a voluntary mentor or advisor. 4) *Internationalization potential.* Teaching is in English and education has an international focus, with the aim of preparing students to become global citizens, and the students are provided with opportunities to participate in global activities.

The next stage of the method envisaged identifying and defining the assessment criteria. Also, at the ***third level,*** the sub-criteria defined for second level criteria groups were set using the same 2030 strategy as previously. In order to make it easier for all the experts to carry out the evaluation, handouts were prepared in which each defined sub-criterion (third level) was described. (Table 2)

Table 2: Defined sub-criteria in the research by the authors

Linking with industry	
Flexible distance learning	Students choose their own courses and, if necessary, have a mentor who assists in studies.
Training in companies	Training is provided in companies in the profession.
Integration of entrepreneurial programmes	The programmes of professional and higher education institutions not only prepare young people as employees but also to focus on opportunities to develop an entrepreneurial career - practical knowledge of starting and running a business.
Apprenticeships and trainee programmes	Develop apprenticeship or trainee programmes in educational institutions by integrating practical tasks and regular practice in the labour market environment.
Researches commissioned by companies	Meaningful tasks and environment-related projects for students.
Development of innovative products	Creation of labs and workshops according to industry needs.
Digitalisation and use of information technologies	
E-learning	Accessibility of massive online open course (MOOC) services
ICT integration in the learning process	Use of information and communication technologies in teaching and learning processes.
Digitalisation of schools and libraries	Creation of digital content and free access to learning materials in the e-environment.
High quality of study infrastructure	Education infrastructure is crucial elements of learning environments in schools and universities.
Use of smart devices in the learning process	Meaningful use of smart devices in the learning process.
Teaching STEM	Introduction of the best STEM solutions in higher education in Latvia.
Retraining and qualification upgrading	
Distance learning	Access to the modern study process and digitization of Latvian libraries.
New study process organization	Some of the lessons are taught by teachers in the classroom, while some of the content is explained in a virtual environment.
Mentoring programmes	Adults without specific pedagogical education as a voluntary mentor or advisor.
Coupon (guarantee) system	Higher education institutions with more students receive more municipal and state funding.
Recognition of non-formal education	Recognition of non-formal knowledge, skills and competencies to provide a person with the opportunity to receive a formal education document.
Internationalization potential	
Teaching in a foreign (English) language	A student with higher education must be fluent in at least two foreign languages.
International online practice opportunities	The opportunity for students, alongside their studies, to go online for example to Microsoft, Google or other global companies.
Number of guest lecturers	Increase in the number of guest lecturers contributes to healthy competition and ensures a higher level of quality in the educational institution.
Student mobility	Regular contacts between schools in Latvia and other countries, student and teacher exchange and internship programmes (for example, the Erasmus programme)
Internationally recognized university	Teaching is in English and education has an international focus, with the aim of preparing students to become global citizens.
International conferences	Students are provided with opportunities to participate in global activities.

At the ***fourth (the lowest) level,*** the following alternatives for the Latvian education system that meets labour market requirements scenarios were analysed. These alternatives are set as possible solutions in the 2030 strategy to create one of the best educational systems in Europe:

1) *Universities as the Centre of Social Networking* under the guidance of which parents, educatees, as well as a wider local community, including entrepreneurs, representatives of professional and sectoral associations, participate and co-operate.

2) *E-universities and use of Information Technologies (IT).* IT have entered in our daily lives and they should be used skilfully in the learning process. In addition, institutions of higher education may create distance learning programmes, using e-technologies, which mainly take place in the e-environment. It could acquire the skills necessary for economic activity and would improve the general level of digital competence.

3) *Lifelong education.* By increasing the role of lifelong learning in society, the ability of every person, especially a young person, increases to see the necessity and to use education and career development opportunities throughout their lives. In the nearest future, a solution should be found for the way to create a link between the system of formal education and digital education.

4) *Contextual Education.* Systematic cooperation between general, vocational and higher education institutions should be oriented towards the development of individuality and necessary competences in the youth (skills, knowledge and personal traits) and for curriculum development, improvement of teachers' competences for teaching more than one study subject.

The next step envisaged performing an expert evaluation (procedure of obtaining experts' ratings) to find out the importance of ratios for each factor. After the survey, all the data were processed. When all the project hierarchies had been correctly formed, calculations were done. The result of calculation shows which of the alternatives was the most acceptable in the aspect of all the mentioned criteria. The results of the experts' survey were further analysed taking into account the context of digital education.

Summarizing the expert ratings for criteria groups for a ***higher education system*** that meets labour market requirements, the highest average rating was given to "Digitalisation and use of information technologies" – 0.43 (Figure 2). Then "Internationalization potential" and "Industry bound" followed with an identical rating – 0.21, yet "Retraining and qualification upgrading" followed with 0.14; thus, the experts considered the most important need for the education system in Latvia was to create a learning environment that would promote the cognitive process and develop the competences/skills that match the demand of the labour market.

Figure 2: Expert ratings of criteria groups for a higher education system that meets labour market requirements. Source: authors' calculations and figure.

At the same time, assessing the defined scenarios by criteria group in relation to the following criteria groups - *Industry bound, Digitalisation and use of Information Technologies* and *Internationalization potential* - the highest average score was given to *Contextual Education*. A similar rating (for the criteria "Contextual Education" with a rating of 0.39) was given in the summarizing assessment of all the groups of criteria (Fig.3).

Figure 3: The summarized assessment of the development scenarios for the digital education system by the experts. Source: authors' calculations and figure.

However, there was rather considerable dispersion of the expert ratings, namely, the lowest rating of the scenario was 0.14, whereas the highest was 0.57, which indicated expert disparity. The next advisable scenario was "Lifelong Education" – 0.25, and the scenario "University as the Centre of Social Networking" – 0.23, the scenario "E-universities and use of IT" with a rating of 0.13, which was the lowest.

The criteria group "E-universities and use of IT" had the lowest rating among all the criteria groups, which might be because of the common idea of the experts that the future higher education system should be oriented towards the development of individuality according to the challenges of the digital transformation and labour market trends.

Taking into consideration the ratings provided by the experts of possible development of digital competence in the higher education system in line with labour market trends, it is possible to conclude that currently in Latvia young people are not sufficiently prepared for the digital economy and society. Therefore, it is very important to facilitate collaboration among academics, policymakers and practitioners and to modernise the education and training systems. It means that it will increasingly depend on the link between the educational system and changes in the labour market, as well as the capability to prepare a person for work in changing conditions during his or her whole life.

Conclusion and Recommendations for a Future Research Study

The research findings show that the concept of *digital competence* is much broader than the concept of digital skills. Digital competence is a combination of knowledge, skills and attitudes, including the development of soft skills such as problem solving, collaboration and creativity. Consequently, digital skills are the important component of digital competence.

According to the labour market trends, the demand for highly-qualified, competent to use technology in different situations and for different purposes, employees will considerably increase in Latvia. Therefore, the education system has to adapt to the labour market challenges, enabling every young individual to build up their digital competences in the process of education through implementing the elements of digital education in various study programmes at all the levels of the education system, as well as through lifelong learning. This requires maintaining the holistic approach to targeted digital education management.

The analysis of the development of digital competences in the education system and the hierarchy analysis performed allows concluding that: *firstly,* despite the widespread availability of technology almost everywhere in the education system, there is still a large gap between educational technology adaptation in education organisations and trends in building digital competences. *Secondly,* studies show that the one of the challenges of higher education is the lack of a unified vision among students, education providers and employers about the aims and content of education. These three stakeholders rarely cooperate with each other, which makes it difficult for employers to find and recruit employees with the skills needed in a fast-changing work environment. Because of this reason, there is a prediction about the increasing gap between universities and private companies.

In order to reduce the labour market disproportions, it is necessary to provide significant changes in the education system, the quality of contemporary education content and the required impact on the labour market. In order to ensure access to a modern learning process and information, digitalisation of all schools and libraries of Latvia should be implemented. In addition to the usual learning process, educational institutions should create distance learning programmes, using e-technologies (Saeima of the Republic of Latvia, 2010).

It is important to the universities to ensure that courses are delivered by the lecturers who are highly-qualified, creative, progressively-minded, and well aware of theories and practices (experienced in practice and research) and who are interested in integrating the elements of digital education in their courses. The mission of university lecturers is to assist every student in comprehending and developing their personal traits and abilities, to encourage them to use technology in different situations and for different purposes.

Significant attention should be paid to lifelong learning, as we live in a very dynamic period when one speciality throughout the working life is not enough. It is advisable to develop a strategic action plan for competitive lifelong learning in Latvia with priority competencies defined, which needs to be acquired, based on the desired objectives to be achieved.

As regards improving the general level of digital education in Latvia and the necessity to focus on a sustainable strategy in order to meet the demands of the labour market, in the future it is advisable to conduct in-depth research into these fields, and researchers have to elaborate recommendations for the Ministry of Education and Science on the (1) possibility of development of youth digital competence in the education system, (2) and research needs to analyze how the collaboration among academics, policymakers and practitioners facilitate digital education management in order to become involved in the development of new approaches to enhance digital competence in educational contexts.

Abstract

The fundamental decision problem in the process of managing an (fast-moving consumer goods) FMCG industry is the development of a transport plan ensuring the right selection of vehicles for tasks and a rational distribution of the supply stream in the transport network. The specificity of delivered goods requires shortening the time of delivery and ensuring appropriate transport conditions. An important element especially in the FMCG industry is the quality of transport processes, which is part of the company's competitive advantage and leads to a reduction in the logistics costs of operations. In connection with the above, it is important to have tools supporting decision making in this area. This study assesses the possibility of using linear programming methods to optimize the implementation of transport processes based on the simplex algorithm. The objective function was to minimize transport costs. On the basis of daily estimation of chicken egg sales and the production capacity of suppliers, a mathematical formulation of the problem was made and limitations in the values of decision variables were indicated. Then, based on the results obtained, a freight transport plan was developed.

Keywords: Securing Delivery, Transport Issue, FMCG, Delivery Schedule

Introduction

The specificity of the transport industry is characterized by multidimensional decision problems in the area of transport means planning and management. They usually concern the optimization of the transport process by minimizing costs and empty runs, setting transport quotas, determining the minimum route in the communication network or the maximum stream of the transport network.

We are constantly looking for new solutions and methods to increase the efficiency of transport processes that affect the high level of end customer service. An important problem is therefore the planning and implementation of such transport work of motor vehicles, which will allow to minimize costs while using their maximum efficiency. Reliable provision of transport services based on economic efficiency is the basis of competitiveness in the transport industry, therefore methods for minimizing operating costs are constantly being sought.

The main aim of the article is to analyze the possibility of using the simplex algorithm in the decision-making process related to the rationalization of vehicle route mapping in an enterprise distributing products in the FMCG (fast moving consumer goods) network. A mathematical formulation of the problem was made based on the weekly sales estimation and daily eggs production capacity of suppliers. On this basis, an optimal distribution of the size of the supply stream has been developed, aiming to minimize transport costs. Then, the results obtained were summarized and directions of possible further works were indicated.

Review of the literature - condition of the problem

Ensuring the correct transport of FMCG loads plays a key role in managing the company operating in the above industry. It is estimated that about 30% of losses of fast moving products are caused by inadequate transport conditions. Therefore, the rational selection of vehicles for the implementation of tasks and the duration of the transport process are key factors influencing the decision making in the process of developing distribution plans. Effective planning and management of an enterprise's fleet is usually implemented by optimizing the allocation of the supply volume stream so as to maintain the quality of delivered goods and minimize transport costs.
The effectiveness of distribution processes and their quality significantly affects the logistics costs of business operations, but also their competitive advantage. The problem of route planning includes rationalization of deliveries from producers to recipients leading to minimization of transport costs in the network. In operational research, it is included in the group of vehicle routing or vehicle routing VRP (Vehicle Routing Problem) [17]. Efficient planning and management of an enterprise's fleet is usually achieved through the optimal allocation of vehicles to individual transport tasks. For this purpose, linear programming methods can be used, including those based on the simplex algorithm. They make it possible to plan the transport of goods in accordance with the adopted objective function, e.g. minimizing costs or time to complete tasks. The transport issue was formulated in 1941. by FL Hitchcock [7], while the algorithm for its solution was developed by GB Dantzig, and then introduced to economic sciences by Koopmans [32]. In the literature, the above tool is most often used to study transport problems (open and closed), transport and production problems, and to determine production locations or minimize empty runs.

The analysis problems of securing continuity of transport supply in costative is of interest to many studies available in extensive literature [14], [18], [30], [36]. The most frequently available studies are based on the functions of mathematical modeling [1], [3], [22], [28], [31]. The purpose of the research is to minimize the function of the overall costs of planned transport. To solve such problems commonly used simple algorithms, ie. Hungarian algorithm method, simplex method, the nodal analysis and the top-left corner transport matrix analysis [12], [14], [18], [36], [39]. Among the more complex methods, the minimum element of the cost matrix or the VAM (Vogel Approximation Method) should be listed [29], [33]. There are also numerous publications solving the problem of allocation by heuristic methods, i.e. genetic algorithm, particle swarm algorithm, or fuzzy sets [6], [12], [15], [21], [26], [27], [31], [39]. In addition, in practice, modern IT systems are increasingly used to optimize the allocation, which automatically develop the concept of an interactive planning system using specific automatic generation and optimization procedures. The programs allow not only the construction of the plan [18], [20], [38] but also its ongoing verification of implementation [3], [13], [22], [25], [28].

In transport practice, the problem of optimal allocation of tasks to means of transport is much more complicated and leads to the construction of significantly complex mathematical models, the solution of which requires the use of specialized algorithms and methods. Due to the dynamics of actions implemented in transport enterprises, very high algorithm speed is required, enabling planners to work in almost real time. In addition, the complexity of the issue is increased by numerous and difficult to define restrictions, e.g. special delivery conditions, provision of additional services as part of the transport task, designated time windows for loading and unloading, current changes in the transport plan, random events and multidimensional relations between the customer and the recipient and the driver. Constantly changing market requirements and the fact that rational allocation of tasks for means of transport is key in the aspect of economic efficiency of an enterprise, the above issue is a current problem and is of interest to many authors.

Transport issue with application of linear programming

Planning the allocation of means of transport to tasks was based on linear programming using a simplex algorithm. The algorithm for solving transport problems allows determining the volume of deliveries for which the sum of transport costs in the analyzed network will be the lowest. Transport network means a set of routes and transport points in a given area [7]. It can be represented by a structure in the form of a *G* graph, where:

$$G =< W, L > \tag{1}$$

where:

W – set of numbers of vertices of graph G having interpretations of transport nodes,
L – set of arches of the graph G, constituting direct connections between nodes in the transport network.

In each network, a set of transport nodes numbered with the index i [10], should be distinguished, for which W is a set of numbers of distinguished nodes (1):

$$W = \{1, \dots, i, j, \dots, \overline{W}\}, \tag{2}$$

where:

$\overline{W}$ – the number of transport hubs identified.

However, the elements of the set of arches are defined as follows [4], [11]:

$$L = \{(i, j): \eta_{ij} = 1, i \neq j, i, j \in W\}, \tag{3}$$

where:

η_{ij}– mapping of transport connections in the network.

In the transport issue, it is assumed that the transport network is bipartite and full (fig. 1). All available nodes can be divided into two groups, i.e. deliveries ($i=1,2,\dots,m$) and pickup ($j=1,2,..,n$). However, for each arc is determined unit cost of transport of the products transported c_{ij}.

Fig. 1: Bipartite and full transport network [12]

The solution to the above problem is to find transport volumes x_{ij}, that minimize the total cost of transport z, satisfying the needs of n customers in line with the supply offered by m suppliers [8]. The above network interpretation makes it possible to formulate the problem in mathematical form. The objective function is to minimize transport costs:

$$z(x_{ij}) = \sum_{i=1}^{m} \sum_{j=1}^{n} c_{ij} \cdot x_{ij} \rightarrow min, \tag{4}$$

under conditions determining:

– total inventory level in all warehouses:

$$\sum_{j=1}^{m} x_{ij} = a_{i,} \quad i = 1, \dots, m \tag{5}$$

– total demand of all customers:

$$\sum_{i=1}^{n} x_{ij} = b_{j,} \;\; j = 1, \dots, n \tag{6}$$

- and

$$x_{ij} \geq 0, \qquad i = 1, \dots, m, \qquad j = 1, \dots, n \tag{7}$$

If the inventory level in the warehouse is equal to the customer's demand, the data is a balanced transport task. In market conditions, the above assumption is most often not met, therefore unbalanced tasks are widely used. There are two variants:

- inventory in the warehouse is smaller than the needs reported by customers:
-

$$\sum_{i=1}^{m} a_i < \sum_{j=1}^{n} b_j \tag{8}$$

- the demand for products is less than the available stocks:
-

$$\sum_{i=1}^{m} a_i > \sum_{j=1}^{n} b_j \tag{9}$$

The authors in the article adopted a procedure based on the simplex method, because it is also possible to reduce unbalanced TP to balanced TP by adding appropriate variables. The essence of which is to study subsequent basic (acceptable) solutions presented in canonical form, using three main iterations:

- finding any underlying solution to the problem,
- checking the optimality of the indicated solution,
- constructing further acceptable solutions that are not worse than the previous one.

The search procedure ends when it is determined that the current solution is the best for adopted restrictive conditions. The results of individual stages are presented in the following simplex tables. Since the algorithm consists in studying the basic solutions of the canonical form, in the case of solving unbalanced transport problems before building the first table, all inequalities should be reduced to the form of an equation by introducing new variables. In the case of inequalities of the type "≤", additional free variables should be placed on the left, while with regard to the inequalities of "≥", free variables should be subtracted from the left and replaced by so-called artificial variables. Building the objective function, for free variables as coefficients one should take *0,* while for artificial variables so-called coefficients *M,* where *M* is a number approaching infinity [9].

Selection of transport means for implementing tasks in the transport network – case study

The subject of the research of this study is a trading company from the FMCG industry dealing in the sale of chicken eggs, which it purchases from selected producers (designated P1, P2 and P3). The company has signed contracts with 3 contractors for the delivery of goods to specific distribution centers (A, B1, B2, C1, C2). The contract specifies the annual minimum order quantity, which, according to the received monthly sales forecast for a specific type of product, is spread over 12 consecutive months, and these in turn into individual weeks and days. The location of individual manufacturers and customer distribution centers is shown in fig. 2 and in tab. 1 and 2.

Fig. 2: Arrangement of chicken egg producers and delivery pickups (own elaboration)

Tab. 1: Locations of individual distribution centers of the company's clients (own elaboration)

Contractors	Locations of distribution centers	Contracted, minimum annual order quantity
K1	A: Warszawa	6 900 000
K2	B1: Płock, B2: Wrocław	25 500 000
K3	C1: Kraków, C2: Szczecin	10 200 000

Tab. 2: Locations of chicken egg production plants (own elaboration)

Manufacturers	Production plant locations	Contracted, minimum annual production volume
P1	Julianowo	6 900 000
P2	Bydgoszcz	25 500 000
P3	Białystok	10 200 000

Each producer produces 6 types of chicken eggs, which, depending on the type of farming (cage [K], litter [SC] or free range [WW]) and size (M or L) are packed in the appropriate type of unit packaging (egg tray). The daily production capacity of individual suppliers is presented in tab. 3.

Tab. 3: Daily production capacity of individual suppliers (own elaboration)

Manufacturer	Size M			Size L		
	cage farming	free range	barn reared	cage farming	free range	barn reared
P1	88 816	9 033	22 399	50 720	20	5 453
P2	44 408	54 195	7 466	25 360	120	1 818
P3	14 803	27 098	44 798	8 453	60	10 906

In order to prepare the delivery, each of the unit packages is packed into collective cartons, and then onto a pallet in accordance with the following specification. For the type of packaging containing 10 eggs in size M and L, it is assumed that 1 EURO pallet contains 50 collective packaging and 600 individual packaging. The weight of one pallet is estimated at 415 kg. Deliveries are planned on the basis of product sales estimation developed for the following weeks of the year based on a 7-element moving average method. The survey was based on a forecast of individual recipients' needs prepared for the 10th week of 2019 (tab. 4-8).

Sum	**83 246**	**106 570**	**85 318**	**90 443**	**118 514**

Based on available daily estimates, it is planned to select means of transport for the tasks being carried out, assuming that trucks with a GVW of up to 24 tons and a load capacity of up to 33 pallets are used for transport. Having information about the forecasted sales volume of eggs to individual departments and about the daily production capacity of individual manufacturing plants, the supply volume was divided between individual suppliers and recipients in the supply network. For this purpose, the linear programming method using the simplex algorithm was used. The objective function was to minimize transport costs, which is implemented by striving for the lowest mileage of vehicles in the network. In the first step, the distance between individual branches in the network was calculated, which will be used to estimate transport costs. It was assumed (based on market research) that the cost of transporting products over a section of 1 km is PLN 2.6, and then the cost matrix is plotted. Then a tabular record of the transport issue was made and the search for the optimal solution began.

Tab. 9: Table of unit costs of transport, supply of producers and consumer demand (own elaboration)

		Recipients j=5					Supply producers A_i [palettes]
	c_{ij}	A	B1	B2	C1	C2	
Manufacturers i=3	P1	603.20	455.00	1 323.40	1 305.20	1 567.80	30
	P2	845.00	413.40	743.60	1 154.40	712.40	25
	P3	551.20	761.80	1 411.80	1 268.80	1 963.00	20
	B_j	10	7	9	27	16	
		Consumer demand [palettes]					

Then a mathematical formulation of the problem was made, where:

- goal function:

$$z\,(x_{ij}) = 603.20 \cdot x_{11} + 455.00 \cdot x_{12} + 1\,323.4 \cdot x_{13} + 1\,305.2 \cdot x_{14} + 1\,567.8 \cdot x_{15} + 845.0 \cdot x_{21} + 413.4 \cdot x_{22} + 743.6 \cdot x_{23} + 1\,154.4 \cdot x_{24} + 712.4 \cdot x_{25} + 551.2 \cdot x_{31} + 761.8 \cdot x_{32} + 1\,411.8 \cdot x_{33} + 1\,268.8 \cdot x_{34} + 1\,963.0 \cdot x_{35} \rightarrow min. \quad (10)$$

- conditions for recipients:

$$\begin{aligned} x_{11} + x_{21} + x_{31} &= 10 \\ x_{12} + x_{22} + x_{32} &= 7 \\ x_{13} + x_{23} + x_{33} &= 9 \\ x_{14} + x_{24} + x_{34} &= 27 \\ x_{15} + x_{25} + x_{35} &= 16 \end{aligned} \quad (11)$$

- conditions for producers:

$$\begin{aligned} x_{11} + x_{12} + x_{13} + x_{14} + x_{15} &\leq 30 \\ x_{21} + x_{22} + x_{23} + x_{24} + x_{25} &\leq 25 \\ x_{31} + x_{32} + x_{33} + x_{34} + x_{35} &\leq 20 \end{aligned} \quad (12)$$

- boundary conditions:

$$x_{ij} \geq 0, where\ i = 5, j = 3 \quad (13)$$

Since the supply of producers exceeds the demand, the above problem is an example of an unbalanced transport problem. Before calculating the transport plan, it should be reduced to a closed issue. To this end, a fictitious recipient *D* should be introduced whose demand (b_6) is equal to the excess of supply over demand, i.e.:

$$b_6 = \sum_{i=1}^{3} a_i - \sum_{j=1}^{5} b_j \quad (14)$$

The search for the optimal solution was based on the Solver application, which is an addition to MS Excel. Table 10 presents the obtained optimal solution.

Tab. 10: Optimal transport plan solution

x_{ij}	A	B1	B2	C1	C2	D	Sum	A_i
P1	0	3	0	27	0	0	**30**	**30**
P2	0	0	9	0	16	0	**25**	**25**
P3	10	4	0	0	0	6	**14**	**20**
Sum	**10**	**7**	**9**	**27**	**16**	6		
B_j	**10**	**7**	**9**	**27**	**16**			

Based on the above calculations, a graphic transport plan was developed (Fig. 3).

Fig. 3: Delivery distribution plan in the transport network (own elaboration)

For the solution thus obtained, the value of the objective function, i.e. transport costs, is PLN 4529.2 with a total vehicle mileage of 1742 km. In no case will the delivery amount exceed 33 pallets, i.e. will be carried out using one truck. Producer 1 should deliver eggs to recipients B1 and C1, producer 2 should supply recipients in western Poland, i.e. C2 and B2, while producer 3 will handle entities A and B1.

Summary

The aim of the article was to analyze the possibility of using linear programming methods based on the simplex algorithm to plan the distribution of the supply stream in the transport network. The enterprises operating on the FMCG market, specializing in the production and distribution of chicken eggs, were analyzed. The starting point for the conducted research were weekly sales estimates based on a 7-element moving average, juxtaposed with the values of daily production capacity of individual assortment groups among selected suppliers. On this basis, a mathematical formulation of the problem of dividing the supply stream in the transport network was made, and limitations of decision variables and the objective function were determined. The aim was to minimize transport costs. The division of tasks was optimized based on the linear programming method using a simplex algorithm. The results obtained allow the development of a transport plan between individual suppliers and recipients. The use of the above tool allows to minimize the logistics costs of business operations. In addition, by minimizing the total mileage of vehicles significantly affects the quality of transport processes carried out by reducing the time of delivery, reducing the possibility of losses in the assortment delivered. In addition, the above tool can be used for other purpose functions, i.e. minimizing delivery time, reducing empty runs, and minimizing the cost of delayed orders.

Intermittent Demand Forecasting Accuracy Measures

Mariusz DOSZYŃ

University of Szczecin, Szczecin, Poland
mariusz.doszyn@usz.edu.pl

Abstract

The aim of the article is to discuss forecasting accuracy measures for intermittent data. It is emphasized that many forecasting errors are inappropriate for intermittent data. Accuracy metrics for such data should feature specific properties. Division by zero must be avoided. They ought to be scale-independent (relative) and also unbiased. It is assumed that a given accuracy metric is biased if it favors underestimated or overestimated forecasts. In this article unbiasedness is particularly emphasized. It was demonstrated that such error measures like MASE favor underestimated forecasts, often zero forecasts. Therefore, other metrics are discussed, such as mean-based errors (mean-based MAPE), Cumulative Forecast Error, Number of Shortages, Periods in Stock. Moreover, the author's proposal is presented – namely the scaled Compound Error. All of these metrics are evaluated on the theoretical and empirical basis. In the empirical research presented measures are evaluated in terms of two forecasting methods: TSB and SES. Zero forecasts were also taken as a benchmark. Forecasts for 355 time series with high intermittence from a company selling work clothes and tools were analyzed. The final remark is that mean-based MAPE seems to be the best accuracy measure for highly intermittent data.

Keywords: Intermittent Demand Forecasting, Accuracy Measures, Mean-Based Measures, Scaled Compound Error

Introduction

Intermittent demand is defined as infrequent or sporadic. It means that in certain time periods the demand is equal to zero. It often happens that times series consist of only a few demands and many zeros. That kind of data requires specific forecasting methods as well as special forecasting accuracy measures. Indications as to which forecasting method is the best frequently depend on the accuracy measure selected. For instance, such error measures like MASE or MAE favor methods yielding lower forecasts, sometimes even zero forecasts. This is unacceptable with regard to stock management and consumer service level. Moreover, many conventional error measures, such as MAPE, could not be used, because they are undefined. For intermittent data the actual values are often zero, thus MAPE could not be computed.

Therefore, the main objective of this article is indicating what the most accurate forecasting error measures are for intermittent data. Furthermore, it is stated that unbiased forecasting error measures should be preferred. It was assumed that an error measure is biased if it favors underestimated or overestimated forecasts. The following forecasting errors will be verified: MASE, mean-based MAPE, Cumulated Forecast Error (CFE), percentage Number of Shortages (NOSp) and Periods in Stock (PIS). Additionally, a new forecasting measure is proposed by the author, one named scaled Compound Error (sCE). The new forecasting measure takes into account both forecast biasedness and precision. All of these error metrics are verified for the TSB and SES method. As a benchmark zero forecasts are also considered, chiefly to find which forecast errors favor underestimated forecasts.

The article is organized in the following manner. In the next section literature review is presented. In order to precisely describe errors, literature review has been combined with methodology. Aside from forecast errors, forecasting methods used in empirical research are presented, including references to literature. On the basis of theoretical properties the best forecasting errors are emphasized. The third

section is an empirical example in which forecasts for 355 intermittent time series and statistical properties of accuracy metrics are verified. In conclusions the best accuracy measures are pointed out and future research directions are indicated.

Methods and Literature Review

An interesting review of forecast accuracy measures is presented in Hyndman and Koehler (2006). Forecasting error measures are separated into five groups:

a) scale-dependent measures

b) percentage errors

c) relative errors

d) relative measures

e) scaled errors.

An ex post forecast error for a single period t is equal to $e_t = x_t - \hat{x}_t$, where x_t is demand (zero or non-zero) in a given period and $\hat{x}_t$ is a forecast. For intermittent data often $x_t = 0$. The most popular scale-dependent measures include:

– Mean Error (ME):

$$ME = 1/H \sum_{t=1}^{H} e_t = \overline{e_t} \tag{1}$$

– Mean Square Error (MSE):

$$MSE = 1/H \sum_{t=1}^{H} e_t^2 = \overline{e_t^2} \tag{2}$$

– Mean Absolute Error (MAE):

$$MAE = 1/H \sum_{t=1}^{H} |e_t| = \overline{|e_t|} \tag{3}$$

In these formulas errors are averaged in an ex post forecast horizon $h = 1, 2, \dots, H$. These are out-of-sample values. There are also different variants of the above measures, in which, instead of means, medians are calculated. They might be more robust with regard to outliers. MSE has an unreal unit, therefore Root Mean Square Error (RMSE) is sometimes recommended, where $RMSE = \sqrt{MSE}$. Mean error is important due to biasedness. Its absolute value informs how biased forecasts are. Scale-dependent measures are not useful for intermittent demand forecasting, because typically forecasts for many products are estimated. If each error has a different unit (or scale) it is not possible to compare (e.g. to average) them.

Percentage errors are scale-independent. The most popular is the Mean Absolute Percentage Error (MAPE). Also symmetric Mean Absolute Percentage Error (sMAPE) is sometimes applied, see Hyndman and Koehler (2006). If we assume that a percentage error for a single period t is $p_t = 100e_t/x_t$, then

$$MAPE = 1/H \sum_{t=1}^{H} |p_t| = \overline{|p_t|} \tag{4}$$

This measure is inappropriate for intermittent demand because it is undefined if $x_t = 0$, which is often the case. Moreover, if x_t is close to zero, MAPE is extremely skewed. Generally, percentage errors are recommended for variables measured on a ratio scale.

MAPE also puts different penalty on positive errors and on negative ones. For example, if in a forecasted period demand $x_t = 2$ and forecast $\hat{x}_t = 4$, then $MAPE = 100\%$. The error is negative in this case ($e_t = 2 - 4$). On the other hand, if $x_t = 4$ and forecast $\hat{x}_t = 2$, then $MAPE = 50\%$. In the second case the error is positive ($e_t = 4 - 2$), but of the same magnitude and MAPE is lower. To eliminate this disadvantage sMAPE was proposed:

$$sMAPE = 1/H \sum_{t=1}^{H} 100 \frac{|x_t - \hat{x}_t|}{(x_t + \hat{x}_t)/2} \tag{5}$$

The main problem with this metric is that if $x_t = 0$, which frequently happens for intermittent data, sMAPE is always equal to 200, no matter what the forecast $\hat{x}_t$ is. Additionally, if demand is low, forecasts will be low as well, which could make the denominator close to zero. It results in a highly skewed distribution of sMAPE. A division by a number close to zero highly increases this measure. The symmetry of sMAPE was also questioned in Hyndman and Koehler (2006), Goodwin and Lawton (1999) and in Koehler (2001). To sum up, percentage errors are not useful for intermittent demand data, mostly because demand is often zero, which makes that kind of errors undefined.

In Hyndman and Koehler (2006), to eliminate scale-dependence, measures based on relative errors are proposed. A relative error for a single period is $r_t = e_t/e_t^*$, where e_t^* is an error for the benchmark method. Naïve forecasts, where forecast for period t is a value from the previous period, often constitutes a benchmark, but for intermittent data it is often zero, which could render that kind of errors undefined. In this class of errors the Mean Relative Absolute Error (MRAE) and the Geometric Mean Relative Absolute Error (GMRAE) are recommended:

$$MRAE = 1/H \sum_{t=1}^{H} |r_t| \tag{6}$$

$$GMRAE = \sqrt[H]{\prod_{t=1}^{H} |r_t|} \tag{7}$$

The above measures may be applied to compare different forecasting methods, but e_t^* could be very small, so the problems resulting from the division by numbers close to zero remain.

Instead of using relative errors, relative measures might be applied. That kind of errors are presented in Hyndman and Koehler (2006), Syntetos and Boylan (2005) or Syntetos (2001). They could be used for scale-dependent or percentage errors. For instance, relative MAE is $RelMAE = MAE/MAE_b$, where MAE_b is a mean absolute error for a benchmark method. If $RelMAE < 1$, then the considered method is better than the benchmark. In Syntetos (2001) it is stated that relative error measures based on geometric mean are robust to outliers. Those kinds of measures require several forecasts for the same series to compute mean or median. In the case of a forecast for one period these measures are undefined (they become a relative error).

To sum up, relative measures are applicable to intermittent data, when forecasting methods are compared. The disadvantage is that if many forecasting methods are compared, there are many possible combinations. There are also non-parametric alternatives, such as Percentage Better (PB) or Percentage Best (PBt), where fractions of better (or best) forecasts are computed for a given method. However, these measures do not take error sizes into account, which could be misleading. For example, method A could yield slightly worse forecasts than method B in nine out of ten cases and a much better forecast in the last case. With regard to the PB (or PBt) method, method B, which is generally worse, will be preferred.

Relative measures and measures based on relative errors are scaled with regard to out-of-sample values (values for an ex post forecast horizon). In Hyndman and Koehler (2006) a new measure is suggested that is scaled on an in-sample MAE from the naïve forecasts. In this metric an out-of-sample MAE is scaled by in-sample MAE for the naïve method. It is called the Mean Absolute Scaled Error (MASE):

$$MASE = \frac{1/H \sum_{t=1}^{H} |e_t|}{1/(N-1) \sum_{n=2}^{N} |x_t - x_{t-1}|} \tag{8}$$

where N is the number of in-sample periods.

If $MASE < 1$, then a verified method is better than naïve (in-sample) forecasts. MASE cannot be computed only if all in-sample values are equal. In Hyndman (2006) MASE is strongly recommended for intermittent data. It is scaled, so it might be applied for large data sets. It could also be computed for all non-trivial cases and it is easily applicable to intermittent demand forecasts. However, two series with the same forecast errors, but different in-sample values will have a different MASE, what might be confusing.

Another widely known scaled measure is the MAE/Mean Ratio. It is a quotient of the MAE/ME, where all the values come from an ex post forecast horizon (out-of-sample values). The problem with this metric is that for intermittent data ME might be close to zero, what inflates variance and makes the distribution of MAE/ME highly skewed.

For intermittent demand data error measures like MASE or MAE could indicated as best these methods that yield the lowest forecasts. In Teunter and Duncan (2009) it is emphasized that sometimes even zero forecasts are pointed as being the best, what is unacceptable for inventory management. Therefore, in this article it is claimed that forecast accuracy measures for intermittent data should take into account biasedness.

Measures that fulfill this requirement are proposed in Prestwich et al. (2014), where mean-based measures are presented. In mean-based measures forecasts $\hat{x}_t$ are compared not with point empirical values x_t, but with the in-sample mean x_t^m. For intermittent data $x_t^m > 0$ if at least one in-sample value is positive, so these errors are always defined. In mean-based errors, instead of $e_t = x_t - \hat{x}_t$, we have $e_t^m = x_t^m - \hat{x}_t$, instead of $p_t = 100 e_t / x_t$, we have $p_t^m = 100 e_t^m / x_t^m$, and so on. The mean of time series could be set as a benchmark if there is stationarity. If series are non-stationary, then x_t^m should be a function of time. Furthermore, moving averages could be applied. Many mean-based errors can be defined. For example, the mean-based MAPE is estimated as:

$$mMAPE = 1/H \sum_{t=1}^{H} 100 \frac{|x_t^m - \hat{x}_t|}{x_t^m} \tag{9}$$

where x_t^m is an in-sample mean. It is always defined for intermittent data and is scale-independent, so forecasts for many time series could be compared. It also informs about the percentage deviations from mean level of demand rate. The disadvantage is that the actual values in the forecast horizon do not matter. If for two items in-sample means and forecasts are the same, mMAPE will also be the same, even if the actual values in forecast horizon are very different. Also forecasts equal to in-sample means are highly favored.

Interesting proposals concerning metrics important on account of biasedness are presented in Wallström and Segerstedt (2010). Measures like Cumulated Forecast Error (CFE), Number of Shortages (NOS) and Periods In Stock (PIS) are proposed.

Cumulated Forecast Error is the sum of errors in a given period:

$$CFE_H = \sum_{t=1}^{H} e_t \tag{10}$$

For unbiased forecasts CFE should be close to zero. However, CFE gives no information about forecast errors variability. Therefore, in Wallström and Segerstedt (2010) it is suggested that the maximum and minimum of CFE should be analyzed as well. $CFE_{max} = max_{t=1,2,\dots,H}\{CFE_t\}$ is the greatest shortage and $CFE_{min} = min_{t=1,2,\dots,H}\{CFE_t\}$ is the greatest surplus in the forecasted period. However, the maximum and minimum could be very volatile, especially in the case of outliers, thus they are not robust variability measures. Additionally, it could be noticed that CFE provides the same information as ME. These two measures (CFE and ME) might be identified, but CFE is useful in the context of the next measure (NOS).

Number of Shortages (NOS) is the number of times when CFE_t is over zero and demand occurs. If CFE_t is positive, demand is underestimated. For each period with positive demand it is checked whether, without a safety stock, shortage will occur. The forecasting method is biased if NOS is very low or very high. If NOS is low, there is a surplus and the forecasting method probably overestimates demand. In turn, if NOS is high, forecasts are possibly underestimated. To enable comparisons, in Wallström and Segerstedt (2010) a percentage version of NOS is proposed.

Percentage Number of Shortages in period $t = 1, 2, \dots, H$ is:

$$NOS_{p,H} = \frac{\sum_{t=1}^{H} NOS_t}{D} \tag{11}$$

where

$NOS_t = 1$ if there is a demand in period t and $CFE_t > 0$,

D – number of (positive) demands.

NOS demonstrates what would happen in a fictitious warehouse with no safety stock, if a given forecasting method is applied. It simulates fictitious stock for verified forecasting method.

The next measure, Periods In Stock, is also supposed to simulate forecast errors impact on stock level. It measures the total number of periods spent by a given item in a fictitious stock or the number of fictitious stock-out periods. This measure is presented in Wallström and Segerstedt (2010). PIS is related to CFE. To be precise, PIS is the integration of CFE over time, with a reversed sign:

$$PIS_H = \sum_{t=1}^{H} (\hat{x}_t - x_t)(H + 1 - t) = -\sum_{t=1}^{H} CFE_t \tag{12}$$

PIS measures not only forecast errors, but also how long it takes to correct these errors. If $PIS_H > 0$, then forecasts are overestimated and stock level is too high. If $PIS_H < 0$, then forecasts are underestimated and stock level ought to be increased.

The last forecasting error measure, the scaled Compound Error (sCE), is the author's proposal. It is scaled and takes into account both biasedness and precision. The formula is:

$$sCE = \frac{|\bar{e}_t| + \overline{|e_t|}}{\bar{x}_{1-N}} = \frac{|ME| + MAE}{\bar{x}_{1-N}} \tag{13}$$

where $\bar{x}_{1-N}$ is in-sample mean.

The scaled Compound Error is a sum of absolute value of scaled Mean Error and scaled Mean Absolute Error, where scaling is obtained through division by in-sample mean ($\bar{x}_{1-N}$). The problem with many forecasting errors is favoring the lowest forecasts, sometimes even zero forecasts. At the same time, those kinds of forecasts are biased. Scaled Compound Error provides the possibility of taking biasedness into account by factor $|ME|$. MAE represents forecast precision. Scaling in this metric occurs with regard to the in-sample mean, which is different than in mean-based measures, such as mMAPE. In mMAPE the in-sample mean is used in an ex post forecast horizon, instead of point empirical demand values. Therefore, in mMAPE forecasts are not compared with empirical demand. In sCE ex post forecasts are compared with empirical values and then they are scaled by the in-sample mean.

With regard to intermittent data there are many other ideas concerning forecast accuracy. For instance, in Snyder et al. (2012) and Kolassa (2016) it is claimed that not point forecasts but predictive distributions should be evaluated. There are also many inventory-based measures focused on inventory level and customer service. Those kinds of metrics are used in Syntetos et al. (2015), Teunter and Duncan (2009), Engelmeyer (2016).

To sum up, after a preliminary analysis, the following forecast errors were assumed to be the most accurate for intermittent data:

a) MASE,
b) Mean-based MAPE (mMAPE),
c) Cumulated Forecast Error (CFE),
d) percentage Number of Shortages (NOSp),
e) Periods in Stock (PIS),
f) scaled Compound Error (sCE).

All these measures are defined for intermittent data.

For the sake of clarity, only two forecasting methods are applied in the empirical example, TSB and Simple Exponential Smoothing (SES). TSB method is presented in Teunter et al. (2011). As a benchmark also zero forecasts (ZF) are tested.

TSB is dedicated to intermittent data. Generally, Croston's method is the basis for intermittent data (Croston, 1972). However, in Syntetos and Boylan (2005) or Syntetos (2001) it was proven that it is biased. Moreover, in Syntetos (2001) or Doszyń (2019) it was indicated that Croston's method sometimes works worse than much simpler alternatives, such as SES or Moving Average.

