use of a single message description language XML during the exchange of information between allied UIS's subsystems. The communication between the allied UIS's subsystems is carried out through standard data exchange protocols supported by the enterprise data transmission network, taking into account the current requirements of regulatory documents.

In the production cycle of the enterprise, the UIS provides:

a) in the regular mode (this is an operating mode of the UIS, in which the functions are performed in full: all components and functionality of the subsystems are available, the provided computing power meets the engineering specification):

- continuous work of divisions in a single environment;
- data exchange between the allied subsystems;

b) in service mode (technological maintenance mode, in which a number of infrastructure subsystem components are withdrawn from operation in a planned manner, application subsystems operate on backup computing capacities. For some components of infrastructure subsystems with preliminary coordination is allowed for a short interruption to switch to the reserve capacities):

- subsystem modernization;
- data back-up;

c) in emergency mode (the mode of operation of the UIS, in which a number of components of the infrastructural subsystems fail as a result of a failure or fault. The mode is characterized by a significant limitation or lack of capabilities to perform the UIS's tasks due to malfunctions of its hardware and software):

- data back-up.

For the UIS in all operating modes, the reliability, safety and security of the information processed in it is ensured. This is achieved at the level of applied subsystems, where the mutual solution of the problem occurs:

- The UIS should provide tools for diagnosing the subsystems' processes that are part of it, including logging and monitoring of the performed process.
- In the event of an emergency, the diagnostic tools should allow you to save the set of information necessary to identify the problem.

At the level of infrastructure subsystems' components are provided:

- Maintaining system logs implemented by the standard hardware and software of each of the infrastructure subsystems' components, indicating the date, time, status data at the time of the occurrence of malfunctions, errors, and incidents.
- Providing standard, documented hardware and software interfaces for remote monitoring provided by the subsystem architecture.
- Ensuring the possibility of modernization related to the release of new versions (releases) of software, including operating systems with preservation (with the possibility of expansion) of the functionality of all subsystems implemented as part of the implementation of the UIS.

Requirements for the qualifications of personnel are established by the job descriptions approved and applied for each staff unit at the enterprise. Employees who have been instructed in accordance with the system role, certified and have an account are allowed to work in the UIS (by the time it is put into operation). Also, by the beginning of the industrial use of the UIS, the staff of the necessary fully-staffed personnel is being trained both in standard courses corresponding to the system role and in the framework of instruction according to user instructions developed for this role. Specialists are organized into the necessary working groups with established work schedules.

To calculate the minimum staffing level of administrators, you must consider:

- subsystem availability indicators and a wide range of administrative responsibilities requiring a permanent presence at the workplace;
- need to provide a substitute for vacation or illness.

The UIS installed on an enterprise's hardware platform with a performance not lower than the minimum requirements for a system should ensure that all requirements specified in the initial task for the system's functioning are met. The UIS's components can undergo changes under the conditions of business processes, and it is necessary that the infrastructure subsystems ensure the operation of the application subsystems that are part of the UIS for all categories of users, including geographically remote ones, with centralized databases and logical structure.

UIS's components are configured with the ability to implement:

- scalability by the number of users;
- setting and changing the configuration of user workstations;
- independence from changes in the organizational structure of subdivisions while maintaining the composition and content of the functions performed;
- the ability to relocate users within the corporate network.

The UIS's components can be modernized and developed when the parameters of the automation object are changed within the framework of industrial production, as well as when the composition of the requirements for the functions and types of support is changed. The modernization and development of the UIS's components is carried out by subject matter experts and application service programmers using appropriate software that automates the modernization and development process, as well as documenting the results. When expanding the functionality or the number of UIS's users, an assessment is carried out and the need for technical means is determined to preserve the temporal characteristics of functioning.

None of the UIS's components can be the cause of emergencies. All UIS's components are configured for the correct processing of user actions and error messages from the operating system; they are correctly informed of erroneous actions on their part.

UIS's hardware and software is provided with the necessary maintenance and configuration of individual modules without UIS's components.

The UIS performance is restored within 4 hours if the application software fails, if there are no hardware problems, it does not require restoring the operating system, deploying and configuring special software on servers, or restoring data using the latest backup.

Providing protection against information loss at various failure levels of the software and hardware complex (for example, server, DBMS, etc.) is carried out using the data of the replicated server. This ensures data integrity, and restoring the database to the state at the time of the last transaction completed by the subsystem occurs regardless of a failure or loss of electrical power. However, in case of damage to the DBMS transaction logs, the restoration of the state of the system component occurs at the time of the last data backup, but no more than one day before the failure.

Ensuring the UIS reliability is carried out at the stages of development and operation. At the stage of development of the EIS, structural redundancy of critical components of the EIS is provided, including the introduction of additional components into the structure that perform the functions of the main ones in case of failure.

The solutions used to create infrastructure subsystems as part of the UIS are based on reliability indicators that allow:

- ensure the availability factor of infrastructure subsystems as a whole is not worse than 0.95;
- within 24 hours to restore the operability of the target application of UIS's subsystems using the resources of infrastructure subsystems.

Convenience, unambiguity and stability of user communication with software and hardware are the prevailing factor for all types of interfaces. The user interface of the UIS's components is a standard

solution for all users and includes the ability to customize to user requirements (changing the order of menu sections, highlighting the most frequently performed functions in a separate list). The UIS's user interfaces are implemented in a modular fashion with the greatest possible unification and typification of the solutions used. Design of screen forms is carried out taking into account the specified requirements, while:

- all screen forms of the user interface within the subsystems are performed in a single graphic design, with the same arrangement of the main controls and navigation;
- similar graphic icons, buttons, and other control (navigation) elements are used to indicate similar operations. The terms used to indicate typical operations (adding an information entity, editing a data field), as well as the sequence of user actions when they are performed, are unified.

During the operation, maintenance, repair and storage of system components, the following requirements must be adhered to:

a) Maintenance of UIS's components is performed by administrators of subsystems.

b) Engineering solutions for the development and modernization of the UIS's components are provided for the possibility of a planned shutdown of the individual components of the subsystem for routine maintenance without loss of functionality and stop the UIS as a whole.

c) The operation of UIS's software and hardware includes the following types of services:

- runtime service;
- scheduled maintenance;
- accident operation;
- modernization of the subsystem's modules and elements;
- disaster recovery.

d) Operational maintenance provides daily monitoring of the functioning of the UIS's software and hardware using stand-alone administration tools for the UIS components. Operational service does not affect the performance of the functions of the UIS's components for the provision of information services in general. During operational maintenance, documentation of ongoing procedures and operations, analysis of the functioning of the UIS's components and elements, development of recommendations for improving the operation of the UIS are carried out. At the same time, a periodic review of the regulations and the introduction of the necessary changes to the operating procedures is carried out on the basis of the experience in operating the UIS.

e) Preventive work includes periodically checking the relevance of the regulations, checking and maintaining the components, checking the operability of the backup procedures for individual UIS's elements and components, backup and data recovery procedures for which such maintenance and procedures are provided for by operational documentation. Preventive work is also documented during the procedures and operations, an analysis is made of the functioning of the UIS's components and elements, recommendations are made to improve the work of the UIS.

f) A backup copy of the current version of the UIS's components application software is stored on magnetic or optical media and is available for use by maintenance personnel.

g) Operation in case of accidents of UIS's components provides for the procedure for transferring services to redundant elements, notifying management and users about switching to redundant elements, ensuring the relevance of software and information support, operability of redundant elements of UIS's components, and carrying out the necessary set of emergency recovery work.

h) When upgrading UIS's components, it is necessary to provide for a set of regulated procedures for withdrawing from service and replacing obsolete modules and elements, putting updated modules and elements into operation, and documenting actions taken.

i) Disaster recovery is carried out on the basis of the regulated recovery of UIS performance, data recovery in case of malfunctions and hardware failures, recovery of software media, analysis of malfunctions and causes of the accidents. During restoration, the work and operations performed are documented, the causes of the accidents and the functioning of the UIS's components and elements during an accident are analyzed, recommendations are developed to ensure the reliability of the UIS and the necessary changes are made to the restoration procedures.

Information protection from unauthorized access at the level of application subsystems is implemented by the application software subsystems.

Design and engineering solutions for the construction of UIS are implemented on the basis of the requirements of the current legislation on copyright and related rights for patent purity, which govern the creation of automated systems. Being parts of the UIS software and hardware should be patented. In this regard, the purchase of software and hardware products, rental of means and communication lines are carried out only by those organizations that have rights to such activities. Engineering tools and means of communication are certified in the relevant state structures in order to obtain permission to operate in data transmission systems.

When developing an UIS, it is envisaged to use unified forms of input documents, international, state and industry classifiers, unified protocols for the exchange of information between all levels of the UIS. Also, the reporting documents generated by the UIS's components have a unified content in terms of the formats of the data presented and a unified presentation for each type of report.

System software is unified by version and composition within the implementation object and automated working station.

Automation of information flows in accordance with the list of information flows from the subsystems is based on the developed model of work processes in accordance with the functional applied architecture of the UIS. In this case, the loading of data received from outside, the integrity control of the electronic document during processing and transmission is implemented in accordance with a custom state model and the authority to process or confirm it. Monitoring the integrity of the data during the passage (processing and transmission) is carried out in accordance with the regulations for data transfer.

When saving data, daily data backup is carried out with the backup stored on magnetic or optical media. The recovery procedure is standard for the used DBMS and OS and provides recovery from the last copy and restoration of changes of the current day from the transaction log.

The software of the UIS's components is implemented in high-level programming languages, which ensures the solution of all tasks for the implementation of the functions of the UIS. It is allowed to use high-level languages that meet the requirements of implementing the tasks of the subject area with user interaction with the UIS's components at the level of the graphical interface. As part of the UIS's components, means are needed to describe the subject area and the automation object, as well as document the results. The software used is independent of the types of client workstations and server equipment, if this is not provided for by the developed documentation of preliminary UIS projects.

The organization of the functioning of the system and the interaction between the personnel of the subsystems and the personnel of the automation object are determined by the following factors:

- Operating procedures for application and operation of the UIS's components;
- Actions of officials to ensure the application of UIS's components;
- Actions of maintenance personnel to maintain the health of UIS's components;
- Organization and procedure for repair and restoration of UIS's components;
- Concepts of sources and consumers of information of UIS's components;
- Composition of users who are consumers of information;
- List and presentation of data for exchange in the UIS.

Discussion

The system is built in such a way that the erroneous actions of personnel do not lead to fatal consequences, e.g. destruction and the impossibility of its restoration. For this purpose, the system is

divided into subsystems, and thus a failure in one subsystem does not affect the performance of other subsystems and the system as a whole.

For putting into service the UIS, it is necessary to comply with the established requirements and carry out the planned work on the preparation of information for putting, for which is necessary the following:

- bringing data to a form suitable for processing by UIS's subsystems;
- bringing the structure of information processing business processes to the form corresponding to the developed requirements;
- creation of conditions for the operation of subsystems, under which the compliance of the subsystems with the requirements is guaranteed.

In order to optimize resources during the operation of UIS, it is necessary to create and further improve the structure of the department of information technology with the creation of additional work places for specialists in support of UIS.

Thus, if you have a unified information system, you can take the following steps, such as integration with Supply Chain Management system (SCM) and Customer Relationship Management system (CRM).

Conclusion

At this stage of research, it was planned to combine 12 application subsystems in the enterprise's UIS taking into account infrastructural subsystems, but as part of the outline design, the need to include 3 more application subsystems was revealed: the subsystem for requirements management, the subsystem design and integration of the product systems, taking into account their physical features, mutual influence, external conditions and the subsystem of planning, management and monitoring of production and logistics.

Based on a sufficiently large number of UIS's subsystems and, accordingly, a large number of information flows arising from data exchange, it was concluded that in order to ensure interaction, it is necessary to unify data exchange mechanisms.

Thus, in the continuation of research, it is additionally necessary to consider the issue of developing a subsystem of integration interaction. It is clear that for many product data management systems, for example Teamcenter, there are so-called standard integration modules with other systems, but in the current project it is necessary to integrate data exchange into the product development process at different stages of the life cycle, to define a unified data exchange format, transfer regulations and etc.

Issues of a unified data exchange of the designed subsystem of the integration solution will be highlighted in further research.

Abstract

This study uniquely highlights an underlying factor (climate change) which has not been acknowledged in Nigeria's farmers-herders clashes which has claimed many lives. Autoregressive Distributed Lag (ARDL) is applied on data of seventeen agricultural crops grown in Nigeria for 36 years. Climate change variables include: CO2 emissions, temperature and mean annual, while livestock is represented by the production index. The paper investigated the nexus of climate change with crop production and livestock production. The results indicate a long run relationship between crop production and climate change but there is no long run relationship between livestock production and climate change. To overcome the effect of rainfall uncertainty, it is recommended that agricultural firms partner with energy companies (and/or government) to invest in combined hydro power and irrigation project – especially, in drought-prone areas. The government should increase its expenditure on agriculture (both capital and recurrent) to especially support farmers and agro-allied companies who have been affected by the COVID-19 shutdown. This could increase the level of mechanized farming with modern equipment, farming implements and enhanced seedlings which are resilient to climate change to boost crop and livestock yield. National orientation programmes aimed at enlightening Farmers and Herders about emerging changes in climate extremes.

Keywords: Agriculture, CO_2 Emissions, Climate Change, Sustainable Development Goals.

Introduction

Climate change and failure in the mitigation/adaption measures are the leading threats to the global economy, after COVID-19 (World Economic Forum, 2020). Available data shows that the last decade has been the warmest ever recorded with 2016 being the warmest year during the period (National Aeronautics and Space Administration, 2020). Furthermore, the data indicates that since the late 19th century, the average temperature of the earth's surface increased by over 1.62 degrees Fahrenheit (0.9 degrees Celsius). Consequently, increasing concentration of greenhouse gases in the atmosphere is changing precipitation patterns, raising temperature, spurring frequent extreme weather events, and shifting growing seasons (Egbetokun, Osabuohien, Akinbobola, Onanuga, Gershon & Okafor, 2020).

Meanwhile, Nigeria's agriculture and agro-allied industries could potentially drive the economy's growth and diversification from crude oil (Gershon, Ezenwa & Osabohien, 2019) However, it is largely climate fed - depends mainly on rainfall and temperature. Moreover, infrequent fluctuations in rainfall and temperature patterns have distorted the standard April to October rainfall period and October – March harmattan weather or dry season. On the one hand, untimely rainfall and climatic extremes could threaten potential agricultural investment (Gershon & Patricia, 2019). Excessive rainfall, on the other hand, can

prompt the development of many pest and diseases which affect crop yields and animal breeding. Increasing temperature also provides a conducive atmosphere for the breeding of pests which damage crops.

More so, the outbreak and spread of Corona Virus disease, popularly known as COVID-19, has proven that Nigeria cannot rely on crude oil as its main source of revenue. Global oil prices which recently plunged to a 17-year low creating a gloomy macroeconomic outlook for most oil-exporting countries – including Nigeria. Reviving the dwindling economy requires deliberate and strategic action to fully reap the benefits of agriculture and minimize its vulnerability to climate change and/or COVID-19.
In 2019, the sector accounted for 25.16% of real GDP growth. Crop production and livestock farming remain the major drivers of the sector as they accounted for 85% and 8% respectively of agricultural GDP in 2019. (National Bureau of Statistics, 2019).

Against the above background, this paper sought to: (a) ascertain the types of the relationship that exists at the nexus of climate change, crop and animal production in Nigeria; (b) determine the difference between climate change's effects on crop yields and livestock production.

The Autoregressive Distributed lag (ARDL) estimation technique is applied with data from 1981-2016 (36 years) to analyze the variables of interest. This seeks to highlight possible actions to minimize the vulnerability of Nigeria's agricultural sector to climate change towards achieving SDGs 2 and 13 which remain critical for economic progress. Farmers and agro-allied businesses could be incentivized to benefit from the potential positive effects of climatic factors and guard against negative effects.

To highlight the relevance of this work, a review of relevant literature is presented hereafter. Subsequent three sections contain respectively, methods; result presentation with discussions; as well as, the conclusion with recommendations.

Literature Review

Adedeji, Tiku, Waziri-Ugwu and Sanusi (2017) employed regression analysis to show that rainfall has a positive and significant effect on rice yield while temperature was found to affect rice yield negatively. However, greenhouse gas emissions which are the primary causes of climate change apart from the natural variations in temperature and rainfall were not included in the model. Ayinde, Muchie and Olatunji (2011) demonstrated that rainfall and temperature have positive and negative effects on agricultural productivity respectively using descriptive statistics and co-integration technique. It was also observed that the previous year's rainfall has a negative, significant effect on current year agricultural productivity.

Agba, Adewara, Adama, Adzer, & Atoyebi (2017) using time series data showed that rainfall had a positive, significant on crop output in the short and long run while temperature and carbon dioxide emissions had a negative, significant effect on crop production only in the long run. Aondoakaa (2012) demonstrated that a weak, positive significant relationship exists among temperature, rainfall and crop yield during a 10year period in Abuja. Using correlation and regression analysis. A longer and wider dataset should have been collected to account for annual changes in temperature and rainfall. Other factors that affect crop yield such as soil fertility, land, irrigation should also be included in the model.

Exenberger, Wolters and Pondorfer (2014) also showed that middle and low-income countries are affected by increased temperature, changes in precipitation, frequency of droughts and these adverse effects are more pronounced in Sub-Sahara Africa. Conversely, climate change rarely affects agricultural production in high-income countries. The results also revealed that technological heterogeneity is a reason for cross-country differences regarding how climate change affects agricultural production.

Ekpenyong and Ogubagu (2015) concluded that in the long run, agricultural productivity is affected by increased carbon emissions. The Autoregressive Distributed Lag was employed for analysis using 1984-2014 as the time period.

Ejemeyovwi, Obindah and Doyah (2018) applied Fully Modified OLS and found out that a positive, significant long-run relationship exists between crop production and CO2 emission. This implies that increased carbon dioxide emissions will increase crop production over time. The result obtained here differs from that of other studies as CO2 emissions had a positive, long-run effect on crop production in spite of its usual notion of pure negativity. This is also in contrast to the existing hypothesis that rising CO2 levels in a tropical country (like Nigeria) negatively impact crop production. Reasons for obtaining this result could be due to types and seasonal properties of crops used in determining the crop production index which was used as the dependent variable.

Climate change factors examined in the reviewed studies include rainfall, temperature and carbon dioxide emissions. Measures of agricultural production popularly examined include crop production and agricultural productivity. The effect of climate change on livestock production has received limited attention in Nigeria - probably due to its complex nature and peculiarity of nomadic farming in the country.

Methodology

Data Sources

The data used in this study were sourced from World Bank Development Indicators; Food and Agricultural Organization; CBN Statistical Bulletin and World Bank Climate Change Portal.

Definition of Variables

Mean Annual Rainfall

This is defined as an average of the total amount of rainfall recorded during a year in Nigeria. Rainfall is included in the model to capture the natural aspect of climate change; climate change induced by fluctuations of weather variables. Adequate rainfall is also a necessary requirement for growth and chemical processes that take place within the crops. It is measured in millimetres (mm). Average rainfall data in the study is for a period of 36 years.

Mean Annual Temperature

The mean annual temperature refers to the average of the total temperature recorded during a year. It is included in the model to capture the natural cause of climate change that is fluctuation in annual temperature. It is measured in degree Celsius (°C).

Carbon Dioxide Emissions

This refers to the amount of CO2 (a greenhouse gas) released into the atmosphere over a specified area and a particular time. For this study. it captures the amount of CO2 released annually in Nigeria. CO_2 emissions in this paper is measured in kilotons (kt)

Arable land

Arable land refers to land that is fertile enough for ploughing and growing crops.. Increased availability of arable land enables farmers to grow more crops which will result in higher crop yield, hence its inclusion in the model. Data on arable in this research arable is measured in square kilometers

Manure Application

Manure is organic matter derived from animal faeces which can be used to improve soil fertility in agriculture. It is a necessary fertilizer that stimulates crop growth. The amount of manure applied to the soil is measured in kilograms (kg) in this paper.

Crop yield

Also known as "agricultural output", crop yield refers to the measure of grains generated from a unit of land. It is measure in kilograms/hectare in this study. Crop yield is the dependent variable, it depends on the aforementioned variables. It is measure in kilograms/hectare in this study.

Agricultural Government Expenditure

This refers the amount allocated and spent (both current and recurrent) on agriculture by the government during a year. It is recorded is in Naira billion. Adequate agriculture expenditure is necessary to purchase farm implements and ultimately increase crop yield.

For the livestock production model, the variable below is inlcuded;

Livestock Production Index

Livestock production index is number that shows the relative level of the aggregate volume of products such as eggs, cheese, honey, wool, and hides and skins etc. for each year in compared to production in the base period 1999-2001. It is used as standard to depict the amount of products derived from livestock in Nigeria annually. It is also a dependent variable, impacted by the other variables listed above.
Data on the aforementioned variables spans from 1981-2017, a period of 36 years.

Model Specification

Following the works of Iheoma (2014), and Agba, Adewara, et al (2017), the modified model to examine the effect of climate change on crop production is specified as;

$$Y = f\,(MAR, MAT, CO_2E, AL, CMA, AGE) \qquad (1)$$

Where f= functional relationship
Y= Crop yield (dependent variable)
MAR= Mean annual rainfall
MAT= Mean annual temperature
CO_2E= Carbon dioxide emissions
AGE= Agricultural government expenditure
AL= Arable Land
CMA- Crop manure application
Independent variables; MAR, AGE, AL, CMA are expected to positively influence crop yield while MAT and CO_2E are expected y to have negative effects on crop yield

Following the work of Iheoma (2014), the modified model to examine the effect of climate change on livestock production is given as;

$$LPI = f(MAR, MAT, CO_2E, AGE) \quad (2)$$

Where:

f= functional relationship
LP1 = Livestock production index (dependent variable)
MAR= Mean annual rainfall
MAT= Mean annual temperature
CO_2E= Carbon dioxide emissions
AGE= Agricultural government expenditure
Dependent variables MAR and AGE are expected to positively influence the livestock production while MAT and CO_2E are expected to negatively nfluence livestock production.i
Stating eq 1 in its non-linear form gives;

$$YIELD = MAR^{\beta 1}\ MAT^{B2}\ CO_2E^{\beta 3}\ AL^{\beta 4}\ CMA^{\beta 5}\ AGE^{\beta 6} \quad (3)$$

Stating eq 2 in its non-linear form gives;

$$LPI = MAR^{\gamma 1}\ MAT^{\gamma 2}\ CO_2E^{\gamma 3}\ AGE^{\gamma 4} \quad (4)$$

In order to state the econometric form eq (3) model, it has to be linearized.
The linearized crop production model is given as;

$$YIELD = \beta_0 + \beta_1 MAR + \beta_2\ MAT + \beta_3 CO_2E + \beta_4 AL + \ \beta_5 CMA + \beta_6 AGE + \ \mu \quad (5)$$

Where;

β_0= constant/ intercept parameter
$\beta_1 - \ \beta_6$ = slope coefficients
μ = stochastic error term
Whereas the linearized livestock production model is given as;

$$LPI = \ \gamma_0 + \ \gamma_1 MAR + \gamma_2 MAT + \gamma_3 CO_2E + \ \gamma_4 AGE + \ \mu \quad (6)$$

Where;
γ_0 = constant/ intercept parameter
$\gamma_1 - \gamma_4$ = slope coefficients

Estimation Technique

This research study employs the Auto regressive Distributed lag to determine the type of the relationship exists between climate change and agricultural production in Nigeria. The econometric techniques to be performed are briefly discussed below

Augmented Dickey Fuller (ADF) Unit Root Test

Economic data collected overtime tend to be non-stationary and if used for analysis may yield spurious regression results. Hence there is need to test data for stationarity prior to model estimation. The Augmented Dickey Fuller (ADF) unit root test is used to detect stationarity or the presence of a unit root in a time series data at a level of significance (1%. 5% or 10%) between variables

Autoregressive Distributed Lag (ARDL) Model Estimation

This is one of various methods to estimate a model taking into account information regarding the long run and short run relationship between the variables in the model. In an ARDL model, the present value of the dependent variable is expressed as a function of current and lagged values of the independent variable(s)

as well as lagged values of the independent variable. The optimal lag length of variables in the may be determined by a number selection criteria. The main steps involved in co-integration technique are ARDL Bound's Test, ARDL Co-integration Test and Vector Error Correction

Results and Discussion

Descriptive Statistics

From Table 1, the mean is the value average of the series and summarizes the whole time series data over a single period with a single variable. It is a measure of central tendency while the standard deviation is a measure of dispersion. The standard deviation measures how much the series deviate from the mean. There is the likelihood of a large coefficient if the mean is larger than the standard deviation. On the other hand, there is the likelihood of a large coefficient of variation if the mean is smaller than the standard deviation.

Table 1: Descriptive Statistics of Variables

Descriptive Statistics	CY (In Millions	LPI	COE (In Kilotonnes)	CMA (In Thousands)	AL (In Millions)	AGEXP (In Billions)	MAR (in millimetres)	MAT In (Degrees centigrade)

Source: Researchers' Compilation 2020

The median is the middle of the series and is often seen as a social measure as its value is better reporting income than the mean. The mean of crop yield provides that average crop yield of Nigeria's 17 majorly produced crops is 91.42 million which appears quite low when compared to the maximum value of 159.05 million, although crop yield has been substantial on average. Increased crop yields will certainly aid Nigeria to boost her agriculture production in light of her significant agriculture resources. The mean of AGEXP is relatively low when compared to its maximum value suggesting that agriculture government expenditure has been low on average over the period of 1981 to 2017. All other variables, LPI, COE, CMA, AL, MAR and MAT have all been high on average as their mean values are quite high relative to their maximum values.

Further, from the table, we see that the mean is greater than the standard deviation for all variables except AL, indicating a possibility of small coefficient of variation. However, the standard deviation of AL is greater than the mean indicating the possibility of a large coefficient of variation. Skewness is the extent to which a distribution differs from a normal distribution. A long right tailed distribution indicates positive skewness while a long left tailed distribution indicates negative skewness. From the table, we observe that LPI, CMA, AGEXP have a long right tail while MAR, MAT, CO_2E and CY have a left tail. The skewness of a normal distribution is zero.

Kurtosis measures how flat or peaked a distribution is. If the kurtosis of a distribution is greater than 3, it is peaked; if it is less than 3, the distribution is flat. From the table. it is observed that AL is the only variable with a peaked distribution while the others have a relatively flat distribution.

Econometric Results

Unit Root Test Results

The Augmented Dickey-Fuller test was used to check for the stationarity of the variables in this research. If ADF t-stat is greater than the absolute critical value at 5%, the variable is stationary but if it is less than the critical value, it is not stationary. The results of the test are presented in Table 2.

Table 2: Results of Augmented Dickey Fuller Unit Root Test of Variables

Variables	Series at Levels			Series at First Difference			Order of Integration
	ADF Statistic	Critical Value at 5%	Remarks	ADF Statistic	Critical Value at 5%	Remarks	
CY	-0.808	-2.951	Not Stationary	-3.130	-2.951	Stationary	I(I)
LPI	-1.639	-3.540	Not Stationary	-5.989	-3.544	Stationary	I(I)
AGEXP	-2.999	-3.544	Not Stationary	-7.111	-3.548	Stationary	I(I)
AL	-1.920	-3.540	Not Stationary	-4.575	-3.548	Stationary	I(I)
MAT	-5.283	-3.540	Stationary	8.550	-3.548	Stationary	I(0)
MAR	-3.889	-3.540	Stationary	-6.946	-3.552	Stationary	I(0)
CMA	-2.938	-3.540	Not Stationary	-7.685	-3.544	Stationary	I(1)
CO_2E	-1.838	-3.540	Not Stationary	-5.908	-3.204	Stationary	I(1)

Source: Researchers' Compilation 2020

The results show that the variables are a combination of I(0) and I(1) variables. MAT and MAR were stationary at level while CY, LPI, AL, CMA, CO_2 and AGEXP were stationary after first differencing. This necessitated the use of bounds test for cointegration.

Bound's Test Crop production

From table 4 the F-statistic (10.59235) is greater than the upper bound of 3.61 at the 5% level of significance. As such one concludes that a long run relationship exists between CY and its respective independent variables, MAT, MAR, CO2E, AL, CMA and AGEXP.

Table 3: Test for Counteraction Result for Relationship between Crop Production and Climate Change

ARDL Bounds Test			
Null Hypothesis: No long-run relationships exist			
Test Statistic	Value		
F-statistic	10.59235		
Significance	Lower Bound I(0)	Upper Bound I(1)	
10%	2.12	3.23	
5%	2.45	3.61	
2.5%	2.75	3.99	
1%	3.15	4.43

Livestock Production

The ARDL bounds test was also used to check for cointegration between climate change and livestock production. From the results presented in Table 5, the F-statistic (1.055450) is lower than the upper bounds of 4.01 at 5%. It is, therefore, conclusive that there is no long run relationship between the dependent variable LPI and its respective explanatory variables, MAT, MAR, CO_2E, and AGEXP.

Table 4: Test for Relationship between Livestock Production and Climate Change

ARDL Bounds Test			
Null Hypothesis: No long-run relationships exist

Interpretation of Long Run Coefficients for Crop Production

From the table, the coefficient of mean annual rainfall (MAR) is 11. 476. A unit increase in mean annual rainfall will lead to an 11.476 increase in crop yield. It is statistically significant. The coefficient of mean annual temperature (MAT) is -30.443. A unit increase in mean annual temperature will result in a -30.443 decrease in crop yield. It is however statistically insignificant. The coefficient of carbon dioxide emissions (COE) is 2.427. A unit increase in carbon dioxide emissions will cause a 2.427 increase in aggregate crop yield. It is statistically significant.

The coefficient of crop manure application (CMA) is 14.580. A unit increase in crop manure application will lead to a 14.580 increase in crop yield. It is also statistically significant. The coefficient of arable land (AL) is 1.433. This means that a unit increase in arable land will result in a 1.433 increase in crop yield. It is statistically significant. The coefficient of agricultural expenditure (AGEXP) is -2.370. A unit increase in agricultural expenditure cause a -2.370 decrease in crop yield. It is also statistically significant.

The coefficient of the constant is -12.254 which connotes that the value of crop yield will decrease by -12,254 when the independent variables are kept constant. The lag of the error correction term (Cointeq(-1)) is -0.969 and is statistically significant which indicates that 96.90% of errors in the previous period are corrected in the current period. This is a high speed of adjustment of the estimated ARDL Error correction model.

ARDL Results for Livestock Production

Interpretation
The R squared of the model is 0.7938 which connotes that 79.3% of the variation in the dependent variable, Livestock production index is explained by the explanatory variables. The probability of F- statistic which measures the joint significance of the variables is 0.000000 indicates that the estimated ARDL model is correctly specified. The Durbin-Watson statistic of 2.017181 indicates that there is no serial correlation in the model.

The coefficient of LPI(-1) IS 0.7653 implying that a unit change in one period lagged livestock production index will result in a 0.7653 unit change in current period livestock production index and it is statistically significant. The coefficient of MAR is -0.1865 suggesting that a unit change in current period mean annual rainfall will lead to a 0.4162 change in the livestock production index. It is also statistically significant.

The coefficient of MAT is 1.6392 implying that a unit change in the current period mean annual temperature will bring about a 1.6392 unit change in the livestock production index and it is statistically significant. The coefficient of COE is 0.000185 meaning that a unit increase in current period carbon dioxide emissions will result in a 0.000185 unit increase in the livestock production index. It is statistically significant. The coefficient of AGEXP is 0.0794 which shows that a unit change in current period agricultural expenditure will bring about a 0.0794 unit change in livestock production index. It is statistically significant. The coefficient of the constant term C is 11.0784 meaning that the value of livestock production will increase by 11.0784 keeping all explanatory variables constant.

Discussion of Results

The bounds testing confirms the study's hypotheses of a long run relationship between climate change and crop yield but, no long run relationship between climate change and livestock production. Furthermore, ARDL cointegration test results showed that climate change affects both agricultural subsectors differently and through different channels. Specifically, rainfall has a positive and significant effect on both crop yield and livestock production, while temperature has a negative effect on both subsectors - though insignificant for crop production. Also, CO_2 emissions affects crop production positively while it affects livestock production negatively.

The ARDL results for crop production showed that a long run relationship exists between climate change and crop production. Mean annual rainfall and CO_2 emissions significantly influence crop yield while mean annual temperature had an insignificant effect on crop yield. The non-climatic variables (agricultural expenditure, crop manure application and arable land) also affect the yield of 17 major crops produced in Nigeria significantly in the long run. Furthermore, the results provide evidence of the economic significance of the coefficients of each variable.

Meanwhile, the mean annual rainfall had a positive effect on aggregate crop yield in Nigeria in line with the *apriori* expectation and existing literature (Ayinde, 2011; Adedeji et al, 2017; Aondoakaa, 2012; Agba et al, 2017). As such, increased rainfall due to climate change will lead to increased crop yield particularly in dryland areas with poor irrigation systems. In contrast, Nwachukwu, Ezeh & Emerole (2012), Jonsonn (2011), and Enete (2014) observed a negative relationship between rainfall and crop yield. However, mean annual temperature had a negative effect on crop yield. This implies that increased temperature caused by increased greenhouse gas emissions will reduce aggregate crop yield in Nigeria. Ayinde et al (2011), Adedeji et al (2017), Jonsonn (2011) and Ajetemobi et al (2015) arrived at similar results. On the other hand, Aondoakaa (2012), Nwachukwu et al (2012) concluded a positive relationship exists between temperature and crop yield.

CO_2 emissions has a positive effect on crop yield. This goes against the *apriori* expectation and results from existing literature. Possibly, CO_2 emissions do not affect crop yield directly, but causes higher temperature and reduced rate of photosynthesis which negatively affects aggregate crop yield in Nigeria. Ejemeyovwi et al (2018) obtained similar result while Agba et al (2017) concluded that CO_2 emissions has a negative effect on crop production.

Arable land showed a positive effect on crop yield. This is in line with the *apriori* expectation and existing literature as increased availability of arable land enables farmers to grow more crops which in turn increases crop yield. Crop manure application showed a positive effect on crop yield too in line with the *apriori* expectation and as manure is used to fertilize towards increased crop yield. Contrary to *apriori* expectation, government's agricultural expenditure showed a negative effect on crop yield. Previous research outcomes indicate increased government expenditure on the agricultural sector is meant to boost yield of crops by making farm implements and funds available for farmers. This could be indicating that increases in government expenditures require better channels or more effective distribution mechanism to achieve the expected result. Perhaps, government expenditure into the agricultural sectors is leaking away or being diverted inappropriately.

Livestock Production

The ARDL results showed that no long-run relationship exists between climate change and livestock production. The findings for each variable are discussed herewith. The four-period lagged mean annual rainfall has a positive and significant effect on the livestock production index. This is in accordance with the *apriori* expectation and existing literature as rainfall provides water for livestock and growing of forage crops to feed livestock. The two-period lagged temperature has a negative and significant effect on the livestock production index, confirming the *apriori* expectation from existing theory. Increased temperature causes heat stress in livestock, dries up water bodies that provide water for livestock and increases the spread of pests and diseases which negatively affect livestock production.

The current period lagged CO_2 emissions has a negative effect on livestock production index, as expected but the estimate is not statistically significant. Government's expenditure on agriculture in the current period has a positive and significant effect on livestock production in Nigeria. This outcome appears to supports existing government-backed herders-support programmes and justifies proposed rangeland management initiatives to address the herders-farmer disputes in Nigeria (Chiluwa & Chiluwa 2020; Chukwuma, 2020; Mbih, 2020).

Conclusion and Recommendations

Conclusion

Climate change is a major reality for all countries of the world including Nigeria. It has a significant influence on various sectors of Nigeria's economy, one of which is agriculture as examined here with

extended linkage to farmers-herders dispute. This is because, as has been shown here, climate change impacts on agricultural outputs (of farmers and herders) - crop yields and livestock production. Both outputs are central to the Nigerian economy given their contribution to food security in Nigeria and the government's initiatives to diversify away from the petroleum sector (Fubara, Iledare, Gershon & Ejemeyovwi. 2019).

So far, this paper has examined the effect of climate change on agricultural production in terms of crop yield and livestock production in Nigeria over the period 1981 to 2016. The findings of the study revealed that a long-run relationship exists between climate change measured by (rainfall, mean annual temperature and CO_2 emissions) and crop yield. However, no long-run relationship exists between climate change measured by mean annual rainfall and temperature, CO_2 emissions) and livestock production. Meanwhile, results here suggest that the effect of climate change on agriculture depends on the measure of agriculture production and climate change employed in studies.

This study has contributed to literature in two ways: firstly, it employs aggregate output of 17 crops main produced in Nigeria - cassava, cocoa, groundnuts, kolanut, maize, melon, millet, oil palm, plantain, rice, rubber, sorghum, soybeans, yam, cashew, sesame and potatoes. As such, it offers a more representative sample of aggregate crop production in Nigeria. Secondly, the study uses the livestock productivity index to ascertain the effect of climate change on Nigeria's agricultural sector. Thereby, it has uniquely highlighted an underlying factor (climate change), previously acknowledged, in Nigeria's farmers-herders clashes which has claimed many lives.

This study was limited by the lack of data on the emissions of other greenhouse gases and livestock production values in Nigeria (offering better representation than the index). Future studies on climate change and agriculture could investigate how other greenhouse gases (apart from carbon dioxide) affect crop yield and livestock production in Nigeria and across West Africa. Additionally, further endeavours could analyze the comparative effect of climate change on the yields of individual crops produced in Nigeria's six geopolitical regions. This study could be extended to cover selected states in Nigeria where climate change impacts on rainfall and temperature are perceived as more severe for agriculture.

Recommendations

Based on the empirical results obtained in this study, businesses, policymakers and government agencies should consider the following strategies:

The government should implement strategies to boost environmental sustainability, initiate mitigation initiatives to reduce the carbon footprint on agriculture and also enforce policies to curb greenhouse gas emissions. The trend analysis of carbon dioxide emissions shows that these emissions have increased considerably since 2000. Strategies that can be employed include: charging taxes on carbon emissions, promoting greater use of renewable energy resources, promoting sustainable agricultural practices through reduced use of inorganic fertilizers, as well as, encouraging afforestation and the use of organic manure
Farmers should devise adaptation initiatives aimed at reducing the vulnerability of crops to the effects of climate change on agriculture in Nigeria. Such initiatives include farmers growing crops and raring animals that are resistant to adverse weather conditions; government incentive support for research and technological innovations to boost crop yield (such as biotechnology). To overcome the effect of rainfall uncertainty, it is recommended that agricultural firms partner with energy companies (and/or government) to invest in combined hydropower and irrigation project – especially, in drought-prone areas.

The government should increase its expenditure on agriculture (both capital and recurrent) to especially support farmers and agro-allied companies who have been affected by the COVID-19 shutdown. This could increase the level of mechanized farming with modern equipment, farming implements and enhanced seedlings which are resilient to climate change to boost crop and livestock yield.

National orientation programmes aimed at enlightening farmers and herders about emerging changes in climate extremes should be implemented by the government. This is to ensure farmers make informed decisions regarding crop production and livestock rearing paying attention to changes in climate.

Abstract

Complexity of business processes within enterprises make the implementations of ERP systems more difficult and complicated projects. Traditional approach to project management becomes insufficient thus new ways and concepts are being considered. Companies developing and implementing ERP systems start researching of agile methodologies. Beside of their obvious advantages like faster system productive operation those frameworks have another set of challenges, conditions and restrictions comparing to traditional ones. Leading ERP vendors like SAP, Oracle or Microsoft sell their products with own agile methodologies – ready-made receipts for successful implementations. Since ERP projects are amongst biggest organizational efforts for most companies, they must verify whether such approach is meeting their expectations. The up to date effort made by project managers must be shifted and they need to focus on another factors like closer look to fit/gap analysis and resulting changes to standard or more on-going coordination of different modules during realization phase. The article discusses some advantages and drawbacks of contemporary project management methodologies used in the area of ERP implementations.

Keywords: PMBOK, Agile project management, ERP systems, SAP Activate

Introduction

World becomes smaller when IT facilitates collaboration between companies residing in different time zones, countries and even continents. The growth of information amount, its complexity and interdependencies caused the development of tools that are able to manage all aspects of data. In business environment, the central part of IT ecosystem is usually taken by Enterprise Resource Planning system – ERP. Gartner established the term ERP in 1990 to describe the evolution of materials requirements planning (MRP) and manufacturing resource planning (MRP II) as they were extended to include other processes of the whole enterprise. ERP systems evolved rapidly during the 1990s as they were seen as a cost-effective way to replace multiple, old systems with a standardized package that could also address issues like introduction of EURO or "millennium bug" (Perkins, 2019).

ERP systems integrate various processes within organization allowing the flow of information/work between departments and thus increasing of organization's overall performance. The vendors of major ERP systems (SAP, Oracle or Microsoft) promise to cover most business areas ranging from financials through marketing and sales, logistics, manufacturing to human resources. As the systems are composed of standardized modules, only a certain level of configuration is possible - most companies implementing ERP will need to adapt or even completely rework their business processes to fit the requirements of the system (Davenport, 1998). This makes the decision of implementing an ERP system to higher level – not only mere technical installation of a software but usually a deep transformation of business processes impacting whole company. Panorama Consulting Solutions, which regularly surveys businesses on the outcomes of their ERP projects, found in 2015 that just 58 percent of organizations rated their latest project a success, while by 2019 that figure had risen to 88

percent (Fruhlinger et al., 2020). Although the trend is positive, the consequences of a failed software rollout can be serious, including shareholder lawsuits and financial problems.

On the other hand the benefits of implementation of ERP are significant. They vary from operational performance improvements to the perception of the company on the market. As observed by Tan et al. (2014), publicly traded firms in the USA not stock value increase when they announce implementation of ERP systems, showing that investors view this decision positively and indicating the potential for future growth. Introduction of ERP system is a major project requiring a significant level of resources, commitment and changes throughout the organization. It is often the biggest project that an organization has ever launched (Moon, 2007). The outcome of this fact is the abundance of methodologies for project management that mitigate the risk of failure for the enterprise.

Since Agile Manifesto was published (Alliance, 2001), agile methodologies have been gaining more and more attention in the IT world. The new way of project management focused mainly on delivering working software, allowing incremental delivery of new functionalities meeting the expectation of project stakeholders thanks to their constant feedback, was promptly adapted by software companies. Although at the beginning agile management was neglected in ERP projects, at some point the scale of "products" grow sufficiently big to draw attention of decision makers. Large scale ERP projects were traditionally implemented with waterfall methodologies due to their complex nature involving software and business operational changes. This approach had drawbacks - although the full process was predicted and planned, the final outcome - the product, might not meet customer's expectations. First attempts were made to adapt some agile features to well-established procedures – as the result major ERP publishers like SAP, Oracle or Microsoft have prepared their own methodologies – respectively: SAP Activate, Oracle Unified Method and Microsoft Sure Step.

This paper describes various project lifecycles according to PMBOK and shows some of their usage aspects in ERP implementations. In particular predictive (waterfall) and iterative (agile) approaches are overviewed. SAP Activate methodology is presented as an example of agile approach to ERP project management.

Project lifecycles

PMBOK stands for Project Management Body of Knowledge and it is the entire collection of processes, best practices and guidelines that are accepted as standards within the project management industry. It is maintained and developed by Project Management Institute (PMI), a global not-for-profit association of PM professionals. The first edition of the PMBOK Guide was published in 1996 and until now six versions have been published – last in 2017. As other project management standards, PMBOK covers all processes that form a project – it covers all processes directly associated with project management as well as topics concerning general project environment like budgeting and forecasting, organizational behavior or management science. In the intention of authors the PMBOK standard describes knowledge and practices that are "applicable to most projects most of the time and there is a consensus about their value and usefulness" as well as "the application of the knowledge, skills, tools, and techniques can enhance the chance of success over many projects" (PMI, 2017).

"A project life cycle is the phases that a project passes through from its start to its completion" as PMBOK® Guide 6th edition explains (PMI, 2017). By its nature, each project has a start and an end and several stages that it needs to pass as it progresses across these two points. The number of phases differs among industries and even every project – the structure of stages can vary as well. PMBOK defines four general phases that can be applied to any project: Starting the project (Initiation), Organizing and Preparing (Planning), Carrying out the work (Execution) and Ending the project (Closure). During all phases, group of processes called Monitoring and Control is executed simultaneously to allow constant measurement of work progress, various performance indicators and allow to react accordingly.

The introduction of ERP to organization's business ecosystem have various aspects – first of all a particular system must be selected from many available on the market. Requirement analysis must be

performed to discover business critical needs and select proper ERP packages (modules) the would address them. Parameters that will affect the decision include cost of licenses, terms of contract with potential integrators (the companies that implement the software), availability of maintenance services, time needed and level of changes that organization must undergo to start operating particular ERP. Than the implementation itself - there are many ERP implementation methodologies available on the market, both generic and widely available for practitioners and proprietary, published by the ERP vendors along with their systems. When ERP system is implemented, it needs constant process of improvements ranging from installation of technical updates, fixing of minor problems to implementation of new features that enrich system functionality. There are several examples of approaches available in literature for each of aspects – acquisition process is commonly modelled as six-stage process. Maintenance process is described in detail by ITIL, a set of detailed practices for IT service management that focuses on aligning IT services with the needs of business. The focus in this paper is on general approach of implementation aspect.

PMBOK distinguishes five different life cycles - predictive, iterative, incremental, adaptive and hybrid. Predictive cycle, known as well as waterfall was traditionally a standard for project management. This approach assumes planning of whole project at its beginning. Gathered customer requirements are base for the scope of the project and they serve as the foundation for other phases. Detailed planning allow reduction of estimation errors in areas of quality, time, cost or risks. During execution of the project it is allowed to have more precise planning called "progressive elaboration" or "rolling wave planning" but any changes to scope need close examination as they usually influence the time and budget (called sometimes "golden triangle of project management – time, scope and cost). Because of this, the waterfall model is not flexible when new requirement is presented. Changes in the project are more expensive as it progresses.

Figure 1: Predictive cycle – own elaboration based on PMBOK

Iterative approach assumes that, the final product is known but cost and time of tasks can vary. Large projects are split into smaller parts and then executed in smaller cycles. Gathering of requirements and detailed planning takes place at the beginning of each iteration and at the end it delivers smaller portions of functionalities. At the end customer receives full functionality. In terms of flexibility, this approach is placed by PMBOK between predictive and incremental. During the project, there are several chances to reschedule or reevaluate changes, but the changes themselves are technical rather than corresponding to scope – iterative cycle could handle the changes faster and less expensively.

Figure 2: Iterative cycle – own elaboration based on PMBOK

Adaptive Life Cycle (change-driven or Agile) requires project charter (a document containing project statement of the scope, objectives, etc.) as well but unlike previously presented cycle the project team reviews it regularly and is allowed to modify it. It means that the aspects of initiation phase can be carried during whole project. At the beginning only general idea of the product is available - detailed scope is planned at the beginning of each iteration (called sprint) with close cooperation of customer and vendor. In addition to iterations being sequential or overlapping, they could also run in parallel. As they are usually limited to 2 – 4 weeks the inherited risks of providing erroneous solutions is mitigated. The approach requires two critical success factors to provide successful (ie. within the budget and on time) results – the customer must actively take part in team's work and the team must be able to provide new requirements for each cycle. According to Sharma and Hasteer (2016) the most popular framework available on the market is SCRUM.

Figure 3: Adaptive cycle – own evaluation based on SCRUM methodology (Borowiec, 2019)

Hybrid cycle is literally an approach that take different proportions of features from other cycles – mainly from predictive and adaptive with stress put mostly on scope changes. The parts of the project well defined are realized according to predictive project plan and the unknown parts are progressed with adaptive methods. In such approach the WBS can co-exist with backlog and sprints can be executed in parallel to traditional phases.

Agile implementation of ERP system based on SAP Activate methodology example

SAP SE (later referenced as SAP) is the world's largest provider of enterprise application software - 92% of Forbes Global 2000 companies belong to SAP customers (SAP SE, 2020). It holds the first place as software company in Dow Jones Sustainability Index for 13 years. Although it's traditional ERP software (called "on-premises") was the market share leader, SAP have developed as well a broad portfolio of cloud business solutions becoming top vendor in this area. In its almost 50 year history the company have travelled a long way in approach of providing the software from installation on mainframes to accessing it via web. The concept of supporting the customers and consulting companies in systems development was changing over time as well. The first methodology that SAP prepared for implementation of its ERP was called ASAP – it was providing a toolkit for vendor evaluations as well as benchmark for project cost-effectiveness/performance. ASAP has been evolving from guidance of installing the software into full project management methodology. It was including changes in the SAP ERP itself and developments in surrounding Project Management and IT best practices.

SAP Activate was introduced along with SAP new product - S/4HANA, as a tool to accelerate the process of its adoption. SAP Activate is a framework consisting of three components:

1. best practices - that deliver scenarios for real-life business processes and best practices for migration and integration,
2. configuration tools for cloud and on-premise versions of software,
3. SAP Activate methodology that uses agile techniques to implement the SAP S/4HANA solution in the cloud or on-premise (SAP SE, 2020).

SAP Activate methodology is aligned with the PMBOK Standard – it is the successor of ASAP and SAP Launch (implementation of SAP cloud solutions) methodologies. The vendor states that it is modular and agile methodology – it supports deployment at the beginning and later continuous business development. The methodology also enables co-innovation with customers and is accessible for partners. It builds on the ready-to-run business processes (1) and their documentation from SAP Best Practices – so called Scope Items are basis of solution architecture providing detailed business processes guides as well as built-in test cases. It uses the configuration tools (2) to adjust the baseline solution to customer needs based on the results of the fit/gap analysis, which is conducted in the Explore phase. It also provides project teams with structured approach to implement the solution (3), but also with the solution and product specific content for implementation or transition to SAP S/4HANA - standardized roadmap and project plans are available for adaptation for each company involved.

Figure 4: SAP Activate phases – own elaboration based on SAP SE (2020)

In sections below each phase is described briefly. Although SAP Activate have proven its ability to deliver successful project there are practitioners still emphasize some questions to consider to avoid possible pitfalls (Osterhaus, 2018). The methodology consists of six phases – four core and two additional that reference several PMBOK process groups:

Discovery

Discovery is classified as an additional phase. Although it is not core for the project, it plays very important role, as it allows setting the business contexts and the goals of whole project. It puts much stress on setting the long term strategy for digital transformation of the company combining the S/4HANA technology as well as other available to build competitive advantage (called the Road Map). The broad perspective of the phase includes workshops with users to facilitate value and impact analysis, preparation of implementation scenarios and technical infrastructure review.

In terms of PMBOK this phase includes elements of Initiation and Planning process groups. Although it is difficult to imagine a project without selection of technology and future use planning the phase has no formal quality gates (formal way of specifying and recording the transition between critical stages in the project lifecycle). Since the stakeholders are not fully identified at this point there is a risk of neglecting parts of the scope. Potential problems that companies might have include as well insufficient level of understanding the expectation and assumptions made by both sides when signing the contract (Scheck et al., 2019) and underestimation of IT infrastructure needs especially when running in cloud environment.

Prepare

Prepare is core phase where the initial work for project preparation is done. Based on findings of previous phase, project governance is defined, resources are identified and management plan for running the project is prepared. During this phase the team should be officially formed, roles and responsibilities should be established and staff should be trained on the methodology and tools available/chosen.

From PMBOK perspective this phase contains processes from Initiating, Planning and Executing groups. Special attention must be given in this phase for proper setup of not only project plan but as

well quality assurance processes. Customers should actively identify all interfaces with currently used systems in its IT landscape and understand restrictions that apply in new system. The user trainings for methodology is probably the last moment when organization must realize and adopt agile approach for project management.

Explore

Explore is second core phase. At this point the fit/gap analysis is performed based on a system where SAP Best Practices for respective business area are installed. The team closely examines the preconfigured processes provided by SAP to find how they can be applied to the company, additional configuration requirements are gathered and configuration gaps established. The technical environment is created at this time – sandbox and development systems must be up-and-running and IT infrastructure must be examined to provide the proper sizing of infrastructure. All needed items form the backlog that will be the baseline for implementation in later phases.

The activities in this phase are mostly referencing to PMBOK's Execution process group. Risks in this phase include improper output from fit/gap analysis resulting in wrong understanding of what standard SAP business process offers. Superficial documentation of gaps found during the workshops, in future can seriously affect budget and time needed for implementation of workarounds or process fixes.

Realize

Realize is the core phase for agile approach – it is used for iteratively and incrementally build functionalities of the backlog. Process of customizing, configuration and custom coding build on top of best practices is run recursively by project team during the sprints. The customer/product owners is involved in prioritization of tasks that are delivered and tested according to their needs. The initial data migration is run to check if process works smoothly. Unit and sprint tests of functions are done in this phase as well as integration of all components needed by the organizations is examined.

The activities in this phase are mostly referencing to PMBOK's Execution process group. Although Monitoring and Control processes are used across whole project, the additional stress is pointed here because of several iterations. The activities now depend heavily on products form previous phases but it is also the moment where typical size of ERP implementation projects plays important role. As the quantity of modules (like Finance, Sales or Inventory Management) grow, the number of interdependencies increases as well. Issues with proper planning of functionalities sets can result with delays in certain modules that cannot be implemented before others. For instance Production Planning depends on Inventory Management and this in turn on Finance – appropriate level of coordination between consultants must be maintained to execute the sprints in the way that all parties involved have planned sufficient functionalities to continue the work.

Deploy

Deploy if the final core phase – all processes, data migration, IT infrastructure is checked again to confirm readiness to switch into business operations with the new solution. If the decision is made to start operation on new system, the cut-over activities are performed. When customer starts operating new system after go-live, the team starts hyper-care activities to support the business to adopt the new functionality.
This phase is built as well around Execution processes from PMBOK and contains elements of Closing group. Issues occurring in this phase do not significantly differ from typical "waterfall" implementations and include mainly poor quality data migration, cutover issues and initial system stability problems.

Run

Run is an additional phase that represents the deliverables and tasks to run and operate the SAP solution. This phase allows handling of proper operation of the implemented system. It includes administration of the system, monitoring of process metrics (both – technical and business), providing analytics for review, ALM processes (small enhancements/fixes outside the project release and change management of software) or optimization of services. During this phase the goals of digital transformation of the company (the Road Map) is reviewed – decision makers need to state weather they are still important, adjust the strategy and start planning of new features.

Although it is mentioned as the last phase in the SAP Activate methodology, it is focused on PMBOK's Planning process groups. Operation of the company during this time finally tests the strategy of whole project. BAU (Business as Usual) activities continue and they are mostly associated with tasks out of standard project management scope.

Conclusions

"SAP Activate is a clear process of structured and solution-specific practices, carried out in a standardized environment, that puts business users in the driver's seat" this sentence taken from SAP marketing materials (SAP SE, 2020) shows both – strengths and weaknesses of the methodology. On one hand it provides standardized approach with track of proven successful implementations and as proprietary methodology was designed to be used with SAP systems, so it reduces project management time and effort by providing so called accelerators. It promises to enable business users to do their own configuration thus minimizing the employment of external consultants. On the other hand, organizations that have limited experience with internal project management using agile methodologies can have problems with cooperation with service providers operating the SAP Activate methodology. The involved stakeholders without IT background can oversee some technical problems (for instance interfaces) while SAP itself have troubles with providing consistent view on its own products (especially after acquisitions of external companies SAP offers systems with almost identical purpose like SRM or Ariba), their evolution and support plan (SAP WM module's maintenance was announced to be ended in 2025 with its functionalities taken over by Extended Warehouse management, now it is going to be prolonged with new name (Wehler, 2019) - Stock Room Management) and aggressive SAP sales sometimes not taking into account customer's needs. This mixture is something that organization must understand, accept and try to evaluate risks with mitigation plans – but that is pure essence of project management.

Abstract

The use of digital technology is leading to radical business changes. Value propositions change, traditional business processes are rethought from simple linear chains and value creation flows to more complex two-way network systems and network value space. New types of business models based on digital platforms are being introduced. The article focuses on the digital transformation of a business model based on digital platforms. The results of the analysis of various digital business models of companies in different fields of activity are presented. Information on what types of companies and which business models most clearly demonstrate their high competitive position is summarized. The characteristics of new types of business models of next-generation firms are given.

Keywords: Digitalization, Digital Platforms, Business Model, Value Chain, Network Value Space.

Introduction

In search of competitive advantages and the achievement of sustainable competitiveness, firms traditionally turn to management tools to increase the efficiency of using their own resources, their combination and the synergy effect. However, the variability of the competitive environment and the dynamism of economic processes are so rapid that it requires the search for "new combinations," among which, according to J. Schumpeter, is the production of a new good or the creation of a new quality of a good (Shumpeter 1982). Increasingly, the competitive success of the company is associated with its business model. Initially, the business model was considered as a way of doing business, which provided the company with income and profit.

Currently, many researchers agree that the business model describes the processes of exchanging value, a value between different participants in the business process. This is reflected in the writings of such authors as H. Chesbrough (Chesbrough 2006; 2010), D. Teece (Teece 2010), A. Osterwalder and his co-authors (Osterwalder, Pigneur and Tucci 2005), Y. Baldina, N. Masyuk. (Baldina and Masyuk 2019), P. Petrichev (Petrichev et al 2018), N.K. Temnova (Temnova 2019), S.I. Mezhov, A.V. Boldenkov (Mezhov and Boldenkov 2016), etc. A. Afuah, C. Tucci (Afuah and Tucci 2001) characterize the business model as a system that consists of components, the relationships between them and the dynamic processes within; the focus is on activity; the main focus is value.

A value-based approach to doing business was proposed by M. Porter (Porter 2013), where he argued that competitive advantages cannot be understood when looking at the firm as a whole. The real advantages must be found in the value chain - separate but interconnected economic actions that the company performs in order to deliver a certain value to its consumers. The value chain is characterized as a sequence of transformations of material and intangible resources in order to create value for the consumer. To understand the value chain, M. Porter proposed dividing all the activities of the company into primary (primary) and auxiliary (supporting) and characterize each of them with the processes involved in creating value for the consumer.

The main activity of the company is directly related to the physical creation of the product and its delivery to the consumer. The main activity processes are supply logistics, production processes, distribution logistics, marketing and sales, service, after-sales service, and customer support, etc. The auxiliary activities of the company provide support for the primary activities, and its processes are technology development, human resources management, procurement, maintenance infrastructure, and others

Since each firm has unique “manufacturing combinations” unique to it (Shumpeter 1982), the value chain for each firm is also unique. Its analysis allows you to determine in which processes the value is most successfully created or added; which activities are most important in the chain; who controls the value chain. By exploring the chain processes step by step, you can establish where the company is competitive and where it is vulnerable.

The development of the value approach was the idea that the consistent implementation of all processes that are carried out with the product from the development of its concept to delivery to the consumer forms the stream of value creation. This idea was reflected in the Lean Production business model, which was first implemented at Toyota and presented in the work of D. Roos, J. Womack, and D. Jones (Roos, Womack and Jones 2007). The business model based on Lean Production was a breakthrough in management and quality management without significant additional costs, as well as in ensuring long-term competitiveness.

The evolution of the idea of the possibilities of increasing the benefits received from the value stream has led to the understanding that success and sustainability in modern business are achieved by contracting, which allows combining the interests of counterparties in the formation of the value stream for the end-user. In these conditions, the value chain or stream goes beyond the boundaries of the company and is further formed together with suppliers, transport, and trading enterprises as a stream of creating value for the consumer. Each participant in the flow is not only responsible for their processes but also brings their understanding of what is valuable to the consumer in the perception of the final product and the way it is received. The integrating principle in the processes of creating, transforming, and implementing value for the consumer is the business model. She, as the most flexible management tool, is transformed under the influence of factors of the external environment and the internal environment of the company.

The transformation processes of the business model have become especially active with the advent of digital technologies and digital platforms (Masyuk, Bushueva and Bragina 2018). They provide completely different competitive opportunities for the companies that implement them, and in comparison sharply reduce the effectiveness of business models without digital technologies. This is manifested in the fact that the old business model ceases to be a source of value for the consumer, does not allow stable profit-making in the long term, and deprives the company of the opportunity to maintain a profit flow even in the medium and short term. The use of innovative digital platforms can be attributed to “creative destruction” (Shumpeter 1982), as previous methods and tools give way to new, more advanced ones from the standpoint of competition.

The platforms include virtual trading platforms, a set of users, interaction intermediaries, software, and network systems. The platform is a special type of business model of the company, the company itself, and a trading platform organized by the company, which provides its operation with a system of technologies and equipment. The platform research issues are reflected in the works of A.