Generally, in the TSB method smoothing values are updated differently with regard to demand size. If $x_t > 0$, then:

$$\hat{x}_t^+ = \hat{x}_{t-1}^+ + \alpha(x_t^+ - \hat{x}_{t-1}^+) \tag{14}$$

$$\hat{p}_t = \hat{p}_{t-1} + \beta(1 - \hat{p}_{t-1}) \tag{15}$$

where

x_t^+ – demand size (non-zero demand),

$\hat{x}_t^+$ – smoothed demand size,

$\hat{p}_t$ – smoothed sales probability,

$\alpha, \beta \in \langle 0,1 \rangle$ – smoothing factors.

If $x_t = 0$, then:

$$\hat{x}_t^+ = \hat{x}_{t-1}^+ \tag{16}$$

$$\hat{p}_t = \hat{p}_{t-1} + \beta(0 - \hat{p}_{t-1}) \tag{17}$$

Sales probability is updated in each period, which is important with regard to obsoletes. A forecast is the product of an adjusted demand size and sales probability: $\hat{x}_t = \hat{x}_t^+ \hat{p}_t$.

In SES smoothing assumes the following form:

$$\hat{x}_t = \hat{x}_{t-1} + \alpha(x_t - \hat{x}_{t-1}) \tag{18}$$

Empirical Verification

In the research demand is identified with sales. It is justified because in the considered company consumer service level is close to one. The proposed forecast errors are evaluated with the assumption that for intermittent data the TSB method should be the best and zero forecast ought to be the worst, with SES lying between the other two. Hence, errors for which $TSB \succ SES \succ ZF$ are treated as being the best. As many as 355 real intermittent demand time series were analyzed. These are weekly data, where the first 205 weeks consist of in-sample values and the next 5 weeks are out-of-sample values. For the last 5 out-of-sample values ex post forecast errors are estimated. So, for each time series forecasts were calculated on the basis of 205 weeks and then ex post forecasts for the next five weeks were computed.

The data derives from a company selling mostly tools and work clothes. Weekly sales frequency, defined as a share of non-zero sales during 205 weeks, for each item was smaller than 0.20 and, on average, equal to 0.10. Descriptive statistics, but only for non-zero sales, are presented in the following table.

Table 1: Descriptive statistics for non-zero demand for all products (n – number of products, $Q_{1.4}$ – first quartile, Me – median, $Q_{3.4}$ – third quartile)

N	Min	$Q_{1.4}$	Me	$Q_{3.4}$	Max	$\overline{CV^2}$
355	1	1	1	2	2911	4.48

Source: own calculations.

With regard to quartiles, most of the products are slow-moving. The third quartile is equal to 2, so 75% of all sales were equal to 2 or less. However, the maximum is high and equal to 2911, thus there are also products sold in higher quantities (with a different scale). Furthermore, an averaged coefficient of the variation is high ($\overline{CV^2} = 4.48$). This is the result of outliers. The coefficient of variation for a given time series is a relation of variance and squared mean, but only for non-zero sales.

In the next step forecast errors were verified. The chosen characteristics of analyzed forecasting errors are presented in the following table.

Table 2: Descriptive statistics of chosen forecast accuracy errors for TSB, SES and ZF

		Min	$Q_{1.4}$	Me	Mean	$Q_{3.4}$	Max
MASE	TSB	0.00	0.05	0.49	1.62	1.18	81.60
	SES	0.00	0.05	0.43	1.64	1.21	81.60
	ZF	0.00	0.00	0.00	1.26	0.59	81.60
mMAPE	TSB	0.00	0.36	0.74	0.77	1.00	9.37
	SES	0.00	0.39	0.81	0.91	1.00	7.78
	ZF	1.00	1.00	1.00	1.00	1.00	1.00
CFE	TSB	-196.22	-0.79	-0.03	-	0.08	73.72
	SES	-180.83	-0.71	-0.02	-	0.36	74.71
	ZF	0.00	0.00	0.00	-	1.00	100.00
PIS	TSB	-221.15	-0.43	0.10	-	2.16	588.65
	SES	-224.12	-0.62	0.10	-	2.11	542.48
	ZF	-240.00	-4.00	0.00	-	0.00	0.00
NOSp	TSB	0.00	0.00	0.00	0.09	0.20	0.80
	SES	0.00	0.00	0.00	0.09	0.20	0.80
	ZF	0.00	0.00	0.00	0.10	0.20	0.80
sCE	TSB	0.00	0.21	1.58	5.18	3.42	273.33
	SES	0.00	0.17	1.39	5.24	3.67	273.33
	ZF	0.00	0.00	0.00	4.35	2.05	273.33

- Values not computed.
Source: own calculations.

Generally, values of MASE lower than one are preferable, because the forecasting method is then better than the naïve alternative. The median of MASE for all methods was lower than one, so at least half of the forecasts are performing better than naïve forecasts. The means of MASE are higher than one, which is due to outliers causing some errors to be very high. The maximum of MASE is extremely high due to outliers. In such cases positional measures like a median should be used to evaluate forecast quality.

The minimum of MASE is equal to zero for all forecasting methods. All quartiles and mean values of MASE are lowest for ZF and highest for SES, with TSB lying between the two. Therefore, with regard to MASE, zero forecasts turned out to be the best forecasting method. The explanation is that for intermittent data there are mostly zeros, so MASE is the best for ZF. However, zero forecasts are unacceptable due to inventory management and especially – consumer service level. TSB performed very similarly as SES.

Fig. 1: Distribution of MASE for considered forecasting methods

Source: own elaborations.

The forecasting method works better if mMAPE is lower. However, percentage absolute deviations from in-sample means and not from the actual values are calculated. The actual out-of-sample values do not matter, which is a disadvantage of this metric. Mean-based MAPE for ZF is by definition equal to one, so all the used positional measures are on this level. The minimum of mMAPE was the same for TSB and SES. The first quartile, median and mean are better for TSB. The median for TSB is 0.74, so percentage deviations from in-sample means are quite high and consist 74% of in-sample means. But for intermittent data in-sample means are usually very low, hence it was expected. For all the forecasting methods the third quartile was equal to one. The maximum was highest for TSB. To sum up, mMAPE seems to be promising for intermittent data. ZF was indicated as the worst method and TSB – as the best one, which is consistent with expectations.

Fig. 2: Distribution of mMAPE for considered forecasting methods

Source: own elaborations.

The next forecasting errors, CFE and PIS are scale-dependent, therefore means are not calculated. But positional statistics can be analyzed. These measures are important due to forecast biasedness. Generally, values close to zero are preferable. If CFE is positive, forecasts are underestimated, if CFE is negative – forecasts are overestimated. Ex post forecasts were calculated for the last 5 weeks. Hence CFE is presenting what happened with the stock level for a given item if it depended only on a given forecasting method. The minimum of CFE was lowest for TSB and only slightly better for SES. These values are the result of an extreme fall of sales in the forecast horizon, which causes forecasts to be highly overestimated. For ZF the minimum of CFE is equal to zero, because forecasts always remain on this level. The medians of CFE for all forecasting methods are close to zero, thus at least half of the forecasts are unbiased. High maximal values are the result of outliers. In those cases sales were very high in comparison to forecasts. The distribution of CFE (Figure 3) informs that TSB works in a similar way to SES. ZF errors dominate in the interval with zero, but there are also many underestimated forecasts in the last interval.

Fig. 3: Distribution of CFE for considered forecasting methods

Source: own elaborations.

PIS is the cumulated sum of CFE, but with an inverse sign. It informs about the number of periods that products spend in the fictitious stock. Differently from CFE, negative PIS is a result of underestimated forecasts. The medians of PIS are close to zero, so forecasts are generally unbiased. The results obtained for TSB and SES are similar. The minimum of PIS is an effect of outliers. The maximum is high for TSB and SES. For these cases forecasts are overestimated. TSB and SES are very similar due to CFE and PIS. ZF is underestimated. Overall, these errors provide the same kind of information.

Fig. 4: Distribution of PIS for considered forecasting methods

Source: own elaborations.

For all forecasting methods the values of NOSp are almost identical. Only the means are slightly different, but very close to 0.10, so for considered items, on average, there are 10% periods with shortages. The maximum share of shortages for all methods is equal to 80%.

Fig. 5: Distribution of NOSp for considered forecasting methods

Source: own elaborations.

For all forecasting methods the minimum of sCE is the same and equal to zero. Generally, descriptive statistics favors the ZF method. TSB and SES work in a very similar manner. The first quartile and

the median are lower for SES, while the median and mean are in favor of TSB. The maximum is an effect of an outlier and is the same for all methods. To sum up, sCE indicates ZF as the best option, which is unacceptable for inventory management.

Fig. 6: Distribution of sCE for considered forecasting methods

Source: own elaborations.

Conclusions

With regard to theoretical properties and empirical findings it could be stated that not all forecasting error measures are appropriate for intermittent demand data. Usually errors are calculated for large data sets, so accuracy metrics should be relative. Measures also ought to be defined for intermittent data, where actual values are often equal to zero. In this article, after a preliminary selection, six accuracy measures were analyzed: MASE, mMAPE, CFE, NOSp, PIS, sCE.

Overall, if one measure has to be chosen, it would be mMAPE. MASE favors underestimated forecasts, which could result in unsatisfactory consumer service level. In turn, CFE and PIS are interesting on account of forecast biasedness, but they are scale-dependent. Therefore, it is hard to verify these errors for many forecasts at the same time. But, to some extent, it could be achieved by means of their distributions, which was presented in the article. NOSp might seem to be useful, but in the presented research it was hard to discriminate forecasting methods due to this error. The author's proposal – sCE – takes into account biasedness, but despite this it also favored the lowest forecasts.

Mean-based MAPE behaved correctly. It is scale-independent and always defined for intermittent data. Therefore, this error measure could be recommended. The disadvantage of this metric is that the actual values in the forecast horizon do not matter, because forecasts are compared only with the in-sample mean. What is more, in order to use an in-sample mean as a reference point, series should be stationary. However, for intermittent data it is often an acceptable assumption.

In the future research mean-based error measures will be verified on different datasets with intermittent time series.

The research paper is written as part of the state grant for 2020 (№0851-2020-0034).

Abstract

Modern international relations show that the most developed and leading states often resort to armed force in order to ensure their own interests. Conflict prevention and preventive diplomacy should be the main way to overcome tensions in international relations. It is important that all states are equally protected from the global risks and threats and bear a common responsibility for their reflection. Therefore, the international community has faced with the need to create an effective mechanism for managing modern processes. A special role in solving this problem belongs to the UN, the unique universal mechanism to ensure international peace and security. At the same time, it is necessary not only to maintain the main responsibility of the UN Security Council for keeping peace, but also to strengthen the function of its control over the occurrence and settlement of conflict situations. The paper analyses the use of force in modern international relations and determines the directions for improving political and legal measures in this area.

Keywords: International Relations, Conflict Prevention, International Security, Use of Force.

Introduction

Currently, the scale of threats that can destroy international security, plunge the world into chaos and instability remains significant. These include the danger of nuclear proliferation, proliferation of biological, chemical and other types of weapons of mass destruction, the growing number of regional conflicts, the danger of a new round of the arms race, etc.

In accordance with international law, the grounds for the use of force against sovereign states arise in two cases. In the exercise of the state's right to individual and collective defense, or pursuant to decisions of the UN Security Council on the elimination of a threat to peace, violation of peace or an act of aggression. Arbitrary military measures bypassing the UN Security Council, including prevention of a 'humanitarian catastrophe' are inadmissible. Meanwhile, modern international relations obviously demonstrate that the most developed and leading states often resort to armed force in order to ensure their own interests. In this regard, it is necessary to more clearly define the legal aspects of the use of force in international relations. Conflict prevention and preventive diplomacy should be the main way to overcome tensions in international relations.

The purpose of the study is to analyze the use of force in modern international relations and determine the directions for improving political and legal measures in this area.

Research Material and Methods

During the research process, there were used the following research methods: system analysis, historical and legal method, and formal logical method, method of comparisons and analogies, and generalization. The problems of the legitimate and unlawful use of force and maintaining international peace and security were studied in the works of the following scholars: Kotlyar V.S. (1999, 2005), Davydov Yu.P. (2002), Tuzmukhamedov B.R. (2006), Kaufman Y. (1956), and Morgenthau H. (1967).

Research Results

The use of force in international relations is the use of the armed forces of states individually or collectively (as a part of coalitions) for the purposes and methods compatible with the UN Charter and other norms of international law. The main provision of the UN Charter, the prohibition against the use or threat of force in international relations, is stated in Article 2 (4): All members of the United Nations shall refrain in their international relations from the threat or use of force against the territorial integrity or political independence of any state, or in any other manner inconsistent with the Purposes of the United Nations. The term 'refrain' is used in subsequent UN documents as a prohibition. The Charter defines two situations of lawful use of armed force.

Firstly, these are collective actions to maintain or restore international peace and security (Article 42), carried out on the basis of the decision of the UN Security Council and under its leadership. Moreover, the use of armed force bypassing the UN Security Council is unlawful, for example, under the pretext of the responsibility to protect the population from genocide, war crimes, ethnic cleansing and crimes against humanity.

Secondly, it is the exercise of the right to individual or collective self-defense in response to an armed attack (Article 51). In this case, the state or states exercising the right to self-defense have to immediately report to the UN Security Council the measures taken. In this situation the key importance is the determination of the moment the attack begins, it is a moment when the right of self-defense arises.

However, these provisions enshrined in the UN Charter are regularly violated. For example, deployment of international forces in Kosovo in 1999, the bombing of Libya by NATO members in 2011, the invasion of the United States and its allies in Iraq in 2003, the invasion of British and French troops in Egypt in 1956, and the US intervention in Grenada in 1983 and others.

Make decision to use unilateral military force abroad, states resort to various arguments, mostly political rather than legal. Ensuring the democratic nature of political processes is perhaps the most unconvincing argument for the use of military force abroad. It opens up the broadest scope for manipulating public opinion and applying double standards. Thus, the UN Security Council resolution 940 adopted on July 31 stated that 'the goal of the international community is to remove the military leaders and restore democracy in Haiti' and that the situation 'continues to constitute a threat to peace and security in the region' (Official Website of the UN). Many Latin American countries were against the resolution. Mexico's UN ambassador, Victor Flores Olea stated that this resolution 'sets an extremely dangerous precedent in the field of international relations', because the crisis 'does not constitute a threat to peace and international security' (Knowledgr.ru). Cuban Foreign Minister Roberto Robeyn supported him. Brazilian President Itamar Franco also strongly opposed the UN decision, saying that it violates the basic principles of peaceful co-existence between countries. Uruguay pointed out that the situation in Haiti poses no threat to international peace and security, and its representative at the UN, Ramiro Piris-Ballon, said that his country 'will not support any military intervention, unilateral or multilateral' (Knowledgr.ru). Later, on January 17 1995, the UN Secretary-General Boutros Boutros-Ghali presented a report on the result of the intervention in Haiti, noticing the ongoing repression in Haiti, a complete lack of justice, worsening economic situation in the country (Knowledgr.ru).

The use of force abroad to protect human rights has also been significantly discredited over the past two decades. An example of unsuccessful military actions to ensure human rights was the events in the territory of the former Yugoslavia in the middle-second half of the 1990s. Violations by the Serbian participants in the conflict were used as a pretext for military intervention, while the illegal actions of the Albanian, Bosnian, and Croatian structures towards the Serbs were practically not restrained by anything (Nikiforov, 2011).

The conflicts that caused the greatest number of civilian casualties either did not meet with effective opposition from the international community (the Rwandan genocide, the First and Second Congo Wars), or were directly caused by the actions of foreign states declaring human rights protection (the Iraq war) as one of the tasks. The study analyses two examples of the use of force in international relations.

March 20–May 1, 2003 the combined forces of the United States and the anti-Iraq coalition conducted a military operation against Iraq. Official Washington initially called the military operation in Iraq 'Shock and Awe', later it got the name 'Freedom of Iraq'. The official reason for the invasion was the connection of the Saddam Hussein regime with international terrorism, in particular the Al-Qaeda movement, as well as information from the CIA about the weapon of mass destruction in Iraq, which subsequently did not find confirmation.

The decision to use military force against Iraq was supported by 45 states of the world. 32 states sent their military forces there. 98% of invading forces were provided by the US and the UK. The US and the UK planned to vote in the Security Council on the relevant resolution that they had developed, but refused, as Russia, China and France made clear that they were ready to use their veto power to block passage of a new Security Council resolution authorizing force against Iraq. Ignoring this, the United States launched a military operation. On March 20, 2003, Russian President Vladimir Putin issued a statement in connection with the start of the bombing of Iraq by the US and UK armed forces. In this statement, V. Putin called the military action against Iraq a big political mistake. The President of the Russian Federation stated that 'the military actions are being carried out in Iraq contrary to world public opinion, contrary to the principles and norms of international law and the UN Charter' (Ria.ru).

The war entailed the most negative consequences for the political, economic and humanitarian situation in the country and the region. In addition to numerous casualties, the war destroyed public infrastructure throughout the country, including water supply, electricity production, transport, employment structures, food supplies, etc.

Former British Prime Minister Tony Blair, in an interview with CNN in October 2015, apologized for the mistakes in the war and admitted that there were 'elements of truth' in the theory that the invasion of Iraq by the US and its allies in 2003 became one of the main reasons of the rise of ISIS (Edition.cnn).

In 1969, in Libya, under the leadership of Captain M. Gaddafi, the king was overthrown and a socialist regime established. During Gaddafi's reign, Libya entered the Guinness Book of Records as the country with the lowest inflation. In terms of GDP per capita, it ranked first among African countries. Education, health care and even the most expensive medicaments were free. The government provided free electricity to the citizens of Libya, and the price of petrol was 14 cents per liter. M. Gaddafi has implemented the world's largest irrigation project. The so-called 'Great Man-Made River', the world's largest irrigation project, was developed to provide fresh water resources throughout the country. The system was funded by the government of M. Gaddafi, who called it the 'eighth wonder of the world'.

In 2011, protests prepared by the West began in the city of Benghazi. On the 18th of March 2011, the UN Security Council adopted Resolution 1973, which a lot of people called the treat to international law. Firstly, the resolution extended the previous sanctions and introduced a number of new against Libya. Secondly, there was a demand for an immediate ceasefire, but without specifying the

addressees of this requirement. Thirdly, the resolution granted the right to participating countries to protect the country's civilians by all necessary means, except for direct military occupation of the country. It was not really prohibited to use armed forces or aerial attacks. Fourth, the sky over Libya was declared closed, with the proviso that any measures can be taken by the UN member countries to meet this requirement (Official Website of the UN).

On the 19th of March, a military operation began against the regime of M. Gaddafi with the participation of the armed forces of several states: the USA, the UK, France, Canada, Belgium, Italy, Spain, and Denmark. The result of the military operation was the actual collapse of Libya as a single state. The immediate damage from the NATO bombing is estimated at 14 billion USD. The Libyans have lost a number of social guarantees that they had previously. In the country itself, terrorism and banditry have spread. According to the representative of the Office of the United Nations High Commissioner for Refugees, Melissa Fleming, as of March 2, 2011, the number of refugees in the conflict area reached 180 thousand people (Ria.ru).

'The oil-rich country, a key departure point for some of the thousands of migrants travelling to Europe, once had one of the highest standards of living in Africa, with free healthcare and free education. But the stability that led to its prosperity has been shattered' (BBC.com).

The establishment of a unipolar world at the end of the 20th century contributed to the fact that the unilateral use of force became regular. However, improving the international legal framework for the use of force in international relations is possible, but it requires a more detailed examination.

1. The agreement on the meaning of aggression. It can be based on the provisions of UN General Assembly Resolution 3314 on 14 December 1974. In accordance with them, aggression is equated not only invasion, attack or annexation by the use of force, but also with bombardment by the armed forces; the blockade of the ports or coasts; the use of foreign armed forces located in the territory of a state in contravention of the conditions provided for in the agreement; the action of a state in allowing its territory to be used for perpetrating an act of aggression against another state. This list can be supplemented by a significant use of force against civilians of a foreign state, diplomatic workers, air and sea vehicles.

2. Agreement based on the principles of countering unlawful use of force in international relations. It should provide a list of issues and conditions that are not recognized by the parties to the agreement as circumstances justifying the use of force by some states against other states.

3. Treaty based on the principles of the use of force to counter the proliferation of nuclear weapons and weapons of mass destruction. This treaty should establish a clear procedure for establishing violations of the international regime for the non-proliferation of nuclear weapons and weapons of mass destruction. Its components should include a political charge; auditing; verifying audit findings; administering a warning; in case of urgent need – making a list of objects subject to targeted liquidation; forming multilateral military units carrying out the liquidation in accordance with the decision of the UN Security Council.

4. Treaty on the principles of the use of force to counter state-sponsored terrorism. The agreement should establish a procedure for establishing and verifying the facts of state-sponsored terrorism, making a list of objects and persons subject to targeted force on the territory of foreign states by multilateral forces acting in accordance with the decision of the UN Security Council.

All these international agreements will contribute to improving the regulatory framework for the use of force in international relations. At the same time, the main international legal principles for the use of force in international relations, already contained in the UN Charter, must be preserved.
Another possible solution to this problem is a 'reanimation' of the Military Staff Committee, a subsidiary body of the United Nations Security Council. It would be responsible for the operational command of the International Rapid Reaction Forces, which would include elite specila forces of permanent members of the UN Security Council and other states based on decisions of their

governments. These forces could be used to conduct 'hot spot' military operations against infrastructure facilities, organizational structures, and individuals identified by the UN Security Council as a significant threat to international peace and security (Minakova, Parkhomchuk, Golovin, and Bukreeva, 2018).

Conclusion

The changes that took place in the world at the end of the 20th and the beginning of the 21st centuries radically changed the conditions for the development of international relations. The prospect of their global transformation has been opened up. It is imperative that this process proceed evolutionarily, enabling the world community to adapt to new circumstances. In the new modern conditions, it is important that all states are equally protected from the global risks and threats and bear a common responsibility for their reflection. Therefore, the international community has faced with the need to create an effective mechanism for managing modern processes.

A special role in solving this problem belongs to the UN, the unique universal mechanism to ensure international peace and security. At the same time, it is necessary not only to maintain the main responsibility of the UN Security Council for keeping peace, but also to strengthen the function of its control over the occurrence and settlement of conflict situations.

Strengthening the international legal basis of the world order and ensuring the rule of law in international affairs should be one of the priority tasks of the world community.

Impact of Internal Conditions at The University on The Possibilities of Implementing EU Projects

Waldemar SZCZEPANIAK

Czestochowa University of Technology, Faculty of Management, Czestochowa, Poland
waldemar.szczepaniak@wz.pcz.pl

Abstract

Funds from the European Union budget obtained for the implementation of projects under long-term financial perspectives are also an opportunity for public universities to intensify their development. Possibility of obtaining EU funding is influenced by many factors, including internal factors at the university. Therefore, main purpose of the study was to analyze and assess impact of internal factors at the university on possibility of obtaining and implementing EU projects by universities. First part of the article is theoretical and has been prepared based on analysis of literature in the field of project management. Second part of the text is based on primary data collected during the survey among EU project managers implemented at public technical universities in Poland. Results of the study indicate that the strongest impact on possibility of obtaining EU funds and subsequent implementation of EU projects by public technical universities will be affected by increase in the size of owned infrastructure and the number of researchers.

Keywords: EU Project, Project Management, Public Universities, Internal Conditions.

Introduction

Currently, most entities, regardless of whether they are private or public entities, implement many projects simultaneously. Therefore, these projects compete with each other for limited organization resources. In the case of EU projects, part of funds necessary for their implementation comes from EU funds, which are allocated based on announced competitions. This means that units applying for support from EU funds also compete with other organizations for a limited pool of European funds.

In the process of absorbing EU funds, public universities compete with each other for limited resources available under programs directed to universities in a given country. It is noticeable that some universities are doing much better in this process than others. Therefore, it is important to make efforts to determine factors which increase absorption capacity of public universities.

Projects are implemented under time and cost constraints. This is particularly evident in the case of projects co-financed from external sources, including in particular EU projects, for which acceptable categories of costs that can be planned, as well as the time frame determined by periods of eligibility of these costs have been determined.

Key resource limitations are defined at the planning stage of an EU project, which is based on the assumption that changes in the project during its implementation may not lead to an increase in the value of funding. This means that if a given expense has not been planned in the project budget, then it will be possible to bear it only from university's own funds. An important limitation in this respect is also provision of resources necessary to make own contribution and cover any ineligible costs. Value of own contribution is defined in competition documentation as a percentage share in total costs of the project. This means that the greater the value of a project, the greater in monetary terms will be own contribution required by university. In turn, ineligible outflows may be known at the stage of budget preparation, when a given cost cannot be financed under the announced competition and will be planned in the budget. Most often, however, ineligible costs are unplanned and arise during implementation of the project.

Project constraints

Project is a special type of organized activity. Its main characteristics are temporariness and uniqueness. This means that each project has a specific start and end time, and there are significant differences between the projects that allow them to be identified as unique (Miedziński, 2012). A specific type of projects are projects co-financed by the European Union and falling under its policy, called EU projects (Domiter and Marciszewska, 2013). Receiving co-financing from EU funds is associated with compliance with specific standards and guidelines, which are also an element that distinguishes EU projects from other projects (Büttner and Leopold, 2016).

All projects, irrespective of the source of financing, serve to achieve assumed goals. Achieving them determines whether the project will be successful. Organizations that manage projects and project portfolios are more likely to achieve their goals, and these activities alone increase the probability of successfully completing the project. This is due to formalization of project planning process, defining procedures for its implementation, as well as placing greater demands on project managers (Anantatmula and Rad, 2018).

Bearing in mind that project management process is at least a medium-term process and in the case of large long-term projects, elements of strategic planning can also be included in project management process, which should translate into increased chances of successful completion of the project (Papke-Shields and Boyer-Wright, 2017). It is worth emphasizing that the use of project management methods and tools increases not only probability of successful completion of the project (achievement of goals and indicators) but also of successful implementation of project results and success of the investment in a project itself (Badewi, 2016).

In the project management process, various methods and techniques are used to ensure effective project implementation. Recently, the use of modern methods of automating data collection and processing enabling preparation of an integrated project plan has been increasing (Pellerin and Perrier, 2019). Attention is also paid to aspects of sustainable development as elements affecting successful completion of the project (Carvalho and Rabechini, 2017). Sustainable development is becoming increasingly important in implementation of projects, this is mainly due to requirements set by project stakeholders. This applies not only to taking into account aspects of sustainable development within emerging project products and results, but also to sustainable management of project implementation process (Kivilä, Martinsuo and Vuorinen, 2017). This is particularly important in projects co-financed from the EU, in which one of criteria is compliance with Community's horizontal policies, including principles of sustainable development. It should be emphasized that stakeholders play a significant role in the entire project implementation process and stakeholder management should become an element of comprehensive project management (Martens and Carvalho, 2017)

Ultimately, the project manager and his team have greatest responsibility for project's success. That is why it is so important to increase employees' knowledge and competence in project management. It is also important to use previous experience and use best practices. Development of project management should therefore go in the direction of strengthening competences of people and organizations (Radujković and Sjekavica, 2017).

Each project has some limitations (Mishra and Moktan, 2019). Because all resources, including human resources, are limited in every organization, individual projects compete with each other for access to them (Perez and Gomez, 2016; Ballestín and Blanco, 2011). Launch of many projects, regardless of assessment of availability of resources in the organization, will therefore lead to the fight for them, overloading employees, poor quality of products and project results, and delays in design work (Sońta-Drączkowska, Ziemski, 2010).

Second key limitation in projects is time. The period of implementation of EU project is specified in co-financing agreement, but it is possible to end the project earlier or extend its implementation period. Each time, however, this will require obtaining consent of the Intermediate Body and signing

an annex to the contract. What distinguishes EU projects is one more limitation in project implementation resulting from cost eligibility periods. Each financial perspective of the European Union has a specific funding framework. In the current financial perspective, eligible costs can be incurred between 1 January 2014 and 31/12/2023. This means that project implementation period specified in the grant agreement may not go beyond these dates. On the other hand, costs that would be incurred outside eligibility period automatically will become ineligible costs and will have to be covered by university's own funds.

Methodology of Research

The article is based on analysis of literature and results of own research. The project management study was conducted among EU project managers implemented by public technical universities in Poland in the previous financial perspective of the European Union. Studied population was determined on the basis of data from national information system SIMIK 07-13. An additional criterion, apart from the source of financing used in the identification of projects in the system, was implementation of a project by a public technical university alone or as part of a consortium / partnership in which the university was a leader. As a result, 659 projects meeting the adopted criteria were identified, out of which projects were selected based on random selection. A systematic sampling was taken as a sampling scheme for every k^{th} unit, with k = 5. As a result, every fifth completed project was drawn from each of eighteen public technical universities in Poland.

The survey questionnaire was prepared on an internet platform. An invitation to complete the survey was sent by email to the managers of the projects drawn. A total of 132 invitations were sent, to which 85 respondents replied by completing the questionnaire in full, which gave a 65% response rate. The survey questionnaire concerned one project and included closed and semi-open questions. The rank-based questions were based on a five-point Likert scale, where extreme answers were placed on opposite sides, very significant - completely irrelevant, so the middle answer "hard to say" was treated as "neither high nor low", " average".

A limited number of questions with a narrow scale of answers were factors facilitating the study. The survey questions were adapted to the specific terminology used in the implementation of EU projects. The main limitation of the study, especially in the case of questions relating to aspects of management, was the subjectivity of expressed opinions. This is due to the willingness of respondents to show their project as efficiently and effectively managed in the eyes of outside persons.

Research Findings and Discussion

Possibility of obtaining and implementing EU projects by public universities is influenced by many factors, which can be divided into external and internal factors. External factors include those over which the university has no direct impact, such as the amount of funds allocated under the competition and the requirements applicants that determine how many institutions will compete for funds. Second group consists of internal factors that can be shaped by universities to increase the chance of obtaining funding and successful completion of the project. During the survey, internal factors affecting possibility of obtaining EU funding and subsequent project implementation by public technical universities were assessed. Results obtained are summarized in Table 1.

Table 1: Assessment of the impact of increase of these factors on the possibility of obtaining EU funds by public technical universities

Specification	Very significant		Significant		Hard to say		Not relevant		Completely irrelevant	
	L*	U**	L*	U**	L*	U**	L*	U**	L*	U**

** number of answers, ** share in %*
Source: self elaboration based on research, n=85.

In the current financial perspective of the European Union, financial support for development of university infrastructure has been significantly reduced. This is due to assumption that necessary infrastructure was created as part of financial perspective for 2007-2013. Therefore, support was directed mainly to implementation of research and development projects using already existing infrastructure. Funds for this purpose in Poland come mainly from Intelligent Development Operational Program. This means that in current competitions, largest opportunities to receive funding are those universities that have the best-developed infrastructure, primarily research infrastructure. Therefore, it is not surprising that respondents' assessment indicates that greatest impact on the possibility of obtaining EU funds, and thus on the implementation of EU projects, has an increase in size of their infrastructure (74.1% of respondents described this impact as significant and very significant). Similarly, an increase in the number of researchers was mentioned almost equally often (64.7% of respondents described this impact as significant and very significant), which was caused by the same reasons. Having a modern laboratory base is of little use if the university does not have scientific staff who will work on it. Third factor is of a more general nature and is associated with an increase in the amount of equity (53% of respondents described this impact as significant and very significant). Given the growing share of competitions requiring the university to make its own contribution to cover part of eligible costs of the project, an increase in equity may significantly increase absorption capacity of EU funds by public universities.

In order to summarize results obtained, received answers were assigned to appropriate ranks, i.e. "very significant" 5 points, "significant" 4 points, "hard to say" 3 points, "irrelevant" 2 points and "completely irrelevant" answers 1 point. Basic descriptive statistics for the assessment of impact of the increase of these factors on the possibility of obtaining EU funds by public technical universities are presented in Table 2.

Table 2: Descriptive statistics for assessing the impact of increase of these factors on the possibility of obtaining EU funds by public technical universities

Specification	Average	Median	Mode	Standard deviation
Total assets	3,3529	3	3	0,8267
Equity value	3,3765	4	4	0,9255
Net revenues	3,0000	3	3	0,9512
Number of researchers	3,6824	4	4	1,1256
Number of administrative employees	3,4235	3	3	1,1890
Size of owned infrastructure	3,9412	4	4	0,8501
Other	3,3529	3	3	0,8267

Source: self-elaboration.

In-depth analysis with basic descriptive statistics allowed to indicate, based on weighted average values, that three key factors are the size of owned infrastructure (average = 3.9412, median = 4, mode = 4, standard deviation = 0.8501), number of researchers (average = 3.6824, median = 4, mode = 4, standard deviation = 1.1256) and the number of administrative employees (average = 3.4235, median = 3, mode = 3, standard deviation = 1.1890). The highest level of standard deviation was observed for both academic and administrative staff, which means that in these cases respondents had the most different grades. In addition, statistical analysis based on weighted average value showed that since the increase in the amount of equity (average = 3.3765, median = 4, mode = 4, standard deviation = 0.4728), the increase in the number of administrative employees has a greater impact on possibility of obtaining EU funds by public technical universities, although it has a lower median and dominant value. Acquiring an EU project, its implementation and completion each time involve preparation of relevant documents by beneficiaries. Therefore, participation of university administrative staff is important in this process. Increasing the number of administrative employees can therefore have a positive impact on improving internal processes at the university related to obtaining EU funds and subsequent project implementation. Summing up the analysis of factors affecting acquisition of EU funds by public technical universities, an impact map was developed, which is presented in Figure 1.

Figure 2: Map of influence

Source: self-elaboration.

At the center of the map is the absorption capacity of a public technical university, while individual factors regarding the interior of a university are placed around it. The greater the distance from the center, the greater the impact of a given factor on possibilities of obtaining EU funds and subsequent successful implementation of the project.

Conclusion

By applying for EU support for the implementation of development projects, public universities, like other entities, compete with each other for available funds. A limited pool of EU funds means that only certain projects will receive funding and will be able to be implemented. Many factors, including internal factors at the university, have an impact on success of acquiring and implementing EU projects.

Results of the study indicate that the strongest impact on possibility of obtaining EU funds and subsequent implementation of EU projects by public technical universities will be affected by increase in the size of owned infrastructure (74.1% of respondents described this impact as significant and very significant) and the number of researchers (64.7% of respondents described this impact as significant and very significant). It should be noted that this is confirmed by the way in which funds are allocated to the current financial perspective of the European Union, where emphasis has been placed on cooperation between science and business. This cooperation should be based on using existing infrastructure potential of the university. Thus, universities that have more developed infrastructure and have more scientists have a much greater chance of obtaining funds for EU projects.

Administrative staff is necessary to ensure an adequate level of project management, which translates into increased opportunities for successful completion of the project. The project manager and the team play a key role here, but without support of university's administrative units, it is not possible to efficiently spend funds and settle them under EU projects. Therefore, it is necessary to underline a need for proper preparation not only of the project itself, but also of the organization that plans to implement it, placing particular emphasis on project management, which is to enable effective project implementation under time and cost constraints.

Costs in EU projects are often associated with a need for universities to provide required own contribution and to secure funds to cover ineligible costs. Since it is not possible to unequivocally determine whether ineligible costs will occur and what their value will be, then universities should not engage all of their resources, some of them should remain at the disposal as a reserve for eventual coverage if they occur. Respondents pointed out a need to increase own funds at the university's disposal as one of internal factors having a significant impact on possibility of obtaining and implementing EU projects.

Public universities interested in increasing absorption capacity of EU funds should strive to develop their infrastructure and use it effectively. To this end, it is worth intensifying cooperation with an industry, which, by outsourcing research work to universities, gains access to innovative solutions and products, while universities acquire funds for purchase of equipment and employment of research workers. These funds are also partly allocated to administrative costs and profit generated will be an element increasing university's equity. Thanks to these activities, absorption capacity of EU universities will increase, and in consequence university will develop further and it will be able to intensify cooperation with industry. Undoubtedly, an additional effect of these activities will also be an increase in innovativeness of the country's economy.

Abstract

Proper nutrition is one of the key factors affecting the accomplishment of tasks by soldiers. Nutrition in field conditions takes place with the use of food rations, which include, among others, accessories, such as cutlery and disposable tableware and warmers. The Polish Armed Forces should meet the new demands of the modern battlefield. Involvement in various armed conflicts and peacekeeping missions around the world increases the demands for contemporary soldiers. Therefore, it must be provided with appropriate conditions to perform the tasks entrusted to them. One of the elements that can help soldiers can be modernization of equipment, including food equipment. The updating of the equipment can be associated with innovative heating techniques, e.g. using solar energy. The increasing use of food rations during field training causes that more and more post-consumer waste is generated. In the face of legal changes resulting in the withdrawal of certain plastics from the market, new solutions should be sought for biodegradable or compostable materials, the introduction of which will contribute to the broadly understood environmental protection.

Keywords*:* Equipment, Food Rations, Innovations

Introduction

Contemporary military operations are characterized by great diversity in terms of their character, dynamics and location. Due to the participation of the Polish Armed Forces in the structures of NATO and the European Union, Polish troops are involved in operations in various regions of the world, which are associated with activities in various climatic and terrain conditions.

Military logistics is inseparably connected with the concept of conducting military operations, which is understood in many ways. On the one hand, it is perceived as a scientific discipline about the planning and use of military materials and services resulting in support and maintenance of combat readiness. On the other hand, these are specific actions supporting combat readiness, which includes the following areas: materials management, repairs, transport, military infrastructure and hospitalization.

It can be assumed , follow Wiech and Stawicki (1992) the basic task of modern military logistics, that is securing the functioning of the armed forces, is still valid. However, the conditions for its functioning have changed. It is primarily associated with technological development and the opportunities offered by modern industry and science. Currently, the armed forces should be smaller, but more mobile and more effective in operation.

Quoting Smal (2010), military operations under the North Atlantic Alliance are characterized by the participation of many countries. Therefore, NATO member countries ratify and implement a number of standardization documents and allied publications. Those related to logistics include NATO's common policy in logistics or logistics doctrines. More detailed documents are standardization

documents, specifying common procedures and technical requirements for individual tasks carried out by logistics.

One of the components of modern logistics is supplying soldiers with food. Due to the role of nutrition in human life, nutrition of soldiers is a key issue in the functioning of the army, which during combat operations may find itself in a survival situation, without the possibility of supplying food. For this reason, an important aspect for modern armies is the design of food rations which will provide soldiers with adequate food, that can be prepared regardless of living conditions.

Purpose of the paper

The purpose of the article was to assess the suitability of equipment and accessories found in food rations or used in the process of feeding soldiers using rations

Research Hypothesis

Taking into account NATO standardization requirements for food rations, it can be assumed that the rations used in the Polish Armed Forces do not fully meet the requirements of STANAG 2937. The use of innovative solutions in the field of heating meals and water purification would increase the versatility of effective use of rations in the conditions occurring during operations. The verification of the above hypothesis was based on the analysis of documents constituting a source of information in the area of equipment and accessories used in food rations.

Food Rations in the light of NATO requirements

The success of modern military operations depends on many factors. The basic ones are the amount and quality of the measures used and the way they are used. Also during food rations designing, attention should be paid to their functionality and simplicity of use in various operating conditions. To facilitate the process of food ration designing according to NATO standards, appropriate documentation has been developed.

The current document was updated and released in 2019 STANAG 2937 Operational Rations for Military Use, at the same time, attachments regarding specific types of rations were developed: AMedP-1.11 "Requirements of Individual Operational Rations for Military Use" - edition B and AMedP-1.18 "Requirements of Group Operational Rations for Military Use ”- edition A.

Food rations according to STANAG 2937 should meet many requirements for interoperability, which ensures the efficient functioning of the feeding system and creates conditions for reducing the costs of operations. These requirements concern food products in rations as well as equipment enabling the preparation and consumption of meals.

NATO requirements for equipment and accessories for preparation of meals from food rations

The ability to heat meals in food rations is one of their most important features. Consuming a hot meal during increased activity, especially on the battlefield, has a positive effect on maintaining the appropriate level of soldiers’ morale. In addition, this is important especially in adverse weather conditions.

The necessary equipment needed to heat and consume individual rations was specified in the allied publication AMedP-1.11. It is recommended that this equipment would be inlcuded as component of ration. If such a solution cannot be used (e.g. due to practical reasons), it is allowed to create separate sets with the necessary accessories, which will be issued separately, but will be a component of the ration (with the established NSN - NATO Stock Number).

On the other hand, the AMedP-1.18 publication refers to group food rations, which specifies two types of rations – ready-to-eat group rations and cook-prepared group rations. In the case of ready-to-eat group rations, they can be consumed cold as well as hot.

Ready-to-eat rations can be self-heating or be adapted for heating in hot water. In addition, all necessary accessories for heating, dispensing and consuming meals should be included in the set of rations. If this is not possible, all accessories for heating, dispensing and consuming rations should be issued separately as a component of the ration (with the established NSN).

Cook-prepared group rations require more time and equipment to prepare. Their preparation and distribution require the use of some type of kitchen. It is also necessary to use appropriate kitchen equipment that enables heat treatment of dishes. It is recommended that accessories for issuing and consuming reasons are included in it. Just as the first type of group ration, packages with accessories for issuing and consuming rations can be issued separately.

Another issue is determining the requirements for water purification. In both mentioned annexes to the STANAG 2937 documentation, water-related issues are discussed in relation to two points - water requirements and methods of water purification. In the points related to the requirements for water, attention is drawn to the fact that most food rations require the use of drinking water to prepare meals or beverages. It is recommended to secure the amount of drinking water that will allow you to prepare the ration for its intended purpose. According to NATO documentation, the best way to avoid the need for water purification is to supply it in the right amount as drinking water through proper transport. Such proceedings will avoid problems with the delivery or use of water purification equipment. However, even a sufficient supply of drinking water for nutritional purposes may not be sufficient to avoid the need for water purification in all situations, especially when the use of field water sources is necessary during operations due to environmental conditions, distribution and encountered threats on the battlefield. In such situations, it is recommended to supply water purification equipment separately with the appropriate instructions for use (this also applies if some type of water purification agent is included in the package with the ration).

Equipment and accessories for preparing and consuming the meals used in food rations of the Polish Armed Forces.

The requirements included in STANAG 2937 documentation are requirements at the NATO level. Poland as a member country applies the provisions included therein. In addition, the requirements for food rations are specified in the national documentation. In Poland, these requirements have been included in the Defence Standards and Military Technical and Technological Documentation.

Currently in the Polish Armed Forces there are three types of Individual Food Rations: S-R, S-RG and S-RS and Group Food Ration PS. Each of these rations is intended to use during different operation. Depending on the type of ration, the relevant documentation contains a detailed description of the requirements for individual ration components - food products and accessories for heating and consumption of meals.

Meal Heating Possibilities

In pursuance of the most possibly effective meals heating, various methods are used. The type of heaters used in food rations of the Polish Armed Forces depends on the following factors:

- Type of ration,
- Meal's packaging and meal's size intended to heat,
- Time we have for heating,
- The numbers of meals and drinks to be heated.

Fig. 1. Elements of Individual Food Ration S-R with an individual flameless chemical heater

Fig. 2. Elements of Individual Food Ration S-RG with Military Kit for Cooking and Heating Meals

Each of the individual food rations used by the Polish Army consist meals to heat. To heat meals in ration S-R and S-RS an individual flameless chemical heater is used (Fig. 1). It is a single-use heater, used to heat meals in the form of canned food in soft aluminium packaging or water in the field conditions. For heating water, a suitable bag made of PA / PE material resistant to high temperatures is used. The flameless heater consists of two elements: a protective cardboard envelope and a plastic bag with a sachet of reaction mixture. The heating process is the result of an exothermic reaction between the reaction mixture and added water, which is an essential substrate to occur the reaction. What's important, it can be bottled water as well as water from a natural water reservoir. During the reaction, generated temperature is higher than 100°C which allows to heat canned food without fire within 15 min to 62°C.

On the other hand, meals occurring in ration S-RG are heated with usage of kit for cooking and heating meals (Fig. 2). The kit includes: folding metal burner - stove, two waterproof tubes: the first one with 8 fuel tablets and the second one with universal metal can holder, matches (min. 12 pcs.), storm matches (3 pcs.) and a plastic bag for a used kit. This kit allows you to prepare hot meals and drinks. The attached holder is adapted to hold or lift metal cans, which can also serve as a vessel for heating water. The construction of the set and the amount of fuel and matches allow for its multiple use. The fuel used does not release harmful substances when used. It also does not affect the organoleptic characteristics of prepared meals. The heated meals reach a temperature of approx. 65°C within 10 minutes, water - approx. 80°C.

Heating meals for groups of soldiers requires different solutions. If feeding in field conditions is done using a PS Group Ration, then field kitchens are used to prepare meals. This solution applies to canned food in thermoformed plastic trays for 5 or 10 people. This canned food is heated by immersion in hot water in specially designed baskets (Fig. 3). The heating time is about 40 minutes.

Fig. 1: Field Kitchen KPZ 100 with special basket.

It is worth to note that the use of PS Group Ration takes place primarily in the field conditions, when there is no access to fresh food. However, it may happen that as a result of stock rotation, soldiers in the garrison will be fed in the canteen by using this group ration. Then the food products in plastic trays can be heated in the stationary kitchen using available kitchen equipment. Thanks to the unification of the size of trays to the dimensions of ½ GN containers, it is possible to heat these trays in bain-maries with water or in convection steam oven. Preparing meals from PS Group Ration in places with kitchen facilities and a place to eat meals do not require a lot of effort and is an uncomplicated process.

Water Protection in Operation Conditions – Water Acquisition and Purification

During operation is extremely important to provide soldiers with adequate quantity and quality of drinking water. The human body in a high degree consists of water, so it is very important to prevent dehydration. Water loss means weight loss and consequently reducing the body's exercise capacity. It is particularly important to replenish fluids in the case of soldiers who are exposed to heavy water loss when performing combat tasks.

In connection with the above, particular attention should be paid to solutions in the field of acquisition and purification water for the needs of use in the preparation of meals and beverages, but not only.

The amount of water needed to prepare meals and beverages varies depending on the type of ration. To prepare beverages that are part of one set of S-R Ration, 250 ml of water is needed, which gives 750 ml for daily meals. Similarly, to prepare beverages that are part of the S-RG Ration you need water in the amount of 1750 ml for one set. On the other hand, to prepare meals from products that are in PS Group Ration, for a group of 10 soldiers it is necessary to have 20, 1 litre of water (breakfast – 10.1 l, lunch – 5 l, dinner – 5 l). These amounts do not include water necessary to heat the products.

Except using water for nutritional purposes, it is also necessary for sanitary and hygienic purposes as well as production and services purposes. In each of these areas, water must be safe for the user, especially microbiologically. Water contamination can be catastrophic for a single soldier and for a larger group also.

To realise the above objectives, in the Polish Armed Forces the responsibility for protecting water is divided into several entities:

1. Engineering Service - water extraction and purification (individual water purification agents and group filters),
2. Medical Service – allowing water for consumption (tests),
3. Food Service - water storage and distribution.

In the case of water purification devices, they are subject to Defence Standard NO-46-A200, specifying the requirements and test methods for consumables used in military water purification devices in field conditions. These materials include filtration and sorption materials, ion exchangers, disinfectants, coagulants and agents for the regeneration of cation exchangers. Currently, water purification accessories do not appear as a part of the food ration of the Polish Armed Forces.

In the article of Mazurczuk et al. (2011) we find out that supplying troops with water is one of the most important logistical undertakings. In operation conditions it is recommended to supply bottled water, safe for direct consumption. However, combat operations may cause that bottled water will not be available. Then, using appropriate equipment, activities relevant with extraction, purification and distribution water from natural reservoirs (ponds, lakes, rivers) are undertaken. For carrying out of above activities are responsible sappers from engineering troops. In the same paper we can read, that the process of water purification used in military equipment consists of several partial stages: oxidation and chlorination, coagulation, sedimentation, filtration and sorption on activated carbon deposits, chemisorption on catalysed activated carbon and ion exchange. The following types of water purification filters are differentiated:

1. Individual (pocket) filters for a single soldier;
2. Portable backpack or transportable sets for small units (teams, vehicle crews) - capacity 30-50 l / h;
3. Portable sets for companies, medical points, resistance points, command posts - capacity 200-500 l / h;
4. Transportable stations (trailers / cars) for branches from the battalion up - capacity from 1 to 15 m3

As we can find out in paper of Wewior (2015) it should be remembered that in water obtained in field conditions from any source, contamination always occur, therefore, especially in the context of preparing meals and beverages, such water must be brought to normative quality. The process of water purification must be oriented on many levels, because the pollution present in the natural environment can be of various origins, among others mechanical, biological, bacteriological or radioactive.

In the article of Mazurczuk et al. (2011) we can find information about currently water purification solutions in the Polish Armed Forces. One of them is the KSW-12 container water purification station. This station has the highest capacity (10-12 m3 / h). Its task is to treat surface and underground water from natural and purposeful admixtures for nutritional purposes. Another of the used devices is the FPW-350 filter (Fig. 4), operating in settling technology. This filter purifies water with a capacity of 350 l / h. His working time can be 150 hours, up to the exchange of deposits. For the FPW-350 operation, a generator set and an electric pump were used, which considerably facilitates filter operation. The next one small device is the FPW-50 filter (Fig. 5), designed for emergency supply of drinking water for self-standing teams (groups of 10 people). This filter is a device with a capacity of 50 l / h, and the purification of 20 litres of raw water takes place within approx. 25 min. from the moment of starting the electric pump for pumping water. This pump can be powered from the cigarette lighter socket or via an adapter, directly from the battery. In case of a failure of the electric pump or lack of power source, water can be pumped using the hand pump, provided with the filter.

Fig. 4. FPW-350 pump and filter unit KSW-12.

Fig. 5. FPW-50 pump and filter unit

As an element of emergency water purification, the Polish Armed Forces use also an individual filter. Its modified version for the civil market is presented in Fig. 6. This filter eliminates most of the harmful admixtures. As a sorbent in this filter, chemically oxidized DTO activated carbon was used, with an oligodynamic silver layer on the surface. In addition, water disinfecting tablets are placed in the cap. Their task is to eliminate microbial hazard. The filter can be used to purify 20 litres of water with a maximum capacity of 10 litres / day. Importantly, this filter has a certificate of compliance with STANAG 2136 MED.

Fig. 6: Modified version of Individual water filter.

Possibilities in preparing and consuming meals from food rations

Due to the increased mobility of conducting military operations, the requirements for the equipment have changed. These changes should concern the following areas:

- use in diverse climate and terrain conditions,
- using light and tough materials,
- applying eco-friendly solutions,
- simplicity of use.

Meeting the requirements mentioned above can significantly simplify operating of soldiers and give them the opportunity to focus on performing their tasks. In addition, the use of pro-ecological solutions may be an indication for other armies and society that the fight against global climate change can be fought on various fronts.

Solutions for Heating Meals

In the article of Forbes-Ewan et al. (2016), researchers noticed that food technology has paramount importance in the period leading up to war or between battles. It's time for soldiers to prepare and consume meals. The provision of adequate quality and quantity of water and food is the major determinant as to whether troops will be fit to fight. The earliest food preservation technologies, like smoking or drying did not need to be heated. To heat meal soldiers have used fire. Currently, when contemporary operations are faster and more mobile, soldiers need suitable equipment. The latest innovations in food technology are: flexible packaging, retort pouches and freeze-drying food. Both flexible packaging and retort pouches are made of multilayer material, which provides a barrier to moisture and air. Freeze-drying food need to be rehydrate by using water (hot or cold). Freeze-drying

food also need to have high-barrier packaging to maintain very low moisture (< 2% by weight). All of these products had longer shelf lives than commercial foods. But if soldiers want to eat hot meal, it necessary to heat pouch or heat water to prepare freeze drying meal.

For individual heaters, one of the options is to use reusable bags. An example of a set of reusable bags is shown in Fig. 7.

Fig.7: Set of reusable bags of Individual Flameless Heater.

Presented kind of set should consist of one reusable outer bag, optionally one drink bag (reusable) and depending on the number of meals to heat - the appropriate number of disposable chemical heating inserts. Reusable bags should be made of materials resistant to high temperatures. Multiple use is possible thanks to the use of an additional layer of aluminium in the bag structure. Heating meals and beverages is a result of contact of the reaction mixture with water. The size of the outer bag makes possible to heat the meal and beverage at the same time, which significantly reduces preparation time. Moreover, this requires usage of only one heating insert. In addition, taking into account modern ecological problems, endurance tests of bags made of plant materials are carried out. After usage, these bags could be biodegraded.

Also heating meals from a group food ration requires the search for alternative methods, which could increase the operational capabilities of troops. Currently, along with the transport of food rations, it is necessary to transport heavy field kitchens. A more mobile solution could be usage of the Multimeal flameless heater (Fig. 8). This heater allows simultaneous heating of meals and water / beverage in a specially designed bag, resistant to high temperatures. Using such heater allows simultaneous heating of 4 trays with food, i.e. preparing a meal for groups of different sizes, depending on the needs and the heated assortment.

To heat meal to a temperature 62°C takes about 40 minutes, while it takes about 20 minutes to heat a water / beverage to a temperature 80°C. Moreover, thanks to used materials this bag has insulating properties, which allows you to maintain the desired temperature when stored in low as well as in high environment temperatures. This is especially important when a meal cannot be eaten immediately. The construction and compact size allow to heat meals / beverages e.g. during a march. The heating process is possible thanks to the use of chemical heating inserts - the reaction mixture in contact with water (of any origin) leads to an exothermic reaction. In addition, the unused heater can be folded, making it three times smaller in size. The described properties as well as light and tough construction make this heater very useful in very different climate and terrain conditions.

Fig. 8: Multimeal flameless heater

In case of lack of access to water, an alternative method may be the electric heater (Fig. 9). This heater is used to heat 1 tray with food from group food ration or a bag with water. Optionally, it can be used to simultaneously heat several individual meals (e.g. in doypack). The most important feature of this heater is necessity to connect to an energy source. However, what is important, it can be energy from various sources. First of all, the energy source for the electric heater can be alternating current (230 V) as well as direct current (12 / 24V). In addition, after connecting a portable solar panel, the source of energy may come from the sun, which is particularly desirable e.g. in desert areas. Importantly, energy can be supply at the moment of use or it can be drawn from a previously charged battery.

Fig. 9: Electric heater and canned food in plastic tray

The above possibilities of sourcing energy allow for widely using the electric heater. By using alternating current, placing several heaters side by side allows you to create a self-service food point, that can be arranged in garrison as well as in field conditions. On the other hand, you can get energy by connecting the heater to the cigarette lighter socket. This solution allows to prepare a hot meal while a group of soldiers are moving in a combat vehicle. Technical solutions used in the electric heater are very innovative. Heat conduction takes place through nanocomposite heating mats, ensuring optimal heat distribution, while minimizing energy loss. The applied insulation technology means that the heat generated is directed primarily at the heated meal. In addition, highly specific fabrics with hydrophobic or waterproof properties were used. The above features make the heating process very effective.

The heating time to 62°C for trays with food from the PS group ration ranges from 40 to 60 minutes, depending on the assortment. It takes about 20 minutes to heat the water to 80°C. The temperature during heating is controlled by an electronic system in which the achievement of subsequent temperature zones is signalled to the user by coloured diodes and sound signals. Another important feature for user is light total weight of the electric heater, which is about 2,5 kg. In addition, the winter tests show that the temperature of the canned food in plastic trays being in the closed heater at an ambient temperature of 0°C dropped by only 2-4°C after 60 minutes from the end of heating[1]. It is extremely important in the context of using the heater in moderate climate conditions, especially in the autumn and winter season. In addition, the reliability and functionality of the electric heater is confirmed by the positive opinion of polish company Rosomak S.A., which has a long-term tradition in repairing, upgrading and producing special equipment for the Army.

The last proposed heating solution is the multifunctional set for cooking and heating meals (Fig. 10), combining the new solutions described above. This set consists of three heating systems that can be used depending on the conditions in which the meal will be prepared.

Fig. 10. The multifunctional set for cooking and heating meals.

The multifunctional set consists of the following elements: transport bag, electric heater, Multimeal flameless heater, sachets with heating substance, bag for heating water, solar system with battery, soup spoon, serving spoons, plastic 1 liter bag to measure water, cleaning tissues and disposable knife. The construction and components of the set allow for a complete independence in the preparation of meals in various climatic and field conditions during military operations. The mobility of the whole set is also affected by the total weight of only about 13 kg.

Solutions for Water Purification and Filtration

As we can read in articles by Smith (2018) and Mitchell and Ensley (2019) water is a nonnegotiable component of all military operations. The soldiers, which are water purification specialists, in a time of crisis take contaminated water from a natural sources and purify it, so it is safe for consumption, whether it be showering, cooking or drinking. Water shortages can completely degrade combat effectiveness. For example, the reliance on bottled water contracts throughout Operation Enduring Freedom and Operation Iraqi Freedom has lulled Army leaders into a complacent view of water supply. This approach potentially could be a base for disaster in future conflicts. After long wars in static and arid environments, Army leaders have neglected the potential of using water purification equipment and instead have relied on bottled water to meet their needs. Army doctrine must evolve to reemphasize the importance of bulk water purification and distribution. Thanks devices for water purification and distribution equipment, Army units hold the potential to be self-sufficient on the battlefield. Self-sufficiency increases a commander's flexibility and operational reach. To fully attain water self-sufficiency, high-level Army leaders must reallocate water purification equipment to enhance unit freedom in purification and distribution. Moreover at the field-grade level, Army leaders must emphasize the importance of training and maintenance on this equipment.

Accordingly also devices for water purification and filtration should be modified in a way to use on an increasingly larger scale, which help soldiers to perform easier their tasks. One of the modifications may be usage of solar panels that can power an electric pump in a group filter. This solution would be a great help in hot climate conditions, if it is impossible to draw energy from the cigarette lighter or battery. The group filter set with solar panel is shown in Fig. 11.

Fig. 11: The group filter with solar panel.

Solutions for Meal Consumption Equipment

Each set of food rations consist of accessories for consumption. In the case of individual food rations these are disposable cutlery and in the case of S-RG - disposable cups for beverages, additionally. Meals are consumed directly from the packages, which aims to minimize the volume and weight of ration. For PS Group Rations, each set includes disposable cutlery, cups for beverages, and trays. In addition, breakfast and dinner sets include disposable soup bowls. Due to changes in European legislation that will eliminate plastic cutlery from the market in the coming years, it will be necessary to use substitute materials in food rations. It is also worth considering alternative material solutions for plastic disposable trays.

Currently used disposable cutleries are made of polystyrene (PS). One of the materials which, due to its properties, could be a substitute for it seems to be polylactide (PLA), whose strength parameters are similar to polystyrene (PS). In the article of Faris et al (2014) mentioned, that polylactide are mostly made from renewable natural resources, e.g. wheat, potatoes, rice and corn. Modified PLA forms have properties similar to polypropylene and polyethylene. In addition, PLA has excellent organoleptic characteristics, making it ideal for contact with food. Starch based plastics have been processed into eating utensils, plates, cups and other products. Importantly, polylactide can be combined with many additives to optimize it for special applications. Under appropriate conditions, with controlled temperature and humidity, PLA is a biodegradable and compostable material. Also disposable straws that would disappear from the market in the future could be made from PLA.

Another element of ration that could be modified in the nearest future is a disposable tray, currently made of polypropylene (PP). In our opinion the material which could replace polypropylene is recycled PET (rPET – recycled polyethylene terephthalate). In the article of Makkam and Harnnarongchai (2014) mentioned that PET is widely used in industrial productions, such as beverage bottles, packaging films and textile fibers. Products made of rPET plastic may contain up to 100% recycled plastic if they meet all sanitary standards (resulting from contact with food). However, during the recycling process PET undergoes hydrolytic and thermal degradations, and consequently its viscosity, melt strength and mechanical properties. Despite the temperature restrictions on the use of rPET (deformation at temperatures above 65°C), it seems reasonable to consider the use of recycled PET material, especially in the context of changing law.

Plant-origin materials can be used to produce all the consumption accessories. An example set of accessories is shown in Figure 12.

Fig. 12: An example set of accessories made from ecological materials

Conclusions

The success of military operations depends on many factors. This paper presents solutions in equipment and accessories supporting soldier's feeding. This article describe solutions, which are using in the Polish Armed Forces and some which are innovative.

The use of new solutions in packaging of meals from food rations requires the use of new solutions in equipment for heating meals. This equipment should enable soldiers to prepare meals in all combat conditions. To meet the requirements of the modern battlefield, it is necessary to constantly modify the equipment solutions to make them more mobile.

It is important not to rely only on bottled water. More attention should be paid to the use of water purification equipment. It's because operating conditions can force the use of such solutions. Therefore, during field training, water collection, purification and distribution should also be trained in various conditions.

Along with the development of technology, it's necessary to use eco-friendly solutions skillfully. On the one hand they are more and more important for the world opinion (e.g. the use of biodegradable materials), and on the other hand they allow to use the full potential of the natural environment (e.g. by using solar energy to heating meals)

Value Innovations in Management of Organizations

Beata SKOWRON-GRABOWSKA

Czestochowa University of Technology, Management Faculty, Czestochowa, Poland,
E-mail: beata.skowron-grabowska@wz.pcz.pl

Abstract

Purpose – The purpose of this paper is to present the concept of value innovations, particularly in a model notion. **Design/methodology/approach** – The literature is examined from different perspectives. First, enterprises must present products and services in their offer that are of the nature of value innovations. Decisions taken by enterprises in order to instigate new consumer needs and satisfy them in an appropriate way in the new dimension of value were taken into account in the model decisions. Second, the tasks of the managerial staff in the process of competing and managing resources in enterprises with the aim of achieving value innovations were emphasized. **Findings –** An important emergent theme from the literature is the importance of taking a complete view, and the innovation nature in enterprises. At the same time, it is also apparent that this requirement to take such a complete and systemic view of the problematic issue of the management of organizations indicates the high level of variety and validity. Organizations that function on the market are obliged to undertake challenges that are formulated by consumers. This could done within an organization that develop value of innovation. **Research limitations** – The scope of this review is by design limited to a cross-section of the literature in this area. **Practical implications –** This review of the literature serves to highlight the dependence between innovation and creating value in management approach in enterprise. **Originality/value –** This study reviews a sample of literature in the field of value innovation, and in doing so provides some recommendations for the conduct of future research.

Keywords: Management of Organizations, Value Innovations.

Introduction

In the process of the functioning of organizations, there is a multitude of intricate problems that determine the aims and tasks for current and strategic activities. Among these problems are innovations that determine the development and position of enterprises on the market, which are of particular importance. However, global innovations have become a subject point of analysis in terms of value innovations. Their concepts are identified with the process of the discovery of needs by consumers with the simultaneous necessity to satisfy them. In the claim that there are new values for clients in the generated needs, the basis for the manufacturing and effective provision of new products and services is created, which are created from the beginning by consumers. These processes are identified with the value innovations and are reflected in the management of organizations, particularly by means of their consideration in business models. In business models organizations are located in terms of their resource potential that is directed towards value innovations as a result of the integration of the domain of supply and demand on the market.

The enterprise-client relation is of key significance when viewed from the perspective of the resource and competence spheres. In the area of management, decisions in the sphere of resources, inter-organizational relations and innovativeness and values are all significant. These processes have an impact on the competitive position by means of the skills of the managerial staff in terms of their potential to generate value, particularly value innovations. The potential of value innovations results from the novelty of the demand created for clients, while the offers of enterprises in this area are synchronized with the aims of the organization. The execution of the aims of enterprises in the challenges of the processes of management requires taking the issues of sustainable development into account.

An ideal premise for the implementation of sustainable management is that of value innovation, whose priorities are concentrated on the requirements of clients which are directed in an appropriate way. In this manner, a client accepts the sustainable development of enterprises as the consequence of activities preferred in the theories of the science of management, as well as the challenges of the sphere of business. The position of the capital of intangible goods is emphasized in terms of the opportunities to implement the sustainable management of organizations. The use of intangible goods is ensured by the personnel of enterprises.

Literature Review

The management of organizations determines a multitude of intricate problems, which in turn determine the functioning and development of enterprises. Enterprises are obliged to conduct constant analysis of the issues that have a strong impact on the range and directions of enhancing activities on a competitive market. The market currently creates important challenges for enterprises in the sphere of innovations, which have an impact on the competitiveness of an organization in a significant way. The evolutionary nature of innovations with the integrated dynamic development results in the emergence of a new phenomenon that is defined by the term value innovations.

In the areas of the innovative activities of organizations, particularly those shaping the position of entities/consumers on the market, there are premises for the generation of values in a systemic notion. Within this range there is a group of clients of the organization, for whom the system of values is created. With regard to the afore-mentioned relations, R. Krupski assumes that activities in the sphere of innovations, their scope, function and position in the systems of management render the definition of value innovations possible. The author further claims that activities in the afore-mentioned sphere "which transgress standards are termed value innovations." (Krupski, 2014)

An important element in the situation of creating the market by organizations is that of the needs discovered by the clients, coupled with the simultaneous awareness of the necessity for rapid fulfilment. (Pine, Gilmore, 2017), The fulfilment of this aim is rendered possible by innovativeness via the effective provision of the required new products or services, while taking account of the financial and cost aspects. (Plinke, Rese, Utzig, 2015) Fulfilment of such generated needs creates new values for clients. (Bertola, Colombi, Vacca, 2017)

The concept that integrates innovativeness with the new dimension of values for clients created by organizations may be acknowledged to be that of value innovations. The aforesaid definition is the result of the further claim that the notion of value innovations "is not the effect of the adaptive processes for the environment, but the manifestation of the creation of the environment." (Krupski, 2014) Enterprises should aim to cultivate the value innovations. (Krawiec, 2002)

The fundamental place for the creation of values relating to innovations is that of an enterprise that has the potential for resources at its disposal, which ensures the achievement of the surplus of revenue over costs. Individual review of the economic results of enterprises with the increasingly expanding inter-organizational relations creates the justifiable basis to state that it is essential to overcome the restrictive barriers. These barriers determine the boundaries of the activities of an individual enterprise.

It is purposeful to indicate resource management in a process notion for the continuation of analysis, while also to emphasize the importance of inter-organizational relations in the sphere of values and innovativeness. (Fig. 1)

Fig. 1: Value innovations in management

Source: Self-analysis on the basis of C. Mele and T. R. Spena, M. Kolurio, Co- creating value innovation through resource integration International Journal of Quality and Service Science Vol.2 No.1, 2010 (pp.60-78).

The diagram above may be acknowledged to be at the root of the problem in terms of the management of organizations geared towards value innovations. Interactions occurring in the area: innovativeness – value – management determine the spatial framework for preparing the models of the management of value innovations. The consequences of the appropriately prepared and implemented model variants facilitate the growth of the competitive position of enterprises.

In the opinion of W. Dyduch and M. Bratnicki, potential is being created in the skills of the managerial staff for the creation of values, while also the methods of capturing them (Dyduch, Bratnicki, 2015). Perhaps this fact is similar to the aims and results of value innovations as the team of managers in the organization creates the needs of clients.

The expansion and growth of intensity of the activities of enterprises occur in the value innovations as novelty results from the demand created for the clients. Such an offer is presented by enterprises that operate in differing model conditions. Decisions on the basis of models are aimed at achieving the goals of the organization.

The execution of the goals of an organization requires constant analysis of supply and demand on the market. The dynamics of the market cause the necessity to adjust to the changing requirements of clients. Value innovations are among these important requirements, but also taking the problems of sustainable management into consideration. (Fig. 2)

Fig. 2: Creating sustainable value chain

Source: Prepared on the basis of: J. Bee, P. Diby, M. Mbacke and B. Wettstein, Nestle: Sustainable Value Chain Management from the Farm to the Fork [In] CŚR (s.313-325) s.314.

Emphasizing the importance of the sustainable development of an organization is on the one hand the result of activities preferred in the science of management, whereas on the other hand social challenges and opportunities that are required by the current business goals (Regans, Zuckerman, 2008). The prevalence of the highest standards of business in multiple model concepts is the direct indication of value innovations. These innovations occur as a manifestation of the creation of new needs by means of the environment. The multitude of manifestations currently created may be exemplified by the restriction and even elimination of foil packaging. However, the problem of the client remains the lack of possibility to apply a substitute that is less harmful to the natural environment. The identification of threats however, is the potential challenge for sustainable management, while also innovations (Kwartalnik, 2017) for their creation require the capital of intangible goods.

The report on the state of intellectual property in the world in 2017 entitled "Intangible capital in global value chains" (Kwartalnik, 2017), which was published by the World Intellectual Property Organization is deemed to be meritorically significant. In this report, concentration was geared towards the value of intangible goods for the first time. It was stated that…" almost one third of the value of all goods created worldwide and sold in the period of 2000-2014 was constituted by intangible goods. It is assumed that thanks to intangible values, the value of products grows significantly. (Kwartalnik, 2017) Significant differentiation prevails in the sector as intangible goods are prevalent in one sector, while their significance is lower in other sectors. The afore-mentioned facts are taken into account in the problematic aspects of the sustainable management of organizations. The management of innovations illustrates great importance.

The central decision making points are the aims and challenges of the sustainable management of organizations. New innovative products fulfil the requirements of clients. At this juncture, innovative ties are created. The afore-mentioned ties are confirmed by the integrated nature of innovativeness, while also sustainable management in the context of value innovations. The process-product approach with the simultaneous consideration of the requirements of clients in the sphere of innovations have an impact on the decision making sphere by determining the area for the management of organizations of

a sustainable nature (Rutkowski, 2017). The afore-mentioned context causes the fact that it is expedient to refer to the approach, according to which it is important to ...”create a sustainable global financial system." (Mikołajek-Gocjena, 2018) In the context of the sustainable aims, the innovativeness of ecosystems is inherent, within the framework of which the suppliers, clients and other entities all function. An innovative ecosystem should be acknowledged by all entities as a priority in their business activities, one which is realistic to implement within the framework of the rules of radical innovations. (Rothaermel, 2017). The processes of management in this sphere are expanding automatically into value chains, if the particular enterprise is its link. (Wirtz, Elsaber, 2017)

In subject-related literature, the significance of personnel is illustrated in the process of sustainable management. Personnel resources constitute an important entity in the management and development of an organization. Ensuring the development of an enterprise is the result of sustainable management thanks to innovations (Martins, Zambalde, De Souza Bermejo, Henrique, 2019), which require the appropriate level of involvement of the employees. The personnel approves of the creative behaviour and while expecting the appropriate resources of knowledge creates inventions that facilitate innovativeness. As a result of this process, sustainable values of innovative values of an innovative nature are created by the employees. (Lee, Raschke, Louis, 2016)

In IT systems, there is an increasing concentration on virtual organizations. In these organizations, there is growing interest in innovations created in enterprises. Virtuality is identified with the ability to generate partnership ties between enterprises. The essence of cooperation is determined by complementary organizations cooperating in the chain with the aim of maximizing value for clients by means of the utilization of innovations. Independent enterprises are to be found in the virtual model of the organization which create a virtual value chain, which is geared towards one goal – the creation of value, (Walters, Rainbird, 2007), while maintaining sustainable management. The potential of innovativeness and creativity of enterprises, which constitute its genotype falls into the strategy of development. (Nowodziński, 2013) The execution of the strategies of innovation facilitates the achievement of the synergy effect, which subsequently ensures the growth of efficiency of the enterprise (Brzozowska, Szymczyk, 2018). By assuming the base point of these deliberations to be the creation of new values as a result of the execution of the strategies of innovation, it is possible to accept the indication as fact that the sustainable management of an enterprise ensures growth in value for clients. (Gutierrez-Renteria, 2017)

Hence, the appropriate strategy also facilitates the achievement of a high level of value innovation.

Empirical Research

The current market situation constitutes the sphere and trends occurring in the processes of management in enterprises. Indicating a client as the fundamental entity that has an impact on the domain of management in the supply and demand relation causes the fact that the enterprises search for activities that enable customer satisfaction on the market. One of these activities is the creation of the needs of a consumer in the form of value innovations. In enterprises that are geared towards innovative products and are characterized by a high level of added value, it is necessary to indicate the flexibility and speed in terms of reacting to the needs of clients. The EU programs lead to the fact that in the sphere of innovativeness in Poland positive dynamics of change are in evidence. Nevertheless, it is essential to underline the fact that the answer to the question of whether the direction chosen within the framework of the EU programs and specified in the economic organizations in the sphere of innovative development is integrated and strategic activity is significant. Analysing the innovative problems from the viewpoint of strategy indicates the accuracy of the view of A. Sopińska and P. Dziurski with regard to the significant…” degree of utilizing cooperation with the environment in the process of generating value for clients as a result of the innovation created, while also the internal mechanisms applied with the aim of acquiring some of this value for themselves.” (Sopińska, Dziurski, 2018), The authors assume that innovations may be executed with the aim of achieving value as a strategic aspect in the links of the value chain. A strategic aspect also requires taking account of the sustainable value chain, as well as value innovations. Value creation is an idea that has long been recognized in enterprises (Porter, Kramer, 2019) especially in the context of innovation. The execution

of value innovations is possible thanks to the cooperation of enterprises with various entities, particularly those representing the sphere of R&D. This may be exemplified by the research results regarding the cooperation of enterprises with universities in Spain. The research of Soetanto D.P. and Jack S.L. indicates that there is a positive impact of networks in enterprises and universities on the use of resources. The resources were divided into tangible and intangible resources. (Soetanto, Jack, 2013). Regarding the tangible resources, there is a prevalence in the use of equipment and laboratories, which were defined at the level of approximately 10%. The importance of intangible resources is over three times higher in the evaluation of enterprises and relates to the acquisition of university knowledge, the competences of employees, innovative projects and student apprenticeships. (Soetanto, Jack, 2013).

This research aims to build an understanding of the cooperation the relationship between enterprises and universities. In this case, the data were collected from participants in their working environment using short survey with three questions. This method allowed the capture of data about the research problem, and gave the researcher the flexibility to build hypotheses. A total of 76 interviews were conducted in different production enterprises with senior and middle managers. The businesses were selected using random sampling.

The analysis of each single question such that the results obtained from the interviews of each of the organisations can be compared. Interviews were listened, transcribed and analysed. Data analysis involving display and verification was ongoing throughout the analysis. The main intention was to comprehend how these firms engaged in collaborative relationships with universities and their importance for successful innovation.

The interviewees in all organisations confirmed analyses derived from the data. This provides a reasonable degree of validity. The survey was conducted in May and June 2019.

The author at hand conducted her own pilot research with reference to several significant issues in the sphere of innovations in enterprises. The essence of problems is characterized by the following questions and answers from the survey sheet:

Customer demand creates value innovations	**Entities cooperating with universities**		**Total**
	Yes	**No**	
Yes	**37**	**12**	**49**
No	**15**	**12**	**27**
Total	**52**	**24**	**76**

Does a dependency exist between the features of X “Customer demand creates the value of innovation” and Y “entities cooperating with universities”?

Enterprises that select the cooperation with universities would likely pursue a greater degree of innovation creation because that kind of cooperation would help to create value available for clients. Based on this rationale, two hypothesis are proposed:

H_o : The features of X and Y are dependent (there is a dependency between the case of a firm cooperating with a university and the case of whether the demand of clients creates the value of innovations).

H_1: The features of X and Y are independent (there is no dependency between the case of a firm cooperating with a university and the case of whether the demand of clients creates the value of innovations).

The Yates correction for chi-square statistics test:

The Yates correction. In small tables of dimensions of 2 x 2, it is possible to correct the approximation of the chi-square statistics by a reduction in the absolute value of the differences between the expected and observed multiplicities by multiplying it by 0.5 prior to the operation of increasing to the square (Yates correction). The correction causes a more careful evaluation and is usually applied in a situation when there are small multiplicities observed in the table in such a way that some of them are lower than 10 (a more thorough analysis of this subject may be found in the following: Conover, 1974; Everitt, 1977; Hays, 1988; Kendall and Stuart, 1979; and Mantel, 1974). (Help for Statistica 13.0 program)

$$\chi^2 = \sum_{i=1}^{2}\sum_{j=1}^{2}\frac{\left(\left|n_{ij} - \hat{n}_{ij}\right| - 0{,}5\right)^2}{\hat{n}_{ij}}$$

where: n_{ij} –empirical numbers, $\hat{n}_{ij}$ – theoretical numbers.

	Test statistics	p-value
Chi-square (df=1)	3.21	p= 0.0733
Chi-square corrected by Yates	2.35	p= 0.1252

At the level of significance of 0.05, there is no basis to reject the null hypothesis, namely whether the customer demand creates the value of innovations and has an impact on whether the firm undertakes cooperation with universities.

Resources of enterprises enabling the manufacturing of products and creation of services as value innovations	**Entities cooperating with universities**		**Total**
	Yes	**No**	
Yes	30	15	**45**
No	22	9	**31**
Total	**52**	**24**	**76**

Does a dependency exist between the features of X "**Resources of an enterprise that facilitate the creation of products and services as value innovations"** and Y "**Entities cooperating with universities**"?

	Test statistics	Column 2
Chi-square (df=1)	0.16	p=0.6918
Chi-square corrected by Yates	0.02	p= 0.8844

At the level of significance of 0.05, there is no basis to reject the null hypothesis, namely whether **the resources of an enterprise that facilitate the creation of products and services as value innovations** have an impact on whether the firm undertakes cooperation with universities.

Resources of enterprises enabling the manufacturing of products and creation of services as value innovations	**Entities cooperating with science and technology parks**		**Total**
	Yes	**No**	
Yes	**35**	**10**	**45**
No	**22**	**9**	**31**
Total	**57**	**19**	**76**

Does a dependency exist between the features of X **"Resources of an enterprise that facilitate the creation of products and services as value innovations**" and Y "**Entities cooperating with science and technology parks**"?

	Test statistics	p-value
Chi- square (df=1)	0.45	p= 0.5004
Chi-square corrected by Yates	0.16	p= 0.6860

At the level of significance of 0.05, there is no basis to reject the null hypothesis, namely whether **the resources of an enterprise that facilitate the creation of products and services as value innovations** have an impact on whether the firm undertakes cooperation with science and technology parks as the sphere of R&D.

The aforesaid analysis confirms the theory that the processes of creating value innovations are aided by the cooperation of enterprises with scientific and research entities, particularly of the nature of sustainable cooperation, which determines the management of resources and the supply and demand relation on the market.

Summary

The analysis of the theory of management presented in the sphere of value innovations, while also the pilot research conducted facilitate the formulation of conclusions. The fundamental conclusion that is necessary to accept is the fact that the importance of value innovations is rising in the business activities of enterprises as a derivative of the cooperation between consumers and enterprises with reference to the creation of needs, while also the possibilities of satisfying them. Consequently, there is a subsequent integration of supply and demand on the market. The processes of generating value innovations require the cooperation between enterprises and scientific and research entities. The basis of the evaluation of cooperation constitutes the research results on enterprises and universities in Spain, which reveal the fact that intangible resources create innovations. The author at hand conducted an evaluation of customer demand for the creation of value innovations in a pilot research study. Enterprises cooperating with scientific and research entities generate value innovations for clients. Their source is integrated and sustainable resources, particularly intangible resources.

Future Research Topics

Further studies should be made on the development of cooperation between enterprises and universities,. Also, further empirical research should be made to facilitate measuring the relationships between universities and enterprises. Furthermore, the possibilities of creating business model of cooperation should be analysed.

Determinants of the Technology Innovation Implementation in Small and Medium-Sized Enterprises

Małgorzata OKRĘGLICKA

Czestochowa University of Technology, Częstochowa, Poland
m.okreglicka@wp.pl

Abstract

Technology is the main factor of efficiency and competitiveness of modern enterprises. The implementation of technological innovations not only allows to achieve a competitive advantage, but is an important factor in the survival of an organization. Therefore, it seems advisable to constantly research the causes and benefits related to the implementation of new technologies in various types of organizations. These analyzes allow for more effective use of appropriate management tools and methods, which will translate into operational efficiency. The main aim of the research is to diagnose and assess the level of determinants and expected advantages of technology innovations implementation in enterprises. The additional aim of the research was to establish if there are correlations between the above variables and the management style in enterprise. To achieve of the main aim, a survey was realized in 2019 among 160 small and medium-sized enterprises in Poland. Using descriptive statistics, the intensity of impact of specific determinants and advantages of implementing technological innovations was indicated. In addition, independence of perception of these factors has been demonstrated from the management style in enterprises.

Keywords: Innovations, Leadership Style, Management, Smes, Technology

Introduction

Many reasons confirm the attention paid to small and medium enterprises (SMEs) in management literature. Basically, SMEs create the largest group in the business system including 99.8% of the corporate sector in Europe (European Commission, 2018; Havierniková et al., 2017). Just because of that, SMEs play a fundamental role in economic growth and stability. The importance of new technologies and innovations for competitiveness and growth of enterprises seems to be a truism among researchers, managers, and policy makers (Martínez-Román et al., 2019). Since Schumpeter (1942) stated that innovation is an essential factor for company development and economic growth of the country, the definition of innovation and factors to enhance it within businesses, they have become a primary concern to researches of innovation for the last decades. Despite its importance, knowledge on innovation in SMEs remains incomplete and inconsistent in the literature (Amara et al., 2008; Lemańska-Majdzik, Sipa, 2015).

Definitions of innovation are varying, but generally it refers to new approaches or solutions, which result in meaningful improvements. They include the creation, development or implementation of new or better ideas according to production, services, strategies, procedures etc., which finally generate added value for economy and society (MacNeil et al., 2019). Innovativeness is also described as the degree to which an organization implements new ideas or technology in relation to their competitors to gain competitive advantages relative to time, cost, and quality of products and services. Hence, innovations are not only a means of survival in the contemporary market but is also an important driver of growth, productivity, and competitiveness (Chege, Wang, 2020). Moreover, it is considered to be the key element of organizational sustainability and regional advantage in the era of non-linear dynamics and rapid change (Sharma, 2018). In order to pursue new market opportunities, entrepreneurs endeavor to bring innovation in the offered products or services, and, indirectly, entrepreneurship plays a key role in boosting the economy (Zeb, Ihsan, 2020). From this point of view, innovations are important not only to business performance but also to society to the extent it is related to employment,

productivity and growth. In this sense, diverse countries promote policies in order to leverage research, development, and innovation (Cardoso et al., 2020). Although coexistence with innovation involves risks and barriers for companies, this is one of the main ways to gain competitive advantage (Biancolino et al., 2013).

The remainder of this paper is organized as follows. The second section discusses a literature review with detailed theoretical context that describes different aspects of technology innovations. The third section discusses the research methodology. Section 4 presents the results of empirical research, while section 5 covers the conclusion, implications, and recommendations for future research.

Literature Overview

The technological innovation refers to the process of technology and economic integration, bearing in mind the fact that the main purpose of technological innovation is the commercial application of technologies and market success of new products and services (Liu et al., 2012). The technological innovation in enterprise refers to use the new knowledge, new technology, new ways of production and operation solutions to increase market shares and capitalize the market value of the technical and economic activities through improving quality, innovative products, and innovative services (Zheng, Yao, 2011).

Technology innovations are described as an approach that provides a competitive advantage to an enterprise (Chege, Wang, 2020) by assisting in market diversification and generating new commercial opportunities (Damanpour, Gopalakrishnan, 2001). They enhance service quality, improve employee productivity, and lessen operational costs (Karadag, Dumanoglu, 2009; Kuncová et al., 2016). Technology innovations will develop a novel decision-making behavior, and will evolve over time. As technology matures, technological opportunities are relatively easy to spread, which means that technological innovations become the foundation of organizational values and sustainable development (Ho et al., 2029).

To bring out the advantages of technological innovations, work processes and organizational resources need to be properly adjusted (Burge, 2014) so that the structure of the organization, its human resource management as well as resource allocation could take advantage of the technology implementation. However, a crucial aspect in the assimilation of technological innovation is the psychological needs of the employees and their approach to these innovations and to the coexisting changes in organizational processes. In practice, employees very often resist to changes, and are willing to prefer known organizational culture and climate over new ones; in this way, the implementation of technological innovations can create a sense of uncertainty and announce the addition of new tasks that many employees definitely prefer to avoid (Hasgall, Ahituv, 2018; Fiala, Hedija, 2019).