Kovalenko (Kovalenko 2016), B.B. Kovalenko and K.Yu Rodimenkova (Kovalenko and Rodimenkova 2018), I.Z. Gelishanov and his co-authors (Gelishanov, Yudina and Babkin 2018), K. Linz, and his co-authors (Linz, Stevensand and Zimmerman 2019), N. Masyuk et al(Masyuk, Bushueva, Vasyukova and Kiryanov, 2018), etc.

Research Methodology

There are various methods and approaches to the study of the causes and mechanisms of the transformation of a business model. The transformation process occurs according to the laws of dialectics because the dialectic approach is used to understand the patterns in its development. As methods for studying the causes of the transformation of business models and understanding the economic interests of participants in the transformation process, a synergistic combination of value and system approaches has been adopted.

The study focuses on the digital transformation of a business model based on digital platforms. A comparative analysis of various business models of companies in different fields of activity expands these ideas.

The modern transformation of business models occurs as a process of digital transformation. The meaning of digital transformation is not in technologies as such, but in the changes brought about by the widespread use of digital technologies. Therefore, digital transformation is not so much a characteristic of the level of application of new technologies as a characteristic of creating and maintaining an effective business model. Digital technologies force management to radically change business models in all sectors. So, in the field of finance and credit, the places of banks, insurance companies, and investment companies are gradually taken by manufacturers of mobile devices and applications, such as Apple, PayPal, Google, Yandex, as active creators of new client services. Representatives of a major retailer, such as IKEA, are claiming a share of the financial operations of their customers, intruding on the insurance industry to sell insurance policies along with furniture and other non-food and food products. Digital technology is being actively introduced into other industries, undermining, and even destroying them. So Uber undermines a sustainable taxi business, Airbnb - the hotel business, Amazon, Alibaba, Ozon - the retail business.

The study of the processes of the active penetration of digital transformation into the economy allows us to generalize and systematize information about which types of companies and which business models most clearly demonstrate their high competitive positions.

1. Companies with developed digital capabilities and a business model based on mobile technologies (Amazon, Google, Yandex). Companies of this type actively enter existing markets and create a new attractive value proposition for consumers, for example, mobile devices and applications. According to the forecasts of analysts of the World Telecommunication Union (ITU), in 2020 the number of Internet users will exceed 4.1 billion people, of which more than 65% prefer access to the Internet using mobile devices (Internet-access (World Market) 2020).

2. Companies with a strong market position and a business model based on digital technologies that provide mobile interactions with customers in offline and online formats. Companies of this type are widely present in the service sector, primarily in trade. According to ITU, in 2019, the volume of online sales on a global scale exceeded $ 2.36 trillion. Each year, this figure is growing on average by 16 - 18%, while global trade is increasing annually by 2.1 - 3.3%. According to the information agency RosBusinessConsulting (RBC), a significant increase in these indicators is also expected in Russia. If in 2018 the volume of online trading exceeded 1.29 trillion rubles. and amounted to 4.07% of the retail turnover, then by 2024, the volume is expected to increase to 2.78 trillion rubles. and 8.5% of turnover, respectively (world market) 2020).

3. Companies that are successful in one industry or industry use digital technology and digital tactics to cross-industry boundaries and enter another industry. This trend is observed in many areas. For example, households are perceived by banks, insurance companies, realtors, and other counterparties

from other areas of activity as a very attractive market niche for which there is competition with the use of digital technologies.

The processes of digital transformation are so radical that we can talk about a digital revolution based on the opportunities that digital technologies provide. There are the following justifications for this. Firstly, this relates to Big Data and methods of digital processing of arrays of information. Secondly, these are digital online platforms as a complex of devices and programs that provide digital space and the process of user interaction with complex standard solutions as a platform. Thirdly, the digital transformation has led to the rethinking of traditional business processes from simple linear chains and value stream to more complex two-way network systems and value network space in search of competitive advantages and opportunities for sustainable functioning.

Digital technologies can lead to large-scale changes, as they become available to most companies. But technology is still just a tool that does not always create a competitive advantage. To form and maintain it, it is necessary to change the business model, to offer customers attractive service conditions, which is made possible through the use of digital technologies; Create a new value proposition that buyers find it possible to pay. Fulfillment of the above conditions may become a prerequisite for the creation of new types of business models of the next generation company (Table 1).

To determine what type of business model a firm should choose based on strategic development plans, the manager must answer the following questions to make a choice. Firstly, the company is an elementary part of the value chain or part of a more complex digital ecosystem, where the leader provides not so much control as the dynamics of maintaining and using the ecosystem. Secondly, what is the degree of awareness of the head of the company about the needs of customers? Thirdly, to demonstrate an understanding of the prospects for interacting with customers through digital technology.

Having determined which characteristics of business models are more consistent with the firm's goals, the manager can make an informed decision whether the firm should retain the old business model or should it move on to a new digital business process model. So, for a firm that remains part of the value chain, you can maintain the old business model of a supplier of tangible or intangible resources. This is true for companies which are working in B2B interactions.

Table 1 : Comparative characteristics of new types of business models

Type of business model	Characteristics of business model
The business model of a provider of tangible or intangible resources	The manufacturer or seller delivers the product to the consumer on a contractual basis, directly or through intermediaries.
Omnichannel business model	An integrated value stream is created, forming a multi-channel system of interactions with consumers.
The business model of the modular manufacturer or seller	The supplier of tangible or intangible products prepares them for use by the consumer at one of the stages (in the module) of the product life cycle.
The business model of the ecosystem driver of value space	The ecosystem organizer coordinates the creation and development of a network of companies, mobile devices and technologies, customers to create value that is essential for all ecosystem participants.

Source: (Moazed and Johnson 2019), adapted by the authors

The omnichannel business model, as well as the business model of a modular manufacturer or seller, is used by large retail chains (for Russia - Okay, Lenta, Perekrestok, etc.), the activities of which are an example of creating and supplementing a value chain. The leaders of such firms control everything related to the movement of the product: prices, deliveries, product placement, sales time frames. However, managers do not always know who supermarket buyers are and why they are buying

certain products. Digitalization allows consumers and businesses to know more about each other and find more benefits.

Firms with a business model of the value ecosystem driver are rapidly increasing revenues and profits. Most large companies can use historically established fruitful interactions with customers or take advantage of the networks, namely the assets and capital of digital business partners, to develop in the space of value. The ecosystem driver (Amazon, Ozon, Wildberries, Lamoda) provides consumers with more choices, offers the best price.

The value for consumers increases due to the fact that different suppliers sell similar (or even identical) goods often at different prices or with different levels of service; Due to quick feedback, suppliers manage to improve the quality of their products and services. For example, thanks to Amazon's work with suppliers, consumers get everything at once in one place, they have more choice and more detailed information on prices and quality. The Amazon platform allows you to see data on all the actions taking place in the ecosystem.

The largest Russian ecosystem driver is the Savings Bank of the Russian Federation. A leader in the application of digital technologies, the bank not only provides customers with classic banking services but also expands its network space through non-traditional banking. Understanding the needs of customers, the bank offers such services as Sber-Market, Sber-Logistics, Market Place (created in the same ecosystem as Yandex), House-Click (real estate portal), Sber-Mobile, Sber-Food etc. These services form the value space of consumers who respond to the bank with loyalty and commitment.

Discussion

The need for digital transformation is no longer in doubt since this is the future of the business, which has already come for some enterprises but not yet for others, but which cannot be left. The question is when and how will the company carry out a digital transformation. In a digital economy that has already become a reality, many firms cannot succeed simply by adjusting management methods and business models that have led to success in the past. As a result of the widespread use of digital technology, radical changes are taking place in the business. Value propositions, consumer preferences, monetization methods, requirements for key competencies, operational models, strategic control are changing.

When deciding to maintain or transform a business model, a manager must understand that he sets his company apart from others and compete with one or more competitive advantages. In the digital economy, they are the digital content of products and information, the customer experience of multi-channel and multiple products, the presence of internal and external digital platforms.

Conclusion

Initially, the business model was characterized as a way of doing business, which provided the company with income and profit. The application of the value approach has expanded the idea of the essence of the business model, which is interpreted as an integrating principle in the processes of creating and exchanging value between participants in the business process. The business model, as the most flexible management tool, is transformed not only under the influence of the external and internal environment of the company but also under the influence of digital technologies. As a result of the widespread use of digital technology, radical changes are taking place in the business. Value propositions change, traditional business processes are rethought from simple linear chains and value creation flows to more complex two-way network systems and network value space. In search of competitive advantages, firms are introducing new types of business models based on digital online platforms. Platform business models provide new opportunities in creating value for all participants in the process and expand the benefits of organizing and using the network value space. Therefore, business leaders seek to incorporate digital platforms into their business models.

Abstract

Performance is a category measured in numerous areas of operation of decision-making units. One of such areas is logistics supporting the functioning of supply chains and networks, so that the processes of flow of material goods, services and information create added value with each activity. Optimal movement of resources is possible thanks to the management of logistic processes, primarily in the context of available infrastructure and logistics operation services. For this reason, the logistics performance index (LPI) was adopted as the measure of logistic processes, and the Data Envelopment Analysis (DEA) methodology was adopted to assess the performance of logistics process management. Based on the review and analysis of the source literature, it has been shown that the performance of the implementation of logistics processes is the basic category of analysis in the implementation of information and decision-making processes in supply chains and networks, and the DEA methodology is an important tool in assessing logistics performance, which can be considered as a measure of the degree of implementation of logistics processes.

Keywords: Data Envelopment Analysis, effectiveness, logistics management, logistics performance index, logistics processes.

Introduction

Logistics is an application-oriented branch of science. It allows modelling and analysis of the economic system from the point of view of material, product and information flows, including time and space and creating value for people. Its task is to design and implement a flow system with the help of available scientific methods. In the field of logistics, problems related to configuration, organisation and control of flows in the system are solved. Logistics plays a conceptual and instrumental role in shaping customer satisfaction. Logistics goals are achieved thanks to the implementation of physical displacements of materials and products, as well as flows of capital and information through subsequent stages of activities of an enterprise or a group of enterprises. Therefore, an inseparable element of functioning of logistics are processes related to the flow of all types of resources, whose effectiveness affects profits and performance (Long 2018, Dias, Ierapetritou 2017; Ierapetritou, Nihar Sahay 2016), and thus market success (Nitkiewicz 2013). Therefore, logistics processes are the basis for the competitiveness of the logistics system, i.e. in a broad sense of the supply chain or network. Therefore, the importance of logistics processes in the functioning of the logistics system forces the implementation of their management. Logistic process management is understood as planning, organising and controlling the implementation of activities that improve processes related to the flow of all types of resources in the system. However, a problem of how to measure the level of logistics process implementation, appears. In the present paper it was assumed that a measure of the degree of implementation of the logistics process, are indices forming the Logistics Performance Index (LPI). This index is considered the most important measure showing and comparing the situation of the logistics sector of countries around the world (Çemberci et al., 2015). The efficient operation of supply chains and networks depends on the effectiveness of decisions in relation to the implementation of logistics processes. Logistic processes are aimed at increasing the exchange value and use value of products with spatial, as well as temporal value (Gaschi-Uciecha, Podgórska, 2015). The spatial value means that the logistics processes lead to the

efficient transfer of the product to its destination, while the temporal value that they lead to the transfer of the product in a timely manner. The transfer of the product to the right customer at the right time is the primary goal of logistics process management, which includes comprehensive planning, organisation and control of processes and logistics activities implemented to ensure the efficient and effective flow of all types of resources between partners in the supply chain or network. An important element of logistics processes is also quality assurance (Nowicka-Skowron, Ulewicz, 2015), as well as the role of feedback associated with the process of quality improvement in the supply chain (Drljača, 2019).

Traditional decision analyses are mainly focused on maximising profits and minimising costs (Moghadam et al. 2016). In management, however, what counts is the relationship of costs and profits, and more generally of the expenditure incurred and the consequently obtained results. This relationship expresses performance of operations, which is the basic category of the operation of supply chains and networks. Therefore, the following hypothesis 1 was made:

"*The performance of implementing logistics processes is the basis for creating new spheres of control (regulation) relating to information and decision-making processes in supply chains and networks*".
Logistics processes focus primarily on delivering goods to the customer in accordance with their needs as to quality, time and cost. These are often complex processes, characterised by a multitude of goals that are not rarely contradictory. Such situations require the use of tools to support the logistics process management so as to ensure the rationality of the operation of the supply chain and network as a result of an integrated, multidisciplinary and transparent approach (Della Spina 2016). Classical approaches to assessing the performance of operation of the supply chain and network are inadequate to the complexity of decision-making situations. Performance defines the degree of achievement of the goal at specific inputs and is thus associated with the concept of performance. Performance is understood as the possibility of achieving the assumed goals using a given method. These categories should therefore be considered together as they complement each other. Thus, based on the analysis of the literature, hypothesis 2 was verified:

"*DEA models are a vital decision tool in the assessment of logistics performance, which is a measure of the degree of the implementation of logistics processes*".

Logistics Performance Index as a measure of the degree of implementation of logistics processes

The management of logistics processes should lead to increased performance of system operation. The starting point for improving the performance of the system operation is therefore a process-based approach, and the process becomes the basic category of analysis for each organisation. Therefore, the identification of logistics processes that ensure the efficient and effective flow of resources in the system is an essential element of its operation.

Logistics includes activities aimed at guaranteeing the performance and effectiveness of all procedures related to the flow of all types of resources from origin to destination, while meeting the required quality of service, including reliability of information and sensitivity to customer needs (Domingues, Reis, Macário, 2015, p. 663). Logistic operations are necessary to efficiently and effectively solve problems related to transportation, storage, and packaging, and thus to ensure the competitiveness of enterprises and countries (Çakır, 2017, p. 177). The operational measure of effectiveness is performance (Śliwczyński, 2011). There are many approaches to measuring performance in the source literature (Kabak, Ekici, Ülengin, 2019; Schøyen et al., 2018; Hammes et al., 2020). In the paper, logistics performance is described using elements which form the logistics performance index (LPI). LPI is understood as a weighted average obtained on the basis of six basic areas, which include:

1. customs clearance – the performance of the clearance process (or speed, simplicity and predictability of formalities) by border control authorities, including customs,

2. infrastructure – the quality of trade and transport related to infrastructure (for example ports, railways, roads, information technology),
3. international shipments – ease of organising shipments at competitive prices,
4. logistics competencies – the quality of logistics services (for example, the competencies of carriers, customs agents),
5. tracking & tracing – options for identifying and tracking shipments,
6. timeliness – the timeliness of shipments in reaching their destination within the designated or expected delivery time (punctuality of deliveries).

The logistics performance index reflects the organisation of logistics processes that affects the image of the state. Focusing on the image of the state built in the majority of the image of economic entities is all the more justified because the European Commission in the task defined as service performance suggests creating a quality mark related to the level of logistics service provided. Logistics performance, because of the way it is understood and measured, determines market development. The international market requires organising and synchronising flows through strategic nodes and networks that facilitate transport, storage, protection and any other value-added services that are necessary because of the characteristics of the goods being transported (Puertas, Martí, García, 2014). Investing in logistics infrastructure should be treated as an area of investment with the greatest possible benefits that bring the highest profits from future economic growth (Tang, Abosedra, 2019).

Data Envelopment Analysis in Examining the Performance of Economic Systems

The Data Envelopment Analysis (DEA) is a frequently used method in the study of social and economic performance. DEA is a nonparametric method of assessing the effectiveness of each of a set of comparable decision variants (Saen, 2010). It is indicated that DEA is the best tool to identify best practices or success (Premachandra, Chen, Watson, 2011). DEA allows finding the best combination of possessed resources within a given technology, which is understood as a way of transforming resources into desired results (Anokhin, Wincent, Autio, 2011). In other words, thanks to DEA models it is possible to determine the performance of an entity on the basis of the performance index calculated including numerous inputs and results simultaneously (Song, Wu, Wang, 2011). Therefore, it allows the determination of technical efficiency, which is considered a difference between the stated level of production of a given enterprise and the limit of its actual production capacity (Nieszporska, 2007).

In order to assess the technological efficiency of units belonging to a certain set it is necessary to (Guzik, 2009):

1. specify a set of J assessed entities $O_1, ..., O_j$ (e.g. countries, regions, economic entities),
2. specify a set of R results of activities that will constitute the basis for assessing the performance of the examined entities,
3. specify a set of N inputs allowing the achievement of predetermined results,
4. specify for each entity the amount of the corresponding results y_{rj} ($r = 1, \ldots, R, j = 1, \ldots, J$) and inputs x_{nj} ($n = 1, \ldots, N, j = 1, \ldots, J$),
5. specify the relative technological performance of individual entities.

It should be remembered that inputs are quantities enabling obtaining certain results of activity and do not have to be considered in the sense of accounting, finance or productivity analysis. In other words, it is a quantity that should be, ceteris paribus, increased to obtain an increase in result. In turn, technological performance is determined by the effectiveness of transforming inputs into results. Therefore, the technology of the entity will be its vector of empirical inputs and results.
To assess technological performance, an indicator understood as the ratio of the value of results to the value of inputs is used, which is calculated according to following formula:

$$E_j = \frac{\sum_{r=1}^{R} u_r y_{rj}}{\sum_{n=1}^{N} v_n x_{nj}},$$

where: E_j – performance index of the j-th entity,

u_r – valuation of the unit of the r-th result (unit value of the r-th result if the market prices of the result are known),
v_n – valuation of the unit of the n-th input (unit value of the n-th input if the market prices of the input are known).

The performance index formulated in this way:

- is normalised in the range [0; 1],
- its higher value means higher performance,
- determines at least the relative performance of the entity.

The set of entities, inputs and results should be characterised by:

- homogeneity – compared entities should be by definition homogeneous or almost homogeneous, and not inherently different,
- non-negativity, which applies in particular to inputs and results (if results or inputs are expressed as negative quantities, it is necessary to add to them a certain constant), although in the case of results, their negativity is allowed if the model is focused on inputs (focus on inputs means that inputs are minimised while the results are reduced to a lower level),
- uniformity of measurement units, which means that a given type of input and result must be measured in all units with the same unit of measurement,
- uniformity of the direction of preferences – for the quantity being a result, its increase must be assessed positively from the point of view of the purpose of operation of the examined entities, while for inputs, its increase, ceteris paribus, is assessed unfavourably.
- significance of inputs – there must be a clear relationship between input and at least one result,
- an adequate number of entities, which should be significantly greater than the total number of inputs and results, although this is not a prerequisite for the study.

Thanks to DEA models it is possible to identify the performance limit, which is formed by effective entities (Liu et al., 2011). However, it should be remembered that the DEA method allows the determination of only relative performance, because of the fact that to calculate efficiency, information on many decision-making units is used.

Application of DEA methodology to assess the effectiveness of Logistics Process Management

The increase in the complexity and uncertainty of decision-making situations in the area of logistics and the insufficiency of previously applied methods to support the decision-making process have contributed to the more frequent use of DEA methodology to support logistics decisions. Table 1 presents the logistics decision areas that are supported by the DEA methodology most often.

Table 1: The logistics decision areas supported by the DEA methodology

Logistics decision areas	Literature
Selection of suppliers of raw materials	Dobos and Vörösmarty (2019), Visani et al. (2016), Boudaghi and Farzipoor Saen (2018); Cheng et al. (2017), Jauhar and Millie Pant (2017), Rashidi and Saen (2018), Zhou et al. (2016), Shabanpour et al. (2017), Dobos and Vörösmarty (2018), Toloo and Nalchigar (2011),
Selection of service providers	Park and Lee (2015), Azadi and Farzipoor Saen (2011), Steven and Egbers (2011), Schøyen et al. (2018), Lai et al. (2015), Holden et al. (2016), Baltazar et al. (2014), Hamdan and Rogers (2008), Lun et al. (2015)
Evaluation of logistics performance (macro- and microeconomic approach)	Mariano et al. (2017), Martí, Martín and Puertas (2017), Chen (2018), Rashidi and Cullinane (2019)
Location of distribution centers	Yazdani et al. (2020)
Transport fleet management in distribution centers	Andrejić, Bojović and Kilibarda (2016)
Optimization of transport activities	Lai et al. (2015), Bai et al. (2019), Gupta et al. (2019), Muñuzuri and Muñoz-Díaz (2019)
Selection of software supporting the implementation of logistics processes	Smirlis, Zeimpekis and Kaimakamis (2012)
Assessment of the effectiveness of tourist services	Huang (2018), Chaabouni (2018)
Assessment of the effectiveness of the supply chain	Badiezadeh et al. (2018)

The DEA methodology is widely used in assessing the performance of logistics processes implemented in various systems. Most often it is used in the selection of suppliers of supply raw materials and logistics service providers. Less often, the DEA methodology is used to assess logistic performance, although it is applied in this area at both the macro- and microeconomic levels.

The application of the DEA methodology to assess logistic performance in the context of an environmentally oriented logistics concept was mentioned by Mariano et al. (2017). They assumed that logistics includes a number of activities such as freight transport, storage, border checks and payment systems, and thus improving logistics performance is the key to economic growth and competitiveness. However, logistics processes are associated with carbon dioxide emissions, which is a serious problem in implementing logistics processes. The authors proposed the development of an alternative index for LPI with the DEA methodology application that allows:

- inclusion of the environmental dimension in the index by taking into account a variable determining the level of carbon dioxide emissions in transport,
- application of weights for each dimension (environmental, economic, technical one),
- determination of the index as a relative measure, allowing a comparison of the study entities.

The proposed index, in addition to six elements of the LPI index (customs, infrastructure, international shipments, logistics quality and competence, tracking and tracing, and timeliness), also included gross domestic product and carbon dioxide emissions for the transport sector, the environmental variable being input to the system, and the other elements outputs from the system. The proposed index assesses the logistic performance of the country in dynamic terms (at the assumed moment or period) and allows ranking of countries in this respect. Country ranking, in turn,

can be used to identify best practices that may form the basis for national or international public policy, identification of possible priority objectives for these practices, and identification of the best means of their achievement. In addition, they developed a dynamic index using the Malmquist index to assess the evolution of logistics performance in each country.

DEA methodology for ranking countries in context of Logistics Performance Index was also used by Martí, Martín and Puertas (2017). These authors ranked the countries according to the criteria constituting the LPI components, but using the DEA methodology, creating the DEA-LPI model. They considered three scenarios:

1. First scenario (base)
- Inputs: Customs, Infrastructure, Ease of arrangement shipments,
- Outputs: Logistics quality and competence, Tracking and trading, Timeliness.
2. Second scenario
- Inputs: A single constant variable
- Outputs: Customs, Infrastructure, Ease of arrangement shipments, Logistics quality and competence, Tracking and tracing, Timeliness.
3. Third scenario
- Inputs: Logistics quality and competence, Tracking and tracing, Timeliness,
- Outputs: Customs, Infrastructure, Ease of arrangement, Shipments.

Comparing the original LPI with DEA-LPI, the authors observed a high degree of correlation between country rankings made using both indices, taking into account three scenarios.

The primary aim of the study of Rashidi and Cullinane (2019) was to assess the sustainable logistics performance of OECD countries. According to the authors, the assessment of the performance of sustainable logistics operations requires the development of an aggregated tool that would ensure a balance between the economic, environmental and social aspects of logistics performance at national level.

Therefore, the following criteria for assessing individual aspects of logistics performance were adopted: “logistics activity” reflects the economic aspect, “energy use” and “greenhouse gas emissions” reflect the environmental aspect, and “rate of job creation” reflects the social aspect. The environmental variable “greenhouse gas emissions” has been considered as input, while the other variables are output. Using the DEA methodology, a new index called the sustainable operational logistics performance (SOLP), which was integrated with the LPI index, was created. Thus, the “sustainable logistics performance index” (SLPI), which is an interesting and potentially useful alternative to LPI and is the sum of LPI and SOLP, was obtained.

Chen (2018) also used the DEA methodology to assess logistics performance. In this study, three inputs and three outputs were included:

- Inputs: investment in fixed assets in transport, storage and post (100 million yuan), number of employed persons in transport, storage and post at year-end of 2009 (person), length of transport routes at year-end of 2009 (km);
- Outputs: freight traffic (10, 000 tons), freight ton-kilometers (100 million ton-km), gross regional product in transport, storage and post (100 million yuan).

The highlighted inputs reflects capital, labour and transport costs, respectively, in the logistics sector. The first two effects represent the regional performance of the logistics sector, while gross regional product reflects the direct economic benefit of the logistics industry.

Therefore, he logistics performance index allows for a holistic approach to the problems arising with the flow of material and information resources in logistics systems. It enables monitoring of progress in the implementation of activities related to transport, storage and service of these processes. Increasingly, basic logistics processes relate to current concepts in the economy, e.g. sustainable

development. Therefore, the multitude of features characterising logistics processes requires the use of tools that will allow the assessment of their degree of implementation and, as the examples show, the DEA methodology is increasingly becoming this tool.

Discussion and Conclusions

Performance is a measure that includes the effectiveness, as well as the efficiency and productivity of the system, including the logistics system. In a sense, it reflects the degree of rationalization of operations in the logistics system, or striving to shape the appropriate structure of processes that are the source of logistics costs and an appropriate level of customer service. Therefore, logistics has an impact on the structure of the added value, as well as the structure of inputs necessary to create this value. Thus, performance is affected by numerous organisational solutions, including those related to the operation of the logistics system. As part of these solutions, factors are defined as inputs and resulting benefits. Therefore, the basis for creating new control spheres in logistics is determined by the performance of processes implemented in supply chains and networks.

Performance allows for a comprehensive assessment of activities taken in the system, and in particular compares benefits from the implementation of the processes that create these activities to the input necessary for their achievement. Most often, performance is measured by financial analysis indices. This most likely results from the access to relevant data necessary for their calculation, which is recorded in every economic system. Unfortunately, these indices include only those benefits and inputs, which are expressed in monetary units. Numerous limitations are also associated with the use of econometric models in the performance study, mainly because of the inability to determine partial results and inputs. The DEA methodology is free of these limitations, and its common application in the decision-making process results from:

1. a possibility to study entities described by numerous inputs and results,
2. the use of less detailed information than in case of indicator methods or econometric models,
3. a possibility to express results and inputs not in monetary units, but in their natural ones.

The specific nature of the modern market shows that consumers currently expect not only the production of goods, but above all their delivery. Activities that enable the continuous flow of materials, goods and products, as well as accompanying intangible assets are becoming priority issues. For this purpose, however, it is necessary to create the appropriate infrastructure that will enable efficient operation of supply chains and networks. This infrastructure consists of elements such as transport infrastructure, warehouse infrastructure, packaging and information technology infrastructure. These elements complement each other and together they guarantee an efficient flow of resources in a specific time and space at specific costs. The logistics performance index reflects all elements of the infrastructure necessary to implement logistics processes, and is therefore a good measure for determining the degree of this implementation.

The DEA methodology is supported by the decision-making process in the implementation of logistics processes. It is also used to assess the performance of logistics processes that are becoming the most important source of operating costs of supply chains and networks. Performance and efficiency are categories that should be considered together. Performance determines the degree of implementation of logistics processes and can be measured by the logistics performance index, and the DEA methodology can be used to compare supply chains (at the micro- or macroeconomic level) in terms of performance, while assessing the technical efficiency of their operation.

Limitation and Future Research

Obviously, the presented discussion does not cover all possibilities in the area of decision-making within the framework of logistics processes management using the DEA methodology. However, they indicate a variety of solutions in relation to the assessment of the performance of process implementation and a variety of consequences of made decisions. The disposition of the effects caused by the implementation of each of the possible solutions allows them to be compared and

ranked according to the decision-maker evaluation system, while ensuring the rationality and effectiveness of the entire process of the assessment and decision-making. Therefore, DEA models are an important decision-making tool in logistics. Undoubtedly, research in this area should be deepened and extended to include the assessment of logistics processes management performance at the enterprise level.

Abstract

The development of agricultural production in modern conditions takes place in a difficult socio-economic situation, which is associated with the introduction of economic sanctions at the international level against Russia; retaliatory embargo; emerging environmental threats to the sustainable functioning of agriculture as the most vulnerable sector of the agricultural sector of the economy. Such factors lead to the need to search for scientific methods and techniques in working capital management that provide positive economic results that contribute to improving the sustainable development of the agricultural industry, both as a whole and for individual agricultural enterprises. In order to exchange experience in improving the functions of working capital management of integrated agro-industrial formations, the article deals with the use of analytical models to assess the elements of capital, its composition and structure, and the reasons for changes necessary for the development of a program-oriented approach to agricultural production management. Based on the study of mechanisms for regulating own funds of integrated agricultural enterprises, the author substantiates the peculiarity of the system-target approach necessary for developing a working capital management strategy. Disclosed is the sequence of policy development working capital of agricultural enterprises, based on practical examples in the hierarchy of agricultural production, as the results of functioning of agricultural enterprises depend on effective working capital management, efficient use of material and financial

resources, which ensure a continuous process of agrarian business. The directions of improving the process of managing a holistic working capital policy using a systematic approach to the relationship of all management tools taking into account the characteristics of agricultural production are substantiated.

Keywords: Analysis, Management, Capital, Models, Programs, Target Approach, Methods, Mechanism.

Introduction

The agro-industrial complex is characterized as a complex economic system that aims to develop agricultural production, provide industrial and processing enterprises with raw materials, and meet the needs of the population with quality food products. One of the conditions for achieving this goal is a competent management system (Polyanin A., 2017) that ensures sustainable development of agricultural production, stable functioning of integrated agro-industrial enterprises, and efficient use of resources.

The creation of a mechanism for managing the sustainable development of agricultural enterprises is associated with the problem of combining their financial interests, the availability of funds to ensure high solvency, and the rational use of production resources in a market economy. Effective transformation of financial resources (Grafova G. F., 2004), turnover of funds, as well as profitability of business processes, ensure the financial well-being of not only the agricultural enterprise, but also its owners and staff. The volume and composition of financial resources in the agribusiness system in modern conditions are of paramount importance, since they ensure the autonomy and independence of the company. Thus, the management of working capital and its rational use acquire an important role in the conditions of the Russian economy's recovery from the crisis situation and stabilization of the external market, which determines the relevance of scientific research in this area.

The policy of working capital management of integrated agro-industrial enterprises is characterized as a set of scientifically-based program measures that should be aimed at the effective movement of structural elements of capital, increasing the results of their use for the purpose of maintaining and developing agricultural production. To date, there is an urgent need to reform the agricultural policy, the legal framework for its implementation, making management decisions on the formation of a strategy for the development of the agricultural sector of the economy, individual sectors and economic entities of the agro-industrial complex, choosing forms and methods of rational management by agricultural producers, applying effective management methods and techniques, searching for reserves to increase sustainability.

The purpose of the research is to develop the methodological foundations of working capital management based on improving analytical tools when applying the program-target approach in agricultural production for evaluating and controlling material and monetary resources, developing recommendations for making management decisions on the composition and structure of capital, determining the need for material resources, and selling products of integrated agro-industrial formations.

The research objectives include: application of analytical models in the mechanism of working capital management (Sheremet, A.D., 2017), formation of a model of the program-target approach to working capital management, justification of the program-target approach for the relationship of hierarchical levels of management in the field of agro-industrial production, optimization of working capital losses in the agricultural business as a result of inefficient capital management.

Modern Concepts of Working Capital Management in Agribusiness

Increasing the activity of agricultural enterprises depends to a large extent on the constructive mechanism of management (Zagaytov I., Ternov K., 1994), the combination of its elements and functions that allow to concentrate the impact of the managing entity on the managed object. New

conditions for the development of the agribusiness system require improving functional approaches to managing the sustainable development of agribusiness enterprises, developing methods of analysis and forecasting, and forming information support for making management decisions.

In modern conditions, it is particularly important to determine the most effective options for the formation and use of working capital (Blank Ia, 2008). The availability of working capital of agricultural enterprises and their effective use are important factors that affect the results of production activities, since they depend on the quality, completeness and timeliness of agricultural work, therefore, the volume of production, its cost, and financial condition.

The development of the mechanism for managing current assets of agribusiness enterprises is based on improving methods and scientific approaches to the organization of a set of interrelated tools, the main purpose of which is to maximize profits (Petrova Yu.M., 2016).

For the purposes of working capital management, the composition of working capital is classified according to various criteria. Many scientists consider working capital as a set of production funds and circulation funds in value form (V. I. Barilenko, 2012). Circulation funds consist of finished products, funds in settlements with customers, as well as funds necessary for the purchase of raw materials, materials, fuel, etc.

According to the Brothers A.V., the Current assets of agriculture can be divided into two parts (Bratchev A.V., 2011). The first of these parts includes items and materials that have not yet entered the production process and are in production stocks (stocks of seeds and planting materials, feed, fertilizers, pesticides, fuel and lubricants, spare parts). The second group consists of items and materials that are already in the process of production in the form of products that are being produced, but not yet finished (young animals, animals on fattening, work in progress.

Modern concepts of working capital management of agricultural enterprises is to determine the strategy and directions of production development, working capital parameters in accordance with the specifics of agriculture. Many agribusiness enterprises form their strategies using high-quality terminology that corresponds to the directions of Federal and regional agricultural development programs, and are defined by specific goals and objectives. A well-organized business largely determines the business development strategy (Abrams, J. B., 2010).

Currently, the problem of optimal working capital creation in the sphere of agricultural production is associated with the presence of negative phenomena, which is caused by the use of inefficient methods of management. The lack of own sources of working capital created by the enterprise for many agricultural organizations leads to the need to attract borrowed funds (Mezdrikov Yu.V., 2007). This situation leads to an increase in the cost of paying interest on the use of borrowed funds and credit resources, which often leads to a decrease in the solvency and financial instability of subjects.

Program-Target Approach to Managing Elements of Working Capital in Agricultural Production

Policies of working capital management in agriculture are determined by the targets of the state program of development of agriculture, as well as specific industries, which include agricultural production (2012) the Structure and content of policy allows you to define a guideline for the formation and use of overall working capital and its individual elements, based on the use of program-target approach in the system of agrarian business (Merenkova, I. N., 2013). Taking into account the specifics of the agricultural sector of the economy, the sequence of the system-target approach can be represented as a relationship between segments of agricultural production, elements of working capital aimed at achieving common targets.

The analysis of production indicators for the livestock industry shows that the indicative program indicators were exceeded in 2017 by 0.9%, the growth rate in comparison with 2016 was 1.3%. Over the past five years, the industry has also seen an increase of 2.3%. The main areas for which there is

effective development of agricultural production in the livestock industry, and for which there is an increase in output are: poultry growth target of 6.9%; pig farming – an increase of 5%.

Despite the ambiguity of development of branches of agrarian sector of economy, at the end of 2017, an increase of profitability of agricultural enterprises in relation to indices of 0.3%. Over the five-year period from 2013, the increase in the coefficient of profitability of agricultural enterprises amounted to 7.0%, compared to the previous year, there is a decrease in the coefficient.

Fig. 1: Consistency of the system-target approach in the policy of working capital management in the agro-industrial complex

Investment is one of the positive factors that have affected the growth of agricultural production. The index of physical volume of investments in fixed assets of agricultural enterprises was 103.1% in 2017, which is higher than the planned figure of 2.5%, but much lower than the indicator of 2016.

Table 1-Dynamics of actual indicators of the State program for agricultural development (in comparable prices),% *

Indicators	year 2013	year 2014	year 2015	year 2016	year 2017		Change in 2017 data in comparison		
					plan	actually	with the plan	C data from 2016	data from 2013
Indices of agricultural production for all categories of farms (by the previous year)	105,80	103,50	102,60	104,80	101,70	102,4	+0,7	-2,2	-3,4

Average monthly salary accrued to employees of agricultural enterprises, rubles	16853	19243	21626	24106	21790	26280	+4490	+2174	+9427

**National report on the progress and results of the implementation in 2017 of the State program for the development of agriculture and regulation of markets for agricultural products, raw materials and food for 2013-2020.*

Factor of growth of agricultural production was the growth of labor productivity, growth of labour productivity increased compared to target and last year. In the management system of agricultural production, it plays a significant role in managing the internal environment of enterprises (Parushina, N. V., Lytneva, N. A. 2016).

Analysis of the results of agricultural development by industry shows that in 2017, the crop production increased the acreage of grain and leguminous crops. The gross grain harvest amounted to 135.4 million tons, which is characterized by a growth rate of 12.2%, including winter and spring wheat growth of 17.1%. The volume of gross wheat harvest in 2017 amounted to 85863.1 thousand tons, and last year it was equal to 73294.6 thousand tons. Over the five-year period from 2013, the gross wheat harvest increased by 64.8% or 33772.3 thousand tons, while the yield for this crop increased annually and in the analyzed period reached 31.2 C / ha, 6.4% higher than in 2016. the Increase in production volume compared to last year and in dynamics is observed for such crops as sugar beet, soy, rapeseed. Special attention is paid to the production of rapeseed. From 2013 to 2016, the cultivation of this crop decreased all the time, from 1259.2 thousand tons to 998.9 thousand tons, respectively. In 2017, the increase to the previous year was 151.1%, the yield increased by 143.6% .

Table 2-Dynamics of crop production by agricultural enterprises of all categories in Russia*

Types of agricultural crops	**year 2013**	**year 2014**	**year 2015**	**year 2016**	**year 2017**	**2017 in % of the**	
						2016	**2013**

Sunflower for grain	14,50	13,10	14,20	15,10	14,50	96,03	100,0
Soybean yield	12,60	12,30	13,0	14,80	14,10	95,27	111,91
The yield of rapeseed	11,30	12,60	11,20	11,0	15,80	143,64	139,82

**National report on the progress and results of the implementation in 2017 of the State program for the development of agriculture and regulation of markets for agricultural products, raw materials and food for 2013-2020*

The decrease in gross harvest in 2017 is observed for such crops as corn for grain, for which the growth rate by 2016 is 86.5%, the decrease was almost 15%. For such crops as corn for grain, sunflower for grain, sugar beet, soy, there is a decrease in productivity in comparison with 2016. the Largest decrease in productivity in 2017 for corn for grain, by 2016, the yield was 88.92%, and by 2013, 97.8%.

Fig. 2: Dynamics of yield of grain crops by agricultural enterprises of all categories in Russia

In order to support agricultural producers and ensure their sustainable development, the state implements management actions to Finance agricultural production. In comparison with 2016, 11.3% of budget funds were allocated for the implementation of the State program in 2017 to support the agro-industrial complex.

The main amount of budget funds is used to Finance the programs "Promotion of investment activities in the agro-industrial complex" and "Development of agro-industrial sectors". The volume of credit resources, which is used for the development of agriculture issued the "agricultural Bank" in the amount of 1104,9 billion rubles, including short-term lending 870,1 bn and investment lending 234,8 billion.

State programs are supported at both the Federal and regional levels of government. Data from the territorial body of the Federal state statistics service for the Orel region indicate that the volume of agricultural production for all farms in actual prices in 2018 amounted to 67.2 billion rubles. in the crop industry, the volume of production is 44.7 billion rubles, in the livestock sub-sectors, it reached 22.5 billion rubles. The share of the volume of production produced by agricultural enterprises accounts for 72.6 % of the total volume, peasant (farm) farms and individual entrepreneurs produced 11.0 % of production, 16.4% were created in households of the population (Orel, 2018).

Analysis of data on agricultural production in the Central Federal district indicates that the Oryol region ranks eighth in agricultural production. The growth rate of agricultural production at comparable prices in relation to 2017 is 106.5 %. The increase in production of crop production-8.5 %, in the livestock industry-3.0 %, in peasant (farm) farms, the index of production was 109.7 %. Production of agricultural products per capita in the Oryol region in 2018 amounted to 89.9 thousand rubles, which is significantly higher than the figures for the Russian Federation, equal to 34.9 thousand rubles, and for the Central Federal district – 35.2 thousand rubles.

According to the analysis, improving the management system at the regional level has helped to stabilize the situation in agriculture in the region, which in turn contributes to increasing the sustainability of the development of agricultural enterprises.

The Orel statistical office provides the following data on the development of agricultural production in the sub-sectors of crop production in 2018: "... the threshing of grain and leguminous crops in weight after completion amounted to 3,193. 8 thousand tons (100.5 % by 2017). In comparison with 2017, the gross harvest of millet increased 5 times in the farms of all agricultural producers in the grain group, winter triticale almost doubled, spring wheat - by 15.4 %, oats-by 14.8 %, corn for grain-by 9.8 %, spring barley-by 9.1 %, winter rye-by 8.2 %."

Improving the mechanism for managing agricultural production at the regional level has allowed us to achieve positive dynamics in the development of the industry, to ensure the stability of the functioning of individual enterprises (Kyshtymova E. A., 2017).

The analysis of indicators of sustainable development of the industry indicates an increase in the profitability of agricultural production. The profitability of asset management was 1.1%, and the profitability of goods, products, works, and services sold was 30.4%.

Agricultural organizations in the region in the 1st quarter of 2019 are characterized by the highest return on product sales of 30.4%. In second place are organizations engaged in educational activities 16.6%, in third - organizations of manufacturing industries 8.2%.

Fig. 3: Indicators of profitability of organizations in the Oryol region in the 1st quarter of 2019*

** Information on the results of the government of the Orel region in the field of agro-industrial complex in 2018.*

For certain types of activity, there is a loss: wholesale and retail trade 0.1%, transportation and storage activities 0.1%, the provision of administrative and related additional services 3.1%. The worst results are observed in the field of health and social services, for which the loss was received both on assets of 2.9% and on the sale of services of 11.3%.

The data of the comparative analysis showed positive high results for agriculture. However, these are the results of only 1 quarter, which may change towards the end of the year in a downward direction. In this regard, at the level of regional management, there is a task to ensure sustainable development of both individual agribusiness enterprises and the agricultural sector of the Oryol region as a whole. 2018 is characterized by an increase in the amount of funding for organizations that carry out animal husbandry. 477 million rubles were allocated for the development of this industry, which is 2.4 times more than in 2017, and 221.2 million rubles were allocated for the development of livestock breeding.

"In 2018, support was provided to 14 novice farmers in the amount of 25.2 million rubles, 1 family livestock farm – 9.0 million rubles, 4 agricultural consumer cooperatives received grants for the development of material and technical base in the total amount of 41.6 million rubles. Grantees created 31 permanent jobs and provided a product growth of at least 10 %" (Orel,2018). In addition, investment activities in the agricultural sector of the region are carried out in the following areas:

- it invests the amount of 280 million rubles in the modernization of production project "the Modernization of dairy complex, and forage with the goal of increasing the number and productivity of cattle population" implemented by the limited liability company "Jupiter" Bolhovskogo area industry dairy farming;

- investment of the project implemented by the limited liability Company "inter Finance project" Znamensky district of the Oryol region for the new construction of a dairy farm for 1200 heads of cattle has begun;

- investment projects are being implemented for the development of meat livestock by integrated agricultural enterprises "Znamenskiy selection and genetic center" limited liability Company and "Miratorg" Agricultural and production enterprise limited liability Company.

Major investment projects are being implemented in the food and processing industry of the region for milk processing, cheese production, etc., which promote agricultural products to the population, taking into account their needs and demand.

The effectiveness of implemented projects depends on the set of measures of each agricultural enterprise separately, aimed at ensuring their sustainable development, sustainable development of individual territories and the entire region as a whole. A significant role is played by the control of enterprise resources (Lytneva, N., 2019).

Final conclusion

At present, "...one of the most important directions of the state agricultural policy is strategic planning, development of forecast balances of production and consumption of the main types of agricultural products, priority development in the regions of those branches of agro-industrial production that most meet the natural and socio-economic conditions of the subject of the Russian Federation" (Nechaev V., 2010). In this regard, there is an increasing need to improve the tools of the program-target approach to working capital management in the hierarchical system of agricultural management.

The application of the program-target approach will improve the quality of management of working capital elements for making management decisions to achieve program goals and objectives of agricultural development in modern conditions of economic uncertainty.

Agricultural enterprises need new models where the main parameters and variables are the characteristics of agricultural products. This will allow us to evaluate development options and

formulate targets, rationally approach the formation of effective measures for the placement, preservation and increase of their own working capital, integrate management functions to maximize the profit of agricultural production.

Abstract

The paper has examined the results of the treaty provisions related to defence expenditures in NATO member states and compared them with the Russian Federation's defence expenditures. By use of appropriate economic tools as well as the available data (sometimes estimated), the authors have proved that the treaty provisions on defence expenditures thresholds of 2% of GDP and 20% on the army's modernization have not been implemented in most member states. The analysis of the structure of these expenditures has shown that NATO member states have predominantly incurred expenditures on personnel of about 56%, contrary to Russia. Moreover, calculation of the expenditures at the USD market rate and according to purchasing power parity (PPP) has indicated significant inaccuracies in Russia's real expenditures, which are 3 times higher. Maintaining such disparities in the future can threaten security not only in Europe, but also in the world.

Keywords: Strategic Concept, National Security, Financial Analysis, NATO, Defense Expenditure

Introduction

Basic necessities, which every country is obliged to provide, ensure a sense of security and welfare. They also involve maintaining country's independence and sovereignty as well as security of the borders so that citizens could function and perform their duties peacefully. One of the determinants of the security level in the modern world has been and will remain the state of the army in terms of the number and training of soldiers as well as possession of the most modern equipment. The financial resources and defence expenditure result directly in the strength of the army and its military capability. These funds depend on many factors such as the state's economy and financial policy. The dynamics of civilizational development and international threats require more and more funds for defence expenditure. This issue seems to be extremely important. It is also the constant subject of discussions among politicians and entities responsible for the country's security. With time and transformations in the geopolitical and military situation in the world, the requirements for the North Atlantic Pact have also changed (Banasik, 2015; Krzysztoń). It is due to the imperial policy of some countries. Russia's war doctrine poses a threat for NATO, and in particular for Central and Eastern Europe. That issue, among others, has inspired the Authors to write this paper. ***The aim of the paper is to compare the financial expenditure allocated to defence in the North Atlantic Alliance member states in reference to the Russian Federation's expenditure.***

This paper presents the scale of expenditures related to maintaining the independence and sovereignty of individual countries. It can also have a positive impact on budget planning in the years to come.

For the purpose of the study, the following methods were applied: monographic, analysis, expert, participatory observation, induction and deduction, synthesis and comparison (Apanowicz 2005; Szarucki 2016).

The following were the sources of information: available literature, magazines, press articles, interviews, reports, authors' own experiences as well as the documents found on the websites of NATO and Russian Federation, mostly in English or Russian.

The used reports come from the official NATO sources and show the current and estimated future defence expenditures. These amounts actually reflect the government's military expenditures and those to be incurred during the tax year(Jeppesen 2019).

Notably, these are sensitive data, often unpublished and cited as estimates. This is especially true of the Russian Federation's statistics, where most of the expenditure is concealed and defence expenditure is hidden in the other ministries' budgets. Thus, it is just an attempt to approximately render the actual image of reality.

Financial Policy of Defence Expenditures

Nowadays, none of the country's leaders run the peaceful foreign policy, and undoubtedly, Russia is regarded as one of the countries that pose the greatest threat to the world's peace. The country headed by Vladimir Putin raises concerns around the world, in particular as a serious threat to Central and Eastern Europe. The fall of the Berlin Wall, one of the symbols of the Cold War, followed by the collapse of the Warsaw Pact in political and military terms, as well as the USSR disintegration marked a new era in the history of Europe and the world. It also posed a challenge for NATO, which until then regarded the Warsaw Pact, and in particular the USSR, as its main enemy.

The new geopolitical situation led to major changes in the structure of the North Atlantic Pact and a new approach towards the countries outside the 'Iron Curtain'. As part of the plan to increase security in Europe, NATO launched programmes to enable former EU countries, as well as countries that gained independence as a result of the disintegration of USSR and the Socialist Federal Republic of Yugoslavia, to join the Pact structures.

At different time, the number of NATO member states increased from 16 in 1991 to 29 in 2017.

Simultaneously, the NATO strategic concept has fundamentally changed. In 1991, the so-called new strategic concept was launched, which aimed at maintaining sufficient conventional and nuclear forces capable of deterring possible aggressors and complying with measures to prevent possible armed conflicts in the world (Mierzwa i Tomaszycki 2020).

The concept of 1991 did not specify a definite adversary, which resulted in a decrease in defence expenditure in many countries, reduction in the armed forces' personnel and the USA troops' presence in Europe and a significant reduction in the number of logistics stocks as well as military equipment and infrastructure. Over the years, the United States' initiative in Europe was declining, while the Russian Federation's military capability was growing. For a long time, Russia also kept investing heavily in military potential.

In recent years, Russia has started to pursue a particularly aggressive policy towards Central and Eastern European countries. Explicit military interventions involved the war with Georgia in 2008, Ukraine in 2014 and the incident in the Kerch Strait of November 2018. Russia's more sophisticated and covert actions consisted in a cyber attack on Estonia in April 2007 (Wierzbicki 2015), the coup attempt in Montenegro in 2016 (Rybczyński 2018), the attempt to block the Macedonian agreement with the Greeks in 2019 (Strzelecki 2018), or combat exercises and reconnaissance operations in Norway by Russian Specnaz in 2019 (Czermiński 2019). Those are just examples of Russia's actions within the "hybrid war" or "conflict below the threshold of war".

Those events led to a new approach towards the Euro-Atlantic defence policy and they started dynamic changes in the strategic concepts both in NATO and EU countries.

Further NATO summits in: Newport in 2014, Warsaw in 2016, Brussels in 2017 and 2018 totally changed the approach towards real international threats and those in Central and Eastern European countries. The last NATO Summit in London of December 2019 was particularly important for Poland and the Baltic states (Białczyk 2019). Since 2014, Russia has been identified as the main aggressor and the greatest security threat to the NATO member states. In view of these facts, it was necessary to develop a new defence policy and strengthen the "Eastern wall" with Russia.

In this context, NATO leaders, frequently using the terms of 'cohesion' and 'coherence', stress that unity is essential for success. Thus, 'cohesion' and 'coherence' have become distinctive indicators of the NATO current strategic concept in the defence, military and institutional policies, which also requires a new approach towards the management policy of the Alliance's finances.

In order to clarify and implement the concepts that are crucial to the current conception, it is increasingly important to understand what 'NATO Cohesion' and 'NATO Coherence' mean.

NATO cohesion means a level of political and ideological unity and solidarity between the members of the Pact. That mainly applies to the principles on which the Alliance is based. In particular, it refers to the member states' commitment to joint defence policy in order to deal with threats and challenges facing the Alliance. On the other hand, NATO coherence means consensus between the member states on augmentation of the Alliance's capabilities and possibilities necessary to ensure the maximum effective implementation of the NATO mission which, among other things, includes: strategic plans, resource requirements, material capacities, operational procedures, command structures, number of soldiers and logistics infrastructure (Chojna- Duch 2010; Hodges, Doran, Bugajski 2019).

The new conception not only leads to an increase in defence expenditure incurred by individual member states but also changes the structure of it (Bartz 2002; Baszczyński, Borsuk i Stańczyk 2009). According to the former NATO Secretary-General Anders Fogh Rasmussen, ‘an alliance that cannot ensure collective defence will lose its cohesion in achieving collective security’.
The issue of defence expenditure posed a challenge for the Alliance as it was raised at the NATO Summit in Brussels in 2018.

The defence budget of the Alliance members is set at 2% of GDP for each member state, of which 20% should be allocated to modernization of equipment and research. In the press release published by the NATO Department of Public Diplomacy 4 days before the NATO Summit in Warsaw, it was stated that "after years of cuts and constraints on defence budgets (until 2014), the trend was halted in 2015 (at that time a minimum increase in defence budgets of 0.6% was noted) and that defence expenditure was projected to increase by 3% in 2016. The countries that comply with the NATO's recommendations of 2% of GDP defence expenditure include: the United States (3.61%), Greece (2.38%), the United Kingdom (2.21%), Estonia (2.16%) and Poland (2.0%). The increase in such expenditures reflects the Alliance’s greater understanding for the need to strengthen the military capabilities and potential in the face of increasing traditional and non-traditional threats and security challenges” (Soloch i Pietrzak 2011).

Further on in this paper, the authors present the detailed analysis of defence expenditures in different aspects (Dylewski 2010, Kożuch i Ucieklak-Jeż 2014).

Comparative analysis of defence expenditures of the NATO member states vs the Russian Federation.

NATO's primary mission is ensuring the security of its members. Extension of the defence budget is the Alliance’s response to the contemporary security threats and how planning and investing in funds

is adapted to the current and future challenges (Baczyński, Borsuk i Stańczyk 2009; Mierzwa, Rupa i Sienicki 2018).

Moreover, defence expenditures involve intensified efforts to accelerate work on new military technologies and innovations as well as investments to enhance the capabilities to combat global terrorism. The concept of "defence expenditures" is worth explaining as it is a concept much broader than expenditure on the army. The essential amounts of defence expenditures are invested in maintaining the size of the armed forces and military equipment and infrastructure at the appropriate level, the process of training each soldier/military specialist, equipping the military sub-troops with equipment corresponding to the current battlefield conditions(Frysztak 2011; Klecha I Lis 2012)

The comparative analysis of defence expenditures incurred by the member states started at 2% of GDP thresholds established in the NATO's new strategic concept. Figure 1 illustrates how this indicator changed in NATO countries in comparison to the Russian Federation over the years of 2013-2018.

Fig. 1 : Comparison of defence expenditures of NATO vs the Russian Federation in the years 2013-2018 in [%].

The above Figure shows a slight reduction in defence expenditures incurred by the United States from 2013 to 2018 (by 0.73 % points). The attack of 11.09.2011 on the World Trade Center changed the United States policy resulting in an increase in the funds allocated to defence to 5.29 % of GDP. The factor which halted that increase again was the financial crisis which began in the United States in 2007. The crisis affected all major global economies - which contributed to a slowdown in GDP growth and consequently a decrease in defence expenditures not only in the USA, but also in European countries. The budgetary constraints of the United States affected the overall defence budget of the North Atlantic Alliance, which at that time also indicated a downward trend.

During the same period, an increase in defence expenditures was noted in the Russian Federation. The upward trend was reported there until 2016, followed by downfall. In 2017, compared to the previous year, the funds allocated for that purpose fell by 1.3 %, and a year later by another 0.3 % points. The reduction in expenditures spent by Russia in recent years has been the result of the intensified modernization policy of the Russian armed forces in the previous years as well as the embargo imposed on Russia due to its aggressive policy. Michael Kofman (the CNA think-tank expert on Russia) stated the thesis on the website "War on the Rocks" that the Kremlin does not want to fall into the trap of overwhelming defence expenditures as it did during the Cold War. In his opinion, that was, among other things, the cause of the USSR economic disintegration in the 1980s (Kucharczyk 2019). Based on the Kofman's analysis, it can be inferred that the Russians plan to spend on defence about 2.5-3 % of GDP in the coming years. Consequently, modernization will no longer take place at such a dynamic pace as in the previous years.

Fig. 2: Estimated defence expenditures of NATO countries in 2014 and 2018 counted as a share of GDP in [%]

Figure 2 shows the rate at which NATO increases its defence potential. The statistics refer the comparison of 2014 and 2018.

After analyzing the above data, it can be concluded that the vast majority of countries comply with NATO recommendations and increase their defence expenditures. However, the rate of this growth is insufficient for most member states. According to the publicly available data, it fell from 6% in 2017 to 3.8% in 2018. The threshold recommended by NATO of 2% of GDP in 2018 was only reached by the USA, UK, Greece, Estonia, Poland, Lithuania and Latvia.

Defence expenditures incurred by the USA and NATO with its allies in the years 1989 – 2018 are also worth considering. Figure 3 shows the average amount that 29 NATO member states spent on defence compared to the USA and European countries with Canada.

Fig. 3: Defence expenditures of the United States, NATO, and the allies in Europe and Canada.

Based on the above data, it can be stated that the percentage of NATO's total expenditure (NATO Total) is 2.36% of GDP. Without the United States (whose expenditure in the entire budget of the North Atlantic Pact accounts for about 70 %), it appears that the member states of Central and Eastern Europe, together with Canada, spend only 1.48%. Thus, it is obvious how the whole world's security, not just Europe's, depends on the USA military power. With such knowledge, it can be concluded that the USA leaders undoubtedly have the greatest impact on creation of the financial policy of the entire Alliance.

Another comparison which reveals disparities in funds invested in military expansion by some world powers is presented in Figure 4. Clearly, it confirms the previous thesis. The following countries have the largest military expenditures: the USA 36% and China 14% respectively, while the North Atlantic Alliance spends 50.4% of its global expenditures on defence.

Fig. 4: Military expenditures of the selected countries and NATO in 2018 in [%]

After the preliminary analysis, there arises a question: Does the current Alliance ensure the security of its members? Unfortunately, based on the information gathered so far, an unequivocal answer is currently not possible. Other aspects that may distort the picture still need to be analyzed.

Comparison of expenditures on modernization of the NATO armed forces vs the Russian Federation

One the most important comparisons, presented by many authors in their scientific papers, which defines (Pietrzak i Soloch 2016; Szatkowski 2019; Szmidtka 2016) the rate of development of the armed forces recommended by NATO, also refers to the budget allocated to military modernization. The North Atlantic Alliance recommends that this rate should oscillate at 20% including research, development and modernization expenditures.

Modernization of the armed forces is aimed at increasing the military capabilities of a given army by purchasing new and technologically advanced equipment as well as modernizing the existing equipment that the army is provided with (Polak 2015; Wolny 2017). It consists in the replacement and installation of modern and more durable advanced subsystems, which significantly affects the useful value of equipment. Figure 5 shows the expenditure on modernization of the armed forces in percentages in the NATO states and Russia in 2018 (Trusewicz 2018). The Russian data available on the world forum, indicate that Russia's expenditure amounts to 50-60% (the list includes an average value of 55%). The largest percentage refers to the smallest country of Luxembourg, which spends 41.8% of its budget on modernization of the army, Latvia (35.4%) ranks second, followed by Romania (34.4%). etc.

Fig. 5: Expenditures on modernization of the Member States' armed forces in 2018 in [%]

This overview shows that numbers are delusive. Luxembourg's military budget converted to a percentage of GDP is the largest, while it ranks last in NATO expenditures. On the other hand, Greece, which ranks second in respect of its defence expenditure, spends 12.4% of its budget on the purchase of modern equipment. On average, NATO European countries, along with Canada, spend about 12% on modernization of their armies (see Figure 6). 2017 marked a significant breakthrough as then military expenditure increased by 8.8% points compared to 2019.

Fig. 6: Expenditures on military equipment of Central and Eastern European countries with Canada in [%]

More accurate analyses take into account the structure of expenditures, which is important, i.e. which activities consume the cash streams allocated from the budget. (Milewski 2016)

Most of NATO expenditures are not directly those spent on improvement of military capabilities, such as soldiers' wages and pensions and maintaining the current units for which they are responsible (Jankiewicz, Mierzwa i Tomasiewicz 2018; Persson 2019). Contrary, the Russian Federation authorities focus more on modernization of the army. It is difficult to state how true these data are as from year to year they are concealed by the Russian statistical offices RosStat. They do not disclose official figures which are only estimates. That leads to a reduction in the integrity of Russian statistics and thus thwarts a real analysis.

Expenditures on personnel and equipment modernization – comparison of Russia and the North Atlantic Alliance

The issue of military funds does not only account for the amount funds allocated to the armed forces, but also how it is distributed. Table 1 shows the percentages of expenditures on military equipment and human resources.

Table 1: Expenditures on personnel and equipment modernization in 2014-2018 - Russia, NATO in [%]

	Russian Federation		**North Atlantic Alliance**	
	Military Personnel	**Military equipment**	**Military Personnel**	**Military equipment**
2014	25	68	57,24	13,14
2015	20	56	58,35	14,74
2016	18	56	57,81	15,31
2017	24	51	52,85	17,29
2018	25	46	53,44	19,51
Średnio	**22,4**	**55,4**	**55,93**	**16,59**

The above overview indicates that there is a large disparity of personnel expenditures and those spent on the wider modernization of the army. The North Atlantic Alliance spends an average of 55.93% on personnel and 16.59 % on military modernization. In contrast, the Russian Federation spends 5.4% on modernization of the army and 22.4%. on personnel. Thus, the Russian Federation has a huge advantage in allocating more and more funds to the purchase of new military equipment and modern technologies.

Comparison of On Defence Expenditures Incurred by NATO And the Russian Federation [In USD Bn]

Continuing the analysis, it is worth paying attention to the amount of expenditures spent by the United States and other member states of the North Atlantic Alliance (see Figure 7). Based on the Figure below, a large difference between the USA and other NATO members can be observed. The United States spent on defence USD 685 billion in 2019 and the expenditure declined by USD 11 billion compared to 2013.

Fig. 7: Defence expenditures of the United States and Central and Eastern European countries in 2013-2014 in [USD bn].

Meanwhile, the funds spent by the European part of NATO and Canada increased by USD 50 billion during the same period. Probably, that was due to the promotion of President Donald Tump's new financial policy in recent years. However, calculating these amounts for each member state, on average gives an increase of USD 1.7 billion a year, which is very insubstantial. The authors compared these expenditures with those of the Russian Federation (see Figure 8).