For SMEs technological innovations are particularly important. SMEs are able to differentiate themselves among their global competitors when they implement up-to-date technologies and head towards the digitization of business, as well as develop creative products which allow them quickly respond to the new market dynamics (Gupta, Barua, 2016; Bagheri et al., 2019).

Leadership is crucial for effective functioning of any organization. The fundamental of leadership is its persuading power on human resources as an organizations' source of competitive advantage, and the resultant outcomes (Gemeda, Lee, 2020; Betakova et al., 2018). The leadership style determines many aspects of economic activity. It affects the attitudes of organization members, the organization of tasks and processes, and openness to changing environments.

There is a lot of systematization of leadership styles. One of the basic is the traditional leadership distinction proposed by Lewin et al. (1939), who has specified 3 major leadership styles (Sousa, Rocha, 2019): autocratic, democratic and laissez-faire. Each of these styles has many advantages and disadvantages and one cannot conclude on the obligatory advantage of one of the styles over the other when it comes to the effectiveness of the organization.

Methods

The main aim of the research is to diagnose and assess the level of determinants and expected advantages of technology innovations implementation in enterprises. The additional aim of the research was to establish if there are correlations between the above variables and the management style in enterprise. To achieve of the main aim, a survey was realized in 2019 among 160 small and medium-sized enterprises in Poland.

The research group consists of small and medium-sized enterprises (SMEs), because of this, the research group can be described as purposeful. The enterprise sample was selected in convenience way, and for this reason, the results of the research could be treated as initial and should not be generalize.

To assess the determinants and expected advantages of technology innovations implementation the 5-point Likert scale was adopted. Then, descriptive statistics for variables was presented. The next step of the research was a calculation of Kendall Tau coefficient, as one of the most commonly used coefficient within non-parametric methods, for p-value = 0.05 between the above factors and management style, which was assess as intensity on a 5-point scale of one of the main management styles, i.e. autocratic, democratic or laissez-faire style in managers opinion.

Within the group of determinants, which was analyzed by implementation of technology innovations, there are six factors:

D1. Need to reduce / optimize costs
D2. The need to gain a competitive advantage
D3. Willingness to improve the quality of products / services
D4. Customer expectations for a lower product / service price
D5. The need to improve the way the company operates
D6. Opportunities for obtaining subsidies for innovative solutions

Expected benefits combined with the implementation of innovative technological solutions in enterprises eleven factors were selected:

A1. Improving the quality of products / services
A2. Performance improvement
A3. Cost reduction / optimization
A4. Improving resource efficiency
A5. Increased flexibility of actions
A6. Better matching to customer expectations
A7. Less downtime, breakdowns
A8. Higher company profitability
A9. Acquiring new customers
A10. Increasing the scale of production of products / services
A11. Entering new markets

Results

Among the determinants of the implementation of technological innovations, the desire to improve the quality of products and services was indicated as the most significant (mean of answers = 4.28). High indications were also obtained by the factor regarding the need for competitive advantage (mean = 4.20), which was also characterized by the lowest standard deviation, which indicates a significant uniformity of response (Fig. 1). In turn, the lowest grade was obtained by the factor related to the possibility of obtaining subsidies for innovative solutions, where also the divergence of grades was the largest (St. dev. = 1.08).

Fig. 1: Descriptive statistics for determinants of the implementation of technological innovations (n=160)

When examining the relationship between factors affecting the implementation of technological innovations and the intensity of a particular management style (Tab. 1.), one should point to correlations of weak or very weak intensity, which has been statistically confirmed for many factors. It should therefore be concluded that the strength of the impact of individual factors on technological innovation does not significantly depend on the style of business management.

Table 1: Kendall's Tau correlation analysis (p<0.05)

leadership style	D1	D2	D3	D4	D5	D6
autocratic	-0,07[i]	-0,13	-0,21	-0,07 [i]	-0,11	-0,08 [i]
democratic	0,11	0,14	0,21	0,15	0,08 [i]	0,15
laissez-faire	-0,03 [i]	0,15	0,14	0,09 [i]	0,02 [i]	0,05 [i]

[i] *p<0.05*

The analysis of benefits from the implementation of technological innovations, expected by entrepreneurs from the SME sector, indicates that higher profitability of operations as a result of technological development is expected (average answer = 4.43). Entrepreneurs expect similar improvement of efficiency in the company, and in this case it should be pointed out that the answers are significantly uniform (0.61).

The least significant for entrepreneurs in the empirical study turned out to be the benefit of greater flexibility of actions (average = 4,025), which probably results from the characteristics of small business, which is somewhat flexible in nature. Similarly, the factor related to the reduction of downtime and failures (average = 4.09) was obtained.

Fig. 2: Descriptive statistics for expected advantages of the implementation of technological innovations (n=160)

As in the case of the determinants of the implementation of new technologies, there is a weak correlation between the benefits of this implementation and enterprise management styles. For statistically significant results ($p < 0.05$), Kendall's Tau coefficient ranged from 0.00 to 0.08, which in practice indicates that adopting a specific management style does not affect the perception of the importance of specific benefits from technological innovations.

Table 2: Kendall's Tau correlation analysis (p<0.05)

leadership style	A1	A2	A3	A4	A5	A6	A7	A8	A9	A10	A11
autocratic	-0,11	0,00 [i]	-0,01 [i]	-0,12	-0,17	-0,12	-0,02 [i]	-0,11	0,02 [i]	0,04 [i]	0,01 [i]
democratic	0,06 [i]	0,04 [i]	0,07 [i]	0,05 [i]	0,24	0,21	0,00 [i]	0,02 [i]	0,22	0,11	-0,03 [i]
laissez-faire	0,04 [i]	0,07 [i]	0,08 [i]	0,14	0,14	-0,04 [i]	0,04 [i]	0,07 [i]	0,07 [i]	0,07 [i]	0,13

[i] *p<0.05*

The research allowed to determine the perception of the significance of specific determinants and benefits of technological innovations, while pointing to the negligible impact of management style on the studied variables.

Conclusion

The modern SME sector has the opportunity to develop only by implementing technological innovations, especially in the field of digital technologies, which will allow to maintain a competitive position on the market in the era of industry 4.0. With the increasing use of new technologies, the business environment is becoming more and more competitive. Hence, organizations work constantly to improve their production processes, retain their market shares, and survive the competition in a cost-effective manner (Gillani et al., 2020; Havierniková et al., 2019). Additionally, consumers have easy access to information about market offers because of information and communication technologies, thereby raising the demand for economical and personalized products with high quality and shorter lead times (Horváth, Szabó, 2019).

The conducted research shows that the most important reasons for implementation of technological innovations in SMEs are achieving competitive advantage and expectation to improve the quality of products and services. In turn, the expected advantages when implement the technological innovations are higher profitability of operations improvement of business efficiency. The correlation analysis shows that the perception of analyzed factors is not dependent on management style preferred in the enterprise.

The presented research could bring some implications for researches and business practice. In particular, entrepreneurs can rethink and modify innovation policies to meet the challenges of the modern world, such as digitization and production automation. It should be also noted that empirical research has shown several limitations, among which the lack of representativeness of the research group comes to the fore. This resulted in, among others, the inability to statistically confirm all relationships between the variables studied. Hence, research needs to be developed in the future along with more details on the factors determining the implementation of technological innovations.

Abstract

The article is devoted to stablecoins as special types of crypto-assets. The aim of the study is to characterize the economic nature and effective mechanism for managing stablecoins. Cryptocurrencies and stablecoins are similar, but still different types of digital assets, which are based on blockchain technology. The features of stablecoins are their issuance by specific issuers, as well as the availability of real provision, binding to some highly liquid underlying asset. It is proved that stablecoins, being a digital analogue of an asset, in particular national currencies, perform certain functions of money, but nevertheless they are not a new type of money. The functioning mechanism of stablecoins is determined by two elements: the stabilization mechanism and ensuring the rights of the issuer and the owner of a stablecoin. The approaches to the management of stablecoins are disclosed on the example of the management model of the global stablecoin Libra. The anonymity often found in stablecoins can be used to hide financial transparency and facilitate various financial crimes. Stable coin issuers, operators and intermediaries should fully disclose the terms of their services, and service consumers should receive detailed information about their rights and how to link the coin to the underlying asset. Stablecoin holders should be protected as much as possible from erroneous and fraudulent transactions. Financial risks associated with stablecoins require state regulation of these types of crypto assets.

Keywords: Stablecoin, Crypto-Asset, Digital Token, Cryptocurrency, Currency, Security, Risks.

Introduction

Until recently, the topic of stablecoins did not attract much attention either from corporations, or from the banking community, or from academic science. However, the situation has changed dramatically in connection with the Facebook project for the release of the Libra stablecoin that appeared in 2019. As Lael Brainard, a member of the US Federal Reserve Board of Governors, noted, because of its potential global reach (2.7 billion network users), the Facebook project makes the discussion about what form money can take, who can issue it, and how payments can register and implement (Brainard, 2019). Chairman of the House Financial Representatives Committee of the House of Representatives Maxine Waters expressed concern that Facebook is seeking to create a “global financial system” that will compete with the US dollar (Clayton, 2019).

Of course, the Facebook project made the discussion about the nature of stablecoins and their impact on the financial system more acute. Therefore, the central banks of developed countries and their financial regulators, international financial organizations quickly responded to this project, expressing concern about the possible destabilization of the entire global financial system, given the huge number of Facebook network participants. The widespread belief that cryptocurrencies do not pose a significant risk to financial stability, could certainly change with the launch of global

stablecoins. At conferences of finance ministers and central bank governors G7 (July 2019) and G20 (October 2019), it was emphasized, in particular, that global stablecoins pose serious risks associated with the fight against money laundering and terrorist financing, protecting consumer rights and their data, with fair competition, tax compliance. Therefore, the finance ministers of the EU countries made a joint statement on stablecoins on December 5, 2019, in which they again emphasized that global stablecoins should not begin to be legally used in the EU until all the legal, regulatory and supervisory risks and challenges associated with them will not be evaluated, defined, and eliminated (Council of the EU, 2019).

Thus, the theme of stablecoins is quite relevant. Unlike cryptocurrencies, not so many works are devoted to the functioning of stablecoins. Nevertheless, we would like to highlight the detailed report of the G7 working group on global stable coins (G7, 2019); the report prepared by the staff of the European Central Bank D. Bullmann, J. Klemm, A. Pinna (2019); the historical and theoretical work of G Samman and A. Masanto (2019). It should also be noted the work of Japanese and Swiss authors (Makiko et al., 2019; Berentsen and Schär, 2019), specialists from the International Monetary Fund (Tobias and Mancini-Griffoli, 2019), and employees of the Reserve Bank of Australia (Dark et al., 2019), which examined in detail the various types of stablecoins and the risks involved. A large empirical study on stablecoins was conducted by Blockchain. Data was collected on 57 stable coins in a wide range of categories (Blockchain, 2019).

Satblecoins are a challenge for both monetary and tax policies. Among the pressing issues of developing credit systems (for example: Naumenkova et al., 2020; Mishchenko et al., 2019), the influence of information technology occupies an important place (Naumenkova et al., 2019); this is true for taxation in general (Fedotov and Pokrovskaia, 2017; Bannova et al., 2016; Lvova et al., 2016), stimulation of investment activity (Ivanov et al., 2019a; Ivanov et al., 2019b), tax support innovation (Victorova et al., 2019a; Victorova et al., 2019b)

A review of existing research on stablecoins shows both commonality of opinion and disagreement. The subject of our study is two debatable issues: a) what is the economic nature of stablecoins and b) what should be an effective mechanism for managing the provision of stablecoins.

Research Methodology

In the study of the identified issues, we proceed from the following grounds.

Firstly, the understanding of stablecoins is based on the theory of money. In our opinion, money expresses relationships based on trust. They have three functions: the unit of account, the means of accumulation, and the means of circulation (payment).

Secondly, when analyzing the provision of stablecoins with fiat currencies, it is necessary to see the differences between the money issued by credit institutions and the money of central banks.

Thirdly, stablecoins are an independent form of digital financial assets, secured by the value of underlying assets, and not just a type of cryptocurrency. “Digital financial assets”, in our opinion, can be defined as digital analogues of cash and securities operating in a particular information and communication system.

Economic Essence of Stablecoin

The concept of stablecoin does not have a single universally recognized definition. In many studies, stablecoins are seen as a kind of cryptocurrency that eliminates their most important drawback - high volatility (Clifford Chance & R3, 2019). According to Japanese scientists Makiko Mita, Kensuke Ito, Shohei Ohsawa, Nideyuki Tanaka (2019), stablecoins are cryptocurrencies with price stabilization mechanisms that correspond to the price of another currency with lower volatility. In the Financial Stability Report published by the US Federal Reserve in November 2019, stablecoins are seen as a form of cryptocurrency whose value is tied to the underlying asset or basket of assets (Board of

Governors of the Federal Reserve System, 2019). This understanding of stablecoins is based on the history of their appearance from the world of crypto assets. In stablecoins, many are attracted by the idea of combining in them the price stability of fiat currencies and the well-known "advantages" of cryptocurrencies.

However, there are other points of view. So, D. Bullmann, J. Klemm, A. Pinna (2019) characterize stablecoins as digital units of value that are not a form of any particular currency (or their basket), but rather use a set of stabilization tools to minimize fluctuations their prices. According to G. Samman and A. Masanto (2019), a stable coin is a digital token, a digital representation of real assets. The Financial Stability Board considers stablecoins as a crypto asset designed to maintain a stable value relative to another asset (usually a unit of currency or good) or a basket of assets (Financial Stability Board, 2019). Stablecoins are not considered by the Financial Stability Board as a type of cryptocurrency, but as a type of crypto-asset, along with cryptocurrencies.

According to the Japan Financial Services Agency (JFSA), the characteristics of stable currencies differ from the characteristics of virtual currencies and, therefore, they do not fall under the legal competence of cryptocurrencies. According to the Japanese Payment Services Act, companies that issue stablecoins must register as an “Issuer of prepaid payment instruments” or “Providers of money transfer services” (Helms, 2018). Based on this, it can be assumed that stablecoins in this case are considered as electronic money in that sense, as is understood in the legislation of the EU and Russia.

The Swiss financial market supervision authority FINMA has a special look at the nature of stablecoins (FINNMA, 2019):

– when qualifying stablecoins, it is necessary to be guided by two principles:
1) “the same activity, the same risks, the same rules, the same supervision”, and
2) “the prevalence of the essence over the form”, i.e. paramount importance should be given to the economic function and purpose of stablecoin;
– to determine the nature of stablecoins, it is necessary to know the composition and management scheme of the assets providing them;
– in some cases, stablecoins can be considered as a bank deposit or security;
– the essence of stablecoins is largely determined by the features of the design of stablecoin and the mechanism of stabilization of its price;
– in the payment system using stablecoins, the issues of combating money laundering and the financing of terrorism must be resolved.

As you can see, according to FINMA, there is no common pattern for determining the economic nature of stablecoins. It is necessary to study each specific issue of stablecoins, focusing on their economic function and specific features.

On the Internet, of course, one can also come across statements about stablecoins as another financial bubble. However, the prevailing opinion is the need to conduct research on this topic.
Summarizing the various points of view on the nature of stablecoins, it is necessary, first of all, to note that cryptocurrencies and stablecoins are close, but still different types of digital assets (Fig. 1).

Common characteristics of cryptocurrencies and stablecoins are: blockchain technology, the absence of intermediaries and the presence of consensus in decision-making on transactions. The fundamental difference is in two points: a) cryptocurrencies are created by the system itself (mining), and stablecoins are issued by specific issuers, b) stablecoins have real security, are tied to some highly liquid underlying asset, and cryptocurrencies do not have security, and their prices are determined only supply and demand.

The question arises: are stablecoins a new type of money, a type of electronic money, digital token or securities? The methodology of disclosing the economic content of stablecoins involves determining the goals of their creation, the functions that they perform, the analysis of the types of support and their management. As various studies show, stablecoins can perform the following functions. Firstly,

it is the implementation of payments, and, above all, cross-border. The challenge is to make them simple, fast, cheap, affordable and safe. Secondly, stablecoins can be used as a unit of account (allows you to measure and compare the cost of goods and services). Thirdly, they can become a means of storing (saving) assets for a long time without losing their value. Fourth, stable coins provide the convenience of arbitration between trading floors, as conventional cross-border transfers are processed slowly (up to several days). Fifth, they perform the function of hedging risks when negative news is predicted for the cryptocurrency market. In this case, cryptocurrencies can be instantly converted into stablecoins, but the usual exchange of cryptocurrencies for any fiat currency would require hours and even days.

Fig. 1: Types of Digital Financial Assets

Source: compiled by the authors, relying more on studies by the American Securities and Exchange Commission (SEC) and the Swiss FINMA.

Stablecoins, being a digital analogue of an asset, in particular national currencies, in our opinion, perform certain functions of money, but are not yet a new kind of money. Rather, they are similar to electronic money that operate in PayPal, WebMoney, Yandex.Money, Qiwi, etc. payment systems with the difference that the national currencies operate in these payment systems, and stablecoins operate in payment systems, being a digital coin, secured by various assets. In their current definition, electronic money can only be tied to one currency, but not to a basket of currencies, or to non-monetary assets. In addition, a whole security management unit is created for stablecoins, which is absent, for example, in Yandex.Money.

Stablecoins are also close to defining them as digital payment tokens. For example, the Monetary Authority of Singapore believes that “stable coins” consist of digital tokens, which are backed by a reserve of real assets. However, under Singapore law, they cannot be classified as “electronic money” or “digital payment tokens” (Allen & Overy, 2020). In Libra and JPM Coin projects (JP Morgan Chase project) stablecoins are considered as digital tokens.

In our opinion, stablecoins are a new form of payment instruments. This is a digital asset with a cryptographic signature, written on the blockchain, usually supported by some real asset. They can be considered as a special type of electronic money, as a kind of digital payment token, provided by specific assets. Such an understanding of stablecoins, for example, is most consistent, as it seems to us, with the Japanese legislation on payment services, which was mentioned above.

The functioning mechanism of stablecoins is determined by two elements: a) the stabilization mechanism and b) ensuring the rights of the issuer and holder of a stable coin. The stabilization

mechanism itself includes the provision of stablecoins and ways to maintain a stable value. The list of rights of the issuer and the owner of the stablecoin is especially important in matters of converting stablecoins into fiat currencies and on the issues of redemption of coins. The legal qualification of stablecoins depends on how these issues are resolved.

Stablecoins Management Mechanism

In the literature, depending on the provision, three types of stablecoins are provided that are secured: a) fiat currencies (one or several fiat-collateralized), b) physical assets (gold, other types of precious metals - commodity-collateralized), c) one or multiple cryptocurrencies (crypto-collateralized). In addition to secured stablecoins, so-called non-collateralized algorithmic stablecoins are also distinguished when supply and demand are balanced by means of a set of rules expressed in the program code (Fig. 2).

Fig. 2: Types of providing stablecoins

Source: Stablecoins in detail: Basic schemes, operating principles and prospects Available at: https://coinspot.io/analysis/stejblkoiny-v-detalyah-osnovnye-shemy-principy-dejstviya-i-perspektivy/

The allocation of stablecoin types depending on the types of collateral raises the question of provision management models. The binding of the most popular stablecoin Tether (USDT) is carried out to the US dollar in the ratio of 1: 1. This means that if Tether Limited's bank account is replenished by $ 1, it issues 1 USDT token, and if dollars are withdrawn from the company's account, then USDT tokens are redeemed. So, the mechanism of maintaining a one-to-one exchange, at first glance, is quite simple. The problems are who and how provides this ratio: the USDT issuer himself, or the custodian (bank, custodian) on his behalf, and what are the guarantees here. For example, when providing stablecoins with US dollars, the problem may be the presence of credit risk, since the bank, the depositary, is at risk of excessive lending and possible bankruptcy.

Things are much more complicated with unsecured stablecoins, which are controlled by algorithms. For example, the stablecoin Kowala (kUSD) is algorithmically "tied" to the value of 1 US dollar. However, this binding to fiat currency is provided not by a stock of real assets, but by program code and mathematics. The following principle applies here: if the value of one stablecoin exceeds $ 1, the supply of coins increases, and when the cost is less than $ 1, the supply decreases (that is, the coins are "burned"). The mechanism of such regulation is carried out through smart contracts with the participation of traders (Dark et al., 2019). Supply and demand can also be regulated using bonds (Blockchain, 2019).

For the most part, the literature does not contain a detailed description of the control system for providing stablecoins. Therefore, in our opinion, of great interest is the model of managing the global stable coin Libra, the central place in which is occupied by the independent non-profit organization Libra Association. Members of this association are various organizations from around the world. One of its main tasks is managing the technical development of stablecoin and resolving issues of the organization itself. She will also manage the operations of the Libra Reserve Support Fund, including the creation and destruction (or "burning") of stablecoin. An independent Calibra division is being created for operational project management. Within its framework, the social network with the same name with a digital wallet should appear, which will allow payments to be made in WhatsApp and Messenger (Libra, 2020). Such a management system allows to a certain extent to avoid the monopoly of one company - Facebook.

In our opinion, the stablecoins collateral management system should, in principle, include an independent collateral management company, depositories / central depositories, a collateral verification system (audit), and possibly collateral insurance.

Conclusion

Technologies are changing the world of payments and opening up opportunities for transactions to be convenient, fast and cheap for users. At the same time, new payment methods pose new risks. Stablecoins also carry risks associated with legal uncertainty, cybersecurity, market integrity, data privacy and consumer protection. It should also be borne in mind that collateral alone does not guarantee stable price stability during a financial and economic crisis. In addition, the risk of breaking into the payment system and the storage system of assets transferred as collateral doubles: not only stablecoins, but also the collateral itself can steal. Storage of assets in commercial banks carries credit risk.

What could be the consequences of introducing stablecoins? For example, banks may have reduced deposits, since some of them will be converted into stablecoins. At the same time, the currency supply of stablecoins will be stored in the largest banks, which may help strengthen the latter. Concerns are also expressed that dollar stablecoins may lead to dollar dependence of countries with weak economies, and the widespread use of global stablecoins can to some extent weaken the dominant role of the US dollar.

The ten-year history of cryptocurrencies does not give reason, in our opinion, to consider them as the future of money. The five-year history of the first generation stablecoins (2015-2019), due to their small number and scale of use, shows a low demand for them.

As for the second generation of stablecoins (the Facebook project to create the Libra, the JP Morgan Chase project to create the JPM Coin, the project of the largest banks in the world to create an institutional stable USC coin), such global coins can have the most significant impact on payment systems, on monetary and credit policy of central banks and in general on financial stability. The consequences of their widespread use without proper regulation can be devastating for the entire global financial system. Therefore, the regulation of global stablecoins should be carried out within the framework of the international regulatory framework.

Regardless of the economic and legal qualifications, stablecoins should be evaluated in terms of combating money laundering and combating the financing of terrorism. Anonymity, often found in cryptocurrencies and stable coins, can be used to hide financial transparency and facilitate various financial crimes. Stable coin issuers, operators and intermediaries should fully disclose the terms of their services, and service consumers should receive detailed information about their rights and how to link the coin to the underlying asset. Stablecoin holders should be protected as much as possible from erroneous and fraudulent transactions.

It should be said that serious steps have already been taken in this direction. Thus, the EU adopted the EU directive 843/2018, which significantly limits the crypto sector due to the introduction of strict

anti-money laundering measures and the mandatory KnowYourClient procedure (EU, 2018). The FATF adopted in 2019 the final version of the recommendations on the regulation of cryptocurrencies and the activities of cryptocurrency services operators (FATF, 2019). All this, of course, will contribute to transparency in cryptocurrency systems, including stablecoins.

The penetration of large technology companies into the banking system is inevitable. However, the issue of any stablecoins, especially "global stable coins" such as Libra, should not be allowed until the issuer protects the rights and interests of its customers and provides evidence that significant risks will be eliminated. In any case, the beneficiary of innovations should be the consumer of financial services.

The prospects for the study of stablecoins are largely related, in our opinion, to two areas: a) using interbank transnational settlements and b) projects for creating digital currencies of central banks.

Abstract

The paper addresses key challenges for investment activity in the Russian Federation. The research also shows that investment behavior of Russian companies differs depending on the industry and the region of activity. This allows suggesting the mechanisms for overcoming investment passivity of the Russian business. We argue that necessary measures in this field are the following: improving the investment climate, especially in terms of guaranteeing stable fiscal business environment, protection of entrepreneurs from the law enforcement agencies of pressure, reform of the judicial system in the direction of its real independence from the executive authorities; increasing financial availability for Russian business, primarily cheaper borrowing; ensuring the growth of real incomes of the population and, accordingly, poverty reduction; technical re-equipment of companies based on modern technologies.

Keywords: Investments, Investment Behavior, Investment Activity, Russia.

Introduction

In the development of the Russian economy over the past 20 years, both ups and downs GDP growth rates and investments in fixed assets (after this – investments, capital investments) have been observed (Ivanov et., 2018; Ivanov et al., 2019; Lvova et al., 2018). The recovery of economic growth in the country was expected due to a significant increase in investments in fixed assets in 2017. Thus, the growth of investments in 2017 amounted to 4.8%, and the share of investments in GDP increased to 21.5% (Rosstat, 2019a), which also had a positive effect on GDP growth (GDP growth in 2018 compared to the previous year was 2.3%). However, in the future, a progressive increase in the growth rate of investment in fixed assets in 2018 and 2019 did not happen (Grigoriev, 2019). At the same time, the share of investments in GDP decreased in 2018 to 20.7% (Rosstat, 2019a). In 2019, the growth turned out to be insignificant - the share of investments in fixed assets compared with 2018 increased by only 0.3 percentage points and amounted to 21%. GDP. Details on the dynamics of Russia's GDP and investment in fixed assets from 1999 to 2019 are presented in Fig. 1.

Fig. 1 : GDP and investment growth in Russia (Rosstat, 2019a; Rosstat, 2019b; Grigoriev, 2019).

According to Message from the President of the Russian Federation to the Federal Assembly of the Russian Federation of 01.15.2020, it is planned that since 2020 the annual investment increase should be at least 5%. The task is problematic, but despite significant challenges, there are certain prerequisites for its implementation.

Note that the trend of investment activity of a business in Russia is not homogeneous for various types of activities and territories of the country. There are sectoral and regional growth points, the identification of which is relevant and significant for the development of investment policy. In addition to the question of how the investment behavior of companies differs depending on the industry and the region of activity, the paper analyzes key challenges for investors, which allows us to justify the mechanisms for overcoming investment passivity of business in the Russian Federation.

Business investment activity in the regions of the Russian Federation

An analysis of regional features of investment activity is especially relevant for Russia, taking into account its federal structure and significant differences between regions in terms of the level of business activity, consumption, etc. For the analysis of investment activities of Russian companies by region, the data of the SPARK-Interfax information system were used. We analyzed 10 thousand largest companies by assets— the total amount of all Russian companies currently more than 4 million.

We researched the acquisition of non-current assets by companies in 2018 was (more recent data are not available in the SPARK system). To analyze the investment activities of companies in a particular region we summarized data for the largest organizations in this region, which fell into the 10 thousand largest Russian companies. We consider the region where the company was registered since taxes are paying in this region.

As a result of the analysis, the following data were obtained. The most significant share of investments falls on city of Moscow – this is 33.4% of the total amount of investments of the 10 thousand largest Russian companies. In absolute terms, this is 2 756 820 million rubles. Next,

Moscow is followed by the Tyumen region (15.33%) and St. Petersburg (6.33%). They are followed by the Moscow region (4.67%). Thus, 4 regions account for almost 60% of investments, and two of them merge into one - the Moscow metropolitan area.

Analyzing the outsiders of the rating, we noted that in 6 regions investments amount to less than 1 billion rubles and in relative terms, 0.01% or less. Among them are the Stavropol region and five republics of the North Caucasus. The difference between the size of investments in large companies in Moscow (2,756,820 million rubles) and Kabardino-Balkaria, which closes the list (17 million rubles), is 162 thousand times.

It can be assumed that these figures will change a little bit if we analyze not only the largest companies. The revealed trends and patterns also reflect the flows of population migration in Russia and the attractiveness of the regions for investors.

Sector features of investment activity in Russian Federation

During the investment stagnation from 2015 to 2019, some sectors continued to show steady growth in fixed capital investments, while others stopped investing.

Which Russian industries are leading in terms of capital investments? First of all, we are talking about mining. In the first half of 2019, investments in mining increased by 5.3% in annual terms, including in coal mining by 36.3%, in oil and gas – by 3.8%. High rates of investment growth in the first half of 2019 took place at textile enterprises (an increase of 89.6%), freight rail transport – 79.8%, coke production – 62.3% and some other sectors (Rosstat, 2019a).

The most significant reduction in investment activity was observed in manufacturing. However, in this area, for specific subsectors, rather high investment growth rates remained. In particular, this applies to the production of chemicals and products, paper and paper products and other sectors.

Note that active investment is characteristic of enterprises with a high margin level, which correlates with the features of investment financing, which will be discussed later. Accordingly, investment passivity is observed, first of all, in those sectors where there is a low margin level, insufficient demand for manufactured products.

Curiously, the low growth rate of investments in manufacturing is simultaneously characterized by a reasonably high growth rate of financial investments. So, in 2018, the growth of financial investments in companies in the industry amounted to 31.2%, while the total volume of financial investments exceeded 12% of the volume of financial investments in all types of economic activity and significantly exceeded the volume of financial investments in the field of mining.

Summary results for the most significant cases are presented in table 1.

Table 1: Some financial indicators dynamics of Russian companies in the analyzed industries

Industry / Indicators, years	Total	Transportation and storage, total	Mining, total	Including		Manufacturing, total	Including	
				Coal	Metal ore mining		Chemical production	Paper production
1. Investments in fixed assets at actual prices, billion rubles								
2015	2,146.6	13,897.2	2,385.3	80.5	158.4	2,167.6	312.6	39.9
2016	2,424.1	14,748.9	2,710.4	98.6	159.1	2,103.3	367.8	51.7
2017	2,659.4	16,027.3	3,023.2	139.9	187.1	2,296.5	424.8	69.5
2018	2,983	17,595	3,199.6	167.6	254.1	2,584.9	498.6	86.4
2. The growth rate of investment in fixed assets by sector, %								
2016 г. to 2015 г.	–0.2	5.5	9.2	11.6	–7	–10.6	9	20.2
2017 г. to 2016 г.	4.8	4.9	6.1	37.1	12.8	5.4	11	29.6
2018 г. to 2017 г.	4.3	5.8	2.9	14.3	30.2	7	11.8	19.5
2018 г. to 2014 г.	–3.5	–26.3	23.7	9.1	29.9	–6.5	63.1	36.1
3. Sales margin, %								
2016	8.1	10.8	27.2	23.8	54.7	10.5	24.5	20.1
2017	7.5	9.7	25.9	30.6	50.3	11.5	19.8	20.5
2018	12.3	8.8	33.6	31.4	57.3	12.8	26.5	28.1
4. Return on assets, %								
2016	6.4	5.3	10	8.1	21.4	6.6	13.8	16.1
2017	5.3	4.7	11	16.5	15.6	5.5	8.6	13.2
2018	6.4	4.1	17.3	11.6	17.6	6	6.1	17.3
5. Financial investments in actual prices, total, billion rubles								
2017	165,669	13,095	7,641	548	2,093	22,632	1,235	261
2018	246,503	22,508	11,977	491	5,711	30,116	1,523	494
6. Short-term financial investments in actual prices, total, billion rubles								
2017	147,083	7,736	6,988	306	1,155	19,055	1,098	252
2018	213,867	11,471	11,086	388	866	25,052	1,456	487

Reasons investment passivity of Russian business

What is the reason for such a significant difference in the investment activity of Russian companies? According to a survey by the Rosstat of the heads of large and medium-sized companies, the most significant reasons were insufficient equity, uncertain economic situation, high interest on loans and insufficient demand for products (Rosstat, 2019a).

The Ministry of Finance of Russia has a slightly different opinion, ranking the reasons for investment passivity: an increased level of economic uncertainty and dependence on the pricing environment in commodity markets; an insufficient degree of protection against possible risk scenarios due to the low level of the accumulated reserves of the sovereign; an unbalanced structure of budget expenditures that does not contribute to the correction of structural imbalances in the economy; the presence of structural barriers to development associated with distortions of the competitive landscape and incentives for investment, the quality and effectiveness of public administration, demographic trends and the development of human capital.

Note that the Ministry of Finance of Russia does not recognize the significant impact of the challenges of insufficient equity and high interest on loans. There are some reasons for this position. Significantly, that the companies demonstrate low investment activity, are active in financial investments. Many of these volumes of investments are much higher than the volume of investment in fixed assets. If in 2017 this excess was 10.3 times, then in 2018 it increased to 14 times (see table 1). However, more importantly, for decades, the primary source of financing of capital investments in the Russian Federation are own funds. Moreover, their share in the structure of investment financing is increasing, which, however, is not accompanied by an increase in investment activity (Table 2).

Table 2: Dynamics and structure of investments of Russian companies by sources of financing (excluding small enterprises)

Indicator	1st half of 2018 г., %	1st half of 2019 г., billions of rubles	1st half of 2019 г., %
Investments in fixed assets – total	100	5,041.5	100
Equity	59.7	3,032.5	60.2
Liabilities – total	40.3	2,009.0	39.8
Including: bank loans	8.0	532.0	10.5
loans from other organizations	4.1	230.2	4.6
budget resources	12.1	537.1	10.6
funds of organizations and the population raised for construction	3.2	189.8	3.8
Others	12.2	495.5	9.8

Source: compiled by the authors on (Rosstat, 2019a).

Among the liabilities, the most significant volumes have the budget funds (federal, regional and local). According to the results of the 1st half of 2019, the share of budget funds decreased by 1.5 percentage points in annual terms, which was a significant factor in the low growth rates of investments in fixed assets in 2019. At high interest rates, the share of funds raised from Russian loans commercial banks remains negligible. In the 1st half of 2019 it amounted to only 10.5% of total investment in fixed assets.

In these circumstances, the position of the Central Bank of Russia (CBR), according to speech by E. Nabiullina at the International Finance Congress is, above all, to "make corporate loans more attractive for banks". Meeting the needs of the real sector in the "cheap" and "long" loans (Miroshnichenko and Tarsova, 2018; Grinko, 2019; Grinko et al. 2019) to provide the required rate of growth of the economy of the CBR is currently not among the priorities, as the "cheapening of credit resources will mask structural problems and lead to macroeconomic instability". However, studies of

emerging economies note the negative aspects of this scenario (Mishchenko et al., 2019;; Iwasaki and Kumo, 2019; Naumenkova et al., 2020).

However, the reasons for the current situation with the financing of capital investments are varied. In particular, it highlights the decline in purchasing power due to a decrease in real disposable income. In the 1st quarter of 2019, real incomes of the population decreased by 2.2%. In 2017, only in 14 regions of Russia, the median salary exceeded 30 thousand rubles per month, and in 14 regions it was less than 17.3 thousand rubles (Rosstat, 2017).

The literature in this context it is also often considered a high tax burden on business (see, e.g., Sinenko et al., 2018; Victorova et al., 2018). However, our study showed the speculation of such statements or at least the paradox of such conclusions (Lvova et al., 2016). When analyzing the impact of the tax burden on the investment activity of a business, it is essential to take into account its differentiation by sector (Fedotov and Pokrovskaia, 2017; Kireenko and Nevzorova, 2019). The most significant industry average tax burden, taking into account the burden on insurance premiums in 2018, was observed in the mining sector – 43.5% and the gross margin in 2018 was 33.6%. The tax burden in the field of manufacturing is 7.1%, in the field of transportation and equipment – 6.5%, i.e. six times less than in the field of mining. At the same time, both the margin and the growth rate of investments in fixed assets in these areas were also lower than in the mining sector.

Conclusions

The investment passivity of Russian business, of course, is primarily due to external challenges. International economic sanctions have a negative impact, limiting the possibilities of attracting foreign investment, obtaining cheap loans by foreign financial institutions from Russian financial institutions, and acquiring and using modern foreign technologies by Russian companies. However, the study showed that the main reasons that hinder the investment activities of Russian companies are associated with the slowness of solving the internal problems of the functioning of the national economy.

As the main mechanisms to overcome the investment passivity of Russian companies and, accordingly, priority measures to accelerate economic growth, in our opinion, are necessary:

1) improving the investment climate, especially in terms of guaranteeing stable fiscal business environment, protection of entrepreneurs from the law enforcement agencies of pressure, reform of the judicial system in the direction of its real independence from the executive authorities;

2) increasing financial availability for Russian business, primarily cheaper borrowing;

3) ensuring the growth of real incomes of the population and, accordingly, poverty reduction;

4) technical re-equipment of companies based on modern technologies.

According to the authors, measures in these areas will contribute to enhancing the investment activity of Russian business.

Abstract

The aim of the study is to identify forms of spending free time by students. Students are a social group that thanks to their young age and energy can become a factor of social change and influence the transformation of entire society or region. The basic method of collecting the research material was a diagnostic survey, in which the author's own questionnaire was used. The study was conducted in February of 2018 and of 2020. The students turned out to be a very diverse social group, so it's impossible to talk about any group-specific way of using leisure. There are, however, clear differences in the ways of spending free time related to gender and employment status. Leisure of young male students is clearly dominated by the use of computer and the Internet.

Keywords: Leisure, Time Budget Of The Population, Forms Of Free Time Use, Computer Games, Students.

Introduction

Real (clock or calendar) time is an important subject of research in economics, sociology, psychology, philosophy and practice of economic life. The success of economic entities (enterprises or individuals) as well as the level of socio-economic development and economic well-being depend on the use of time and time resources. In the context of contemporary scientific research, real-time resources are treated as the basic determinant of the quality of life, in both the individual and the social dimension [Czaja 2011]. In the past, as an aftermath of the theory of value developed by Adam Smith, the attention of researchers focused mainly on working time, because it was the input of productive work that was considered to determine the national wealth [Bartkowiak 2008]. Today, as a result of socio-economic changes, technological progress and globalization, free time and its management play an increasingly important role in human life. Free time gets systematically extended as a result of changes in labour legislation and of automation of production processes that increases work efficiency. As a consequence, there is an increase in demand for goods and services that meet the needs related to leisure management. The release of labour resources resulting from technical progress in the agricultural and industrial sectors has caused the shift of human capital from these sectors to the one of services [Walczyna, Łucjan 2012]. Development of the service sector has proved necessary both for the economic development and for smooth operation of all areas of the economy [Schulze 2011]. An increasing proportion of service activities is dedicated to leisure activities (e.g. hotel and catering services, information and communication, education, culture, entertainment and recreation). Time management refers to the proportion of working time and free time. It is a subjective – even if economically conditioned – decision of the individual, as it depends on the financial situation of the individual and on his institutional environment. According to economists, time is the most valuable resource at the disposal of a human being. Its uniqueness lies in the fact that it is not only a measure of life duration, but also a non-renewable and indispensable resource in the production and consumption of any goods [Nowak 2010].

The study of population's time budgets shows that the amount of time devoted to leisure activities is gradually increasing [Kolny 2016; Roettke 2017]. On the other hand, the use of free time affects many areas of family, personal and professional life, and also translates into economic processes and

social issues on a macro scale. Therefore, it seems very important to acquire knowledge about time management for various age groups and various levels of education. The way of spending free time adds to the overall image of young generation, and also provides information on the preferences, values and attitudes of young people towards important social issues. Students are a social group that thanks to their young age and energy can become a factor of social change and influence the transformation of entire society or region, so it is not without significance to study and learn about ways of spending free time by this social group.

The aim of the study is to identify forms of spending free time by students. The discussion is divided into three parts. The first explains the concept of leisure and how to interpret it. The second part describes the methodology of researching the population's time budget and contemporary changes in individual behaviour patterns. The third part presents results of the analysis of research results. The basic method of collecting the research material was a diagnostic survey, in which the author's own questionnaire was used. The research was carried out twice, in February of 2018 and of 2020, on a research sample of 468 people, i.e. first-degree students.

Actual Free Time Resources – Methods of Interpretation

Leisure time, observed as early as in ancient times, became a recognizable category only at the turn of the eighteenth and nineteenth centuries [Mroczkowska 2008]. Aristotle pointed out the separation of leisure time and working time, at the same time clearly emphasizing the relationship between leisure and culture, art and self-realization. Free time was supposed to serve the pursuit of perfection, it was filled with activities conducive to human development (including philosophy, contemplation or science). In economic theory, time started to be noticed during the development of value theory. While searching for sources of value, Adam Smith and David Ricardo built a labour-based value theory, according to which value was created solely by productive work [Bartkowiak 2008]. There was a question of measuring working time using clock time. Working hours vary depending on employees' abilities and the arduousness of their work. Karl Marx, in his turn, undertook to solve the problem of qualified work and introduced the concept of socially necessary time [Czaja 2011]. He saw time as an economic "surplus" that created added value. Therefore, working time was analysed in the theory of economics, while leisure was often seen by economists as belonging to the private sphere of an individual, and therefore was excluded from detailed research of economics for a long time. Today, traditional macroeconomic measures – GDP and GNP – are criticised as inaccurate measures of the volume of production in the economy, because they fail to cover e.g. the value of free time [Juster, Stafford 1991].

Nowadays, the issue of free time is dealt with by representatives of various scientific disciplines, including sociology, psychology, physical cultural studies, education studies, medicine and economics. This results in an abundance of definitions of free time that focus on specific aspects, significant from the point of view of a given area of science.

The most common criteria of delimiting working and leisure time are [Dumazedier 1960]:

- voluntary nature,
- selflessness (not-for-profit, non-commercial nature).

An individual, by his own volition or under the influence of the institutional environment, decides to carry out activities that bring him pleasure. He fills his leisure time, of which he can freely dispose, with activities that positively affect his personality. The amount of free time is the time that remains after performing the activities required to satisfy physiological needs and perform mandatory activities which depend primarily on the point in the individual's life cycle. A young person learning in a full-time education system, another one on his working age and still another already retired will have very different scope of duties. According to Barbara Pisarska, the structure of an individual's time budget depends on many factors, among which the most important are [Pisarska 2015]:

- biological factors: health and physical fitness level,

- mental factors: personality, temperament, intelligence level, attitude to life, value structure of needs and interests,
- demographic factors: sex, age, marital status, number of children and stage of family life, household size,
- social factors: education level, professional activity, occupation and nature of work, social environment and origin, place of residence,
- economic factors: income level, household equipment, means of transport, access to recreational equipment, facilities and offer (discounts, large-family card).