Fig. 8: Expenditures of the Russian Federation on defence in 2014-2018 (in USD bn).

According to the above Figure, on average Russia spent USD 72.46 billion on armaments over the studied period. Despite financial problems, Director of the Budget Policy Department of Russia's Ministry of Finance announced that, in line with the project, defence and security expenditures would rise from RUB 1,382 trillion to RUB 2,456 trillion in 2020, and then to RUB 2,523 trillion in 2021 (SIPRI 2019; Trusewicz 2018).

Comparing the expenditures of the Russian Federation with the expenditures of the North Atlantic Alliance, it might seem that the Russian Federation does not stand the slightest chance to defend its borders in confrontation with the United States, let alone the Alliance as a whole. Nevertheless, Russia's policy and its actions arise concern among European countries.

Analysis of The Russian Federation's Finances in Respect of Purchasing Power Parity

The purchasing power of money was taken into account in order to properly analyze the funds incurred on defence expenditure (Samuelson 2002). The expenditures converted to dollars at the USD rate do not account for its purchasing power in a given country. For this reason, calculation of military expenditures in individual countries is difficult (Tymoczko Nr283). The discrepancies are shown in Figure 9.

The Figure above shows Russian expenditures in rubles and dollars at the average market exchange rates. However, these expenditures are increasing in rubles (RUB) and they are decreasing in dollars (USD).

Volatility of exchange rates is not the only problem while applying the market measures to calculate military expenditures. The fact, which seems to be even more important is that many goods and services have different relative prices in a given country and they cannot be traded. That relativity can be essential in calculating relative military expenditures. If the price of goods and services ordered by the Russian Government for military purposes is lower than that of the USA goods and services, the measure of expenditures on the military market, based on the exchange rate, underestimates the capacity of a given shopping basket (Ruboszeki Serwa 2009)

Fig. 9: Comparison of Russia's defence expenditures in RUB and USD at the market exchange rate.

In order to reflect the real purchasing power of money, when converting the currency is necessary, one needs to make use of the indicator called "purchasing power parity" (PPP), often referred to as the law of one price.

Taking into account the above indicator, the Russian ruble is said to be "the most underestimated currency in the world". This indicates that the seemingly weak currency, especially from the viewpoint of abroad, for the Russians themselves has a completely different value – much higher.

According to the most popular institutions dealing with military expenditure (SIPRI and the International Institute for Strategic Research), the Russian Federation is currently spending just over USD 60 billion on its army, an amount similar to France or the United Kingdom. If we simplify the analysis, it can be concluded that the amounts spent by Russia should be multiplied by 2.5-3 in order to receive a more realistic diagnosis.

Applying purchasing power parity we can take into account the differences in relative costs, which significantly changes the amounts of expenditures incurred by countries. The PPP-based estimates provide a more realistic approximation of the actual military expenditures of the Russian Federation. The effects of application of purchasing power parity can be observed in Figure 10.

Fig. 10: Russian military expenditures in the years 2005-2018 at the USD market rate and according to PPP.

Application of these two approaches to measure military expenditures in Russia confirms the previously stated thesis that the possibilities of the Russian army 's modernization are about 2.5 - 3 times higher than those officially reported. According to the Figure, measurements by use of purchasing power parity (PPP), Russia's military expenditures exceeded USD 80 billion in 2015 and, already in 2016, they exceeded USD 200 billion. In 2018, the level of military expenditures remained at about USD 150 billion, due to Russia's debt repayment to the native companies of defence industries. It is easy to notice that this does not coincide with the data demonstrated in Figure 7, where Russia's expenditures amount to nearly USD 70 billion. While converting the amounts to percentages and calculating these expenditures by use of both rates (PPP and the market exchange rate), the difference is huge (see Figure 11).

Fig. 11: Russian military expenditures per dollar and according to PPP in [%]

It can be calculated that at the USD exchange rates, Russian expenditures did not exceed 14% of its expenditures - even at its peak (2013). After depreciation of the ruble in the years 2014-2015, the

indicator decreased significantly as it fell below 10% . However, observation of the PPP indicator creates a different situation. Even before the start of the modernization programme in 2011, expenditures oscillated around 20% - as purchases increased in the years 2012 - 2016, Russian expenditures soared to 35% and then it fell to 25% in 2018. Figure 12 illustrates Russia's position among the world's largest military powers calculated according to PPP.

Fig. 12: Military expenditures of the selected powers according to PPP rates in 2005-2018 (in USD bn).

As shown above, Russia ranks 5th among the world's largest military powers. While the USA remains the leader in defence expenditures, the distance to other countries decreases during the studied period. Clearly, China's economy is accelerating, as its military expenditures are increasing from year to year. This may mean that in the near future, China's vigorously developing economy may obtain such military capability that, along with Russia, it may threaten international security.

Final Conclusions

The paper examined the results of the treaty provisions related to defence expenditures in NATO member states and compared them with the Russian Federation's defence expenditures. The comparative analysis was multifaceted and led to the following conclusions:

(1) Treaty provisions put forward consecutively at the NATO Summits in recent years, which established the 2% of GDP thresholds, have not been implemented in most member states despite understanding and declarations on the part of their governments. Only the USA, UK, Greece, Estonia, Poland, Lithuania and Latvia have have fulfilled these recommendations.

(2) The recommended amount of expenditure on the army's modernization and new technologies, which should constitute 20% of defence expenditures, has been implemented by 16 countries, which is only half of all. On the other hand, the analysis of the structure of expenditures has indicated that NATO member states predominantly incur expenditures on personnel of about 56% and on the army's mdernization of about 16%. Contrary, the Russian Federation has a reversed proportion as 22% of its expenditures is on personnel (despite the larger number of soldiers), and about 55% on the army's modernization.

(3) Calculation of expenditures at the USD market rate and according to purchasing power parity (PPP) indicates significant inaccuracies in Russia's real military expenditures. Calculating the expenditures according to purchasing power parity, the amounts that Russia spends on the army's maintenance are 3 times higher than the amounts found in the statistics. Thus, Russia

ranks 5th among the world's greatest military powers. Maintaining such disparities in the future may threaten international security, taking into account for example, the joint military capabilities of China and Russia.

It is worth noting that although the level of Russian military expenditures is much higher, it does not necessarily mean a serious threat to other countries. Russia has to spread its military budget for many different purposes and categories such as: research and development of the cutting edge weapons – hypersonative weapons, maintenance of all entities responsible for the deterrence strategy along with the world's largest arsenal of tactical nuclear weapons. Moreover, Russia has to train, equip and maintain one of the largest conventional armies in the world, while the army's activities comprise very vast areas, borders and oceans at the two ends of the huge country. Obviously, it is necessary to discuss and analyze whether defence expenditures ares increasing rapidly enough in NATO European countries in order to take appropriate actions. Such was also the application objective of this paper, to be regarded as a voice in the discussion and put forward for further in-depth research. The authors realize that due to the difficulty of obtaining data, the presented image is only an approximate version.

Abstract

In our paper we present the method of estimating the cost of capital of portfolios characterizing the Polish, EU, US, Japanese and global markets. We introduce the classical CAPM and the three factor Fama-French model. Model tests are run on 252 monthly returns of stocks listed on the markets in the years 1995-2017. The assessed cost of capital refers to the company project portfolio with real options of these projects. Stock returns are generated by the companies implementing projects and real options modifying these projects. Such procedures for estimating the cost of capital may be a valuable tool for large institutional investors to make optimal investment decisions. We use the bootstrap method to estimate the confidence interval of the cost of capital. The cost of capital is assessed for systematic risk estimated at 36, 60, 120 and 180 monthly periods, and for risk premium estimated at all 252 months. The length of the beta estimation period, and the type of model used has little effect on the cost of capital in the case of developed markets. The highest values of the cost of capital are found for the US market portfolio. The lowest values of the cost of capital are found for the Japanese market portfolio. The cost of capital assumes different values and different variability of the results for the Polish market.

Keywords: ICAPM, Cost of capital, Risk premium, Bootstrap method

Introduction

The scientific financial literature provides several basic methods for estimating the cost of capital. Commonly known procedures are the Build-up Model, CAPM applications, expanded CAPM Cost of Capital Formula (see: Pratt, 2002), and the Intertemporal Capital Asset Pricing Model (ICAPM) proposed by Merton (1973). The boundary condition of the applicability of the ICAPM to estimate the cost of capital is limited to companies listed on stock markets. The model proposed by Hamada (1972) attempts to overcome this limitation. The cost of capital can also be estimated by other methods, e.g. the discounted cash flow method or the method based on the yield on company's own bonds with a risk premium (see: Brigham, Gapensky, 2000, p. 260). It should be noted that each method is based on historical returns or capital flows that are extrapolated into the future.

Another methodological assumption is the fact that the above-mentioned methods of estimating the cost of capital use market returns being returns perceived by an external investor.

The presented interpretation of the cost of capital results in the possibility of using CAPM (ICAPM) mainly for the assessment of portfolio managers. In particular, planned investments in characteristic

portfolios built by large institutional investors may be examined. Therefore, the intended investments concerning selected markets can be subject to evaluation.

The estimation of the cost of capital may also apply to individual companies. However, in this case the cost of capital is related to a hypothetical portfolio of investment projects of company as seen by the external investor. Such a portfolio is a combination of undergoing and planned projects, weighted with selected real options. As a consequence, the cost of capital determined in this way can't be considered as a benchmark for the implementation of new company projects but only as an important indicator for the investor. If the investment projects implemented by the company were not influenced by real options, then the sufficient condition for a correct estimation of the cost of capital would be the use of pricing procedure consistent with the CAPM (ICAPM). Causes and consequences of inconsistent pricing in light of the CAPM are presented by Jagannathan and Wang (1996), Berk, Green and Naik (1999) and Bernardo, Chowdry, and Goyal (2007). Zhi, Guo and Jagannathan (2012, p. 205) state that "… the CAPM could work well on the option-adjusted risk premium and beta". The cited Authors propose procedures to modify the relations between options and pricing and construct the option-adjusted beta, and option-adjusted stock returns. The basic condition for the pricing consistent with the CAPM (ICAPM) is generating multifactor-efficient portfolios by the pricing application used (see Fama (1996)). This seems to be in line with Ferson's and Locke (1998), who state that the necessary condition for estimation of the cost of capital using ICAPM is proper estimation of the risk premium which is more important than the estimation of systematic risk. The research of Prat (2002), and Mauboussin and Callahan (2013) show that if the length of the measurement period is shortened, the standard error risk premium estimation increases. Damodaran (2017) states that the risk premium on the US market at the beginning of 2013, depending on the research method, varied in the range of 3.20% to 6.02%. The cited research results support the use of long historical periods. Ibbotson Associates recommends using the entire available historical period.

The existing literature studies of the cost of capital estimation relate primarily to individual companies. Graham and Harvey (2001), and Welch (2008) indicate that the classical and multifactor CAPM are the most popular methods of estimating the cost of capital, while the method of dividend discounts is cited as the least popular. Kozarević and Džafić (2014) use the classical CAPM to estimate the cost of capital of companies listed on the Sarajevo Stock Exchange.

As early as in the 1970s, the research of Fama and MacBeth (1973) shows the compatibility of stock pricing in light of the CAPM for portfolios. It seems advisable to make an attempt to estimate the cost of capital for characteristic portfolios of a given market, see Cochrane (2001, p.445). To our knowledge, there is a lack of thorough literature studies estimating the cost of capital of the characteristic portfolios of selected markets. The results of such research would allow us to direct the portfolio managers to a given characteristic portfolio and a given market. Such studies would enable large institutional investors, in particular investment funds, to take optimal decisions in the field of investment policy.

The aim of our study is to estimate the cost of capital of stock portfolios characterizing the selected markets, using the classical CAPM and the Fama and French (1993) ICAPM pricing application[1]. The study is based on portfolios consisting of stocks listed on the Polish (PL) market and Developed markets such as EU, US, Japanese (JPN) and Global (GL) markets. Our work differs from the methods of risk premium estimation adopted so far. The risk premium is estimated on the basis of two procedures presented in the next section.

The estimation of the cost of capital is also associated with the determination of the error value at the assumed level of significance. Therefore, we use a method to create a confidence interval of the cost of capital. Because the distribution of the cost of capital is unknown, we use the bootstrap method to evaluate its error.[2]

In Section 2 we present the methodologies for estimating the cost of capital using the CAPM and ICAPM applications. Section 3 presents the data and procedures of portfolios construction. Section 4 presents and analyzes the estimated systematic risk and risk premium components, average cost of

capital and its bootstrapped confidence intervals for characteristic portfolios, and statistic test results comparing the values of cost of capital for different boundary conditions for the PL and the tested Developed markets. In the last two sections, we present the Discussion and Conclusions.

Theoretical Model Approaches

The financial form of ICAPM can be expressed as follows:

$$E(r_i) = E(RF) + \sum_{k=1}^{K} \beta_{ik} E(F_k), \quad (1)$$

where β_{ik} is the systematic risk vector of stock *i*, $E(F_k)$ is the expected value of risk premium vector defined as the expected value of factors F_k for the analyzed market, $E(RF)$ is an expected return on a risk free asset, and $E(r_i)$ is the expected return on an analyzed asset.

In the case of CAPM, $E(r_i)$ depends on one factor defined as an excess on market return *RM* over risk free asset. In the case of FF application, $E(r_i)$ depends on well known three factors: *RM-RF*, *HML* and *SMB*.

We use the estimators of $E(RF)$, β_{ik} and $E(F_k)$ to get the value of cost of capital $Ccap_i$ as follows:

$$Ccap_i = \widehat{E(RF)} + \sum_{k=1}^{K} \widehat{\beta_{ik}^T} \widehat{E(F_k)}, \quad (2)$$

where $\widehat{\beta_{ik}^T}$ are systematic risk components for *i* asset estimated using *T* investment periods. We use two procedures to estimate $E(RF)$ and $E(F_k)$.

Procedure 1

The expected returns of $E(RF)$ and $E(F_k)$ are estimated as an arithmetic average of RF_t and F_{kt}, t=1,…,T, according to Eq. (3):

$$\widehat{E(RF)} = 1/T \sum_{t=1}^{T} RF_t \quad (3a)$$

$$\widehat{E(F_k)} = 1/T \sum_{t=1}^{T} F_{kt} \quad (3b)$$

In the case of CAPM:

$$\widehat{E(F_1)} = E(RM - RF) = 1/T \sum_{t=1}^{T} (RM_t - RF_t) \quad (4)$$

while for the FF model:

$$E(F_1) = E(RM - RF) = 1/T \sum_{t=1}^{T} (RM_t - RF_t), \quad (5a)$$

$$E(F_2) = E(HML) = 1/T \sum_{t=1}^{T} HML_t, \quad (5b)$$

$$E(F_3) = E(SMB) = 1/T \sum_{t=1}^{T} SMB_t. \quad (5c)$$

Procedure 2

The corresponding two-pass econometric model is built, according to Eqs. (6) and (7):
In the first pass:

$$r_{it} - RF_t = \beta_{i0} + \sum_{k=1}^{K} \beta_{ik} F_{kt} + e_{it};\ t = 1, \ldots, T;\ \forall i=1,\ldots,m, \quad (6)$$

where F_{kt} is the value of *k* factor model in period *t*.

Once the estimators $\widehat{\beta_{ik}}$ are calculated using (6), then we use them to get the estimator $\widehat{\gamma_k}$ of the parameter γ_k using the following second pass equation:

$$r_{it} = \gamma_0 + \sum_{k=1}^{K} \gamma_k \widehat{\beta_{ik}} + e_{it};\ t = 1, \ldots, T;\ i=1,\ldots, m \tag{7}$$

The estimated values of γ_0 and γ_k are estimators of the expected returns of $E(RF)$ and $E(F_k)$ according to Eqs (8) and (9):

$$\widehat{E(RF)} = \widehat{\gamma_0} \tag{8}$$

$$\widehat{E(F_k)} = \widehat{\gamma_k} \tag{9}$$

The estimator $\widehat{\beta_{ik}^T}$ in equation (2) is obtained from the following equation:

$$r_{it} = \beta_{i0}^T + \sum_{k=1}^{K} \beta_{ik}^T F_{kt} + s_{it};\ t = 1, \ldots, T;\ \forall i=1,\ldots,m. \tag{10}$$

In order to assess the accuracy of cost of capital estimation we use bootstrap methods by bootstrapping the residuals of models (3a,3b), (4), (5a,5b,5c), (6), (7) and (10).

Data and model digitization

We evaluate the cost of capital using the CAPM and FF model. We analyze 252 monthly returns of the stocks listed on the US, EU, JPN, GL and PL markets in 1995-2017, and characterized by their positive book value. We estimate the cost of capital for 25 Fama-French characteristic portfolios for the examined market. The portfolios are formed in two directions on book value (*BV*) to market value (*BM*) and capitalization (*Size*) at the end of the month of the previous quarter. The quintile portfolios are formed on *BM*. Those portfolios, in turn, are divided into other quintiles formed using the *Size* calculated for each stock company. *BM* and *Size* for portfolios are arithmetic means of these functions of various portfolio securities. Returns on given portfolios are average stock returns weighted by market capitalizations.

Finally, we calculate the average estimated cost of capital of 25 portfolios, weighted linearly. Such a procedure is used for each market.

The return and model factor values for the Developed markets are taken from the Kenneth R. French-Data Library.[3] All returns are calculated on the basis of prices in US dollars, and include dividends and capital gains. Market return *RM-RF* is the return on a region's value weighted market portfolio minus the US one month T-bill rate.

The factors of CAPM and FF model are calculated in the case of the Polish market. The data for defining the stock return, *BV* and *Size* of the Polish market are provided by the Warsaw Stock Exchange (WSE). The monthly value weighted portfolio returns, as well as the factor values are calculated on the basis of prices in the Polish currency, and include dividends and capital gains. Market return *RM-RF* is the return on the Index of the WSE (WIG) minus the Polish one month T-bill rate.

The expected value of risk premium vector $E(F_k)$ and the expected return of risk free asset $E(RF)$ are estimated from the entire historical period.

If Procedure 1 is used $\widehat{E(RF)} = 1/252 \sum_{t=1}^{252} RF_t$ and $\widehat{E(F_k)} = 1/252 \sum_{t=1}^{252} F_{kt}$.

If procedure 2 is used, systematic risk β_{ik} and risk premium components γ_k are estimated on the basis of the two-pass econometric model using 252 months. The regression parameters are estimated using GLS method according to the Prais–Winsten procedure where first-order autocorrelation of the residual components is taken into account. The heteroscedascity of residuals is justified by the transformation of variables. The errors-in-variables are corrected by Shanken's (1992) statistic.

Researchers recommend different periods of beta estimation. In the case of cost of capital assessment we use regression (10) to estimate betas from 36, 60, 120 and 180 last months. The period of 60 months is most often appropriate (see: Prat, 2002, p. 82). However, due to observable extended business cycles in the last two decades we pay more attention to betas estimates from the last 60 and 120 months.

Results and their Analysis

In Table 1 we show the values of the bootstrapped beta components estimated for the PL, EU, US, JPN and GL markets by the CAPM and FF model.

The medians of $\widehat{\beta_{\iota M}}$ and $\widehat{\beta_{\iota,SMB}}$ components are the highest for the US market, and the lowest for the PL market. The medians of $\widehat{\beta_{\iota,HML}}$ are the highest for the US market, and the lowest for the GL market.

If the Polish market is analyzed, the differences between the maximum and minimum beta values, estimated on the basis of 36, 60, 120 and 180 monthly periods, are 0.47 for $\widehat{\beta_{\iota M}}$, 0.03 for $\widehat{\beta_{\iota,HML}}$, and 0.25 for $\widehat{\beta_{\iota,SMB}}$. If Developed markets are analyzed, the differences between the maximum and minimum beta values range from 0.02 to 0.09 for $\widehat{\beta_{\iota M}}$, from 0.02 to 0.04 for $\widehat{\beta_{\iota,HML}}$, and from 0.01 to 0.05 for $\widehat{\beta_{\iota,SMB}}$. The differences between the maximum and minimum beta values, estimated on all the tested markets range from 0.27 to 0.71 for $\widehat{\beta_{\iota M}}$, from 0.15 to 0.16 for $\widehat{\beta_{\iota,HML}}$, and from 0.28 to 0.55 for $\widehat{\beta_{\iota,SMB}}$.

Notes: This table presents the average medians of bootstrapped systematic risk components (β) of 25 Fama-French portfolios estimated using 60, 120, 180 last months. The median of risk using 36 last months are available from the Authors on request. The Polish (PL), EU, US, Japanese (JPN) and Global (GL) markets are analyzed. The medians, and confidence intervals are calculated using the bootstrap distributions with 5000 iterations. Max[a] – differences between the maximum and minimum beta values, estimated on all the tested markets on the basis of 36, 60, 120 and 180 monthly periods, Max[b] – differences between the maximum and minimum beta values, estimated on a given market on the basis of 36, 60, 120 and 180 monthly periods. 1996-2016, 252 months.

The above results indicate more stable values of systematic risk components in the Developed markets. However, the length of the estimation period has the greatest impact on the risk component due to market portfolio, $\widehat{\beta_{iM}}$.

In table 2 we show the risk premium components for the Polish and Developed markets estimated using two procedures explained in Section 2.

The risk premium $E(\widehat{RM-RF})$ estimated for the Polish market by Procedure 1 is negative, and equal to -0.80% monthly with corresponding *p*-value 6.79%. On the other hand, the risk premium $\widehat{\gamma_M}$ estimated by Procedure 2, both by the CAPM and FF model is positive (however statistically equal to zero) end equal to 2.11% and 2.58% with corresponding *p*-values 18.39% and 15.67%, respectively.

The risk premium $E(\widehat{RM-RF})$ estimated for the US market (by Procedure 1) is positive, and equal to 0.60% monthly with corresponding *p*-value 3.56%. The risk premium $E(\widehat{RM-RF})$ estimated for JPN, GL and EU markets is statistically equal to zero and ranges from 0.05% to 0.51%. The risk premium $\widehat{\gamma_M}$ estimated for Developed markets (by Procedure 2), both by the CAPM and FF model (except GL market and the CAPM estimation) is also statistically equal to zero.

FF	-1.14 (26.58)	0.47 (9.40)	0.30 (6.38)	0.38 (1.58)	0.06 (64.37)	0.03 (81.36)	2.14 (0.35)	2.83 (0.00)

Notes: This table presents risk premium components estimated by two procedures: 1) $E(\widehat{RM-RF})$, $E(\widehat{HML})$, $E(\widehat{SMB})$ - as an arithmetic average of factor components, and 2) $\widehat{\gamma_M}$, $\widehat{\gamma_{HML}}$, $\widehat{\gamma_{SMB}}$ - in the second pass CAPM and FF regression using the panel returns on 25 portfolios sorted by BM and capitalization (Size). The corresponding p-values appear in brackets. The Polish (PL), EU, US, Japanese (JPN) and Global (GL) markets are analysed. RF_t is the 91-day Polish T-bill rate for Polish market, and the US one month T-bill rate for the Developed markets. GRS-F is F-statistic of Gibbons et al. (1989) and its corresponding p-value indicated below in brackets. $Q^A(F)$ reports F-statistic and its corresponding p-value, for Shanken's (1985) test that the pricing errors in the model are jointly zero. The errors-in-variables are corrected by Shanken's (1992) statistic. The Prais-Winsten procedure for correction of first-lag autocorrelation is used. The heteroscedascity of residuals is justified by transformation of variables. 1996-2016, 252 months.

Zero or negative values of the risk premium $\widehat{\gamma_M}$ estimated by the CAPM prove the incorrect model specification for a given market, whereas zero or negative values of $\widehat{\gamma_M}$ estimated by the FF model do not contradict the ICAPM assumptions, and prove the priority impact of risk premium due to *HML* and *SMB* factors (see: Fama, 1996, 463-464).

The risk premiums due to *HML* and *SMB* estimated by both procedures assume similar values on all the tested markets.

The risk premium due to *HML* assumes the highest positive values (above 2% with corresponding *p*-values below 0.16%) for the Polish market. Also, the risk premium due to *HML* assumes positive values for the EU, JPN and GL markets, equal to about 0.38%, 0.38% and 0.34%, respectively, with corresponding *p*-values from 1.57% to 9.14%. The risk premium due to *HML* for the US market is positive but insignificantly different from zero, equal to 0.24%.

The risk premium due to *SMB* assumes insignificant and close to zero values for all tested markets.

The portfolios closest to the multifactor-efficient portfolios are generated by the FF model only for the JPN market. The GRS-*F* and $Q^A(F)$ statistics are small at 1.01 and 1.13, respectively, with *p*-values of 45.45% and 31.52%, respectively.

In table 3 we show the average bootstrapped medians and confidence intervals of the cost of capital for 25 Fama-French portfolios estimated by the CAPM and FF model.

Tab. 3: Average percentage cost of capital (*Ccap*) for 25 Fama-French portfolios estimated for the Polish and chosen Developed markets by the CAPM and FF model

Notes: This table presents the average bootstrapped median and confidence intervals of the cost of capital for 25 Fama-French portfolios estimated by the CAPM and Fama-French (FF) model. The Polish (PL), EU, US, Japanese (JPN) and Global (GL) markets are analyzed. The widths of corresponding 95% confidence intervals appear in brackets. $\widehat{\beta_{\iota M}}$, $\widehat{\beta_{\iota,HML}}$ *and* $\widehat{\beta_{\iota,SMB}}$ *are the loadings on the market factor and HML and SMB factors estimated from the first-pass time-series regressions. The bootstrap distributions are determined with 5000 iterations; 1996-2016, 252 months.*

Figure 1 shows the graphic distribution of medians and confidence intervals assessed cost of capital for beta estimations from last 120 months.

In table 4 we show *p*-values of normality statistic of the bootstrapped *Ccap* using 60 and 120 last month periods (from the whole period of 252 months) for beta estimation. Table 4 also shows the results of Wilcoxon rank sum test examining the equality of bootstrapped medians of *Ccap* using betas estimated from 60 and 120 periods (hereafter denoted as β_{60} and β_{120}).

a)

b)

Figure 1: Average percentage cost of capital for 25 Fama-French portfolios estimated for the Polish and chosen Developed markets by the Fama-French model a) and CAPM b)

Notes: The figure shows the cost of capital bootstrapped medians and 95% confidence intervals (marked by vertical sections) for Polish (PL), Japanese (JPN), global (GL), EU and US markets. Beta components are estimated using 120 last months. The bootstrap distributions are determined with 5000 iterations.

Two procedure are used. 1996-2016, 252 months.

Procedure 1

Fama-French: $Ccap_i = E\widehat{(RF)} + E(\widehat{RM - RF})\widehat{\beta_{iM}} + E(\widehat{SMB})\widehat{\beta_{i,HML}} + E(\widehat{SMB})\widehat{\beta_{i,SMB}}$

CAPM: $Ccap_i = E\widehat{(RF)} + E(\widehat{RM - RF})\widehat{\beta_{iM}}$

Procedure 2 II pass econometric model

Fama-French: $Ccap_i = \widehat{\gamma_0} + \widehat{\gamma_M}\widehat{\beta_{iM}} + \widehat{\gamma_{HML}}\widehat{\beta_{i,HML}} + \widehat{\gamma_{SMB}}\widehat{\beta_{i,SMB}}$

CAPM: $Ccap_i = \widehat{\gamma_0} + \widehat{\gamma_M}\widehat{\beta_{iM}}$

Notes: This table presents the p-values of chosen statistic tests of the average bootstrapped distribution of the cost of capital for 25 Fama-French portfolios estimated by the CAPM and Fama-French (1993) FF model. The bootstrap distributions are determined with 5000 iterations; NSW – Shapiro-Wilk normality test, Tmed – Wilcoxon rank sum test, 1996-2016, 252 months.

Discussion

In order to estimate the confidence interval for the cost of capital we use the bootstrap method. As a result we get that differences between the maximum and minimum β_M and β_{SMB} bootstrapped medians (estimated on the basis of 36, 60, 120 and 180 months) are the largest for the Polish market, and several times higher than for the Developed markets. These results indicate the stability of all risk components on the Developed markets and the instability of risk components β_M and β_{SMB} on the Polish market in 1996-2016.

The risk premium is one-dimensional due to the *HML* factor, and insignificant due to the *RM* and *SMB* for the PL, EU, JPN and GL markets. All the components of the risk premium are insignificant for the US market. The risk premium due to the *HML* assumes the highest positive values (above 2% monthly) for the Polish market. The risk premium due to the *HML* is several times lower for the EU, JPN and GL markets (about 0.38% monthly).

The analysis of Ccap on the Developed market

The bootstrapped medians of *Ccap* estimated by two Procedures assume similar values. However, assessed 95% confidence intervals are many times wider if Procedure 1 is used (see Tab. 3 and Fig. 1). It means that the application of Procedure 2 made it possible to estimate the *Ccap* with higher accuracy.

It is interesting to note that the length of the beta estimation period has little effect on the "nominal values" of the bootstrapped *Ccap* (see Tab. 3).[4] However, (due to different widths of the confidence intervals) the bootstrapped medians of *Ccap* estimated using the β_{60} and β_{120} are significantly different at the level of about 0.00% (for all the tested markets and the both Procedures, and the CAPM and FF model, see Tab. 4).

Interestingly the "nominal values" of bootstrapped *Ccap* estimated by the CAPM and the FF model are similar (see Tab. 3 and Fig. 1) – despite the incorrect specification of the CAPM and generating multifactor-efficient portfolios only on the JPN market, and only using the FF model (as evidenced by the data in Tab. 2). However, the bootstrapped medians of *Ccap* estimated by the CAPM and the FF model are significantly different at the level about 0.00% (for all the tested markets and both procedures, and the CAPM and FF model).[5]

The highest "nominal values" of the bootstrapped medians of *Ccap* are found for the US market portfolio. If Procedure 1 is used the *Ccap* is equal to about 10.34% yearly for the CAPM and 11.53% for the FF model with the confidence interval of about 15.38% and 15.67%, respectively (average for all tested periods of beta estimation). If Procedure 2 is used, the *Ccap* is equal to about 11.64% for

the CAPM and 11.54% for the FF model with the confidence interval of about 2.76% and 1.32%, respectively (see Tab. 3).

If Procedure 1 is used the *Ccap* for the EU market portfolio is equal to about 8.06% for the CAPM and 9.12% for the FF model with the confidence interval of about 14.90% and 15.36%, respectively. If Procedure 2 is used the *Ccap* is equal to about 9.24% for the CAPM and 9.07% for the FF model with the confidence interval of about 1.37% and 0.86%, respectively (see Tab. 3).

If Procedure 1 is used the *Ccap* for the GL market portfolio is equal to about 7.87% for the CAPM and 8.28% for the FF model with the confidence interval of about 13.25% and 13.68%, respectively. If Procedure 2 is used the *Ccap* is equal to about 8.26% for the CAPM and 8.21% for the FF model with the confidence interval of about 1.49% and 0.74%, respectively (see Tab. 3).

The lowest "nominal values" of the bootstrapped medians of *Ccap* are found for the JPN market portfolio. If Procedure 1 is used the *Ccap* is equal to about 2.81% yearly for the CAPM and 3.70% for the FF model with the confidence interval of about 14.54% and 16.27%, respectively. If Procedure 2 is used, the *Ccap* is equal to about 4.15% for the CAPM and 3.77% for the FF model with confidence interval of about 2.06% and 1.37%, respectively (see Tab. 3).

The analysis of Ccap on the Polish market

The "nominal values" of bootstrapped medians of *Ccap* for several beta estimation periods are negative, and confidence intervals are wide (about 22%). The positive "nominal values" of bootstrapped medians of *Ccap* are estimated with several times narrower confidence intervals (about 5% for Procedure 2 and about 11% for Procedure 1). It can be assumed that the negative median values result from large errors in the estimated cost of capital, which may result in a lack of multifactor efficiency of the generated portfolio (see Tabs 2 and 3).

The medians and confidence intervals of estimated cost of capital by two Procedures are different from each other. Also, the length of the beta estimation period has a major impact on the estimated cost of capital.

The bootstrapped medians of *Ccap* estimated using the β_{60} and β_{120} are significantly different at the level of about 0.00% for the CAPM and FF model (see Tab. 4).

Similarly to the Developed markets, the "nominal values" of bootstrapped *Ccap* estimated by the CAPM and the FF model are similar (see Tab. 3). However, the bootstrapped medians of *Ccap* estimated by the CAPM and the FF model are significantly different at the level of about 0.00%.[6]

The estimated cost of capital, using the CAPM or ICAPM discretized by market returns, is related to a hypothetical portfolio of investment projects as seen by the external investor. According to the proposed procedure, the estimated cost of capital, according to the above-quoted statement by Prat (2002, p. 185), may be a valuable indicator for portfolio managers. However, such an estimate of the capital cost cannot be considered as a benchmark for making decisions regarding new investment projects of stock companies.

Conclusions

Our work leads to the following conclusions related to the estimation of the cost of capital:

Developed Markets

1) The cost of capital estimated by both Procedures assumes similar values. The using of the two-pass econometric model (Procedure 2) made it possible to estimate the cost of capital with higher accuracy than in the method defined by Procedure 1.

2) The length of the beta estimation period, and the type of model used (CAPM or FF) has little effect on the cost of capital.
3) The highest values of the cost of capital are found for the US market portfolio (about 10.34% and 11.53% yearly for the CAPM and FF model, respectively – for Procedure 1, and 11.64% and 11.54% yearly for the CAPM and FF model, respectively – for Procedure 2).
4) The lowest values of the cost of capital are found for the JPN market portfolio (about 2.81% and 3.70% yearly for the CAPM and FF model, respectively – for Procedure 1, and 4.15% and 3.77% yearly for the CAPM and FF model, respectively – for Procedure 2).

Polish Markets

5) The cost of capital estimated by both Procedures assumes different values. The reason may be a greater impact of the beta estimation period on the cost of capital of 25 FF portfolios, compared to the Developed markets
6) If Procedure 2 is used, the values of cost of capital estimated by the CAPM and the FF model are similar.
7) If Procedure 2 is used and betas are estimated from 120 or 180 months the cost of capital medians are positive and equal to about 0.36% – 0.48% yearly, assuming the widths of corresponding 95% confidence intervals of about 5%.
8) The negative values of bootstrapped median of confidence interval result from a large error in the estimated cost of capital (assuming the widths of 95% confidence intervals of about 22%) and do not represent the cost of equity capital of companies' projects.

Overeducation Among Highly-Educated Employees in Poland

Anna BEBEL

Wroclaw University of Economics and Business, Wroclaw, Poland
anna.bebel@ue.wroc.pl

Abstract

This paper presents the issue of overeducation affecting highly-educated employees on the Polish labor market. It analyzes the risk of occupational mismatches according to age, gender, place of residence, economy sector and size of the company, form of employment, field of study, and other factors. Statistical methods were used (descriptive statistics and logistic regression). In this study, a logistic regression model was used to estimate the probability of overeducation for different independent variables. Although the percentage of overeducated women was lower than that of men, more factors affected the risk of occupational mismatches among women. Factors such as: sector and job position, part-time work, and the time spent looking for the first job of over a year proved to be significant for the risk of overeducation.

Keywords Overeducation, Labor Market, Logistic Regression.

Introduction

Poles want to be educated. They associate higher education with a better job, higher wages, and greater employment stability in the future. Higher education in Poland is steadily increasing (in 2000, 12.5% people aged 25–34 had higher education, in 2006, the share was 24.7%, and in 2016, it grew to as much as 44.6%). A survey conducted among people aged 15–64 (European Commission) found that for persons older than 15 years, the percentage amounted to 7.4% in 1996, 13.9% in 2006, and 22.8% in 2016. However, a larger number of educated employees can lead to a phenomenon called *overeducation*, i.e., the need to work in positions below one's level of education. Although the rate of unemployment among people with higher education is low in Poland – 3% in 2016 (LFS, 2017) – it is important to also analyze such factors as the level of occupational mismatches with respect to the situation of such people on the labor market.

There are several important issues to address in the context of such mismatches. How important is the problem of overeducation for the Polish labor market is and who is particularly at risk of it? Does occupational mismatches vary across regions? What other questions related to the dynamics of overeducation should be asked? The aim of this paper is to identify the correlates of educational mismatches on the Polish labor market. There is no single theory of overeducation. Some authors have proposed to consider overeducation in the context of semi-formal economic models (Freeman 1976, McMillen et al., 1999). There have been also several proposals on how to theoretically explain overeducation. The most important are the human capital theory (Becker, 1962), job competition theory (Thurow, 1972), signaling theory (Spence, 1973), job assignment model (Roy, 1951; Tinbergen, 1956) developed by Hatrog (1977) and Sattinger (1993), and the theory of skill heterogeneity (Green and McIntosh, 2007). A new explanation was proposed by Bulmahn and Kräkel (2002), according to whom employers hire higher-educated people (than needed) to avoid a breakdown of the production process, as such workers are more capable of improvisation. Recent theories also characterize overeducation from a sociological perspective as a new form of labor market stratification (Caspada-Munsech, 2017).

Studies on overeducation pay more attention to return estimates (including the effect of overeducation on wages) than to the potential causes of the problem. It has been shown that working below one's skill level may have a negative impact on wages (with exception of results achieved by Groot and van den

Brink (2000)), productivity and job satisfaction (Allen and van der Velden, 2001; Fleming and Kler, 2008; Green and Zhu, 2010; Mavromaras, Mcguinness and Fok, 2009; Mavromaras, Sloane and Wei, 2015; Peiro, Agut, and Grau, 2010; Verhaest and Omey, 2010; Wincenciak, 2016).

The latest works in the field of overeducation focus, among others, on the incidence of and factors influencing occupational mismatches, especially with respect to the characteristics of overeducated employees. Research indicates a correlation between occupational mismatches and gender and family status. Married women are more at risk of being overeducated (Büchel and van Ham, 2003). Similar results for the Polish labor market are presented by Baran (2016), whereas other authors indicate that women in Poland seem to be less prone to being overeducated than men (Kucel and Vilalta-Bufi, 2012, Kiersztyn, 2013). Nevertheless, there is a lack of recent research in this area, and the issue of overeducation is worth updating, as more and more women take up and complete university studies and use the acquired qualifications on the labor market.

Studies also indicate that one of the disadvantaged groups are young workers, especially those with tertiary education (Dekker, de Grip and Heijke, 2002; Frei and Sousa-Poza, 2012; Vahey, 2000). Research also indicates the importance of completed degrees and the level of education. In many countries, technical and scientific degrees lead to a lower risk of overeducation than humanistic and social sciences degrees (Barone and Ortiz, 2011; Ortiz and Kucel, 2008; Reimer, Noelke, and Kucel, 2008). In Poland, different studies yield different conclusions: some have similar results (Baran 2016), while other studies indicate the opposite effect, with technical degrees leading to a higher risk of overeducation than social sciences (Kucel and Vilalta-Bufi, 2012). Employees with a master's degree are less exposed to occupational mismatches than those with a bachelor's degree (Barone and Ortiz, 2011). One of the more interesting studies also shows a relationship between the business cycle and the scale of overeducation (Assirelli, 2015; Di Pietro, 2002; Verhaest and van der Velden, 2013). This thread is becoming particularly relevant in the current period of recession that is affecting the global economy.

Gaps in research related to overeducation indicated in the subject literature include individual, contextual, and structural factors that can affect the probability of overeducation among employees (Caspada-Munsech, 2017). The article presents the development of research on the causes of overeducation and the correlations between individual factors and factors related to the labor market and the risk of overeducation and is an attempt to fill the aforementioned research gap. The article is also a contribution to the discussion concerning overeducation on the Polish labor market, because there is no unanimity regarding the relationship between overeducation and gender, field of study, and spatial diversity.

Different methods for measuring overeducation can be used, primarily (Overeducation in Europe…, 2003):

1) Objective measure – involving a systematic job evaluation (comparing the employee's level of education with the level required for a given position);
2) Subjective measure – in which respondents assess the level of education and training needed to apply to or work at a given position;
3) Empirical method – a person is perceived as overeducated if his or her level of education is more than one standard deviation higher than the mean for a given position.

It should be noted, however, that all of the above-mentioned methods lead to similar results (McGuinness, 2006; Sloane, 2003). In this paper, overeducation was assessed using the second of the three methods, which resulted from the availability of survey results containing a subjective assessment of occupational mismatch (which, taking into account the similar results provided by all the methods, justifies the choice of such a method).

Method

Descriptive statistics primarily refers to two factors that are considered to be important in the context of occupational mismatch, i.e., gender and field of education. Two types of overeducation, formal and actual, are considered. Formal overeducation refers to the formal requirements associated with applying for the position held. Actual overeducation means the level of education actually required for this position. A person is considered as overemployed if the level of education required for a given position is lower than his or her education.

The socioeconomic distribution of overeducation in 2016 was analyzed using logistic regression on a sample of working respondents with higher education. The logit model is a special case of the generalized linear model (McCullagh, Nelder, 1989). Binary logistic regression is used to explain the dichotomous qualitative variable Y depending on the level of exogenous variables X_1, X_2, ..., X_n (qualitative or quantitative). The explained variable is usually represented by a zero-one variable and takes the value of 1 if the event occurred or 0 if the event did not occur (Agresti, 2002).

Dependent Variable

The model can be written as:
$Y^*_i = X'_i \beta + \gamma OED_i{-}1 + c_i + u_i$,
where i denotes the individual, OED_i is a binary variable which takes the value of 1 for those respondents who are overeducated and 0 for those respondents who are well-matched, X'_i is a vector of explanatory variables, c_i is an individual-specific measure of unobserved heterogeneity, and u_i is an error term.

Independent Variables

The use of logistic regression helped to find the statistically significant predictors of the risk of overeducation. The following qualitative predictors were analyzed: family status (marital status and having children), the age of the youngest child under 3 years old, place of residence (voivodship, rural or urban areas), field of study completed by each respondent, level of higher education (Bachelor or Master degree), size and sector of the company, position held in the company, part-time job, form of employment, period of unemployment, period of looking for the first job, and type of employment contract). These variables were introduced to the model using zero-one variables. One of the quantitative variables was the number of children. The variable age was taken into account in two ways:

1) As a categorized variable – three age categories have been distinguished (25–31, 32–38, and 39–45 years), represented in the model by two zero-one variables (the youngest age group, 25–31 years, became the reference group)
2) As a continuous variable minus 25 (in this case, 25-year-olds formed the reference group).

The use of the logistic regression model should help to find answers to potential research questions, including:

- Do employers have greater educational requirements towards younger employees?
- Does living in rural areas increase the risk of occupational mismatches?
- Is below-qualifications employment is more likely among the graduates of specific fields (e.g. artistic, humanities) with the same level of formal education?

The empirical data used in this paper come from a wider study carried out as part of the project "Resourcefulness of Polish Families" at the Wroclaw University of Economics and Business in 2016. The survey was conducted on a randomly selected nationwide sample of Poles with higher education (at least a bachelor's degree). A total of 902 interviews using the CAPI technique were carried out. The study selected a random sample of households, stratified with proportional allocation, and representative by age, gender, and place of residence.

The sample was divided into three sub-samples, i.e.:

a) Sub-sample A: respondents aged 39–45 years (301 interviews);
b) Sub-sample B: respondents aged 32–38 years (300 interviews);
c) Sub-sample C: respondents aged 25–31 years (301 interviews).

The criterion for selecting such a research sample was the desire to analyze the situation on the labor people of people who began their studies during the political transformation in Poland (after 1989), which brought changes in the educational and professional possibilities of Poles. New career paths appeared along with negative phenomena – not only unemployment, but also employment below one's desired working time or below one's qualifications. Cohorts were distinguished based on shared educational and professional experience acquired by adults since 1990.

Results

Descriptive Statistics

The risk of overeducation should be strongly related to the field of study that the graduate has completed also (depending on the profession) the graduate's gender. Table 1 presents the range of overeducation according to gender.

Table 1: Incidence of overeducation among highly-educated employees aged 25-45 years according to gender (own calculations)

	Total	**Men**	**Women**
Overeducation in the first job (formal)	50.9 (0.017)	48.4 (0.027)	52.6 (0.022)
Overeducation in the first job (actual)	48.3 (0.017)	48.1 (0.027)	48.4 (0.022)
Overeducation in the present job (formal)	39.4 (0.017)	42.2 (0.027)	37.5 (0.021)
Overeducation (actual) in the present job	41.5 (0.017)	44.4 (0.027)	39.7 (0.022)

Notes: *Standard errors are indicated in parentheses.*

The level of overeducation is higher for the first job than at the later stages of one's professional career. For the first job, however, the level of formal overeducation is higher than that of actual overeducation. The opposite is true for the current job: actual overeducation is higher than formal overeducation. Interestingly, in the case of the first job, the level of overeducation is higher among women than men. The opposite is true for the current job, where the percentage is higher for men. This means that women more often than men start working below their level of education; however, over time, their professional situation improves, and they achieve positions consistent with their education (a change by 9 and 14 percentage points for formal and actual overeducation, respectively). For men, this change is less significant, with the level of overeducation decreasing by 4 and 6 percentage points for formal and actual overeducation, respectively.

The field of completed studies also seems important for the level of overeducation. Table 2 presents the level of overeducation according to field of study and gender. The lowest occupational mismatches appear, for both men and women, among employees with a degree in Law, while the highest mismatches appear among those with a degree in Arts (for women) and Other degree (e.g., Physical Education; for men). Furthermore, about half of employees with a Technical degree worked below their qualifications (this rate was higher for men). This phenomenon was similar among employees with a degree in Economics. However, the situation was different among graduates of other social sciences universities. In their case, a smaller proportion of men than women remained overeducated. Overall, overeducation affects men more than women.

Table 2: Overeducation in Poland according to field of study and gender (%) (own calculations)

Field of study	Overeducation (formal)			Overeducation (actual)		
	Total	**Men**	**Women**	**Total**	**Men**	**Women**
Humanities (excluding Law)	35.2 (0.04)	36.0 (0.07)	34.7 (0.06)	36.9 (0.04)	32.0 (0.07)	40.3 (0.06)
Law	17.6 (0.1)	0.00 (0.00)	27.3 (0.14)	17.6 (0.1)	16.7 (0.17)	18.2 (0.12)

Technical	48.0 (0.04)	54.3 (0.06)	44.5 (0.04)	49.5 (0.04)	55.7 (0.06)	46.1 (0.04)
Natural and Agricultural Sciences	42.9 (0.09)	41.7 (0.15)	43.5 (0.11)	45.7 (0.09)	41.7 (0.15)	47.8 (0.11)
Other (e.g. Physical Education)	66.7 (0.11)	80.0 (0.2)	62.5 (0.13)	66.7 (0.11)	80.0 (0.2)	62.5 (0.13)
Total	39.4	42.2 (0.03)	37.5 (0.02)	41.5	44.4 (0.03)	39.7 (0.02)

Notes: *Standard errors in parentheses.*

Overeducation (formal): Less than higher education is required at a given position (based on the respondents' answers)
Overeducation (actual): Actual level of education required at a given position, less than higher education (based on the respondents' subjective assessment)

Logistic Regression Results

Factors that may affect mismatch on the labor market include:

1) Individual and family features (such as age, family situation, place of residence, or field of education);
2) Characteristics of the current workplace (sector and size of the company, position held, working time);
3) History of employment (characteristics of the first job – time spent looking for it, type of employment contract, the longest unemployment period).

Many of the previously mentioned predictors (such as age, field of education, level of higher education, family situation, length of unemployment, employment contract in the current and first job, and company size) were found to be insignificantly correlated with the dependent variable and were not included in the model (using the Method of Forward Stepwise in SPSS). For the place of residence, only the distinction between urban and rural and Masovian Voivodeship (including, in particular, Warsaw) as the place of residence was found to be a significant predictor in the model. Table 3 presents the risk of occupational mismatches depending on selected factors broken down by gender.

Notes: *SE – standard error; *** p<0,01 ** p<0,05 * p<0,1*

A. Directors, senior government officials, and management staff (managers, heads, and team leaders)
B. Specialists and free professions/freelancers (e.g., doctors, lawyers, artists, teachers, and chief accountants)
C. Office workers (e.g., secretaries, primary level officials, and accountants)
D. Traders, insurance agents, sellers, and waiters
E. Employees of uniformed services (e.g., soldiers, policemen, firemen, and customs officers)
F. Other physico-mental workers (e.g., nurses, drivers, couriers, hairdressers, and beauticians)
G. Physical workers.

For women, the correlation between the place of residence and overeducation was significant. Living in a city reduces the risk of occupational mismatches by almost 60% for formal and over 50% for actual

overeducation. The effect is similar for living in the capital (risk reduced by almost 70%). Interestingly, no such effect occurred for men. For women, overeducation is also strongly associated with part-time work. Such work increases the probability of occupational mismatch four times. However, there is no such correlation for men.

For men, on the other hand, the impact of the length of time spent looking for their first job is significant. If the time is over 12 months, the risk of overeducation increases by about 200%. The sector in which a person works is also significant. Working in the private sector has a significant negative effect on the probability of being overeducated compared to the public sector (public enterprises and state and local government units). This effect is much stronger for men than for women: the probability increases more than two times higher for women and three times higher for men (for actual overeducation). Working in educational, financial and IT services reduces the risk of overeducation by up to 80%. Physical work is associated with a significantly higher risk of overeducation among both women and men (up to nineteen times higher), while for women, working in a free profession or as a specialist reduces it (by over 80%).

Research results do not support the hypothesis that employers have greater educational requirements towards younger employees, since age did not prove to be a factor significantly affecting the risk of overeducation. There is a certain relationship between field of study and the level of overeducation, but this relationship proved to be insignificant in the logistic regression model. However, this problem is worth analyzing further using other methods. In fact, living in a rural area increases the risk of overeducation compared to other places of residence.

Conclusions

The Polish labor market seems extremely attractive to people with higher education. This belief is present among parents who wish for their children to complete university studies, and manifests itself through a very low unemployment rate among this group of employees. However, despite such benefits, higher education on the labor market may be associated with overeducation, i.e., the need to work at a position below someone's level of education. Overeducation can be considered as a significant problem among people with higher education, especially taking into account that about 40% of them think that they work below their education.

A certain relationship between the completed field of study and the level of overeducation is noticeable (although it did not prove significant in the model). Overeducation does not particularly vary across regions, although living in the Mazowieckie Voivodship stands out from the rest of the country as a factor that reduces the risk of occupational mismatch. The study seems to confirm the observations made in other countries, including Switzerland (Frei and Sousa-Poza (2012)), that overeducation is not age-related (it does not decrease with the age of the employee); rather, employees of all ages are at risk of overeducation. The family situation (relationship, number and age of children, etc.) also had no significant impact on the risk of occupational mismatch, nor did the longest period of unemployment and the form of employment (in the first and current job) or the size of the company. On the other hand, factors such as sector and job position, part-time work, and the time spent looking for the first job of over a year proved to be significant. However, more variables were significant for overeducation among women than men. Although the percentage of overeducated women was lower than that of men, more factors affected the risk of overemployment among the former.

Among the particularly vulnerable to overeducation are rural residents, employees in the private sector and long-term job seekers. The important issues that should be analyzed further in the context of overeducation include determining the source of differences in factors influencing overeducation among men and women, the reasons for the greater sensitivity of women to particular factors or the situation of immigrants and their offspring on the Polish labor market (as in Poland this is a dynamically developing phenomenon, especially in recent years). Another subject worth researching is whether the level of overeducation will increase in Poland due to the recession caused by the events in recent months (Covid 19 pandemic).

Acknowledgment

The project is financed by the Ministry of Science and Higher Education in Poland under the programme "Regional Initiative of Excellence" 2019 - 2022 project number 015/RID/2018/19 total funding amount 10 721 040,00 PLN.

Acquiring New Customers and Gaining Their Loyalty in Online Enterprises

Anna PADLOWSKA

Częstochowa University of Technology, Częstochowa, Poland
E-mail: anna.padlowska@pcz.pl
ORCID: 0000-0002-2631-1371

Abstract

The purpose of this paper is to present the possibilities of acquiring new customers and gaining their loyalty in online enterprises. The author attempts to identify the most useful tools to acquire and maintain customers. The online market is very difficult for contemporary enterprises, as it involves many challenges. Meeting the expectations of contemporary customers is difficult, but also beneficial, which makes it worth trying and gaining as many benefits as possible. The article uses questionnaire surveys that were conducted using the Internet and aimed to show the number of people shopping online and to show the tools needed for acquire and retain customers in online enterprises. 50 respondents from all over Poland took part in the survey. According to the survey, 77.5% of Poles over 15 years old shopping online in Poland. According to the respondents participating in the research, the main tool used to acquire and retain customers in online enterprises, is clear and well-prepared website of the company, advertising on local and social portals, whisper marketing, opinions about the company and its products on the internet portals. It should also be mentioned that the conducted research did not exhaust the topic and are a good basis for the further research.

Keywords: customers, managing in online enterprises, modern technologies, online shopping

Foreword

The contemporary methods of acquiring and maintaining customers are improving and becoming easier to apply. The Internet is a place of economic activity, both for commerce (sales and auctions) and services (online banking and insurance). It should be noted, however, that customers have access to an unlimited selection of goods and services. Online shopping has become very common and convenient for customers. The ability to apply the latest technologies to search for attractive products is very useful in meeting the increasing expectations of customers. The accessibility of services and products via the Internet enables the customer to obtain all the necessary information concerning a product from home. Shopping online saves a lot of time, makes products available round the clock and enables choosing the best offer available on the market. Purchasers have tools to find the best price or quality offered. The Internet makes it possible to compare product prices in many traditional and online shops. The development of online shops makes it possible to reduce maintenance costs and offer attractive prices. Technological development also enables searching for new products on the market that are necessary to meet the high demands of the contemporary society. All aspects of the social life must be of the highest possible standard to make people satisfied. Accordingly, entrepreneurs must make their products available online. This has many advantages as well as certain disadvantages. Each entrepreneur must determine for himself how he is going to function in his industry in the domestic and international market as well as online. Online businesses reach an unlimited number of potential customers who may buy the products they need via the Internet.

Traditional and online enterprises

Currently, there are many different types of economic operators in the market. Diversity in many areas of operation enables acquiring a specific group of customers who should be the target group of a product. Obviously, not every entrepreneur determines a specific group of customers. Often, a product is initially dedicated to a specific group of customers.(Taranko 2013, p.7) However, once the product is released on the market, the group of customers grows much bigger. All this depends on the interest in a product and the customers' wish to have it. Enterprises that operate in the market should look at the products and services they offer through the eyes of customers. Enterprises operating in various industries sell their products through traditional outlets. However, this is not enough nowadays. Customers force entrepreneurs to create new shopping possibilities through internet shopping and mail orders. Online businesses have more possibilities to acquire new customers whom they could not reach in the traditional way.(Bilińska-Reformat 2014, p.186) Obviously, customers, too, appreciate the ability to shop from home or from work. In order to meet the needs of both traditional and virtual customers and to be ahead of competitors, it is necessary to implement innovative solutions in services as well as in production.(Bettencourt, Brown, Sirianni 2013, p.13) Customers shopping online represent more than half of all the consumers. Adapting to market needs makes it possible to gain major financial benefits.

The right approach to the customer is also important, because acquiring customers is more difficult online than via traditional sales channels. Numerous studies conducted by the US Consumer Chamber have shown that attracting a new customer costs an enterprise five times more time and money than maintaining an existing customer.(Cichosz, 2005, p.112) Thus, it is important to build lasting relationships with existing customers and ensure the overall satisfaction of all consumers. The contemporary customer has many tools, e.g. to compare multiple product offers at the same time. The level of customer service, i.e. approach to the customer is very important here, and it is often analyzed by customers. An important tool that is often used by customers of online stores is verifying the opinions about a seller or product range before concluding a transaction. Social media provide the Z generation consumers with the new ways to connect with businesses. They can above all express their opinions about the company's products. It should be noted, however, that having extensive knowledge about an enterprise does not always help avoid dishonest sellers.(Maciejewski 2014, p.235) It also happens that some negative opinions are not justified, but they may result in the loss of many potential customers. It should be noted then that, although the Internet is a very useful tool, it may also cause unexpected loss. One factor that increases the competitive possibilities of an enterprise is employee creativity.(Pachura, Nowicka-Skowron 2010, p.118) Every entrepreneur must analyze the profitability of such solutions, and every customer must decide for themselves whether certain information is true or not.

The relations between customers and entrepreneurs are determined by the areas of application of the Internet: (Skuza, Przedlacki, Pałaszewski 2001, p.22)

- B2C Business to Customer, which means relations between a business and individual customers that involve retail trade and selling services and information to consumers,
- B2B Business to Business, which means market contacts between enterprises in business trading that cause integration of added value chains from raw material suppliers to the end customer,
- C2B Customer to Business is the reverse of the B2C system; here, the initiating party is the customer who wishes to buy a product or service and determines the parameters of the transaction and the price they are willing to pay,
- C2C Customer to Customer means auctions for individual customers (device, automobile and other auctions).

The above types of relations linking online buyers and sellers should be based on common service standards and good business practices. (Chodak 2008, p.38) Only such relations can strengthen online business and yield financial profit.

Using the Internet in economic activity gives many possibilities to make work easier both in contacts with the customers and in any other area. Nowadays, the companies try to do everything to make the product visualization allow the best idea and imagination of how in fact the product looks like in the reality.

The ability to send information fast and to communicate fast is nowadays much needed and required in any developing enterprise in the market. (Wolny, 2016, p.284) Enterprises that want to reach an unlimited number of customers and contractors and improve their business must have unlimited access to the Internet. This is why the number of enterprises with broadband access to the Internet is increasing (fig. 1).

Fig. 1: Enterprises with broadband access to the Internet

Source: www.parp.gov.pl

Figure 1 shows a major increase in the percentage of enterprises with broadband access to the Internet among all the enterprises. In 2010, they represented 69%, and in 2015, their number grew to 91.9%. In subsequent years, their number continued growing and it reached 95.6% in 2018. By the end of 2020, 100% of enterprises are expected to have access to broadband Internet.

Also, many enterprises have mobile access to the Internet, which enables faster and continuous contact with customers. This trend is shown in figure 2.

Fig. 2 : Enterprises with mobile access to the Internet

Source: www.parp.gov.pl

Figure 2 shows enterprises that have mobile access to the Internet via various devices. In 2010, 30% of enterprises had such access, in 2015, the number grew to 61.5% and in 2017, it was more than 66.8%. In subsequent years, the number of enterprises with mobile Internet access continued growing.

Access to mobile and fixed electronic sources reduces the time between order and delivery. All activities associated with access to the Internet, which is now the most important communication

tool, make it possible to take faster and more efficient actions in every area of operation of enterprises.

Customers of Online Enterprises

A vast majority of the society are customers of online enterprises. The number of persons of all ages doing their shopping online is increasing.(Piorunowska-Kokoszko 2014, p.96) The vast majority of online shoppers are aged 16-34 years, representing more than 54%, followed by persons aged 35-49 years, and the least numerous group are persons aged over 50 years (fig. 3).

Fig. 3: Poles using the Internet.
Source: ecommercepolska.pl/files/9414/6718/9485/E-commerce_w_polsce_2018.pdf

The data presented in figure 3 show generation groups and their activity in the online world. More than 77.5% of Poles aged over 15 years use the Internet. 48% of them are men and 52% are women. The most numerous age group are persons aged 25-34 years (30%), followed by persons aged 35–49 years (27%), 16–24 years (24%) and 50+ years (19%) who represent the lowest percentage of Poles using the Internet. Compared to previous years, the number of persons shopping online increased in the more senior age groups (35–49 and 50+) and in the youngest age group (16–24).

Using the Internet to do shopping has multiple advantages, including but not limited to: (Kucia, 2002,p.29)

- Saving time, round-the-clock access to shops

- Easy and fast access to information

- No need to carry the shopping home

- Being able to verify the opinions of other product users

- Saving money, e.g. competitive product prices.

However, this form of shopping has some disadvantages, too: (Jaciow, Wolny 2011, p.676)

- Not being able to examine a product “closely”

- Not being able to have the product immediately upon purchase

- Concerns about the safety of a transaction (e.g. payment)

- Concerns about problems with delivery

- Being used to traditional sales channels.

In the Internet, consumers may search for specific products and share information about them over a long period of time. (Gołąb-Andrzejak, 2014, p.765) They may also leave their opinion and successfully persuade others to buy or not to buy a given product. A satisfied customer will not only leave a positive opinion about an enterprise and a product but they will also be loyal over an extended period of time. Information collected by a consumer may change their decision or reassure them that their decision is right. Searching for information on products takes place on a mass scale and is not limited geographically. Online businesses may sell products to customers all over the world. The Internet reduces the distance between the customer and the manufacturer, which makes transactions faster.

General access to the Internet enables communication in the social, cultural and business spheres. According to research, the largest groups are representatives of the young generation, for whom the Internet is the most important source of communication and a tool they use in all the aspects of their lives. (Wolny, 2015, p.853) What makes this generation different is that they are used to technology. For representatives of the young generation, constant access to the Internet is normal and evident, because the Internet has been there in their lives since they were born.(Stopczyński, 2016, p.206) Another group are persons who must function in the changing environment focused on continuous contact and using the Internet to be constantly connected for private and professional purposes. These persons are aware of how fast the world is changing and try to be up to date with the changes. It should be noted, by the way, that they highly trust online shopping. (Gołębiowska, 2016, p.134) Persons aged over 50 years also have to learn to use new technologies that make it easier to do many things. Introduction of changes requires readiness of the employees engaged in the process of their implementation. (Huizingh, 2011,p.2) Thus, changes should be introduced in the right way and employees should adapt on an ongoing basis so that their work may become easier thanks to the Internet.

The situation in the other Member States of the European Union as regards online shopping in 2017 was as follows (fig. 4).

Fig. 4: E-shopping in top EU Member States

Source: www.ec.europa.eu/eurostat

Figure 4 shows the percentage share of EU Member States in online shopping. The first is the UK, with a score of 87%, followed by Germany – 82%, Denmark – 81.8% and Luxembourg – 80%. Poland is in the 14th place with a score of 53%. The lowest share in online shopping was reported in Macedonia (16%) and Romania (18%). The ability to do shopping online depends on a number of factors, such as access to the Internet, number of online stores, being confident about buying things without seeing them, etc.

Analysis of Research

According to analyses, the most frequent customers who shop online are young people aged up to 30 years. Accordingly, the respondents of the research belong to three age groups. The questionnaire was performed by means of an online survey and it was supposed to present the tools of acquiring and maintaining customers in online enterprises. The survey was answered by 50 respondents from

across Poland. The first group were persons aged up to 30 years – 67%, the second were persons aged from 31 to 50 years – 4% and the third were persons older than 50 years – 9% (fig. 5).

Fig. 5: The age of respondents

Source: Own elaboration based on the survey

The majority of respondents were professionally active and had limited time to do shopping and search for the products they needed. Among the most important reasons for choosing this type of transactions, they indicated the speed of transactions and fast product delivery to the required address. Also the ability to use the Internet is higher in the first and second groups than in the case of older persons who do not know how or are afraid to use such solutions.

Concerning the question about the tools used to acquire and maintain customers, the respondents most often chose the following options (fig 6).

Fig. 6: The tools used to acquire and maintain customers.

Source: Own elaboration based on the survey

Based on the data from figure 6, the following tools used to acquire and maintain customers in online enterprises may be listed:

- A clear website of the enterprise – 32%

- Discount coupons, promotional vouchers, rebates offered by the enterprise – 12%

- Advertising in local portals and social networks – 24%
- Whisper marketing – 15%
- Opinions about the enterprise and its products in Internet portals – 16%
- Other – 1%

These tools are used by the respondents and it may be assumed that the presented research sample suggests the importance of creating a clear website for every enterprise that wants to have the right level of online product or service sales. Another important thing is advertising products and services in local portals and social media. According to Ł. Bojar, Vice President Sales & Marketing of Senetic, which is a global solution provider for companies and public institutions, the most important thing in building relationships with a customer is currently adapting to his custom needs occurring at the moment. Through this approach, the client's attachment to the company and his loyalty in the future take place. Obtaining positive and reliable opinions as well as whisper marketing were also indicated as important tools that help acquire customers. Note should also be taken of discount coupons and promotional vouchers for both new and existing customers.

Conclusion

To some up the above deliberations, it may be definitely stated that nowadays, it is a must for enterprises to be active in the Internet. Accordingly, establishing and maintaining the best possible relations with customers wins their loyalty for the company. Entrepreneurs who want to acquire new customers present a product that has the best possible price and quality and also try to provide additional services at no extra cost. Such measures make it possible to acquire new customers as well as maintain the existing ones. All the tools used to contact customers should be constantly upgraded. Direct contact with customers makes it is possible to find out about customer expectations and meet customer needs. Nowadays, contact means mainly the use of online messengers that are active 24 hours a day, 365 days a year. An undeniable advantage of online sales are lower operating costs and a broader range of products offered by online shops compared to traditional shops. In order to offer many products, it is not necessary to have such a big shop or warehouse as in the case of traditional shops, which generate high maintenance costs. Nowadays, all the well-functioning enterprises offer the option to buy their products and services online. The online services market is very large, which means that e-entrepreneurs need to be innovative in order to gain a major position in that market. Individual customer approach helps build trust and profit from product sales.

Intergenerational Differences and Similarities in Private and Professional Life of the X, Y, Z Generations' Representatives

Anna PADLOWSKA

Częstochowa University of Technology, Częstochowa, Poland
E-mail: anna.padlowska@pcz.pl
ORCID: 0000-0002-2631-1371

Abstract

The objective of this paper is to show the intergenerational differences and similarities in the understanding of the world by three generational groups: X, Y and Z. The social, economic and financial differences across all the generations tend to be very significant, which is why taking advantage of emerging opportunities and a completely different approach to life is so interesting in the context of the explored subject. Showcasing the differences and similarities between the generations will help us understand the need for lifelong learning. Using the surveys, own interview and observations was carried out by the author on a selected group of respondents in the Śląskie Voivodeship. Based on surveys conducted on a randomly selected group, the author will explore whether change is a positive or negative phenomenon.

Keywords: Generations X, Y, Z, Modern Workers, Technological Development

Introduction

The following paper is based on the author's observations and the survey concerned the perception of life and work among different generational groups, which makes finding significant differences concerning different generations a given, since there have always been differences between representatives of different generations, which involved various areas of life.(Wrzesień, 2007, p.140) In many cases, the perception of the world by more experienced generation X is completely different from that presented by Y and Z generations, and these differences in worldviews have always been highly controversial, leading to many disputes.(Kroenke 2015,p.95) The Y and Z generations have always believed that they have the right to make their own decisions, believing that the opportunity to learn from their own mistakes and gain their own experience is a necessary prerequisite to gaining wisdom in life.(Kopertyńska, Kmiotek, 2014, p.42) On the other, hand, it is difficult for generation X to identify the opportunities for development and Y and Z generations willingness to grow, as they often tend to impose their own point of view and attempt to force them to make decisions which are right in their mind. Thus, the subject matter of this paper aims at encouraging further analysis of the topic at hand.

Characteristics of Generational Diversity Between Generations X, Y And Z

These days, the most important issue connected with generational analysis is the multi-faceted perception of life in the context of differences and similarities between the examined generations. It should be noted that in subject literature, the generational limits may vary slightly between various authors. The labour market sees several generations working hand in hand, in spite of their different approaches to work and leisure time, their competencies, as well as their requirements and demands concerning themselves and their employers. Representatives of generation X prefer personal or written communication, while representatives of Y and Z generations are adept at operating and working in the virtual world, which to them serves as a basic means of everyday communication. Another important matter concerns flexibility concerning professional and social mobility in search of a better place, which does not represent any obstacle for the Y and Z generations. These days, mobility is often ensured by means of private road transport.(Hopkins 2016, p. 155) Generation X are

used to a sedentary lifestyle and having one permanent job. It should be noted that the need to adapt to changing working and living conditions is often a very difficult life experience for the representatives of generation X. The current lack of opportunities to secure permanent employment forces employees to react quickly to the circumstances, changing their competencies and workplaces. All the representatives of the examined generations want to achieve satisfaction and sufficient conditions in private and professional life.

The older generation on the labour market, which actively participates in social life comprises people born between 1965 and 1980, often referred to as the Generation X.(Adamkiewicz 2016, p.171) This group includes people characterised by great diligence and loyalty to their employer. The representatives of this group are committed, yet cautious, entrepreneurial and creative. Generation X is motivated by the financial aspects of their jobs, as well as their desire for self-fulfilment, self-improvement, prestige and recognition. Generation X employees are attached to their workplaces and rarely exhibit professional mobility. They also feel the need to have their own place on Earth. When building a house or buying an apartment, they want to stay there for the rest of their lives. They surround themselves with things that are supposed to serve them for a long time, which does not result in excessive consumerism.(Reisenwitz, Iyer 2009, p.97) The representatives of generation X often face the need to gain new experience in social and professional relations with other generations. They face the need to modernise their experiences and patterns used throughout their lives due to the impact of technological innovations that change their lives. This generation is oriented towards professional development, while maintaining a healthy work-life balance.(Rutkowska 2007, p.325)

The next generation, for whom modern technologies are not a problem, is referred to as Generation Y.(Fazlagić, 2010, p.63) The representatives of this generation were born in 1981-2000, and they are characterised by a completely different approach to work and life than their predecessors. Generation Y is characterised by less loyalty towards their employers. Generation Y is well-educated, oriented towards development and opportunities for gaining new experiences, as well as fulfilling their interests. They are also credited with greater flexibility and openness to change, a willingness to learn and an unwillingness to make long-term commitments, compared to previous generations. These characteristics are said to stem from the need to adapt to a rapidly changing environment. What this generation cherishes the most is satisfaction with their jobs and the connected remuneration. If problems ever arise, they are willing to change their job or even their place of residence. Generation Y is passionate and focuses on friendly atmosphere at work, they like working in groups, while keeping up the boundaries of individuality.(Kaczyńska, Kałuziak, Stankiewicz-Mróz 2015, p.69) The representatives of this generation have no great difficulty in establishing remote social and professional relationships. They are also characterised by their ability to multitask, which is often manifested in working for several employers at the same time or in combination with running their own businesses, while also working for others. Using the tools at their disposal, they are able to efficiently manage their time and opportunities, combining even several professions at the same time. Generation Y considers prestige and high social position to be important, they also like flexibility in terms of working conditions and time, while focusing on putting their personal development plans into practice.(Piwowar-Sulej 2009, p.194)

The youngest generation, which is also referred to as Generation Z, is made up of people born since 2001. According to observations, those are people with a low level of loyalty to the employer.(Nolan 2015, p.70) This generation is often characterised as entitled and self-interested, pursuing their goals with no regards to others. They are hardly reluctant to express their own opinions or needs to their employers. Some of their disadvantages include lack of respect for privacy, unrealistic life expectations, irresponsibility at work and lack of interpersonal skills.(Smolbik-Jęczmień 2013, p.92) They are also characterised by a lack of patience, which manifests itself in the desire to obtain immediate effect of work, feedback or satisfaction of needs. Generation Z may experience difficulties with teamwork. Electronic means of communication serve as their main way of communication in both personal and professional lives, while Internet remains their main source of the required information. People from the Z generation function most of the time in the virtual world, to which they are accustomed from the beginning of their life. They treat it on an equal level with the real world.(Korombel A., Ławińska 2019, p.1023) They use it at all times and everywhere, they also use social media both in their professional and social lives.(Adamkiewicz 2016, p.171)

The representatives of all generations have their own approaches to life and work. The changes of lifestyles between generations and generational changes pose many challenges for mobility service providers and further increase the need to shift the demand for mobility services towards sustainable urban mobility.(Hopkins 2017, p.380) Generations Y and Z show great commitment to their shopping behaviours, they are consumers who want to get as many modern gadgets as possible, which they use to showcase their status and social prestige.(Parment 2013, p.191) They do not remember the world without the Internet or their mobile phones, which is why they communicate solely through them on a regular and constant basis. The representatives of the Z generation spend a lot of time in the Internet, searching not only for the solutions to their problems, but also communicating with others and looking for new ways of spending free time.(Biel 2020, p.59) Generation Y and Z lack the ability to find information in places other than the Internet. Representatives of the Y and Z generations often expect employers and co-workers to give them specific tasks, because that reflects the way they were brought up. Young people are not able to work independently, they were brought up by their parents planning their time and rewarding them immediately after their tasks were done,(Fazlagić 2008) which is why they continue with this approach in adulthood. Socially, they are oriented towards fulfilling their own dreams and needs, as well as receiving the expected and corresponding rewards. This clash of the presented worlds in many companies is a difficult test both for older workers, who need to show patience and understanding of this approach to work and life, as well as to adapt to change.(Mazur-Wierzbicka 2016, p.173) Workers from the X generation are forced to operate in the virtual world, which for them is often very difficult and time consuming; however, it is essential for the companies to survive in the changing labour market. They tend to transfer the solutions they use in their professional work to their private lives, which allows them to be more efficient in the virtual world and to deal with many matters without having to leave home. Whereas representatives of the Y and Z generation tend to be unable to understand certain behaviours of older people, which are often misunderstood. The opportunities to quickly acquire and process information using the available electronic sources enable a broader analysis of the issue at hand.

Research Methodology

The results of the study presented in this paper are based on a quantitative survey conducted by means of a questionnaire, partly on an interview and the author's own observations with 100 respondents from Śląskie (Silesian) Voivodeship, encompassing representatives of each of the characterised generational groups. The survey and an interview were conducted between October and December 2019. Both the interview and the questionnaire are the same set of questions asked to the various representatives of generational groups. The group of respondents included employed people aged 18-50, both women and men, working in the private and public sector. Some of the respondents were also students at the time of the survey. For the purposes of the paper, the author assumed that the representatives of Generation X are people aged 40-50, while Generation Y comprises people aged 20-39, and Generation Z is made up of 18 and 19-year olds. The paper includes only some of the responses provided by the respondents, which enable us to determine their priorities and characteristics concerning the subject at hand.

The main part of the questionnaire consisted of introductory questions, the conclusion and the supplement, and the survey results will be presented in this order. In the first part, they asked about gender, age, place of residence, education. In the second part, the question was, among others, about the values that are most important in the lives of respondents, about maintaining a balance between personal and professional life, ways of communicating, the purpose of undertaking professional work. The introductory questions were aimed at characterising the groups of respondents participating in the survey.

Analysis of the Surveys

The following results can be presented from the research part, referring to the results of the author's surveys, interviews and observations:

The surveyed group was dominated by the representatives of Generation Y, who made up 54% of the total number of respondents, with the remainder being Generation X - 25% and Generation Z - 21% (Fig. 1.)

Fig. 1: Quantitative aggregation of the respondents, broken down by generations.
Source: Own compilation

Among the respondents, there were 78% who worked in the private sector: 61% from generation Y, 12% from generation Z and 5% from generation X, and 20% of them had their own enterprises: 17% from generation X, 2% from generation Y and 1% from the generation of Z. While the remainder constituted employees of state-owned enterprises. Nearly 62% of the respondents were lower-level employees, 27% were in expert positions, and only 11% held managerial positions. The youngest generation - Generation Z, was mostly represented by respondents, who were still in education and who were just entering the labour market, which is the reason for a smaller number of papers presenting their attitudes as employees.(Stachowska 2012, p.34-36) However, all researchers, who focus on analysing the functioning of this generation agree that its representatives do not know the world without a computer, telephone, Internet and many other electronic devices. Their functioning both in private and professional life is influenced to a very high extent by constant access to wireless communication systems and smart electronic tools, which are said by some to be an indicator of belonging to this generation. Representatives of Generation Z therefore expect that modern technology, which is ubiquitous in their lives, will also be available in their workplaces, as well as in interactions with superiors, colleagues and customers. In their professional life, they seek opportunities for development and participating in interesting tasks.

The survey asked, among other things, about the values that are most important in the lives of the respondents. The vast majority - 69% of the respondents - considered family to be the most important value: 29% from generation X, 25% from generation Y and 15% from generation Z. 21% chose good health: 10% from generation X, 7% from generation Y and 4% from generation Z and 9% chose work: 5% from generation X, 2% from generation Y and 2% from generation Z, the remaining 1% chose a different value (Fig. 2).

Fig. 2: Values represented by respondents.
Source: Own compilation, based on surveys

The data presented in Figure 2 shows that in spite of different views on life, family remains the most important value for most respondents. This result may stem from the fact that the Polish society has a deeply rooted notion that a family is an important aspect of a happy and fulfilled life. Many people believe that good family relationships help to overcome even the greatest difficulties in life. Another noteworthy aspect is the fact that representatives of the representatives of the Y and Z generation have a completely different attitude to having a job. In many cases, they keep living with their parents for a long time, which undoubtedly lowers the pressure on them to get a job that would allow them to support and sustain themselves. Given these circumstances, starting their own family is no longer one of their top priorities, which enables them to forgo the need to have money to support a family and focus on looking for a perfect job and frequent changes. The representatives of Generation X knew that when they reached adulthood, they had to become independent, which is why getting a job and having their own money was a priority for them.

Another important question in the context of the subject at hand was the work-life balance among generations. In this question, 75% of the respondents considered it to be very important. (Fig. 3.)

Fig. 3: The importance of work-life balance.
Source: Own compilation, based on surveys

The analysis of the results presented in Fig. 3. makes it apparent that this question is understood differently by representatives of different generations. For Generation X, this balance is associated

with combining family and professional responsibilities in the context of the whole life and family. On the other hand, the representatives of Generations Y and Z focus on their own lives, with their aim being spending their free time outside of work on their own development or travelling. The possibilities of achieving a balance depend on how one perceives the concept of professional and personal life. Nevertheless, every generation would like to be able to separate these two life roles.

Another important question for the analysis was the use of means of communication in both personal and professional lives (Fig. 4.)

Fig. 4: Means of communication used by the examined generations.
Source: Own compilation, based on surveys

In fig. 4, we can see the respondents' answers concerning the ways they communicate. The choice between online and telephone communication made it a difficult question for many, since the representatives of the Y and Z generation do not see any difference between these two modes; therefore, these two modes of communication should be considered one. The analysis of the results clearly shows that personal meetings no longer serve as the foundation of social communication, which is now based on the use of modern tools for faster and more efficient communication without leaving home. Communication via letters is virtually no longer practised. These days, the majority of the society takes advantage of the significant benefits of telephones and instant messengers for facilitating social and professional relationships, which also facilitate contact while travelling. Back in the day, telephone calls abroad used to be very expensive, but these days all people need to communicate for free is access to the Internet. Changes in the way we communicate are most visible in relation to differences between generations.

The last question, which exhibits the differences in the perception of work among the respondents is the purpose of taking up employment (Fig. 5.)

Fig. 5: The purpose of taking up employment.
Source: Own compilation, based on surveys

The data presented in Fig. 5 show that 41% (that is 13% from generation X and Y and 15% from generation Z) of all respondents take up employment due to the need to obtain funds needed to support themselves and pursue their dreams. 23% of all respondents were people for whom the most important objective was to gain new skills and experience. The data also show that 14% contains 6% from generation X, 5% from generation Y and 3% from generation Z of respondents named prestige and social respect as the key reason. According to the study, taking up employment is an important factor for all respondents, regardless of age.

The results of the survey enabled the author to obtain answers to the most important research questions posed earlier: are the differences in the perception of life and work are beneficial for socio-economic development in intergenerational terms. By analysing the results of the survey, it can be concluded that there have been significant changes which have a positive impact on development. Today's employees are satisfied with the working conditions, tasks and interpersonal relations within their organisations.

Conclusions

To sum up, it should be noted that the presented social and economic behaviours of all the examined generations are inextricably linked to the development of all aspects of life. The changing environment, the constant desire to improve and make life and work easier, forces the search for new solutions. Changes in the labour market are linked to changes in private life and therefore everyone, regardless of age and social status, needs to adapt to some extent. The studies carried out enabled the author to showcase and confirm the key goal, namely the need for lifelong learning. All the representatives of Generations X, Y, and Z participating in the survey agreed that making changes is necessary and inevitable, only the sheer number of these changes can be frightening for the representatives of generations X, who are not used to experiencing so many changes in such a short timeframe. They remember the times when life seemed to be calmer and their jobs felt more secure. These days, they are forced to function in chaotic times, where everyone is focused on quickly gaining everything they want at the expense of health and family life. On the other hand, representatives of the generation Y and Z are accustomed to such behaviour; they are able to understand many changes that can help them get a better job and home, or better their living conditions. Communicating is also normal for them, as long as they can use their phones, instead of personal contact. Back in the day, family and company meetings were the only way to develop social ties. These days, such meetings are often held without personal contact, using innovative technologies. This is caused not only by upbringing and getting accustomed to phones and the Internet, but also by the lack of time; therefore, it should be noted that many things have changed the world for the better - it has become more global, and distance is no longer a barrier. The benefits of taking advantage of innovations in professional and private life are very important, they just need to be used in a skilful manner, while giving everybody time to get used to them. Social and economic development in relation to contemporary life of all social groups is irreversible and allows to improve the quality of life.

Preferred Organization Management Styles. The Perspective of Polish Family Businesses

Anna LEMAŃSKA-MAJDZIK

Czestochowa University of Technology, Poland
anna.lemanska-majdzik@pcz.pl

Abstract

Management is one of the most important functions in the organization, therefore, the level of management determines the adaptation of the organization to variable environmental and business conditions. Among the conditions for effective management, it is possible to distinguish the level of knowledge, skills to be a manager, the level of power as well as the desire to manage organizations, but most of all the adopted relevant attitude which affects the management style. The literature review indicates a wide range of divisions involving organization management styles, which confirms that the management situation is affected by the factors which determine the style and, what is more, in the case of family businesses, the combination of familiness and business. Therefore, the management of family businesses includes the combination of both formal and informal mechanisms, which may arise inside or outside the organization, which directly influences the mixed management styles of such organizations. The objective of the article is to show what management styles are dominant in the management of family businesses taking into account the divisions adopted. The reasoning is based on the results of the research on a group of Polish family businesses. The research conducted in 2018 clearly indicates that there are mixed management styles in family businesses, which combine relevant styles associated with management in family businesses. The most dominant management style in the case of the simple style division is the autocratic style and, in the case of the extended division, the integrated style.

Keywords: Management Styles, Leadership and Power, SME Sector, Family Business.

Introduction

Family businesses are the largest group of enterprises operating in all economies in the world. The vast majority of family businesses are enterprises from the sector of small and medium entrepreneurship which, while operating in local and regional markets, are characterized by specific features. The specificity of the operation of family businesses is due to the features characteristic exclusively of this group of organizations as well as the combination of business with family conditions. The impact of familiness on entrepreneurship can be perceived both in terms of allocation of organizational resources as well as in terms of organizational behavior affecting the performance or, more broadly, market success. Therefore, the management of family businesses may result from the family nature of entrepreneurial intentions. The adopted style of managing family organizations may be due to a number of factors which are directly related to the family nature of the business as well as the conditions of the business environment. Nevertheless, the adopted style of management of this type of organizations may differ from the style of managing non-family enterprises.

The objective of the article is to indicate what management styles are dominant in the management of family businesses, taking into account the divisions adopted. The reasoning is based on the author's own research conducted in 2018 on a group of Polish family businesses belonging to the SME sector.

Leadership and Power in Family Businesses – Literature Review

Leadership in the organization is the process of influencing others. It consists of various components, among others, authority, power, influence, acceptance and responsibility (Yukl 2010). It is particularly

important since it affects the performance of the organization or creates the conditions for the development of organizational culture (Schein 2010). Leadership is thus culture-related and Daft (2005, p. 22), Toor and Ofori (2009, p. 534) even emphasize that leadership creates changes in the enterprise, doing so in the face of organizational culture. According to Lievens, Van Giet and Coetsier (1997, p. 416), leadership is the key factor in organizational variability of each company.

The organizational structure of the enterprise forming its framework should provide the organization with an appropriate system of mutual relations, which is logical and transparent for all its members. However, this is not possible without the rules and principles in force in the organization, which are established and determined by managers (Stoner et al 2011, p. 335; Mynarzova et al 2016), and in the case of family businesses, also by owners. Power and authority in the process of business organization includes the manner of holding power as well as the approach of the owner, manager or a person in charge to employees, including decision-making and delegation of power (Lemańska-Majdzik 2019). In the case of family businesses, all areas of the organization are affected by ownership in the family business. The ownership of family businesses may vary in terms of at least six dimensions which often interact. These dimensions include (Daspit et al 2018):

- a number of families or family members participating in ownership,
- a share of family ownership,
- dispersion of ownership among families or family members,
- relationships between owners,
- demographic characteristics of owners,
- nature of the owners' involvement in management bodies, such as board of directors, advisory board or family board. Each dimension separately and in combination creates a set of original resources enabling the acquisition of competitive advantage of family businesses.

Power and authority in the organization have a significant impact on its shape and market behavior, therefore, in the case of organizing family businesses, the family members of business owners play an important role. The involvement and competence of the family members participating in the operations of the family business, in the opinion of Więcek-Janki (2014), determine the competitive advantage and the figure of the person in charge or the owner managing the family business is crucial in gaining the advantage.

According to La Port, Lopez de Silanes and Shleifer (1999), power in the family organization affects financial capacity and management processes. Family businesses, compared to non-family ones, have weaker financial results and poorer management structures. In turn, Bloom, Genakos, Sadun and Van Reenen (2012) claim that, in this group of enterprises, it is more difficult to introduce new practices related to management and the possible duration of their introduction is much longer than in the case of non-family businesses. These differences may be due to how managers and owners perceive their roles and responsibilities in companies. Safin (2007, pp. 300-301) pinpoints that owners in family businesses constitute the management pillar of this type of organizations.

In the case of family businesses, management control and leadership, which are inseparable, are therefore of particular importance. There is no management control without leadership and the opposite. Management control is defined as a system in the social, cultural, political and economic environment applied by the manager or the owner in order to adapt employee behavior to organizational objectives or the management of internal and external interrelations (Sorenson 2000; Jogulu 2010). It consists of the control of results, processes and culture, without excluding each other but rather overlapping and strengthening in everyday implementation. The control determines the results expected from employees (also known as performance measurement). This type of control provides flexibility, requires the delegation of powers and promotes creativity among employees in order to search for alternative operations to achieve the previously defined set of objectives. The process control focuses on measures/behavior of employees and promotes strong and positive organizational culture,

allowing the organization members to monitor each other and to possess self-awareness in the activities for the benefit of the development of the family business (Efferin 2015).

The nature of family involvement in the management and ownership of the company are the primary source of heterogeneity of the family business. Such involvement affects the implemented objectives and performance of the enterprise, which results from the implementation of not only the objectives related to the maximization of the economic value of the enterprise but also the implementation of family objectives, which is characteristic of family businesses (Daspit et al. 2018).

Among the determinants affecting the management style of family businesses, as indicated by Krajewska-Nieckarz and Klimka (2014), the owner's parental attitude should also be distinguished. This is due to the fact that, in this type of organizations, it is the owner that has a decisive vote in strategic decisions in the company (Gorzeń-Mitka, Okręglicka 2015). However, while conducting the analysis of the management style, the attention should also be drawn to the company's profile, field of its activity or organizational culture which prevails in the company. Koziński and Listwan (2005, p. 104) emphasize that the general manager has a decisive vote in terms of the selection of the management style, therefore, in the case of family businesses, it will often be the owner.

Management is both influencing the employees of the organization and the relationships between them (Bielski 2002, p. 205). It occurs that the skillful management of employees in the company affects the level of their motivation, degree of their involvement and appropriate level of interpersonal relations (Jasińska 2009). The management of the organization is the determination of strategic objectives of the company, e.g. the selection of the organization's production profile, cooperative relationships, range of services etc. In management, it is necessary to know the market, to be able to recognize customer needs, which is often possible through experience and intuition. Effective management is related to the appropriate impact on employees, which can be achieved through actions for the benefit of the change in their behavior (Gach, Pietruszka-Oryl 2005, p. 213).

Management is one of the most important functions in the organization, and thus the level of management of managers determines the organization's adaptation to the variable conditions of the environment. Among the conditions of effective management, in the opinion of Wachowiak (2001, p. 15), there are, among others, the possession of power, abilities to be a manager as well as the desire, but most of all the adoption of the appropriate attitude which affects the management style. The subject literature provides a number of divisions including management styles in the organization, which confirms that the management situation is influenced by factors which determine the style. For instance, according to Fiedler, it is the atmosphere at work, the manner of constructing tasks for employees or the manager's authority and the scope of their power. According to Halal, the management situation is influenced by the types of tasks to be performed and determinants motivating employees, and according to Yetton, the manner of solving problems in the organization is critical. In turn, Hersey and Blanchard claim that these are the abilities and predispositions of employees and the degree of their involvement in work (Wachowiak 2001, p. 29; Leszczewska 2007, pp. 105-106).

The simplest division of management styles distinguishes the autocratic, democratic and liberal (non-interference) management styles. Wachowiak (2001, p. 29) indicates that it is not possible to determine which of the three suggested management styles is the best one. This is due to the fact that the management style should be adjusted to the situation in the organization, therefore, in the case of family businesses, the management style is the combination of all three styles. It turns out that, depending on the situation, the first, the second or the third style is dominant (Balogun, Hailey 2008). For example, in the situation of creative tasks, managers ought to manage organizations following the democratic or/and liberal style, in turn, in the case of duplicated tasks, reconstructive ones, they should manage the organization following the autocratic style (Wajda 2003, p. 92).

Another interesting division of management styles which may also be assigned to family businesses is the division according to J.W. Reddin's division, who relied on the flexible approach to the manager who must refer to the existing situation in the organization. By expanding the management network,

created by Blake and Mouton, he distinguished four basic management styles, such as: related (friendly), integrated (comprehensive), separated (isolated) and dedicated (zealous) (Michalska 2015, p. 75).

One of the most important stages of the life cycle of the family business is the moment of the transfer of ownership and leadership. Lack of succession planning is one of the most important reasons for which many first-generation family businesses do not survive their founders. The preparation of the business transfer is a long and complex process entailing a range of difficulties (Vassiliadis et al 2015). Then, family businesses face the dilemma of long-term survival, not only overcoming the difficulties common to all types of business activities but also the conflict which directly results from their family-business nature of the relationships in the enterprise (Brenes et al 2006).

Management in family businesses also includes the manner of management of financial, human, intellectual, social and organizational capital (Gersick, Feliu 2014). In this way, the management of family businesses includes the combination of formal and informal mechanisms which may arise inside and outside the organization. Practices in the field of the management of family businesses may affect employees' activities, strategic behavior and company's performance and may include the use of financial control systems, recruitment and involvement of non-native resource managers, implementation of human-resource practices, decentralization of power and increased involvement of management board (Dekker et al. 2013).

Research Methodology

Due to the specificity of family businesses (Sułkowski 2011; Lemańska-Majdzik et al. 2016) and the mixed management style declared in the previous studies, the decision has been made to test the relationships for two different management styles (Basco, Pérez Rodríguez 2011):

- for the basic division, including autocratic, democratic and liberal styles,
- for the extended division (based on the Reddin's model), including related, integrated, separated and dedicated styles.

The objective of the article is to indicate what management styles are dominant in the management of family businesses, taking into account the adopted divisions.

The research on a group of enterprises from the SME sector, i.e. micro-, small and medium enterprises, was conducted in 2018. 358 Polish family businesses participated in the research, classified by employment size as micro-, small and medium enterprises. During the study, an anonymous questionnaire consisting of closed-ended questions was used, which was addressed to the owners/managers of the surveyed enterprises from the south-central Poland. The questionnaires were completed primarily by the owners or managers of family businesses. The selection of enterprises was random, i.e. the fact of accepting the enterprises for the research was determined by a chance.

Research Results and Discussion

The preferences concerning the management style (basic division) in family businesses are presented in Figure 1. The respondents used the 7-point Likert scale where 1- definitely not, 2 - not, 3 - rather not, 4 - average, 5 - rather yes, 6 - yes, 7 - definitely yes.

Fig. 1: The preferred management style (basic division) in family businesses, N=358

Based on the conducted research, it can be concluded that the liberal management style in family businesses occurs in the case of nearly 7.3% of the respondents since only 26 of the surveyed Polish entrepreneurs declare that this management style occurs in their enterprises. On the other hand, as many as 256 respondents indicate that this management style is not dominant in their family businesses. The democratic management style in family businesses is indicated by a total of 50% of the surveyed Polish entrepreneurs, i.e. 179 companies. Moreover, 57 family businesses declare that this management style does not occur in their family businesses. The conducted research shows that the autocratic management style in family businesses is indicated by a total of 189 respondents. Therefore, it turns out that nearly 52% of those questioned declare that the autocratic style is the management style in their enterprises. At the same time, it turns out that as many as 111 respondents declare that this management style does not occur in their family businesses (Fig. 1).

Fig. 2: Descriptive order statistics of the preferred management styles (basic division) in family businesses, N=358

Figure 2 illustrates the descriptive order statistics of the preferred management styles in family businesses. The conducted analysis indicates that the preferred management style in the surveyed enterprises is the autocratic style consisting in the fact that the entrepreneur sets the objectives and tasks of the company themselves while fully getting involved in the company's operation through ongoing control and verification of employee operations. The average value for the autocratic style amounts to 4.32 on the 7-point Likert scale. This level deviates from the average value by +/-1.99 pts. The minimum value for this management style indicated by the respondents amounts to 1.00, whereas

the maximum value is 7.00 on the 7-point scale. Another style preferred by the owners or/and managers of family businesses is the democratic style which somehow limits the company's owner, providing maximum freedom to employees. This style consists in encouraging employees to co-decide in the process of the company's operation. The conducted analysis shows that the average value for the democratic style amounts to 4.12 on the 7-point Likert scale and the level deviates from the average value by +/-1.87 pts. In the surveyed family businesses, the liberal style, which leaves employees maximum freedom, is indicated the most rarely. The person managing the company in this style attempts to interfere in employee operations as little as possible, however, provides them with appropriate tools and working conditions. The respondents assess that, in the case of family businesses, this style of management occurs very rarely, determining its level in the process of business management at 2.67. The level deviates from the average value by +/-1.71 pts. It follows that, in practice, this management style does not occur in the surveyed family businesses.

The preferences concerning the management style (extended division based on the Reddin's model) in family businesses are presented in Figure 3. The respondents also used the 7-point Likert scale where 1- definitely not, 2 - not, 3 - rather not, 4 - average, 5 - rather yes, 6 - yes, 7 - definitely yes.

Fig. 3: The preferred management (extended division) in family businesses, N=358

The results of the conducted research indicate that a total of 154 Polish entrepreneurs running family businesses declare the related management style, which amounts to 43.02% of all the indications. The related style is not the management style in family businesses in the case of 111 companies. The distribution of responses concerning the integrated management style in family businesses indicates that it is the most frequently indicated management style in the surveyed enterprises. A total of 243 respondents indicate that this style is the management style in their enterprises, which amounts to as much as 67.88% of all the surveyed Polish companies. Only 66 respondents declare that this style does not occur in their enterprises. The research results also show that two management styles – separated and dedicated – occur the most rarely in the surveyed companies. In the case of the dedicated style, the respondents indicate that it occurs in the process of the management of family businesses in 67 companies, which amounts to 18.75% of those questioned. In turn, in the case of the separated management style, such a declaration is made by 34 respondents, which amounts to merely 9.50% of the surveyed family businesses (Fig. 3).

Fig. 4: Descriptive order statistics of the preferred management styles (extended division) in family businesses, N=358

In Figure 4, the descriptive order statistics of the preferred management styles in family businesses are presented. The conducted analysis indicates that the preferred management style for the owners or/and managers of family businesses is the integrated style consisting in the fact that the manager focuses on both currently performed tasks and appreciates individual employees. Group debates are the form of setting tasks to them and they assess employees in terms of their suitability. It can be concluded that the manager is far-sighted and manages people by showing them ideals and setting ambitious tasks. The average value for the integrated style amounts to 4.81 on the 7-point Likert scale. This level deviates from the average value by +/-1.61 pts. Another management style preferred by the owners or/and managers of family businesses is the related style, in which the manager focuses on employee problems and to a small extent on tasks. They like contacts with subordinates and have the ability to settle conflicts, however, not to stimulate subordinates to operate. The analysis indicates that the average value for this management style amounts to 3.95 on the 7-point Likert scale and the level deviates from the average value by +/-2.01 pts. In the surveyed Polish family businesses, the dedicated style, in which the manager is focused on tasks, wants to gain dominance over others, giving instructions and clues to subordinates, is the management style indicated by the respondents rather rarely. They operate in the short term and assess subordinates from the point of view of their suitability for the performance of tasks, however, they consider rewards and punishments to be the best management tools. The respondents assess that, in the case of family businesses, this management style occurs rather rarely, determining its level at 2.67 on the 7-point Likert scale. The level deviates from the average value by +/-1.15 pts (in practice, this management style does not occur in the surveyed family businesses). The most rarely indicated management style in the surveyed family businesses is the separated style, in which the manager is hardly oriented to tasks and people. They impose punishments in the form of withdrawing decision-making powers, avoid innovation, prefer known and tested methods, moreover, have difficulty in establishing contacts and cooperation with people. The manager applying the separated management style appreciates rationality and finds it destructive to give in to one's emotions. The respondents assess that, in practice, this management style does not occur, determining its level at 2.11 on the 7-point Likert scale. This level deviates from the average value by +/-1.61 pts. In practice, this management style does not occur in the surveyed family businesses.

Conclusions

The research conducted in 2018 on a group of Polish family businesses of the SME sector indicated that, in this group of enterprises, mixed business management styles are dominant. This is confirmed by both the research on a group of Polish family businesses (Wachowiak 2001, p. 29; Sułkowski 2011; Koziński, Listwan 2005, p. 104; Safin 2007; Sobiecki et al 2014) and the international research (Basco, Perez Rodriguez 2011, Daspit et al 2018, Ramadani, Hoy 2015; Toor, Ofori 2009; Belias, Koustelios 2015), which indicates that the management style in family businesses is the combination of relevant styles associated with the management of a family business in which one or two styles are dominant. Therefore, in the study, the author has made an attempt to indicate what management styles are dominant in the management of family businesses, taking into account various divisions.

Summing up, it can be indicated that, while adopting the basic division of management styles, in which the autocratic, democratic and liberal styles are distinguished, the most dominant management style in Polish family businesses is the autocratic style, followed by the democratic one, and the least dominant is the liberal style. In turn, while adopting the extended division, taking into account the Reddin's model, in which the related, integrated, separated and dedicated styles are distinguished, the most dominant management style is primarily the integrated style and the rarest one – the separated style.

The obtained results encourage the continuation of the literature and empirical studies, particularly in terms of the continuation of the analyses of the research material collected, including the use of the cluster analysis for the construction of groups combining relevant management styles in relation to the adopted divisions, i.e. basic and extended division. In view of the particularly important role of family businesses in national economies and their large share in enterprises in total, it is worth conducting the research into this type of organizations in the future.

Practices of Flexibility in The Area of Organizational and Innovative Change Management in Family Businesses

Anna LEMAŃSKA-MAJDZIK

Czestochowa University of Technology, Poland
anna.lemanska-majdzik@pcz.pl

Abstract

Flexible operations of the organization are primarily due to changes in the business environment, but the multidimensionality of the concept of the flexibility of operations leads to the considerations in terms of organizational behavior from the perspective of enterprise management. The flexibility of operation, as a characteristic of family businesses, is identified in all management areas, including the area of organizational and innovative change management. Family businesses are a special group, among others, characterized by the type of management, level of innovativeness, acquisition and mobilization of capital, cultural continuity, but also stability. The objective of the article is to assess the level of flexible operations in the area of organizational and innovative change management by family businesses. The survey using the authors' research tool, conducted on a group of Polish family businesses, enabled the conclusions to be drawn using statistical methods. The conducted analysis indicated that, among the factors affecting the level of flexible operations in the area of organizational and innovative change management, including the implementation of changes and innovation and new technologies, there are the ones characterizing enterprises as family businesses. The determinants conditioning the level of flexible operations in the analyzed area, based on the conducted research, include the participation of family members in the power in the company as well as the generational profile of the company.

Keywords: Enterprise Management, Organizational Flexibility, Changes and Innovation, Family Business

Introduction

Changes in the macroenvironment of the organization, considered as turbulent, unexpected and uncertain, force enterprises to undertake flexible operations. However, flexible organizational operations, necessary in the era of changes, are not only due to the turbulence of the environment but also from conditions for competitiveness.

Family businesses, characterized by specific features, may affect their abilities in terms of flexible operations which, will become the standard. In this case, the level of organizational flexibility results from internal conditions of this type of organizations and allows them to adapt to market changes and customer needs in a flexible manner. It is the family spirit occurring in business that makes that market advantages can be achieved by enterprises in a flexible manner. Moreover, the flexibility of operations as a characteristic of family businesses, according to the literature review, is identified in all management areas.

Shimizu and Hitt (2004) point out that family businesses, as a specific group of enterprises, have the ability to rapidly identify significant changes in the market, engage their resources in new, often strategic solutions and quickly respond in the business environment, which causes that they become flexible in all areas of management functions.

Creating flexible organizations is a response to challenges of the environment and flexible companies may effectively respond to the dynamic environment (Sanchez 1995) and competitive changes. The flexibility of operations means that entrepreneurs flexibly modify plans or decisions continuously, adapting to changing circumstances (Brettel et al 2012), at the same time, they can make changes in a relatively short time and, at comparatively low expenditures. These changes are often radical, including the change in primary objectives or strategies and can be made in all areas of the company's operations (Lemańska-Majdzik 2019).

The objective of the article is to assess the level of flexible operations in the area of organizational and innovative change management by family businesses. In the article, the authors relate to own research carried out in Poland in 2018, using the authors' survey questionnaire for family business owners.

Practices in terms of the implementation of change, innovation and new technologies in family businesses – results of the literature research

The ongoing process of globalization pinpoint the significance of the ability of the company to engage in the development and implementation of innovation and organizational changes (Camps, Marques 2014; Mynarzova et al 2016), however, in order to capture new business opportunities and translate innovativeness into better results of the company, something more than just the ability to develop products is needed. Innovation is directly related to creating value for the enterprise (Lee et al 2012), which determines the operation of the organization and has a positive impact on its development. The enterprises which are pioneers in the market implement innovation easily, thus increasing their opportunities for survival and development (Cefis, Marsili 2006). This situation also applies to family businesses which are often defined as enterprises set up by a creative person with leadership qualities (Duran et al 2015). The research by, among others, Craig and Dibrell (2006) indicates that family businesses may have characteristics favorable for innovativeness. While establishing business objectives, family businesses remain unanimous, pointing out that the factors affecting their market success, in addition to the organization members, are just the implemented innovation. The report on the state of family businesses in Poland indicates that the high level of investment expenditure linked to innovation has been rising in recent years just among such firms (Barometr firm rodzinnych 2016). The research conducted on a group of family businesses shows that the innovation which is financed mainly with the EU funds and own resources of family members participating in the company's activities is being implemented more and more often and increasingly intensively.

The research indicates that family businesses place great emphasis on innovation (De Massis et al 2013; Röd 2016; Sharma, Salvato 2011). However, the opinions on this issue are divided, some studies show that family businesses are more innovative than non-family businesses (Muñoz-Bullón, Sanchez-Bueno 2011), while others show the opposite (Block 2012). The commitment of the owner's family to the company is also defined as the family spirit, which is an important distinguishing feature of this type of organizations. It turns out that a significant part of the portfolio of the company's resources is an important component in understanding the operation of the family business (Kellermanns et al 2012; Carnes, Ireland 2013). The research into innovativeness of family businesses (Llach, Nordqvist 2010) confirms that the family may affect the efforts of family businesses for the benefit of innovation.

The literature review additionally indicates that family businesses, characterized by the overlapping of private life and business, have unique characteristics, which may provide a competitive advantage over non-family businesses (Habbershon et al 2003; Röd 2016). Innovation in family businesses is idiosyncratic due to the family engagement in the company's activities and the decision-making process (Rondi et al 2018). Therefore, the innovative attitude of the family business can be defined through its strategic orientation resulting from the participation of the family in business activities. It is also due to the climate, philosophy and practices influencing the development of innovation in

family businesses. According to the literature devoted to family businesses, two dimensions of the family business innovative attitude are identified: propensity to take risk, attachment to tradition.

As indicated by the research at the company level, propensity to take risk is lower in family businesses than in their non-family counterparts and depends on the degree of the family involvement in business (Li, Daspit 2016). Therefore, propensity to take risk is the propensity of the family business to engage in behavior with uncertain consequences. For this reason, the family business with propensity to take risk tolerates uncertainty, encourages to personal initiative within a family group (Isaksen, Tidd 2007). The studies by De Massis et al. (2016) shed light on the significance of the past family business in terms of innovation, identifying "new innovativeness" assigned to family businesses, known as "innovation by tradition". Family businesses, while implementing innovation, reject the past to make space for the future, whereas the innovation strategy indicates that some family businesses have a unique set of possibilities allowing them for interpretation and reinterpretation of expertise, which is remote in time, thus they implement innovation based on tradition (De Massis et al 2016; Gorzeń-Mitka, Okręglicka 2015). Therefore, attachment to tradition is regarded as the extent to which the family business is anchored in its past and wishes to forward it to the future. Family businesses with high attachment to tradition attach great importance to their history, wishing to preserve their heritage, whereas family businesses with low attachment to tradition focus more on the present than on the future and consider their status quo as the starting point for creating something new. The past is treated as the stage which the company must leave and take on new challenges aimed at evolution (Kammerlander et al 2015).

When relating to the categorization of innovative family business attitudes into separate theoretical types, the multidimensional approach to the recognition of the complex and interdependent nature of innovation in the family business can be adopted (Cornelissen 2017). According to Rondi, De Massis and Kotlar (2018), family businesses can take four different orientations or attitudes to stimulate innovativeness (see Figure 1).

Figure 1: Typology of family business innovation postures (Rondi et al 2018)

The combination of the dimensions including propensity to take risk and attachment to tradition determines the framework of various innovative attitudes with alternative orientations which the family may achieve in business, developing the philosophy, climate and innovative practices. In relation to these two dimensions, the typology of four heterogenous combinations can be identified, each of which, in the opinion of Rondi, De Massis and Kotlar (2018), leads family businesses to commitment to highly innovative behavior.

From the point of view of family business innovation, the ownership structure, which undoubtedly affects the results in the area of innovation, is also important. Family businesses need to simultaneously combine various innovation objectives, including gradual and radical innovation but

the intensity of these objectives may vary over time (Sharma, Salvato 2011) and depends on management characteristics (König et al 2013). It turns out that the companies managed by the founder are more innovative than those managed by a larger number of family members or connecting family clans (Block 2012). On the one hand, family businesses are known for combining financial objectives with socio-emotional objectives concerning organizational wealth, leading to long-term orientation and greater openness to innovation. On the other hand, the literature suggests (Chin et al 2009) that the ownership of the family, in particular tighter control by a larger share in ownership is linked to lower innovativeness. Families who build their own capital also have a greater incentive to closely monitor how the money is spent, which favors the saving policy but may also discourage from innovation expenditure, particularly in relation to radical innovation with unknown origin (Chrisman, Patel 2012).

While considering the multigenerational nature of family businesses, it turns out that that the founders of family businesses are often remarkable innovators. However, many family businesses managed by subsequent generations seem to lose this ability (Kraiczy et al 2015). Following this way of thinking, it can be concluded that favoring the potential successor during their upbringing may lead, among others, to nepotism, lack of professionalism or even corruption (Jaskiewicz et al 2013). Therefore, instead of a constant search for new opportunities, the tendency to optimize the existing strategies may dominate in many older family businesses. As a result, the subsequent loss of innovativeness may threaten the longevity of the company. Moreover, other factors, such as harmful family conflicts (Eddleston, Kellermanns 2007), insufficient management systems and lack of competence and/or legitimacy of the successor (Carney et al 2015) often contribute to a harmful effect of the loss of innovativeness. The international studies show that along with a growing number of generations, innovation performance in family businesses is constantly declining. Future generations may be less oriented to innovation in their operations (Beck et al 2011), however, intergenerational cooperation is also considered as the factor positively influencing the level of innovation in family businesses (Hauck, Prügl 2015).

The results of other studies conducted on a group of family businesses also indicate that family businesses are particularly good at innovation on the basis of their unique history and resources and a long-term perspective, which stimulates them to engage in more radical innovation ensuring their long-term stability. It turns out that family businesses are initially reluctant to engage in discontinuous innovation, however, when they do that, they adapt new technologies faster and more efficiently than non-family businesses (Penney, Combs 2013). Kiełtyka (2016) pinpoints that it is the ability and flexibility of the use of new technologies that affects the success of the organization, creating organizations of the future.

The above considerations led the authors to carry out the research in this area in terms of flexible operations in the field of the implementation of changes and innovation by Polish family businesses.

Flexibility in the implementation of changes, innovation and new technologies by family businesses – results of the empirical research

Research Methodology

The primary objective of the article is to assess the level of flexible operations in the area of organizational and innovative change management by family businesses.

To accomplish the assumed objective, the following research questions were formulated:

- What is the level of flexible operations in the process of the implementation of changes, innovation and new technologies in family businesses?

- Does the level of flexible operations in the area of management of organizational changes and innovation in family businesses depend on the participation of family members in the power in the company?
- Does the level of flexible operations in the area of management of organizational changes and innovation in family businesses depend on the generational profile of the company?

The research was carried out in 2018 on a group of Polish family businesses. Both small and medium family businesses, classified by the number of employees (according to the EU standards) participated in the research, i.e. a total of 346 companies. During the research, the tool of the authors' survey questionnaire was used, previously subjected to operationalization in order to verify its reliability. The entrepreneurs-owners of the surveyed family businesses took part in the research. In order to accomplish the objective of this study, only the selected research area, including the implementation of innovation and new solutions by family businesses, was subjected to the analysis.

Results of the own Research and Discussion

The operationalization of the research tool allowed for the identification of two dimensions in the area of flexible operations associated with organizational and innovative change management, namely:

- implementation of changes in the organization (KZOI_WZO),
- implementation of innovation and new technologies (KZOI_WINT),

therefore, in the subsequent research, these two dimensions are subjected to the analysis.

Flexible operations in the dimension of KZOI_WZO were rated by the respondents at a rather low level of 3.33 on the 7-point scale. Q25 indicates that at least 25% of the family businesses rated flexible operations in this dimension at the level of up to 2.60. In turn, the value of Q75 indicates that at least 75% of the surveyed family businesses rated flexible operations in the dimension of implementation of changes in the organization at the level of up to 4.00 on the 7-point scale. Flexible operations in the dimension of KZOI_WINT were rated by the respondents at a quite high level of 5.29 on the 7-point scale. It turns out that at least 25% of the family businesses rated flexible operations in this dimension at the level of up to 4.50, at least 50% of the respondents – at the level of 5.50 or lower, and at least 75% of the surveyed family businesses rated flexible operations related to this dimension at the level of up to 7.00 on the 7-point scale (see Table 1).

Table 1: Descriptive statistics for the dimensions concerning organizational flexibility in family businesses

Dimensions	N	Average	St. deviation	Min	Q25	Median	Q75	Max
KZOI_WZO	346	3.33	1.00	1.00	2.60	3.20	4.00	6.60
KZOI_WINT	346	5.29	1.33	1.00	4.50	5.50	6.00	7.00

Another stage was to explore if there are relationships between the levels of flexible operations in the identified dimensions (KZOI_WZO, KZOI_WINT) using tau Kendall's Tau. The conducted analysis of the correlation of the variables showed that there is a positive statistically significant relationship between the identified dimensions (Kendall's Tau=0.19). This means that along with an increase in the value of one dimension there is an increase in the value of the other one (see Table 2). The above considerations lead to the confirmation of the results of the authors' research into the frequency of undertaking flexible operations which influence their number. At this point, one may agree with the research results by Batarlienė et al. (2017), who claim that the frequency of undertaken operations positively affects the number of undertaken actions.

Table 2: The relationships between the level of flexible operations in the dimensions related to the implementation of organizational changes and innovation in family businesses

Dimensions	KZOI_WZO	KZOI_WINT
	Kendall's Tau ($p < 0.05$)	
KZOI_WZO		**0.19**
KZOI_WINT	**0.19**	

Another stage of the conducted research was the analysis of flexible operations in the area of organizational and innovative change management in family businesses in relation to the participation of family members in the power. When analyzing the surveyed family businesses, it is worth pinpointing the participation of family members in the company's activities since, as indicated by the subject literature, the power in the hands of the family determines the organizational behavior of enterprises (Mullins, Schoar 2016; Daspit et al 2018). The literature review leads to the identification of three situations in which 1) the power is exclusively in the hands of the family, 2) the power is in the hands of both the family and people outside the family and 3) the power in the family business is in the hands of people outside the family. During the analysis of the obtained data in this study, two situations were identified, the first, in which the power is exclusively in the hands of family members and the second, when the power is in the hands of both the family and non-family members. An attempt to identify the third group of family members failed due to the lack of such a declaration by the respondents. This phenomenon, as indicated by the literature review, is quite common in this type of organizations because entrepreneurs-owners or family members involved in the company's management do not want to give all the power to outsiders (Jogulu 2010).

During the conducted analysis on the assessment of the organizational flexibility in family businesses in relation to the participation of family members in the power in the company, the nonparametric Mann Whitney U test was applied. In the case of the Mann Whitney U test, probability observed p was used instead of critical values. Therefore, if this probability, according to the calculations, is found to be lower than the assumed level of significance of $\alpha=0.05$, the zero hypothesis (H0) is rejected for the benefit of the alternative hypothesis (H1).

Table 3: Statistics of the Mann Whitney U test for the dimensions related to the flexible implementation of organizational changes and innovation broken down by the power in the company

Dimensions	U	p	r Wendta
KZOI_WZO	10143.5	**0.080***	0.126
KZOI_WINT	11467.0	0.871	0.000

** tendencies towards differences, statistically insignificant relationships at the probability level of $p<0.05$*

The research showed that, in the case of the dimension of KZOI_WZO, there are tendencies towards differences, whereas, in the case of the dimension of KZOI_WINT, there are no differences in the level of flexible operations between the companies in which the power is exclusively in the hands of the family and the companies in which the power is in the hands of both the family and people outside the family (see Table 3). Therefore, subsequently, the subject of the analysis was only the dimension of KZO_WZO. It turned out that the level of flexible operations in the dimension of KZOU_WZO was the highest in the group of family businesses in which the power in the company was in the hands of both family members and managers from the outside of the family (mixed power), at the level of 3.54. It turns out that at least 25% of the family businesses rated flexible operations in this dimension at the level of up to 2.60, and at least 75% of the surveyed family businesses rated flexible operations related to this dimension at the level of up to 6.60 on the 7-point scale. In turn, when the power in the companies was exclusively in the hands of family members, the level of flexible operations was slightly lower, at the level of 3.27 on the 7-point scale. Moreover, at least 50% of the respondents rated flexible operations associated with this dimension at the level of up to 3.20 on the 7-point scale (see Table 4). Therefore, it can be concluded that more flexible

operations in the area of organizational and innovative change management, including the implementation of changes in the organization, are introduced by family businesses managed both by family members and external managers.

Table 4: Descriptive statistics concerning the flexibility of operations broken down by the power in the family business

Dimension of KZOI_WZO								
Power in the company	N	Average	St. deviation	Min	Q25	Median	Q75	Max
Family	261	3.27	0.96	1.00	2.60	3.20	4.00	6.20
Mixed	85	3.54	1.10	1.40	2.60	3.40	4.20	6.60
Total	346	3.33	1.00	1.00	2.60	3.20	4.00	6.60

Another stage of the conducted research was the analysis of the relationships between the generational profile of the company and flexible operations in the area of organizational and innovative change management. The literature review enabled the identification of three generational groups of family businesses (Sułkowski 2004; Vassiliadis et al 2015), namely: 1) the 1st generation/the company's founder, 2) the 2nd, 3rd generation and 3) the 1st and next generation simultaneously.

For the conducted analysis, the nonparametric analysis of variance (Kruskal-Wallis test) was used, which indicates the existing differences in the distributions for the level of the flexibility of operations in the analyzed dimension broken down by the generational profile of the companies.

Table 5: Statistics of the Kruskal-Wallis test for flexible operations in the dimensions of the implementation of organizational changes and innovation broken down by the generational profile of the company

Dimensions	H	p	Epsilon-squared
KZOI_WZO	5.401	0.067*	0.015
KZOI_WINT	1.427	0.490	0.004

** tendencies towards differences, statistically insignificant relationships at the probability level of p<0,05*

The conducted analysis using the values of the statistics of Epsilon-squared, indicated the tendencies towards differences. These are statistically insignificant relationships with the probability level of $p<0.05$, however, these tendencies will be subjected to the further analysis. In the case of this dimension, Epsilon-squared=0.015, which is the evidence of a very weak tendency towards differences (see Table 5).

Table 6: Probabilities observed of the post hoc Kruskal-Wallis test concerning flexible operations broken down by the generational profile of the company

KZOI_WZO	Generational profile of the company		
	1st generation/ the company's founder	2nd, 3rd generation	1st and the next generation simultaneously
1st generation/the company's founder		0.335	0.149
2nd, 3rd generation	0.335		0.972
1st and the next generation simultaneously	0.149	0.972	

The subsequent analysis showed that probabilities observed of the post hoc Kruskal-Wallis test for the dimension of KZOI_WZO, concerning flexible operations broken down by the generational profile of the company, do not confirm statistically significant relationship or tendencies towards differences (see Table 6), therefore, it cannot be concluded that such differences between the groups exist.

Conclusions

The research carried by the authors among Polish family businesses, the objective of which was to assess the level of flexible operations in the area of organizational and innovative change management by family businesses, allowed for responding to the first research question:

- The level of flexible operations in the process of the implementation of changes amounts to 3.33, whereas, in the process of the implementation of innovation and new technologies in family businesses, it amounts to 5.29 on the 7-point Likert scale.

Moreover, in the article, the research was conducted into the impact of the participation of family members in the power in the family business on the level of flexible operations in the area of organizational and innovative change management. On the one hand, the literature review indicates that the commitment of family members positively affects the level of flexible operations in family businesses (Daspit et al 2018; Chrisman, Patel 2012). On the other hand, the literature points out (Mullins, Schoar 2016; Bloom et al 2012) that the commitment of family members has a negative impact on the implementation of changes and flexibility of family businesses. The obtained results of the authors' research partially confirmed the studies referred to and the second research question can be responded to:

- Yes, the level of flexible operations in the area of organizational and innovative change management in family businesses does depend on the participation of family members in the power in the company. Moreover, the participation of people outside the family positively affects the level of flexible operations in terms of the implementation of organizational changes.

The obtained research results did not confirm (no statistically significant relationship) that the generational profile of the family business affects the level of organizational flexibility. These results are inconsistent with the research results by Liu et al. (2015), who indicate that the level of the company's flexibility is determined by future generations who manage family businesses, which, in the opinion of Giambatist et al. (2005), influences the level of management, including the level of propensity to changes, innovation and new technologies. Therefore, the third research question can be responded to:

- It cannot be unequivocally confirmed that the level of flexible operations in the area of organizational and innovative change management depends on the generational profile of the company.

The multidimensionality and a wide range of topics of the analyzed scientific problem do not exhaust the subject matter in question. It can be assumed that they are just the starting point for subsequent literature and empirical studies. Due to a significantly important role of family businesses in national economies and their substantial share in a total number of enterprises, it is worth carrying out the research into the level of organizational flexibility in relation to other areas of management in the future.

Telemedical technologies: The Needs of Elderly People in Poland

Agnieszka PIASECKA-ROBAK

University of Lower Silesia, Wroclaw, Poland
agnieszka.piasecka-robak@dsw.edu.pl

Abstract

Telemedicine is still an uncontested space in Poland (Chan Kim, Mauborgne, 2015). Exploring it in detail is worthwhile, because it can affect the process of successful aging, whose rates are very low in Poland (OECD, 2017, Online). Telemedicine and telehealth can offer elderly people an important value – autonomy and independence. It also makes the monitoring of the health condition and vital functions of the elderly possible, which is an additional asset in the times of the pandemic. The article discusses the condition of seniors and describes what seniors and their caregivers actually expect of telemedical solutions and which solutions they accept and reject. The research proceeded in three stages. The unobtrusive measures method was applied in the first stage, comparative analysis in the second stage, and a survey on the usefulness of telemedicine devices in the third stage (Babbie, 2004; Webb, 1966; Øyen, 1990). The aim of the survey was to design an optimized device for the elderly and their caregivers, according to the rules of the Design Thinking process (Brown, 2009; Brown, Wyatt, 2010).

Keywords: elderly people, design thinking, education, telemedical technologies

Introduction

According to the statistical data of Statistics Poland (GUS, Poland's central bureau of statistics), Poland's population reached 38,383,000 people at the end of 2019. The number was lower by 28,000 than at the end of 2018. At the same time, a negative natural population growth was recorded as the number of births was lower than the number of deaths by 35,000, representing the lowest value since World War Two. The total fertility rate dropped, consequently precluding what is referred to as generation replacement. The proportion of people in the retirement age bracket was 21.5% of the total population, with people aged 65 years old and older accounting for nearly 18%. Seniors aged 80 years old and older made up as much as 18% of the elderly population (GUS, 2020, Online).