Also interesting is the approach of John Rawls, who within his theory of rational justice proposes to treat leisure as one of the basic social goods that make the basis of individual's self-esteem [Rawls 1994]. According to Julie L. Rose, citizens have the right to free time and can use it to pursue their own goals, whatever they may be [Rose 2016]. Mostly, free time is considered as the opposite of time spent on for-profit activities. According to Małgorzata Bombol, free time is the time during which a person does not perform any obligatory activities. It is a natural element of an individual's functioning, set out from the 24-hour time budget [Bombol 2008]. Leisure time is defined more comprehensively, i.e. in two ways, by Ryszard Winiarski. In the quantitative way, he defines it as the part of daily time budget that remains after performing all professional and non-professional duties and after satisfying the basic bodily needs (physiological and hygienic). In the qualitative way, he defines it as the time which an individual can freely dispose of, allocating it, for instance, to leisure, entertainment and self-improvement [Winiarski 2011]. Undoubtedly, free time is what distinguishes an individual, his personality and decision-making capacity.

Increasingly, leisure activities are reflected in consumer needs - new forms of relax and recreation are sought, and free time is becoming the time allocated to the acquisition of increasingly sophisticated goods and services [Niezgoda 2014]. It seems that free time is becoming another consumer good. More and more often it is not just a "time to do nothing", but it becomes a good (service) with which we can display our position at work and in society.

Free time is an important element of our lives. The amount of time and ways of using it determine the quality of work performed, training and professional development, everyday well-being and health, i.e. the overall quality of life [Kwilecki 2011].

Study of The Population's Time Budget and Life Cycle - Changes in Behavioural Patterns

In economic sciences, the way in which man organizes his time is referred to as managing the time budget. Time budget is a total of the time periods planned for implementation of various life activities [Pięta 2008]. The study of the population's time budget provides information on how time organization changes in connection with the changes taking place in both economy and social life. It provides information about many aspects of life, including the distribution of time spent on various spheres of life. In Poland, surveys of population's time budget are conducted by the Central Statistical Office (GUS). Household sample for the study on time budget is selected randomly (multistage random selection). The studies are carried out on a sample representative at the country level, and participation is voluntary. The surveys are conducted by the direct interview method, using paper-based questionnaires (PAPI). The last survey was conducted by the Central Statistical Office in 2013 and it was the fifth study on this subject, and at the same time the second one carried out in cooperation with the Eurostat. The study was carried out on a sample of 10.3 thousand households. The study subjects were people aged 15 and over who kept time diaries for 2 days; one weekday and one weekend day [Nowak, 2010]. It is worth emphasizing that starting from the 2003-2004 study, it follows all the methodological standards recommended by the Eurostat and the International Association for Time Use Research. Particular emphasis was placed on working time (for-profit and not-for-profit) and free time.

The structure of the daily time budget, developed on the basis of an indicator of the duration of activities per day, changes throughout the human life cycle along with its successive stages and

adopted social roles - from adolescent through adult (parent and employee) to pensioner [GUS 2016]. Each of these stages is characterized by different needs, which are reflected in the type and intensity of activities performed. The time available to an individual during the day is divided into ten groups of activities, i.e. [GUS 2016]:

1. satisfying physiological needs (including sleep, meals, personal hygiene etc.),
2. professional work,
3. learning (at school or university),
4. household chores,
5. voluntary work in organizations,
6. using mass media (e.g. watching TV, listening to the radio),
7. social life (e.g. social meetings, cinema, cultural events),
8. personal passions (e.g. computer and internet use, hobby)
9. participation in sports and recreation,
10. commuting.

In the study of time budget, groups of activities from 6 to 9, i.e. the use of mass media, social life, personal passions, and participation in sports and recreation are assumed to be the activities freely opted for by an individual, i.e. his leisure time (free time). Research shows that free time is getting extended and working time is reduced. In the years 1976-2004 in Poland, the time devoted to professional work during the day decreased from 7h10m down to 6h53m [Kolny 2016].

In subsequent time budget surveys, changes in the free time use by individuals were observed. These changes occur under the influence of various factors that can be divided into technological, demographic, economic and cultural ones. Technological factors are associated with the development of new technologies, especially in the area of communications, new forms of sales or availability of e-services. Demographic factors affecting changes in household time budget include the aging of population, slowing down of natural population increase, and increased life expectancy. The level and sources of income, as well as the prices of goods and services are economic factors affecting the management of free time. In turn, the elevated expectations and changes in consumer preferences and mentality, manifested in the growing importance of qualitative aspects of life, as well as the growing importance of free time, are examples of cultural factors affecting the distribution of time budget [Murawska 2015].

The development and dissemination of new technologies causes a significant increase in the time spent on activities related to computer use. Research conducted in the United States by Mark Aguiar (Princeton University), Mark Bils (University of Rochester) Kerwin K. Charles and Erik Hurst (both from the University of Chicago) demonstrated that young men aged 21-30 showed a significantly greater decrease in the number of hours worked than older men or women. Since 2004, there has been a significant change in activity patterns in the group of young men who devote more and more of their free time to computer games, i.e. recreational use of a computer [Aguira et al. 2017]. It is pointed out that for young men computer games are a kind of luxurious way of spending time and, moreover, for an increasing number of young men this is the main and only activity during the day. In 2015, young men aged 21-30 allocated 5.2 hours a week to computer games, which means an increase by 45% when compared to 2004, while their total leisure time increased by just 4% [Aguira et al. 2017].

Similar conclusions can be drawn from research conducted in Poland by the Central Statistical Office, although comparisons are difficult due to a different methodology used. Considering the average duration of free time activities in Poland, with reference to the years 2003/2004 and 2013 it can be stated that in 10 years this did not change and amounted to 4h39m. A detailed analysis indicates, however, that there have been some quite significant changes in the ways of spending free

time. The time spent on social life and the use of mass media has decreased, while the time for personal passions (in particular for using the computer or the Internet) and participation in sports and recreation increased. In the period between 2013 and 2003/2004, computer use as a form of spending free time by people over 15 y.o. increased by an average of 18 minutes per day.

In 2013 in Poland, young men aged 16-24 living with parents devoted 2h7m daily to games (individual, social or computer) as leisure activity, while with slightly older men, aged 25-44, it was 1h57m. Married men aged 16-44 spent 1h46m on games. Women aged 25-44 played the shortest - 57 minutes. Women aged 16-24 spent 1h06m of their free time on games. At the same time, married women aged 16-44 spent 59 minutes gaming, i.e. 47 minutes less than men of this category [GUS 2016].

Student Ways of Spending Free Time – Study Results

The academic community is a very diverse social group, but the main responsibilities of young people are related to the role of 'student', as appropriate at this phase of life, while the role content seems to most strongly determine the framework of the individual's functioning [Zaniewska 2012]. For a student, free time is the time remaining after satisfying physiological needs (sleep, meals, hygiene) and after fulfilling the duties and obligations arising from the role of a student and a family member. This is the time that a young individual, already emancipated from parental control, has at his disposal. The academic youth can use their free time e.g. for leisure, fun, developing own interests and abilities, activities developing their personality and creative abilities, as well as participation in social life. The value of free time, in the context of young people, is not only related to its functionality, but also has a formative, self-improving context, even when this is not intentional. Along with individual development, the forms of spending and managing leisure time change, and therefore the more developed and mature the subject is, the greater self-improvement value of free time. Modern technologies have greatly influenced the ways and forms of spending free time, especially among young people. Students are a social group that, on the one hand, is a significant driver of the creation of novel leisure activities, and on the other benefits most from all kinds of novelties.

In order to identify the leisure activities of full-time students, surveys were conducted in February of 2018 and of 2020 on a sample of 468 first-year undergraduate students of Economics and Management. The research was carried out by direct survey among students of two academic centres, i.e. Wroclaw University of Economics (Branch in Jelenia Góra) and the University of Szczecin.

Table 1: Respondents by sex and employment status

Specification	Total sample size	2018		2020	
		women	men	women	men
Number of respondents	468	159	108	114	87
Financially dependent on parents	225	99	43	54	29
Financially independent	52	13	13	12	14
Mixed – partial dependence on parents supplemented with own earnings	191	47	52	48	44

Source: own work.

The structure assessment of the academic youth sample according to sex showed that a majority of respondents were women, constituting 60% of the sample in 2018 and 57% in 2020 (Table 1). During the period examined, the structure of student population surveyed changed significantly in terms of employment status. In 2018, more than a half (53.2%) of the surveyed students were fully dependent financially on their parents, 37.1% were dependent on their parents and additionally earned some extra money, and 8% of students were financially independent. In 2020, 41.3%of the total number of surveyed students remained financially dependent on parents (decrease by 11.9 percentage points), those partly dependent on parents and earning extra money made 45.8% (increase by 8.7 percentage

points), while the employed made 12.9% (increase by 4.9 percentage points). In both survey years we observed large differences between genders in terms of employment status. Women students were far more often financially dependent on their parents. In 2018, the percentage of women students dependent on their parents was 62%, and men 40%. In 2020, the proportion of women dependent on parents dropped to 47%, i.e. by 15 percentage points, and the proportion of men dropped by 7 percentage points to reach 33%. The number of full-time students combining studies with work has clearly increased.

The study assumed that free time included such activities as social life and entertainment, participation in sports and recreation, the use of a computer for entertainment, and the use of mass media. The research conducted showed that the students' free time was 6.7 hours on an average weekday in 2018, and 7.4 hours in 2020 (Table 2). The increase in the amount of free time results from the changes in class planning introduced at universities. Increasingly, students only have classes on selected days of the week - usually three days a week. Limitation of the number of study days results, on the one hand, from a change in regulations, i.e. in the Higher Education Law, which set a minimum number of class hours to be 1800, and the number of ECTS (European Credit Transfer System) points at 180. On the other hand, the arrival of students from low-birth-rate years has allowed the accumulation of classes on selected days of the week, as universities have free lecture halls. During weekend days (Saturday, Sunday) in 2018, students had 8.6 hours free, and in 2020 it was 8.7 hours of free time.

During the period analyzed, the structure of students' daily time budget changed. On weekdays, the biggest change was to reduce the time spent on physiological needs (sleep) by 1.3 hours and the study time (contact classes) by 0.4 hours. The time spent working (an average of 1 hour per day) and enjoying social life (increase by 0.4 hours) was extended. The time spent at computer for weekday entertainment increased slightly, i.e. from 2.6 hours in 2018 to 2.8 hours in 2020. On weekend days, the time spent on physiological needs (sleep) decreased by 1.2 hours, and the time for for-profit work increased (by 1 hour). The ways in which students spend their free time have changed only slightly. Students spend their free time mainly using the computer for entertainment (computer games) - 2.6 hours a day, or enjoying social life and entertainment for about 2 hours.

Table 2: Structure of the students' daily time budget in 2018 and 2020 (in hours)

Activity	2018		2020	
	Weekday	Weekend day	Weekday	Weekend day
Physiological needs	8.8	9.7	7.5	8.5
Learning (attending classes)	5.5	1.2	5.1	1.5
Household chores	1.7	1.9	1.6	1.8
Employment (paid work)	1.3	2.5	2.3	3.5
Voluntary work in organizations	0.2	0.1	0	0
Social life and entertainment	1.7	3.2	2.1	3.2
Sports and recreation	0.9	0.9	1.2	1.4
Computer use for entertainment	2.6	2.8	2.7	2.6
Use of mass media	1.5	1.7	1.4	1.5

Source: own work.

However, data on the time spent using a computer for entertainment should be interpreted cautiously, because also phones are increasingly used for entertainment. Mobile phones (smartphones) are great not only for communication purposes, but also for listening to music, watching movies or playing games. Mobile phones have become multifunctional devices. This means that every student can use the telephone for 'all day' entertainment. In fact, students spend much more time on entertainment than the research showed. They admit that while performing various duties or working, they often use their phones for entertainment purposes in the meantime.

When analyzing the leisure activities by gender, significant differences – often resulting from social roles – become apparent. Women much more often than men spend time with their families and do housework (Table 3).

Table 3: Students' forms of spending free time, by sex, in 2018 and 2020

Forms of spending free time	2018		2020	
	F	M	F	M
I take a rest	59%	51%	62%	62%
I catch up on sleep	48%	32%	36%	47%
I read	25%	20%	27%	13%
I listen to music or watch TV	55%	44%	43%	48%
I spend time with my family	69%	47%	71%	49%
I go out	41%	32%	45%	24%
I practice sports	14%	32%	25%	38%
I do household chores (cleaning, DYI)	23%	5%	32%	13%
I play computer games	11%	60%	11%	48%
I learn	14%	10%	14%	15%
I engage in my favourite pastime or hobby	19%	36%	25%	32%

Source: own work.

Comparing the structure of the women's (F) and men's (M) time budgets, it can be observed that both sexes mainly take a rest in their leisure time (62%). With other forms of activity, significant differences were revealed. During their free time, 71% of women spend time with their family, while in the case of men it was 49% (a difference of 22 percentage points). The biggest difference between men and women was observed with the activity of playing computer games. In 2018, as much as 60% of men and only 11% of women indicated this way of spending their free time (a difference of 49 percentage points). In 2020, it was respectively 48% men and 11% women (the difference was 37 percentage points). Importantly, young men significantly reduced their use of computer for entertainment during the period studied, while with women this share has not changed. In their free time, women usually spend time with their families, take a rest, leave the house (go shopping) and listen to music or watch TV. On the other hand, young men usually take a rest, play computer games or catch up with sleep in their free time. More and more students practice sports in their free time. In 2020, 25% of women and 38% of men get involved in sports in their leisure time. Men much more often than women have time for their favourite pastime or hobbies. On the other hand, women more often do housework (cleaning) in their free time - in 2020 this form of leisure activity was indicated by 32% of women and 13% of men. Our research shows that the students' forms of spending free time are determined by their employment status. Students who are fully dependent financially on their parents usually spend their free time with their families, take a rest or listen to music. They devote the least time to household chores (catching up with cleaning, DIY). Students who are financially independent during their free time listen to music, take a rest or play computer games, spending the least time on learning. In turn, students who remain financially dependent on their parents, but also earn extra money in their free time, most often spend time with their families, take a rest or sleep. They spend the least free time on computer games and learning.

Fig. 1: Students' forms of spending free time, by employment status, in 2018 and 2020 (in %)
Source: own work.

Conclusions

Free time is a very important element of everyday life, and decisions on how to spend it are made directly by individuals. The form of spending free time depends on many factors, among which the most important are individual needs, age, gender, education, behavioural patterns and employment status (financial situation).

The students turned out to be a very diverse social group, so it's impossible to talk about any group-specific way of using leisure time. An analysis of forms of spending free time by gender has shown that leisure activities pursued remain strongly influenced by social stereotypes that determine the division of tasks and social gender roles. In their free time, women more often than men spend time with their families, leave the house (shopping) and clean up (overdue cleaning). Men, in turn, more often catch up with sleep, play computer games or devote time to their favourite pastimes or hobbies.

Students more and more often take up paid work while still studying. In the period examined, this was mainly due to the globally good economic situation as well as to the statutory limitation of the number of class hours.

Acknowledgment

The project is financed by the Ministry of Science and Higher Education in Poland under the programme "Regional Initiative of Excellence" 2019 - 2022 project number 015/RID/2018/19 total funding amount 10 721 040,00 PLN.

Abstract

The article consists of three parts. The first part covers the characteristics of process maturity, presents a comparison of process mature and process immature organizations, and introduces the models of process maturity. The second part of the study focuses on the definition of innovation and its typology according to the Oslo Manual. The final part includes a proposal for a research model which would verify the phase of the organization's involvement in shaping the process maturity model depending on the type of innovation. The article is an attempt to identify hypotheses and research questions that can be used in potential empirical research.

Keywords: Process Maturity Innovation, Process Maturity Model.

Introduction

In the world of globalization, continuous development and change, enterprises try at all costs to seize the opportunities presented to them and eliminate high uncertainty and high risk. In addition, the technological progress and industrialization strongly affect the way modern organizations are managed. The process of changing methods of management happens on several levels, including structural, work management systems, competences, technologies and organizational procedures as well as key values (Gierszewska and Wawrzyniak, 2001, p.14).

In recent years, the change that has determined the functioning of enterprises is the application of the process thinking paradigm in management sciences. By reorganizing thinking and moving away from linear flows towards optimizing them, a new philosophy and management school was created. The process thinking paradigm assumes a horizontal view of the enterprise as a set of interrelated processes (Hammer and Champy, 1996, pp.45-49). The process approach was implemented in phases (Smith and Fingar, 2007), and their last stage happened in the 1990s. resulted in a departure from the application of revolutionary changes, in favor of evolution, in which the analysis and control of processes in the company, as well as supporting their information systems, played an important role.

It would seem that process management, so intensively implemented and accepted at the beginning of this century, should lose its currency today in favor of other concepts, e.g. two-handed organization or organizational agility. The exact opposite happened, mainly due to the need to perceive the organization through the prism of processes and thus determining its effectiveness and bottlenecks - including organizational ones. Interest in the process approach, in the context of the organization's maturity and level of its innovativeness, seems to be the next stage in the development of this archaic, but still valid, management concept. Therefore, the article presents a research problem that aims to link the stages of process maturity with the kinds (types) of innovations that are directly related to the process approach.

Process Maturity - The Essence of The Issue

Enterprise process maturity is defined in different ways. It depends primarily on whether the approach is one- or multi-dimensional. The vast majority of process maturity models are based on currently functioning enterprises, which are used for the analysis of the level of implementation of process management (Raczyńska, 2017).

In order to determine the level of process maturity in an enterprise, the advancement of implemented process management methods and techniques is assessed. It is key to identify the strengths and weaknesses and classify functional solutions in the area of solutions (Bitkowska, 2009, p 105 and more). Without achieving individual stages of development in process management, it is extremely difficult to achieve a high level of maturity (Bitkowska, 2008).

W.S. Humphrey, the author of the concept of Business Process Maturity, defines it as the degree of identification, management, measurement, control and effectiveness of processes. According to him, enterprises with high process maturity should be proactive, i.e. implement processes in accordance with established procedures and defined objectives (Humphrey, 1987, pp.1-10).

Another definition defines process maturity as a dimension of coverage and proficiency, thanks to which it is possible to compare the effectiveness and efficiency in the context of processes (Rosemann, 2004, p.6). On the other hand, in the Polish literature on the subject one can find the definition offered of P. Grajewski, according to which the process maturity of an enterprise is a certain range within which the organization's processes are formally defined, managed, flexible, measured and effective (Grajewski, 2009, pp.381-388). In addition, the author states that factors affecting maturity result from the desire to constantly improve the organization in the context of processes (Grajewski, 2016, pp.124-125).

The identified features of process maturity in the organization show how a process-oriented enterprise should operate and what behaviours should be eliminated (Kalinowski, 2018). The distinguishing features of process maturity describe maturity models that present ways to develop organizational capacity. In the literature, the most frequently presented models are a) stages-of-growth models, b) stage models and stage theories (Paranto and others, 2003). In the era of growing interest in process maturity models within various organizational areas, it can be concluded from the literature review that the CMM / CMMI and BPMM-OMG models have so far been best described, providing inspiration for the newly emerging ones. In Polish literature, on the other hand, one can find a model authored by, among others, K. Nowosielski, who served as the starting model for further considerations (Bitkowska , 2009,pp.156-157) .

The big advantage of using maturity models is their structured and hierarchical form. Each level of maturity is a defined range of states that should be achieved in a sustainable manner to achieve full maturity. Each subsequent level builds upon the previous one, introducing increasingly more developed and advanced processes to the organizational culture until the organization is capable of self-improvement and continuous development.

Types of Innovations - Process Context

Innovation as a term has not only been very broadly and ambiguously defined, but also widely abused, even in spite of its slightly more negative connotations in the past. Until the mid-nineteenth century, the only people able to envision the applicability of their ideas were the innovators themselves (Zabłocka-Kluczka, 2019, p.18). Apart from the multitude of definitions, due to publication restrictions, a complete and uniform definition of innovation was needed - primarily for statistical and comparative purposes. It was initiated by the OECD as part of the Oslo Manual, in which experts proposed the following definition: “An innovation is the implementation of a new or significantly improved product (good or service), or process, a new marketing method, or a new organizational method in business practices, workplace organization or external relations” (OECD, 2008, p.48). The quoted definition of innovation covers a relatively wide range of implementable innovations. However,

in a narrower sense, innovation could be defined as the simultaneous implementation of one or more types of innovation. When creating the above definition, the OECD experts considered the novelty of the implemented "innovation" in a given organization or the fact that it significantly improved the organization's functioning.

The source also described four types of innovations. According to Oslo Manual experts they are (OECD, 2008, p.50):

1. product innovations – "the introduction of a good or service that is new or significantly improved with respect to its characteristics or intended uses. This includes significant improvements in technical specifications, components and materials, incorporated software, user friendliness or other functional characteristics";
2. process innovations - "the implementation of a new or significantly improved production or delivery method. This includes significant changes in techniques, equipment and/or software";
3. organizational innovations - "the implementation of a new organizational method in the firm's business practices, workplace organization or external relations";
4. marketing innovations - "the implementation of a new marketing method involving significant changes in product design or packaging, product placement, product promotion or pricing;"

Product innovations can be based on new applications or combinations of existing resources and knowledge. New products may take the form of a product or service that is distinguished to a large extent by individual features or purpose from other products previously manufactured by the enterprise. The changes introduced with new product may be small or involve significant improvements (OECD, 2008, p.50). Process innovations often accompany product innovations. Their goal can be to reduce unit costs of production or delivery, but also to improve the quality of finished products delivered to customers (Kamińska, 2014, p.80). The implementation of process and product innovations requires the high involvement of business participants, in addition, it is a period in which the costs incurred by entrepreneurs increase, which can be demotivating and discouraging for many. However, innovations can also lead to cost reductions by implementing process innovations, leading to staff reduction and the consequent savings. The simultaneous introduction of innovative product solutions may force the company to introduce new organization management methods included in the group of organizational innovations, thanks to which enterprises implement new business practices or operating standards in which the company decides to build a foundation of good practices based on existing knowledge and experience. The last group included in the above typology are marketing innovations. Their goal is to improve the satisfaction of the needs of recipients, entering new markets, or positioning of the product against the competition in completely novel way (OECD, 2008, p.54).

The innovations presented in the next part of this study will be compared with the organizational maturity model of the organization.

Process Maturity Versus Innovation - The Foundations of The Research Process

Innovations are among the six factors mentioned in the subject literature that affect the process maturity of an organization. In addition, J. Sanders and J.L. Lindermann provided evidence that process management can lead to innovations of much greater quality (Sanders and Lindermann, 2014, pp. 335–358). Similarly, De Boer's team specifically names technological innovation as a success factor in pursuing the process maturity of enterprises (De Boer and others, 2015, pp. 908-927). It was also observed in the study of the authors L. Roslyakov and P. Ravesteijn, based on the T test statistics, that the maturity of an enterprise's processes relative to its innovation varies depending on the number of employees in the enterprise. In addition, conclusions have been drawn that say that improved processes and knowledge seem to have a positive impact on creating innovation in organizations (Ravesteijn and others, 2016). A review of the literature revealed that while there are studies on innovation and maturity of business processes, the relationship between them has not been sufficiently studied. Therefore the research project was launched.

The first stage of the research process was the analysis of the literature on the subject. That stage allowed, therefore, to make a general hypothesis according to which: *A higher level of innovation favors achieving higher levels of process maturity.* The main research question posed in the planned empirical research is: *What is the nature of the relationship (positive or negative) between the company's process maturity and innovation?* The model subjected to verification, will be the model of S. Nowosielski, which aptly captures the stages of process involvement in the context of types of innovation, according to the Oslo Manual.

In this approach, the correlation of the following empirical matrix will be examined - Table 1.

Table 1: Summary of S. Nowosielski's process maturity model and types of innovations

Level of process maturity	Name of the level	Type of innovation
Level 0	Lack of process awareness	product innovations; process innovations; organizational innovations; marketing innovations;
Level 1	Awareness of the need for a process approach	
Level 2	Identifying and documenting processes	
Level 3	Measurement and keeping record of process results	
Level 4	Planning and controlling processes	
Level 5	Systematic improvement of processes	
Level 6	Process management	

Source: own study.

In this perspective, a detailed research question arises, whose purpose is to determine how product / process / organizational / marketing innovations affect achieving higher levels of enterprise process maturity? At the same time, determining the impact of the type of innovation on the implementation of the hierarchy of process maturity in the organization becomes a key part of the research.

The research project prepared in this way allows to distinguish five areas of process maturity - Table 2, around which a questionnaire will be prepared, submitted to respondents via the Internet surveying CAWI (Computer Assisted Web Interview) technique.

Table 2: Identified areas for enterprise process maturity

Level of process maturity	Name of the level	Type of innovation
Level 1	Awareness of the need for a process approach	product innovations; process innovations; organizational innovations; marketing innovations;
Level 2	Structuring processes	
Level 3	Implementing processes	
Level 4	Monitoring processes	
Level 5	Systematic improvement of processes	

Source: own study.

However, questions about specific types of innovations will include implementations that are completely new to the organization or significant improvements in products or services. Research concerns both manufacturing companies and services providers, the industry is not relevant in this case. The third stage of the research project is the implementation of research. The collected data will be processed and analyzed which will allow to draw conclusions and recommendations.

Conclusion

The use of a process approach has many benefits for the company. The most important ones include obtaining a uniform description of the company, preparing the company to implement a quality management system according to ISO 9001, as well as to implement a workflow system and manage the company's electronic resources (including documents). Identification and classification of areas for

improvement are also becoming extremely important, allowing for continuous improvement of the operation of one's own enterprise and the improvement of relations with external clients by responding to their needs and reducing the costs of products / services, which will result in increasing the financial result of the enterprise (Bitkowska, 2009, p.22).

What is important from the point of view of a modern organization is an attempt to identify tools supporting process maturity, which certainly include innovation. The article presents initial theses and research assumptions that will be verified during further theoretical and practical work.

Acknowledgment

The project is financed by the Ministry of Science and Higher Education in Poland under the programme "Regional Initiative of Excellence" 2019 - 2022 project number 015/RID/2018/19 total funding amount 10 721 040,00 PLN.

Abstract

The program assumptions and areas of expertise of the IBIMA conference provide an opportunity to present the results of research on the assessment of trust in the information included in online advertising. This problem is a kind of cognitive gap in research on categories of trust and research on various areas of marketing, including: relationship marketing, B2C and B2B marketing, online marketing, and marketing communication. The paper presents an excerpt of study results obtained in the course if an original NCN grant of the National Science Center in Poland, titled *Information Asymmetry in On-Line Advertising in the Context of E-Consumer Behavior Manipulation* [2018/29/B/HS4/00563] in 2019. The primary objective of this article is an empirical assessment of Internet users' trust towards information contained in online advertising. The structure of the considerations includes three issues: 1. theoretical context of the problem justification, 2. assumptions of the research model and 3. evaluation and discussion of the results obtained. The conclusion shows the constraints and implications for further research. The source of the analysis are the results of original research done in 2019 on a group of students of the Faculty of Management and Marketing at a university of economics in Poland.

Keywords: Online Marketing, Manipulation, Online Advertising.

Introduction

The context of the theoretical problem justification refers to two basic categories: social trust and advertising as an informative characteristic of a company's marketing offer. Trust is the subject of extensive international research in various scientific disciplines: sociology, psychology, organizational theory, management, and marketing sciences. The problem of trust in advertising, including specifically information which is the essence of a message, is cognitively important, and at the same time it is relatively little recognized in existing scientific research. The main current of research on trust in the fields of sociology and psychology tackles the essential features, conditions and dimensions of social trust. Similarly, in management sciences, including marketing and its particular areas, the scientific discourse concerns the importance of trust for the realization of the organization's market objectives and strategies, relations on B2B and B2C markets, organizational ties, and creating a community around the brand in social media etc. This is clearly a growing trend of research in management sciences. Trust in on-line advertising is a cognitively important and significant problem, yet it has not been included in mainstream trust and advertising research. The main aim of the article is to empirically assess the confidence of Internet users in information included in Internet advertising messages.

The Theoretical Context of Research Problem Justification

The importance of trust in advertising messages is determined by the significant role of advertising in shaping consumers' behavior and influencing their market decisions. In the presentation of the context of theoretical justification, we would like to emphasize the most important aspects that allowed us to create a research model as well as its empirical verification.

Trust is a complex cognitive construct. It is multidimensional. Similarly, its conditions, characteristics, consequences, models and measurement methodologies are numerous. While conducting the narrative on the basis of management sciences, let us emphasize the most important features relevant to the title

issue of the article. The *definiens* of the category of trust relates to a broad and varied approach. It is heterogeneous both within the discipline and, understandably, between the variants of approach. Literature review also leads to such conclusions [Kennig, 2018]

The literature assumes that trust is a feature of the evaluation of interpersonal relations or relations expressed on the "I-object" plane and determines certainty about the future actions of a given person or the properties or states of a given object. Trust is treated as a variable, both situational and relational. It has an individual and a social dimension, taking micro and macro perspectives. It is both a real, concrete category and a completely abstract one, characterized by relations in large and very large social groups, including international ones. Trust in business management is the subject of research in the intra- (work environment) and inter-organizational dimensions (relations between the company and its environment, both in B2C and B2B relations, in the processes of cooperation and coopetition). Trust is the certainty or a specified, high degree of probability of certain expected behavior of another party or of particular declared states of ownership of an object. As such, it eliminates uncertainty, reduces risk and creates the rationale for making a specific, rational or reasonable decision when there is insufficient or even excess of information. Trust reduces uncertainty in mutual relations and facilitates decisions the consequences of which will be revealed in the future. P. Drucker was right when he wrote that modern enterprises are not built on strength, but on trust [Drucker, 1999]. This is why the importance of trust in business relationships is nowadays widely accentuated and, it seems, adopted as a paradigm in management sciences [Morgan, Hunt, 1994].

The category of trust is studied at different levels. In management sciences it is an area of research on management in an organization, HRM, interpersonal relations and relations in systems: superior-subordinate, organizational climate, knowledge management and organizational culture, business relations and cooperation networks in market channels. In marketing, the category of trust occupies an important place in business relationships, research both on the B2C and B2B market, in customer satisfaction and loyalty research. In market research on buyer behaviors, trust is an important variable that explains or mediates between a company's offer and the final purchase decision and consumer satisfaction. It is an important element in valuing offers, focusing on finding relevant information and evaluating each variant of the market behavior process. Trust is a key element of a customer's market lifecycle, and strategies to form customer trust - in each phase of the cycle: acquisition, maintenance and possible loss - are important parts of customer-oriented business strategies. Trust in customer value models is of similar, significant importance, which is a condition of the CLV category itself, the elements determining the buyer's life value and a component of the calculation methods for this category. In relation marketing, the main stream of theoretical studies and empirical research is to identify the importance of trust - including the credibility of relationship partners and participants in the communication - in the interaction, evaluation of the strength of the relationship, its value, and conditions. Trust is an essential element of any basically relational marketing model, based on an evolutionary and subjective approach (e.g. the classic R.M. Morgan and S.D. Hunt's model).

Trust is the level of customer engagement in relations with the company. It is a basic and key condition for the benefit of each customer, both individual and institutional. This is part of the transition from transactional marketing to relationship marketing, based on the category of trust and creating a kind of "community of experiences and expectations". Among the foundations for the creation of such ties, trust is crucial.

This reflection aptly corresponds with the emphasis on the social dimension and the importance of trust in institutions, including the institutions of life and the public sector, in the media, in the culture of trust in the development of social capital on a broad scale [Fukyama, Blomquist, Atkinson &Butcher, Sztompka]. New areas have emerged on the map of research on trust in the last decade, including trust in information and communication technologies [Lippert Swierz, 2005]. This last area, under the conditions of the "fourth industrial revolution" [Schwab, 2016], the digital transformation, and the creation of the "human digital" [Ch. Skinner, 2018] represents a significant challenge for further research.

Trust research accurately emphasizes the importance of the credibility of participants in the communication and relationship. Credibility is treated as an important premise for the multiplication of previous experiences for an a priori assessment of future events and at the same time an opportunity to shape long-term business relationships. Each of these components of trust is important for the presentation of the second pillar of the theoretical justification of the title issue of the article.

Advertising is a mass media form of communication characterizing the company and its product offer, shaping consumer needs and preferences. Quite commonly, at a certain level of generalization, three types of basic functions: informative, persuasive, and competitive, are assigned to advertising. They are the subject of specific tasks: shaping brand awareness, promoting its identity and image, providing consumers with information - arguments for purchasing and choice preferences, creating a community around the brand in social media, and shaping post-purchase experiences, buyer loyalty, and creating long-term relationships. The modern market, with its wealth of product offerings, with excess of demand and supply (that can be described as manipulative supply) shifts the importance of these functions from informational to persuasive and competitive. The latter seems to be still gaining in importance, due to the mechanisms of sectoral competition, globalization and standardization of production. T. Levitt was right claiming that today there is no competition between what companies make but rather what they add to their products in the form of advertising [Levitt, 1969].

Advertising is a transfer of coded information through the media. M. Bruhn, and more broadly the German school of marketing identifies advertising with the medium, treating both categories in an inseparable relationship when writing about *Mediawerbung* (media advertising) [Bruhn 2008, Bruhn 2013]. As such, advertising is information of a specific nature. It is not a complete description of one's offer, but an abbreviation, often incomplete and simplified. This highlights the system of European law in which advertising, due to its information "limitations", does not constitute an offer but is merely an invitation to conclude a contract. Advertising is an expression of encoding the sender's intentions into a form acceptable to the media and economic account requirements. Such a code is USP [Reeves]or a unique value of advertising, expressed in the form of a specific creative strategy, whose basic element is the advertising slogan, the nature of the message and the style of communication. Advertising can, and certainly is, an incomplete, ambiguous, hidden message. Such a message is aptly expressed by a passage from a poem by the Polish poet B. Leśmian: . …*and the words roam and ramble across the sky, and pretend they mean something more than what they mean . . .*

Trust in information can have its affective (emotional) and cognitive dimension. These dimensions are also important elements of the discussion on social trust and the methodology of measuring it in general - they are also critical for the evaluation of information contained in online advertising and the model adopted. These two dimensions of trust are referred to by the assumptions of the strategy of message creation in advertising, the nature of slogans, as rational or emotional on the one hand, and on the other hand - positive and negative. Each of these strategies of creating a message and formulating the character of advertising has a significant impact on the formation of trust. It has specific relevance in different market segments and sectors, and different phases of the market life cycle of a product.

The message may express the asymmetry of information between the advertiser and the addressee. Each of the parties to the marketing communication process may have a separate set of information in terms of quantity and quality. This situation was at the basis of the concept of "information asymmetry" by G. Akerlof, later developed by M. Spence, J. Stieglitz and other researchers [Akerlof, 2015].

The above current of reflection allows us to state that advertising is a kind of information game in which three entities participate: 1) company - broadcaster of the advertisement, 2) consumer (addressee of the advertisement), and 3) media. Each of the participants of the communication process is important in the analysis of the title issue of the article. Their broader analysis is beyond the scope of the paper. We only wish to underline the key issues related to the trust. Research on trust focuses on the nature of the participants' relationships: credibility, historical experiences, identity and image. Such a characteristic refers fully to the analysis of the trust of consumer, as the addressee of the advertisement in relation to its "unique value". This is the first, fundamental dimension of the relationship and at the same time a premise for measuring consumer confidence in the information contained in the advertising message. The link between the two sides of the marketing communication process is a kind of "information interest community". This "community" and the level of identifying the issue includes the media. The reasoning behind this position is as follows. The consumer and the company are the basic participants of the marketing communication process, carried out in the form of advertising through the media. This rationale is reinforced by our position in a slightly different ontological perspective: the company communicates with the market through the media, which, in McLuhan's view, are a type of information: *The medium is the message,* and the modern man is *an extension of the media* [McLuhan, 1962]. Therefore, we treat rust in the information contained in advertising as the basic plane of

the relations and realization of the participants' needs of various nature and configurations, especially in medium and long periods. These needs express themselves and rotate - like a spiral - around the world of interests of each subject of communication, seemingly different values and levels of usefulness, but aiming at a zone of compromise. An important, but naturally not the only link in this "world of interests" is trust towards information. In this configuration, the mechanism of integration and interaction can, with some caution, be compared to the Triple Helix. The category was proposed in the study of the Triple Helix Model Lawton Smith, & Leydesdorff, 2020, Etzkowitz H., Leydesdorff L.,2000]. Trust in information in online advertising initiates the behavior of the addressee of the advertisement. It is a premise for the evaluation of individual sources of information (forms and types of online advertising), as well as, in a slightly broader perspective, the evaluation of the credibility of the sender of the message and the credibility of the medium (Figure 1). The key platform for the formation of the trust is their interdependence. In the case of online advertising, it is clear and obvious. They are expressed in the common field of interest, their interconnection and conditionality. That community expresses the integration and convergence of action. We explain them from the perspective of the goals of each entity - a participant in the marketing communication, emphasizing the connection of two constructions: credibility and trust. As it seems, an important argument in the discussion could be the modern convention of perceiving categories of trust, which was presented by R.J. Lewicki, D.J. McAlister, and R.J. Bies. We adopt their position in clear opposition to the traditional current of research, which treated trust as the opposite of mistrust in a linear system, i.e. being two poles of the same category - the probability of a certain state of relations occurring in the future. The concept of Lewicki, McAlister and Bies [1998] is fundamentally different. It rightly assumes that contemporary conditions of communication, development of means of social communication mean a multitude of relations, a multitude of connections and interactions, together with a wide set of various conditions, often emergencies. An important role in forming trust in relations is played by context in every dimension: psychological, historical, cultural, technical, social, and economic. Each of these elements can be analyzed in different aspects, but this statement about the multiplicity of connections, including informative relations and the importance of media conditions for the formation of a certain level of trust in relations between the company, the sender of the advertisement, the addressee-consumer (Internet user) seems to be sufficient. Instead of the classic mainstream question: "Do I trust?" and the antinomy of "trust - mistrust" (lack of trust) in the new approach, forming trust can be expressed by the metaphor of concentric, wave-shaped circles of communication (following the example of a HUB model) and the question of how trust is built up in the relationships of participants in communication through the media in a horizontal and vertical arrangement. This approach is also an argument for analyzing the problem of e-consumer confidence in the advertising broadcast by the company in a three-dimensional perspective, including the medium of transmission of the advertising message.

An indispensable premise for the effective functioning of a company in the competitive structures of the modern market is to reach a potential customer and provide them with a package of information about the advantages of the promoted product (in all its concentric circles - T. Levitt) and benefits associated with its purchase in comparison with the utility set offered by competitors. Through advertising and other instruments of integrated marketing communication, the company creates needs and preferences, encourages purchases, promotes its identity and image, and pursues its other goals in different time horizons. From the point of view of the article's objective, we would like emphasize that the essential function, a specific mission of communication is seen in ensuring a constant, informative presence of the company on the market - in the awareness of potential buyers, media, and events. The contemporary world of the media, the world of the Internet and the development of information and communication technologies together with their important feature, which is non-synchronicity and multidimensional communication, entitle us to identify such a function.

The importance of advertising for the consumer, as the addressee of the advertisement is multidimensional and determined by different perspectives. The adopted profile of the article and the research issue provide a prerequisite to emphasizing two aspects.

First of all, advertising has an educational function in a broad sense: it provides information about the product, its properties and attributes, conditions of use, attractiveness in relation to competitive ways of satisfying the need, but it also constitutes a source of information about the advertiser: its identity,

mission, history, market position, attitude to important challenges from local communities, stakeholders, the environment (e.g. CSR, business ethics, climate change, etc.) and forms of its involvement [Sanak-Kosmowska, 2018].

Secondly, we stress the completely new role of the consumer in the process of market communication in the conditions of the development of the Internet, information and communication technologies, the digital transformation of all areas of social and economic life, the development of digital society, and the creation of the "digital human" [Skinner, 2018]. The traditional model of one-to-many communication replaces the model of communication in a hypermedia computer environment, with the main many-to-many formula [Hoffman, Novak, 1996]. The addressee of the advertisement is first of all an Internet user with an extensive network of informational contacts, crossing the borders of market segments, industries, sectors, time, cultures, and countries. The global reach of the Internet has translated into a global range of communication and a multitude of relations in communication between the company and the market. This environment has created a new type of recipient of the advertisement, the network user, namely, a com-sumer - the recipient who consumes information and who simultaneously creates it. A recipient entering broadly and deeply into on-line communication, interactions, looking for relevant information (including in order to solve purchasing dilemmas) and willingly shaping it by their own opinions, modifications of the evaluations expressed in forums, in social media among brand fans, revealing the desire to integrate groups and micro-communities around a specific problem, including the problem shown in on-line advertising [Wiktor, 2016]. The opinions of Internet users published online must be taken into account by the advertisers affected by the issue, assessment, or information. The form of such a relationship is to consult on the brand, its credibility, but also to comment on it online, which makes online communication vertical.

The opinions of Internet users become an important platform for two-way modification of the advertising message: they enhance or negate it, thereby forming a level of trust. They also become a key element of the research model for the title issue of the article. They allow to explain the two adopted dimensions of research on trust in advertising. The first, horizontal one concerned communication in a traditional environment, explained by a linear, as it were, horizontal flow of information in either a one-to-one or one-to-many formula. The second, vertical dimension describes the mechanism of the formation of trust in the hypermedia digital environment (Fig. 1).

Fig. 1: Horizontal and vertical dimensions of trust in online advertising. Source: own research

Opinions, interactions, multiplicity of relations in "many-to-many" online communication results in the fact that the trust of a particular addressee in the information provided via advertising is a result of

many different conditions, including opinions and comments of Internet users and information published by them online. This may be an element characterizing the "second helix" in the perspective of the triple helix model.