Though typical of European countries, the increase of the overall average life expectancy is correlated in Poland with exceptionally low indices of what is known as *successful aging.* Admittedly, according to the Eurostat data, sixty-five-year-old males and females in Poland can expect to live, respectively 16 and 20.5 more years on the average, but their estimated prospective periods of "healthy life" are considerably shorter, specifically 8.2 years for males and 8.9 years for females (OECD, 2017, Online). Health-related issues are highly relevant to successful aging, and the prospects for Poles to "successfully age," i.e., to grow old retaining satisfactory levels of cognitive and physical functions, are scarce. Poland's successful aging rate is among the lowest in Europe and currently stands at 1.6%, which represents a vast difference from Europe's best outcomes in this respect: 21.1% in Denmark and 17% in Sweden, and even from the European mean value of 8.5% (Hank, 2011). This makes it clear that it is exigent and urgent to apply knowledge in the fields of gerontology, andragogy, and counselling in order to improve telemedical technologies in the senior sector and to optimize practices and interventions for senior citizens. This is particularly pressing at the present moment, when post-traditional societies have an immense freedom of choice and enjoy nearly unlimited possibilities. At the same time, however, this abundance may cause decision paralysis (Schwartz, 2004). Given this, a reflexive approach to successful aging becomes particularly important, as does reflexive designing of one's own life (Giddens, 2013), including in the context of developing telemedicine technologies.

Telemedicine is a new and still untapped Blue Ocean (Chan Kim, Mauborgne, 2015) on the Polish map of products and services which can affect successful aging. Telemedicine is defined as "the natural evolution of healthcare in the digital world" (ATA, 2020, Online). It is based on the real-time interactive communication in which information about health status is exchanged between a patient (an elderly person) and a physician/practitioner/caregiver at a distant site through telecommunications equipment (AHRQ, 2020, Online; CMS, 2020, Online). In telemedicine, medical knowledge and technical solutions, therein information technologies, are innovatively combined with each other. One of its purposes is to offer the elderly as users a value they cherish, specifically as much self-reliance and independence as their psychophysical condition permits. Telemedicine also makes it possible to regularly monitor the health status and vital functions of the elderly. Additionally, it affords opportunity to rapidly respond to whatever irregular, unwelcome developments or incidents take place.

The aim of this article is threefold. First, discussing the condition of polish seniors. Secondly, describing what seniors and their caregivers actually expect of telemedical solutions and which solutions they accept and reject. Thirdly, designing an optimized device for the elderly and their caregivers, according to the rules of the Design Thinking process.

Materials and Methods

The research process was sequenced in three stages. The first stage employed the method of *unobtrusive measures* (the non-reactive research method, e.g., content analysis) (Babbie, 2004; Webb, 1966). The situation of the elderly in Poland was analyzed on the basis of the existing statistical data (GUS, Eurostat, OECD, WHO). The investigation also involved exposing the limitations of the health care and social welfare systems for the elderly, whereby statistical data were used together with the literature. This stage aimed to (1) describe the problems, needs, and condition of seniors in Poland as accurately as possible; and to (2) identify the potential weak points where the health care system failed to adequately respond to the real problems and needs of seniors. The second stage involved a *comparative analysis* of the existing telemedicine solutions for the elderly available on the Polish market in terms of the features they offered. The collected data were used to select the technically most valuable solutions which could respond to seniors' still unmet needs and were relatively easily acceptable to the elderly. In the third stage, a survey study was carried out among senior to find out about their views on the utility of telemedicine devices, possibilities of applying them, and their key functionalities. The goal of the survey was to help design an optimized device for seniors in conformity with the definition and rules of the *Design Thinking* process (Brown, 2009; Brown, Wyatt, 2010). The research sample surveyed for this purpose included thirty seniors and thirty caregivers from their families.

The research process complied with the principles of Design Thinking, understood as "a human-centered innovation process that emphasizes observation, collaboration, fast learning, visualization of ideas, rapid concept prototyping and current (…) analysis which ultimately influences innovation and (…) strategy" (Lockwood, 2009, xi). Design thinking now requires the social designer be sensitive to generational problems and to know how to solve problems, regardless of the complexity of these problems (Nijs, 2019, 65).

Fig. 1: Apply the Design Thinking process in order to design an optimized device for the elderly

The author was guided by the notion of value innovation (Chan Kim, Mauborgne, 2015), which helps (1) explore potential users in order to eliminate the factors which the market has so far taken for granted but which are not considered salient values by these users, e.g., including social media options in telemedicine devices; (2) reduce some factors clearly below the standards in place in order to avoid the mistake of too numerous possibilities on offer (in keeping with B. Schwartz's notion that the wider the choice, the greater the user's decision paralysis and sense of loss caused by making this rather than any other choice [2004]); (3) increase some factors clearly above the standards in place to prevent users from having to compromise (e.g., the accuracy of heart-rate measurement, operating time without charging the device); and (4) produce a new quality not offered yet by the device developers, e.g., a telemedicine device as offering a new experience of old age which enables seniors to function independently at home and in their close, familiar environments with the sense of security afforded by a device that monitors vital functions.

Results

1. <u>Orientation on the user's needs as the cornerstone of Design Thinking – non-reactive research results:</u>

1.1. The situation of the elderly in Poland is difficult and worrying. The major problem faced by Polish seniors include: the lack of economic security and the lack of medical and care support for the elderly. The situation of people suffering from neurodegenerative conditions, such as dementia and Alzheimer's disease is a matter of particular concern.

1.2. The elderly's right to decent life is essentially put at risk by factors such as: long waiting times for specialized medical procedures, limited access to specialized physicians and geriatricians, increasingly shorter hospitalization periods, the decreasing number of hospital patients older than 75 years of age, the reduction of beds in or even the closing of geriatrics wards.

1.3. Elderly care in Poland is predominantly provided by families (about 85% of caregivers for the elderly are so-called natural caregivers, i.e., family members and loved ones). Seniors, their caregivers, and members of social organizations advocating for the elderly report that there is no operating system of support for dependent seniors (especially dementia patients) and their caregivers. Social support is provided by volunteers of NGOs, in particular religious ones, e.g., Caritas (Caritas Polska, Online);

1.4. It is exigent to launch systemic policies and interventions aimed at counteracting what is known as indirect discrimination. Indirect discrimination involves implementing ostensibly neutral solutions or failing to actually implement any action, which results in restraining seniors' right to a long and independent life (RPO, 2018, 9-10; see United Nations. General Assembly – Resolution, 2019, Online). Such policies and interventions should: (1) support holistic approaches to the needs of the elderly and their expectations of the support they receive; (2) seek to put in place a community support system which is adequate to differing (aggravating in time) dependence of the elderly and results from consultations with seniors, especially in terms of the incidence of potential risks and discriminatory practices; (3) promote multi-sector engagement (cooperation of the public, private, and non-governmental sectors) in the professionalization of social support through devising comprehensive offers; (4) use state-of-the-at technology in order to support basic communities (mainly families of the elderly) and informal caregivers of depended seniors, in compliance with the principle of subsidiarity; and (5) strive to make sure that the elderly with limited self-reliance enjoy the right of independence, activity (correlated with their possibilities), and self-determination;

1.5. The most frequent diseases and conditions among Polish seniors were identified. They were arterial hypertension, back and neck pain, movement-impairing osteoarthritis, coronary disease, and diabetes. Complaints concerning motor abilities, sense organs, and self-servicing capability included vision and hearing impairments, impeded walking and problems with self-servicing understood as performance of daily activities which form the basis of an adult's existence (GUS-EHIS, 2015; GUS, 2018, 12-14). The elderly in Poland often suffer from "geriatric syndromes," that is, disorders caused by multiple comorbidities which require help from other people aided by telemedicine technologies which facilitate daily lives of the elderly and their caregivers.

2. Experience-based approach to the problem as the cornerstone of Design Thinking: Findings of comparative research:

2.1. Prevalent telemedicine devices used in Poland include "life wristbands" and remote senior care services. Telemedicine wristbands have been implemented in five Polish cities for a few months now. The scope of functionalities of these devices is considerably constrained, and they serve the elderly in a very limited way. This is linked to cost reduction efforts at the level of local self-governments, whose responsibilities include care for seniors. However, the actual demand for such wristbands has not been studied yet; nor has their functionality in the context of seniors' needs been examined.

2.2. The most frequent features offered by producers of telemedicine devices include: heart-rate monitoring, senior fall alert, and instant help button.

2.3. The most popular telemedicine devices available on the market offer the following functions: (1) bilateral communication (possibility of making and receiving phone calls); (2) button for contacting a caregiver or another designated person; (3) SOS button calling a pre-defined number (e.g., 112) and sending text messages to pre-defined telephone numbers; (4) GPS/LBS location; (5) heart-rate monitoring; (6) sleep monitoring (providing the caregiver with information about deep and light sleep); and (7) pedometer and calorie counter.

2.4. Some telemedicine devices also contain the following features: (1) Virtual wall (marking the safe zone within which the wristband wearer can move); (2) Movement sensor; (3) Fall sensor; (4) Listening to the environment (the caregiver can at any time discreetly listen to the environment in which the senior finds him/herself, for example, when voice contact is impossible or hindered); (5) Reminder of cyclic functions (drinking water, taking medicines, moving) and (6) Alarm (indicates a failure of the device).

2.5. Telemedicine devices very rarely are furnished with the following features: (1) Temperature sensor (monitoring the temperature level in the closest surroundings); and (2) Voice notification about the current time.

3. Testing, i.e., interviewing seniors about the solutions which they believe can work in the real world: Survey study results[i]:

3.1. More than half of the respondents (46 people; 76.66%) had never heard of telemedicine devices for seniors before. None of the respondents had ever used telemedicine devices, though 14 people (23.34%) had heard of them.

3.2. Eighty-five percent of the respondents (51 people) thought it was a good idea for the elderly who had problems with independent functioning to use telemedicine devices. None of the respondents (0%) found it was a bad idea, while 15% of the respondents (9 people) formed no opinion on the issue and answered "I do not know."

3.3. Asked to select three major features of telemedicine devices which would facilitate care for the elderly, the seniors and their caregivers opted for: (1) bilateral internal communication (36 votes – 60% of answers); (2) incident reporting (39 – 65%); and (3) fall sensor (35 – 58.3%). The functions less frequently chosen for their utility included: (4) reminders of cyclical activities (26 votes – 43.3% of answers); (5) senior GPS location (24 – 40%); (6) movement sensor (16 – 26.66%); (7) alarm (12 – 20%); (8) listening to the environment (11 – 18.33%); and (9) heart-rate monitoring (10 – 16.66%). The respondents believed that the following features were least needed in telemedicine devices: (11) pedometer and calorie counter (1 vote – 1.66%); (12) temperature sensor (3 – 5%); (13) voice notifications about the current time (3 – 5%); (14) virtual wall (3 – 5%), and sleep monitoring (5 – 8.33%).

3.4. Asked to pick the three main features of telemedicine devices which could be most relevant to elderly users, the senior respondents and their caregivers chose the following: (1) bilateral internal communication (39 votes – 65% of answers); (2) reminders of cyclical activities (35 – 58.33%); and (3) incident reporting (34 – 56.66%). The functions whose utility was less frequently recognized included: (4) fall sensor (19 – 31.66%); (5) heart-rate monitoring (12 – 20%); (6) alarm (11 – 18.33%); and (7) senior GPS location (10 – 16.66%). The features which were lowest-rated for usefulness in telemedicine devices were: (8) pedometer and calorie counter (1 – 1.66%); (9) virtual wall (2 – 3.33%); (10) listening to the environment (3 – 5%), (11) voice notifications about the current time (3 – 5%); (12) sleep monitoring (3 – 5%); (13) temperature sensor (5 – 8,33%); and (14) movement sensor (6 – 10%).

3.5. Asked to state which three features of the wristband were redundant, both the senior respondents and their caregivers selected: (1) pedometer and calorie counter (52 votes – 86,66% of answers) and (2) voice notifications about the current time (36 – 60%). The choice of the third function was more problematic, as the respondents hesitated among (3a) sleep monitoring (18 – 30%), (3b) temperature sensor (15 – 25%), and (3c) listening to the environment (15 – 25%). Other features the elimination of which was considered by the respondents also included (4) virtual wall (12 – 20%) and (5) movement sensor (11 – 18.33%). The respondents less frequently opted for the exclusion of: (6) alarm (7 – 11.66%); (7a) heart-rate monitoring and (7b) senior GPS location (6 votes and 10% of answers each); (8) fall sensor (3 – 5%); (9a) bilateral internal communication and (9b) incident reporting (2 votes and 3.33% of answers each). None of the respondents suggested removing reminders of cyclical activities from telemedicine devices as their redundant feature.

The table below brings together the choices of useful functionalities of telemedicine devices as reported by the senior respondents (A) and their caregivers (B), together with the scores for the three discarded functionalities whose inclusion was not considered indispensable for the monitoring of seniors' health status (C). Column 6 presents the total scores for all functionalities, showing which of them had the lowest and the highest number of positive votes. The votes from column 5 (C) were subtracted from the sum of positive votes from columns 2 (A) and 3 (B), which resulted in some negative scores in column 6 (D). The functionalities which have the lowest scores in column (D) were the least attractive ones to the respondents.

Table 1: The respondents' assessment of the functionalities of telemedicine devices (stage 3 of the research study)

Functions of telemedicine devices[ii]	Most important for the elderly votes (picks) (A)[iii]	Relevant to the caregiver votes (picks) (B)	Key functions of telemedicine devices votes (picks) (A)+(B)	REDUNDANT functionalities votes (picks) (C)	Sum of the votes obtained votes (picks) (D) = (A)+(B) – (C)[iv]
Function 1	39 (65%)	36 (60%)	**75**	2 (3.33%)	**73**
Function 2	6 (10%)	16 (26.66%)	22	11 (18.33%)	11
Function 3	5 (8.33%)	3 (5%)	8	15 (25%)	-7
Function 4	34 (56.66%)	39 (65%)	**73**	2 (3.33%)	**71**
Function 5	19 (31.66%)	35 (58.3%)	**54**	3 (5%)	**51**
Function 6	12 (20%)	10 (16.66%)	22	6 (10%)	16
Function 7	10 (16.66%)	24 (40%)	34	6 (10%)	28
Function 8	1 (1.66%)	1 (1.66%)	2	**52 (86.66%)**	- 50
Function 9	3 (5%)	11 (18.33%)	14	15 (25%)	- 1
Function 10	11 (18.33%)	12 (20%)	23	7 (11.66%)	16
Function 11	3 (5%)	3 (5%)	6	**36 (60%)**	- 30
Function 12	2 (3.33%)	3 (5%)	5	12 (20%)	- 7
Function 13	3 (5%)	5 (8.33%)	8	18 (30%)	- 10
Function 14	35 (58.33%)	26 (43.3%)	**61**	0 (0%)	**61**

Combining the needs and negations of the elderly respondents and their caregivers indicates that the most expected functionalities of telemedicine devices that facilitate the daily monitoring of seniors' health status are comprised of: (1) Bilateral internal communication (the possibility of calling a designated person to repot the lack of supplies – such as food or medicines – or an event that requires an intervention) (73 votes); (2) Incident reporting (a senior presses the button to call for help or to report an incident) (71 votes); (3) Reminders of cyclical activities (e.g., drinking water and taking medicines) (61 votes); and (4) Fall sensor (51 votes). The respondents' lowest assessments were given to the features including "Pedometer and calorie counter" (52 negative votes) and "Voice notifications about the current time" (36 negative votes).

Conclusion

Telemedicine devices offer a real opportunity for improving the quality of life of elderly people and supporting families in their care for seniors. While they are not popularly known to the Polish public, they invite a considerable approval and are identified by families, relatives, and caregivers as providing aid in the process of caring for the elderly.[ii] Telemedicine devices can alleviate the burdens to the health care system, which grapples with staff shortages and long waiting times for specialist consultations and procedures (difficult access to specialists is a ubiquitous problem in Poland). More than that, telemedicine devices can also secure the health and lives of the elderly by enhancing their control over diseases, complaints, and their own condition. The constant monitoring of vital processes and events round the clock can effectively support long-term therapies and make seniors feel less controlled by their loved ones or professional carers. Consistently with the policies defined in *Health 2020*, telemedicine devices can become an important component of the patient-oriented health care system in Poland as well (WHO, 2013, 3). For this to happen, the key requirement to be met by telemedicine devices is that they should contain an array of universal features, because too circumscribed a focus on a particular group of clients with narrowly defined diseases and disfunctions may prove ineffective in case of multiple coexisting disabilities. Such universal features undoubtedly include options of bilateral communication and "incident reporting" (so-called instant help buttons). They are particularly important for sustaining seniors' social participation and minimizing their sense of social exclusion. The awareness that seniors can count on quick help from another person who will rapidly respond to incidents requiring intervention will bolster their sense of security and satisfaction from life. This will affect their self-esteem by fostering the feeling of autonomy and, consequently, of self-worth and self-determination.

If telemedicine devices meet the needs of the elderly and their caregivers in terms of the functionalities they offer and their simple, attractive forms that encourage daily use, they may promote quite a new experience of aging. The improved opportunities for living on one's own in one's familiar environment, coupled with the awareness that one's vital functions are systematically monitored, can be reasonably expected to reduce people's fear of helplessness, disability, and suffering alone in oblivion. Importantly, telemedical devices can also contribute to eliminating "indirect discrimination" by buttressing seniors' right to live independently as long as possible and by bolstering the quality of their daily functioning. In this way, telemedicine devices may influence the "successful aging" rate in Poland, as they offer their users the paramount value of autonomy and self-reliance (adjusted to their health status).

---

[i] The research sample included 63 respondents: 42 females and 21 males. As some survey questionnaires were incomplete (some respondents passed over some questions), 60 surveys were selected (30 filled in by the seniors and 30 by their caregivers) to ensure the comparability of results. Females accounted for 66.66% of the total sample, and males for 33.34% thereof. The age distribution within the senior sample facing problems in daily functioning was as follows: people aged 56-65 years old made up 40% of the sample (12 people), respondents aged 66-75 years old formed 33.34% of the sample (10 people), and individuals aged 76 years old and older accounted for 26.66% of the sample (8 people). As for their caregivers, 16.66% were people younger than 29 years old (5 people); 33.33% were caregivers aged 30-40 years old (10 people); 16.66% were individuals aged 41-55 years old (5 people); 20% were caregivers aged 56-65 years old (6 people); 10.02% were people aged 66-75 years old (3 people); and 3.33% were individuals aged 76 years old and older (1 person). In both samples, the majority of the respondents had university-level education (23 people in each group, 76.66%) or secondary education (6 people in each group, 20%). One person (3.33%) had trade-school education.

[ii] The survey carried out in the third phase of the research study stirred so much interest among the respondents that ¼ of the sample asked the Author for very detailed data about the foreign telemedicine technologies and devices which are already available on the market. In their opinion, such devices can significantly improve the quality of functioning and security of both the cared-for and the caregivers.

Being "Eco" As the Future for The Cosmetics and Household Chemistry Market in Poland. The Preliminary Research

Abstract

Purpose. The aim of the article is to learn the behavior and opinions of consumers of the cosmetics and household chemistry market in Poland. **Methodology**. Our analysis is based on data collected by survey method. In the analysis we use the data provided by 222 respondents – the consumers in Poland. The survey was created by the authors of the article to find out the opinions and behavior of respondents regarding pro-ecological behavior while shopping in the cosmetics and household chemistry sector at the end of 2019. Descriptive statistics and graphic data presentation were used to present the research results. **Findings**. Research results have shown that Poles are very environmentally aware and implement many behaviors in their daily lives in order to counteract climate change. 85% of respondents declare their willingness to buy cosmetics and environmentally friendly household chemistry. As the most important product feature, determining the choice of cosmetics and household chemicals, respondents indicated the composition of the products offered. **Originality/value**. This paper makes two major contributions to the literature and business practise. First, it presents possible green activities on the cosmetics and home chemistry market. Secondly, it presents consumer opinions on the demand and criteria for selecting this kind of products in Poland. This analysis may be the basis for building production, promotion and sales strategies for enterprises operating on the cosmetics and household chemistry market in Poland.

Keywords. Green marketing, green sales, green products, cosmetics market, eco-friendly consumers, eco-friendly market.

Introduction

In the world, for the last few decades researchers have observed a significant change in the consumer behaviour from choosing products based on its physical attributes such as size, color, flavor or aroma to other important features like environment and health (Kirilenko and Sedjo, 2007). In Poland, the topic of ecology has been treated quite marginally so far, but nowadays disturbing information on the state of the environment and the impending climate crisis is becoming more widely announced. One of the most important documents is the IPBES global report 'The Global Ecosystem Assessment' on biodiversity of nature (https://ipbes.net/global-assessment) presented in May 2019 in Paris, stating that the current rate and scale of extinction of millions of species of plants and animals have never been observed before. This report has been widely commented on in the media, and it can be assumed that it has significantly affected Polish consumers. As a result, the producers' market faced implementation of changes.

21st century consumers are becoming more and more conscious of the products they purchase. They have become more informed buyers, for whom not only price is the main criterion for selection. They make more rational and thoughtful purchases, and with certain groups of products, they become less receptive to advertising. At present, producers need to have some added value that will allow them to

distinguish themselves from competitors. It becames common among consumers to expect companies to be involved in local affairs or global issues, especially those regarding the environment (Kantor and Hübner, 2019). Consumers play an important role in the exploitation of the environment. They purchase products, so they have an impact on the resources consumed or the devastation of the natural environment (Witek, 2017). Due to striving for rational use of natural resources, the desire for ecological consumption has developed (Angowski and Domańska, 2016). They begin to be interested not only in the price of the product, but also in its composition and how it was produced and what impact it has on the environment (Baer-Nawrocka and Szalaty, 2017). It has led to creation of a new category of consumers who have started working on to find out ways and means to at least mellow down the effect of climate change. We call this category of customers as the eco-friendly consumers (Kirilenko and Sedjo, 2007).

At the same time, market behavior of many companies, including those from the cosmetics and household chemistry sector, shows that they are taking more responsibility for the effects of their actions on the environment. Frequently, the implemented solutions are innovative, and as such they contribute to image building of modern, pro-ecological and socially responsible enterprises. It can also be seen that companies effectively use pro-ecological activities to strengthen their image, and thus – competitive advantage. However, it is worth noting, that more and more introduced changes are obligatory, therefore real competitive advantage should result from activities that go beyond legal regulations (Stefańska, 2016). Continuous dynamic changes are also observed on the Polish cosmetics market. Recent years have brought intensive development and currently the Polish cosmetics market is at the forefront of Europe (6th place). Due to the fact that natural and organic cosmetics, which until now generated about 33 billion dollars of global profit, are gaining more and more interest worldwide, with buyers from countries of North and South America (Brazil), Europe (France, Sweden, Germany, Italy, Great Britain) and Asia (Japan, China and Korea) (Rybowska, 2015), and an increasing number of reports on the state of climate in Poland, it seems reasonable to check current consumer preferences on the cosmetics and household chemistry market in Poland. Therefore the purpose of the article is to learn the behavior and opinions of consumers of the cosmetics and household chemistry market in Poland.

Natural Cosmetics Market in Poland

The cosmetics market that has undergone intense development in the recent years, is one of the largest and most promising ones in the Polish light industry. The value of the Polish cosmetics market in 2016 amounted to PLN 16 billion, while in 2002 it was PLN 9 billion (Report: Branża Kosmetyczna Sektory Banku Zachodniego WBK, 2017). The Polish market has reached this level due to continuous development over the past fifteen years. The cumulative real market growth in this period was 32%, i.e. on average 2% annually, while in contrast, nominal cumulative market growth was as much as 78%. The industry leap is impressive, especially when compared to the situation in other European countries, as Poland is the sixth cosmetics market in Europe and is growing the fastest. This is even more vital because other large markets, such as French and Italian, not only have not recorded increases, but even contracted (by 0.19% and 1.09%, respectively). As a result, the estimated value of the cosmetics market in Poland in 2021 amounted to PLN 20 billion.

Today more than ever, the green trend is a part of the world economy; more and more consumers eat green, drive green cars, use green electricity, wear green clothes and naturally, turn to green cosmetics. According to Euromonitor, the 5% worldwide growth of the cosmetic sector in 2007 was mainly due to the input of green products (Cervellon et al., 2011). In Europe, the market for organic cosmetics is extremely dynamic, with a growth of 20% per year (Ecozept, 2010).

Natural cosmetics account for 4% of the entire cosmetics market in Poland (Report: PMR Rynek żywności bio i kosmetyków naturalnych w Polsce. Analiza rynku i prognozy rozwoju na lata 2019-2024, 2019). Forecasts indicate that this segment will grow dynamically in the coming years, even twice as fast as the entire cosmetics market. The increase in popularity of natural cosmetics is related to, among others, growing ecological awareness of consumers. Consumers try to avoid products tested on animals or those that contain a large amount of chemical compounds. The growing number of people declaring veganism or vegetarianism is also important – this translates not only into diet, but also to

other purchase. In turn, the market for cleaning and washing products in Poland generated revenues of over EUR 1.27 billion in 2018, and according to forecasts, these revenues will increase to EUR 1.34 billion in 2023, which means an annual average increase of 1,7% in 2010-2023 (Report: Branża Chemii Gospodarczej. Wzrost znaczenia polskich producentów na świecie, 2019).

It will also be essential for the industry to keep up with the trend, which in the wide horizon changes the perception of the concept of "health". Nowadays it is not only "lack of illness" but it is associated with the term "physical and mental well-being". This is definitely an area for development by the cosmetics industry, which until now has not been defined in these categories.

The Essence of Being "Eco" In the Cosmetics and Household Chemistry Industry

Green Composition

The market for green products is booming all over the world in a variety of industries. Green product is defined as “one that has less of an environmental impact or is less detrimental to human health than the traditional product equivalent” (Kumar, 2005). The term "eco" is nowadays frequently used by producers in many industries. Many cosmetic products introduced on the market are advertised as natural, ecological or biological. The recognition of criteria and the multitude of signs placed on product packaging results in confusion for both consumers and producers themselves (Pawlik et al., 2017).

Many cosmetics manufacturers advertise their products as "natural", "eco" or "bio", but there are no legal regulations defining these concepts (Kantor and Hübner, 2019). The definition of natural cosmetics turns out to be imprecise, and was only introduced in the Guidelines of the Committee of Experts on Cosmetic Products at the Council of Europe's Public Health Committee in September 2000. Since then, this definition has not been standardized in any document (Platta and Żyngiel, 2014).

As a result, various organizations in Europe have developed and introduced their own certification rules for natural and organic cosmetics. In order to harmonize the definition and production rules of such cosmetics, the main European certification organizations: BDIH from Germany, COSMEBIO & ECOCERT from France, ICEA from Italy and SOIL ASSOCIATION from Great Britain developed common COSMOS standards in 2010 (http://cosmos-standard.org, accessed on: January 25, 2017.) The COSMOS standard distinguishes two categories of products: organic cosmetics and natural cosmetics.

Organic cosmetics should consist of at least 95% of organic raw materials processed by physical methods (e.g. extraction, distillation, drying), including a minimum of 20% ingredients from organic farming, and the presence of no more than 5%. For natural cosmetics, the amount of 5% of synthetic substances is allowed. As fragrances, only natural essential oils can be used in natural cosmetics, while as preservatives synthetic substances identical to natural ones (e.g. benzoic, salicylic, sorbic acid and benzyl alcohol), which together can constitute no more than 5% of the product. Cosmetics that meet the above requirements are marked with the certification organization's name or logo, e.g. ECOCERT or BDIH. The composition of each product must be declared in accordance with the International Nomenclature of Cosmetic Ingredients INCI, while the organic ingredient should be marked with annotation: "comes from organic farming" (Pawlik et al., 2017).

Green Marketing

Due to the universality of the "eco" trend, many companies want to promote their products with its usage. Marketing is a process in which companies are creating values for consumers and build relationships in order to capture value from customers in return (Kotler and Armstrong, 2013). In recent decades, marketing has become a powerful tool that has successfully fueled consumption around the world. However the side effect of such marketing activities is over-consumption and current climate

problems (Sheth and Sisodia, 2006). Therefore, green marketing is more and more frequently mentioned.

Researchers have found a newline of research that has been given various labels, such as ecological marketing (Fisk, 1974), green marketing (Ottman, 1993;), greener marketing (Charter, 1992), environmental marketing (Peattie, 1995), enviropreneurial marketing (Menon and Menon, 1997) or sustainable marketing (van Dam and Apeldoorn, 1996; Fuller, 1999). The first definition related to Green Marketing dates back to 1976, when Hennion and Kinnear highlighted that Ecological Marketing was "concerned with all marketing activities that have served to help cause environmental problems and that may serve to provide a remedy for environmental problems" (Hennion and Kinnear, 1976). Although some authors distinguish these labels conceptually (see, for example, Van Dam and Apeldoorn, 1996), they are normally considered synonymous terms referring to the same field of study: the analysis of how marketing activities impact the environment and how the environmental variable can be incorporated into the various decisions of corporate marketing (Chamorro et al., 2009). The basic definition of green marketing is as follows "marketing of products that are presumed to be environmentally safe" (Mishra and Sharma 2008). That mean, that green marketing is producing and promoting reusable and eco-friendly products (Schiffman and Wisenblit 2014).

Green marketing probably can play some role in, at least, reducing to some extent the impact of climate change since there is sufficient evidence to support the fact that human activities are the major contributors towards climate change. Green marketing is the marketing of products and services in ecofriendly manner. It can be practiced in all the product categories (Kirilenko and Sedjo, 2007).

Awareness regarding green products and green marketing has increased and it is becoming more important as now people are more concerned about their environment and becoming more socially responsible. The objective of green marketing is to satisfy the needs and desires of the customers, and keep the company responsible in maintaining long-term social and environmental gains. All green marketing activities are focused, along with environmental concern, on green marketing (Zulfiqar and Shafaat, 2015).

In the cosmetics and household chemistry market, green marketing activities in Poland so far have been manifesting in communicating the natural composition of products (although it is not always so), in informing about the biodegradability of packaging or offering consumers the possibility of returning the packaging for reuse. However, it seems that these activities will soon be insufficient, because an increasing number of consumers are sensitive to the authenticity of the actions, and not just the "eco" label.

Going forward, if considering this sort of approach, one should bear in mind that (as with carbon neutral) the era of ''little things that make a big difference'' has probably passed. It is a fallacy that we can avert a global climate change disaster without significant change (Grant, 2008). To have any chance of success, green marketing needs to use the existing structures and thinking, to ensure environmental issues become a core component of how the markets and marketing operate. Marketers need to broaden their activities, creating alternative ways of presenting value and costs, changing the way businesses talk about human interactions and the environment, and reframing consumption from a focus on acquiring goods, to ways to sustainably achieve desired satisfaction (Polonsky, 2011).

When considering the relationship between ecological activities and strategies of commercial enterprises, it is worth mentioning the phenomenon of "greenwashing" (Lyon and Montgomery, 2015). "Green window dressing" or "green lie" include, among others, the use of a positive pro-ecological image of products to strengthen the company's image, while not complying with the overall strategy of the company, which is not based on the concept of sustainable development. There are fears that the pro-ecological strategy of enterprises may be misued in order to create the halo effect, i.e. extending the pro-ecological image to products or enterprises not authorized to do so. It is worth emphasizing that trading companies can fulfill the aforementioned role of "green gate keeper" and limit the phenomenon of producers' greenwashing, especially since in the case of "falsification of the product image" the image of retailers would also suffer (Stefańska, 2016).

Green Sale

To be able to speak about the complementarity of the company's activities in the field of ecology, apart from the product and marketing activities, it is very important to conduct sustainable sales. First of all, it can rely on sales promotion (price discounts, free samples of goods and others), which is designed to accelerate consumer purchasing decisions by offering them immediate or deferred benefits. Thanks to sales promotions, many customers will come into contact with an eco-friendly product or service for the first time, try them out and may repeat such purchases in the future. Authentic satisfaction with this type of goods will cause consumers to issue positive opinions about them in their environment. This can be an incentive to buy this product for others and it may increase the number of consumers who choose environmentally safe products (Pabian, 2015). A company that wants to conduct truly sustainable sales should also conduct consumer education, focused on the goals and assumptions of balanced development, as well as on the implementation of the principles of sustainable consumption in everyday life (Kobylińska and Zbierzchowska, 2011).

Many researchers are also currently dealing with the issue of selling methods in the context of minimizing the carbon footprint. Some retailers and also researchers have been actively claiming that internet shopping yields environmental benefits (Rotem-Mindali and Salomon, 2007). Equally, consumers seem to have a widely held view that online purchases and home delivery are beneficial to the environment because they reduce personal travel demand (Matthews et al., 2001). However, a review of literature studies and research conducted by Halldórsson, et al. shows that this is the case only if more items are purchased in one shipment (Halldórsson, et al., 2010). For this reason, sellers wishing to act in accordance with the principles of sustainable sales, should promote purchases of more items during one-off purchases.

Another important issue in the context of "green" sales is the packaging of the purchased goods both in traditional sales and e-commerce. Just a few years ago, shopping bags (most often referred to as "plastic bags") were added, free of charge, in stores to the purchased good while shopping (Żakowska, 2007). Since legal regulations in this area have been put into force in Poland (last consolidated text, Journal of Laws 2005, No. 175, item 1458, as amended), sellers have been legally obliged to record the amount of plastic bags disposed of and the recycling fee (Zarębska, 2013). Therefore, an increasing number of sellers are choosing paper or cloth bags – which are reusable. The situation is similar in the case of the thinnest plastic bags used for products by weight – more and more often manufacturers offer reusable material bags as an alternative. The same rules apply to e-commerce enterprises, including online stores in particular, because for these enterprises all waste management activities are, in principle, the same as for traditional trade. The difference is that virtually every order in e-commerce involves the need to package the product, which is why waste management and packaging in particular, is especially important in this form of business. Each stage of product logistics, from the manufacturer, through the online store to the final buyer, involves the use of packaging. Some packaging, due to its specificity, can be used only once, then becoming waste, an example of this would be stretch film (Łagutko et al., 2018). Therefore, e-commerce stores wishing to operate in accordance with the principles of sustainable sales, are trying to use recycled cardboard, paper adhesive tape in their packaging, and use e.g. a scraper or paper as a filling.

Research Methodology

Data Sources

Our analysis is based on data collected by survey method. The survey was created by the authors of the article to find out the opinions and behavior of respondents regarding pro-ecological behavior when making purchasing decisions related to the cosmetics and household chemistry sector at the end of 2019. The survey consisted of 10 questions, 4 of which concerned metric data, and 6 were the actual questions in which the respondents were asked:

- whether they are afraid of a potential climate disaster,

- whether they implement pro-ecological behavior in everyday life,
- what features they take into account when choosing cosmetics and household chemistry,
- if they would choose cosmetics and household chemistry limiting their harmful impact on the environment.

Selection for the study was convenient. 222 people took part in the study, of which nearly 70% were women (155 people) and 30% (67 people) were men. This result indicates that, most likely, women in households buy cosmetics and household chemistry. The surveyed population consisted of 35 people (15.8%) under 20 years of age, 29 people (13.1%) people between 20 and 30 years old, 124 people (55.9%) people aged 31-40 years, 28 people (12.8%) aged 41-50 and 6 people (2.7%) over 50 years of age. The vast majority of the surveyed sample were residents of large cities with more than 500,000 inhabitants. In the research sample they constituted 112 people, which is more than half (50.5%). 29 (13.1%) people from the sample live in cities with 100-500 thousand inhabitants, 50 people (22.5%) live in cities between 10,000 and 100,000 inhabitants, and 31 people (14%) from cities inhabited by less than 10,000 citzens.

Research Results

The first question that the respondents were asked, was about their awareness of the risks of climate change and how much they care of it. Respondents' answers presented in Figure 1 show that as much as 93% of respondents are somewhat to very highly concerned about climate change, of which 68% are highly and very highly concerned. It could indicate that the ecological awareness of Polish society is increasing and that they are aware of the consequences of not counteracting climate change.

Figure 1: Respondents' level of concern about climate change

Source: own study

Another topic of interest of researchers was whether and to what extent respondents care for ecology in everyday life (e.g. by segregating garbage or using reusable shopping bags). The results presented in Figure 2 show that 67% of respondents do this often and very often. In addition, as many as 29% use this type of practice with moderate intensity, and only 7% do it rarely or not at all. These results may indicate that Poles are not only aware of the state of the climate, but also try to implement remedial behavior in their daily choices.

Figure 2: Frequency of everyday ecological behavior implemented by respondents
Source: own study

To have a bigger picture of the situation, researchers asked the respondents if they sometimes choose a less favorable, but more environmentally friendly solution (e.g. buy a more expensive paper shopping bag instead of a cheaper plastic one; go to a distant cafe, because they do not use plastic straws). The results, which are presented in Figure 3, are also surprising. More than half of the respondents (54%) often or very often decide to choose more environmentally-friendly solutions, even at the expense of their own interests. And only 17% never or rarely choose such solutions. This result may indicate that caring for the environment has become for many people very essential, and they are able to give up their own comfort or material values.

Figure 3: Frequency with which respondents choose less favorable but environmentally friendly solutions
Source: own study

To obtain detailed data on the cosmetics and household chemistry sector, respondents were asked what criteria they take into account when making purchasing decisions in the cosmetics and household chemistry sector (Figures 4 and 5).

The results indicate that both in the case of household chemistry and cosmetics, the most important criterion determining the choice, is the composition. This is important information for producers indicating that consumers are becoming more aware and have knowledge about used ingredients. Therefore, it can be assumed that products with a "better" composition are more popular. In the case of household chemistry, the next features taken into account by the respondents are the price, availability and brand of the product. This may indicate that in the case of household chemicals, products that are

easily accessible and their price is not different from other products on the market. The quality and effectiveness of products were less important in this category.

In the case of cosmetics, it is clearly seen that the aforementioned composition has a decisive influence on the purchasing decision. It seems that the brand, price and availability of products are in this case a less important category. It is also worth noting that in open-ended section in the survey, respondents declared up to 6 times that non-testing products on animals (cruelty-free) is of great importance to them.

Source: own study

To get specific guidance for the household chemistry and cosmetics sector, respondents were also asked whether they would be willing to buy household chemistry products and cosmetics that limit the harmful effects on the environment. The results of their answers, presented in Figure 6, show that the vast majority gave an affirmative answer (85%). This is a clear tip for the industry on seeking competitive advantages.

Conclusions

The cosmetics and household chemistry market has been recently one of the most dynamically developing in Poland, therefore it is worth thoroughly analizing the needs of consumers in order to be able to develop a solid competitive advantage. It was the strongest motivation for the authors to address this subject. However, it is necessary to mention that in our empirical research the sample has not been tested for representativeness. Moreover, our research has in fact a pilot feature. Consequently, the obtained findings should be treated as a contribution to an in-depth discussion in this area.

The research results presented in the article showed that Poles are becoming more and more aware of climate change, which has an impact on their purchasing decisions and behavior. Understanding the opinions and expectations of consumers in this area, it can and should become the basis for building production, promotion and sales strategies by companies operating in this market. Consumers, in addition to the features they expected from traditional products on the market (such as price, brand, availability or effectiveness), pay more and more attention to "good" composition, and non-testing on animals. Therefore, it appears that market success requires taking this information into account and responding to consumer needs. However, to get a full picture of the situation, extended research in this area would be worth conducting, which will not be based only on the respondents' declarations, but will track their real purchasing choices.

Abstract

The purpose of this work was to analyse the quality of the product made by hand with spot welders and to analyse the quality of the product made by the industrial robot "Fanuc Robotics S-420i". The product was a front panel of the car body, made of semi-finished products in the process of spot welding. In conclusion, it was stated what is the impact of production automation on the quality of the product. Applications of robot welding process are used not only because of better quality parameters, but also due to significant reduction of production costs and less fatigue of employees. The robot operator is a quality controller and contributes to quality management.

Keywords: production automation, product quality, industrial robots

Introduction

The quality of products delivered to the market is currently determined and assessed by an increasingly demanding customer, forcing companies to increase the effectiveness of their operations (Abramson 1999). The customer more and more often demands diversified products, fulfilling many functional and safe functions even in extreme conditions. Among such competitive criteria as cost, flexibility, speed, reliability and quality, quality is becoming a priority. What are the benefits of automation of production in this respect? Is automation necessary for companies? Will manual work be a thing of the past? Why do people want robots to replace their work? Such and many questions arise in the modern world.

The modern economy operates in the industrialised, technical and technocratic world, where it seeks to make robots work for people - and people will only manage them (BORCZYK 2003: 14-15). Robots will do hard work for people, and they can do something else. But will they do it right? Will it be a qualitatively more reliable product? Surely robots are more efficient, more resistant to fatigue, they are faster. But will they improve product quality? Doesn't manual work seem more accurate,

qualitatively better and more precise? These and other questions are answered in this work. It wasn't the quantity, productivity or production costs that were the subject matter of the work, but the quality of the product, a specific product for the automotive industry - before and after automating the workplace (Bigvand, Fay 2017).

In practice, robotics is used in many economic locations, be it in the agricultural industry (Lowenberg-DeBoer, Huang, et al. 2020), whether it also affects the way employees are employed (Daron, Restrepo. 2019). Therefore, no matter where automation is applied, it is important that it usually has positive effects on economic growth (Alpeeva, Volkova 2019). The product described is not a decoration, but it is a part of a car body intended for the automotive industry. So the most important thing here is the quality of durability, reliable, which depends on our health and life. Improvement in quality is noticeable in Japan. Newer and newer industrial robots are used in production, not only to improve productivity, but also quality (Panchev 2017: 484-487). Robots produce machines, machines produce goods, man as a consumer evaluates the quality of products and tries to improve it, but not by directly affecting the product, but by improving the machine (Witting 2005).

A modern organisational unit bases its market competitiveness and survival in the market on an information system in which information determines, among other things, the efficiency of logistics management and is the driving force behind logistics strategy. The information needs have led to the creation of an information system that provides continuous access to up-to-date, accurate and truthful information. An information system includes information resources and those elements which enable the power supply, maintenance and provision of those resources to the user. An information system in which information technology is used to acquire, collect, process, and transmit information is called an information system (Knapiński, Pietras 2017).

In order to make the most of these technologies to significantly accelerate the development of manufacturing companies and increase competitiveness in the global market, a new paradigm is being discussed worldwide. Industry 4.0 or the fourth industrial revolution are just some of the terms used to describe the phenomenon of extensive implementation of intelligent devices on production lines that can communicate autonomously along the value chain (Dendera-Gruszka, Kulińska 2018). In this approach, machines and programs collect information on an ongoing basis to automatically improve their configuration and provide valuable indicators and calculations to help employees make quick decisions and deliver better quality goods and services. Industry 4.0 in technological terms is a group of modern and developing technologies which are the basis for the changes currently taking place in manufacturing industry (Graham, Burns, et al. 2019). Previously, companies used preventive maintenance methods, rules for servicing machines at regular intervals or reacted when a breakdown occurred. A predictive maintenance method can be used in a factory equipped with intelligent technologies (Kubińska-Jabcoń E., Niekurzak M. 2019).

The aim of this work was to compare the quality of the product made by hand spot welding machines with the product made by the industrial robot "Fanuc Robotics S-420i". The product was a car body front panel, made of semi-finished products in the spot welding process. The research methods used in this work were: observational methods, methods of analysis and logical construction and comparative methods. The research was carried out in the Opole automotive company in 2017-2019.

Methodologies for Quality Measurement

Reliability assurance is a series of activities that ensure that the product reliability requirements be realised in a product life cycle. However, as reliability assurance activities are usually only implemented in design and usage, the integration of reliability assurance with quality control in production has not attracted the attention it deserved, thereby hindering production performance improvement to satisfy increasingly stringent customer requirements (Yihai, Changchao, Zhenzhen, Jiaming 2018).

The first difference between quality assurance and quality is the difference in importance for the customer. Quality, high quality should, in the customer's understanding, be associated only with his full satisfaction with the purchased product (service) and entail other benefits such as: (Dahlgaord, Kristensen, Kanii 2001: 26) reliability, speed of service (delivery), appropriate price/goods ratio, warranty, etc. As regards the concept of quality assurance, it is possible to talk about the customers' (recipients') trust in a given company, brand or type of product (so-called steel, loyal customers). The second difference - when using the concept of quality we always refer to a specific product, good, service or contract. And quality assurance usually refers to the company, plant - generally the organisation. The third difference - the highest goal for quality is to produce only good, compliant products - a requirement that generally stems from the previous differences, i.e. achieving the goal: "zero errors", "zero defects". The highest objective for quality assurance is the state of a well-organised organisation, i.e. "no conflicts", where employees will be satisfied with their work both materially and immaterially (the need for respect, self-fulfilment, being in a group, achieving success, etc.). In order to be able to realize such an ambitious task set for the company, which is management through quality, one should take a serious interest in the implementation of the quality assurance system according to the international ISO 9000 series standards (Doroszewicz 2002). Although these are not obligatory standards, they are becoming more popular in Poland, where since 1990 about 1000 certificates confirming the compliance of the quality assurance system with the chosen model of the standard have been granted. The collection of ISO 9000 series standards constitutes a series of standards that can be divided into those related to internal quality assurance (ISO 9004 family) and external quality assurance: ISO 9001, ISO 9002, ISO 9003. The ISO 9000-1 standard, as a basic standard, is a set of guidelines to facilitate the selection of the right model for a quality system in a particular company (Ciepiela, Kozioł 1978).

In the last years of the 20th century, societies of technologically and civilizatically developed countries have been experiencing radical changes, referred to as global information society or "third wave" society. From the economic point of view, new technologies are of particular importance, especially information technologies (computerisation, automation and global information networks eliminating the distance barrier, knowledge is becoming the main production factor). The problem of ownership and supervision of knowledge, which is the main "device" and the driving force behind the development of societies, has become important. New knowledge-absorbing organisations are emerging and centres of economic attractiveness are moving towards places such as the "Silicon Valley". Information is one of the most important factors of production, as before, capital and labour. The growing importance of knowledge, which is becoming the most important factor of the new order, has led to the identification of so-called knowledge-absorbent sectors of the economy. Radical restructuring has begun - traditional and non-organic sectors are disappearing and new types of industrial production (computer, electronic, biochemical, aviation) are emerging (Gołębiowski, Janasz, Prozorowicz 2002: 192).

The growing importance of knowledge is particularly evident in natural sciences (new discovery in astronomy, physics, mathematics, biology or chemistry) (Mas-Tur, Modak 2019). Knowledge as a production ingredient has led to the fact that white-collar workers are the most important in a company: scientists, engineers, technicians, programmers and managers (Ivanov, Das, Cho 2018). The choice of the model of the quality system should depend on the functional and organisational capacity of the company in relation to the manufactured products or services. The basis for building such a system may be the requirements of one of the models of quality assurance systems:

a) ISO 9001 - model of quality assurance in design, development, production, installation and service. The quality assurance system is appropriate for companies offering products, which from design, through the production cycle to service are created in this organization,
b) ISO 9002 - model of quality assurance in production, installation and service. The model covering quality assurance in production, installation and service of a company (no design or construction element),
c) ISO 9003 - Model for quality assurance in final inspections and tests,

d) ISO 9004-1 - serves the so-called internal quality management. It contains basic assumptions for the implementation of the quality system understood as: "organisational structure, distribution of responsibilities, procedures and resources enabling quality management". This standard attributes particular importance to the management's declaration to the quality policy: it defines the necessity of involvement of all employees in the quality development process. "We are at the beginning of a new era of human development - the age of quality. The process of its creation is accelerating and irreversible". The higher the quality, the greater the benefits for the company, and thus the fewer faults and higher productivity (Figure 1 illustrates some of the benefits). A satisfied customer "returns", which gives the company a competitive advantage (Fiorino, Barone, et al. 2019).

Fig.1: Some benefits of quality management [own study]

Maintaining Product Quality

Maintaining the quality of a product is an integral part of the quality science of product durability from the moment it is manufactured to the end of its use. It includes technical, technological and organisational measures to achieve the objectives during storage, storage, transport and use of goods. It is based on explaining the mechanisms of changes taking place in products, i.e. aging and spoilage of stored goods and developing methods to counteract these phenomena (Kulińska, Masłowski 2018). The notion of quality assurance is formulated in the PN-ISO-8402 standard as "systematic and, if necessary, proven activities carried out under the quality system to arouse appropriate confidence that the facility will meet the quality requirements". Thus, it is a modern field of science and technology involving the preservation of the initial quality of products obtained from natural resources, produced during the industrial process or obtained as a result of agricultural activity in order to extend their desired properties over time (Waluya, Iqbal 2019). The possibilities of modern technology and technology allow for the production of huge quantities of material goods. The mass and high efficiency of production of industrial products, especially regionalisation and specialisation lowering production costs cause that these products, before they reach the final recipient, waiting for possible further processing or delivery, must be in conditions allowing to maintain their initial properties at least during the guarantee period. Currently, technologists have at their disposal highly efficient technologies and air conditioning devices, effective preservation methods, as well as excellent packaging materials, thanks to which there are possibilities to slow down the operation of product degradation mechanisms.

Each product has specific characteristics and is sensitive to specific factors. These characteristics can be called the sensitivity of the product. On the basis of the sensitivity of the product to external and internal factors, it is possible to determine the exposure against which the product should be protected. The physical, chemical and biological exposures are shown in Figure 2. However, only the sensitivity of a product to physical, chemical and biological exposure cannot establish a complete list of exposures against which the product should be protected. This is due to changing product properties and external conditions.

Fig. 2: Distribution of exposures acting on the product [own study]

Indeed, the exposures described may have a negative impact on the product, but when analysing them carefully, it is not difficult to see that the same factors that adversely affect the quality of the product are often used to prolong its shelf life. Pressure (negative pressure), temperatures (both negative and positive), radiation (infrared, ionizing, ultrasound), gases - all of which, depending on the values and conditions, can be used for maintenance or product quality parameters (Witting 2005).

Comparative Analysis

The company, located in Opole, belongs to a global automotive company with its headquarters in the USA. The company produces accessories and car body parts of well-known and valued brands. The location of production plants is strictly dependent on the company's strategy, macro- and micro-environment. The company produces in such countries as: Belgium, Brazil, Canada, China, France, Germany, India, Italy, Japan, Mexico, Poland, Slovakia, Spain, Korea and USA. A characteristic feature of the factory is the specialization in which the company "rotates". The company mainly deals with metal joining: spot and hump welding and MigMag gas shielded welding. Most technological processes are automated.

The analysis has expanded the description of the technological process of the welding station, which is performed by an operator performing welding with a manual welding machine and industrial robot Fanuc Robotics.

Welding is the process of permanent joining of elements without adding a binder. It consists in heating up the elements to doughiness and then pressing firmly. The following types of welding are distinguished: electric, frictional, ultrasonic. In robotics, electric resistance welding is most often used, which, due to the method of obtaining and the shape of the weld (place where the elements are placed), is divided into two: point welding (the diagram is shown in Fig. 3), hump welding (point welding at the projection points), linear welding, short-circuit welding (strong pressure on the elements to be welded) and spark welding (small pressure providing current contact in several places). The application range of resistance welding is very wide: spot welding is used in the manufacture of cars, airplanes, railway cars and metal goods, hump welding - in the manufacture of cars, refrigerators, linear welding - for the manufacture of thin-walled tanks and pipes, short-circuit and spark welding - for connecting railway rails, rebar, chain links, bicycle wheel rims (Masłowski, Kulińska 2018). However, robotized spot welding is used primarily in the automotive industry, in the process of building car bodies (Jezierski 2006: 217). For example, it can be stated that the car body assembly process is robotic in more than 90 %.

Fig. 3: Spot welding process: 1- connected sheets, 2 electrodes, 3 power source, P- clamping force. [own study]

The spot-welding process is particularly easy to robotise due to the accuracy achieved by the robots and the possibility to perform the welding in any position. Robots used for welding, most often articulated robots, should be characterized:

- a sufficient number of degrees of freedom such that the bend in the required position resulting from the geometry of the welds can be performed,
- working space dimensions to ensure access to all points,
- the required positioning accuracy.

The use of industrial welding robots requires appropriate equipment and above all the selection of a suitable welding machine. To cooperate with the robot, welding machines equipped with the following functions are used:

- microprocessor-controlled power source. After the operator has selected the type of operation of the device and the sheet thickness, the device control system automatically selects the correct current

value and welding time and, if necessary and justified, dynamically regulates these values during the welding process. If the welding current is too low, an acoustic warning signal is activated,
- built-in mains voltage control system recognizing low-voltage states, with automatic measurement and control of welding current. This ensures stabilization of the welding current, multi-programmed correction of the welding current as a function of the number of welds performed, the so-called stepper,
- automatic control of the welding process, especially the clamping force of the electrodes to the elements to be connected.

The company has at its disposal, among others, Fanuc and Motoman robots presented in Figure 4.

Fig. 4: Fanuc S420iF robot in spot welding process (left), Motoman UP-6 robot with welding, sealing and bonding function (right) [own study].

The company combines metal elements: car bodies, complex structures (front panels, steering rods) and A-class components (doors and accident protection - bumpers). Until February 2007, the factory received semi-finished products from the German factory. After the purchase and launch of the PME 630t progressive press, the company punched the semi-finished products on site, which significantly reduced logistics costs. The figures below show several finished products for the automotive industry manufactured in the Opole company.

Fig. 5: Side door guides (1), Body bracket (2), Fuel tank (3), Rear bumper (4) [own study].

Product Analysis Before Automating the Technological Process

The factory received semi-finished products, which were joined by hand welding machines at 42 welding points. Three employees worked in one shift, performing the standard of 125 front panels (fig. 6).

Fig. 6: Front panel [own study]

Figure 6 shows a finished body element for the Opel Astra II consisting of 7 elements - connected by welding machines according to the technological instruction:

A) prior to commencing work, the first shift has inspected the workstation according to the maintenance instructions for Z10,
B) The FT-227 part of the FT-227 is fitted on the fixing studs and closed with a tensioner (Figure 7),

Fig. 7: operation I: the FT-227 part (left), the appearance of the pin that fixes the position of the part (right) [own study].

C) then, on the left side of the instrument, the parts KT-258, KT-262 and FT-225 are inserted (Figure 8). The clamping tensioners were tightened,

a b c

Fig. 8: appearance of semi-finished products: a) KT-258, b) KT-262, c) FT-225 [own study].

D) the treatments were performed on the right side of the instrument. Parts KT-259, KT-263 and FT-224 have been installed (Fig. 9). The clamping tensioners were tightened,

a b c

Fig. 9: appearance of semi-finished products: a) KT-259, b) KT-263, c) FT-224 [own study].

E) welding started with welder A - welder on the left side with horizontal welds (fig. 10),

Fig. 10 :Manual welding machine: appearance of the manual welding machine with horizontal welds (left), worker performing the welding (right) [own study].

F) 6 side welds were made (Fig. 11). Then 2 top welds were made,

Fig.11: Side welds made with a hand welding machine with horizontal welds [own study].

G) after 8 weldings with welder A, welding with welder B (vertical welder) started. 8 welds were made - 4 on the left side of the FT-227 part and 4 on the right (Fig. 12),

Fig. 12. a) view of the welding machine electrode - working on the left side of the front panel, b) view of the welding machine - working on the right side of the panel, c) view of 4 welds on the left side of the panel, d) view of 4 welds on the right side [own study].

H) after the welder B has been put away, welding with welder C (from an adjacent position with horizontal welds) started. On the right side of the device 5 side welds and 1 top weld were made (fig. 13),

Fig. 13: operation I with welder C: a) worker holding welder C, b) making 5 side welds, c) making 1 top weld [own study].

The total number of welds made in operation I was 22: welder A- 8, welder B- 8, welder C- 6.

I) The tensioners were opened, part of the fixture was removed and handed over to the adjacent position (end of Operation I),

J) the part pre-welded in operation I was taken, placed on the pins fixing the FT-227 semi-finished product (Fig. 14) down, the tensioners were fastened. Welding with C welding machine (with horizontal welds) was started. On the left side of the part 3 welds were made (Fig. 15), on the right side 5 welds were made (Fig. 16),

Fig. 14. Shifting a semi-finished product and starting operation II [own study].

Fig. 15: execution of 3 welds on the left side of the panel: a) view of executed 1 weld at the end of the panel, b) view of 2 welds near the spotlight [own study].

Fig. 16. Making 5 welds on the right side of the panel: a) view of 2 welds under the headlamp, b) view of 2 welds above the headlamp, c) the weld made at the end of the panel [own study].

K) at the end of operation II, the instrument was turned by 180 and 12 welds were made (Fig. 17) with the D welder (with vertical welds),

Fig. 17: View of the rotated front panel a) and the arrangement of 12 welds: b) on the left side of the part, c) on the right side [own study].

The sum of welds performed in operation II was 20: welder C performed 8 welds, welder D-12 welds. The welds made by the D welder were checked for burrs. Burrs were removed with a pneumatic grinder.

L) The panel was removed from the instrumentation and controlled according to the self-control card, M) after operations I and II (42 welds in total) the green signal lights were lit (Fig. 18). This is a sign that the correct number of welds on each weld has been made,

Fig. 18: Lights indicating the correct number of welds made: green light indicating the left side of the device (left), signal received from the right side (right) [own study].

N) packing of the finished product into a container.
The two operations described above were performed by 3 people in shifts, who operated 4 **manual** sealers. The standard was 125 finished elements for the customer. The work before automation was hard, because one sealing machine weighed 150 kg and it was very difficult to reach all sealing

points. There were a lot of burrs that had to be removed. One shift replaced 8 electrodes, which also had to be cleaned after several operations.

Product Analysis after the automation of the Technological Process

After automating the technological process, one employee per shift produced 225 finished elements according to the technological manual:

A) before commencing work, the first shift has inspected the workstation according to the maintenance instructions for Z19 - new panel welding workstation (Fig. 19 - left),

B) the FT-227 part (Fig. 19 - right) is fitted on the fixing studs (Fig. 20) and closed with a tensioner,

Fig. 19: Robotized welding station for the front panel (left) and the first part of the panel fixed with a tensioner (right) [own study].

Fig. 20: Positioning pins: a) left hand pin of the instrument, b) right hand pin [own study].

C) Then, on the right side of the instrument, the parts KT-258, KT-262 and FT-225 are put on the fixing pins. The fixing tensioners are closed. Figures 21 show the activities discussed, performed by the station operator,

Fig. 21. Fixing the components on the right-hand side in operation I: a) part KT-258 mounted on the position fixing pins, b) fastening of the fastener, c) overlapping semi-finished product KT-262, d) fastening of the panel, e) fastening of the part KT-262, f) overlapping and fastened part FT-225 [own study].

D) after this operation, the parts KT-259, KT-263 and FT-224 were placed on the left side of the instrument. They were pressed with the clamping tensioners - as shown in Fig. 22,

Fig. 22: Fixing the components on the left-hand side in operation I: a) part of the KT-259 mounted on the positioning pins, b) fastening of the fastening tensioner, c) KT-263 overlayed on the pin, d) panel for tightening the KT-263 part, e) properly closed tensioner, f) part of the KT-263 fixed [own study].

E) after all the semi-finished products have been installed, the welding cycle was started by means of a green, pulsating button (Fig. 23)

Fig. 23: Green button on the control panel, indicating that all parts are well fixed and the welding process can begin [own study].

(F) the part pre-welded in operation I was removed. The FT-227 part was placed on fixing pins (Fig. 24 a, b) and the tensioner was fastened (Fig. 24 c, d),

Fig. 24:(a) panel overlayed by left-handed fixing pin, (b) right-handed fixing pin supporting the panel and Operation II: (c) panel turned by 1800, (d) panel fixed with tensioner [own study].

G) The welding cycle is started with the green (flashing) button.

A green flashing button marked the insertion of all components and the closing of all fastening cylinders. If the button did not flash green, the completeness of the components and the closure of all actuators was checked. Information about the problem was shown on the display (fig. 25), and a red light was lit with the word "Alarm" (fig. 26). The "Reset" button had to be pressed at the time of the alarm. If the stand did not react, maintenance had to be notified.

Fig. 25: Siemens display, showing errors made by the operator [own study].

Fig. 26: Operator's panel signaling the alarm [own study].

One employee made 225 finished front panels for the Opel Astra II. There were no burrs (as in the case of manual welding machines) and there were no shortages of material. The Fanuc Robotics S-420i distributed the welds very precisely and had the function of automatically sharpening the electrodes, which used much less.

From the above analysis of the production processes, it appears that there were significant advantages for the product made with the Fanuc Robotics S-420i industrial robot, because:
- there were lower production costs (there was one operator working on one shift, who made 225 finished elements, rather than the previous one - 125 elements made by three employees),
- less fatigue of employees (one welding machine weighed about 150 kg). Three workers operating 4

manual welding machines, during a shift, made 125 finished parts, times 42 welds, which gives us 1750 welds per person!

- good funnel. A lot of space was taken up by the distribution of semi-finished products for production (near the welding station). In the case of the automated station - the distribution of materials and the production socket was at least 2x smaller,
- Production downtime was almost zero (previously caused, among others, by: frequent replacement of used electrodes or temporary rest of employees),
- very good quality parameters. In manual welding, the welds were inaccurately distributed, there were burrs and the welded joints were not strong enough. There were many material shortages due to incomplete components. There were many returns by customers.

Conclusion

In the analysis of the product and in the conclusions it can be seen that the product quality is definitely better after using the most modern production technologies. In the automotive industry the most common robotic applications are welding stations. An example of such an application is a station working in the Opole automotive factory, which produces pre-assembled car body parts. This workstation uses an industrial robot Fanuc Robotics S-420i, controlled by an R-J2 controller, together with a superior control unit S7 315-2DP, which - apart from supervising the robot's work - also controls two welding devices. The first device, equipped with 15 pneumatic cylinders, is designed to ensure repeatability of the geometry of the workpiece to be welded, while the second device, equipped with 3 pneumatic cylinders, only immobilizes the workpiece to be welded. The OP7 operator panel is used to communicate with the operator.

Applications of the robot welding process are used mainly due to very good quality parameters, their repeatability and a high increase in production efficiency - which was also confirmed by the described installation. Before the modification, the double stations equipped with a manual welding machine and a welding device with manual clamps that fix the elements to be welded - operated by three employees - achieved an output of 125 pieces of finished components per shift. After modification, 225 finished components are produced in one shift. It should be noted that the robotized station is operated by only one person (employees who are no longer required to operate the described robotized station, after training, have filled the newly created positions). In this way, the efficiency of produced elements per one employee has increased over four times - with repeatable, very good quality parameters.

The basis for the operation of a production enterprise today is to satisfy the needs of customers at the lowest possible price. To obtain a good quality product at a low price, the company should invest in new and improved production technologies.

An excellent example is a company from Opole. After the production processes were automated, production costs dropped significantly. After the purchase of the press, logistic costs dropped. The company achieved four times its productivity, improved working conditions, ergonomics and invested in training. An additional motivator is job responsibility. The robot operator has become a quality controller, the number of deficiencies has decreased, and most importantly, the robot has replaced the heaviest physical work and is not exposed - like a human being - to loss of health or life. There are defects in every company. This includes too high a turnover of workers due to low wages. Tower Automotive Poland, despite the fact that production has quadrupled, has not been able to double its earnings, which can be explained by large technological investments.

Polish Controlling Students' Perception of Accountant and Controller Professions

Marta NOWAK

Wroclaw University of Economics and Business, Wroclaw, Poland
marta.nowak@ue.wroc.pl

Abstract

The study investigates controlling students' perception of accountants and controllers. The research is qualitative and takes a behavioral approach using projection and narrative analysis. The findings show that there is a general agreement among the controlling students that an accountant's work is important, repeatable, rules-based, and scrupulous. The ambiguity of the image concerns accountants' personality (malicious versus majestic) and their position in the company (looked down to versus respected). Nevertheless, the accountant's image among controlling students is, to a large extent, coherent. For the controller as well, people with experience in this position underline a problematic part of his work. There is a general agreement among the respondents concerning the controller's actions and tasks, which are seen as important, information-related, and numbers-focused. Similar to the accountant's image, most disagreements relate to the character of controllers (caring and friendly versus dangerous and double-faced). People with no accountant nor controllership experience tend to perceive them in a more idealistic manner, sometimes regarding them as to be omnipotent or more one-sided, negative way.

Keywords: Behavioral Accounting, Controller, Accountant, Perception

Introduction

The perception of different positions in the company is crucial for potential job-takers. It also constitutes significant research filed for academics. The understanding of the controlling student's comprehension of the accountant and controller's profession is interesting for accounting and human resources management researchers. It can also give fruitful insight for employers, members of accountants' and controllers' associations, and students who plan their careers in accounting or controlling.

There were the number of studies related to the perception, image, identity and stereotype of an accountant, e.g. (Caglio 2019), (Nishiyama et al. 2014), (Dalton et al. 2019), (Dellaportas et al. 2019), (Burns 2007), (Smith, Jacobs 2011), (Malthus, Fowler 2009), (Jacobs, Evans2012), (Nga, 2012), (Czarniawska, 2012), (Sugahara, Boland 2006), (Germanou, Hassall 2005), (Baldvinsdottir et al. 2009), (Gendron, 2014), (Low et al. 2012), (Miley, 2012), (Smith, 2017), (Evans, Fraser 2012), (Wells, 1996), (Parker, Warren 2017), (Wessels, Steenkamp 2009), (Warren, Parker 2009), (Nowak 2019), (Nowak 2017). The studies related to the same aspects of the controller's (or management accountants) profession were scarce (Hiller et al. 2014), (Ahrens et al. 2010), (Lambert 2012).

The goal of the present study is to identify the perception of the accountant's and controller's profession by students of controlling. The research questions are the following:

1) How are accountants perceived by controlling students?
2) How are controllers perceived by controlling students?

The study takes a qualitative, ideographic research approach. The projection technique is used. The Forced Metaphor Elicitation technique is applied.

Research Group and Method

The research group consisted of 15 part-time students of the second year of Master Studies at Wroclaw University of Economics and Business. Accounting was a general field of their study, and they were majoring in controlling. Therefore the group was educated in both accounting and controllership and trained to be accountants or controllers. As the research had a qualitative character, the number of people taking part in the study is sufficient. Among the respondents, there were 13 women and two men, which is characteristic for Poland where the accountant profession and accounting education are feminized a lot, which was investigated by Masztalerz (2018) and Kabalski and Szwajcar (2015). The average age of respondents was 21 years old. The research took place in October 2019.

The respondents' task was to associate the accountant and controller with the animal and explain their proposal of metaphors. The zoomorphic metaphor was used previously in the field of psychology by Woodside (2008).

Research Results

The results are presented in Table 1.

Table 1: Metaphors for accountant and controller and their justifications

No.	Gender	Age	Experience in the accountant's profession	Experience in the controller's profession	The proposed metaphor for an accountant and its justification	The proposed metaphor for a controller and its justification
1	M	23	Y	N	Ant – small, meaningless, hardworking, engaged	Lion – dangerous, unpredictable, ruler of jungle, strives for blood
2	F	23	N	N	Monkey – malicious, petty	Snake- cunning
3	F	23	N	N	Owl – wise, calm	Lemur – a lemur, was the king in "Madagascar" movie, is crazy
4	F	29	N	N	Ant – works a lot, regularly, systematically, does the work which is beneficial for a business unit	Cat – outside kind and friendly, inside searches for an occasion to destroy ☺
5	F	23	N	N	Sloth – calm, self-controlled, anemic	Lion – guards the order, father of the whole company
6	F	23	Y	Y	Ant – many documents to account in a short time, which needs a fast mode of working	Boar (burrowing in the ground) – dismantles everything into constituent parts, searches for details
7	F	35	N	N	Owl – it is widely acknowledged that	Fox – is cunning, inquisitive and capable

					owl is associated with a wise person wearing glasses, thorough who lives to investigate, read, and improve her skills. Owl Is majestic, sits and observes or counts in case of an accountant	of smelling everything out, visits each hole to check if there is anything to eat and to fetch the prey
8	F	25	N	N	Parrot – the accountant's work seems repeatable and possible to train. Parrot has the ability to repeat words.	Falcon, because controller should have falcon's eyes and should be sensitive to details
9	M	22	Y	N	Alpaca – obedient, humble, patient, focused	Llama – curious, brave, territorial, patient
10	F	22	Y	N	Rabbit or hare – is faint, inquisitive, easily adapts to changes on the way (tax changes, etc.)	Lion – is wise and prudent, does not hurry in decision-making
11	F	27	N	N	Fox – smells everything out	Cheetah – precision. Concentration on result, numbers, speed
12	F	24	N	Y	Dog – well trained knows the rules and sticks to them	Fox – has to be cunny, needs to have a lot of information, is not necessarily available, has to manage in difficult situations, and must be fast
13	F	23	N	N	Eagle – watches over the company, everybody feels respect for him, knows what is essential for him to	Badger – hardworking, when controls and spots mistakes and spots them out so everybody fears
14	F	24	N	N	Owl – scrupulous, notes down everything, precise, well-organized	Dog – sniffs everything out, explorer, likes to run a lot and check, curious
15	F	23	Y	N	The dog acts according to patterns and does not rut out of the line; if he lost something, he searches for it until he finds it	Lion – guards his pack and keeps everything in one piece

The most popular metaphors for accountants are ants and owls. Three respondents proposed them. Two people introduced a dog metaphor. Other metaphors recommended by one person only are monkey, sloth, parrot, alpaca, rabbit, hare, fox, and eagle. The narration justifying these metaphors characterize accountants as having many intellectual qualities ("owl – it is widely acknowledged that owl is associated with a wide person in glasses, thorough who lives to investigate, read and improve her skills; “owl is majestic, sits and observes or counts in case of an accountant"; "owl – wise, calm”), working in a very fast and organized way ("ant – a lot of documents to account in a short time, which needs a fast mode of working"; "rabbit or hare – is fast, inquisitive, easily adapts to changes on the way (tax changes, etc.)"), calm (“sloth – calm, self-controlled, "anemic; "alpaca – obedient, humble, patient, focused”), scrupulous ("owl – scrupulous, notes down everything, precise, "well-organized), hardworking ("ant – small, meaningless, hardwiring, engaged”; “ant – works a lot, regularly, systematically, does the work which is beneficial for business unit”). The role of an accountant in a company is perceived as underestimated and looked down on (“ant – small, meaningless, hardworking, engaged”; “alpaca – obedient, humble, patient, focused”). The accountant’s work seems to be repeatable ("parrot – the accountant's work seems repeatable and possible to train. Parrot has an ability to repeat words. "). An accountant is perceived to be humble and obedient (“dog – acts according to patterns, does not rut out of the line”; “dog – well trained knows the rules and sticks to them”; “alpaca – obedient, humble, patient, focused”). He or she is seen as knowing the rules, sticking closely to them and adapting to them (“rabbit or hare – is fast, inquisitive, easily adapts to changes on the way (tax changes, etc.)”; “dog – well trained knows the rules and sticks to them”; “dog – acts according to patterns, does not rut out of the line”). Accountants can be malicious (“monkey – malicious, petty”). An accountant is also perceived as an important, respected person (“eagle – watches over the company, everybody feels respect for him, knows what is most important for him”), characterized even by majesty (“owl – it is widely acknowledged that owl is associated with a wide person in glasses, thorough who lives to investigate, read and improve her skills”; “owl is majestic, sits and observes or counts in case of an accountant”). An accountant is also perceived to be well-informed or able to get the information that he/she needs (“fox – smells everything out”; “dog – acts according to patterns, does not rut out of the line; if he lost something he searches for it until he finds it”). Also, some physical aspects of accountant’s look are given (“owl – it is widely acknowledged that owl is associated with a wide person in glasses, thorough who lives to investigate, read and improve her skills”;” owl is majestic, sits and observes or counts in case of an accountant”).

There is a general perception of an accountant that emerges from the respondent's narration – that accountant's work is important, repeatable, related to knowing and applying the rules, and needing scrupulous actions. The ambiguity of the image is concentrated on the personality of accountants (malicious versus majestic) and their position in the company (looked down to versus respected). Anyway, the accountant image can be characterized as coherent.

The most frequently used metaphor for the controller is a lion (chosen by four people). The second popular metaphor is a fox. Here are also other animals that appear to be associated with controllers: snake, lemur, cat, boar, falcon, cheetah, badger, lama, dog. According to justifications of metaphors, controllers are cunning and clever (“snake- cunning”; “fox – is cunning, inquisitive and capable of smelling everything out, visits each hole to check if there is anything to eat and to fetch the prey”; “fox – has to be cunny, needs to have a lot of information, not necessarily available, has to manage in difficult situations, must be fast”). They are perceived to be dangerous, as well (“lion – dangerous, unpredictable, ruler of jungle, strives for blood”). Moreover, controllers are seen as unpredictable (“lion – dangerous, unpredictable, ruler of jungle, strives for blood”; “cat – outside nice and friendly, inside searches for an occasion to destroy”). Moreover, according to respondents, controllers are dangerous (“lion – dangerous, unpredictable, ruler of jungle, strives for blood”; “cat – outside nice and friendly, inside searches for the occasion to destroy"; “badger – hardworking, when controls and spots mistakes and spots them out, so everybody fears”). The role of the controller is perceived as a guard of a company (“lion – guards his pack and keeps everything in one piece”; “lion – guards the order, father of the whole company”). Controllers also are viewed as crazy (“lemur – lemur was the king in "Madagascar" movie, is crazy”). Many associations relate to the controller's tasks. Some of them refer to decision-making (“lion – is wise and prudent, does not hurry in decision-making”). Others connect with analytical skills and actions (“boar (burrowing in the ground) – dismantles

everything into constituent parts, searches for details") and concentration on details ("falcon, because controller should have falcon's eyes and should be sensitive to details"). The respondents are aware of the necessity of getting (or rather haunting for) necessary data, which is sometimes difficult to achieve ("fox – has to be cunny, needs to have a lot of information, not necessarily available, has to manage in difficult situations, must be fast"; "boar (burrowing in the ground) – dismantles everything into constituent parts, searches for details"). Therefore controllers are perceived to be curious ("llama – curious, brave, territorial, patient"; "fox – is cunning, inquisitive and capable of smelling everything out, visits each hole to check if there is anything to eat and to fetch the prey"; "dog – sniffs everything out, explorer, likes to run a lot and check, curious"). Moreover, respondents underline a controller's concentration on numbers and results ("cheetah – precision. Concentration on result, numbers, speed"). Sometimes the controller is perceived to be ruthless ("lion – dangerous, unpredictable, ruler of jungle, strives for blood"; "badger – hardworking, when controls and spots mistakes and spots them out so everybody fears").

There is a general agreement among the respondents concerning the controller's actions and tasks. Similar to the accountant's image, most disagreements relate to the character of controllers (caring and friendly versus dangerous and double-faced).

Conclusions and Discussion

The interesting founding is how experience in profession influences the perception of the job. People with expertise in an accountant's work have a more realistic approach to this profession. They see the expectations towards an accountant and disadvantages of his/her work ("alpaca – obedient, humble, patient, focused"; "dog – acts according to patterns, does not rut out of the line, if he lost something he searches for it until he finds it"; "ant – small, meaningless, hardworking, engaged"; "ant – a lot of documents to account in a short time, which needs a fast mode of working"; "rabbit or hare – is faint, inquisitive, easily adapts to changes on the way (tax changes, etc.)").

For controller as well, people with experience in this position underline demanding part of his work ("fox – has to be cunny, needs to have a lot of information, not necessarily available, has to manage in difficult situations, must be fast"; "boar (burrowing in the ground) – dismantles everything into constituent parts, searches for details").

People with no accountant nor controllership experience tend to perceive them in a more idealistic manner, sometimes regarding them as to be omnipotent (accountant-owl is majestic, accountant fox smells everything out, everybody feels respect for owl accountant, controller-dog sniffs everything out) or more one-sided, negative way (accountant-monkey is malicious and petty, cat controller appears to be kind and friendly but inside searches for the occasion to destroy).

What is interesting, the male respondents (who are the minority in this group) perceive the job from the power-submission perspective including fighting element (accountant - alpaca is humble and obedient, accountant-ant is small and meaningless, controller-lion is a dangerous ruler striving for blood, controller- llama is territorial).

The study is consistent with findings of concerning employer-employee relations and its perception by accounting students of IIIrd year of bachelor studies (Nowak 2018). The comparison can be made due to the fact that the present research on the perception of accountant and controller is done among young people who are just starting their professional careers; therefore, they see themselves as present or future accounting employees. Study of Nowak showed that the employee is often perceived as an ant, small fish or bee – quite busy and hardworking, but also underestimated.

The study is also, to a large degree, consistent with the study of the perception of an accountant's job by accounting students of IIIrd year of bachelor studies majoring in accounting performed by Nowak (2017). The owl metaphor is most prevalent in both studies. Also, such aspects of the accountant's intellect as wisdom are underlined. Both studies show that an accountant's work is perceived to be slow, precise, demanding patience, and scrupulous. Also, both respondents group notice such disadvantages of an accountant's work as being underestimated and looked down upon and needing

repetitive actions. Even conclusions about physical appearance (wearing glasses) are similar. Nevertheless, there are some differences. Bachelor students majoring in accounting are more optimistic about the accountant's job and position in a company than master students of controlling. Also, younger and less experienced full-time bachelor students are focusing more than part-time managerial accounting and controlling master students on the observable aspects of the accountant's work and his look.

The results are also consistent with the research of Nowak (2019) conducted among statutory auditors. They also tend to compare accountants to hardworking animals. The ant is popular, but also working ox or horse are the examples. Apart from mentioning hard-work as a hallmark of an accountant's job, also the necessity of obeying rules and adaptation to them is given the important aspect of an accountant's work. Moreover, intelligence and learning capabilities are stressed as the principal accountant's abilities.

The manner in which students perceive accountants and controllers is partly the result of their education. During accounting lectures and workshops, professors focus mostly on rules, guidelines, law. The students usually are assessed by tests in which they are to account for, to perform different accounting operations. The model of teaching is rather unified, and it is based on Polish accounting law and international standards. The teaching pattern is highly defined by the fact that accounting is regulated in terms of by whom and how it should be performed. Therefore animals associated with accountants and the justifications of metaphors focus as aspects such as sticking to the rules, repeatable work, being well-trained.

The controllers are perceived in a slightly different manner by the students. As controlling is not imposed by the law (although it can be forced by headquarters of the corporation), it can be used in a variated way. Students during their education not only get knowledge on different controlling tools, but they also learn a lot about controlling organization, selection of controlling instruments, and their application for various types of business units and organizations. Moreover, they are taught about the controller's job itself and his tasks, and the meaning of performance of this job for the results of a company. Therefore students chose the metaphors showing high importance (e.g., lions) and justify the metaphors by describing different controller's 'tasks (such as dismantling everything into pieces which is characteristic for budgetary control and analysis).

Consumer Towards New Products on The Polish Market

Krystyna MAZUREK-ŁOPACIŃSKA

Wroclaw University of Economics and Business, Wroclaw, Poland
krystyna.m.lopacinska.@gmail.com

The project is financed by the Ministry of Science and Higher Education in Poland under the programme "Regional Initiative of Excellence" 2019 - 2022 project number 015/RID/2018/19 total funding amount 10 721 040,00 PLN

Abstract

The purpose of the paper is to present the behaviour of Polish consumers of various consumer sectors towards new products with the emphasises put on the changes in these behaviours in 1995 - 2018. The analyses were conducted in the segments of consumer types resulting from the Rogers' model, i.e. innovators, early followers, early majority of late majority and marauders. The paper presents development of this consumer typology on the Polish market. It is shown that the behaviours of Polish consumers towards new products depend on the basic characteristics of these consumers, such as: gender, age, education and source of income. It is recognised how consumers representing the surveyed groups assess new products offered on the Polish market. The paper presents the differences between the considered consumer groups in terms of sources of information used when purchasing consumer products of various industries. The analysis is based on the results of nationwide surveys conducted in the long term, i.e. 1995, 2001, and 2017-2018. The research results show a relatively higher susceptibility of Polish consumers to new consumer products than the Rogers' model, as evidenced by the greater number of innovators and early followers on the market of each studied product group. Consumer responses to new products clearly vary depending on their age, education and source of income. The typology of consumers observed on the Polish market according to their approach to new products influences their declared evaluations of these products, which confirm more positive attitudes of innovators, early followers and the early majority as opposed to sceptical and even critical attitudes of the late majority and conservatives-marauders. They also differ in terms of the type of information sources from which they obtain information about the market offer of products. This was the basis for the presented in the article, enterprises oriented recommendations, regarding the necessity of marketing activities towards specific groups of consumers differentiation

Keywords: New Products, Consumers-Innovators, Followers;

Introduction

High competition on the modern market is a factor determining or even enforcing the processes of creation of product innovations designed to encourage consumers to familiarize with the offer of enterprises. Innovative dynamism is a feature of modern markets. The process of innovation acceptance by consumer is a special case of market decision making. Considering the length and the course of individual phases of this process, i.e. the cognitive, affective and behavioural phases, the typology of consumers according to the Rogers' model (Rogers 1995) should be indicated. It includes innovators and early followers, early and late majority and conservatives. The course of these phases is the shortest for innovators who, from the very beginning, are positive about innovations, present great interest in them and are ready to accept new products. Early followers need a little more time to collect data about innovations, but they also buy a new product relatively quickly. The decision-making process lasts much longer in the case of consumers belonging to the early and late majority, and even more in the case of conservatives who express sceptical attitudes towards all innovations. The purpose of the paper is to present the behaviours of Polish consumers towards new products in

1995 - 2018 in the segments of the types of consumers mentioned before. The following research questions were formulated:

- what is the consumer typology on the Polish market, resulting from the Rogers' model and what are the changes in this typology in the indicated long term?
- what is the diversity in behaviours of Polish consumers towards new products, depending on the basic characteristics of these consumers, including: gender, age, education and source of income?
- how do consumers representing the analysed groups evaluate new products offered on the Polish market?
- what sources of information are used by innovators and other consumer groups while purchasing products from various sectors?

The analysis is based on the results of nationwide surveys conducted in the long term, i.e. at the beginning of the system changes in 1995, on a population of 1004 consumers, then in 2001 on the population of 1079 respondents and in 2017 - 2018 on the population of 1328 respondents in 10 voivodships selected from 16 voivodships in Poland. The % share of the surveys conducted in each voivodship corresponded to the share of the voivodship's population in the total Polish population. The applied samples are comparable according to the basic criteria, i.e. age, sex, education, place of residence city-village, main source of income and income situation. The study applies the method of quota sampling, while selecting respondents within the above-mentioned groups.

Factors Determining the Adoption (Acceptance) And Diffusion of Innovations

The article assumes that consumer innovativeness is expressed by the tendency to buy new products more often and faster than other people or being more susceptible to new ideas. Various reasons for such innovation are indicated, including the expression of the need for stimulation and search for novelty, as well as the need to emphasize the uniqueness and independence from the experience of others (Roehrich, 2004 p. 671). According to Rogers, consumer sensitivity to innovations can be measured by the number of innovations adopted by them in a given period or by the tendency to introduce change in consumption.

While the adoption (acceptance) of innovation concerns a specific consumer, the diffusion of innovation consists in the spread of innovation on a given market through various (direct and indirect) channels of communication with the buyer. People-to-people contacts, and mutual interactions of individuals generated by reference groups play an important role in this process. The course of this process depends on a number of factors related to product features, consumer characteristics and the patterns of consumption they follow. The impact of marketing factors and information&communication technologies that increase access to information about a new product and stimulate interest in the innovation is also extremely important. The adoption of innovation by a consumer depends primarily on the following factors. (Filser, 1994, Robertson, 1975):

a) the importance of the product in the hierarchy of consumer needs,
b) the level of recognition of the product by the consumer's social environment, especially by the basic reference groups,
c) product prices - in relation to the purchasing power of the consumer,
d) product features that make it distinguished on the market,
e) the nature of innovations and their perception by consumers,
f) the speed of making decision by the consumer,
g) the consumer's propensity to take risks.

Ad. a) The greater the importance of a product in the hierarchy of consumer needs, the greater its involvement in acquiring market information and experiences related to the product, and thus greater readiness to adopt the product.

Ad. b) High recognition of the new product by reference groups shapes positive consumer reactions and accelerates purchase, while giving the product a specific symbolic value.

Ad. c) The high price of a new product in relation to purchasing power of the consumer creates a natural barrier in the decision-making process. This process becomes more complex, and its result depends on the strength of the influence of the level of urgency of needs, as well as the prestigious importance of the product.

Ad d) The product features that distinguish it on the market, such as: complex structure and technological design, explicit symbolic values, a high level of risk to health or life, affect the extension and complexity of the decision-making process regarding the purchase of this product.

Ad e) Decisions to adopt a new product depend on the nature of the innovation and its perception by consumers.

The process of making decisions about the purchase of absolute innovations, i.e. products that meet the needs that yet have not been met is the longest. This is because, while creating new needs, these products lead to fundamental changes in consumption (e.g. personal computer, mobile phone, television, video recorder). In the case of continuous or dynamically continuous innovations, consumer reactions are shaped by the factors corresponding to the specific character of these products. And so in the case of new food products, product quality, price, nutritional value, habit, positive opinion of other customers, information on the packaging, brand, convenience and origin of the product are the most important factors determining the purchase of the product as declared by young consumers are:. (Bartkowicz, 2018).

International studies (World Innovation Panorama, 2015) conducted in key regions of the world (North America, Latin America, Asia, the Middle East, North Africa and Europe) have shown that the dominant trend in food product innovation is the pursuit of pleasure expressed by such product attributes as: sophistication, a wealth of impressions, exoticism and fun. The second most frequent trend in product innovation is "health" highlighted by product features such as: naturalness, medicine and vegetation(Figiel 2017, p.107). These trends in food market innovation are a response to the expectations of modern consumers.

Ad f, g) The pace of diffusion of innovation also depends on such features of consumers as the ability to make quick decisions and to take risks. Certain innate personality traits that predispose consumers to specific market behaviours are usually the basis for these characteristics.

In comparison with "late buyers", innovators are distinguished by a large interest in marketing products, sensitivity to promotion and considerable susceptibility to influence from media. They are more willing to take risks and are less attached to the brand (Schiffman, 2010).

High susceptibility to adopting innovation also results from personality features, as well as from the demographic and social characteristics of innovators. Innovators are usually young, educated, rather wealthy people, of highly prestigious professions.

Trendseters following new market trends, as well as designers and artists who often experiment and strive to create these trends, are characterized by high sensitivity to new products. In turn, celebrities play the role of a medium for communicating consumer trends (Mróz 2013, p. 119).

To determine the level of consumer innovativeness, it is important to recognize the sources of obtaining information about the market offer, including new products. To succeed in launching a new product, it is necessary to communicate with customers at an earlier stage, whereas social media are the best channel of this communication.

Diffusion of Innovations of The Polish Market

The respondents' choice of one of five answer options allowing to qualify them in the appropriate category of consumers more or less susceptible to innovation was the basis for the analysis of this process in relation to the Polish market.

Therefore, the percentage structure of consumers by type of response to these products can be considered as a measure of the diffusion of new products.

Table 1: Consumer behavior towards new products (percentage of respondents)

Types of consumers		food	clothing, footwear	cleaning supplies	cosmetics	household appliances	RTV equipment	tourist equipment	books
Innovator	1995	10,5	15,4	10,3	12,9	6,2	6,9	4,9	30,2
	2001	12,5	14,5	12,4	15,3	6,1	7,3	5,0	26,4
	2017 2018	16.4	20,7	8,1	14,6	10,4	11,0	5,6	29,8
An early follower	1995	25,7	32,5	23,7	25,6	13,8	15,7	14,2	32,1
	2001	28,1	33,6	22,4	22,0	14,5	16,0	11,7	26,0
	2017 2018	30,8	39,4	18,7	20,7	19,7	18,1	15,0	28,7
Early majority	1995	23,3	19,1	29,2	22,6	28,8	28,2	25,2	9,8
	2001	23,5	17,1	29,0	22,9	21,2	20,1	17,6	9,8
	2017 2018	21,2	19,5	29,0	26,1	29,0	30,2	24,9	13,7
Late majority	1995	22,6	17,1	25,9	22,3	36,9	35,3	32,8	11,5
	2001	22,3	16,4	24,7	21,7	39,0	35,9	26,5	13,6
	2017 2018	14,5	8,4	21,0	20,5	25,5	26,5	23,6	14,5
Marauder	1995	18,3	15,8	10,9	16,4	14,3	13,8	22,9	16,3
	2001	13,6	18,4	11,5	18,1	19,2	20,7	39,3	24,3
	2017 2018	17,1	12,0	23,1	18,2	15,3	14,2	30,9	13,4

Source: Own study based on surveys carried out in 1995, 2001 and in the period of 2017 -2018.

After years of functioning of unsustainable market in Poland, new products were especially strong incentives for consumers to make shopping decisions. This was demonstrated by the implemented models of innovation diffusion, which were different from the E. M. Rogers model by a much larger share of innovators and early followers, although this was significantly dependent on the nature of the product. Surveys conducted in 1995-2001 and 2017-2018 on nation-wide representative Polish populations showed that the number of innovators, i.e. consumers declaring that they like to be the first to buy a new product in this period represented 12.1 - 14.6%, i.e. more than in the Rogers' model[1] (Tab. 1).

Also the number of early followers (buying a new product relatively quickly, even though after some reflection) was higher than the number expressed by the Rogers' model. It reached in 1995-2018 about 22.9 - 23.9%.

Approximately 20.2 -24.2% of buyers waited for the product to be tested by others before making the purchase decision, while it is worth noting that the number of consumers of the so-called late majority who buy a new product when most friends have already purchased it and rated it positively declined from 25% in 1995-2001 to 19.3.0% in 2017-2018. The number of marauders, i.e. people who are reluctant to buy new market products, which reached 16.1-18%, after a slight increase in 2001 (20.5%) was relatively closest to the Rogers' model in the discussed period of 1995-2018.

[1]According to this model, innovators constitute only 2.5% of all buyers, customers early accepting a new product represent 13.5%; the majority accepting innovation early constitutes 34%, the late majority also constitutes 34% of buyers, whereas conservatives 16% (Rogers, op. cit.).

It should be emphasized that diffusion of innovation is considerably dependent on the nature of the product. The proportions between the groups of buyers of mechanized household appliances and radio and television equipment are the closest to the Rogers' model. The number of innovators in the purchase of these products is more than twice smaller than in the purchase of other goods. The number of early followers is also smaller. Considerable caution in buying new types of equipment results from their high prices. Over 60% of consumers make decisions to buy these products after others have already purchased them and rated them positively. In the case of tourist equipment, the number of conservative-marauders (39.3 - 30.9%) was the highest in comparison with other products in 2001-2018 and, which is important, it increased when compared to 1995.

Meanwhile, in the case of most of goods, the share of conservatives decreased, which proves the growing openness of consumers to market novelties. The exception applies to responses to new food products and cleaning products, as the number of customers who reluctantly buy these new products increased in the discussed period, for food from 13.3 to 17.1%, and for cleaning products from 11.5 to 23.1%. On the other hand, positive changes are observed in other consumer groups, i.e. innovators, early followers and the early majority because in each of them more and more people purchase market novelties. However, the size of the late majority group has decreased, which also confirms positive changes in behaviours towards new products.

The processes of diffusion of innovations were proceeding the fastest on the book market, which results from the special nature of the book as a marketing product. Although the record-high number of innovators (30.2%) in 1995 who liked new publications decreased in 2001 to 26.4%, in 2017-2018 the percentage of innovators returned to a high level, i.e. 29.8%. This proves that Polish consumers are still really open to new publications in all age groups, but especially in the 50-59 age group (35.3%). Even in the oldest age group, i.e. 60+ age group, the percentage of innovators in 2017-2018 was 21.3%, which could not be observed in any other product group. However, an upward trend in the number of innovators, early followers and early majority is observed in all studied groups of products. Meanwhile, when it comes to the number of marauders who are reluctant to buy market novelties, it is observed that after the phase of increase in this number in 1995-2001 (food is the exception), there was a downward trend in 2001-2018. The exception relates to cleaning products and food products for which the number of marauders increased. This may result from the uncertainty of more conservative consumers who are reserved about innovation in these markets.

The process of diffusion of innovations is determined by individual features of buyers, i.e. socio-demographic, personality and economic characteristics.

The results of the analysis conducted in segments of various groups of goods show a clear impact of consumer age on their declared willingness to adopt an innovation. This is illustrated by the data presented in Tab. 2. Consumers from lower age groups accept product novelties faster. The number of innovators is relatively the largest in the 18-24 age group and is definitely declining in higher age ranges, at a pace depending on the nature of goods.

Table 2: Changes in the distribution of innovators and marauders in 1995-2018 (by age)

Years	Age					
	18-24	25-29	30-39	40-49	50-59	pow. 60
Innovators						
1995	17,7	12,9	13,7	10,6	10,3	6,1
2001	13,6	14,3	13,6	12,3	9,1	7,8
2017/2018	16,3	18,3	1 13,6	9,9	11,6	7,8
Marauders						
1995	11,0	12,5	13,0	14,3	21,8	26,0
2001	12,5	15,3	16,8	20,6	26,2	46,4
2017/2018	15,6	17,4	15,4	22,2	19,5	31,0

Source: Own study based on surveys carried out in 1995, 2001 and in the period of 2017 -2018.

It is interesting to look at the diffusion of innovations among young consumers. In addition to high readiness to acquire new publications, they are also innovators in the processes of purchasing clothing and footwear (26.7%). The number of early followers is also record-breaking in this industry (on average 39.4%). Next there are purchases of new jewellery among young people (23.3% of innovators, 26.6% of early followers). In the 18-24 age group there is also a relatively large number of innovators in the purchase of computers and smartphones (24.4%), and in the 30-39 age group there is a large number of early followers (32.9%), as these are very important products in consumption models of younger consumer generations.

The largest, eightfold differences between age groups are observed in 2017-2018 in the purchase of computers and smartphones (24.4% of innovators among 18-24 age group, and 3.1% in the group of seniors 60 years and older), while five-fold differences observed in 2001 in the case of clothing and footwear decreased in 2018 to three and a half-fold differences (26.7% of innovators aged 18-24 and 7.5% in the group over 60). This is because they are products quite often purchased, and changes in these products, especially those that meet the diverse needs of consumers, are increasingly better accepted by older people. In 2017-2018, the difference between age groups is also similar in relation to the number of innovators on the food market (19.3% among 18-24 year-old buyers, and 4.3% for people over 60). This seems to be justified by a greater willingness to try new products and differentiate consumption patterns presented by young people, as well as greater food traditionalism of elderly people, which is also influenced by health limitations.

Threefold differences between age groups in terms of the number of innovators relate to such products as cosmetics, mechanized household appliances, consumer electronics and tourist equipment. The smallest, because twofold differences between age ranges in relation to the number of innovators are noticed on the market of cleaning products and the book market, but also here the regularity of faster diffusion of innovation among younger buyers is confirmed. This regularity is less evident among early followers; their shares in general buyer populations are more even, and in many markets the largest share of early followers is observed in the 18-24 age group (clothing, household appliances, books), 30-39 age group (food, electronics, books), and also 40-49 age group (cleaning products, tourist equipment).

In the segment of buyers reluctant to buy market novelties, older people, mainly aged 60+ predominate, and their share among the so-called marauders is more than twice as large as among 18-24 age group.

In 1995–2001, the number of marauders in all age groups increased at a faster pace, with the higher the age of consumers. In the 60+ age group, the number of people reluctant to buy market novelties increased from 26 to 46 percentage points, and among 18-24 age group of consumers, the number of marauders increased by just one percentage point. This trend continued in 2017-2018 only in younger and middle-aged groups, whereas a decrease in the percentage of marauders respectively from 26.2 to 19.5% and from 46,4 to 31.0 % is observed among mature consumers, i.e. aged 50-59 and 60 years old and older. This may prove the effects of civilization progress, which is associated with greater openness of consumers to innovation.

Meanwhile, still there are differences between age groups in terms of the number of innovators, as the growth rates of the number of innovators are greater in younger age groups. This increase mainly concerns the purchase of books, but also hygiene products and cosmetics.

The importance of consumers' education in shaping their behaviours towards new products is also revealed
(tab. 3) .

Table 3: Types of consumers by approach to product innovations and their level of education (percentage of respondents)

Types of consumers	Level of education			
	Basic	Vocational	Secondary	Higher
Innovator	12, 8	11,6	15,7	17,5
An early follower	14,4	19,3	23,2	29,6
Early majority	24,5	21,1	24,3	29,1
Late majority	16,0	18,5	18,7	23,8
Marauder	32,4	29,5	18,1	22,9
Total	100,0	100,0	100,0	100,0

Source: Own study based on surveys conducted in 2017-2018

Conducted research shows that as regards most products, the number of innovators is the highest among buyers with higher and secondary education. This also applies to the number of early followers, and to the early and late majority in 2017-2018. On the other hand, among consumers with primary education, people who are reluctant to buy market novelties have relatively the largest shares. These shares are two to three times higher than in the population of people with higher education and concern most products except for clothing and footwear as well as jewellery, where the differences are smaller. In the case of tourist equipment as well as computers and smartphones, the share of marauders is the highest among consumers with vocational education. In terms of the number of innovators, the reduction of disparities between consumer groups with different levels of education is a positive phenomenon. Only in the case of cosmetics and books, the share of innovators in 2017-2018 was about twice higher among consumers with higher education. The relatively large disproportions between the number of innovators and marauders in relation to durable goods (i.e. in mechanized household appliances, consumer electronics and tourist equipment) observed in 1995–2001 across education levels were also caused by larger differences in the level of purchasing power of the studied consumer groups.

The education factor determines consumer behaviour towards new products not by itself, but also in some correlation with income.

Growing consumer income increases their propensity to buy innovations. This is reflected by the greater share of innovators in the higher income groups, and the smaller share for those reluctant to buy market novelties. This regularity refers to all goods, even though the strength of the impact of the income factor on diffusion of innovation depends on the type of product.

The shares of the first buyers of mechanized household appliances and electronics were in the highest income group four or five times higher than in the lowest income group. In the case of tourist equipment and cosmetics, the differences were threefold, and in other cases two-fold.

Only in the purchase of cleaning products the percentage shares of innovators are not clearly differentiated in the segments of income groups, although such a relationship is manifested to some extent in relation to people who are reluctant to buy market novelties. These people have relatively the largest share among the consumers with the lowest incomes.

Research also shows the diversity in diffusion of innovations depending on the gender of consumers. Women are more prone to adopt innovations occurring in the markets of food, clothing and footwear, washing agents, cosmetics and books. Men are more willing to accept new products on the markets of all types of mechanized equipment, because they more frequently make buying decisions related to these goods.

Consumers' Opinions on New Products

The changes taking place on the market influence the improvement of consumer opinion about new products, because in 2017-2018 almost every fifth of the respondents (19.8%) claimed that the

products increased the usability for the customer, while in 2001 such belief was expressed by only 12% respondents. However, the number of respondents who expressed negative opinions about new products did not decrease, because in the analysed period it remained at the level of approximately 37% of respondents. They emphasized the apparent features of new products, unnecessary increase of the product price and even misleading the consumer. Furthermore, the percentage of those consumers who perceive new products only in terms of expanding the choice on the market decreased from 50% to 43.2%. This is presented by data in Tab. 3.

It is interesting that, men are more convinced about actual increase in the usability of the product and provision of real benefits to the customer, while women are more critical in this respect. However, they appreciate more the greater customer choice thanks to new products.
The study shows that in 2017-2018 the actual usability of new products was also noticed by relatively more young people, i.e. 18-24 years old (26.4%) and 25-30 years old (20.1%), while among mature people i.e. 50-59 years old by only 7.9%, and in the case of those over 60 years old this refers only to 4.0% of them.

The basic source of income of respondents defining their socio-professional status is an important criterion for assessing new products. The perception of the real advantage of new products in terms of increasing product usability and generating additional benefits for consumers is observed mainly among self-employed people (31, 4%), as well as among freelance professionals (19.6%) and white-collar workers (19, 9%). Freelance professionals, similarly to farmers, also appreciate most the role of new products in increasing consumer choice, representing 54,3% and 60.0%, respectively. The most critical opinions about new products are expressed by people living on unemployment benefits and pensions.

They emphasize that apparent product changes mislead the consumer. This is indicated by 28.6% of respondents in the first group, and 18.9% in the second group respectively. It is related to the income situation of these consumers, which is confirmed by opinions about new products analysed in the segments of income groups. Among respondents declaring a very good income situation, one in three expresses good opinions about new products, while emphasizing that they increase the usability of the product, whereas among low-income consumers only one in ten expresses such an opinion.

The general attitude and readiness of the consumer to accept an innovation is also an important criterion for assessing new products. In general, innovators are more positive about new products, and this concerns all industries. The greatest differences between the opinions expressed by innovators in comparison with other groups of consumers concern composite products, i.e. mechanized household appliances, electronics, computers and smartphones, as well as services. And so rate of innovators indicating that new products of these industries actually increase the usability for the client is 41-44%, in the group of early followers it is by half smaller, i.e. 21-29%, and in subsequent groups it decreases even more and amounts to 19-24 for early majority, 10-15% for late majority and 5- 16% for marauders. This is most clearly seen in relation to computers and smartphones, as illustrated in Tab. 4.

Most consumers, apart from innovators, perceive new products mainly from the perspective of increasing consumer choice. Even in groups of early followers, every third consumer emphasizes above all this aspect of new products, and in the late majority group it is indicated by every second consumer. The differences between innovators and other consumer groups in terms of the evaluation of new products are much smaller in relation to food and drugstore products, clothing and footwear, as well as jewellery and books. However, in each of these cases, the advantage of innovators is confirmed when it comes to their conviction about greater usability of new products. In this group, there are relatively fewer sceptics indicating that apparent changes in product characteristics mislead the consumer. The rate of such sceptics among innovators is at the level of 5-8% in relation to all studied products except cleaning products and books. Meanwhile, critical opinions emphasizing only apparent changes in product features that mislead the consumer are declared much more often in other consumer groups, i.e. nearly twice as often (12-18%) among early followers and the early majority.

Table 4: Consumer opinions about new products (number of respondents in %)

Lp.	Consumer opinions	2001	2017-2018
1.	Increase usability for the customer	12,0	19,8
2.	They seem to distinguish the product from others	10,6	14,6
3.	They make the product more expensive	12,9	9,0
4.	Increase the customer's choice	50,4	43,2
5.	Mislead the consumer	14,1	13,4

Source: Own study based on surveys carried out in 2001 and in the period of 2017-2018.

The exceptions are opinions about cleaning products, which are even more favourable than among innovators not only in the groups of early followers and early majority, but also the late majority, which may result from the lower sensitivity of these groups of consumers to changes introduced in these products.

The relatively highest scepticism towards new products is expressed by marauders, who, beside pointing to apparent changes in new products, also more often emphasize that new products are distinguished only by a higher price than other consumer groups. This is indicated by nearly twice higher rates of respondents among the marauders (10-17%) than among innovators (4 - 10%) in relation to almost all analysed product groups except for clothing and footwear, as well as computers and smartphones, where differences of opinion between these groups are threefold.

The reasons for the greater scepticism of consumers - marauders are different for each of these product groups, as new models of computers and smartphones can be treated with distance by people less oriented in the progress of their production technology, while critical opinions about new clothing and footwear products can generally result from negative or indifferent attitude to changing fashion trends.

In order to effectively influence the attitudes and behaviours of the analysed consumer groups, it is necessary to identify where they obtain information about the offer of goods and services. Despite the diversity of the share of these sources of information in the segments of products, there is a regularity, according to which reference groups (relatives and friends) play a dominant role as sources of information about the offer. This is declared on average by almost every second respondent. Then consumers also use their own experience (33 4%), online advertising (28.7%) and social media (25.7%). TV commercials are a source of information only for every fifth respondent, and every tenth respondent indicates obtaining knowledge about the offer from store advertisements and directly from sellers. Press advertisements (4.0%), press releases 2.2% and radio advertisements (2, 3%) are marginal in this respect.

Conclusions

Polish consumers expect from new products facilitating everyday life, but also meeting their needs in a more rational way thanks to better prices and adapting to the latest consumer trends (Żółcińska, 2020).

Susceptibility of Polish consumers to new consumer products, shown in the research is relatively higher than in the Rogers' model. It results from the specificity of behaviours of these consumers shaped in the process of transformation from the unbalanced market to the saturated market. Thus the number of innovators and early followers on the market of each studied product group is greater. Research on this typology of consumers depending on their age, education or source of income revealed the importance of these features in shaping behaviours towards new products.

Greater susceptibility to innovation characterizing young, better-educated and more affluent people, perceiving reality more optimistically, makes them opinion leaders. While consciously or unconsciously influencing the environment, they provide people with patterns of meeting the needs. The level of integration of opinion leaders with their social group which is higher than among

innovators is an important premise that determines the direction for future research on diffusion of innovation. Behaviours towards new products and opinions about them significantly depend on the level of knowledge about new products. This is particularly evident in the convenience food market (Olejniczak, 2009).

The evaluations of new products presented in the paper by individual consumer groups are a cumulative expression of knowledge about these products and emotions related to them. These are important elements of attitudes towards the discussed products. The analysis of these evaluations allows for verification of presented typology of consumers according to their declared behaviours towards new products. There is a clear diversity of sources of information about the offer used by individual consumer groups. Innovators' preference of online sources, especially when buying high technology products, is justified by the greater advancement of these consumers in the use of new information and communication technologies. The relatively large significance of own experiences in the behaviour of early followers towards new products indicates that this group of consumers strive to find their own arguments confirming their decisions concerning choice. However, the early and late majority is distinguished from others by greater susceptibility to the impact of information obtained from reference groups, which affects their opinions and behaviours towards new products. In the attitudes and behaviours of the most conservative group, i.e. marauders, internet sources are relatively less important while own experience as well as reference groups and traditional forms of communication, such as television commercials are more important. Furthermore, this group values information obtained from sellers more than others, which results from the relatively greater need among those consumers for support from other people while making a buying decision.

Recognising where individual consumer groups obtain information about the market offer of products is extremely important in a marketing communication strategy focused on buyers with different propensity to adopt new products.

The diversity of consumer attitudes and behavior towards new products is a big challenge for companies in their marketing activities. It is necessary to adapt the types and nature of communication messages to the identified consumer groups. Messages send to innovators should contain a large load of professional knowledge about the features that distinguish the product from others, including those highlighting the technical parameters of the product (among others computers and smartphones as well as electronics and household appliances)**.** The most effective in this case are personalized forms of communication corresponding with the consumers-innovators level of knowledge and their readiness to try and test the product. Great possibilities in customization of these messages result from the development of information and communication technologies. There are also special incentives and forms of cooperation with a company, that expects customers to fulfill the role of influencers that, using social media and relationships with many people, are able to influence their shopping behavior.

In turn, marketing messages directed to a group of early followers should emphasize those features that allow them to be distinguished from other customers. i.e. originality, modernity, prestige. Internet and television broadcasts are very effective in this respect. However one cannot forget about and should emphasize the role of customers' own experiences, that they follow in order to verify the emitted communication messages**.** The early majority of consumers are more sensitive to rational arguments persuading them to buy, and especially emphasizing the good relationship between price and quality. Due to their relatively high readiness to trying new products, presentations and demonstrations of new products are effective, as well as the experience of opinion leaders, especially those from aspiration groups.

For consumers representing the late majority, it is particularly important to emphasize, in the communication messages, arguments that create a sense of security and guarantees associated with the product for buyers. Hence, it is effective to refer to expert assessments and favorable test results. Salesmen and sales agents have a big role to play in building customers' trust, explaining product features, and strengthening arguments presented in advertising. (Loudon**,** 1993).Moreover**,** reference groups to which the consumers belong are particularly important in providing pre-purchase

arguments, as similar mentality and perceptions increase the credibility of messages. The increasing use of various forms of internet communication increases the effectiveness of their impact on participants of online communities who exchange information, knowledge and opinions about a new product between each other. Summing up the recommendations for enterprises, it should be emphasized that the most difficult group to reach with the message about a new product is marauders' consumers due to their low interest in new products, and also less frequent use of internet communication channels. However, this group of consumers should not be overlooked in marketing activities, but their interest should be stimulated by deeper recognition of perception mechanisms and strengthening it with appropriately selected promotional arguments, emphasizing the usefulness of a new product and possible benefits, especially of an economic nature. Greater efficiency can be achieved by using a new forms of communication such as content marketing and native advertising. For placing the message in the context of useful and very attractive content makes it easier to raise interest of all groups of the recipients. Moreover, companies should make greater use of the potential of leading users and opinion leaders in the dissemination of innovation process.

Abstract

Teamwork is an important component of modern organizations. It may nevertheless be different in public, for-profit and nonprofit entities marked by structural, cultural and personal differences. The aim of the article was to answer the research questions: are there any differences in the assessment of teamwork between employees of public, for-profit and nonprofit organizations? and are there any differences in collective team engagement between employees of public, for-profit and nonprofit organizations? To this end, a survey study was conducted in 2019 which collected responses from 315 purposively selected teams members in public, for-profit or nonprofit organizations. The Kruskal-Wallis test was performed to test the validity of the formulated hypotheses. The obtained results may suggest the existence of differences between the cognitive and affective-motivational aspects in the approach to teamwork.

Keywords: Team, Teamwork, Collective Work Engagement, Public Organizations, Nonprofits, For-Profits

Introduction

The concept of teamwork has become very popular among management theorists and practitioners. Over the past decades many papers have been written on the topic (e.g. Benevene et al., 2011; Brill, 1976; Katzenbach and Smith, 1993a, 1993b; Lipnack and Stamps, 1997; Morgan et al., 1994; Salas et al., 2015; Wise et al., 1974). Some researchers have pointed to the advantages of teamwork (Sundstrom et al., 1990; Drew and Coulson-Thomas, 1997; Salas et al., 2000, 2005; Vašková, 2007; Hanaysha and Tahir, 2015). However, although teamwork can boost efficiency and effectiveness, it is not a priori more efficient than individual work (West and Markiewicz, 2004). Its course and outcome depend on various factors: personal, interpersonal, organizational (D'Amour et al., 2008; Martin-Rodriguez et al., 2005), or those related to job attitudes (Morgan et.al., 1994) or feedback in a given type of organization. Liao-Troth (2003), based on the example of paid employees and volunteers, found that differences in job attitudes result from organizational culture rather than individual approach to work. The organizational context can therefore be an important determinant of teamwork. This work may differ for public, for-profit and nonprofit organizations, as each of these is significantly different in structural (Toepler and Anheier, 2004), axiological (cultural) and personal terms (Van der Wal et al., 2008; Almond and Kendall, 2000; Goulet and Frank, 2002; Benz, 2005; Borzaga and Depedri, 2005; Borzaga and Tortia, 2006; Lyons et al., 2006; Melnik et al., 2013; Mirvis, 2006).

Despite the growing interest of researchers in the subject of teamwork, there are few publications comparing it in organizations representing three main sectors: public, for-profit and nonprofit. Instead, most such comparisons have been limited to two sectors (Benevene et al., 2011; Sharma and Bajpai, 2014; Chen and Rainey, 2014), with no cross-sectoral studies in sight, including those assessing teamwork and collective team engagement. With this article, we hope to reduce this research gap.

The purpose of the article is to answer the following research questions:

Q_1: Are there any differences in the assessment of teamwork between employees of public, for-profit and nonprofit organizations?
Q_2: Are there any differences in collective work engagement between employees of public, for-profit and nonprofit organizations?

The article is divided into sections, which are as follows: introduction, literature review, methods, results and conclusions.

Sectoral differences between public, for-profit and nonprofit organizations

In the literature, it is common to see modern organizations being divided into three main groups: public (governments, local governments, and their agencies), commercial and nonprofit. Commercial organizations provide goods and services, while nonprofits are agents of change occurring in people (Drucker, 1990). This typology is semi-teleological and arose from the division of company activities and goals into private and public. Moore (2000) puts this somewhat differently by saying this differentiation stems from two key variables: defining source of revenues and the value produced by organizations.

Sectoral boundaries are becoming blurred. Hybrid organizations are emerging that operate in various organizational fields, combine business and social logic, and are linked to both the market and civil society (Cooney, 2006; Davies and Doherty, 2019; Evers and Laville, 2004; Knutsen, 2016; Jager and Schroer, 2014; Litrico and Besharov, 2019). Despite the resulting cross-cutting of knowledge and practices, organizational management is still very much sector-specific due to the differences between commercial, public and nonprofit entities. Toepler and Anheier (2004) used an ideal-typical comparison to also point out some differences in areas such as: function, outputs, distribution criteria, size, structure, decision-making, accountability and control, participants, motivation.

All these differences have an axiological basis and concern basic cultural values. Van der Wal et al. (2008) point to the existence of two separate and relatively classic value systems for public and commercial organizations. Accountability was recognized as the most important value in public decision-making, followed by lawfulness, incorruptibility, expertise, and reliability. In enterprises, meanwhile, the ability to yield profit is valued the most (Van der Wal et al., 2008) alongside those economic values which are oriented to the company's performance and include: competition on the market, growth, profitability, quality, adaptation, rigour in management, professional integrity, will to be number one (Calori and Samin, 1991; cf. Marcoulides and Heck, 1993; Van der Wal et al., 2008). Differences can also be found by comparing the public sector to nonprofits. In public organizations, universalism and equity are largely predominant, whereas nonprofits lean more towards particularism and responsiveness (Lipsky and Smith, 1989-90). For third-sector entities, the principal value is solidarity (Jager and Schroer, 2014; cf. Whitman. 2009).

Organizations can also differ in approach. The literature indicates differences in the personality, motivation, values and attitudes shown by paid and non-paid workers. Paid employees are the pivot of activities run by public and for-profit organizations while non-paid staff fuels nonprofits. Nonprofits, therefore, rely on employees' beliefs, views, passions and are a manifestation of their ethical attitude towards the world (Rothschild and Milofsky, 2006). Volunteering is therefore the way to go for nonprofits, which is why concepts such as altruism (Smith, 1981; cf. Rose-Ackerman, 1997) and pro-social orientation of volunteers (Briggs et al., 2010; cf. Bussell and Forbes, 2006; Studer and von Schnurbein, 2012) are often brought up. Volunteers have been shown to be more agreeable and extraverted than paid workers (Elshaug and Metzer, 2001) and also seem to demonstrate a larger sense of control over their own fate and stronger causative optimism than non-volunteers (Olkowska, 2008). Pearce (1993) argues that both categories differ in job attitudes while Liao-Troth (2003) found that differences are due to organizational culture and not individual approach to work. His research suggests that, when analyzing staff behavior in organizations representing different sectors, the organizational context should be taken into account (cf. Studer and von Schnurbein, 2012). This stance was adopted among others by Melnik et al. (2013) who found that managerial capability is positively correlated with overall

employee satisfaction in the workplace. They also found that job satisfaction is strongly linked to salary and individual perception of work environment while nonprofit work is associated with greater overall job satisfaction. In general, nonprofit employees appear to be more willing to 'offer work' and are more loyal to organizations than employees in other organizations (Almond and Kendall, 2000). Benz (2005; cf. Borzaga and Depedri, 2005; Ren, 2013) found nonprofit employees to be more satisfied with their work than those in the commercial sector. These sector-specific differences do not concern just employees but also managers. Managers in publics and nonprofits share a similar set of values, but have a different perception of the importance of altruism, generosity and individualism (Miller-Stevens et al., 2015; cf. Miller-Stevens et al., 2018). Managerial positions are usually held by women in nonprofits and by men in for-profits (Claus et al., 2013; cf. Lee and Wilkins, 2011). This may suggest a more feminine organizational culture in the third sector (see: Hofstede, 1980). EU countries that can be characterized as *female* have been shown to have more nonprofit organizations while *male* countries have more for-profits (Claus et al., 2013).

Much of the research has not gone beyond analyzing one sector or comparing two sectors. There is significantly less research across three sectors. Studies by Goulet and Frank (2002), Borzaga and Tortia (2006), Lyons et al. (2006), Mirvis (2006) are some of those few. It has been found nonprofit employees experience greater job satisfaction and have greater confidence in their superiors than public and for-profit workers (Mirvis, 2006). Similarly, Borzaga and Tortia (2006) demonstrated that nonprofit employees are usually more content with their work compared to those employed in the other types of organizations even though their salary tends to be lower. Public-sector employees are the least satisfied of all. Lyons et al. (2006) analyzed the differences in general values, work values and organizational commitment between private, public and para-public employees and they observed dissimilarities in work values. They also found that commercial employees are overall more committed than employees in the other two sectors. Previously, Goulet and Frank (2002; cf. Mirvis, 2006; Ren, 2013) showed that organizational commitment ran highest among for-profit employees, followed by nonprofits and with publics coming last.

These structural, cultural, axiological and personal differences provide an organizational context that can influence the course, commitment and assessment of teamwork. We shall have a look at the literature where these issues are raised.

Teamwork in different types of organizations

Teamwork is not by any means a novel concept. We analyzed the contents of Google Scholar and EBSCO databases for the 1980–2019 period[1] and there is clearly a growing interest in this topic (Table 1).

Table 1: Number of publications in Google Scholar and EBSCO databases containing key terms related to research subject (1980-2019)

Database	Element of publication	Number of publications in Google Scholar and EBSCO[2] containing the term 'teamwork' (by time period)							
		1980-1985	1986-1990	1991-1995	1996-2000	2001-2005	2006-2010	2011-2015	2016-2019

	Content	2649	4289	16.319	41.517	68.978	105.110	135.964	114.548

Source: own study based on: https://scholar.google.pl/, http://www.bu.uz.zgora.pl/index.php/pl

In these publication, the word "team' is termed as 'a small group of people with complementary skills who are committed to a common purpose, performance goals and approach for which they are mutually accountable' (Katzenbach and Smith, 1993b; cf. Lipnack and Stamps, 1997; Wise et al., 1974) or more specifically as 'a distinguishable set of two or more people who interact, dynamically,

interdependently, and adaptively toward a common and valued goal/objective/mission' (Salas et al., 1992, p. 4; cf. Devine, 2002). According to Benevene et al. (2011, p. 518; cf. Sangaleti et al., 2017; Katzenbach and Smith, 1993a), most of the definitions (regardless of team type) include the following features: "a group of at least two individuals, who share one or more goals and perform tasks, interact (also virtually) among them, and therefore are work interdependently, having different roles and responsibilities, but also boundaries and linkages to the rest of their organization, to which they are collectively accountable for the work done'.

Teamwork[3] typically involves groups of interdependent employees who work cooperatively to achieve group outcomes (Parker and Wall, 1998). A broader description of team-working employees was presented among others by Brill (1976, p. xvi) who says it 'is done by a group of people who possess individual expertise, who are responsible for making individual decisions, who hold a common purpose and who meet together to communicate, share and consolidate knowledge from which plans are made, future decisions are influenced and actions determined'. Morgan et al. (1994; cf. Salas et al., 2015) are convinced that "teamwork focuses more on the shared behaviors (i.e., what team members do), attitudes (i.e., what team members feel or believe), and cognitions (i.e., what team members think or know) which are necessary for teams to accomplish tasks'.

Teamwork can be largely beneficial. According to Sundstrom et al. (1990), 'it provides more complex, innovative, and comprehensive solutions to organizational problems'. Salas et. al. (2000, 2005) indicate that 'teamwork offers greater adaptability, productivity and creativity than any individual can offer,. Vašková (2007) adds that this productivity growth concerns in particular the spheres which require creativity while solving different tasks, a high degree of adaptability and operational management. She also argues teamwork facilitates employee learning and skill acquisition, as well as information sharing (Vašková, 2007; cf. Froebel and Marchington, 2005). Drew and Coulson-Thomas (1997), as examples of teamwork benefits, indicate 'promotion of effective communication and collaboration, speeding actions, raising the commitment level, creating a more customer-focused culture and increasing organizational adaptability and flexibility'. According to some researchers, teamwork also favors job satisfaction (Hanaysha and Tahir, 2015; Griffin et al., 2001) and staff retention (Heywood and Jirjahn, 2004). We may refer to Acosta et al., (2012) who found that collective work engagement leads to improved business performance, better task implementation in teams, increased scope of positive impacts within the team and team effectiveness, and finally, increased work commitment at individual level. This engagement is 'conceptualized as a positive, fulfilling, work-related shared-state that is characterized by team work vigor, dedication, and absorption which emerges from the interaction and shared experiences of the members of a work team' (Torrente et al., 2012, pp. 338–339). Bakker et al. (2011) suggest that collective engagement refers to the engagement of the team/group (team vigor, team dedication, and team absorption), as perceived by individual employees. Costa et al. (2012, p. 5) define team work engagement as 'a shared, positive, fulfilling, affective-motivational emergent state of work related well-being'. They distinguish the three components of team-level work engagement are conceptualized as the following: 'Team vigour: shared high levels of energy and an expression of willingness to invest effort in work and persistence in the face of difficulties (e.g., conflict, bad performance feedback); for example, team members enthusiastically encourage demoralized colleagues, and explicitly express their desire to continue working; Team dedication: shared strong involvement in work and an expression of a sense of significance, enthusiasm, inspiration, pride and challenge while doing so; for example, team members talk to each other and to others (external to the team) about the importance of their work and about the thrill they feel concerning their work; Team absorption: shared focused attention on work, whereby team members experience and express difficulties detaching themselves from work; such as, team members talking about their work during breaks, commenting on time passing quickly and not engaging in non-work related interactions when working'.

Let us further pay attention to the opinion held among others by West and Markiewicz (2004; cf. Alderfer, 1977; Benevene et al., 2011; Morita, 2001) that, although teamwork can boost efficiency and effectiveness, teams themselves do not generate more productive work than individuals. In their view, introducing teamwork in an organization does not guarantee success; on the contrary, if implemented incorrectly, teamwork may lower efficiency, innovation and satisfaction[4].