The third subject in the study of trust towards on-line advertising was the media. The media play a special role in the advertising transmission. On the one hand, it constitutes information in itself: *medium is the messenger* [McLuhan, 1969]. On the other hand, the media are a bridge through which advertising reaches the chosen audience and through which all media functions of marketing communication are realized: informative, persuasive and competitive. In doing so, they ensure a continuous, informative presence of the company in the media space of social communication. This expresses the basic functions of mass media: transmission and publicity [McQuail,2010]. The important role of the media in advertising is aptly explained by the "publicity model". Their own autonomous function becomes to attract attention and keep it constant, satisfying the sender of the message. The role of the media is not limited to providing marketing information to broadcasters. It also expresses itself in the pursuit of its own goals, often at the expense of media competing for viewers, users, listeners, readers, for their contact time, needs (information and entertainment, opinions, comments) and preferences. This reflection is related to the creation of an attractive image and marketing of the media, concern for maintaining certain standards of functioning, credibility, image and social trust. In this current of reflection, we emphasize an important element, namely, the differentiation between intra-media analysis and intra-media analysis. It is important to analyze the problem of trust. Individual media, including detailed forms and tools of on-line advertising (e.g. websites, company marketing director's blog, personalized newsletter, mailing, brand profiles in social media) may have a different image and create a different level of trust in the information transmitted by each of them. These elements, focused around one's own interests, can express features of a third helix. Combining the horizontal and vertical dimensions of the problem analysis is also important for research on trust in online advertising.

Model Assumptions, Methodology and Characteristics of The Research Group

The theoretical framework of the problem presented above allowed us to indicate the dimensions in which the assessment of trust in advertising could be analyzed. The assumptions of our own simplified test model are shown in Figure 2.

The model is based on the assumption that the following factors have a significant impact on the assessment of e-consumers' confidence in information contained in advertising:

1. The digital competence of the Internet users was assume to be expressed as an index of answers to questions relating to the frequency and manner of using the Internet, the degree of professionalism in relation to websites, online platforms and knowledge in the area of online advertising and marketing, e.g. knowledge of the mechanisms of cookies, retargeting, etc. It was assumed that the higher the digital competences of the respondents, the lower their declared trust in advertising will be. This thesis corresponded with the horizontal dimension of communication and at the same time trust in advertising, based on the knowledge and digital competences of the respondents.

2. The way of perceiving an advertisement represented by an Internet user, including the assessment of forms of advertising and its types. The examined construct was reduced to three dimensions: negative, objective and positive. It was assumed that a positive perception of an advertisement influences the high rating of trust in advertising, and a negative one lowers the declared trust in online advertising. This element of the model reflects the vertical dimension of trust towards advertising.

3. The evaluation of the "informationality" of advertising is a construct relating to the content of advertising. In particular, the construct referred to the subjective evaluation of the comprehensibility and concreteness of the advertisement and its adjustment to the needs of the Internet user. In this proposal, the horizontal dimension of trust in the assessment of the "informational" nature of advertising became more apparent again influenced by "many-to-many" communication. According

to the authors' hypothesis, the higher the informational rating, the higher the level of trust in advertising was.

Fig. 2: Research model.Source: own research

The research results presented in this part of the article are part of the NCN grant: *Asymmetry of information in online advertising and manipulation of e-consumer behavior* [2018/29/B/HS4/00563], carried out in the years 2019-2020 in the Department of Marketing, University of Economics in Krakow. The research was a pilot study primarily performing the functions of substantive and methodological verification of the research tool [Bryman, 2008]. An important element of the study, despite its pilot nature, was the initial assessment of two dimensions of trust in online advertising: horizontal and vertical. The identification of this problem was made possible by the construction of the research model and its verification in the course of own research.

The study (May 2019) involved 138 students of the Cracow University of Economics, studying economics and business. Participation in the survey was voluntary. The online version of the survey was conducted using the Google Forms tool. Filling out the form was encouraged by teachers and students using social networking sites, especially informal discussion groups on Facebook. The students were able to complete the survey at any time and in any place. They could also stop answering at any time by canceling the survey. The time of filling in the questionnaires was not controlled, however, experience shows that it took less than 15 minutes to complete it. Table 1 shows the characteristics of the study group. The study involved 109 women and 29 men. The selection of the samples was purposeful. The respondents were dominated by persons aged 18-25.

Evaluation and Discussion of Results

The starting point for the analysis of the obtained results was the operationalization of the dependent variable expressing trust towards online advertising. The variable distribution is shown in Figure 3. The studied variable ranged from 8 (minimum) to 32 (maximum). The average score of 23.35, standard deviation 3.97.

Fig. 3: Distribution of the dependent variable expressing confidence in online advertising.

Source: own research (N=138).

Table 2 presents the distribution of the examined dependent variables: evaluation of information matching the needs of Internet users (P2a), concretization and comprehensibility of the content of advertisements (P2b), digital competence (K1), and the ways of perceiving the advertising: negative (K3a), objective (K3b) and positive (K3c).

Table 2: Distributions of independent variables. Source: own research (N=138).

Variable	Descriptive statistics (2020-01-24 POLAND)				
	Valid N	Mean	Minimum	Maximum	St. Dev
Adapting to the needs (P2a)	138	0.000000	-1.97554	2.835524	1.000000
Informa-tiveness of advertising (P2b)	138	0.000000	-2.73266	2.420923	1.000000
Digital com-petence (K1)	138	0.782610	0.45833	1.000000	0.133267
Negative perception of advertis-ing (K3a)	138	0.000000	-1.66471	2.594427	1.000000
Objective perception of advertis-ing (K3b)	138	0.000000	-2.56490	1.677828	1.000000
Positive perception of advertis-ing (K3c)	138	0.000000	-2.17709	2.664485	1.000000

In the first stage of statistical analysis carried out with Statistica software, the correlation between individual independent variables and the dependent variable was analyzed. Detailed results have been shown in Table 3.

Table 3: Correlation analysis of the variables examined. Source: Source: own research (N=138).

Variable	Correlations (2020-01-24 POLAND) Marked as correlates are significant with p < .05,000 N = 138 (Missing data was removed case by case)
	Confidence in online advertising (Y)
Adapting to the needs (P2a)	0.195787

Informativeness of advertising (P2b)	-0.254766
Digital competence (K1)	-0.064548
Negative perception of advertising (K3a)	-0.093895
Objective perception of advertising (K3b)	0.485992
Positive perception of advertising (K3c)	-0.341535

The results obtained allow for the analysis of individual relationships between the dependent variables and the independent variable. The relationships between matching the content of the advertising to the needs of the Internet users and an objective and positive perception of the advertising were statistically significant. Analyzing the variables under study in an individual way, it is possible to confirm the negative correlation between the informational function of advertising and trust assessment (-0.255, $p<0.05$) and the negative correlation between positive perception of advertising and trust (-0.341, $p<0.05$). In the light of the results obtained, it can be concluded that the more objective the perception of advertising is, the higher the trust rating (0.486, $p<0.05$).

In the further part of the study, a multiple regression analysis was carried out, allowing to capture the total effect of the examined variables on the independent variable (Table 4). After the reduction of insignificant coefficients, the cumulative effect of the three dependent variables was confirmed. The hypothesis regarding the level of digital competence (K1) of Internet users has been confirmed. The subjective assessment of trust towards online advertising decreases as they grow. At the same time, this may indicate the importance of the vertical dimension of trust. High digital competence allows respondents to communicate freely on the web, including in social media, to critically assess all types of information, including advertising and its distribution in different online communication channels. In addition, the more objective and neutral the perception of information presented in online advertising (K3b) is, the higher the confidence in it. Surprisingly, a positive evaluation of advertising content has the opposite effect: the more positive the evaluation, the lower the confidence in online advertising was.

N=138	Summary of the dependent variable regression: P2.1 SUM (Y) (2020-01-24 POLAND) R = .55623525 R 2 = .30939766 correct. R2= .29393641 F(3.134)=20.011 p					
	b*	St. dev. with b*	b	St. dev. with b	t(134)	p
Constant term			27.84199	1.742741	15.97597	0.000000
Digital competence (K1)	-0.192352	0.073711	-5.73327	2.197040	-2.60955	0.010097

Objective perception of advertising (K3b)	0.457831	0.077254	1.81858	0.306864	5.92634	0.000000
Positive perception of advertising (K3c)	-0.218072	0.075978	-0.86622	0.301796	-2.87022	0.004768

Source: own research (N=138).

The assumptions of the studied model were met. First, the assumption of residual normality was fulfilled. A residual normality chart is shown in Fig. 4.

Fig. 4: Residual normality chart for the research model.

Source: own research (N=138).

On the basis of the statistical analysis, it can be concluded that the tested model also meets the homoscedicity conditions, and therefore has a constant variance of the random component for individual values of the independent variable (Fig. 5).

Fig. 5: Homoscedicity of the residuals for the model under examination.

Source: Source: own research (N=138).

The residuals, for both high and low ratings of trust towards online advertising, have a similar dispersion around the regression line. The assumption of homoscedicity was therefore also fulfilled.

In the light of the results obtained and the statistical analysis carried out, the relationship between the level of digital competence and perception of advertising and trust towards online advertising in both dimensions: horizontal and vertical was confirmed. As a result of the multiple regression analysis, the dependent variables relating to the evaluation of the content of the advertising, and thus the evaluation of its informative character and its adjustment to needs, were reduced (Fig. 6). The relationship between the level of digital competence and trust has been confirmed. The higher the competence, the less trust in the content presented in online advertisements was observed. An important explanation for such results is the specificity of online and many-to-many communication on top of the importance of the vertical dimension in forming trust towards online information. This dimension, which is the activity of Internet users creating and sharing content, especially in the social media environments, clearly enriches and modifies the traditional dimension of analysis and assessment of trust in information on a horizontal level, between the participants of the marketing communication: the company and the consumer in a specific online media environment.

Fig. 6: Verified model of trust towards online advertising

Source: own research.

Limitations of the Research and Implications for Further Research

The limitations of the outlines studies result from their pilot character, the size of the research sample, the targeted selection of participants and the limitations of the structure of elements included in the model. The research was preliminary and exploratory. However, it brought some interesting results, both cognitive and methodical, which are a starting point for wider research. The experience obtained will be used in their design, highlighting several issues. First, we recognize that the index of digital competence requires further verification. Attempts to standardize and objectify it should be made. Secondly, we stress that the model adopted for the pilot study does not take into account all the factors influencing the assessment of the credibility of online advertising and trust in its specific features, forms and ways of organization on the web. Further research should take into account such variables as the assessment of the sender's intentions, the type and content of the message, the characteristics of the various "environments" of online communication, user search strategies (push and pull), the strength of influence of other Internet users, psychological variables of users' personalities, individual differences, which can significantly affect, and, according to pilot studies, do affect the level of trust in online advertising. Certainly, the research should also cover other consumer groups, niches and market segments with different characteristics that are relevant to the creation of target markets.

The presented issues are part of the research on contemporary marketing, wherein a significant development trend is determined by digitalization and internationalization. The problem addressed, its significance and openness in the scientific sense are an incentive to continue research on trust in online advertising on interdisciplinary and, in the long run, international teams. Such premises, combined with a specific methodological standard, can produce valuable cognitive results that will become a significant contribution to the development of marketing science, online advertising and e-consumer market behavior.

Abstract

The idea of responsible socio-economic development represents one of the most interesting concepts formed on the basis of past experiences and observations of both the economic sciences and the economic practice. The paper presents selected dilemmas related to the understanding of the concept, set in the context of the evolutionary progress of theories of socio-economic development. The authors placed emphasis on selected determinants which are deemed as fundamental for this particular approach to civilizational progress.

Keywords: Responsible Socio-Economic Development, Determinants Of Economic Development

Classification JEL: B1, O1, Q00

Introduction

The concept of responsible socio-economic development is representative of the modern set of approaches to complex processes and functional transformations of contemporary societies and the associated economic phenomena initiated in the 20th century. This trend has always been at the centre of modern economic thought, from the early precursor work of R. Cantillon and A. Smith, through the classical school of economics (D. Ricardo, T. Malthus and J.S. Mill), down to their spiritual successors (K. Marks). They also constituted an important part of the input generated by the Older and the Younger Historical Schools of economic thought and of the postulates of the Veblen's institutional economics. Lastly, they were also employed – in a slightly modified form of formal mathematical models of economic growth – by the subjectivism and marginalism trends of economic thought, particularly the neoclassical economics. [Stankiewicz, 2007, Landreth & Colander, 2005] Modern economic literature in its entirety seems to provide such models in great abundance. [Krelle, 1985]

This study places focus on the concept of responsible socio-economic development. The attribute of 'responsible' provides an explicit definition of correlations between the various elements, both objective and adopted. Objective elements can be exemplified by such notions as the availability of economic resources or the existing barriers to growth. Adopted elements, on the other hand, are represented by such notions as values, measures, states, or principles. Thus, the attribute of 'responsible' should be interpreted in relation to an external point of reference. In this sense, the realisation of responsible development shall be a derivative of such relations. This allows us to place the concept in contrast to the ideas of sustainable development or durable development, where attributes of development are related directly to internal qualities of a strategy. Thus, the concept of

responsible development seems to contain much more axiological elements compared to other ideas and approaches to socio-economic development.

This study is aimed at identifying basic determinants that impact the understanding of the notion of responsible development. This is by no means directed towards verification of any specific theses or hypotheses. It is these authors' belief that it may be much more useful, at least at the present stage of studies in the area, to focus our efforts on appropriate formulation of research questions. Such an approach would not only help attain a more precise definition of responsible socio-economic development, but also reduce the amount of information noise. The latter factor has already distorted the course of yet another fascinating concept of the late 20th century, namely: the idea of *Sustainable Development*. In effect, too much energy was placed on terminological disputes rather than methodical realisation of socio-economic development strategies as such. It may also be useful to note that this type of explanatory approach has already been emphasised in other realms of study, such as modern physics and cosmology, and was also found of value in such a notionally and conceptually advanced discipline as mathematics.

The Notion of Responsible Development

The notion of responsible development, as one of the new postulates originated in the late 20th century along with such concepts as *Sustainable Development*, sustainability, integrated development and durable development, was coined in response to the following:

- the apparent inadequacy of the existing 'philosophies' of socio-economic development;
- the negative consequences of economic transformations, such as deterioration of natural environment, income inequalities or rapid pauperisation of whole social strata;
- new challenges of civilizational progress, such as the rise of the information society and the associated development of knowledge-based economy.

The concept of responsible development introduces yet another important aspect, namely: transition from knowledge to wisdom. Knowledge represents an ordered set of information subordinated to certain verification procedures, but devoid of criteria other than those substantiated by scientific evidence. Thus, knowledge provides us with the ability to act effectively and efficiently, but fails to provide other justifications for our actions, such as the legitimacy, justice or any other axiological 'virtue' of our deeds. The concept of responsible development introduces such axiological evaluations as part of its characteristics. To put it in another way, the concept of responsible development takes account of not only the effectiveness and efficiency of strategy realisation, but also of its axiological qualities.

What elements should then be included in the concept of responsible development? Several factors seem of particular importance in this context, namely (Fig, 1):

- potential for effective realisation of specific goals and undertakings;
- internally cohesive representation of the vision of development, ensuring a proportionate representation of each of the following dimensions: economic, social, environmental, institutional, and psychological;
- effects of strategy realisation, perceived from the viewpoint of the entire megasystem: man-society-economy-natural environment-symbolic environment (i.e. broadly defined culture);
- economic effectiveness, based on standard indices derived from cost-benefit analyses;
- socio-psychological consequences introduced by the postulated realisation of development, particularly their humanistic dimensions;
- the advisability of individual actions, with anticipation of their various effects;
- resource feasibility, referring to the suitability and availability of economic resources, both in terms of their volume and quality;
- social responsibility founded on a humanistic dimension of approach to development processes, i.e. with ample representation of such humanistic criteria as the limitation of labour market exclusion and

poverty, and coupled with corporate social responsibility, proper social and interpersonal communication, democratisation of societies, and the spirit of tolerance;
- civilizational responsibility, expressed in a suitable choice of development 'philosophy' (progress, prosperity, human dignity, etc.), but also in respecting the legacy of the past, particularly the most valuable elements of human cultural capital;
- intra-generational justice, including the right of relative equality among men in their pursuit of individual strategies of development and their effects;
- inter-generational justice, which in this context relates to observance of interests and objectives of future generations as part of all present decisions, with the view of ensuring preservation (if not betterment) of both the living conditions and the economic resources available to future generations.

Fig.1: Elements of responsible socio-economic development

As shown in Fig. 1 above, elements constituting the essence of responsible socio-economic development can be arranged into the following groups of functional determinants (layers of influence):

- praxeological-functional determinants describing the feasibility of a given strategy of development;
- economic-functional determinants describing the required level of economic effectiveness for the realisation of a given strategy of development;
- axiological-monitoring determinants related to effective application of principles of inter-and intra-generational justice;
- general civilizational determinants associated with various dimensions and aspects of responsibility within the framework of a given strategy of development (Fig. 2).

The above groups of determinants define the means and the methods available for the realisation of strategies of socio-economic development, both at their design phase and in the course of their subsequent implementation. At the same time, they serve an important role as part of the so-called 'adjustment and perfection monitoring'. This type of monitoring can be a particularly potent determinant in the course of practical implementation of strategies of responsible socio-economic development. In contrast to the concepts of durable and sustainable development, responsible development is not limited to the study of objective limits of such development, but also to supplement it with a suitable set of socio-axiological determinants (which can also be perceived in philosophical, religious or humanistic terms) deemed acceptable by the majority of societies or

communities affected by the planned change. This represents both the essence and the success condition of responsible socio-economic development.

Fig. 2: Layers of functional determinants of responsible socio-economic development

Projects of development strategies and the associated choices should be founded on a strong basis of general civilizational determinants, to help determine the principal directions and attributes of the required course of socio-economic development. These may include, for example: (1) respect for human dignity, (2) respect for human freedom, or (3) satisfaction of the fundamental human needs. These should be supplemented by (4) the right of a just share in benefits brought about by scientific, technical and social progress and development, but also (5) any duties and responsibilities associated with such rights, including responsibility for change. Civilizational determinants also include (6) reduction of the various forms of exclusion, (7) providing access to reliable and verifiable information, and (8) proper access to various forms of interpersonal and social communication. Human relations should be based on (9) tolerance and (10) respect for cultural identity and diversity. Many more determinants can be identified in this context, but they all share the same fundament of broadly defined humanism, empathy and mutual respect.

The layer of axiological-monitoring and adjustment-perfection determinants is a direct descendant of the underlying layer of general civilizational determinants. This layer is associated with the use of various controlled actions designed to emphasise and support the intended direction of socio-economic (civilizational) changes and transitions. For instance, when the focus is placed on protection of the natural environment, the strategy should include identification, creation and implementation of mechanisms that offer proper rationalization of the associated burden placed upon natural resources as well as effective protection of the most susceptible elements of the affected ecosystems. When the emphasis is placed on reinforcing civic engagement and participation, other mechanisms are needed, such as implementation of a mature system of power based on democratic rule, effective protection against power abuse, and incessant education in democracy-related issues. When unrestrained access to information becomes the central determinant of general civilizational development in information societies, the transition should be supported not only by the development of proper technical infrastructure, but also by suitable training of communication and IT skills, and by propagation of civic sense of responsibility for our words.
One characteristic trait common for both layers is their reliance on not only knowledge, but also – and most of all – wisdom. While knowledge is a decisive factor in generating ideas for possible plans of action, it is wisdom that helps us discern the most suitable solutions. A good illustration of this

process is the determination of paths for government intervention taken for the purpose of stabilising the economic situation on domestic markets. In such a scenario, knowledge (in the form of Keynesian economics) offers numerous solutions, from state investment in communication and transportation infrastructure, through increased support for municipal housing and public amenities, investment in environment protection infrastructure, income redistribution (e.g. in the form of guaranteed income), social support, development of gratuitous health care service systems, up to such broad-scale projects as space exploration and militarisation of economy. Each of the above solutions can prove effective in creating aggregated demand, but their effects on individuals and on the civilizational progress as such can be radically different. This is the point where wisdom should take on a dominant role to help us determine the most suitable strategy.

Another layer – that of determinants related to the economic effectiveness of strategies of responsible development – is activated after the conclusive set of viable solutions has been defined. This layer introduces a number of economic effectiveness criteria, i.e. instruments allowing for determination of relations between the expected effects of a given undertaking and the economic outlays required for their realisation. Effectiveness represents one of the elementary categories in economic sciences. As such, it can be employed not only for strictly bookkeeping purposes, but also as a criterion for the evaluation of various forms of economic activities. Modern literature provides us with varied approaches to the concept of effectiveness (such as economic, technical, x-effectiveness), both in static and dynamic perspectives. [Kozun-Cieslak, 2013, Ziolko, 2018] The inclusion of economic effectiveness criteria offers one significant benefit, namely: the optimal (and thus rational) utilisation of the available economic resources for the realisation of individual activities and strategic objectives. In the world of scarce resources, this fact alone makes them indispensable.

The next layer – the one related to praxeological and pragmatic aspects that crown the effective realisation of a strategy of responsible socio-economic development – can be regarded as the ultimate test. If the objectives of a given strategy or any of the associated activities (including their intended effects) cannot possibly be brought to successful conclusion, all the remaining layers become mere verbal expressions of intent or plans of action. It is the praxeological dimension that yields the ultimate attribute of viability to our strategies.

Thus, the recommended sequence in the analyses of determinants of responsible socio-economic development should extend in two directions: monitoring for design and implementation, and monitoring for adjustment and perfection. As such, it can be seen as a joint expression of both knowledge and wisdom.

Responsible Development Relative to Other Ideas of Social and Economic Development – A Retrospective Analysis

Effective realisation of the idea of responsible development does not in any way negate the previous expertise gathered in relation to previous forms and approaches to development strategies carried out in the past. On the contrary. On the one hand, it represents an attempt at integrating some of the best (most advantageous) elements of past strategies. On the other hand, it may serve to eliminate those elements of past strategies that no longer fit the present or future requirements of socio-economic or environmental character.

For it must be remembered that:

- strategies of stagnant preservation have allowed our ancestors to gradually adjust to changes in their environment and to better understand its nature. Colloquial knowledge and, subsequently, scientific knowledge have served them as a fundament for future changes, in the course of a process referred to by Karl Marx as the law of constant development of the productive force;
- strategies of extensive development, typical for changes associated with the industrial revolution, have brought radical changes to economic processes and structures, accompanied by rapid urbanisation, more effective realisation of material human needs (as a result of productivity increase), and serving as fundament for future strategies;

- strategies of intensive development emerged as a resultant of positive outcomes from past development and in response to barriers to such development, as part of the attempt of eliminating them.

The need to formulate new 'philosophies' of socio-economic development is – without doubt – directly related to the emergence of new phenomena and of the increasingly more pronounced cognitive, predicative and decision-making inadequacies observed in the previous theories of growth (development). Most of the past theories have proved to be of little use, despite their elegant formal expressions and their suitability for logical processing. The crisis of the modern theory of economic growth is clearly the product of the authors' fascination with mathematics and quantitative methods, and is further aggravated by the growing discord between the realities of complex socio-economic phenomena and their model-based representations. This can be perceived in terms of a conflict between the non-linear character of socio-economic phenomena and the decidedly linear nature of their formal (model) representations.

Precursors and founders of the early concepts of socio-economic development, such as R. Cantillon, A. Smith, D. Ricardo or T. Malthus, placed their emphasis upon discovery of the real causes of phenomena and their courses rather than the elegance of their formal presentation. [Mayer, 1996] This is fairly evident in such examples as the theory of secular stagnation by D. Ricardo, the Malthusian theory, and – most specifically – in K. Marx' concept of socio-economic formations. This trend seems to place emphasis on driving forces, mechanisms, and dynamics of their operation.

The Older and the Younger Historical Schools sought to identify similarities and contrasts in historic development with the view of separating stages in socio-economic development. Such a static approach can be useful if we try to derive directions of future socio-economic development on the basis of past experiences and their delayed effects. This represents a sort of a comparative analysis of time-delayed feedback, and offers potential for avoiding at least some of the judgement errors and excessive outlays associated with socio-economic development.

Later concepts, such as Veblen's institutionalism, the Schumpeterian approach and neo-institutionalism, have brought some important modifications to the modern theories of socio-economic development, namely:

- interest in the study of barriers to development (for instance, in forms employed by G. Myrdal's concept of cumulative causation and the 'vicious circle of poverty) along with analyses of collapse (catastrophic) risks to civilizational progress, both those of endo- and exogenous character, as exemplified by T. Veblen's concept of civilizational changes;
- exposure of some of the endogenous forces that fuel the socio-economic development processes, such as innovations in the formal approach postulated by J. Schumpeter and continued by P. Romer;
- inclusion, in the best spirit of the German Historical School, of entirely new categories of determinants of socio-economic development, such as environmental, cultural, or information-related aspects.

Without doubt, the above approaches to the subject at hand can also be seen as directly stimulating the development of global modelling in the 1960s and 1970s (such as the WORLD modelling framework) and, consequently, as a fundament for modern holistic concepts of socio-economic development, such as sustainable, integrated or responsible development.

The idea of responsible socio-economic development is construed on the basis of the most impactful elements of the earlier concepts. As such, it utilises knowledge associated with evaluations of process effectiveness and efficiency, identification of barriers and limitations to development, and the study of resource-related determinants of development. It is also strongly influenced by modern disputes on social or even philosophical and axiological aspects of civilizational changes, particularly those related to reduction of civilizational expansion (the Spaceship Earth concept supported by Sagan and Boulding in opposition to the 'cowboy economy' worldview) [Boulding, 1992, Sagan, 2018] or even the *zero-growth model* of growth. [Mesarovic & Pestel, 1977] With such solid fundaments, the

concept of responsible socio-economic development can be seen in terms of a skilful integration of knowledge and wisdom.

Conclusions

The notion of responsible development is utilised in two separate contexts. On the one hand, it represents a substantiated and logically correct concept that describes social and economic changes required to attain desired effects, objectives or states. In this context, the idea represents an integration of past knowledge with wisdom (defined here as effective utilisation of knowledge). The above expectations can also be used to describe any other substantiated and logically correct idea of development and the associated strategies of realisation.

On the other hand, the concept may be used in a purely ideological or political fashion, reducing the idea of responsible development to a narrow path determined by political vision, which does not necessarily correspond with effective civilizational progress or positive change.[1]

The above considerations lead to a conclusion that the effective identification of the notion and the attributes of responsible socio-economic development should integrate the study of general civilizational and axiological determinants of growth with analyses of determinants related to effectivity and praxis.

Assessment of The Impact of The Selected Factors on The Sense of Security in Public Passenger Transport on The Example of The Capital City of Warsaw

Arkadiusz JOZWIAK

Military University of Technology, Warsaw, Poland
arkadiusz.jozwiak@wat.edu.pl

Abstract

The purpose of the article is to analyse and assess the factors affecting the sense of security in public passenger transport on the example of the capital city of Warsaw. The factors were defined on the basis of the standard "PN-EN 13816: 2004 Transport. Logistics and services. Public passenger transport. Definitions, goals and measurements regarding the quality of services" and data collected by the Municipal Transport Authority in Warsaw. A survey was conducted on this basis, the results of which were used to model the level of the sense of security using artificial neural networks (ANN). ANN, among many criteria, enabled the assessment of the key factors having impact on the level of the sense of security.

Keywords: Sense of Security, Public Transport, Neural Modelling

Introduction

Economic development directly impacts the development of mobility. Along with the progress of technology, the mobility of the society has increased and will continue to do so. This issue applies to both freight and passenger transport, including public passenger transport. At the same time, the challenges related to this issue are growing and changing, including the quality of transport services, their efficiency, economy, impact on the environment, or the sense of security in public passenger transport.

The sense of security is one of the key factors determining the extent of using transport services, including public transport. Safety, according to Maslow's hierarchy of needs [1], right after physiological needs, is a fundamental human need. Many studies in the field of psychology have shown that without a sense of security, a human being would not be able to function normally in the longer term.

The sense of security is a very subjective feeling; therefore, an attempt to assess this factor is a difficult process. Depending on various groups of criteria or characteristics that affect the sense of security, this sense is perceived and assessed differently. As a rule, there is no linear correlation between the individual criteria affecting the level of this sense, because it often changes over time. Therefore, it was assumed that the main research problem is the analysis and assessment of factors affecting the sense of security in public passenger transport on the example of the capital city of Warsaw. The factors were defined on the basis of the standard "PN-EN 13816: 2004 Transport. Logistics and services. Public passenger transport. Definitions, goals and measurements regarding the quality of services: and data collected by the Municipal Transport Authority in Warsaw [7]. A survey was conducted on this basis, the results of which were used to model the level of the sense of security using artificial neural networks (ANN). ANN, among many criteria, enabled the assessment of the key factors exerting influence on the level of the sense of security. The purpose of the article is to use artificial neural networks to model the level of the sense of security based on the collected information.

The status of the issue

In the literature, one can find numerous studies related to the quality, technology and the sense of security in public passenger transport [6], [10], [12]. The sense of security during a journey using collective public transport is one of the main requirements posed by the passengers [3].

Analysing the available literature, one can notice a variety of factors taken into consideration when assessing the safety of public transport. Xiaomeng Shi et al. defined the safety of public passenger transport on the example of the subway as: preventing passengers from injury, crowdedness on platforms and on trains, safe and quick exit from the subway [18]. According to [10] the quality of public transport is perceived, among others, as passenger and baggage safety on board, safety while waiting at a bus stop, short journey duration or service availability.

In turn, Torbjørn Rundmo and Trond Nordfjærn have proved in their research that the priority of safety and sensitivity to risk are the most important factors influencing decisions to select public transport as a means of transport [16].

The quality of public collective transport services includes a set of criteria in accordance with the standard PN-EN 13816: 2004P Transport. Logistics and services. Public passenger transport. Definitions, goals and measurements regarding the quality of services, Polish Committee for Standardization, Warsaw 2004, were divided into 8 following categories [11]:

- availability: range of the public transport service offered in geographical units, time units, frequency and type of transport,
- accessibility: access to the public transport system, including connections with other means of transport,
- information: systematic provision of knowledge about the public transport system in order to assist in the planning and implementation of travel,
- time: time issues related to the planning and implementation of travel,
- customer care: elements of the service in order to meet the passenger's requirements,
- comfort: elements of the service in order to ensure that travellers have relaxation and rest,
- security: a sense of personal protection for passengers.
- environmental impact: environmental impact resulting from the provision of the service.

In relation to the quality of transport services, three quality categories can be distinguished: postulated by users, offered by carriers and executed by service providers [15]. All the exemplary categories have a direct impact on the perception of security in the collective public transport.

Artificial neural networks are one of many artificial intelligence algorithms. The application of this type of tools applies to solving non-linear tasks. With the development of technology, the use of artificial intelligence in various market segments is also developing [4], [17]. ANNs find application in, among others, the assessment of the economic efficiency of vehicle exploitation [8], the assessment of transport services [14], or in measuring innovative potential [5]. The next example of another artificial intelligence algorithm is the use of fuzzy logic to assess the quality of public transport [2], or the use of machine learning to plan and predict visits in hospital research.

The analysis of the literature allows for stating that it is possible to use ANN to assess the impact of the selected factors on the level of the sense of security.

Method and the Research Subject

The sense of safety in public collective transport was examined in the area of the capital city of Warsaw. During the study, all available means of public transport offered by the Municipal Transport Authority in Warsaw were taken into consideration, i.e. buses, trams, underground, fast public transport and

suburban rail. The research took into account only those factors which result from the above-mentioned standards and data collected by the Municipal Transport Authority in Warsaw. The set of factors used in modelling the assessment of the sense of security is presented in table. 1.

Table. 1. The set of factors used in modelling the assessment of the sense of security

No.	Identification of factors	Names of factors	Permitted factor value
1	O_{km}	Accessibility of public transport	1-5
2	D_{km}	Accessibility of public transport	1-5
3	I_{km}	Information about public transport	1-5
4	T_{tm}	Duration of urban public transport	1-5
5	J_{tk}	Customer care	1-5
6	K_{pkm}	Comfort in public transport	1-5
7	W_{otm}	Impact on the environment of urban public transport	1-5
8	Z_{pp}	Behaviour of the driver	1-5
9	P_{st}	Technical condition of the vehicle	1-5
10	K_{sp}	Procedure of ticket inspections	1-5
11	S_{st}	Technical condition of the stops	1-5
12	A_{st}	Transport means breakdown	0-1
13	D_{st}	Transport means devastation	0-1
14	W_k	Accident/Collision	0-1
15	Z_{rkm}	Halting public transport for other reasons	0-1
16	Cz_{pkm}	Frequency of commuting by public transport	1-5
17	$Bezp_{ptp}$	A sense of security in public transport	1-5

Source: the author's own elaboration

The scale of the assessment of individual factors was defined as follows:

- 1-5 - where 1 means very poor, 5 means very good,
- 0-1 - where 0 means no event, 1 means the occurrence of an event.

Questionnaire surveys were conducted for such defined factors between 15 September and 31 October 2019. The questionnaire consists of 17 questions. 258 surveys were collected. This way, a total of 4386 responses were collected, which were used to model the assessment of the sense of security in public collective transport using artificial neural networks.

Neural Modelling

While creating a neural network, all factors were used table. 1, and were divided into quantitative input signals (factors 1-16) and quantitative output signal i.e. $Bezp_{ptp}$. Examples of collected data based on surveys used in the neural network learning process are presented in table. 2.

Source: the author's own elaboration

With the use of the results obtained by, among others [8], [9], [13], [14] scientific papers, a *Multilayer Perceptron* was used together with learning algorithms of: conjugate gradients; the fastest fall and BFGS *(Broyden - Fletcher - Goldfarb - Shanno)*. The division of the data set into parts is adopted in the neural modelling:

- 80% - training set used to modify weights,
- 10% - test set used for ongoing monitoring of the learning process,
- 10% - validation set used for assessing the quality of the network after completion of the learning process.

After determining the input signals, output signal and network parameters, the learning process was conducted on a neural network, using the Statistica 13.3 computer program. Examples of its results are presented in table. 3.

Table. 3. Sample results of the neural network learning process

ID	Network name	Quality of learning	Testing Quality	Validation quality	Learning algorithm	Hidden activation	Output activation

Source: the author's own elaboration

The structure of the best neural network took the form of MLP 16-22-1, which means 16 neurons in the input layer, 22 neurons in the hidden layer and 1 neuron in the output layer (fig. 1).

Fig. 1. The structure of the best neural network created MLP 16-22-1

Validation of the neural network and calculation results

In table. 3 the learning quality of MLP 16-22-1 network was estimated at about 99% probability of indicating the correct answer, i.e. the adopted measure of the sense of security in public passenger transport. Testing quality - at the level of 97% and validation quality - at the level of 91%. The best learning algorithm turned out to be the algorithm BFGS 118. The positive learning result of the neural network is demonstrated, among others in the learning graph (fig. 2). It shows that the best network structure was found in the 118th cycle; the share of incorrect answers was 9% and the error was estimated at 0.0023.

Fig. 2. Learning outcomes of the neural network MLP 16-22-1

Also the course of the scatter changes, set to fig. 3, indicates a positive learning outcome of the network.

Fig. 3. The scatter of the dependent variable of the neural network MLP 16-22-1

The results of the calculations presented on fig. 4 show the dispersion between the predicted value of the sense of security (Y axis, the result of the calculation in the network during learning) and its actual value (X axis). The visible concentration of the scatter value near the straight line is the desired result of model calculations.

A global sensitivity analysis was performed for all neural network models presented in table. 3 which consisted in checking how the network error behaves when input signals are modified. In this calculation, the input signal values are replaced by the average of this signal from the training set. After providing such modified input data, the network error was checked. If the error has increased significantly, it means that the network is very sensitive to the signal.
Global sensitivity analysis for created neural networks reflects the impact of individual network input variables on the output signal (table. 4).

Table. 4. Global sensitivity analysis for created neural networks

Source: the author's own elaboration

Considering only the factors resulting from the above standards, the greatest impact on the sense of security in public passenger transport is exerted by:

- K_{pkm} - travel comfort in public transport,
- J_{tk} - customer care,
- T_{tm} - duration of city transport.

In fig. 4 the results of the tests carried out for the factors mentioned above and the sense of security in public passenger transport are presented.

Fig. 4. The results of the tests for the factors: travel comfort, customer care, transport duration and sense of security

From the author's proprietary research it can be concluded that the factors mentioned above strongly influence the assessment of the sense of security. The results obtained are numerically comparable in the groups of assessments and the relationship between the level of the factors mentioned above with the sense of security is visible. The sensitivity analysis for the created neural networks (table. 4) and the conducted author's own studies (fig. 4) confirm the strong impact of the factors mentioned above for the sense of security. Therefore, in the remainder of the article, only the factors mentioned above were subjected to modelling.

Based on the selected neural network MLP 16-22-1 (table. 3), trends of changes in the level of the sense of security were shown when changing the factors mentioned above. These factors were raised by +1 in the first attempt and raised by +2 in the second attempt. Sample data used to model the level of the sense of security with modified factors is presented in table. 5.

Table. 5. Sample data used to model the level of the sense of security with modified factors

The data mentioned above was introduced into the selected neural network and sample results were presented in table. 6 The description of individual columns should be understood as:

Survey data - level of the sense of security indicated by respondents

- ANN - the level of the sense of security reflected by the selected neural network MLP 16-22-1,
- ANN +1 - the level of the sense of security reflected by the selected neural network MLP 16-22-1 with increased selected factors, i.e. T_{tm}, J_{tk}, K_{pkm} *by level +1,*
- ANN +2 - the level of the sense of security reflected by the selected neural network MLP 16-22-1 with increased selected factors, i.e. T_{tm}, J_{tk}, K_{pkm} *by level +2.*

Table. 6. Sample results modelling the level of the sense of security using the MLP 16-22-1 neural network

13	4	4.01	2.84	2.87
14	3	2.97	3.07	3.27

In fig. 5 the results of modelling the level of the sense of security using a neural network for a sample size of 99 are presented.

Fig. 5. Results of modelling the level of the sense of security using a neural network

The calculations show that:

- by raising the level of assessment by +1 of three selected factors, the level of the sense of security increases slightly, based on 99 trials, this level increased on average 0.54 and is within the average rating of 3.5,
- by raising the level of assessment by +2 of three selected factors, the level of the sense of security increases significantly, based on 99 trials, this level increased on average 1.28 and is within the average rating of 4.

Summary

The purpose of the article is to analyse and asses the factors which affect the sense of security in public passenger transport on the example of the capital city of Warsaw, defined on the basis of the standard PN-EN 13816: 2004 and author's own research, as well as the use of artificial neural networks as a tool allowing for modelling the level of security.

The following conclusions were drawn from the conducted tests:

- the developed neural network model correctly maps the output signal, in this case the level of the sense of security in passenger public transport on the example of the capital city of Warsaw based on author's own research,
- the quality of the solutions obtained is around 90%,
- the research conducted demonstrated a positive impact of changing selected factors on the level of the sense of security,
- thereby confirming the thesis whereby artificial neural networks can be effectively used to analyse and solve such problems,

It should also be emphasized that all 3 selected factors were analysed simultaneously, and the impact of individual selected factors on the final result was not considered. The direction of further research should focus on the analysis of the impact of individual factors on the sense of security, these factors should not be limited to the standards mentioned above.

Abstract

Influence marketing as a complement to contemporary market activities enables the formation of opinions and attitudes of users. Unlike traditional direct interactive techniques and marketing tools reaching to consumers without the use of intermediaries, influence marketing focuses on a person - influencer who transmits a communication message through the platform. Business entities can segment a targeted audience that is gathered around influencers, enabling an effective communication message and reduce communication noise that arises due to too much information which is visible through the use of a whole number of ad blockers. The paper focuses on the members of the Generation Z, do they believe in influencers, can influencers affect their attitude on choosing a tourist destination and their way of getting online information at the prefetch stage researching tourist services. The goal is to show how the personal attitudes of the Generation Z influence on the future intentions of behaviour. Authors use a Theory of Planned Behaviour in order to get answers to the question whether and in what way influence marketing effects on personal attitudes of students considering the use of tourism service, and in which the students' attitudes and their intentions are related. Descriptive analysis and multivariate analysis were used in the analysis. Research has shown which variables are important for the selection of the influencer in marketing activities - the number of followers, the frequency of the published content, the number of comments, the rate of response to the comments, the specialized content or something else.

Keywords: influence marketing, tourist services, attitudes, students

Introduction

Three basic problems are solved by forming communication: what to say (message strategy), how to say it (creative strategy) and who will say it (message source) (Kotler and Keller, 2007). The first problem concerns the strategy of the message, and when determining it, the management of the company seeks to find messages, themes or ideas that will be in touch with mark positioning, thus helping to identify points of similarity and points of difference. Some may be directly related to the features of a product or service, while others may relate to several aspects such as the brand's modernity, popularity or tradition. Product customers expect rational, social, sense of satisfaction or fulfillment of the ego.

One of the goals of marketing activities is to sell and promote products by making profits. However, from the point of view and the time of returning invested funds to advertising as part of a marketing mix, we can outline the following advertising goals (Kesić 2003, p. 237):

- "Stimulating primary or selective demand
- Advertising of products or institutions
- Creating direct (action) or indirect effects (preferences, opinions, attitudes)."

The main goals of promotion are to stimulate consumer awareness in an effort to use such products and services as much as possible. Promotion requires financial resources to constantly seek new ways to reach consumers. A trend in promotion today represents the strategy of influence marketing. Unlike the classic ways of promoting influence marketing is aimed at creating an image of an individual whose goal is to inform consumers by using one of the online promotion channels.

The paper focuses on the members of the Generation Z and way of getting online information at the prefetch stage researching tourist services. The goal is to show how the personal attitudes of the Generation Z influence on the future intentions of behaviour.