As mentioned before, the empirical or theoretical research showed that teams are not easily implemented, that the creation of a team of competent members does not guarantee success, and that teamwork does not just happen (e.g. Hackman, 1998). For example, Mathieu et al. (2008) state that a team will fail if its members cannot successfully share knowledge, coordinate behaviors and trust each other. Schmutz et al. (2019; cf. Sheikh et al., 2016) are convinced that if the team is to be effective, team members need to collaborate and engage in teamwork. According to D'Amour et al. (2008) and San Martin-Rodriguez et al. (2005; cf. Honein-Abou Haidar et al., 2017), determinants of teamwork include: interaction factors, which relate to the interpersonal relationship between team members; organizational factors which relate to working conditions within institutions; and systemic factors that are elements external to work institutions, such as cultural, educational and professional systems.
Our analysis of Google Scholar and EBSCO databases revealed that teamwork has been more often analyzed in public and private organizations than in nonprofits (Table 2).

Table 2: Number of scientific publications in Google Scholar and EBSCO databases containing in the title selected key terms related to research subject (1980-2019)

Key terms related to teamwork – selected items	Number of scientific publications containing key terms in title

Despite the growing interest of researchers, only few publications have compared different types of organizations[5], which inspired our research. Sharma and Bajpai (2014), for example, found that public-sector employees have a greater degree of teamwork compared to private-sector workers. They also found that job satisfaction increases or decreases along with teamwork level. Chen and Rainey (2014) similarly showed that public-sector employees are more prone to teamwork than their corporate

counterparts. This was explained by greater formalization in public entities and also the fact that public employees work under greater protection. Benevene et al. (2011), meanwhile, comparing third-sector employees and public organizations, found teamwork is more effective among the third-sectors. Nonprofits show a higher level of members' commitment to teamwork and satisfaction with teamwork. This explains strong commitment to teamwork among nonprofit workers. Among the tri-sectoral studies there is an article by Kalleberg et al. (2006) which found nonprofits and publics to be more willing to use self-directed work teams.

Methods

The cross-sectoral teamwork research was conducted in 2019, in Poland's Lubusz Province. The research process consisted of the following stages: literature analysis, research gap identification, formulation of research questions and hypotheses, sample selection and development of adequate research tools, data collection and analysis, formulation of conclusions, indication of limitations and future directions.

To answer the research questions, the following hypotheses were formulated:

H_1: There are differences in the assessment of teamwork between employees of public, for-profit and nonprofit organizations.
H_2: There are differences in collective work engagement between employees of public, for-profit and nonprofit organizations.

Respondents were selected using purposive sampling[6]. They were asked to assess different aspects of teamwork and also their work teams, including their engagement.

Research tools - questionnaires consisted of 9 original questions in the teamwork assessment part. However, when examining team work engagement, an abbreviated (9-item) version of the research tool was used called "collective work engagement scale' (Torrente et al., 2012). Team work engagement considered three dimensions: vigor (3 items), dedication (3 items) and absorption (3 items). In the research tool, a Likert-type scale ranging from 0 "never' to 6 "always' was used. Questionnaires were given to different team members whose participation in the study was voluntary. A total of 315 questionnaires were completed correctly by team members employed in one of the three types of organizations.

Statistical analyses were carried out using Microsoft Excel. A nonparametric test was also performed - the Kruskal-Wallis test (using Statistica software). This was preceded by examining the normality of the distribution of individual research groups - using the Kolmogorov-Smirnov test with the Lillefors correction, whose results justified performing a non-parametric test.
In the study there were 105 respondents for each of the sectors: nonprofit, for-profit and public. There were more women (59.37%) than men. The average age of team members was 36.6. Every third respondent held a managerial position.

Public team members most often worked in medium-sized (50-249 employees; 35.14%) or large entities (over 250 employees; 35.24%), while other members mostly worked in small or micro entities (up to 50 employees; 27.62% in total). Those were mostly: offices (42.86%), army and police and prison (18.09%), educational institutions (15.24%), hospitals (13.33%).

Every fifth (19.05%) for-profit respondent worked in a company with fewer than 10 employees, while every fourth (25.71%) - in a small, every third (30.48%) - in a medium-sized and every fourth (24.76%) - in a large enterprise. The predominant industries were wholesale and retail trade (23.81%) and manufacturing (22.86%)

Nonprofit employees more often represented associations (74.3%) than foundations (25.7%). Every third (30.48%) worked for an entity with fewer than 10 permanent employees (paid, non-paid, members). Almost half (47.62%) were involved with organizations employing 11-50 people, while the

rest (11.90%) worked for larger organizations. They represented entities operating in various areas but mostly: social and humanitarian aid (37.14%), education and research (35.24%), culture and recreation (24.76 %) or development and housing (22.86%).

Results

The surveys made it possible to determine how employees representing teams operating in organizations from different sectors assess certain aspects of teamwork. It was found that in 6 out of 9 cases (66.67%) there are grounds for rejecting the null hypotheses about the uniform distribution of perceptions of various aspects of teamwork by team members in public, for-profit and nonprofit organizations (H_{1a}-H_{1d}, H_{1f}, H_{1h}) (Table 3). Hence the decision to undertake further analyses.

Table 3: Results of the Kruskal-Wallis test regarding teamwork assessment by the surveyed employees representing organizations from different sectors

Teamwork….	Independent (grouping) variable: organization type α=0,05 Kruskal-Wallis Test		
	H(2,N=210)	**Chi²**	**Result of hypotheses testing[7]**
enables **better results** than individual work	2,668333	2,652632	**H_{1a}**
enables **faster task fulfillment** than individual work	8,051678	7,076936	**H_{1b}**
makes it **easier to develop knowledge and professional** (substantive, job-specific) **skills**	1,660303	1,580268	**H_{1c}**
makes it easier to **develop social skills** (e.g. communication, negotiation, cooperation)	5,672902	5,531561	**H_{1d}**
is **more pleasant** than individual work	1,182612	1,260000	**H_{1e}**
makes **failure less painful** than individually	6,728156	5,393186	**H_{1f}**
makes employees **more motivated** to act than during individual work	0,278604	0,416426	**H_{1g}**
comes with **a smaller sense of responsibility** for outcomes than individual work	1,576336	1,458333	**H_{1h}**
makes **decision-making more difficult** than individually	2,946098	7,960289	**H_{1i}**

Source: own study

Reasons for rejection found

No reasons for rejection found

Based on the results, we found that team members in different types of organizations did not differ in their assessment of the following teamwork features:

- is more pleasant than individual work (H_{1e}),
- makes employees more motivated to act than during individual work (H_{1g}),
- makes decision-making more difficult than individually (H_{1i}).

It was also found that employees of nonprofits' teams less frequently than for-profits or publics thought that teamwork:

- enables better results than individual work (H_{1a}; NPO: 86.67%; F-P and public: 92.38% each);
- enables faster task fulfillment than individual work (H_{1b}; NPO: 78.10%; F-P: 87.62%; public: 90.48%);

- makes it easier to develop knowledge and professional (substantive, job-specific) skills (H_{1c}; NPO: 84.76%; F-P: 90.48%; public: 87.62%);
- makes it easier to develop social skills (e.g. communication, negotiation, cooperation) (H_{1d}; NPO: 92.38%; F-P: 99.05%; public: 95.24%),
- makes failure less painful than individually (H_{1f}; NPO: 57.14%; F-P: 71.43%; public: 59.05%),
- comes with a smaller sense of responsibility for outcomes than individual work (H_{1h}); NPO: 51.43%; F-P: 59.05%; public: 52.38%),

Throughout the research we also looked at how people working in organizations from different sectors assess collective work engagement[8]. It was found that in 3 out of 9 cases (33.33%) there are grounds for rejecting the null hypotheses about uniform distribution (Table 4).

Table 4: Results of the Kruskal-Wallis test regarding perception of collective work engagement by employees of different types of organizations

Statement	Independent (grouping) variable: organization type α=0,05 Kruskal-Wallis Test		
	H(2,N=210)	**Chi²**	**Result of hypothesis testing**
During the task, my team feels full of energy	8,829839	10,69011	**H_{2a}**
My team feels very persistent during the task	3,714753	0,981474	**H_{2b}**
My team feels strong and vigorous during the task	2,640987	2,743062	**H_{2c}**
My team is enthusiastic about the job	5,179776	4,613611	**H_{2d}**
My team enjoys doing the task	4,040115	9.214976	**H_{2e}**
My team feels very motivated to do a good job	0,739699	2,202797	**H_{2f}**
When my team is working, we forget everything else around us	0,928506	1,217200	**H_{2g}**
Time flies when my team is working	8,206857	4,457427	**H_{2h}**
My team feels happy when we are engrossed in the task	3,977609	3,994104	**H_{2i}**

Source: own study

	Reasons for rejection found
	No reasons for rejection found

Statistically significant disparities are only observed for statements such as: '*My team feels very persistent during the task'* (Vigor; H_{2b}), '*My team is enthusiastic about the job*' (Dedication; H_{2d}), '*Time flies when my team is working*' (Absorption; H_2). For the remaining statements, the differences were not significant. Detailed findings related to collective work engagement are shown in Table 5.

Table 5: Collective work engagement from the perspective of employees of different types of organizations

Source: own study

Having averaged the results in the three individual dimensions of collective work engagement, it was found that: a) public employees rated all three dimensions of collective work engagement the lowest; b) for-profit and nonprofit employees rated 'Collective vigor' higher ($\bar{n}$=3.61 and $\bar{n}$=3.59, respectively) than public workers ($\bar{n}$=3.25); c) nonprofits rated 'Collective dedication' higher ($\bar{n}$=3.79) than those employed in for-profits ($\bar{n}$=3.53) or publics ($\bar{n}$=3.46), d. for-profits rated "Collective absorption' higher ($\bar{n}$= 3.58) than those representing nonprofits ($\bar{n}$=3.47) or publics ($\bar{n}$=3.35).

Conclusions

Teamwork is currently one of the most sought-after social competences. Employees skilled in teamwork tend to be more creative, generate better solutions and implement them faster; they also communicate and share knowledge faster, experience greater job satisfaction, etc. This explains the growing interest in teamwork among management theorists and practitioners seeking to pinpoint the prerequisites of teamwork, the possibility of optimizing the teamwork outcomes, etc. Despite the rising popularity among researchers, only few publications comparing different types of organizations exist, which inspired our research. Our results signal the existence of statistically significant differences between employees of teams operating in public, for-profit and nonprofit organizations regarding how they assess certain aspect of teamwork. It was found, among others, that nonprofit employees less frequently (usually by 5-10%), compared to those employed in public and for-profit entities, thought that teamwork enables better results, faster task implementation or development of substantive and/or social skills, but also that it evokes a smaller sense of responsibility for outcomes than individual work. The biggest differences concerned issues related to the feeling of failure and faster task fulfillment under teamwork (approx.12-14%). A larger percentage of for-profit employees, compared to the other two types, claimed that failure is less painful when experienced in a team than individually. The results show that, in the cognitive aspect, for-profit and public employees assess teamwork better than nonprofit team members. This may be due to the higher level of professionalization of commercial and public entities and the development of teamwork training which promotes the essence of teamwork.

Our findings also flagged certain differences regarding collective work engagement between employees of public, for-profit and nonprofit organizations. Using the Collective Work Engagement Scale, it was found, among others, that public team members, compared to the other two, assessed all three dimensions of collective work engagement the lowest. For-profit and nonprofit members rated collective vigor higher than those representing public entities. Nonprofit employees assessed collective dedication higher than those employed in for-profits or publics. Additionally, for-profit workers rated collective absorption higher than employees of nonprofit or public entities.
Our results are partly consistent with the studies by other authors who have analyzed work engagement at individual level. Let us recall that Lyons et al. (2006) found individual for-profit employees to be more engaged than workers in the other two sectors. Similar findings were expressed in Goulet and

Frank (2002; cf. Benevene et al., 2011) where the highest engagement was observed among commercial employees, followed by nonprofit employees and only then public-sector workers.

Attention should be paid to the differences between the cognitive and affective-motivational aspects of teamwork approach adopted by employees representing each type of organization. This is best exemplified by public employees who appreciate teamwork but consider themselves part of the least engaged teams. The opposite is true for nonprofit workers. Perhaps the reason for this is the differences at individual-team level. In the case of cognitive teamwork assessment, employees shared a personal view, while team engagement was assessed in relation to group behavior. Knowing this, the differences could be explained by the impact of the context, e.g. organizational culture. Nonprofits are by default community-driven and collectivist, which is why they have a significant ability to build strong commitment towards teamwork, although their employees may have different views on its essence.

Lastly, let us recognize some limitations of our research. They study concerned Polish organizations, meaning it was implemented in a specific cultural context that should be borne in mind when formulating conclusions. Also, sample selection was purposive and therefore sensitive to generalizations. It might be worth recommending further research, both quantitative and qualitative, to better understand the subject at issue. These new studies should be in-depth and rely on techniques requiring direct contact, interviews, observation, case study, etc.

---

[1] As at 20.03.2020.
[2] Publications that have been peer-reviewed.
[3] In the literature we find various teamwork theories and models, e.g. sociotechnical theory (Kolodny and Kiggundu, 1980), group processes and productivity theory (Steiner, 1972) or input – process–output models (Gladstein, 1984; Hackman and Morris, 1975).
[4] According to Vidal (2007), teamwork has no significant general effect one way or the other.
[5] A comparative teamwork study was also carried out e.g. in the context of differences between: people exercising different professions in the same country (Li, 2013; Asio and Cross, 2015), employees representing the same industry but working in different countries (Wergin, 2003), employees of different professions in different countries (O'Connor et al., 2012), managers working in different countries (Beckmann, 1995).
[6] Random selection was abandoned because it was impossible to determine the number of organizational teams in the studied area. Results therefore cannot be generalized to the entire population.
[7] The null hypothesis (about uniform distribution) is rejected when H value is larger than the Chi^2 distribution (Ostertagová et al., 2014; cf. Jóźwiak and Podgórski, 2012).
[8] Work engagement has been described as 'a positive, fulfilling, work-related state of mind that is characterized by vigor, dedication, and absorption' (Schaufeli et al., 2002).

Abstract

Entrepreneurship, a complex and interdisciplinary concept, is difficult to define unambiguously. Entrepreneurial activity perceived as a process consists of successive stages that involve the establishment of a company and its development as well as stabilisation and cessation of its operation. A deeper insight into the nature of the entrepreneurial process is provided by the GEM approach, which studies people, not companies. The aim of the study is to analyse the level of entrepreneurship in Polish society compared to the average of European countries included in the GEM study. The article defines the level of entrepreneurship on the basis of indicators measuring the participation of adults involved in business activity, starting from taking the first steps to set up a firm, through running it, and finally withdrawing from business. In order to understand the essence of entrepreneurship, the motives for starting a business are also analysed, as motivation is an important factor that determines the future of business ventures.

Keywords: Entrepreneurship, Global Entrepreneurship Monitor - GEM, Poland

Introduction

An important factor of the socio-economic life is entrepreneurship which, for many years, has been the focus of interest of a number of environments proposing its various definitions. The lack of a single consistent definition of entrepreneurship causes that it is not presented explicitly but in a descriptive way, most often with the emphasis on the economic dimension. The indicators created on the basis of the above most frequently relate to setting up a business activity, enterprises of the SME sector or personal characteristics of the entrepreneur

The aim of the article is to assess the entrepreneurial activity in Poland by indicating the percentage of people at particular stages of the entrepreneurial process and specifying the motives that guide people when deciding to set up their own business. The article uses the GEM indicators that reflect four forms of entrepreneurship depending on the stage of development of companies, with particular emphasis on the TEA and measures indicating the reasons why people engage in business activity. For a better understanding of Polish entrepreneurship, the analysed data for the years 2014-2018 are compared to the average for the European countries studied.

Literature Review

Entrepreneurship is a complex phenomenon that involves a great variety of contexts and factors. It can be examined in a broad and narrow perspective. In the first case, entrepreneurship is seen as a process of planning, organising and running a business, as well as taking the associated risk by people called entrepreneurs (Griffin, 2007). Therefore, the meaning of entrepreneurship assumes that everyone who establishes and runs a business is an entrepreneur. In the narrow sense, however, entrepreneurship is the ability to take advantage of arising chances and opportunities to implement projects in the economic

field (Bifulco *et al.*, 2011). This applies to all new ventures undertaken by both newly established and existing companies in the face of certain opportunities and circumstances (Bratnicki, 2011).

According to S. Shane and S. Venkataraman (2000), entrepreneurship includes all activities that consist of identifying, assessing and exploiting opportunities to introduce new products and new services as well as ways of organising, new markets and raw materials. This perception of entrepreneurship is based on the following assumptions (Shane, 2003):

- entrepreneurship requires the existence of market opportunities which, through their objective elements, do not exist only in the consciousness of entrepreneurs;
- Entrepreneurship presupposes that there are differences between people and thus diverse perceptions of emerging opportunities;
- Risk-taking is an integral part of the entrepreneurial process, as market opportunities are usually uncertain;
- The entrepreneurial process requires creating new combinations of resources and introducing innovations that are not necessarily ground-breaking.

The essence of entrepreneurship lies in initiating projects as well as new forms of activity that satisfy needs, generate profits and enable reproduction and development of entrepreneurship.

In the literature on the subject, the phenomenon of entrepreneurship is often presented in the attribute and process approaches (Makieła, 2013; Ropęga, 2016; Czaja, 2014). In the first case, entrepreneurship is perceived as a specific human attitude towards the surrounding world and people, expressed in a creative and active pursuit of improving existing states of affairs, in readiness to take new actions or expand previous ones in order to improve working conditions and quality of life (Wiatrak, 2003). In turn, the perception of entrepreneurship as a process means creating and shaping something new, a set of consecutive actions that have an effect on the market (Ropęga, 2016; Reynolds *et al.,2005*). Entrepreneurship as a process of transforming creative ideas into economically vital activities and implementing creative solutions remains one of the main challenges of management (Kuratko and Hodgetts, 2007). According to the process approach, entrepreneurship is defined as a process of setting up and running a business, which involves several steps. The first stage is based on identifying opportunities, risks and possibilities to operate on the market, while the second one is to develop a business plan and gather necessary resources. Establishing and managing an enterprise is the target and final component of the essence of entrepreneurship in the process approach.

Entrepreneurship can be analysed in both the short and long term. In the first case, it means taking actions aimed at adapting an organisation to the needs of its environment and offering products to meet those needs. In the second one, entrepreneurial activity consists in implementing innovations that determine economic development (Ropęga, 2016).

Nowadays, entrepreneurship is recognised as an element necessary to ensure lasting economic growth, which is a condition for continuous improvement of social welfare (Zięba, 2016; Bhuyan and Pathak, 2019; Horrington and Coduras, 2019). However, according to Baumol's typology of entrepreneurial activity, only one of the three categories – productive entrepreneurship – is valuable in terms of generating welfare (Baumol, 1990). Entrepreneurship is also believed to contribute to economic development because entrepreneurs create new businesses, and new businesses create jobs, intensify competition, and may even increase productivity through technological change (Bosma, 2013).

In the GEM reports used in this article, entrepreneurship is understood as a process in which individuals play a key role. This process encompasses all phases of a business venture's life cycle and all persons who are entrepreneurially active in each of them. Among them are people who have an idea and begin

to invest in creating their future business, those who run companies, and people who withdraw from business activity. However, particular emphasis is placed on the early stages of activity.

In the entrepreneurial process, the GEM uses three stages of development of business ventures. Based on the stage which an entrepreneur is at, he or she can be defined as a potential entrepreneur, nascent entrepreneur or an owner-manager of a mature company. Nascent entrepreneurs are people who are considering starting their own business, while taking some actions aimed at achieving this, and who have worked on organising a company for no longer than 3 months. It should be noted that many enterprises, usually due to a lack of readiness to operate on the market, do not pass the trial period and soon after registration or start-up, owners withdraw from business. A company is established and enters the introduction stage, and later the growth stage, at the moment when salaries for employees or owners have been paid for more than 3 months. Maturity and the ability to maintain a lasting presence on the market as well as further development are achieved by a firm after 42 months of operation. The first two groups of entrepreneurs form the TEA index, which allows forecasting the intensity of entrepreneurial activity in society by taking account of people who are at the stage of creating a new company.

Metothology

On the basis of the GEM reports for the years 2014-2018, the necessary information was selected in order to indicate the level of entrepreneurial orientation of Polish society, juxtaposed against European countries. Due to the vast amount of data included in GEM projects, the research refers to selected indicators of entrepreneurship included entrepreneurial activity and motivation for entrepreneurship. In the assessment of the level of entrepreneurial activity, all stages of the economic venture are taken into account, including the stage preceding the formal beginning of its implementation, i.e. taking first actions towards the establishment of the company. In the GEM study, the focus of attention is, however, the early stages of activity. People involved in setting up a business and managing the company operating for no longer than 3.5 years (the period considered as critical for entrepreneurial activity, the survival of which is the evidence of success) create the key TEA indicator. The last issue discussed in the article is motivation for involvement in a business activity, which translates into the future development of the specific economy.

This study is mainly descriptive hence the statistical methods applied include descriptive tables and graphs plus a set of principal component analyses that provide additional information and details to obtain more accurate interpretations on some specific results.

Results

In the GEM study, which is the basis for measuring the level of entrepreneurship in Poland in this article, the entrepreneurial process involves several consecutive phases, from recognising business opportunities, through running a company, to withdrawing from this activity. The adopted division of the entrepreneurial process into individual stages enables a comprehensive view on the issues related to creating new firms.

Taking into consideration the data presented in Figure 1, it can be noticed that in Poland, in the first two years of the research period, the TEA index and its components were at the same level. In 2015, only the share of people running mature enterprises decreased, and its value of less than 6% was the lowest one in the analysed years. Nevertheless, from 2016 onwards, the values of individual indicators were not as stable. In 2016, the proportion of people at the stage of setting up a company decreased by almost 1 percentage point, with a simultaneous increase in new enterprises. These changes had a positive impact on the TEA index, which in 2016 amounted to 10.7%, thus reaching the highest value in the analysed period as a whole. The improvement observed on the labour market resulted in the fact that a number of already employed people did not decide to launch a much riskier business venture. In 2017, however, the elements constituting the key indicator in the study, including people running young companies, were completely different than in the previous year, i.e. the share of people willing to take

a risk and set up their own business increased by almost 2 percentage points, while the share of people running companies for no longer than 3.5 years decreased threefold. Unfortunately, these changes resulted in a decrease in the TEA index by almost 2 percentage points. The downward trend continued until the end of the analysed period, while both the share of people at the stage of organising their own business ventures and companies present on the market for anywhere between 3 and 42 months decreased in 2018. Due to another decline in the last year of the analysis, only 1 in 100 Poles ran a new company. However, the TEA index fell to the lowest level in the history of the GEM study in Poland and amounted to just over 5%. On the other hand, starting in 2015, the percentage of people running a company for more than 3.5 years had been systematically increasing, as a result of which the proportion of mature companies in 2018 was as high as 13%. It is worth noting that the greater the economic development of a country, the higher the share of mature enterprises in the structure of economic entities. The growing share of this type of companies was undoubtedly an effect of the improvement of the competitiveness of the Polish economy, where companies with a strong enough position were able to stay on the market. On the other hand, however, the level of competition was already so high that it constituted a significant barrier to entry for new business entities. Furthermore, in the period of low unemployment, which amounted to 5.8% at the end of 2018 in Poland, due to the high availability of wage labour, the interest in setting up a business declined. A favourable situation on the labour market increases the sense of employment stability, due to which the number of people willing to risk running their own business decreases.

Fig. 1: The level of entrepreneurial activity in Poland in the years 2014-2018 – setting up and running companies

Throughout the analysed period, the number of male entrepreneurs was bigger than of female ones, but the share of women was steadily increasing. While in the first years of the study there were twice as many male entrepreneurs than female ones, in 2018 the difference decreased to just 1.5%.

Table 1: The level of entrepreneurial activity in Poland in comparison with the average for the examined European countries in the years 2014-2018

Phases and types of entrepreneurial activity	Poland					Europe average				
	2014	2015	2016	2017	2018	2014	2015	2016	2017	2018
Nascent entrepreneurship rate	5,8	5,7	4,6	6,7	4,1	4,8	4,8	5,2	5,1	6
New business ownership rate	3,6	3,5	6,1	2,2	1,1	3,2	3,1	3,4	3,1	4,3
Early-stage entrepreneurial activity (TEA)	9,2	9,2	10,7	8,9	5,2	7,8	7,8	8,4	8,1	10,1
Established business ownership rate	7,3	5,9	7,1	9,8	13	6,7	6,6	6,9	7	6,9

Comparing the data for Poland with the average for European countries examined in the GEM project shows that each year the involvement of Poles in their own business was slightly higher. In Poland, the lowest level of entrepreneurship was recorded in 2015 and the highest in 2017, with respective values of 15.1% and 18.7%. In European countries, on the other hand, the share of people running companies ranged from 14.5% in the first two years to 17% in the last analysed year. In the years 2014-2016 in Poland, far more people ran young companies, i.e. those with a life span no longer than 42 months. Nonetheless, in 2017-2018 this relationship was reversed, and mature companies became the dominant group, whose share exceeded the TEA index 2.5 times in the last year analysed. This means that there were more than 2 owners of mature companies per 1 person running a young company. In European economies, the share of people starting and running new businesses was generally higher than the share of people running companies for more than 3.5 years, as about 6.8% were owners of mature enterprises, and the share of people forming the TEA index was between 7.8% and 10%.

Fig. 2: Discontinuance of business activity in Poland in the years 2014-2018

The constantly changing operating conditions mean that not all companies are able to continue functioning on the market. Therefore, an important measure of the condition of entrepreneurship in a

given country is the indicator reflecting the number of people who have withdrawn from business in the last 12 months. Too much omission may indicate a low level of preparation for starting an enterprise, its improper management or an extremely strong impact of market distortions. In turn, too low a value of this indicator may suggest poor dynamics of the economic system, which maintains an inefficient business structure, e.g. due to complicated exit regulations or state tax policy. Sometimes it can even mean excessive caution in society and thus loss of opportunities as a result of a lack of risk-taking. It is therefore important to consider not only exit indicators, but also how they relate to people's involvement in running their own business.

In Poland, there was a favourable trend in terms of the business discontinuance rate. Considering the extreme years in the research period, there was a decrease in the number of people who withdrew from business, because in the first analysed year the indicator was at the level of 4.2 (the highest value), while in the last year it amounted to 2.4. The changes that had taken place made it possible to come closer to the level recorded in Europe (the average of 2.8%), and in the years 2017-2018 the value for Poland was even better than the average for the European countries studied. In turn, when comparing the discontinuance rate to the level of entrepreneurship, it can be stated that a higher business exit rate in Poland than in Europe, noticeable until 2017, was adequate for countries with a large percentage of people setting up businesses. It should be noted, however, that as time passed, fewer and fewer Polish company owners closed their own businesses, which may indicate better preparation for the role of an entrepreneur who not only properly perceives emerging opportunities, but also accurately assesses his or her own abilities. What is more, the growing share of mature companies indicates faster adaptation to changes taking place in the environment of a business entity, conquering new markets, and thus gaining a competitive advantage and strengthening one's position.

Table 2: Discontinuance of business in Poland in comparison with the average for the examined European countries in the years 2014-2018

		Poland	**Europe average**
2014	Discontinuation with enterprise close	2,9	1,7
	Discontuination - enterprise remains on the market	1,3	0,9
	Discontinuation of businesses	4,2	2,6
2015	Discontinuation with enterprise close	2,1	1,8
	Discontuination - enterprise remains on the market	0,6	0,8
	Discontinuation of businesses	2,7	2,6
2016	Discontinuation with enterprise close	3,1	2
	Discontuination - enterprise remains on the market	0,7	0,8
	Discontinuation of businesses	3,8	2,8
2017	Discontinuation with enterprise close	2,1	2
	Discontuination - enterprise remains on the market	0,8	1
	Discontinuation of businesses	2,9	3
2018	Discontinuation with enterprise close	1,4	1,9
	Discontuination - enterprise remains on the market	1	0,9
	Discontinuation of businesses	2,4	2,8

It is worth emphasising that an entrepreneur's withdrawal from business does not always mean that his or her company ceases to exist. However, as the chart shows, both in Poland and in other European countries, there were definitely more people who, by discontinuing their business activity, closed their companies than those who withdrew from business personally but allowed their companies to stay on the market. Nevertheless, the situation in Poland in this respect definitely improved.

There are numerous and various reasons for discontinuing business activity. Entrepreneurs close their businesses for a number of reasons that can be seen as either positive or negative. On the one hand, it may be a desire to take advantage of a sales opportunity, an appearance of an attractive job offer, or other opportunities elsewhere, or simply planned retirement. On the other hand, discontinuation of activity may be caused by a lack of profitability, problems with access to external financing, tax burden, and sometimes a changing personal situation.

In Poland, the invariably dominant reason for abandoning a business was a luck of profitability. An appearance of another job or business opportunity as well as all kinds of family or personal matters preventing further business activity were equally important. It should be noted, however, that over the analysed years the importance of these factors was decreasing. What is interesting, in 2017-2018 the number of people who withdrew from business due to retirement increased (from 1.7% in 2016 to 9.5% in the last year of the analysis).

The reasons for which people decide to set up and conduct a business activity are necessary for understanding the nature of entrepreneurship of the specific country. The willingness to grasp a chance (an emerging opportunity) has other implications than the establishment of own company out of necessity, most frequently in the absence of earning alternatives. The basis for the identification of positive motivation is the assumption that starting a business is the result of the conscious choice of a better alternative, preceded by an internal impulse. An emerging opportunity for a successful venture in the environment, noticed by a potential entrepreneur, is important in here. The other type – negative motivation – is based on the assumption that a higher level of unemployment remaining for a longer period of time or a risk of losing a job stimulates the desire for self-employment by starting a business activity. Then, creating a company is the reaction to a socially difficult situation or little chances in the labor market. Unfortunately, entrepreneurship out of necessity does not bring effects as good as entrepreneurship undertaken out of desire to grasp a chance, it is characterized by a lower survival rate and a lower growth potential. Strong impact of factors which enforce entrepreneurial behavior is highly responsible for often a low quality of business ventures. This may result in poorer translation of TEA into the number of mature companies in the future and also impede the creation of jobs and value added by the established companies.

Fig. 3: The structure of motivations to start a business in Poland in the years 2014-2018 (% TEA)

The data presented in the figure 3 show that in the analysed period the motivation of Poles to set up and run a business significantly improved. Although each year the main motive for starting one's own business was the desire to take advantage of the opportunities related to running a company, 27-37% of the society started a business out of necessity in the years 2014-2016. As a result of the improvement on the labour market and systematic growth in 2017, only 1 in 7 positively motivated Poles who, due to the lack of an alternative, was somehow forced to start his or her own business. In the last analysed year, this favourable trend slowed down, as slightly more than 8% of people started a company due to

the lack of job opportunities. However, little more than half of Polish society decided to set up a business as a result of seeing it as an opportunity to increase income and gain independence. The favourable situation on the labour market once again influenced the entrepreneurial activity of Poles, and the visible strengthening of positive motivation almost each year was undoubtedly due to seeing a chance for individual development in their own businesses, while fewer people were forced to do so because of the availability of other jobs.

Table 3: The structure of motivations to start a business in Poland in comparison with the average for the examined European countries in the years 2014-2018 (% TEA)

		Poland	Europe average
2014	Necessity-driven	36,8	22,8
	Improvement-driven opportunity	47,1	47,9
2015	Necessity-driven	28,1	22,4
	Improvement-driven opportunity	46,4	47,5
2016	Necessity-driven	26,6	20,9
	Improvement-driven opportunity	52	51,1
2017	Necessity-driven	9	19,7
	Improvement-driven opportunity	67,6	50,3
2018	Necessity-driven	8,4	18,1
	Improvement-driven opportunity	55,1	47,6

In Europe, especially in the first analysed year, significantly fewer people decided to start their own business out of necessity. However, the changes that occurred within the motivational structure of Polish society meant that from 2017, twice as many Europeans as Poles decided to take this step because they could not find employment. On the other hand, the share of people running young companies from the need to take advantage of the opportunity to improve the standard of living was at a similar level both in Poland and in Europe, oscillating around 50% (only in 2017 the share of Poles motivated positively was higher by 18%).

Conclusions

Entrepreneurship is often associated with an effective way of thinking and acting, with the intention of making independent economic decisions, and with the ability to act rationally and achieve measurable market benefits in the form of profit. In the process approach, the essence of entrepreneurship lies in establishing and managing an enterprise. The research conducted shows that in the analysed period of time the share of people involved in entrepreneurship increased both in Poland and in Europe, while the involvement of Poles was slightly greater each time. Until 2016, entrepreneurship in Poland could be described as young, because with a similar level of mature enterprises in Poland and Europe (about 7%), there were more people setting up and running their businesses for no longer than 3.5 years in Polish society. In the years 2014-2017, the key indicator for young companies in the GEM – the TEA index, oscillated around 8% in Europe and 9% in Poland, with the exception of 2016 when it reached its highest level of 10.7%. In the last year covered by the study, the index of young companies in European countries increased to 10%, while in Poland the situation changed dramatically, as the TEA level declined with a simultaneous increase in the share of mature companies. As a result of these changes, for every 5 people running young companies there were 13 owners of companies operating for more than 42 months. In Europe, however, the share of people running companies for no longer than 3.5 years was twice as high and in terms of mature ones almost twice as low (less than 7%). The increase in the share of mature companies in Poland was undoubtedly influenced by the fact that far more people set up their businesses in order to seize the opportunity, not out of necessity, which would mean inability to find a job. It is also worth mentioning that Poland experienced favourable changes

related to the discontinuance rate, as its level not only decreased and oscillated around the average for the analysed European countries, but also fewer and fewer people closed their companies after withdrawing from business, and instead left their enterprises in the hands of other owners.

Although some actions and conditions may ensure greater success when setting up a company, it should be kept in mind that there are a number of uncontrollable factors that pose a risk of failure. However, a potential entrepreneur must be willing to take a risk in order to have a chance to succeed.

Abstract

At the current stage of economic development in Russia, against the background of the recent dramatic changes in industries in many countries that were traditionally owned and controlled by the government before, the government is trying to actively use new opportunities to solve strategically important tasks. One of the effective options for solving the tasks becomes the mechanism of attracting private capital through public private partnership. The article is devoted to the substantiation of the application of the mathematical apparatus of the theory of classical cooperative games to the distinguished tasks of public-private partnership management. The authors also proposed the construction of a game-theoretic mathematical model based on PPPs and developed specific concepts of solutions based on the theory of cooperative games, which allow analyzing PPP projects from the point of view of partnership management by state bodies.

Keywords: Public Private Partnership; Cooperative Game Theory; Game-Theoretic Mathematical Model

Introduction

In Russia, the objects called strategically important for the country cannot be privatized. However, often the funds allocated for the development of such enterprises in the state budget are not enough, and development is suspended until new funds are allocated (Bataevet al (2018); Ahmed and Ali (2006); Demidenko et al (2018); Kaza et al (2018); Kudryavtseva et al (2018)).

As is known, in order to resolve such a contradiction, the mechanism of state private partnership is used in world economic practice. In its general form, PPP combines state resources with their ownership potential, and the resources of private investors with sufficient funds to implement the necessary projects. Note that private business can also contribute its managerial experience and skills, in addition to financial resources, as a share of its contribution to the investment ((Bataevet al (2018); Kuznetsov et (2017); Demidenko et al (2018); Kudryavtseva et al (2018); Lebedev et al (2018); Rodionov and Rudskaia (2018); Rodionov et al (2018); Rodionov et al (2018); Rudskaia and Rodionov (2018)). Each such project is unique, and joint actions of the state and business aimed at its implementation are fixed in the contract for a period equal to the deadline for the implementation of a

specific project. Projects of this kind are usually carried out in various sectors of the economy: from R&D and industry, to the provision of public services. ((Shabunina et al (2018); .Bataevet al (2018); Kudryavtseva et al (2018); Lebedev et al (2018); Rodionov et al (2018); Rudskaia and Rodionov (2018)).

For maximum efficiency of interaction between the state and the private sector, it is necessary to ensure the profitability of joint actions (cooperation) for both the state and private investors. An interesting question is how the composition of the concession participants will be formed, and who is more interested in the implementation of certain PPP projects. Therefore, in this article we will try to answer this question using the mathematical apparatus of the theory of cooperative games.

Literature Review

It is known that the state's need for investment significantly exceeds the possibilities state budget. According to expert data, it amounts to about 300 billion dollars for the period until 2010 ((Dermine, J. (2017); Shabunina et al (2018); Dietz et al (2016); Kudryavtseva et al (2018); Lebedev et al (2018); Rodionov et al (2018); Rudskaia and Rodionov (2018)).

In Russia, in the past ten years, state-owned infrastructure facilities have not been developing or updating. According to the development plan of Russia in 2008-2010, developed by the Ministry of Economic Development and Trade, the pricing environment for products in the fuel and energy and raw materials markets, through the export of which the bulk of the state budget is replenished, can also change in the direction unfavorable for Russia (Evdokimova et al (2019); Kaza et al (2018); Kuznetsov et al (2017); Lorrain and Stoker (1997); Matveev . (2007); Moulin E. (2011)).

With a negative development of events, the presence of contracts for the implementation of projects with private business will positively affect the further development of the economy.

In this case, the state attracts private resources for the implementation of critical strategic projects, effectively manages the infrastructure, improves the quality of services provided and stimulates innovation. It should be noted that the state shares the risks of the projects with investors, in addition, PPP projects are selected so that they have the maximum return on invested capital (Morkovina et al (2015); Morkovina et al (2013); Nabukeera (2016); Pechersky and Belyaev A.A. (2001); Pichtel et al (2014)).

.

The current stage of development of the Russian economy is characterized by favorable conditions for large-scale and long-term investment in infrastructure, which is especially important in a crisis economy, when a number of projects that bring "quick" profit become highly risky or impossible due to lack of liquidity among investors. To ensure guarantees for the return of private sector investment and to support PPPs, the state has created the following institutions:

1. Investment Fund of the Russian Federation: at the beginning of 2008, accumulated funding amounted to 9.7 billion dollars, the planned volume of investment funds for 2009 was 3.6 billion dollars, however, due to the crisis, it is planned to reduce it to 2.1 billion $ (Pichtel, J., (2014), Varnavsky V.G. (2015).
2. The Federal Agency for the Management of Special Economic Zones, whose budget is about 700 million pounds (Rodionov and Rudskaia, I. (2018); Rodionov et al (2018); Rodionov et al (2018); Rudskaia and Rodionov (2018));
3. Special Development Bank, its capitalization totals about 3 billion pounds (Rodionov and Rudskaia, I. (2018); Rodionov et al (2018); Rodionov et al (2018).

It is through the funds accumulated in these institutions that the state is going to fulfill part of its financial obligations for the implementation of PPP projects in the sectors of the Russian economy.
The Investment Fund of the Russian Federation was created in accordance with the decree of the Government of the Russian Federation of November 23, 2005. No. 694 "On the Russian Investment Fund Federation " (Rüßmann et al (2015); Solovieva M.Yu. (2019); Sosnova S. (2017).

According to this decision, the RF IF is formed from the following sources: the estimated difference between the federal budget revenues forming the Stabilization Fund at the base price for crude oil of the Urals brand and the base price of crude oil of the Urals brand reduced by 1 US dollar per barrel; projected reduction in government external service costs debt of the Russian Federation with early repayment of this debt.

The mission of the Investment Fund is to act as a catalyst for attracting private business funds, it can invest up to 75% of the total project costs in the capital of companies or provide a guarantee of 60% of the funds received from the private sector to finance the project. In order for the project to qualify for receiving funds from the fund, it must satisfy the investment criteria of the Ministry of Regional Development, including a business plan that demonstrates the economic viability of the project.

More than 50 applications for projects that are eligible for financing from the RF IF funds were submitted for consideration as part of the selection of investment projects. (Schmidt et al (2015);. Varnavsky V.G. (2015)).

Among the projects reviewed, 23 investment projects relate to the transport industry, 7 projects to the energy sector, 9 projects from the industrial sector, another 6 to housing and communal services, 3 projects are aimed at the development of agriculture, five projects are other sectors of the economy (Schmidt et al (2015);. Varnavsky V.G. (2015); Rodionov et al (2018); Rodionov et al (2018)).
.
It is not surprising that a sufficient number of projects, the implementation of which will be used PPP mechanism refers to the improvement of transport infrastructure.

According to VTsIOM data, 1.5 times more gasoline is required on Russian roads than in developed countries. In addition, the service life of cars is 30% less. The transport component in the cost of production in countries with good roads is 7% -8%, while in Russia this figure reaches 12% -15%. According to expert data, poor road conditions can lead to economic losses of up to 5.5% of GDP Shabunina et al (2018); Dietz et al (2016); Kudryavtseva et al (2018); Lebedev et al (2018); Rodionov et al (2018); Rudskaia and Rodionov (2018)).

We also note that the construction of highways stimulates the development of various areas of business, such as trade, food, light industry, and services.

By 2025, it is planned to build and reconstruct about 8 thousand kilometers of federal highways in Russia, about 13 trillion rubles will be spent on transport infrastructure, this amount is included in the federal target program “Development of the Russian transport system for 2010-2025” (Lebedev et al (2018); Rodionov et al (2018); Rudskaia and Rodionov (2018)).

Since PPP projects are long-term, in this case there are significant problems with attracting financing in the necessary volume and for the right term. Standard & Poor's assesses the prospects for the development of relationships between partners and analyzes the risks that may arise. Also in the near future, she intends to develop a rating of Russian PPP projects that will enter the stage of implementation and organization of financing. In the future, this will contribute to expanding the financing tools for projects implemented under the PPP framework. It is clear that the main problem of PPPs is that the concession agreements may last decades before the final sale of the facility, while for banks lending for more than 15 years is associated with significant risks associated mainly with the borrower (Lebedev et al (2018); Rodionov et al (2018); Rudskaia and Rodionov (2018)).

In this case, if the project is assigned a high rating by a well-known agency, this will increase the confidence of interested investors. Then, even if for some reason the state does not fulfill or defer the fulfillment of part of its financing obligations, with the help of funds already raised, the projects will still be able to be completed. At this stage of the development of partnerships in Russia, it is time to move from the question of whether public-private partnership in the country is possible to practical application PPP mechanism and tools for implementing large investment projects, with a discussion of the terms of their payback, profitability. At the same time, experience shows that it will take a lot

of time to create a really working mechanism that allows solving complex strategically important tasks for the state.

An analysis of the formation of partnerships in the UK shows that the creation of PPP took more than two decades, and currently there is further improvement and development of new models of PPP.

Research Methodology

If in the overwhelming majority of works devoted to the mathematical aspects of the theory of cooperative games, the characteristic function is considered to be initially known, then in applied economic and mathematical studies the complex of problems associated with the methods of its construction acquires fundamental significance.

As is known (Moulin E. (2011); Moulin E. (2011); Owen G. (2008)), one of the most widely used methods for constructing the characteristic function of a cooperative game with transferable utilities is based on finding its values as the results of solving auxiliary non-cooperative games. Namely, each of the potential coalitions of players $S \subset I$ has "rational" reasons to evaluate its utility (or, in other words, the utility that it has reason to rely on in the event of its actual formation) as the price of a coalition-free antagonistic game G with two "integrated" participants: S and I \ S, uniting individual participants ($i \in I$).

Many of the strategies for these integrated players are defined as

$$Z_S = \Pi_{i \in S} Z_i \text{ and } Z_{i/S} = \Pi_{i \in I/S} Z_i,$$

and utility (wins) in some situation z as

$$U_S(z) = \sum_{i \in S} u_t(z) = -U_{i/S}(z),$$

where u_t are the individual utilities of the players (before the formation of coalitions).

Accordingly, the value of the characteristic function for the coalition S is found as

$$v(\{S\}) = U_S(z^*) = \sum_{i \in S} u_t(z^*) = -U_{I/S}(z^*),$$

where z^* is the equilibrium (solution) in the game S, against I \ S.

In the case of a game-theoretic model of public-private partnership, the described approach, with rare exceptions, turns out to be unproductive. This is primarily due to the fact that precedents for the emergence of "anti-coalitions" I \ S for any coalitions S are uncharacteristic. Moreover, the hypothesis that the interests of a possible coalition S and other participants are directly opposed is extremely unlikely. Thus, we conclude that when constructing PPP models, the task of constructing a characteristic function can be solved solely on the basis of an analysis of individual financial and economic characteristics of separately considered projects. Attempts to construct "universal" recommendations, as a rule, lead to inadequate solutions that objectively do not allow us to reflect the real points of contact and disagreement of the interests of potential participants in partner associations.

The task of constructing a characteristic function in the context of a cooperative game-theoretic model of PPP breaks down into two principal stages: determination of the financial and economic indicator laid down in the base for measuring the characteristic function; construction and verification of methods for calculating the values of the characteristic function for all kinds of (potential) participants in a public-private partnership.

As a basis for measuring the characteristic function, various financial and economic indicators can be proposed. In the general case, one can take the proceeds obtained from the results of the project, if there is some specifically designated level of revenue when concluding a concession agreement, which is unlikely in a significant number of cases. This is mainly due to the fact that PPP projects, being long-term, often over 30 years old, will generate income from some year of the project until its completion, and then the project will generate operating income. Thus, in general, it is possible to calculate the forecast value of income using the net present value method (NPV).

Imagine that it will take $(t=\overline{1,T})$ years to implement the project, and the cash flow for the project in the t-th year will be CF_t, the profitability for the project is i, the growth rate is g, in this case the net present value for the project will be as:

$$NPV=\sum_{t=1}^{T}\frac{CF_t}{(1+i)^t}+\frac{CF_{t+1}}{(i-g)(1+i)^T}.$$

The net current discount found in a similar way, discounted by years of the project, could act as the value of the characteristic function.

However, if the profitability required by investors can be calculated on the basis of the CAPM model, then the data on the cash flow of PPP projects are mainly confidential information. Thus, it turns out to be rather difficult to use this indicator, mainly due to the lack of data for its calculation.

On the other hand, you can take the indicator of income that will be obtained during the operation of the object obtained as a result of the project. For example, it may be rental payments received by companies participating in the project. Such an indicator can be calculated if there is information relating to the statistical and predictive. In particular, on the road construction project, such information will be: the number of cars traveling on this road per day, and the estimated fare for each type of car. However, we note that the use of such an indicator is not entirely justified, since it will not take into account income received before the start of operation of the construction project. However, this approach does not have an important disadvantage of a lack of information for its calculation. You can also use the indicator of net undiscounted income, in which case you should also take into account such an economic parameter as expected return. It is advisable to do this when it is possible to conduct a comparative analysis of a number of projects in order to determine some indicator that allows in future to calculate the total undiscounted income. This approach is quite adequate and makes it possible to overcome the inaccessibility of information on project parameters.

Suppose that the participation of an investor in a project in the simplest case will be completely determined by the benefit expressed in monetary form, which he will receive from investing his funds in it. The project income will be an estimate of the net total undiscounted income, since, as previously indicated, the real data on project income is in most cases confidential information. To overcome this problem, a comparative analysis of projects carried out in St. Petersburg was carried out. In this regard, the values of capital costs and undiscounted net total income were studied for a number of similar projects, taking into account the criteria for the payback period and the level of profitability of the investor's own funds. The project average ratio of undiscounted net total income to capital costs was determined: $\text{average}\left(\frac{NDTNI_j}{CAPEX_j}\right)\approx 1{,}8$.

This value was used to obtain an adequate estimate of the undiscounted net total income for the projects under the PPP model (Kudryavtseva et al (2018); Lebedev et al (2018); Rodionov et al (2018); Rudskaia and Rodionov (2018)). The approach described above seems to be the most preferable option for calculating the values of the characteristic function, since it can be used for most of the ongoing projects.

Let us present the calculation procedure in a general form. So, investors are forced to unite in a coalition for the implementation of the project, this coalition according to the results of the project receives a certain amount of money. The values of the characteristic function will be found by grouping agents by different coalitions.

In the game-theoretic model, in addition to many participants, there are also l many projects $(l \in L)$.

Each project proposed for implementation will be characterized with c_l capital expenditures (CarEx) and a calculated estimate of the net undiscounted total income p_l that it will bring to investors.

In turn, investors will have a certain amount of money to invest in projects, $D = \{d_1, d_2, ..., d_n\}$.

The value of the characteristic function will be an estimate of the net undiscounted total income of the coalition from its projects. Moreover, we note that a situation may arise when coalitions will be profitable to invest financial resources in several projects simultaneously $(L = 2^L)$.

In this case, the value of the characteristic function for this coalition will correspond to the income received from the joint implementation of these projects. Then she will receive a greater total income than if she invested money in only one project, which would bring more profit than others.

However, with the simultaneous execution of projects, the coalition's gain will be greater.

Thus, the characteristic function in such a cooperative game based on the PPP model has the following form:

$$v(S) = \max_{L' \in 2^L, \sum_{i \in S} d_i \geq \sum_{i \in L} c_i} \left\{ \sum_{I \in L} p_I \right\}.$$

The characteristic function of the coalition S is equal to the sum of the estimates of the net undiscounted total income for those projects (d) for the implementation of which the corresponding coalition has a sufficient amount of initial funds (starting capital), i.e.

$$\sum_{i \in S} d_i \geq \sum_{i \in L} c_i .$$

We give an example of the use of this general methodology and the calculation of the net undiscounted total income indicator for a cooperative game with three participants. The names of the projects and their main parameters necessary for further calculations are presented in the table one.

Table 1: Casual investment projects sample for Spain

Objects	Capital costs, mln. euro	Net total undiscounted income estimation, mln. euro
Burgos Hospital	275	495
Hospital General de Toledo	300	540
Autovia de Ademuz CV-35	200	360
Granada Light Railway	230	414

Source: www.infra-news.com

There are also three potential participants who possess funds in the amount indicated in table 2 (data on investment volumes were obtained by expert estimates (Kudryavtseva et al (2018); Lebedev et al (2018); Rodionov et al (2018); Rudskaia and Rodionov (2018)).

Table 2: Participants' investment means

№	Agents	Money means, mln. euro
1	Investor 1	185
2	Investor 2	170
3	Investor 3	155

Source: calculation on www.infra-news.com information base

In accordance with the methodology for the formation of the characteristic function, the first stage is that all possible coalitions are formed, and for each coalition of participants the amount of money that they jointly own is calculated. For this amount, players can implement a subset of projects (see table. 3).

Table 3: Coalitions money means

Coalitions variants	Money means, mln. euro
{}	0
{1,}	185
{2,}	170
{1, 2,}	355
{3,}	155
{1, 3,}	340
{2, 3,}	325
{1, 2, 3,}	510

Source: calculation data

Thus, a subset of projects is formed that can be acquired by coalition members. This can be either a single project or several projects, in accordance with the condition of sufficient funds to pay for the capital costs of the project. Consider an example for one coalition {1,2,3}. She has cash in the amount of 510 million euros. In this case, this coalition is suitable for all projects worth less than or equal to 510 million euros, as well as groups of projects whose capital expenditures also do not exceed the available amount of money. Thus, this coalition can implement either individual projects or a group of projects, which is more profitable. So the projects "Burgos Hospital" and "Granada Light Railway" require 505 million euros of investments, as a result of their implementation will bring the coalition 909 million euros of income, which will be the value of the characteristic function for the "full" coalition of participants. Hence, in this example, the characteristic function will have the following form (see table. 4).

Table 4: Characteristic Function Values

Coalitions	Win, mln. euro
{}	0
{1}	0
{2}	0
{1, 2}	540
{3}	0
{1,3}	540
{2,3}	540
{1,2,3}	909

Source Estimated Data

Now we will consider an example of a cooperative game based on a PPP model with five participants and demonstrate how a coalition can form a subset consisting of several projects, and not one as in the previous example (Table 5).

Table 5: Projects

Information on the number of PPP participants and the funds available to them is contained in the table. 6.

Table 6: Data on PPP participants

№	Agents	Money means, mln. euro
1	Investor 1	71
2	Investor 2	63
3	Investor 3	60
4	Investor 4	55
5	Investor 5	53

Source: calculation data

This example also takes data on the size of the proposed investment, based on expert estimates on the amount of invested investments.

Note that the projects are selected in such a way that when all participants are united in a coalition, their total amount of funds will not be enough to implement some of the presented in table. 5 projects. However, with increasing data on the size of investment funds, previously unrealized projects become available.

At this stage of the work, the lack of financial resources for investing in the creation of any object from the sample will not be of fundamental importance in the framework of the PPP model, since it does not affect the formation of the characteristic function of the game.

All kinds of coalitions with an indication of the amount of funds that investors of each such coalition are willing to invest in total are presented in Table. 7.

Table 7: Coalition cash

Варианты коалиций	Money means, mln. euro	Варианты коалиций	Денежные средства,
{}	0	{5,}	млн. евро

{1, 2, 4}	189,00	{1,2,4,5,}	171,00
{3, 4}	115,00	{3,4,5,}	242,00
{1, 3, 4}	186,00	{1,3,4,5,}	168,00
{2, 3, 4}	178,00	{2,3,4,5,}	239,00
{1, 2, 3, 4}	249,00	{1,2,3,4,5,}	231,00

Source: calculation data

Further, for each coalition, we form many projects that it can implement based on the criterion of cash sufficiency. Again, consider an example for a coalition of three members {2,3,5}. She is ready to invest 176 million euros in projects. In accordance with the methodology for constructing the characteristic function of such a coalition, projects and groups of projects are suitable for which the amount of capital costs does not exceed the amount of cash available to it. A selection of the possible for implementation by the considered association of participants in PPP projects that demonstrate the process of calculating the characteristic function values for a given coalition is presented in Table. 8. In this case, the coalition has a choice: either invest in the New Stadium in Lille project, or in the Alicante Tram and Chemnitz Court Buildings project group.

Table 8: An example of the formation of possible options for the acquisition of projects

Projects	Capital expenditures, million euro	NDTNI (Net total undiscounted income) estimation, mln. euro
New Stadium in Lille	170	306
Alicante Tram + Chemnitz Court Buildings	174	313

Source: calculation data

After the formation of many projects for each coalition, a project (group of projects) is selected that brings the greatest profit to the members of the association. Accordingly, the option with the highest indicator of undiscounted net total income by years of implementation is selected from the sequence of projects. It should be noted that for a coalition, it is not just the money and capital costs of the project that are compared, and then the project with the maximum profit value is selected, and options are considered when the coalition has enough funds for two or more projects.

In this case, the total profit of the group of projects and the value of the profit of other possible individual projects are compared. Further, from them, on the principle of maximizing profit, a project or group of projects with the highest value of this indicator is selected. This value of profit is

attributed to the value of the characteristic function for a given coalition. In the example we are considering for the {2,3,5} coalition, the highest value of the total gain is achieved with the implementation of two projects, Alicante Tram and Chemnitz Court Buildings, in which case the coalition's profit will be the largest and will amount to 313 million euros, unlike the others possible options for implementing projects. For all other coalitions, the values of the characteristic function can be seen in Table. 9, they are calculated in a similar way.

Table 9: Values of the characteristic function for a game with five participants

Coalition options	Money means, mln. euro	Coalition options	Money means, mln. euro
{}	0	{5,}	0
{1}	0	{1,5,}	180
{2}	0	{2, 5,}	180
{1, 2}	180	{1,2,5,}	326
{3}	0	{3,5,}	180
{1, 3}	180	{1,3,5,}	326
{2, 3}	180	{2,3,5,}	313
{1, 2, 3}	342	{ 1,2,3,5,}	439
{4}	0	{ 4, 5,}	180
{1, 4}	180	{1,4,5,}	320
{2, 4}	180	{ 2, 4, 5,}	306
{1, 2, 4}	326	{1,2,4,5,}	436
{3, 4}	180	{3,4,5,}	270
{1, 3, 4}	326	{1,3,4,5,}	403
{2, 3, 4}	320	{2,3,4,5,}	403
{1, 2, 3, 4}	439	{1,2,3,4,5,}	540

Source: calculation data

Such a calculation of the characteristic function in the game is logically justified, proceeding from the fact that its values should represent the maximum gain of the coalition of investors formed to participate in the project. Thus, with such a formation of the characteristic function, it is important to adequately determine the financial and economic indicator, based on all available information on the projects.

However, the characteristic function can have another form, for example, the set of its values can consist only of 1 and 0. Suppose that some system consisting of n divisions has the task of jointly performing a certain amount of work. The same volume can be fulfilled either by one "main" and any (one or several) of the remaining units, or all the rest together without a "main" unit. It is necessary to determine the "fair" share of each of the units.

We construct a formal model. Assign each unit of the system in question a serial number, designating the "main" unit with number "1", other units with numbers 2,3, etc. Let S be the coalition of divisions, and I the set of different coalitions. The characteristic function in this game will have a specific form, namely, it will take the values 1 or 0. The characteristic function will be representable as follows: 1 if the work is done, 0 if the work is not done:

$$v(S)=\begin{cases}1, S=\{1,2,\ldots,n\};\\ 1, \{1\}\cap S=\text{empty}, S\neq 1, S\subset I;\\ 0; \text{in other cases.}\end{cases}$$

Note that since a game in a (0-1) -reduced form is some normalization of a cooperative game with arbitrary values of the characteristic function, we can take into account the following point. The value of the characteristic function can be interpreted as a relative measure of the players' desire for cooperation. Thus, the smaller the corresponding value of the characteristic function (great interest in integration), the more opportunities for its implementation and, accordingly, for finding all kinds of divisions. And, on the contrary, the integration of "strong" players requires an accurate search for a compromise solution taking into account the needs of such participants. Moreover, a solution may exist, i.e. there will be a sufficient number of shares, and may not exist. The problem of the existence of a solution in a cooperative game is quite interesting, especially when considering and analyzing it from an economic point of view.

Limitation

Thus, an adequately constructed characteristic function corresponding to the problem being solved within the framework of the game-theoretic model of PPP allows one to draw correct conclusions regarding the modeled relations of the partnership participants. At the same time, the unclearly formulated goal of the problem under study can lead to the erroneous appearance of this function and the impossibility of its application for further analysis. We have listed the main tasks of managing such a complex object as a state private partnership. Their solution involves the use of an adequate mathematical apparatus of the cooperative theory of games. But also when implementing the mechanism of public-private partnerships, it is necessary to consider options for solving the problem of profit distribution. For these purposes, other methods and models of game theory are used.

Significance of Research

The game-theoretic cooperative model of PPP that we have built up opens up ample opportunities in terms of analyzing the patterns of partnerships, as well as the reasons that prevent their emergence.
This model can be considered as an auxiliary mechanism in solving basic problems from the point of view of classical approaches to solving cooperative games with transferable utility: forming a coalition consisting of the number of participants necessary for the implementation of the project; determination of the share of participation (amount of surcharge) for the state in PPP projects.

Abstract

The mechanism of state private partnership allows overcoming the limited opportunities of the state to implement social and infrastructure projects requiring the accumulation of significant financial resources. By combining with private business, the state can transfer to it some of the risks associated with investment facilities, and at the same time use the experience of the private sector in order to improve the quality of services provided and increase the efficiency of infrastructure management. The organization of PPP is a rather difficult task and depends on the correct assessment of the economic feasibility of projects and the degree of satisfaction of the partnership participants with the return on investment.

On the basis of an analytical review, the article obtained informative economic interpretations of the classic solutions of cooperative games with transferable utilities within the framework of the game-theoretic model of PPPs, which allow us to draw informative conclusions about the patterns of development of these relations in the current Russian economy.

Keywords: public private partnership; transferable utilities; game theory model

Introduction

At each stage of economic development, it is important to ensure its further sustainable functioning and increase the investment attractiveness of the business. To realize such tasks, significant investments are needed in the production infrastructure, in the development of industries such as energy, the oil and gas industry, transport, communications, roads. Sectors of the Russian economy are currently characterized by a fairly high degree of competition not only from Russian companies, but also from non-resident companies. Development and modernization of infrastructure is one of the most important tasks facing the state at present.

In the conditions of the modern Russian economy, public-private partnerships are becoming an increasingly effective way of solving both infrastructure tasks that fall under the state's responsibility and for carrying out entrepreneurial activities of private firms and companies. This is especially true in the light of fundamental changes initiated by the global financial crisis (Kudryavtseva et al (2019); Galimova et al (2019); Rudskaia and Rodionov, D. (2018); Borovkova et al (2019); Demidenko, et al (2018)); Lebedev et al (2018); Evdokimova et al (2018); Gasser et al (2017)). '

An important and significant direction of the study of the laws of development of relations between subjects of public private partnership is their analysis from the perspective of the distribution of income derived from the implementation of projects carried out by these partnerships. Considering PPP as some cooperative associations of various economic entities, we naturally come to the thesis about the effectiveness of using the theory of cooperative games for their mathematical modeling.