Influence Marketing

Influence marketing can be observed as part of integrated marketing communication. Influence marketing is just one of the language versions that are used for for marketing campaigns that use influential individuals - influencers. Other phrases used are Influencer marketing or influencer and should not be confused with influence marketing. "Influence marketing focuses on individuals (influencers) pushing products to consumers. Instead, it's about the power of content or context and empowering consumers with relevant data throughout the entire path to purchase, from brand awareness and consideration to purchase decision, which includes comparing products' quality, price, popularity, proximity and even relatability" (Forbes, 2018). Influencers in influence marketing campaign pass their personality and status to the brand they promote. Thanks to social networks influencers have tremendous power and can contribute to brand creation or decline, as they can directly reach their audience. According to Lagrée (2017), social marketing value and influence on social networks are one of most important concepts in the area of online advertising and most companies that promote in online environment must have a "social" strategy. Managers who manage brands recognize their potential and successfully use them to develop sponsorship cooperation agreements. But this co-operation encompasses more photography and photo publishing. Based on the Woods (2016) with social media growth advertising agencies allocating more of their media budgets to social and using influence marketing strategy, because advertising industry is in search of effective strategies to get the most return on investment when it comes to social, There are several factors and dimensions relevant to selecting a person who will advertise a particular product or service. In addition, marketing inflows help create awareness and help to position and to reposition existing products and services. Consumers with a high level of opinion, also called opinion leaders, seeking behaviour tend to search for information and advice from other consumers when making a purchase decision and have a significant influence on consumers' attitudes and behaviours (Chu and Kim, 2011). The whole process of the communication message should begin with determining the targeted audience such as potential product buyers of the company, current users, decision-makers, or having some influence, individuals, groups, a certain part of the public or the public in general. Influencer marketing can bi compared with digital equivalent of word-of-mouth marketing. It is defined as "a type of marketing that focuses on using key leaders to drive a brand's message to the larger market" (Tapinfluence, 2015). Subramani and Balaji (2003, p. 300) define that "the role of the influencer is mainly to create awareness and signal benefits to others within their social network and can be particularly influential in encouraging trial and adoption of novel products and services". It is important to state that Some experts believe influencer marketing has launched a revolution in terms of how a particular message finds a path to a targeted audience as well as potential buyers. "Influencers are generally people who have an influence on other people and they are often considered as Key Opinion Leaders (KOLs). Influencers are mostly famous people and "Celebrity Endorsement" is also the first form of influencer marketing" (Nguyen, 2018). Influencer marketing can also be defined as a presentation of a product or service whose origin is in personal experience. In other words, it is a strategy in which one person, usually familiar to the public, describes the use of products or services, suggesting to potential buyers that they should buy it.

Influence marketing in tourism

As we have mentioned in the last chapter influencers are people who've spent time building their own brand and cultivating their audience online by a different approach. in this category, we can make four basic segment: Celebrities, Industry experts, Bloggers, and content creators and Micro Influencers (Khamis et. al. 2017). Influencers can also be divided according to the content they create (Forbes, 2019):

- Pets
- Parenting
- Fashion
- Fun
- Travel
- Gaming
- Fitness
- Beauty
- Gastronomy
- Home
- Technology and business
- Children

We can conclude that travel and gastronomy as parts of the tourist offer are in are in the domain content for influence marketing. The development of technology "has enabled today's modern consumers, i.e. users, to search for information on a tourist destination in real time or prior to their arrival at a destination using mobile technology" (Kelić et al, 2017, p. 228). The use of social media marketing by Destination Marketing Organizations is "still evolving as the use of social media by travelers and the tourism industry continues to expand" (Sigala et al 2012, p. 112). Tourist destination might identify influencers to seed a word-of-mouth campaign using social media. Di Pietro at al (2012, p. 67) found "that tourists' choice of destinations for travel is influenced by electronic word of mouth". As such, Social Media platforms have proven to be effective as a destination marketing tool. Strategy of using celebrities in the form of endorsements has been generally used for years as a tool in a promotion of tourist destination, retail marketing, and product marketing. However, influence marketing strategy, "is an emerging trend where everyday people who are popular on social media platforms become leaders and inspiration to others on social media" (Bokunewicz and Shulman 2017, p. 214). Influencers create content that is in line with the wishes and needs of their audience. Consumers identify with them and most often pay attention to what influencers promote and are inclined to want the product or service they are advertising themselves. It is therefore important to "adapt the content created in the online environment so as to balance tourism supply and demand in a particular tourist destination" (Kelić et al. 2017, p. 229). In general, creative content has become key to creating competitiveness in the tourism industry and influence marketing is a strategy for delivering information to the consumer. i.e. tourists.

Theoretical framework of the Theory of Planned Behaviour

The Theory of Planned Behaviour is used in numerous social and scientific disciplines. It has been applied more and more in the area of research regarding human behaviour and expanded to research related to personal behaviour (Lin and Chen, 2010; Ajzen, 1991). The premise of the Theory of Planned Behaviour is that "individuals make rational decisions to engage in specific behaviours based on their own beliefs about the behaviour and their expectation of a positive outcome after being engaged in the specific behaviours" (Harding at al 2007, p. 258). The Theory of Planned Behaviour is used to show the impact of attitudes, subjective norms and perceived behavioural control on the intentions of individuals resulting in certain behaviour (Ajzen, 1991) (Figure 1.).

Figure 1: Theory of Planned Behaviour model

Source: Ajzen I. (1991). Theory of Planned Behaviour. Organizational behaviour and human decision, 50, 179-211.

Attitudes toward behaviour are the level to which the performance of behaviour is judged as positive or negative by the individual. Allport (1935) defines personal attitude "as permanent mental or neural willingness gained from the experience, making the directive or dynamic influence on an individual's response to objects and situations that he comes into contact with". Ajzen and Fishbein (1980) defined the attitude toward a behaviour as "a person's general feeling of favourableness or unfavourableness for that behaviour". Furthermore, the same authors defined the Subjective Norm as "a person's perception that most people who are important to them think they should or should not perform the behaviour in question". The third predictor, Perceived behavioural control, "includes the perception of one's own abilities and sense of control over the situation and is defined as a combination of locus of control (belief about the amount of control that a person has over events and outcomes in his life) and self-efficacy (perceived ability to perform the task)" (Ajzen, 2002).

The behavioural intention has been identified in the theory as the most significant predictor of behaviour (Ajzen and Madden, 1986; Ajzen, 1991, Ajzen and Fishbein, 2005).

Tourist Attitudes

According to Lee (Ajzen 1991; Schiffman and Kanuk, 1994, as cited in Lee, 2009, p. 218) tourist attitude describes "the psychological tendencies expressed by the positive or negative evaluations of tourists when engaged in certain behaviours". Tourist attitude is an "effective predictor of tourist participation and satisfaction" (Ragheb and Tate, 1993, as cited in Lee, 2009, p. 218).

The Theory of Planned Behaviour is frequently used to study in the tourism and hospitality industry, especially in tourist attitudes. Some authors describe in which way tourist attitudes influence on intentions toward behaviour: according of travel mode (Bamberg et al, 2003), behaviour of wine tourists (Sparks, 2007), intentions of hunting (Rossi and Armstrong, 1999), visit intentions according perceptions of country, product and cuisine (Kim and Kwon, 2018; Jacobsen, 2000), choosing a travel destination (Lam and Hsu, 2006; Jalilvand and Samiei, 2012), consumer complaining (Yuksel et al, 2006). Furthermore, some authors did not find a significant contribution between attitudes and intention and behaviour (Ajzen, 1992; Lam and Hsu, 2006; Sparks, 2007).

Thus, the following main research hypotheses are proposed:

H1: Attitudes toward influence marketing has a significant impact on the intention of visiting a tourist destination.
H1a: Influence marketing as part of word-of-mouth online marketing is dominant for getting information about a tourist destination by members of Generation Z.

Previous research related to the hypotheses that should be mentioned is research of Iyiola and Akintunde (2011) who had measure "how consumers will form an opinion(s) on a particular product

based on information at their disposal, which will determine whether such product is selected". Bokunewicz and Shulman (2017) analyze "network data from Twitter how destination marketing organizations (DMOs) use Twitter to promote attractions and special events and to build brand awareness". In their paper, they have identified influencers that can aid in DMOs' marketing campaigns. Taking into account previous research, the authors defined hypotheses for the purpose of this paper, focusing on the Generation Z and different social networks.

Research Methodology

The aim of this research is to show how the personal attitudes of the generation Z influence on the future intentions of behaviour. In order to identify content consumers on the demand side, the authors focus on the representatives of Generation Z, also known as Post-Millennials, the iGeneration, or the Homeland Generation, is the demographic cohort following the Millennials. Although there are various definitions of Generation Z, for the purposes of this paper the authors have used a definition according to which "Generation Z is born in the 1990s and raised in the 2000s during the most profound changes in the century who exists in a world with web, internet, smartphones, laptops, freely available networks and digital media" (Singh and Dangmei 2016, p. 2). Authors use a Theory of Planned Behaviour in order to get answers to the question whether and in what way influence marketing effects on personal attitudes of students considering the use of tourism service, and in which the student's attitudes and their intentions are related. The emphasis in the research has been placed only on the predictor of personal attitudes of students. The research has been implemented on a sample of 135 university students (attending only graduate study programs). The description of the sample regarding the observed socio-demographic data has been provided in Table 1.

Table 1: Sample description

		N	%	Missing
Gender	Male	52	38,2	N = 3 % = 2,2
	Female	80	58,8	
Year of study (graduate)	1st	64	47,4	N = 1 % = 0,7
	2nd	70	51,9	
Student status	Non-paying	106	78,5	N = 2 % = 1,5
	Fully-paying	27	20,0	

Source: Authors' research

The data has been gathered using a study questionnaire, in which the study participants were informed about the topic and the aim of the research. Considering that there are no related researches of impact of influence marketing on attitudes of tourist service users through the Theory of planned behaviour authors are arbitrarily prepared questionnaire. Previously in the text, it was stated how the Theory of planned behaviour is frequently used to study in the tourism and hospitality industry, especially in tourist attitudes. But, no one has been studied in relation to influence marketing. So, the self-administered questionnaire was designed to measure the research model variable constructs taking into account the above-mentioned researches. The questionnaire consisted of three sections. In the first part authors want to find out which social networks are accessed by students, do students follow influencer and in what way they impact them and what motivated them to visit a tourist destination. In the second part, the attitudes and the intention toward behaviour were tested and in the last part of the questionnaire were related to the socio-demographic characteristics of the study participants. A five-point Likert measurement scale (ranging from 1-totally disagree to 5-totally agree) was used in the questionnaire. The research results were obtained using the SPSS 18.0 statistical software package. Descriptive analysis, multivariate analysis (correlation analysis, linear regression, factor analysis) and analysis of variance (ANOVA) were used.

Research Results

Most of the respondents (88.9%) own a Facebook profile, then Instagram (56.7%), LinkedIn (31.1%), Snapchat (30%) and Pinterest (28.1%). Other platforms are represented in less than 15% (Twitter, Tripadvisor, Blog, Vlog). Respondents who own a personal Facebook profile and Instagram access and review them once or more times a day, while users who own a personal profile on Linkedin, Snapchat, Pinterest and Vlora access and browse platforms once or more times a year. Also, the results showed that respondents who have created a profile on Facebook and Instagram often or almost always access during the afternoon, evening and night hours.

Research has shown that 97% of respondents know what the term influencer is and that 72% of respondents monitor an influencer on a platform. The most important item in influencing choices to be monitored by the respondents is the subject that the influencer deals with, ie the content being published (4.31), and the frequency of the release of the content (3.34), while the response speed to the comments of the escort and the number of followers are the items that are not very important when selecting influencer (2,38 and 2,21).

Most of the respondents (91.9%) visited a tourist destination in the past year, and as the main motives for visiting the destination are the recommendations of friends (54.1%), blogs, specialized journals and portals (17.8%), information about the destination created by other users (37%), and least motivated by content like tips, and recommendations from online flyers, magazines and brochures (8.9%). We can conclude that word-of-mouth strategy like friends' recommendations and information about the destination created by other users are dominant for getting information. This confirms the auxiliary hypothesis H1a which state that influence marketing as part of word-of-mouth online marketing is dominant for getting information about a tourist destination by members of Generation Z who are present on social networks and track the content of friends and other users - influencers.

Since the paper observed only users views of tourist services, the impact of influence marketing to them and how their attitudes effect on their future intentions of behaviour, in continuation of the paper only the attitudes will be used in the analysis. According to this, authors used exploratory factor analysis to contract variables in a smaller number of common factors (Table 2). The factor analysis and the consistency analysis have been performed on the 7 variables of the predictor Attitudes. The sample included 133 (98,5%) of the study participants. The rest have been excluded from the factor analysis.

Table 2: The results of the factor analysis

Variable of the predictor Attitudes	Factor 1	Factor 2	h^2
I believe influencers are paid by business entities to publish the content as desired	.641		.424
I consider influencers to a large extent influence the creation of attitudes, opinions and decision-making of their followers	.613		.404
I believe that influencers can greatly assist business entities in promoting their products and services	.769		.593
I believe that influencers can provide adequate information on tourist destinations	.602		.409
I think how influencers can influence the decision-making on the choice of a tourist destination	.702		.520
I believe influencers publish content only at their own discretion and motivation		.459	.211

I consider influencers to a large extent influence my own creation of opinions, opinions and making decisions		.874	.798
Eigenvalue	3,52	3,48	
Variance percentage	50,3	49,7	
Number of variables in the factor	5	2	

Source: Authors' research

The Cronbach's alpha coefficient is 0.718, the Kaiser-Meyer-Olkin measure is 0.725, and the Bartlett test is $\chi 2$=251,093, df=21, Sig.= .000. Two factors have been identified through factor analysis, and they were given the following titles:

Factor 1: Attitudes as influencers publish content according to the instructions of business entities and influence their followers
Factor 2: Views as influencers publish content at their own discretion and affect my (student) self-creation attitude

It is necessary to see if there a statistically significant correlation between two extracted factors of students' attitudes and the students' intentions toward behaviour. Table 3 shows the results of the Pearson correlation. Both factors are in positive statistical correlation with the intentions toward behaviour.

Table 3: Correlation analysis (n = 135)

Predictor variables	Intentions toward behaviour	
	Pearson correlation	Statistical significance
Factor 1	.232**	.004
Factor 2	.546**	.000

***Correlation is significant at the level of 0.01*
Source: Authors' research

The linear regression model is shown in Table 4. The results of the regression analysis show a statistically significant positive correlation between attitudes as influencers publish content according to the instructions of business entities and influence their followers (Factor 1) and views as influencers publish content at their own discretion and affect my (student) self-creation attitude (Factor 2) and their future intentions toward behaviour. The model explains the total of 37% of the variance in the intentions toward behaviour. Determination coefficient (R2) measures the ratio of the variance of the dependent variable around its mean value as explained by prediction variables. The larger R means the greater the power of the model in explaining the regression function and the better the prediction of the dependent variables.

Table 4: Linear regression model

Predictor variables	βeta	t-value	Significance (p)	Model summary
Factor 1	.268	3.757	.000	R = 0.606 R2 = 0.367 F = 37.708
Factor 2	.561	8.023	.000	

a. Dependant variable: intentions toward behaviour
Source: Authors' research

Statistical analysis indicates that this confirms the hypothesis H1 which state that attitudes toward influence marketing have a significant impact on intention to visit a tourist destination i.e. users trust

the influencers who know how to present the products they work with and find the best way to get the message to as many people as possible.

Conclusion

Influence marketing enables tourism business entities to let their consumers choose the source and the channel of information that suits them best. The aim of the paper was to analyze to what extent members of Generation Z search for online content what is the influence of influencer marketing on their decisions. The significance of the influencer is best explained by the fact that messages and content are announcing the contributions and popularity of a particular product or service. Collaboration between business entities and influencers has become a trend in marketing activities since the influencers are focused on narrow niches and expert on topics they deal with. Modern consumers become immune to traditional advertising and since influencers spend a lot of time building relationships with their audience, they develop mutual trust in the long term. Although there is no previous research which will support hypotheses, research that served as the basis, analyze only one social network and another tourist destination. Research that was used led to the conclusion of how structure and popularity of influencers allows marketers to cheaply connect with the masses. Based on the above authors have focused on Generation Z and different social networks. Research results has shown that consumers are most trusted by personal sources when it comes to referrals, but it's important to note that many people look at influencers as their friends and people they know. The research included an analysis of the current level to what extent are members of Generation Z familiar with influencers and what is the impact of influence marketing at their attitudes. The aim of the research was to test the proposed hypothesis. The results obtained have confirmed the hypothesis that attitudes toward influence marketing have a significant impact on the intention of visiting a tourist destination. The paper has defined how the personal attitudes of Generation Z influence on the future intentions of behaviour. Although consumer behaviour is influenced by several factors, one of the elements of customer rapprochement is a model in which the targeted audience of influencers becomes a target audience of a business entity. We can conclude that influencers can influence on attitudes of consumers of Generation Z and their behaviour. A well-designed marketing influence strategy that is consistent with the vision and strategy of brand with the use of an influencer who has a strong enough companion base greatly increases the success and profitability of investment in influence marketing in tourism.

This research has some limitations. In paper it observed only the personal (students) attitudes in higher education, so the inclusion of the other predictors of the Theory of Planned Behaviour in the research would complete the image of the intentions toward behaviour among students. Although the sample was only graduate students (from Continental Croatia), some of the research results can be taken as general characteristics of the industry. According to everything mentioned previously, it is necessary to conduct further research in order to resolve the limitations of this research and fill the blanks left by this research.

Perception Of Lean Manufacturıng - Analysis Of Production Enterprises Before And After LM İmplementation

Justyna Maria MYSZAK

University of Szczecin, Szczecin, Poland
E-mail: justyna.myszak@usz.edu.pl

Abstract

Lean Manufacturing (LM) is a concept that is comprehensive in nature and includes a set of many useful methods and tools. Despite the fact that a number of publications highlight measurable benefits related to the implementation of lean, plenty of companies still fail to implement or take any action with respect of LM. For the above reasons, based on existing research described in subject literature, a cognitive gap in the form of a time factor, which significantly affets the perception of barriers connected to the implementation of lean tools, has been identified. Thus, the purpose of this article is an analysis of perception of LM by companies that are before and after implementation of lean tools with reference to four selected cognitive areas. In order to achieve the scientific objective, a CATI survey has been conducted in Polish manufacturing companies, operating in Zachodniopomorskie Province. The research questionnaire has been divided into four parts and included: identification of internal and external barriers, knowledge of lean tools, awareness of expected benefits resulting from the implementation of Lean Manufacturing and plans to implement lean in companies in the near future. Selected methods of multidimensional comparative analysis have been applied. The results have been summarized, compared and discussed.

Keywords: Lean Manufacturing, implementation of lean, manufacturing industry

Introduction

Modern enterprises operate in complex market conditions, which are characterized by high competition, constant struggle for clients' favour, as well as high dynamics of economic processes. Production companies are also facing these problems, but due to their specificity they constitute "the most developed and complex economic activity (...) in which all problems and business processes focus, with all its consequences" (Ficoń, 2007, p. 202). This means that production companies wanting to survive on a dynamic market, must constantly monitor and respond to changes related to their production processes. Therefore, it is necessary to analyze the efficiency and production capabilities, the availability of production resources or even the information technologies used (Information and Communication Technology). The concept of Lean Manufacturing (LM) turns out to be helpful in this respect, which in its scope includes a set of many useful methods and tools of non-uniform nature. In addition, importantly, the LM principles are universal and "can be applied in every industry across the globe" (Womack, Jones, Roos, 2007, p. 6).

Correct implementation of lean tools has a positive effect on all areas of company operations and it is a necessary condition for the next stage which is industrial evolution - commonly called as Industry 4.0. Despite numerous publications from different countries, which describe measurable benefits achieved from a successful implementation of LM, many companies still do not take any activity in this area or, for some unknown reasons, cease further initiative. However, based on existing research described in subject literature, a cognitive gap in the form of a time factor, which significantly affects the perception of barriers connected to the implementation of lean tools, has been identified. The scientific goal of this article is to analyze the perception of LM by companies before and after implementation of lean tools in relation to four selected cognitive areas, which took the form of the following research questions:

- What is the perception of Lean Manufacturing implementation barriers in companies before and after lean implementation, broken down into internal and external barriers?
- What is the knowledge of the surveyed companies about Lean Manufacturing instruments?
- What is the perception of benefits of lean implementation among the surveyed enterprises?
- What are plans related to lean implementation in enterprises with experience in this field, as well as among companies without practice in this area?

In order to achieve the scientific objective, a CATI survey was carried out among Polish Companies (in Zachodniopomorskie Province). It enabled to achieve research objective and answer the research questions.

Literature Review

According to Grzesik (2010, p. 145) "it is now recognized that the manufacturing industry is a key factor that determines the dynamics of development and market situation". Research carried out by Eurostat confirms this view as it indicates that industrial production in EU accounts for 16% of gross value added in economy and provides employment for 31.8 million of people. In Poland, this indicator is also at a high level as industrial production accounts for 20% of gross value added in economy and provides employment for 3.1 million of people. It is also worth mentioning that every tenth EU citizen involved in industrial production works in Poland (Dmowski et al., 2016, p. 21). Therefore, it is extremely important to take action with respect to the concept of Lean Manufacturing, which integrates processes in an entire organization, starting from purchasing, through production, ending with distribution.

The concept of Lean Manufacturing in its present form is based on the Toyota Production System (TPS), which was developed in response to the problems of the Japanese industry in the post-war period (Czerska, 2014, p. 9). Before it was formulated, the most known and widespread concept was the production system set up by H. Ford. It used mass production, economies of scale and powerful equipment, making it possible to produce the largest possible number of parts in the most cost-effecitve manner. Unlike Ford and GM (after the World War II), Toyota had limited capabilities and was forced to produce various vehicles on the same assembly lines. As a consequence, flexibility of assembly lines became the most important for operations of this company, which over time enabled it to obtain, among others, greater customer satisfaction, higher quality and productivity, as well as better use of equipment and space (Liker, 2016, pp. 35-36). The above-mentioned achievements have made the concept of Lean Manufacturing another (after mass production) important stage in industrial evolution.

The success of Toyota, which took the form of the LM concept, is also very popular among scientists who define lean in a different manner. Examples of definitions are presented in Table 1.

Table 1: Selected definitions of Lean Manufacturing

Authors	Definition
Bicheno, J., Holweg, M.	Doing more with less.
Lean Enterprise Institute	The core idea is to maximize customer value while minimizing waste. Simply, lean means creating more value for customers with fewer resources.
Quality Progress Magazine	The permanent struggle to flow value to each customer.
National Institute of Standards and Technology	A systematic approach to identifying and eliminating waste through continuous improvement, flowing the product at the pull of the customer in pursuit of perfection.
	" (...) definition of Lean includes both the people and the process components on the one hand and internal (related to the firm) and external (related to supplier and customer) components on the other hand".

Anvari, A., Ismail, Y., Hojjati, S.M.H.	LM refers to an evolving dynamic new process of production covering the total enterprise, embracing all aspects of industrial operations (product development, manufacturing, organization and human resources, customer support) and including customer-supplier networks, which is governed by a systemic set of principles, methods and practices.
Tortorella, G.L., Vergara, L.G.L., Ferreira, E.P.	LM is a business model that values the human being as the main human element for continuous sustainability in the organization. The interaction between employees contributes to the knowledge acquisition to support future projects of the organization.
Taj, S.J.	LM is a set of concepts, principles, methods, procedures, and tools to reduce losses in the value stream.

Own study based on: Bicheno, J., Holweg, M. (2016). The Lean Toolbox. A Handbook For Lean Transformatıon, Production and Inventory Control. Systems and Industrial Engineering (Picsie) Books. Buckingham, p. 1; Anvari, A., Ismail, Y., Hojjati, S.M.H. (2011). A Study on Total Quality Management and Lean Manufacturing: Through Lean Thinking Approach. World Applied Sciences Journal 12 (9), pp. 1585, 1587-1588; Oliveira de, R.I., Sousa, S.O., Campos de, F.C. (2019). Lean manufacturing implementation: bibliometric analysis 2007–2018. The International Journal of Advanced Manufacturing Technology 101, p. 980.

Lean Manufacturing is a comprehensive and "multifaceted concept that may be grouped together as distinct bundles of organizational practices" (Yang, Hong, Modi, 2011, p. 252). A list of bundles of lean practices should, however, contain well thought-out and deliberately chosen methods and tools. Due to their multitude and their mutual connection, LM implementation should be a process planned for several years. In addition, the sequence of implementation (Knosala, 2017, p. 125), selection of and the number of instruments being implemented is still problematic as no consensus in this respect has been reached to date. Compliance, in principle, was achieved in terms of benefits that arise as a result of the implementation of LM. Perhaps this is due to the fact that effects are visible relatively quickly after the first implementation of a specific method or tool (often at small expenditures, e.g. the 5S method). According to research conducted in Poland, the most frequently mentioned benefits and improved indicators include the following (Horbal et al., 2010):

- efficiency (increase from 5% to 66%),
- use of machines (OEE) (increase from 7% to 59%),
- stocks of work in process (reduction from 30% to 80%),
- area (reduction from 15% to 61%),
- transition time (reduction from 9% to 70%),
- set-up times (reduction from 9% to 96%).

In addition, some companies also mention other benefits, such as (Horbal et al., 2010):

- significant improvement in quality,
- reduction in the number of complaints,
- increase in the number of improvements proposed by employees (from 2 to 10 times more),
- improvement of communication,
- reduction of waste.

Research Methodology

The study has been carried out based on literature research (Web of Science database), which allowed to identify and then systematise and categorize conditions that are key for the implementation of LM in production companies. As a result, a developed matrix of lean implementation conditions was developed, divided into internal (engogenic) and external (exogenous) factors (Frankowska, Myszak, Sowa, 2017, pp. 431-440). On the basis of the obtained results, a cognitive and research gap was identified in the form of limited consideration of temporal aspects (time factor) in the perception of LM implementation barriers. In connection with the above, a detailed literature review was carried out

regarding the barriers faced by organizations in the Lean Manufacturing approach. Next, research methodology was formulated, as a result of which two questionnaires were developed and applied, which included the four research areas: implementation barriers (internal and external), knowledge of LM tools, perceived benefits of lean implementation and implementation plans of the surveyed enterprises. Two types of questions have been used in the questionnaire: multiple choice questions and questions employing Likert scale, ranging from 1 (definitely disagree) to 5 (definitely agree). The first questionnaire was addressed to companies that have not implemented any lean tools, while the second one to enterprises that have experience in this matter, that is, they are implementing lean manufacturing at present or are planning to do so in the future, i.e. to implement further Lean instruments. At the same time, a database of 250 manufacturing companies based in Zachodnipomorskie Province has been created. Nonprobability and quota sampling has been employed in the study, which, as a result, was conducted on a sample of 40 production companies that meet the following criteria:

1. Study no. 1: an organization has not undertaken any activities towards the implementation of LM earlier - 20 companies qualified here;
   Study no. 2: an organization has undertaken activities towards the implementation of LM - 20 companies qualified here.

CATI telephone interview technique (i.e. computer-assisted telephone interview) has been employed to carry out the study. The research material was submitted for analysis, on the basis of which a multidimensional comparative analysis was carried out that enabled to draw conclusions and propose preliminary recommendations. The conceptualization of the conducted research has been presented in a visual way in Figure 1.

Fig. 1: Research methodology

Source: author's own work

Unfortunately, the research sample obtained is not representative and, therefore, the results of the research are of probing character and require confirmation in further research.

Comparatıve analysıs of the research sample

In the group of 20 companies that have never implemented LM, there are 8 small enterprises, 5 medium companies, 4 micro-enterprises and 3 large companies. However, the situation is different among enterprises that have already taken steps to implement LM. This group consisted of 10 medium size and 7 big companies. Only three companies in this group were small enterprises and there were no micro-enterprises.

With regard to the ownership of business, in the group prior to implemntation, most companies were of domestic capital (15), however, there were also enterprises of foreign capital (2) and three public ones. In case of companies in the other group, this structure looked a bit different: there were 10 companies of foreign capital, 9 of domestic capital and one public enterprise.

With respect of the fime of functioning on the market, significant diversity has been observed in both groups. When it comes to the first group, only one company has operated on the market for the period shorter than 5 years, and the remaining entities have been operating for 6 to 10 years, four companies for the period ranging from 11 to 20 years and seven companies have existed for more than 25 years. In the second group, four companies have operated on the market for less than 5 years and the remaining six entities had operated for 6-10 years, four entities for 11-20 years and six companies have existed for more than 25 years.

The respondents in the survey, belonging to the group of companies before implementation, were primarily representatives of senior management (8) and middle management (8), but included also qualit assurance specialists as well. The situation looked similar in the group of companies after the implementation of LM. Respondents included the most-important senior management (8), as well as senior management (6) and specialists (6).

Results and Dıscussıon (Findings)

The study has been divided into four main areas. The first area includes an analysis of the perception of LM implementation barriers in companies before and after lean implementation, divided into internal and external barriers. In connection with the above, the respondents were asked to evaluate the importance and extent of internal factors constituting a barrier to lean implementation in a company (Figure 2). Most assessments fluctuate around average results, but it seems that the most challenging barrier in both categories is having appropriate resources, understood as the right number of employees, sufficient time allocation and their range of knowledge. It is also worth paying attention to financial factors, which are treated as the most prominent internal factors in introduction barriers. Interestingly, this factor does not play such a significant role among enterprises that have already taken actions to implement lean compared to others. Perhaps it is related to the fact that implementation of some LM instruments does not always mean incurring considerable costs. In case of enterprises that have already undertaken lean activities, determinants related to management and organization are of greatest significance, such as: leadership or attitude and necessary competencies to implement the philosophy of lean both among staff and management. The specificity of technologies used in enterprises may also be problematic, especially the level of their advancement. Moreover it seems that the least challenging barrier in both categories is the specificity of manufacturing systems of the surveyed companies, understood as a type and form of production organization and the number of positions and / or plants.

Fig. 2: Average rating of internal barriers for the implementation of Lean Manufacturing
Source: author's own work

Next, respondents were asked to assess external barriers, i.e. the surroundings and conditions in which companies operate (Figure 3). Basically, in all cases pre-implementation fears prevail over post-implementation ones. It seems that this may be related to insufficient knowledge of LM among enterprises, which in turns translates into a huge disparity in responses given. For example, the biggest difference between barriers (before and after) can be seen in the lack of interest among customers as well as external financing. This may mean that limited knowledge of managers leads to companies making hasty conclusions.

Fig. 3: Average assessment of external barriers for the implementation of Lean Manufacturing
Source: author's own work

When comparing the assessment of internal barriers before and after implementation of LM among the surveyed companies (Figure 4), it can be noticed that they are rated similarily, and respondents rather do not see any significant limitations related to their operations. Nevertheless, the difference is visible in the perception of external barriers related to the environment. Ignorance of the knowledge of current

and potential partners (suppliers, customers, experts) may exert negative influencce on actions taken with respect to the implementation of LM.

Fig. 4: Average assessment of pre-implementation barriers and implementation barriers of Lean Manufacturing

Source: author's own work

As far as the second research area is concerned, knowledge of surveyed companies on the subject of Lean Manufacturing has been analyzed. Respondents were asked to identify lean tools that are known to them (prompted awareness) (Figure 5). On average, respondents before implementation of LM declared that they knew more than four LM tools (4,4), among which the following ones: 5S, Kanban and Kaizen were mentioned most often. After implementation of LM, respondents' awareness of LM instrument was raised and they indicated 6,7 LM tools on average. Tools that are known to at least half of respondents include: 5S (16), Kaizen and standarized work (14 each), Kanban and SMED (13 each), MUDA mapping and Poka-Yoke (12 each), Six Sigma and Andon (10 each).

Fig. 5: Knowledge of Lean Manufacturing tools

Source: author's own work

The third of the four areas involved an analysis of perceived benefits of lean implementation among the surveyed enterprises. The respondents were asked about their opinion on the benefits achieved by companies which have implemented LM (Figure 6). Prior to implementation, as many as 40% of respondents of LM had no knowledge in this aspect or believed that companies do not actually have benefit from the implementation of LM. The results obtained seem to be surprising, especially that among the respondents after the implementation of the LM the vast majority (85%) declared that their companies are experiencing positive effects from the implementation of LM. It can therefore be concluded that there is a large disproportion between theoretical and practical knowledge in the field of Lean Manufacturing.

Fig. 6: Lean implementation and achieving benefits by companies

Source: author's own work

Then, respondents were asked to indicate specific benefits that they think the companies gain or they themselves have gained thanks to the implementation of lean (Figure 7). In both cases, respondents above the average (more than 4 points on the Likert scale) indicated the following: better work organization, faster job performance and lower production costs. Moreover, more respondents observe lower benefits in terms of improved timeliness of performance of orders and higher product quality. Compared to other responses, in both cases the greatest discrepancy in the perception of expected benefits is noticeable here.

Fig. 7: Average assessment of the benefits of the implementation of LM

Source: author's own work

The purpose of the last, fourth research area was to examine plans related to the implementation of lean among enterprises with experience in this field, as well as among companies that have never taken action in this area before (Figure 8).

Fig. 8: Future plans related to the implementation or continuation of lean implementation among enterprises before and after implementation of LM

Source: author's own work

Due to the observed positive effects of implementation of lean, companies that have already implemented LM adopt a definitely clear respect on this issue. As many as half of them are determined to continue implementation of further activities in this area. Companies which have not implemented lean yet find it more difficult to adopt a clear position. Although 45% of respondents is willing to implement LM, about one third is undecided, and every fifth examined company will not decide to implement lean in the near future.

Conclusions

The collected research material made it possible to analyze the perception of Lean Manufacturing by companies that are before and after implementation of lean methods and tools in relation to four selected cognitive areas. The first area included an analysis of perception of LM implementation barriers in companies that are before and after lean implementation, divided into internal and external barriers. As far as the second research area is concerned, knowledge of surveyed companies on the subject of Lean Manufacturing has been analyzed. The third area included an analysis of perceived benefits of lean implementation, while the goal of the last, fourth research area was to examine the nearest plans related to the implementation of lean in surveyed enterprises.

Due to the fact that the scientific literature relatively broadly describes various cases of LM implementation along with the description of barriers that come up during or after the implementation of various lean instruments, the new aspect raised in the article is the introduction of time factor. Time factor is a determinant that not only affects the perception of barriers related to the implementation of LM, but also significantly affects the decision to implement LM. An analysis of research results shows that the level of perception of barriers is relatively similar (except for external barriers, where there is a 5 point difference) in both categories of companies. However, barriers present in companies before the implementation of LM are in fact more important, as they limit the actual decision to implement LM.

It is worth adding that knowledge about instruments that can be implemented is developing at a relatively low level. Respondents (from companies before implementation) showed an average

knowledge of 4,4 LM methods or tools, and respondents (from companies after implementation) mentioned 6,7 instruments out of 13 listed tools. A low level of knowledge about the nature, purpose and applicability of a particular LM tool may result in erroneous (seeming) perception and interpretation of internal and external barriers with respect to implementation. For example, companies before implementation, notice above all major financial problems (i.e. willingness to incur expenditures and availability of financial external support). Interestingly, this factor loses importance among companies that have taken action with this respect. Here, the barrier associated with having the right resources, i.e. the right number of employees or the scope of their competence and knowledge, is important.

Analysis of research results also indicates that companies (before implementation) have average awareness of the expected benefits of lean implementation. Only 60% of respondents notice opportunities in this area. Among companies that have knowledge in this field (both before and after implementation of lean), the most often indicated benefits included: better work organization, faster job performance and lower production costs.

As far as future plans related to the implementation or continuation of implementation of lean, companies that have already implemented LM have a much clear position (as much as 50% declare implementation of subsequent activities). Companies that have not yet implemented lean find it more difficult to take a clear position, which results form lack of experience in this area. In total as many as 55% of them are enterprises that are undecided or explicitly declare that they do not plan any activities related to lean implementation in the near future. Because of a small sample the author is aware of limitations of their study, however, the obtained results suggest that it would be advisable to carry out further in-depth, qualitative research in the future.

In conclusion, it should be noted that the conducted research made it possible to obtain research objectives presented at the beginning. Lean Manufacturing is a concept that integrates processes in anentire organization, which is why the knowledge gained from the research on the perception of implementation barriers may in the future enable development of appropriate remedial actions that will prepare enterprises for accepting or continuing lean successfully.

Acknowledgment

The project is financed within the framework of the program of the Minister of Science and Higher Education under the name "Regional Excellence Initiative" in the years 2019 - 2022; project number 001/RID/2018/19; the amount of financing PLN 10,684,000.00

A Creative Team Model

Barbara WASILEWSKA

Opole University of Technology, Poland
b.wasilewska@po.opole.pl

Abstract

This article presents the stages of a comprehensive model of a creative team. The model is the result of several years of research on work teams and consists of four subsequent stages: recruitment, team building, moderation, and talent management. The model incorporates knowledge about different types of thinking, contains creative methods, and constitutes an answer to the concept of the enterprise of the future.

Keywords: Creative Team, Learning, Creative Methods, Recruitment, Talents.

Introduction

A common feature of all teams is collective work, which requires a combined effort and generates synergy. A creative team enjoys a higher freedom to act than a traditional team and is unrestricted by authority, and thus, should be allowed the possibility to experiment. This means that a creative team requires unusual methods of recruitment that will yield employees with particular traits, such as creativity and innovativeness. However, these employees have to be provided the appropriate tools to foster their potential. The potential of a creative team allows it to produce new ideas for solutions in the company. New ideas are almost always constructed from previously acquired knowledge. Truly creative ideas emerge once any ideas that limit thinking have been rejected (Ward, Finke and Smith, 1995).

It goes without saying that the members of a group influence one another, and their dynamics and self-organizing ability may be an example to others. In this context, a group can be thought of as a mentor (Hooker, Nakamura and Csikszentmihalyi, 2014) and constitute a role model for good practices, which is when it becomes a valuable asset to a well-organized company. A creative team also needs a leader. However, management and leadership have not been considered to significantly affect creativity or innovation, at least in the traditional approach (Styhre and Sundgren, 2005). The goal of the creative team model presented in this paper is to change this approach, as the model specifically requires systematic team management based on knowledge about different modes of thinking.

These modes include situational learning, a set of methods of teaching through short but enjoyable everyday activities. In other words, a company should organize work in such a way that the employees are engaged in their tasks. Examples of situational learning methods are incidental learning, the delayed prompt procedure and the instruction–model procedure. This manner of learning is essential in modern educational conditions (Dohn, Hansen and Hansen, 2019). Another example is bottom-up thinking. In contrast to analytical, or top-down, thinking, bottom-up thinking is non-linear and may produce ideas that require combining different branches of science, solving riddles, and searching for new solutions to difficult problems (Hutchinson, 2002; Mlodinow, 2018). Modern forms of engaging employees include design thinking, managing multiple models at the same time, and lateral thinking, all of which provide the employees with a new perspective on the situation or allow them to redefine the problem.

The model presented in this paper is the result of several years of research. Each stage requires a different approach. The model uses methods that are popular and widely available alongside those designed by the author of this paper. Most currently available models of teamwork expect high effectiveness but do not suggest any particular means of maintaining this result. Moreover, they do not create good working conditions, e.g., through organizational culture, nor do they strengthen the potential of the employees. Instead, they focus on managing conflicts within the team and its barriers. The model presented in this study takes an extra step: while it still takes into account group processes, it also provides methods for stimulating potential and promoting talent. The model consists of four subsequent stages: recruitment, team building, moderation, and talent management. From the very beginning, it allows searching for employees who fit the specifics of an innovative company. The model can support teams such as problem-based teams, self-managing teams, interfunctional teams, or virtual teams. The name depends on the company's individual requirements, from expected organizational structure to scope of operation. The company also decides which and how many positions will be based on teamwork.

Each stage of the model involves designing teamwork, performing tasks with each employee, and implementation. The components of each stage include:

- an unstructured interview to establish the company's expectations;
- determining the team composition;
- observation of hidden group processes taking place within the company;
- application of a synectic method focused on group work (participant observation) to identify any disruptions;
- West's innovative group model or the Assessment Center method;
- selection and application of creative problem-solving methods;
- assessment of the applied method and the team (structured interview and open observation);
- drafting of recommendations for the company.

The model supports the concept of the enterprise of the future, which takes on a specific structure and determines future goals.

Stages of the Creative Team Model

Figure 1 shows the structure of the creative team model developed by the author of this paper. The procedure begins with recruiting the team and ends with managing its talents.

Fig. 1: Stages of the creative team model

The model verifies the team's competences, prepares it for innovative work, supports the company's goals, and facilitates management. Individual development programs for each member of the team can be designed based on an assessment of work results.

Step 1: Recruitment to The Creative Team

Establishing work teams whose goal is to be creative is important enough to begin during recruitment and selection for the company. However, noticing typically teamwork-related traits in any single person is not easy. Therefore, companies have to create special tasks, experiments, and work samples in order to observe these traits. A popular means of achieving this goal is the Assessment Center (AC) method, the effectiveness of which has been verified by many studies (Thornton and Rupp, 2006; Taylor, 2007). Because AC evaluates a person's competences and managerial potential, primarily at mid- and high-ranking managerial positions, it focuses on recruiting individual employees, rather than teams. This study retains the rules of AC (Rupp D. et al., 2005), but expands its scope by adapting it to the selection of candidates for creative work teams. Before recruitment to a creative team can begin, the company has to define competences, not only those common for all teams, but also the competences that are specific for creative teams, such as creativity or familiarity with and use of creative problem-solving methods. This study used the following names of competences: creativity, creative problem solving, group decision making, relationship building, and innovativeness. Appropriate behavioral indicators and tasks to verify these competences were prepared (Tomczak-Horyń and Wasilewska, 2019). Table 1 shows a sample description of a competence.

Table 1: Description of competence: innovativeness

Competence name	Innovativeness
Competence definition	Predisposition for innovation (ability to think in an innovative manner); the ability to implement and adapt newly-generated solutions.
Behavioral indicators of the competence	Following technological novelties and social trends. Knowledge of types of innovation, barriers to innovation, and planning and implementation of innovation. Taking advantage of available methods and techniques of creating innovation or creating your own activating methods. Focus on results.

The following task was proposed to verify it:

Non-role-playing discussion

Task type: group.

Name: New department.

Duration: 50 minutes.

Competences studied in the task: creativity, decision making, innovativeness, creative problem solving, building relationships.

Instructions for the participant

Your group's task is to create an innovation department that you will soon join. You have a real influence on the shape of the new department. Design the structure of the department, its positions and scope.

Step 2: Building a creative team using creative methods

The second stage focuses on building the team from the ground up using West's model of an innovative group (2000), which was expanded with new elements based on the research procedure applied in this study. The model helps to indicate the factors that can improve a group's innovativeness (Figure 2). These factors define the group's initial contribution and intragroup processes, thus producing measurable results. The model assumes that once the effect of the organizational context has been accounted for, the final result is determined by the group's contribution.

Fig. 2: West's model of an innovative group (West, 2000)

Use of the model helped to build a team in an organized manner and eliminate any disruptions. However, the key part of the model is the creative methods, which were added to intragroup processes. These methods are (Wasilewska, 2018):

1. Influence engagement: the provocation method, creative warm-up, heuristic rules, and creative thinking strategies.
2. Make sure that every team member is active: the six thinking hats method and personal identification.
3. Create an impasse: reversing and redefining the situation or problem.
4. Remove (emotional) barriers: associations, metaphors, and analogies.

Step 3: Moderation of a creative team

Appropriate moderation encourages searching for innovative solutions, motivates the employees to take action and develops their skills, and allows for teamwork planning. The company should select a moderator for the problem at hand carefully. Many moderators are experts (advisors) in their field. Their primary tasks include:

- leading the discussion;
- making sure that the meeting proceeds according to plan;
- applying creative competences (knowledge, skills, and attitude);
- providing the necessary tools, methods, techniques, and procedures.

Whether the selected moderator is an in-house employee or someone from outside depends on additional requirements and needs related to the problem, such as the complexity of the problem (Wasilewska, 2017).

A creative method may also be selected based on a particular source of insight. M. Sawhney and S. Khosla (2015) propose seven sources of insight, or "insight channels". An attempt was made to assign each method to the inspirations that support it. Figure 3 provides an example.

Fig. 3: Sources of insight and their ascribed creative methods (own formulation based on Sawhney and Khosla, 2015)

The superposition method helps to associate objects that are distant and have, at first glance, little in common with one another. The crushing method indicates four types of faults, which makes it easier to notice a problem. The synectic method is based on four types of analogies and uses what is called a fantasy excursion, which helps to find unusual solutions to a problem by seeking solutions to an analogous problem.

Step 4: Managing talents in the team

Traditional talent management involves a number of comprehensive actions aimed at strengthening the position of highly skilled employees and enabling an effective use of these talents by the company, by means of a specially designed tool, i.e., development programs. Programs related to talent management are often very complicated. However, there are certain basic conditions related to successes and failures that, if met, will ensure effectiveness. An important aspect of any competence model created for this purpose is its adjustment to the company's current situation, mission, strategy, and goals; all this with the company's future in mind. This study took into account these conditions. The starting point for talent management was the results of a questionnaire filled in by the team members and their leader. Tests are used to identify traits that are important for the employees'

development. Next, the employees focus on improving the traits with the lowest score. This allows for designing individual learning plans for each employee (Figure 4).

Fig. 4: Final stage of the model incorporating talents

Kirton's Adaptation-Innovation Theory test (Kirton, 2003) is used to identify each team member's cognitive style – whether he or she is an innovator or an adaptor. Adaptors rely on well-established systems to find solutions to problems, whereas innovators prefer to go beyond the standards to find new, untested solutions. Both styles are considered to be necessary for good teamwork. Every person's cognitive style is partly innate and partly determined by his or her experiences in life. According to Kirton, understanding the different cognitive styles present within the company can greatly improve organizational culture, including diversity and the way changes are introduced.

The leader fills in the Global Transformational Leadership (GTL) scale questionnaire (Carless, Wearing and Mann, 2000). The scale consists of seven dimensions, namely: indicate broad horizons, encourage employees to develop new skills, use individual incentives, support the employees in decision making, introduce innovative ideas and methods, serve as a role model for effective action, and radiate charisma. GTL separates effective managers from ineffective managers, which improves the team's efficiency (Stewart, 2006).

For both the team members and the leader, learning plans are established according to the design of the author of this article. These plans evolve based on the company's current needs, but their core elements are the aforementioned types of thinking. Employee learning plans are established in four steps. These are as follows:

1. Determine the employee's current knowledge, skills, understanding, and methods of learning (based on his or her score from a given test).
2. Establish personal development goals based on familiarity with processes in the company and the specifics, trends, and challenges of the industry.
3. Select learning methods to suit company and personal capabilities and preferred methods, taking into account the value added to the team.
4. Establish how the employee is going to monitor his or her progress.

Furthermore, roles, tasks, and projects can be assigned to specific employees to match their particular cognitive style and skills and ensure optimal results. This also helps establish new organizational behaviors.

According to N. Furr and J.H. Dyer (2015, p. 102), a mental space should be created where the innovation process can take place. The leader should let the employees know that innovation is going to transcend borders. For instance, he or she may demonstrate readiness to revise the company's

fundamental assumptions about its products, clients, and business models. The leader also underlines that uncertainty is acceptable, and that he or she is able to manage it. He or she leads by example, embracing new and different things. Furr and Dyer add that innovation requires dedicated time periods. This means facing specific challenges through observation and experiments. Allocating one or two days for innovation may help the employees to use this time effectively.

The aforementioned learning plans take into account the concept of the enterprise of the future, even though the concept itself has yet to be defined in detail; and although there is a growing number of studies on the subject, they still lack a distinct structure. All that is known so far is that the concept involves increasing the rate of innovation and the speed of learning in a complex, rapidly-changing world (Murray, 2017). Thinking in the categories of the enterprise of the future means developing one's own strategy, identifying and minimizing risks, and transforming traditional, knowledge-gathering organizations into effective, knowledge-based enterprises. The enterprise of the future is a continuous search that enforces interdisciplinary action. Traditional business and organizational models impede the flow of knowledge and fail to produce results. Instead, new business models, strategies or even ecosystems should be designed. An increased capacity for innovation and learning among teams will allow for faster responses to changes in the market or even for leading such changes, and this will provide the enterprise of the future with an opportunity to improve competitiveness. Understanding the essence of the changes benefits the creation of advanced systems and production processes, such as intelligent production technologies, online production services, digital production worlds, support systems for production know-how, and other modern production environments (Schlick, Trzcieliński, 2016). This indicates an increasing demand for creativity in technical teams, such as in maintenance departments.

Summary

Contemporary organizational structures are undergoing a significant transformation. They are becoming more dynamic, sometimes over the course of multiple reconstructions. Furthermore, the importance of teamwork is growing. Employees are expected to be more flexible.

The creative team model presented in this paper is the result of several years of research. Each of its stages requires a different approach. The model uses methods that are popular and widely available alongside those designed by the author of this paper. It requires systematic management achieved through knowledge about different types of thinking. The model supports the concept of the enterprise of the future, which takes on a specific structure and determines future goals.

Further research should aim to enrich the model with new creative methods, to stimulate the search for innovative solutions. It is predicted that an audit will be necessary a year after the company implements the model, which is when new tools should be developed that will improve the model.

Abstract

The goal of the paper is to analyze the reasons why ethical breaches are expanding within several levels in higher education. The research paper conducts a case study at a faculty from a technical university in Romania through quantitative and qualitative research with case analyses on the experience of younger teachers and the pressures they faced in student-teacher issues and associated management behavior. The funding system for public higher education institutions, decreasing number of enrolled students and lack of a proper family educational background for an increased number of students are causing breaches in applying specific university regulations with fairness and objectivity. Avoiding to bear with time-consuming procedures to solve student issues as well as the mechanism for financing university budgets are however the most common reasons that source unseemly actions. Results provide insights on the effects of indirectly tolerating misconduct and the correlated outcomes in the educational process on medium- and long-term: students' performance issues and the decreasing level of acquired skills by university graduates are among the most obvious side effects. The implications of the research highlight the importance of upholding high academic values by starting with one's own example and how they influence students' conduct, teachers' motivation and the overall perception of higher education institutions.

Keywords: Academic Values, Ethical Breaches, Student-Teacher Issues, Teacher Responsibility

Introduction and Literature Review

The decreasing number of potential students due to demographic decline and lower high school graduation rates in recent years are already challenging the majority of universities in Romania as the most important part of their budget is financed according to the number of enrolled and graduating students (Duerrenberger and Warning, 2018). To increase their attractiveness most universities have procedures to evaluate their academic curricula and teaching staff and have started reviewing their internal teaching processes with more objectivity in order to improve the quality of their study programs based on students' and teachers' evaluations and views upon the quality of the educational process and the teachers' performances in their activity. The specific conclusions and/or corrective measures that will arise after these assessments should nevertheless not miss to underline that the university's teaching policy should be supported by strong ethical and moral value (Schwartz, 2017) as to properly complement the educational principles on which it leads its activity to shape the character and skills of its future graduates (Lofstrom et al., 2015).

Students in Romania are currently more exposed to the harsh competitive nature of today's modern society which is enhanced by the rapid technological development and their career choice is still mostly influenced by certain external factors: parents' educational background (Merenkov, Antonova and Popova, 2018) and/or their specific job profile, friends' and colleagues clear career choices and peer pressure, perspectives and opportunities after graduation – mainly related to financial benefits (Havlíček, Dömeová and Hlavatý, 2018). These pressures create huge expectations which are not always met and may sometimes create an urge to try and influence things to go in a certain way, which often translates into ethical breaches and corruptive actions (Puiu and Ogarca, 2015), topics that are not uncommon in Romania's higher education climate (Osipian, 2009). Misconduct always occurs when there is a breach, when the students sense some kind of weakness (Satalkar and Shaw, 2018; Thomas, 2017), but the proportion of these acts is directly influenced by the way the teacher and/or university management handle these cases (Evans and Levine, 2016; Sârbu, Dimitrescu and Lacroix, 2015) and hesitant or inconsistent measures weaken the institutions' ability to proactively prevent further unethical behavior and issues (Hodgkinson et al., 2016). Nevertheless, the role of the university should be to address these concerns of its students (Tabsh, Abdelfatah and El Kadi, 2017) and guide them to not only focus on the degree itself, but instead, to support their acquired knowledge, skills and value of their studies with a proper mindset based upon high ethical values (Savelyeva and Douglas, 2017).

The present paper focuses on a case study conducted within one of the faculties of a renowned university in the Western region of Romania regarding the upholding of ethical issues at several hierarchical levels within the faculty and the higher education institution. The aim of the paper is to provide a comprehensive overview upon the reasons which lead to a very precarious way of handling students' issues and provide insights to better understand the implications and consequences of such unethical and doubtful practices.

Methodology

The research in question uses empirical evidence and the case research method for a data sample to analyze how internal regulations, administrative procedures and ethical conduct are being upheld by using quantitative and qualitative data. The presented case studies are from one of the faculties within an important technical university in the Western region of Romania, which comprises ethical issues, views and conduct of the Head of Department, Vice Dean, Dean and Rector of the institution in regards to specific situations. The main research questions refer to analyzing why certain students seek to obtain passing grades at any cost (**Research question 1:** Why do students who clearly fail certain subjects due to their own lack of academic commitment put up such a struggle afterwards to try and convince the teachers they should be passed regardless?), why regulations and procedures are completely disregarded within a faculty or university (**Research question 2:** Why are internal regulations and procedures of the university ignored in most cases when it comes to students asking for their exams to be reassessed by another teacher?) and why there is a large gap between what is expected and what is in fact delivered regarding ethical behavior (**Research question 3:** What is the reason why teachers with managing positions within the faculty and university impose and praise high ethical conduct within public talks, but fail to do so within their own everyday activity?).

The students in question from the case studies were in their graduation year. A total number of 434 bachelor degree students were enrolled in their last academic year between 2016-2019 (an average of 108 students/graduating academic year), the timespan from which these case studies are presented, in one of the most problematic graduation generation (class of 2017) more than 30% of students had been subject of misconduct issues and 7% had employed corruptive methods towards the teachers from this research. Attendance figures, overall average grades, dynamic of total faculty allocated places and percentage of graduated students are analyzed with methods of data analysis (arithmetic mean, sample size, validity testing) used to provide necessary context. Data was collected from the grade register of the faculty, faculty and university reports (each register and report contains extensive data, only the data regarding the matter is presented), teachers' specific records upon each student, individual discussions with colleagues, group interviews and department/faculty council meetings. Due to the sensitive topic of the paper only the most relevant ideas, information and

comments are presented, despite the extensive amount of data the authors gathered throughout each presented experience.

Results

Case study 1: An assistant teacher receives a surprise visit in his office after an evening lecture from the father of a student who failed to pass her exam at the subject at which the assistant teacher holds the seminar. He accuses the teacher of intentionally not wanting to pass her, is very aggressive verbally and threatens to physically beat the teacher in case his daughter does not pass the exam next time.

Background information: The student was caught cheating at her semester project in the third Bachelor year at the assistant teacher's subject and was failed at the seminar due to this misconduct issue (19 such students were caught from a total of 109). In the fourth Bachelor year, the same student handed in the project after the deadline had passed and sent an e-mail to the teacher letting him know that she left the project at the faculty on Christmas Eve. Despite accepting the project for review, the teacher considered the project very poor (graded it accordingly) and due to the student also not passing the semester evaluation test, failed her again due to poor professional performance and her lack of obtaining a passing grade (at least 5 out of a maximum of 10) at the seminar (6 other students failed as well from the total of 30 which had to redo the seminar). In the fifth year (first extension year) the student managed to obtain a passing grade for the project, but again failed the semester evaluation test. However the average of the two grades was enough for her to pass the seminar at the subject (she was among the 3 students who passed, 4 had failed again). Her results are shown in table 1.

Table 1: Grades obtained by the first student at the seminar, 2016-2018 (source: faculty registry)

	Semester Project	Semester Evaluation Test	Average Grade	Result
3rd Bachelor year	copied	1.50	N/A	**failed**
4th Bachelor year	3.95	4.00	3.97	**failed**
1st extension year	6.25	4.00	5.12	**passed**

In order to pass a subject a student needs to successfully have a passing grade for both the seminar and the exam. All exams have a theoretical and a practical part (an exercise similar to those performed during seminars), with different teachers being in charge of the lecture (gives the grade for the theory part) and seminar (gives the grade for the exercise part) and a student has to obtain a passing grade for each individual part of the exam in order to pass. The student in question had failed to pass the exam 13 times (3 times in the 3rd Bachelor year – twice being absent, 5 times in the 4th Bachelor year – twice being absent in the special 4th presentation and 5 times in the 1st extension year – never even once managing to pass any part of the exam, neither the theoretical, nor the practical part). The 4th presentation was given twice (despite being against university regulations) in order to grant an extra passing chance to the student, but in the 4th Bachelor year she chose to absent on both occasions, whereas in the extension year she failed to pass on both dates (7 out of 10 students managed to pass the exam at the first date). Between the final extension year exams, the student had an argument with the tenured teacher of the subject in the faculty yard, with the teacher being very surprised by her rude attitude, in addition to her spreading rumors at her job that the two teachers do not want to pass her on purpose and also filing a complaint at the Rector's office. The student's results for the exam are highlighted in table 2.

Table 2: Grades obtained by the first student at the exam, 2016-2018 (source: faculty registry)

	1st presentation		2nd presentation		3rd presentation		4th presentation*	
Exam results	*Theory*	*Exercise*	*Theory*	*Exercise*	*Theory*	*Exercise*	*Theory*	*Exercise*
3rd Bachelor year	4	abs	abs	abs	abs	abs	N/A	N/A
4th Bachelor year	4.50	2.50	4.25	4	4.75	3	abs	abs
1st extension year	4	3.25	4	1.75	4.50	2	4	3

Resolution: The two teachers decided to eventually pass the student. "I have never been so scared and intimidated by anyone in my entire life, as by the threats of her father in my office that evening" (assistant teacher); "I could have given her the grade she deserved and fail her again, but I had enough of her and I could not bear to see her again after those ill-mannered allegations" (tenured teacher). The student would afterwards admit within a written statement (submitted to the Dean of the faculty) that she had not prepared for any of the exams and that she had mislead both her father and the Rector into believing that the teachers were at fault, but no actions or measures were taken by the faculty or university management against her.

Case study 2: A junior lecturer is asked to come to the Vice Dean's office and discuss about the exam result of a student who claims she did not deserve to fail. The teacher brings the exam of the student and explains why she did not pass any of the parts, but is constantly interrupted by the frantic reactions and disapproval of the student, encouraged by the interventions of both the Vice Dean and the faculty secretary who consider that the assistant teacher has no right to grade her exam and suggest passing her on the spot would be the "wise solution".

Background information: The student was frustrated because the exam results she was complaining about were after the 4th presentation and failing would have meant starting a year of extension. Nevertheless prior to that, she had a very strange behavior throughout all the previous exam presentations as she would sit until the end of the exam without writing too much and when asked by the junior lecturer why she remained until the end despite not having learned or solved the exercise she answered: "I am not worried, the tenured teacher will eventually have pity and pass me.", neglecting the fact that the exam had two parts, graded by two different teachers. The tenured teacher of the subject had to leave for a business trip and would be away for the exam within the 4th presentation, but he left designated theoretical subjects to the assistant teacher and asked him to take the exam without him. The second student's exam results are shown in table 3.

Table 3: Grades obtained by the second student at the exam, 2016-2018 (source: faculty registry)

	1st presentation		2nd presentation		3rd presentation		4th presentation*	
Exam results	*Theory*	*Exercise*	*Theory*	*Exercise*	*Theory*	*Exercise*	*Theory*	*Exercise*
3rd Bachelor year	abs	abs	4	abs	5.50	4	N/A	N/A
4th Bachelor year	abs	abs	4.25	5	4.25	4	4	4
1st extension year	4.25	4	4	abs	5.50	4	5	5

The student absented at 2 of the 12 presentations and from the remaining 10 attempts she left the exam 3 times prior to the exercise even being given as she had not written a single word on the exam paper for the theoretical part. According to the ranking of the 97 students of the class of 2017, the second student was ranked 88th with an average grade of 6.31 throughout the 4 Bachelor years, within the last 10% of the class by academic results obtained. The distribution of overall average grades obtained by the class of 2017 throughout their 4 Bachelor years is shown in figure 1. Only 5%

obtained very good results (overall average higher than grade 9.00), a quarter of the class had above average results (overall average grade higher than 8.00), whilst more than a half scored within average results (overall average grade between 6.50 and 7.99). One of five students had below average results (overall average grade under 6.50) with the rate of weak and very weak results being of over 40%, a highly unusual amount of students having such weak academic results.

Figure 1: Overall average grades throughout the 4 Bachelor years, class of 2017 (source: faculty registry)

The Vice Dean insisted that he may also grade the theoretical part of the paper (despite him teaching a completely different subject) and that he himself would pass her. At this point the assistant teacher reminded him that in order to pass, she would have needed to also pass the exercise (which he graded) and that it would not make any difference. The Vice Dean then said it is not the junior lecturer's call and decided to have the tenured teacher evaluate the exam after sending pictures by e-mail of both the theory and exercise, but the tenured teacher's response surprised him: "The theoretical part is not suitable for passing in my opinion, it is very weak. The exercise is the responsibility of my assistant (i.e. the junior lecturer) and whatever he says, goes for me as well. Since he is there and I am not it's his decision and whatever grade he gives is final." The secretary then suggested the Vice Dean to annul the exam, but this would have however meant that 6 of the 8 students who had passed would have had to retake the exam, so he would have to think of another solution to help the student.

Resolution: The Vice Dean decided to retake the exam only for those who failed at a date at which the tenured teacher would be present. At that date, after the theory subjects had been given, the student left the exam saying she had not prepared and left without complaints. It would later be revealed that the student had lied at her job that she had already graduated and when asked to present an attestation by her employer she decided to get things solved quickly by asking the Vice Dean to help her in this matter.

Research question 1: Why do students who clearly fail certain subjects due to their own lack of academic commitment put up such a struggle afterwards to try and convince the teachers they should be passed regardless? Answer: The external pressures from either family or job requirements as well as the unrealistic self-evaluation of students' own academic levels lead to a large gap between their expectations and actual reality and creates frustration, often enabling that gap to actually expand over time and sourcing further troubles in both the students' long-term careers and personal development.

Case study 3: One of the youngest assistant teachers of the faculty is visited by a student who has never attended his seminar throughout the entire semester. He explains that he has decided to become a Police Officer back home and just wants to pass the seminar and get his diploma. The assistant teacher explains why this is not possible, but the student says that he does not care because he will still get the situation solved with a wide smirk on his face and terminates the conversation by leaving his office.

Background information: Students have only 7 weeks of lectures and seminars for the subjects from the second semester of the graduation year which are marked by week 10 (after all sessions) and registered at the secretarial office, giving the students at least 4 full weeks for the preparation of their diploma project defense (each semester having 14 weeks). According to the university regulations, in order to pass the semester activity (seminar, project or laboratory) a student must attend at least two thirds of the classes, hand in the required work and have a professional performance which complies with the teacher's minimum passing requirements. The third student came to talk to the assistant teacher in week 11, one week after even the grades for the exam were final and thus the subject ended for that academic year. Despite this setback the student would go and see the other teachers telling them about his change of career plans and claimed he had passed all the exams except for their exam. Meanwhile the assistant teacher received a call from the university asking him about why he failed the student and after his explanations he was told to be "more aware of the situation" and to try to "avoid trouble". The next day after that phone conversation, the student would again come to try and convince the assistant teacher to pass him and stated that this would be "in the best interest of everyone concerned", but the assistant teacher upheld his decision.

Resolution: The student would eventually pass the subject and receive his diploma that summer. Knowing that convincing the assistant teacher would be impossible, the student went to see the Rector, who spoke to the tenured teacher of the subject and told him he could overrule the assistant teacher's grade and change it in the faculty registry but insisted the tenured teacher was not to inform his assistant upon the issue. Both the assistant teacher and the Dean of the faculty were surprised to see the name of the third student among those who would defend their diploma project that summer, because both knew the student failed the other's subject. "He failed my exam 4 times and he begged for another chance, despite being against regulations. I accepted knowing he had already failed in one subject (i.e. the assistant teacher's subject), so I thought it would not make any difference and I also marked his grade in the registry, upon him insisting I do it then for him not to have to remind me to do so in autumn, as we verbally agreed before the exam." (Dean of the faculty) The exam was graded and marked at the secretarial office after the student's meeting with the Rector, despite the student's claim that he had passed everything except the assistant teacher's seminar. The assistant teacher informed the tenured teacher, Dean and Rector about the entire situation, but no corrective actions or punitive measures were taken by the faculty or university management against the student for misleading and deceiving academic staff. Instead, the assistant teacher was informed he could face disciplinary action.

Case study 4: A lecturer is called by the Head of the Department to discuss about his results from the students' evaluations conducted within the university. The lecturer faces a surprisingly harsh feedback and incongruous allegations throughout the discussion, but at the end of the discussion is left even more surprised as he is promised that the imputations would be overlooked if he were to pass a certain student at an upcoming exam.

Background information: After each semester the university conducts an online assessment of the staff's teaching performance and evaluation criteria, as perceived so by the students. The assessment is done at the university, within the faculty's 3 laboratories, because the students are given codes and matching passwords for every subject by a random teacher who is in charge of the process. The results of the assessment are sent from the university database to the Head of Department who then sends them out to the teachers concerned. Table 4 provides an overview of these results.

Table 4: Results of students' evaluation for a specific subject, 2018 (source: university database)

	Tenured teacher			Assistant teacher (lecturer)		
Subject	**Answering students**	**Total number**	**[%]**	**Answering students**	**Total number**	**[%]**
Class of 2018	61	148	41.21	4	148	2.70
Group 5	59	29	203	4	29	13.79
Attendance	**Under 25%**	**Between 25-75%**	**Over 75%**	**Under 25%**	**Between 25-75%**	**Over 75%**
Class of 2018	5	30	26	1	0	3
Group 5	1	17	31	1	0	3

Besides the figures, the Head of the Department also provided some additional remarks he claimed the students had made in regards to the lecturer's performance at the seminar, which were: lack of attractiveness, clarity and interaction. He also added using "too direct language" and making fun of students. The lecturer was shocked and insisted that there had to be a mistake and that those evaluation results could not possibly be associated with him and his performance. He also referred to the low amount of students (under 3%) assessing his performance, the data inconsistency (a student marked he had under 25% attendance, which was impossible because all students passed the seminar and in order to do so a minimum attendance of 66% is required), as well as the very odd overlap of data by group 5 in regards to the class (203% answer ratio is impossible), but the Head of the Department replied by saying "That's what it says, these are the conclusions and I do not wish to comment more." The lecturer was very surprised by these remarks, as his personal feel after the seminar was a very positive one. Upon analyzing the results of his students, similar conclusions would support this feeling, as the overall subject average was 0.39 points higher than the class's overall average grade for their 4 Bachelor years (a 5% increase in the grade), 105 of the 148 students managing to score a higher grade in the subject than their overall average (70% of all students), whilst average attendance figures for the subject's seminar (an indicator of interest and attractiveness) were well above usual average attendance figures (88% on average), exceeding the minimum attendance requirement by 25%. The results of group 5 were no different: almost 2% increase in subject grade compared to overall average, 65% of students scoring higher grades and an 84% average attendance (more than a quarter of students having recorded a 100% attendance). An overview of these figures is provided by table 5.

Table 5: Results of subject grades compared to overall average grade, 2018 (source: faculty registry)

Results	Subject average grade	Overall average grade	Difference	Above overall average grade	Under overall Average grade
Group 1	8.40	8.27	+ 0.13	25	10
Group 2	7.76	7.45	+ 0.31	16	9
Group 3	6.78	6.80	- 0.02	15	9
Group 4	9.32	8.08	+ 1.24	30	5
Group 5	8.14	8.00	+ 0.14	19	10
Class of 2018	8.20	7.81	+ 0.39	105	43

The student the Head of the Department was referring to was related to him and his father was in charge of the maintenance for the faculty's printers and had refused to service and repair the printers "until the situation was solved". Prior to the discussion between the lecturer and the Head of Department, the student had failed the exam 3 times: once leaving the exam after the subjects were handed out (blank paper), then not obtaining a passing grade for the theoretical part and again leaving

the exercise part blank and the third time not managing to obtain a passing grade for any of the parts of the exam.

Resolution: The student would eventually pass them exam. Although he rightly obtained a very good grade at the exercise, his performance at the theoretical part was very poor, but the tenured teacher passed him nevertheless. As a consequence, within the next week all pending problems, maintenance issues and needed repairs of the faculty's printers were taken care of with promptness. The tenured teacher commented: "I could have failed him and we would have still had the problems with our printers, so what would I have gained? This way, everybody wins." In addition, the lecturer's presumed poor assessment by the students did not seem a problem anymore, as the Head of the Department stated: "It's not actually a problem, only a question of balance. I think you need to be more careful with the relationship with certain students and adjust things accordingly when there are specific issues."

Research question 2: Why are internal regulations and procedures of the university ignored in most cases when it comes to students asking for their exams to be reassessed by another teacher? Answer: First of all, these procedures are time-consuming and require hearings, discussions and paperwork, as well as communicating decisions to both the student, teacher and the university administration and are formally registered and will be integrated in the university report, which is perceived as a very negative occurrence. Then there is the chance of the student not being pleased with the resolution, which would mean he pursues and addresses the university directly with a similar procedure involving different staff and Vice Rectors who have to reassess the solution given by the faculty, making it even lengthier. Thus a simple and on the spot fix for the student is much easier for those potentially involved and the faculty and university management prefer this alternative (time and paperwork savings, student leaves happily), despite it being against own regulations, highly questionable as an approach and unethical in most cases.

Case study 5: An assistant teacher is called by the Rector for a discussion regarding the amount of recent complaints received by him and his younger colleagues at the university. Despite always praising the university's ability to provide highly skilled graduates as a result of high ethical standards and academic values, the Rector seems to see things differently when talking to the assistant teacher and suggests that "finding proper solutions for each individual case" would lead to a "wiser long-term outcome". He also mentions that if the assistant teacher were to abide the university regulations too strictly, he would be facing disciplinary action and that this discussion is just a "friendly warning" to prevent such a thing happening in the future.

Background information: The Rector was also aware of the cases previously mentioned and pointed out that if the Ethics Commission from the university would have analyzed the accusations brought upon these younger teachers (including him), regardless of the outcome, their right to be promoted to a superior academic position would have been suspended for a time span of 5 years according to the university's internal regulations. After letting the assistant teacher present his view on the 4 cases, the Rector was nevertheless quite surprised of the amount of details he had not been aware of when judging and interpreting those situations prior to the discussion with the assistant teacher and admitted he had not thought to do some background research on the students who came to complain to him. Despite agreeing with him on the 4 cases, the Rector concluded that it is important for all of them to "get the message" and understand the fact that sometimes the younger teachers need to show "special attention and consideration to certain situations".

Table 6: Student figures and place allocations at faculty level, 2016-2018 (source: faculty registry)

	2016		**2017**		**2018**	
Number of students	1st Bachelor year	Graduates (Class of 2016)	1st Bachelor year	Graduates (Class of 2017)	1st Bachelor year	Graduates (Class of 2018)
	179 (179)	98	156 (155)	98	162 (145)	114
Number	**2016**		**2017**		**2018**	

of allocated places	Bachelor degree	Master degree	Bachelor degree	Master degree	Bachelor degree	Master degree
	155 (185)	115 (140)	156 (180)	110 (140)	156 (180)	110 (140)
Number of own students	**2016**		**2017**		**2018**	
	Enrolled in Master degree	Master degree places	Enrolled in Master degree	Master degree places	Enrolled in Master degree	Master degree places
	46 (98)	115 (140)	42 (98)	110 (140)	49 (114)	110 (140)

The proportion of students enrolled who also graduate at the end of the 4 year Bachelor studies has slowly risen throughout the last 3 years, from 54.7% (2016) to 70.3% (2018), but the number of budgeted places allocated to the faculty has decreased by 13.3% within the last 5 years, from 180 places (2012) to 156 places (2017) due to the declining number of students who manage to finish their Bachelor studies once enrolled within the 1st year compared to previous forecasts. Within the last decade the proportion of students enrolled within the 1st year who actually finish their studies has decreased from around 80% to around 60% (61.2% in 2015, 54.7% in 2016 and 62.8% in 2017), meaning that the proposed number of allocated places for the faculty was also adjusted downwards: from 240 places (2008) to 195 places (2012) and 180 places (2017), an overall decrease of 25% in the last 10 years. The proportion of budgeted places has also been reduced: from around 95% (2008) to 86% (2018) and has also affected the allocations for the master degree programs after 3 consecutive years where the number of enrolled student figures had decreased (by 20% in 2016, by a further 5% in 2017 and another 7% in 2018). Thus, if there were 225 total places available in 2008, this number would decrease by 20% in 2012 (180 total places) and by a further 22% in 2016 (140 total places), more than a third of the available places being cut due to the shift of graduate students' dynamics. Although the proportion of budgeted places has remained at a steady 80%, the deceasing number of enrolled and graduating students has affected the overall budget of the university, as financing is obtained according to the number of enrolled students, on the one hand, and depending upon the number of graduating students, on the other hand. Moreover the retention figures of own graduates in the Master's degree programs (46.9% in 2016, 42.8% in 2017 and 42.9% in 2018) has also declined and is now under 50% for the third year in a row after a constant rate of around 70% or more in previous years. With Bachelor students' graduation figures being rather modest, with low chances of having improved future dynamics and a poor retention of own graduates in the master programs, perspectives are not looking very encouraging for future years in terms of increasing financing for the budget of the university.

Resolution: Knowing the Rector also likes to talk about student figures during his public speeches, the assistant teacher asks if passing them all is what is expected of him and his colleagues. The Rector avoids giving a direct answer, but nevertheless implies it: "I would not want you to do that. Instead of failing them, have them redo their evaluation test/project at the end of the semester until it complies or just give them some extra assignments and eventually pass them." This idea is confirmed within a meeting the Rector has with the faculty staff where he states that the teachers have to show "more consideration and understanding of the circumstances, challenges and situations certain students might face and help them solve their academic issues and avoid generating troubles". Meanwhile, on public and official settings he presents the university as an organization with high academic standards, offering very skilled graduates with a solid educational background and high ethical and moral values and praises the high number of graduates it produces every year. These words were contradicted by local companies who employ many of the university's students at a recent conference on higher education, where several examples were given which contradicted the Rector's praise of the institution's graduates.

Research question 3: What is the reason why teachers with managing positions within the faculty and university impose and praise high ethical conduct within public talks, but fail to do so within their own everyday activity? Answer: Managing positions also mean having to source funding and being in charge of providing consistent figures and the higher the figures, the better the general acceptation is, despite the quantity-quality balance being highly neglected within such an approach. Business is

money is thus valid even when education is concerned, as receiving an extra grant and funding shows to be more important that upholding (even own) ethical values.

Discussion and conclusion

The proportion of students' misconduct is directly influenced by the way the teacher and/or university management handle such issues with hesitant or inconsistent measures thus weakening the ability to proactively prevent further ethical breaches. Lowering assignment difficulty, grading standards or increasing vigilance during exams are only short-term fixes, whereas indirectly tolerating certain breaches in ethics by not applying harsh penalties will further deepen the issue. Education is a continuous process and is the basis of a healthy society, thus the role of those who intervene is essential in developing correct values, respect and responsibility. In a report from 2016 the Coalition for Clean Universities outlines that academic integrity is a major problem of the educational system in Romania, as 77% of students and 34% of teachers perceive that the level of corruption in universities is high. The reason mainly comes from background education, as there is a strong sense of competitiveness and pressure from parents towards their children to have them follow successful careers and outperform them by all means. This is due to certain features and gains they may enjoy as are those of social status, reputation and other benefits resulting from such achievements.

The interference in the educational process by parents or nepotism alters the capacity to objectively assess the qualities, knowledge and academic results of a student and negatively affects his appropriate personal and career progress. Because scandals rapidly catch our attention, we tend to associate strong feelings towards such issues and there is a natural tendency to avoid this happening in higher education as this may cause negative commentaries upon the institutions' reputation if "word gets out", so the silent solutions are usually preferred. A former Dean of the faculty sees things differently: "Students leave university after the completion of their studies, fellow teachers work with us together for much longer than that, and we know our colleagues better than we know the students, so not giving credit to the teachers in student-teacher issues is not the proper way to find sustainable solutions". Authority is however a very important sign of acceptance, as students prefer to look for higher authority when a teacher does not pass them or when they are not pleased with certain outcomes: should the higher authority confirm the teacher's decision, then he gains in reputation and respect from students, however should his decision be overruled, then students will be more likely to continue seeking "second opinions" from higher authorities within the faculty/university.

The rules are thus rules only when it's convenient for those who have to apply them to actually apply them. When there is a situation which implies students, no matter their degree of mistake, fault, lack of proper academic behavior, the rules are usually bent in his favor by a higher authority and the concerned teacher is hindered in his jurisdiction, becoming a pattern followed by those students who do not comply with certain academic standards and then search to seek solving their issue by other means. By not following the established procedures, they obtain their desired result a lot faster and without passing through a thorough examination of the issue by those who decide to overrule the teacher's decision. Teachers faced with such issues will be more likely to shift their focus and motivation towards those activities which add more value to themselves in their academic career and be less concerned with investing their efforts in the teaching process as a consequence of losing their authority, ultimately lowering the quality of the educational process provided. More recent issues (silently solved) include a teacher asking for fictive students at the end of the semester and during the exam, teachers showing up drunk in class or not showing up for more than half a semester or even an unruly student offering to pay a teacher on the spot for a finished bachelor thesis only 2 days prior to the deadline and with another teacher present in the office during the entire scene.

Technical competences will most likely be sooner or later acquired by graduates and strictly focusing on the specific knowledge of a subject and neglecting to develop a deeper understanding of the content will hinder creative thinking and problem-solving skills which are so necessary in today's fast developing technological setting. Moreover, by not imposing a high level of academic values and upholding them, universities will in future lose their reputation as higher education institutions and the level of their students will confirm the decrease in quality and performance of their educational

process. The efforts of the university should thus be oriented towards handling these situations with higher attention and priority, finding solutions to avoid their expansion and providing positive examples by those who are in leading management positions by promoting high ethical and moral values through their own conduct as an inspiration for their fellows, colleagues and students. Future research directions on this sensitive topic could be represented by analyzing career development outcomes on short and medium-term for teachers and students involved and how these issues have affected their subsequent personal and career paths. An important implication to be analyzed within this background is how these types of situations and challenges have shifted young teachers' motivation and conduct and how their decisions in similar issues were affected.

Abstract

This article discusses the requirements for the integration of information systems in a united information environment of an industrial enterprise. Compliance with these requirements allows you to minimize the loss associated with configuring integrated systems in a common system. This integration is based on the subsystems available at the enterprise that operate in the information infrastructure. The principle of information compatibility of subsystems is shown as the intersection of the set of data coming from the source subsystem to the recipient subsystem. The levels of necessary support for the components of subsystems for reliable, uninterrupted and safe operation of a united information space are considered. Describes the characteristics of the necessary work on maintenance and configuration of individual subsystems to prevent emergencies in the entire system as a whole. Reliability indicators of the solutions used to create the infrastructure subsystems are presented. The factors of the order of interaction between the personnel of subsystems and the personnel of the automation object are determined.

Keywords: Information Technology, Industrial Enterprise, Production.

Introduction

The main goals of industrial enterprises in the conditions of the fourth industrial revolution are to increase the competitiveness of products, improve the quality of products and services at all stages of the product life cycle, ensure technological independence in the most sensitive areas, and increase the production of high-tech products. Achieving these goals is possible only through deep information modernization of industry, especially engineering.

Literature Review

The theoretical and methodological basis for the study of complex information systems, which include systems for automating the production environment of an enterprise, are system theory, system and data mining. The greatest contribution to the development of this scientific area was made by M. Lipov (1974), P.B. Moranda (1972), S.V. Novikov M.E. Shooman (1972), C.A. Sukert (1977), K. Wall (1977), S.V. Novikov (2018), A. Bikmullin, B. Pavlov, Z. Khusainov, G. Mingaleev (2019).

The problems of implementing the key technologies of Industry 4.0 in the integrated information environment of an enterprise are considered in the works of scientists V.Komarova, A.A. Zamkovoi, S.V. Novikov (2019), Tikhonov A.I., Sazonov A.A., Novikov S.V. (2019).

Object: industrial enterprises specializing in the production of high-tech products and implementing information and digital technologies in manufacture.

Methods: analysis, systematization and synthesis of data, modeling and algorithmization of processes.

Methodology

One of the main directions of industrial modernization is the development, implementation and application of information systems that allow integrating production processes into the product life cycle.

The general concept is to form a united information system (UIS) to ensure the development and production of the product. UIS is designed to automate the collective work of specialists and heads of design departments, units of design preparation of production, technological preparation of production and technological bureaus of the workshops of the main production in the development, preparation of production and support of product operation. All measures to create an UIS are possible only if there is a prepared IT infrastructure.

The goals of creating the UIS are the following:

1) Ensuring the collective development in electronic form of the products, taking into account geographically distributed process participants and safety requirements;
2) Creation of a united database of the products;
3) Automation of the processes of design and development, production preparation, planning and accounting in production, testing and maintenance;
4) Ensuring the processing and safety of product data.

In the practice of using separate information systems, their composition is quite stable and their list can be described by the following components:

1) Subsystem for the integration of production and operations, human resources management, financial management and asset management (ERP);
2) Product data management subsystem (PDM);
3) Subsystem for managing the production program, projects and cooperation (PM);
4) Master data management subsystem (MDM);
5) Computer-aided design subsystem (CAD);
6) Computer-aided manufacture subsystem (CAM);
7) Computer-aided engineering subsystem (CAE);
8) Advanced Planning and Scheduling subsystem (APS), which includes planning, management and monitoring functions;
9) Manufacturing executive system (MES);
10) Enterprise service bus (ESB).

The subsystems that are UIS's parts during the operation process exchange information through the enterprise service bus. This exchange is based on:

- automation of information exchange in the form of formalized messages (XML – eXtensible Markup Language), transmitted through the ESB integration bus;
- automation of business processes between allied UIS's subsystems in the form of workflow templates;
- automation of computation data management due to the formation of a united information environment.

Data exchange, carried out through the ESB, operates on the basis of the developed data formats, protocols and data exchange regulations between the above-mentioned allied UIS's subsystems.

Results

Information compatibility of UIS's subsystems is ensured on the basis of digital transformation during data exchange between allied UIS's subsystems and bringing it to the format of receiver systems. Such a transformation is carried out by describing the interaction of information systems, and is represented according to the cybernetic principle of the "black box", by the three data sets presented in the Figure 1 for two subsystems.

Fig. 1: Integration of subsytems.

In the Figure 1 S_i, $S_{i+1`}$ are the subsystems, correspondingly;

$(\{x_a\} \cup \{y_b\}) \cap (\{x_v\} \cup \{y_w\})$ is a set of information understood by the first and second subsystems, formed by the intersection of the information bases of these subsystems.

Note: 1. $\{y_c\} \subset \{y_b\}$;

2. $\{y_z\} \subset \{y_w\}$.

The indicated sets for the first subsystem are:

Input of the system — $\{x_a : a = \overline{1,A}\}$ — a set of input information for S_i subsystem;

Body of the system — $\{y_b = f(x_a)\}$ — a set of tasks to be solved for S_i subsystem;

Output of the system — $\{y_c : c = \overline{1,C}\}$ — a set of the solutions for S_i subsystem.

The indicated sets for the second subsystem are:

Input of the system — $\{x_v : v = \overline{1,V}\}$ — a set of input information for S_{i+1} subsystem;

Body of the system — $\{y_w = f(x_v)\}$ — a set of tasks to be solved for S_{i+1} subsystem;

Output of the system — $\{y_z : z = \overline{1,Z}\}$ — a set of the solutions for S_{i+1} subsystem.

The intersection of the sets of information bases of integrable systems defines a special format of communication, including a set of specific (typical, standard) conditions:

$$\left\{ y_w = f(x_v) : w = \overline{1,W} \right\}$$

The resulting format of communication is a necessary component of the integration process, determining the set of valid information involved in the communication of information subsystems. The concept of "communication" is functionally a certain set of information that is unambiguously understood by integrable systems. Communication is ensured by linguistic compatibility due to the