At the conceptual level, the game-theoretic cooperative model of private and state partnerships is based on a fairly simple and logically transparent scheme: the subjects participating in the partnership are players, the income received by them as a result of a joint project, acts as the values of the characteristic function of the game. (Demidenko et al (2018); Bataev et al (2018); Bataev et al (2018); Rudskaia and Rodionov, D. (2018); Kudryavtseva et al (2018); Rodionov and Rudskaia (2018)).

Literature Review

Based on the ideology of the game-theoretic cooperative model, we can distinguish two fundamental situations characteristic of PPP modeling procedures. (Demidenko et al (2018); Bataev et al (2018); Bataev et al (2018); Rudskaia and Rodionov, (2018); Solovieva (2019); Sosnova S. (2017)).

In the first case, partnerships are "formed" around a project representing objective economic interest for all potential participants who do not, however, have the ability to fully finance it.

Accordingly, the state acts as a source of additional financing and, of course, expects to receive its share of the subsequent income brought by the joint project. From the point of view of a cooperative game-theoretic model, the state in the described situation is fundamentally no different from the rest of the partnership and is formally included in many players. Conclusions regarding the share of state participation in models of this kind can be obtained, based on classic conceptual approaches (C-core, N-core and Shapley vector). (Pechersky and Belyaev, (2001); Matveev, (2007); Moulin (2011); Moulin E. (2011); Brusser et al (2007)).

At the same time, a qualitatively different situation is possible. It is characterized, on the one hand, by the objective interest of the state in the implementation of a large (usually socially significant project), which requires the accumulation of significant material resources of the project, and, on the other hand, by the relative disinterest of private investors in the formation of a coalition association capable of successfully completing this project .

From a formal point of view, this situation can be described as follows. By I we mean many players (investors) whose participation is objectively necessary for the successful implementation of a project in which the state is interested. For compact presentation, we will not consider situations in which a project is possible only with the participation of a subset of players. In addition, we note that this simplifying premise is not of a fundamental nature: abandonment of it will only lead to an increase in the "volume" of the model, but will not qualitatively change the conclusions obtained on the basis of the cooperative PPP model.

We will also consider that the utility (income, gain) value of the full coalition v (I) from the implementation of the project "desirable for the state" and the utility value of the sub-coalitions $S \subset 2^1$, obtained by them on some alternative projects are correlated in such a way that the game is balanced (i.e. the conditions of the Bondareva-Shapley theorem are not satisfied).

The emptiness of the C-core in the game, obtained on the basis of the cooperative PPP model, is just a mathematical reflection of the fact of the initial disinterest of private participants in an association capable of implementing a project that is desirable for the state.

Note that the motives that prompt the state to force the project under consideration are considered in this case as extra-model factors. For example, they can be determined at the previous stages of solving the process of developing an investment program. Such factors, as a rule, are caused by social functions performed by government bodies. Indeed, in a significant part of modern infrastructure projects (for example, the construction of a port in Ust-Luga, Western High-Speed Diameter), the initiative to form partnerships entirely belongs to the state side ((Demidenko et al (2018); Bataev et al (2018); Bataev et al (2018); Rudskaia and Rodionov, D. (2018); Kudryavtseva et al (2018)).

Speaking about the reasons that make local associations more attractive for private investors compared to joining a "big" project, it is necessary to pay attention to the negative role of the cost factor in the first role. A certain time elapses from the announcement of the concession tender to the identification of the winner, during which further refinement of the financial model can take place, where, among other parameters, the estimated costs are important.

In the process of establishing a winner in a concession tender, the estimated capital costs of the project can, generally speaking, increase, i.e. investors submit applications based on one amount of capital costs for the project, and as a result receive an adjusted amount of investments in excess of the initial capital costs. So, in the construction project of the Western High-Speed Diameter, the estimated volume of investments grew 2.5 times. Initially, when the concession tender was announced in 2016, it amounted to 84 billion rubles, and by 2008 it had grown to 212 billion rubles. Obviously, the very possibility of such "variations" becomes for the investor a strong argument in favor of the decision to refuse to participate in the project (Bataev et al (2018); Bataev et al (2018); Rudskaia and Rodionov, D. (2018); Kudryavtseva et al (2018) Pichtel (2014)).

Another factor causing the lack of interest of private investors in joining the "big" coalition is the instability of the modern stock market. Its impact is especially visible in situations of free circulation on the stock exchange of a special project company (SPK), created as part of a PPP project. A fall in stock prices inevitably leads to a depreciation of the portfolio of projects owned by this SEC. Thus, the value of the share of equity in ongoing projects in monetary terms is reduced, while the percentage ratio of equity and borrowed capital remains unchanged, which means an increase in capital costs, as well as the search for new sources of financing. The increase in financial risks, in turn, results in the refusal of private investors to participate in the coalition project.

This means that local coalitions may turn out to be "more profitable" for individual market participants. In this case, the situation of instability of the coalition of all participants is analyzed, which leads to a variant of a cooperative game with the absence of a C-core (Bataev et al (2018); Bataev et al (2018); Rudskaia and Rodionov, (2018); Solovieva (2019); Sosnova S. (2017)).

At the same time, uniting the participants into a "full" coalition, which could solve major socially significant problems, turns out to be less profitable for certain private sector entities compared to smaller projects, but having a higher attractiveness for them. In this case, if the state does not interfere with private investors, a "full" coalition may cease to exist.

The social significance of a project is assessed by the state, depending on the degree of importance of the project, it can take on a certain share of financial investments. Or to finance investors with the aim of uniting them into a "full" coalition and excluding the possibility of any member withdrawing from it. This will be of fundamental importance at the stage of selecting investors for the project. That is, if a situation arises when the number of applications for participation in the tender is less than the number of those who have expressed interest in implementing the project, while the submitted applications with the indicated amounts are not enough for its implementation, in this case the state can intervene and stimulate investors to participate mainly with point of view of its implementation for the project community.

Within the framework of the described system of relations, the state can no longer be (due to the objective discrepancy of its interests, goals and objectives) included in the composition of players (potential participants in the partnership). On the contrary, based on the economic content of the described problem, it should be considered as a separate entity that solves the problem of "encouraging" players (private investors) to create a large (complete) coalition that is able to implement the project necessary for the state.

In this context, the problem of determining the necessary costs that the state should incur, stimulating the process of forming a large coalition, looks quite natural.

In our opinion, the following approach can be formulated to solve this problem within the framework of a cooperative game-theoretic model of PPP. Consider this approach.

Research Methodology

The concept of the ε -core as a continuation of the concept of the C-core

One of the main directions of this study is the identification of sustainable solutions that belong to the so-called game kernels (C-core and smallest C-core). Such a decision (profit distribution) is stable in the sense that it is not profitable for any of the coalition S to separate from other players and distribute the gain v (S) among the participants. The C-core is one of the most important concepts in the theory of cooperative games; its definition is based on the ratio of dominance on a variety of divisions. The very concept of the nucleus has an economic content, since it represents the outcome of a cooperative game that cannot be improved by any coalition of participants, that is, it can be said that the nucleus is a state of equilibrium (Matveev, (2007); Moulin (2011); Moulin E. (2011)).

The c-nucleus was introduced by Gillies. By definition, the C-kernel of a game v is the set of all its non-dominated partitions. It is said that dividing x dominates dividing y if there is a coalition S such that d: dominates dividing y from coalition S. Dividing x dominates dividing y from coalition S if two conditions are true: for any member of the coalition S, sharing x will be better than sharing y, that is, $x_i > y_i, \nabla i \in S.$

Formally, the definition of C-nucleus is as follows:

$$C(v) = \left\{ x \in R^1 \middle| x(I) = v(I); x(S) \geq v(S) \right\},$$

for all $S \subset I$, where R is the set of divisions.

Other symbols: assign each unit of the system in question a serial number, designating the "main" unit with number "1", other units with numbers 2,3, etc. Let S be the coalition of divisions, and I the set of different coalitions. By division we mean a vector $\{x_{1,}\ x_{2...}x_n\} \in R^n$, satisfying the next conditions: the condition of individual rationality, reflects the natural requirement that, as a result of the distribution of the coalition's gain, each of its participants should receive no less than it can "earn" individually, without joining any coalition. Equality (2), called the condition of group rationality, formalizes the requirement that the income of a "large" (full) coalition should be distributed among all participants in the game without loss (Matveev, (2007); Moulin (2011); Moulin E. (2011)).

However, it is difficult to establish that a certain partition x belongs to the C-core from this definition, since it is necessary to make sure that there is no such partition y that y dominates x, and the set of divisions is infinite in the general case. In addition, in a cooperative game the C-kernel may be empty, in which case it is not possible to determine the set of undominated divisions (Varnavsky (2015); Varnavsky (2016)).

This approach to solving the problem of "the size of state influence" on the process of forming a large coalition is based on the concept of a ε core. This approach of a cooperative game is the set of divisions satisfying the conditions

$$C(v) = \left\{ x \in R^1 \middle| x(I) = v(I); x(S) \geq v(S) - \varepsilon, \forall S \neq O, I \right\}$$

The notation is identical to the notation in the C-core approach.

According to this definition, the ε -nucleus coincides with the C-nucleus for $\varepsilon = 0.$

Besides, $C_{\varepsilon}(v) \supset C_{\varepsilon'}(v)$, if $\varepsilon > \varepsilon'$, moreover, the inclusion is strict if $C_{\varepsilon}(v) \neq \text{emptyset}$.

Obviously, $C_{\varepsilon}(v)$ has many sharing strategies for large enough ε and, starting with some ε (maybe negative) becomes empty.

Thus, the ε- value determines the moment from which either the C core appears in the game or it becomes empty depending on ε various values.

Traditionally, the value ε in economic applications of the theory of cooperative games is interpreted as “additional” costs arising from the formation of small coalitions (when $\varepsilon > 0$) or, conversely, as additional bonuses received by them (when $\varepsilon < 0$).

In a PPP situation, values ε can be considered as quantitative characteristics of the impact of government on private investors, aimed at reducing the attractiveness of projects for them, involving local associations (small coalitions), and, accordingly, increasing interest in participating in a PPP project (association within a large coalitions). An example of such impacts can serve as measures to strengthen taxation, increasing the cost of "local" projects, and the introduction of additional conditions that cause an increase in indirect costs. Also, government intervention in the processes of PPP formation can be carried out through various forms of tariff policy.

Thus, when potential participants in the partnership do not see the need to create a “full” coalition, since their interests are better taken into account in other local coalitions, which is expressed in the form of the size of the winnings of such coalitions, it seems advisable to use an approach based on the concept of the ε core to determine the actions of state bodies acting as an external force initiating the emergence of a large coalition.

It should be noted that, within the framework of the public private partnership model, a situation may arise when the state needs to implement not a large project, but a series of projects that require small capital costs, but are socially important. In this case, the state is no longer interested in uniting investors into a large coalition, while investors themselves are interested, since the implementation of the project with full cooperation will bring them more income than if they join in the sub-coalition. In other words, if investors choose from a number of investment projects, they will choose a large project and form a “complete” coalition for its implementation, other projects will be unattractive to them.

Then the state can increase the attractiveness of a number of small projects by subsidizing and providing tax benefits for less capital-intensive projects requiring a small number of participants for their implementation, in which case the value - $\varepsilon < 0$.

Similar situations can also be considered and analyzed within the framework of the PPP model, however, in the framework of this study, we are interested in modeling PPP relations in the absence of potential investors' desire to unite into a “full” coalition.

Practical Results

This idea can be illustrated using the following reduced example of a PPP model with three participants. The characteristic function of the cooperative game obtained in the framework of this model is presented in table 1.

The model under consideration, despite its simplified nature in terms of proportional proportions of coalition utility values, corresponds to the real economic situation that arose during the

implementation of PPP projects in the UK in 2015-2017 (Morkovina et al (2017), Nabukeera (2016); Jacobsen et al (2013); Liu (2015); Mirzadeh and Birgisson (2016); Button and Cold (2019); Behrendt et al (2016)).

Table 1: Finding ε figure in game

{1,2,}	4	4	4
{1,3,}	5	5	5
{2,3,}	3	3	3
{1,2,3,}	6	6	6

Source: calculation data

Based on the definition of the ε-core, the standard approach to solving the problem of finding the ε-value will be the use of an adequate apparatus of mathematical methods, most of which are presented in numerous mathematical packages.

For example, to search for the ε value of a and the variant of the division lying in the ε -core, you can use the MS Excel add-on "Search for a solution". The approach implemented in this add-on is based on solving an optimization problem with given conditions on the basis of the theoretical definition of the ε - core.

The sought value ε is 0, thus, $C_{\varepsilon}(v)=0,$ i.e. ε - the core in such a game coincides with the C-core.

Let us analyze several examples of cooperative games with three participants, within the framework of the conditionally theoretical model of PPP, in order to show various options for the dominance of player coalitions. For each game in question, we find a division belonging to the β-nucleus, which is the distribution of the gain received by the players in the event of joining in a "full" coalition. In the examples below, the C-core will be empty, therefore, local coalitions of participants are strong, in which case the value of s will characterize the amount of "surcharge" to the players to create a "full" coalition. Since the cooperative games under consideration present various options for the dominance of coalitions, it is interesting to conduct a comparative analysis of the obtained values ε and examples of dividends located in the ε - core.

Imagine that for the implementation of a major PPP project, it is necessary to unite all possible participants and to prevent the emergence of sub-coalitions of players, that is, the task of finding the amount that will be enough to stimulate investors to create a "complete" coalition. Thus, it is necessary to find the ε value in the described game and the division located in the ε-nucleus. To define a cooperative game, it is necessary to determine its characteristic function. There are three investors with certain financial resources that they are ready to invest in the projects proposed to him. In this case, it is a vector (5; 3,5; 3). The following table shows the distribution of the required capital costs for each PPP project (table 2). The data used in the described model conditionally correspond to the real situation of the construction of a conference center in Dublin ("Dublin International Conference Center"), completed in 2016. This example is reduced in terms of proportional ratios of the size of the share of investments of investors, project parameters and the gain of possible coalitions.

Table 2: Projects parameters in conditionally-theoretic model

Projects	Capital costs, $ mln.	Net total undiscounted income estimation, $ mln.
Project 1	8,5	24
Project 2	6,5	20
Project 3	8	24
Project 4	11,5	25

Source: calculation data

Thus, the characteristic function for an individual coalition, including the "empty" and "full" coalitions, in each of the examples considered below is determined based on the total amount of monetary resources of the coalition that its participants are willing to invest. Next, from the number of projects, such a project is selected that the necessary capital costs for it are no more than the available funds from the coalition of investors. In accordance with the selected project, the value of the characteristic function will be equal to the estimate of the net total undiscounted income for this project.

After constructing the characteristic function in the game, it is possible to determine if the C-core exists, find the Shapley vector, the ε-core.

1. A game with symmetric coalitions
The characteristic function is determined in such a way that the winnings of local coalitions coincide (see Table 3):

$$v(1,2) = v(2,3) = v(1,3).$$

Table 3: Characteristic function figure for game with three participants

Coalition	**V(S)**
{}	0
{1,}	0
{2,}	0
{3,}	0
{1,2,}	20
{1,3,}	20
{2,3,}	20
{1,2,3,}	25

Source: calculation data

The C-core in a game with such a characteristic function is empty, since participation in sub-coalitions is more profitable than joining a full coalition, i.e. investors get more income if they join in coalitions in two, than otherwise.

Table 4: Finding ε figure in game with three participants

Coalition	**V(S)**	**V(S)-ε**	**X(S)**
{}	0		
{1,}	0	-3	8
{2,}	0	-3	8
{3,}	0	-3	8
{1,2,}	20	17	17
{1,3,}	20	17	17
{2,3,}	20	17	17
{1,2,3,}	25	25	25

Source: calculation data

The desired ε is 3.33, the calculated data are presented in table 4. Therefore, it is necessary pay 3.33 units to coalitions to motivate investors to merge into a "full" coalition. In this case, the division belonging to the g-core is as follows (8.3; 8.3; 8.3). The Shapley vector in such a game is (8.3; 8.3; 8.3).

In this example, the shares found on the basis of different approaches coincided. This circumstance may indicate that in the case when in a cooperative game there are only symmetric subcoalitions, the solution to the problem of finding the division located in the ε-core will coincide with the Shapley vector.

2.A game with one “dominant” coalition: the characteristic function is determined in such a way that the gain of one of the local coalitions is dominated by the other two:

$$v(1,2) > v(2,3) = v(1,3).$$

We will check the pattern of change in winnings for individual investors in case of additional ε payments to them, the calculated data are shown in table 5.

Table 5: Finding the ε value in a game with three participants

Coalition	V(S)	V(S)-ε	X(S)
{}	0	-	-
{1,}	0	-5	10
{2,}	0	-5	10
{3,}	0	-5	6
{1,2,}	24	19	19
{1,3,}	20	15	15
{2,3,}	20	15	15
{1,2,3,}	25	25	25

Source: calculation data

In this game, the value ε is 4.66, the division found (9.6; 9.6; 5.6).

The Shapley vector in the game in question is (9; 9; 7). In this case, it is more profitable for two investors to join a “full” coalition with a ε core-based distribution.

3. A game with two “dominant” coalitions: The characteristic function is determined in such a way that the win of two of the local coalitions dominates the last one coalition:

$$v(1,2) = v(2,3) > v(1,3).$$

Table 6: Finding values ε in a game with three participants

Coalition	V(S)	V(S)-ε	X(S)
{}	0	-	-
{1,}	0	-6	11
{2,}	0	-6	7
{3,}	0	-6	7
{1,2,}	24	18	18
{1,3,}	24	18	18
{2,3,}	20	14	14
{1,2,3,}	25	25	25

In such a game with an empty C-core it is 5.9 (see table 6), the found partition is (11; 7; 7), while the Shapley vector is (9.6; 7.6; 7.6) .

Here is another situation when the distribution based on the division lying in the ε-core is not beneficial for the two investors, as their winnings are reduced. However, the gain for the first investor is much better in the case of distribution based on the ε-core, i.e. if the first investor is a "strong" player who possesses a certain kind of resources, for example, an administrative resource, then he can lobby for the necessary distribution of profits.

When considering cooperative games with three participants, in most cases, sharing belonging to the ε-core is more preferable for individual players than sharing found on the basis of the Shapley vector. A more stable situation is when both divisions found on the basis of different approaches coincide. In this case, the contradictions that may arise between individual investors; are smoothed out, and the adequacy of the distribution of profit from the project is confirmed by two approaches to solving the problem of finding the distribution of income from the project.

Consider a summary table of the results of the three examples described above, on its basis we analyze the benefits and losses of each investor when using two approaches to finding interesting dividends, including when local coalitions are strong (see table 7).

Table 7: Search Results for Three-Party Games

A game	with symmetrical coalitions	with one dominant coalition	with two dominant coalitions
E-core sharing	(8,3;8,3;8,3)	(9,6;9,6;5,6)	(11;7;7)
Shapley Vector	(8,3;8,3;8,3)	(9;9;7)	(9,6; 7,6; 7,6)
Value ε	3,3	4,6	5,9

With an increase in the number of dominant coalitions, the ε value grows, this can be interpreted in such a way that in order to motivate investors to join a "full" coalition, more funds will need to be spent, and their size will increase along with an increase in the number of dominant coalitions. This means that it would be more profitable to level out the possibilities of forming a large number of local sub-coalitions that would be "privileged" with respect to others. The smallest value ε is obtained in a cooperative game where only symmetric coalitions exist. Thus, if the state is interested in reducing the amount of the additional payment to investors in order to stimulate their unification into a "full" coalition, it is necessary to choose investors so that their possible participation in the sub-coalitions is not dominated by any other association, i.e. the winnings of the sub-coalitions coincided. Therefore, we can single out the fact that the dependence of the ε - value on the number of "dominant" coalitions is directly proportional, which should be taken into account when conducting concession tenders for the choice of investors for the implementation of the PPP project.

When there is one dominant coalition in a cooperative game, it is necessary to determine which player is the most "strong". In this case, the "strong" participant will be the one with the most cash for investing.

Thus, in the games considered above, investor No. 1, who has 5 units of monetary resources, is a "strong" player. In a game with one "dominant" coalition, this participant receives 9 units in the case of income distribution based on the Shapley vector, and 9.6 units in the distribution based on the s-core concept, which is 6.6% more. The coalition {1,2} is "dominant" in the game, in addition, investor No. 2 has 3.5 units available for investment in projects and is the second "strong" player. The weak player in this example is represented by investor No. 3 with 3 monetary units. Since the {1,2} coalition is "dominant," players 1 and 2 receive more than the third player in the distribution, both in the case of calculating the Shapley vector and in determining the partition belonging to the ε core.

Thus, with this option, investor No. 1 and No. 2 will lobby for the distribution found on the basis of the ε core, despite the fact that with such a distribution, the gain of investor No. 3 decreases from 7 units to 5, 6 units, those. by 25%.

However, he will not be able to get more, because he does not take part in the "privileged" coalition. The situation may change if investor No. 3 has an additional resource that will affect the possible distribution of income. For example, if he possessed an administrative resource, then he could lobby for the distribution of profits based on the calculation of the Shapley vector and get 7 units. However, in this case, only one option is considered for possible dominance over other participants in the partnership, namely the possession of a financial resource.

In the example of a game with two "dominant" coalitions {1,2} and {1,3}, a ε-core sharing is beneficial only to investor No. 1, he receives 11 units instead of 7 units, which is almost 15% more than his Shapley vector distribution gain. While participants 2 and 3 get more precisely when dividing in the form of a Shapley vector. However, investor No. 1 is the "strong" player, and therefore income distribution will be based on the -nucleus, otherwise all participants will not unite in a "full" coalition, and it will be more profitable to participate in local "dominant" coalitions.

Thus, if there are two or more "privileged" coalitions in the game-theoretic model of PPPs, then it is not obvious that the distribution of project income based on the divide found in the calculation of the ε-core will be more profitable for most participants than the distribution based on the Shapley vector , but the "strong" players will receive more monetary units. The task of the state in implementing a socially significant project is to make its implementation profitable for "strong" investors so that they are ready to unite in a "full" coalition.

Limitation

The main comment on the described approach to finding the share of government spending in order to encourage investors to create a "full" coalition is that in the situation of state motivation for the partnership participants, it will be necessary to "add" the value s of each local coalition, and this value will be the same for any subcoalition. However, not all local coalitions will constitute a "counter-threat" to the creation of a large coalition of participants in the partnership.

In this case, we would like to know how much the surcharge should be, which is necessary to make the participants serve as an incentive for unification and neutralize the existing advantages of local coalitions. When considering the problem from this perspective, there arises the option of modernizing the proposed concept ε-core. It is necessary to find the amount of surcharge only to members of the "full" coalition. At the same time, the winnings of local coalitions will not be considered, since within the framework of the proposed approach they will not have a direct impact, since they will remain unchanged.

Significance of Research

The importance of the problem of constructing a characteristic function determines the problem of its determination, which consists of two stages. Based on the considered options for constructing this function, an adequate methodology for its formation was proposed, which allows us to analyze the relations of the partnership participants in terms of the resulting estimate of the net total undiscounted income.

Consideration of classical solutions to cooperative games (C-core, smallest C-core, N-core, Shapley vector) allows us to highlight the disadvantages and advantages of such solutions, as well as to obtain their interpretation in terms of the mathematical model of PPP, based on the principles of proximity of various solutions, which can be a good enough reason for the participants in favor of a particular partnership.

Abstract

The procedure of integration of the Manufacturing Operations Management (MOM) subsystem into a unified information system of an enterprise is considered. As one of the main integrated subsystems at the enterprise, the subsystem of planning, management and monitoring of production is considered, which allows you to organize interaction with other allied subsystems used by consumers of enterprise's products. The structure of the subsystem is considered in details, and the structure of logical connections between the subsystem and allied ones is determined. The list of data groups for exchange between the considered subsystem and allied subsystems is formed. The scheme of interaction of PMM subsystem with allied subsystems in terms of the functions performed is proposed. The proposed integration procedure will allow the company to synchronize all types of productions, logistical support; to reduce the time and complexity of monitoring and analyzing the state of production processes, as well as to reduce the response time of management services to changes (deviations) in production schedules.

Keywords: Integration, Information System, Planning, Monitoring.

Introduction

Currently, most high-tech industrial enterprises are actively engaged in the transition to a digital form of interaction between all participants in the life cycle of manufactured products. This process is quite laborious and requires all participants to be involved in a unified information environment or a corporate system with a clear separation of functions, rights and responsibilities.

The general concept is to form a unified information environment (UIE) to ensure the development and production of the product. The UIE is designed to automate the collective work of specialists and heads of design departments, departments of design preparation of production, technological preparation of production and technological bureaus of the workshops of the main production during development, preparation of production and support of product operation.

The organization of a unified information space for managing the activities of the enterprise is carried out in order to ensure control of the release of finished products, product repairs and upgrades as well as operational monitoring of the state of production activities.

Literature Review

The level of development of life cycle management technologies in world practice is quite high, however, the first experience in introducing and applying such technologies was obtained abroad. In the Russian Federation, there is a shortage of research on this topic, especially works of a complex

nature. This deficit is caused by a number of internal and external factors in the functioning of production systems, but in connection with the stable positive dynamics of high-tech industries development, research in this area is of particular relevance. Among specialists working on this topic, it is necessary to note the works of C. Larman, V.R. Basili (2003), V.N. Evdokimenkov, D.A. Kozorez, M.N. Krasilshchikov (2019), O.N. Dmitriev S.V. Novikov (2019), A.I. Kanashchenkov, S.V. Novikov , D.S. Veas Iniesta. (2019), B. Mandal (2011), A. Telishev, G. Mingaleev, R. Galyamov. (2019), I.Sh. Sharafeev, I.M. Zakirov (2014), T. Wallace (2001) and others.

Methodology

The methodological basis of this research is the system and process approaches to the implementation of measures to improve the industrial enterprise effectiveness at all stages of its products' life cycle.

The creation of a Unified Information System (UIS) is a complex project that provides processes related to the design, production, maintenance and operation of products. As part of the UIS, as a rule, a unified engineering information space is created, which includes a distributed virtual design bureau and digital production (Dmitriev O.N., Novikov S.V., 2019).

Creating a unified enterprise information system allows you to:

- Synchronize among themselves all types of productions (procurement, machining, galvanic, thermal, assembly, repair, modernization), logistical support and provision of complementary parts;
- Reduce the duration, labor effort of monitoring and analysis of production processes state, as well as reduce the response time of the enterprise management services to changes (deviations) in production schedules;
- Reduce losses in processes and accelerate informed management decisions;
- Implement a specific-order accounting system in accordance with applicable law;
- Provide real-time monitoring of labor costs.

The list of tasks to be solved within the framework of the creation and implementation UIS at an enterprise include:

1) Production and supply management in the UIS;
2) Formation of orders for the product range assembly, indicating its composition and manufacturing technology;
3) Synchronous planning and calculation of production and supply schedules;
4) Accounting of the actual performance of production work.

As part of the study, the UIS is presented as an automation object, characterized by a certain set of indicators.

For example, the technical indicator of the automation object is a unified technological space for all production subdivisions during the planning and accounting process in production. The unity of the technological space is to ensure that all operations for all types of productions involved in the manufacture of products are performed, including auxiliary production for tooling, related to the process of creating a production plan and accounting for the implementation of production tasks in a Unified Information System.

Production and economic indicators of the UIS is a combination of changes in labor costs and time of labor use to ensure production processes. These include the following indicators:

- 50 % reduction in the duration and labor effort of monitoring the state of production processes;
- 50% reduction in the labor effort of accounting for the implementation of production;
- Ensuring compliance with regulatory requirements.

The criteria for assessing the achievement of the goals of creating the UIS are:

- in terms of technical indicators - automation of all functions associated with the planning and accounting processes in production, putting the system into industrial operation;
- in terms of technological indicators - the unification of operations when forming a production plan and accounting for the implementation of production tasks, automation of business processes, minimizing redundant and duplicate functions;
- in terms of production and economic indicators - reducing the duration and labor effort of monitoring the state of production processes, reducing the labor effort of accounting for the implementation of production orders, the introduction of a specific-order accounting system at the enterprise.

Unified Enterprise Information system should automate:

- the process of forming the production nomenclature plan and plan for the provision of materials and purchased component parts of the enterprise;
- process of completing production tasks;
- registration procedures for start-up and release in the factory workshop (at the level of processing stage / workshop inputs), production lots, inter-workshop movements (transfer from one workshop to another, receipt at the workshop).

Implementation of the UIS should be carried out in stages, taking into account the interconnections of the production structure of the enterprise with the observance of the principle of scalability, which means ensuring the possibility of connecting structural units to the EIS, both in stages and in other work (without changing the already deployed system components) (Kanashchenkov A.I., Novikov S.V. & Veas Iniesta D.S., 2019).

The functioning of the client parts of the UIS should be carried out within the local network of enterprise subdivisions in accordance with the delimitation of user powers.

Results

At the enterprise under study one of the main UIS's subsystems designed to provide control over the release of finished products, carry out repairs and modernization of products and provide operational control over the state of production activity, is a subsystem for planning, management and monitoring of production (PMMP). This subsystem as applied to the object of study should include the following modules:

- Control over Reference Information and Product Data;
- Production Management;
- Production Logistics;
- Supply Management.

The enlarged functional affiliation of each of the modules is presented in the Table 1.

Table 1: Modules and Their Functionalities

No.	Module	Module Functionality
1	Production Planning	Allows you to plan the supply of inventory and production processes
2	Production Management	Allows you to manage discrete and assembly production, both at the inter-workshop level and at the level of workplaces,

No.	Module	Module Functionality
		taking into account resource limitations (APS – advanced planning)
3	Supply Chain Management	Allows you to manage the supply of materials and components, taking into account production requirements and restrictions associated with suppliers and supply processes
4	Product Data Management	Allows you to manage product data required to support a production management process
5	Production Logistics	Allows you to control the movement and condition of materials and production items
6	Quality	Allows you to register the results of quality control upon receipt of inventory in the workshop and for parts and assembly units of their own manufacture
7	Administrator	Allows you to configure the functionality of the subsystem, configure access rights for users

The subsystem of planning, management and monitoring of production should interact with other allied subsystems used by consumers of enterprise products (Telishev A., Mingaleev G. & Galyamov R., 2019).

A detailed elaboration of the UIS's structure and functioning should be carried out at the stage of developing technical specifications for the subsystems and described in a separate document.

Requirements for the Manufacturing Operations Management subsystem include:

1. Production and supply planning:

- formation of orders for disassembly, fault detection, repair, production and assembly of products on the basis of shipping orders, decisions on modernization and results of fault detection;
- maintaining production plan options;
- calculation (or recalculation) of the production and supply plan;
- analysis of production and supply plan options in terms of deadlines, resource requirements, purchased materials and components;
- adjustment of production and supply plans;
- approval of a production and supply plan option, launching work orders.

2. Dispatching at the level of production subdivisions (workshops):

- plan-fact of orders by workshops, by workshop entrances, by deadlines and priorities;
- configuration control and formation of requirements for issuing;
- start of work at the processing stage with the reservation of materials, third-party components, parts and assembly units;
- disassembly and fault detection;
- accounting of release and defects upon completion of batch processing in the workshop (at the processing stage);
- transfer of batches to the next processing stage or to the consuming subdivision;
- production batch separation.

3. The ability to separately account the launch, release, transfer, receipt of production orders (at the inter-workshop level). Production logistics:

- accounting of the inventory movements: acceptance from the supplier; transfer to production; transfer in production; receipt in production; launch in production; issue in production; acceptance of products, registration of defects and disassembly results; decision on defects detection and defects; separation of batches; adjustment of balances; return of not accepted parts; shipment to customers;

- accounting of the results of control of inventory items, parts and assembly units of their own production entering the workshop;
- monitoring the status, availability and movement of inventory in production at the level of inter-workshop movement.
- formation of a list of work tasks for the batches launched at the workshop level (at the processing stage);
- uploading the list of work tasks to the subsystem “Intrashop production management for the machining shop and the final assembly shop”.
- loading of true condition of fulfilling work tasks from the subsystem “Intrashop production management for the machining shop and the final assembly shop”.

The main goals of creating the subsystem "Planning and Monitoring System" are:

- synchronization among themselves of all types of production (procurement, machining, galvanic, thermal, assembly, repair, modernization), supply of materials of third-party components;
- reducing the duration and complexity of monitoring and analyzing the production processes conditions and reducing the response time of management services to changes (deviations) in production schedules;
- cost reduction and acceleration of informed management decisions;
- implementation of a specific-order accounting system;
- real-time monitoring of labor costs.

The task of creating a subsystem "Planning and Monitoring System" is to automate the following processes:

1) formation of planned orders for production on the basis of transferred orders for finished products from the subsystem Managing the Program, Projects and Cooperation (MPPC), the composition of the product and its manufacturing technology;
2) synchronous planning, calculation of production schedules and logistical support (LS) for a single calculation cycle, taking into account available resources;
3) accounting for the fact of the performance of production work and logistical operations
4) formation of tasks for the completion or manufacture of parts and assembly units, instead of inappropriate products of their own manufacture.

The implementation of the subsystem Planning and Monitoring System (PMS) is carried out in stages, taking into account the interconnections of the production structure of the enterprise with the observance of the principle of scalability, which means ensuring the possibility of connecting structural units to the PMS subsystem both in stages and within other work (without changing the already deployed components of PMS subsystem).

The functioning of the client parts of the planning, management and production monitoring subsystem is carried out within the local network of enterprise divisions in accordance with the differentiation of powers between users of this subsystem.

The Manufacturing Operations Management subsystem is deployed in the form of separate copies of ERP class software at each of the enterprise divisions.

At the same time, interaction between instances of the Manufacturing Operations Management subsystem between themselves is not provided directly.

Each instance of the Manufacturing Operations Management subsystem is hosted on the enterprise server in the internal network.

Each instance of the Manufacturing Operations Management subsystem interacts with an instance of an allied UIS’s subsystem for its enterprise.

The subsystem exchanges information between modules through the internal core of the production planning, control and monitoring subsystem.

The generalized composition of the subsystem is shown in the figure 1.

Fig. 1: The scheme of dividing the subsystem of planning, management and monitoring of production into components

For the subsystem of planning, management and monitoring of production at the enterprise under study, the following operating modes are defined:

1) regular mode, in which the UIS's subsystem provides users and their functions 24 hours a day, 7 days a week (24×7);

2) service mode, in which the UIS's subsystem does not perform its functions. The UIS subsystem goes into this operating mode in the following cases:

- scheduled subsystem upgrade;
- need for maintenance;
- failure of a hardware-software complex caused by failure of elements of a hardware or software base;
- failure of the data network and other emergency situations.

The Manufacturing Operations Management subsystem consists of one integrated ERP-class software product. Access to the modules of the subsystem of planning, management and monitoring of production is carried out using access settings for specific users.

The Manufacturing Operations Management subsystem is deployed at the enterprise in the form of separate copies of software.

The Manufacturing Operations Management subsystem is associated with other functional subsystems of the UIS indicated in the Table 2.

Table 2: The structure of logical connections between the Manufacturing Operations Management subsystem and allied subsystems

	PDM	PM	BOM	TPP	ILS	MOM	MES
PDM		→ ←	←	→ ←	→ ←	→	→
PM	→ ←		←	→ ←		→ ←	
BOM	→	→		→	→	→	→
TPP	→ ←	→ ←	←			→	→
ILS	→ ←		←			←	
MOM	←	→ ←	←	←	→		→ ←
MES	←		←	←		→ ←	

Table 2 presents the composition of the subsystems directly related to the Manufacturing Operations Management subsystem, including:

PDM – Product Data Management subsystem;
PM – Project Management subsystem;
BOM – Bill of Material subsystem;
TPP – Technological Preparation of Production subsystem;
ILS – Integrated Logistics Support subsystem;
MOM – Manufacturing Operations Management subsystem;
MES – Manufacturing Execution System.
The list of information for the exchange between the UIS's subsystems is given in the Table 3.

Table 3: List of data groups for the exchange between the Manufacturing Operations Management subsystem and allied subsystems

Table 3 applies the following abbreviations:

"S" means Source. In this case, an information system is the source of data group instances.

"R" means Receiver. In this case, an information system is a receiver of data group instances.

"SR" means Source and Receiver. In this case, an information system is the source and receiver of instances of data groups (depending on the content of data group attributes).

"N" means Not involved. In this case, an information system is not involved in processing instances of data groups at this stage of the UIS implementation.

The list of data groups for exchange, their sources and receivers can be clarified as part of building the integration solution subsystem.

The general scheme of interaction the Manufacturing Operations Management subsystem with related systems in terms of the functions performed is presented in Figure 2.

Fig. 2: Input and output information of the Manufacturing Operations Management subsystem

The input and output information of the Manufacturing Operations Management subsystem, which is valid for enterprise subdivisions, will be clarified at the next stage of the study.

The format and method of data exchange will be determined as part of the work on building the subsystem of the integration solution.

Conclusion

A detailed review of integration decisions will be presented as part of future research to build an integration solution subsystem.

The results of the project to introduce a subsystem at the enterprise are:

- a deployed and configured PPMM subsystem;
- a generated data model of the subsystem in the form of a set of files containing the necessary configuration settings and business objects;
- developed supporting documentation for the subsystem;
- conducted tests of the subsystem and trial operation, confirmed by the relevant Test Protocols;
- conducted training of personnel for the use of the subsystem.

Abstract

The Internet has enabled consumers to find basic information about many offers at very little cost. For example, databases of accommodation for sale contain information about the price, location, number of rooms and size of a flat. This allows purchasers to assess whether an offer is potentially attractive, but due to the variety of factors involved in choosing a flat (e.g. aesthetic considerations) is insufficient to make a final decision on such an important purchase. In such situations, automizing the choice of an initial shortlist using information from the Internet is a useful approach to choosing an attractive offer while constraining search costs. This article describes an algorithm that constructs shortlists of attractive offers from a database on the basis of consumers' preferences. The length of the shortlist is set by the user. Such shortlists can be treated as a list of flats to be physically viewed or as an initial step in defining such a set. This algorithm can be applied in a range of scenarios, e.g. an employer wishing to hire a specialist employee.

Keywords: Shortlist, Job Search Problem, Heuristic Decision Rule, Online And Offline Search, Limited Rationality, Multi-Criterion Decision Making

Introduction

The Internet allows consumers to find information about a wide range of offers at very little cost. However, due to the limited capacity of humans to process information, this can lead to the paradox of choice (Schwartz, 2004), which states that when there is a large set of offers, a consumer should concentrate on a small subset. In this way, a decision maker (DM) might not purchase the best offer, but this loss is compensated for, since less time and effort are required to make a purchase. Due to their limited rationality, consumers often use heuristics that are adapted to the structure of the problem faced (Simon, 1956: 129; Todd and Gigerenzer, 2000: 727-741).

A shortlist is adapted to situations in which a consumer can gain some information about offers at low cost, but the information required to make an accurate appraisal of an offer's value is relatively costly.

This article considers the use of shortlists when the goal is to acquire a single valuable resource, rather than as a means to choosing several options. For example, Durbach and Davis (2012: 99-116) consider the problem of choosing several ways of reducing electricity bills. On the other hand, Belton (1985: 265-274) considers how a final choice is made after a shortlist has been constructed.

Much work has been recently published on the concept of shortlists (Masatlioglu *et al*, 2012: 2183-2205; Lleras *et al*, 2017: 70-85). Borah and Kops (2019: 401-420) consider search processes where DMs construct shortlists using information obtained from peers. The shortlist heuristic is also useful when offers are categorizable (Armouti-Hansen and Kops, 2018: 507-524) or multiple criteria are considered (Dulleck *et al,* 2011: 395-408).

Manzini and Mariotti (2007: 1824-1839) consider a model where shortlists of offers of ever decreasing size are constructed using a sequence of criteria until a final choice is made. Au and Kawai (2011: 608-614) consider a similar model where a shortlist of offers is constructed using initial information and then an offer is chosen from this shortlist based on a richer set of information.

Although the two papers described above describe the properties of such decision rules, little work has been devoted to optimization models involving shortlists. Ramsey (2019: 75-92) presents a model in which a DM uses a shortlist as a means to making a final decision. The DM cannot precisely measure the value of offers, but can rank offers according to the information currently available. Basic information about offers can be obtained at little cost. However, gaining more precise information about the value of an offer is much more costly. The strategy of the DM is defined by the length of the shortlist, k. The k most attractive offers according to initial information are inspected more closely, after which the best offer on the shortlist is accepted. When the search costs are convex in k, the optimal length of the shortlist is the smallest value of k satisfying the following condition: the marginal costs from increasing k (the increase in the search costs from increasing the length of the shortlist from k to $k + 1$) exceed the marginal gain from increasing k (the increase in the expected value of the offer accepted by increasing the length of the shortlist from k to $k + 1$). Olkin and Stephens (1993: 477-486) consider the problem of selecting a shortlist of candidates for a job when the goal is to employ the best of all the candidates available.

The model presented here addresses some shortcomings of the model of Ramsey (2019: 75-92). Firstly, that model does not explicitly consider the fact that decisions are made at each stage on the basis of multiple traits. Secondly, the value of a shortlist in exploring the range of the offers available is not considered. Various approaches to multiple-criteria decision making can be applied. For example, the TOPSIS approach (Technique for Order of Preference by Similarity to Ideal Solution, see Yoon and Hwang, 1995) measures the attractiveness of an offer according to its distance from the ideal offer in a multi-dimensional space defined by an offer's traits. Górecka *et al* (2016: 1097-1136) present the MARS approach (Measuring Attractiveness around Reference Solutions), which may be interpreted as a generalization of the TOPSIS approach. This paper illustrates the algorithm based on the relatively simple SAW approach (Simple Additive Weights). The overall attractiveness of an offer is measured as the weighted sum of scores according to individual traits. Such a score is either a linear or triangular function of a trait. Kaliszewski and Podkopaev (2016: 155-161) argue that decisions made using more complex approaches can be interpreted as choices made using the SAW approach for appropriately defined weights.

The method is illustrated on the basis of the problem of purchasing a flat from a large database of offers. Figure 1 illustrates a non-automated search process based on forming a shortlist.

Given the potentially large size of a database holding quantitative information, the automated construction of a shortlist is of potentially great use to those searching for a flat. The DM must input the minimum, maximum and ideal values of the traits of interest, together with the relative importance of each trait and the required length of the shortlist. Since a database may contain qualitative information about offers (e.g. type of building, photos), this shortlist can be used as a first step in defining which offers should be physically viewed.

Fig. 1: Flow chart describing the purchase of a flat via the shortlist heuristic.

Section 1 describes the general form of the algorithm. Section 2 presents a simple example illustrating how the algorithm is applied. Section 3 gives results based on a real data set. Finally, some conclusions are made, together with directions for future research.

Description of the Algorithm

This section describes an algorithm for constructing a shortlist of length n from N offers based on k numeric traits, denoted $x_1, x_2, \ldots, x_k$. A shortlist should contain offers that a) are potentially very attractive to the DM, and b) show diversity in their characteristics. The second criterion is particularly useful when a DM has limited knowledge about a particular market. For example, if somebody looking for a flat comes from a different city, the benefits gained from viewing flats with different characteristics/locations may well outweigh those from viewing offers that are all very close to the assumed ideal in terms of size and location, since the DM is likely to make a better informed final choice. We construct a list that maximizes a weighted sum of the average scores of the offers on the list and the average distance between them. To do this, we must define i) a measure of the attractiveness of an offer, ii) a measure of the distance between offers, iii) a measure of the attractiveness of a shortlist [based on i) and ii)]. Note that the raw data required to define the k traits might include more than k variables (to be discussed in Section 2). Let $\boldsymbol{x} = (x_1, x_2, \ldots , x_k)$ be the vector of the values of the traits describing an offer and $\boldsymbol{y} = (y_1, y_2, \ldots, y_m)$ denote the vector of variables in the raw data. By assumption, $m \geq k$ (note that the variables contained in $\boldsymbol{y}$ might precisely correspond to the variables in $\boldsymbol{x}$).

The general form of the algorithm is as follows:

1. The DM states a) the length of the required shortlist, b) the weight of each trait, c) the minimum, maximum and ideal values of each trait, and d) the weight ascribed to the diversity of offers on the shortlist. Since defining the weight of diversity is not intuitive, this could be done by defining the level of knowledge a DM has regarding the market involved as low, medium or high. The possible range of the scores of offers is independent of the number of traits considered. However, suppose that the raw data are standardized to lie in the interval [0,1]. The maximum distance between offers is $\sqrt{m}$. Hence, the weight ascribed to diversity should also take the dimension of the data into consideration (this will be investigated in future research). The minimum and maximum values of each trait are assumed to define hard constraints that an offer must satisfy.
2. The number of offers satisfying the hard constraints is outputted. Based on this, the DM can choose to relax the constraints. If the number of offers satisfying the constraints is sufficient, then any offer not satisfying the constraints is eliminated.
3. The overall score of each offer and the distance between each pair of offers is calculated (see below).
4. If the size of the shortlist is relatively small, an exhaustive search procedure may be used to find the shortlist maximizing the weighted sum of the mean score of the offers and the mean distance between them (this sum is defined below). The algorithm is designed to be used online and the shortlist produced will generally be of at least moderate size (e.g. tens of offers). Hence, the following greedy algorithm is used to find a near-optimal solution in a short time. Initially, the offer with the highest overall score is placed on the shortlist. The algorithm then successively adds offers to the shortlist until the required size has been attained. At each stage the weighted sum of the mean overall score and mean distance between offers is maximized. This is illustrated in Section 2.

Suppose x_i^{min}, x_i^{max} and x_i^{ideal} are the minimum, maximum and ideal values of trait i. The values x_i^{min}, x_i^{max} are called the extreme values of a trait. Let $f_i(x_i)$ be the score of trait i when it takes the value x_i. This score is defined to be one at the ideal value, zero at any extreme value not equal to the ideal value, and vary linearly between the ideal value and any extreme value differing from the ideal value. The function f_i takes one of three forms depending on whether the ideal value is the minimum value, an intermediate value or the maximum. When $x_i^{min} = x_i^{ideal}$, i.e. the minimum value is the ideal value,

$$f_i(x_i) = \frac{x_i^{max} - x_i}{x_i^{max} - x_i^{min}}. \tag{1}$$

In this case, the score according to trait i decreases linearly from 1 at x_i^{min} to 0 at x_i^{max}. When $x_i^{max} = x_i^{ideal}$, i.e. the maximum value is the ideal value,

$$f_i(x_i) = \frac{x_i - x_i^{min}}{x_i^{max} - x_i^{min}}. \tag{2}$$

In this case, the score according to trait i increases linearly from 0 at x_i^{min} to 1 at x_i^{max}. Otherwise, i.e. when the ideal value of a trait is intermediate,

$$f_i(x_i) = \begin{cases} \frac{x_i - x_i^{min}}{x_i^{ideal} - x_i^{min}}, & \text{when } x_i^{min} \le x_i \le x_i^{ideal} \\ \frac{x_i^{max} - x_i}{x_i^{max} - x_i^{ideal}}, & \text{when } x_i^{ideal} \le x_i \le x_i^{max}. \end{cases} \tag{3}$$

In this case, the score according to trait i is a triangular function taking the value of one at the ideal value and the value of zero at the extreme values. Let w_i be the weight of the i-th trait. These weights are non-negative and sum to one. The overall score of an offer is $f(\boldsymbol{x})$, where

$$f(\boldsymbol{x}) = \sum_{i=1}^{k} w_i f_i(x_i). \tag{4}$$

Hence, the overall score of an offer is a weighted average of the scores according to the traits. Let $f(\boldsymbol{x}_j)$ denote the overall score of the j-th offer.

Now we define the measure of distance between offers. Firstly, each variable in the data set is linearly scaled, so that the minimum value is zero and the maximum value observed is one. Hence, the scaled value of y_i, denoted by y_i^s, is given by

$$y_i^s = \frac{y_i - y_i^{min}}{y_i^{max} - y_i^{min}}, \tag{5}$$

where y_i^{min} and y_i^{max} are the minimum and maximum, respectively, of the values of the i-th variable in the data matrix. Let $D(\boldsymbol{y}_j, \boldsymbol{y}_l)$ denote the Euclidean distance between offers j and l according to these standardized values. This is illustrated in Section 2.

The score of the shortlist given by the set of offers S is a weighted sum of the scores of the offers and the mean distance between these offers. Let $\#(S)$ denote the number of offers in S and v denote the weight ascribed to the diversity within the shortlist. The number of pairs of offers in S is $0.5\#(S)[\#(S)-1]$.

We denote the score of the shortlist S by $g(S)$, where

$$g(S) = \frac{1-v}{\#(S)}\left[\sum_{j \in S} f(\boldsymbol{x}_j)\right] + \frac{2v}{\#(S)[\#(S)-1]}\left[\sum_{j,l \in S, l \neq j} D(\boldsymbol{y}_l, \boldsymbol{y}_j)\right]. \tag{6}$$

Note that this algorithm is flexible enough to be applied in conjunction with other approaches to multi-criteria decision problems, e.g. TOPSIS. Also, the algorithm can be used to form a shortlist of attractive offers that satisfy a budget constraint by using price as a variable, but giving it a weight of zero in defining the attractiveness score. The algorithm is designed to use data from continuous distributions. However, it is possible to use discrete variables (as illustrated in Section 3).

A Simple Example

The algorithm uses easily accessible quantitative data. Although the seller decides which information is available, by not taking into account traits significant to clients, the seller would lose business. Dickinger and Mazanec (2008: 244-254) find that for any type of customer looking for a hotel room price, location and ratings from other customers are always important. Hence, Internet search engines for choosing accommodation highlight these criteria. The authors made an overview of real estate databases on the Internet to see how offers are presented (see Table 1). Kok *et al* (2017: 202-211) consider a similar problem from the point of view of an estate agent wishing to value properties in a large database.

Information is always given about price and the number of rooms. Also, nearly all sites give information on size in m^2 and location. Furthermore, in 17 student projects on consumer decisions in the real estate market in Poland supervised by the authors, size and price were always found to be significant and the number of rooms was found to be significant in 16 of the analyses. Location was found to be significant by a large majority of studies. The following example illustrates the selection of a shortlist based on three traits: price, size in m^2 and location. The first two traits are simply two variables from the data set.

Table 1: The main information given about new flats for sale according to geographic region (Based on a survey by the authors)

No.	Geographical region	Number of sites	Main Criteria	Textual description
1	Worldwide	5	price, size in m^2, number of rooms, location, number of bathrooms	Yes
2	Europe (excluding Poland)	8	price, size in m^2, number of rooms, location, infrastructure, number of parking places, information about balconies	Yes
3	North America	2	price, size in m^2, number of rooms, location, number of bathrooms, number of bedrooms	Yes
4	South America	1	price, size in m^2, number of rooms, location, number of bathrooms, number of bedrooms	Yes
5	Australia	1	price, number of rooms, location, number of bathrooms, number of bedrooms, number of parking places	Yes
6	Asia	1	price, number of rooms, number of bathrooms, number of parking places	No
7	Poland	3	Price, size in m^2, number of rooms, location, price per m^2, monthly mortgage payment, floor of building	Yes

The definition of location is more problematic. In a number of projects, location was interpreted as the attractiveness of the district in which a flat is located, while in others it was measured as the distance from the city center. For the purposes of this study, distance from a reference point (to be chosen by the user) is a suitable variable to analyze. However, when considering the distance between two offers, this should depend on the physical distance between the flats and not on the differences between the distances to the reference point. Hence, the data required are the variables (y_1, y_2, y_3, y_4), where y_1 is the price, y_2 is the size in m^2, y_3 and y_4 are the co-ordinates of the flat with respect to the reference point, e.g. distance north and distance east in kilometers. The vector of traits is (x_1, x_2, x_3) where $x_1 = y_1$, $x_2 = y_2$ and $x_3 = \sqrt{y_3^2 + y_4^2}$, i.e. x_3 is the physical distance of the flat from the reference point (e.g. city center or place of work). Instead of measuring the physical distances, e.g. journey time could be used.

Consider the following toy example. A client wishes to buy a new flat at a price between 300 000PLN and 500 000PLN (the ideal price is the minimum price), within 10km of his/her place of work (the ideal distance is 0). The size of the flat should be between $60m^2$ and $100m^2$ with an ideal of $80m^2$. The weights of price, location and size are 0.4, 0.3 and 0.3, respectively. There are six offers meeting the required criteria and we wish to form a shortlist of three offers when the weight ascribed to diversity is 0.3. Table 2 gives the raw data and their standardized values.

Table 2: Raw data and standardized data (in brackets) for the toy example

Number	Price (PLN)	Size (m2)	Distance north (km)	Distance east (km)
1	450 000 (0.60)	84 (0.84)	2.5 (0.70)	-1.4 (0.00)
2	390 000 (0.00)	68 (0.20)	1.4 (0.48)	-0.9 (0.10)
3	440 000 (0.50)	63 (0.00)	-0.8 (0.04)	0.6 (0.40)
4	420 000 (0.30)	76 (0.52)	3.1 (0.82)	1.4 (0.56)
5	410 000 (0.20)	88 (1.00)	4.0 (1.00)	3.6 (1.00)
6	490 000 (1.00)	72 (0.36)	-1.00 (0.00)	1.2 (0.52)

Table 3 gives the matrix of standardized distances between the offers. Table 4 gives the scores according to each trait and the overall score.

Table 3: Distances between the offers

	Offer 2	Offer 3	Offer 4	Offer 5	Offer 6
Offer 1	0.909945	1.145076	0.721388	1.129425	1.072753
Offer 2		0.757364	0.720833	1.326801	1.196829
Offer 3			0.971802	1.540000	0.628967
Offer 4				0.682935	1.090688
Offer 5					1.509967

When no weight is placed on the diversity of offers, then the optimal shortlist of length three simply contains the offers with the highest scores: offers 4, 2 and 1. Assume that the weight ascribed to diversity is 0.3. Applying the algorithm described above, the first offer placed in the shortlist is flat 4 (it has the highest overall score).

Table 4: Scores of the offers using Simple Additive Weighting with weights w1=0.4, w2=w3=0.3.

Number	Price	Size	Distance	Price score	Size score	Distance score	Overall Score
1	450 000	84	2.865310	0.25	0.80	0.713469	0.554041
2	390 000	68	1.664332	0.55	0.40	0.833567	0.590070
3	440 000	63	1.000000	0.3	0.15	0.900000	0.435000
4	420 000	76	3.401470	0.4	0.80	0.659853	0.597956
5	410 000	88	5.381450	0.45	0.60	0.461855	0.498557
6	490 000	72	1.562050	0.05	0.60	0.843795	0.453139

In the second stage, we select the shortlist of length two including flat 4 that maximizes the weighted average of the mean score and diversity. These calculations are illustrated in Table 5.

Table 5: Choice of the second offer to be placed on the shortlist

Shortlist	Overall Scores	Av. score	Distance	Weighted sum
{4, 1}	{0.597956, 0.554041}	0.575998	0.721388	0.619615
{4, 2}	{0.597956, 0.590070}	0.594013	0.720833	0.632059
{4, 3}	{0.597956, 0.435000}	0.516478	0.971802	0.653075
{4, 5}	{0.597956, 0.498557}	0.548256	0.682935	0.58866
{4, 6}	{0.597956, 0.453139}	0.525547	1.090688	0.695089

Adding offer 6 maximizes this weighted average over such shortlists. At the final stage of the algorithm, we consider shortlists of length 3 that include offers 4 and 6. These calculations are illustrated in Table 6. The shortlist generated consists of offers 4, 5 and 6.

Table 6: Choice of the third offer to be placed on the shortlist

Shortlist	Scores	Av. score	Distances	Av. Distance	Weighted sum
{4, 6, 1}	{0.597956, 0.453139, 0.554041}	0.535045	{1.090688, 0.721388, 1.072753}	0.961610	0.663014
{4, 6, 2}	{0.597956, 0.453139, 0.590070}	0.547055	{1.090688, 0.720833, 1.196829}	1.002783	0.683774
{4, 6, 3}	{0.597956, 0.453139, 0.435000}	0.495365	{1.090688, 0.971802, 0.628967}	0.897152	0.615901
{4, 6, 5}	{0.597956, 0.453139, 0.498557}	0.516550	{1.090688, 0.682935, 1.509967}	1.094530	0.689944

Note that in the *i*-th step of *n* in the algorithm, the best of *N-i+1* shortlists is chosen. Hence, the total number of shortlists considered is

$$\sum_{i=1}^{n} N - i + 1 = Nn - \frac{n(n-1)}{2}. \tag{7}$$

Exhaustive search over all the possible shortlists must consider $\frac{N!}{n!(N-n)!}$ possible solutions. In this example, the greedy algorithm considers 15 shortlists, while exhaustive search compares 20 shortlists of length three. Hence, there is little to gain from using the greedy algorithm. However, when *N* is very large and *n* reasonably large, the reduction in run time can be significant. Exhaustive search indicates that the optimal shortlist consists of offers 2, 5 and 6.

Using a Real Data Set: Searching for A Flat in Wrocław, Poland

This Internet site https://www.otodom.pl/ (accessed 14/4/2020) contains information on approximately 10 000 properties in Wrocław. Suppose that the length of the required shortlist is six. Three traits were considered: price, surface area and number of rooms. The associated criteria, together with their weights, are

1. Price: minimum 200 000 PLN, maximum 500 000 PLN, ideal value 200 000, weight 0.6.
2. Area: minimum 50 m^2, maximum 100 m^2, ideal value 80 m^2, weight 0.3.
3. Number of rooms: minimum 2, maximum 4, ideal value 3, weight 0.1.

Note that number of rooms is a discrete variable and the score ascribed to this trait is a 0-1 function. Flats with two or four rooms are acceptable, but obtain a score of zero according to this trait. Flats with three rooms obtain a score of one according to this trait.

There were 195 properties satisfying the criteria. The algorithm was applied five times with differing values of the weight, *v*, ascribed to diversity: 0, 0.3, 0.5, 0.7 and 1. The weight 1-*v* is ascribed to the mean score of offers. When *v*=0, the algorithm returns the six most highly ranked offers based on the SAW method. When *v*=1, the algorithm returns the most diverse range of offers satisfying the criteria and including the one with the highest score. The results are illustrated in Tables 7 and 8.

Table 7: Shortlists constructed for different weights ascribed to diversity, v. The offers are placed in the order that they are added to the shortlist

v = 0					v = 0.3					v = 0.5

For this problem, when the weight ascribed to diversity does not exceed 0.5, then the algorithm returns a shortlist of offers that are all very highly ranked (in the top 12 of the 195 offers satisfying the criteria). Future research will investigate how to determine a suitable value for this weight according to the preferences and knowledge of the DM.

Results and Conclusions

This article has presented an algorithm for producing shortlists of offers from a large database, which may be used when DMs are looking for a unique and valuable resource (e.g. a flat or second-hand car). Such shortlists present a diverse set of potentially attractive offers by maximizing a weighted sum of the mean scores of the offers on the shortlist and the mean distance between them. The weights ascribed to each trait (at the level of determining the score of an offer) and the diversity of offers (at the level of determining the attractiveness of a shortlist) have a significant effect on the set of offers placed on the shortlist. Hence, future research will investigate the robustness of such approaches with respect to these parameters. In particular, the weight ascribed to the diversity of a shortlist should be adapted to a) the clarity of the preferences (or market knowledge) of the DM, and b) the number of variables in the data matrix.

Future research should also consider how robust the algorithm is to the distribution of the raw data. For example, the coefficient of variation of the variables observed may be very different. This can lead to problems in the standardization procedure, e.g. if a city lies in a long valley running from east to west, then a physical distance between two offers in the north-south direction will have a much larger standardized value than the same physical distance between two offers in the east-west direction.

The algorithm presented here is flexible enough to be implemented using any of the wide range of methods available for assessing offers based on multiple traits (e.g. TOPSIS, MARS). Hence, future

research should also compare the effectiveness of such methods when adapted to the problem of choosing a shortlist of offers.

Although the algorithm is designed to be applied to continuous traits, discrete traits may also be considered. Future research will consider in more detail how discrete traits should be incorporated into the algorithm.

Another aspect that should investigated lies in the fact that there may be a conflict of interest between the DM and an organization that gives access to such an algorithm. For example, an Internet site providing data about flats for sale might be more interested in selling flats from a particular developer or those that have been on the market for some time. Such problems are intrinsically game theoretic.

Abstract

In condition monitoring, tracking the health, state and characteristics of a hardware equipment is an expensive task. The target of this article is to recommend an alternative way of monitoring the equipment by using artificial intelligence, in order to minimize maintenance costs. An important aspect therein is to detect faults in the rotating equipment, in particular bearings. We will use the vibration signals of the bearing and different techniques within the Digital Signal Processing field (Mel-frequency cepstral coefficients, Fast Fourier Transform, Short Time Fourier Transform) to pre-process the input signal and extract important features in an appropriate way as to train machine learning models. Dimensional reduction techniques (such as Principal Component Analysis) are used to diminish the time and complexity of training. The trained models will be able to recognize different states of the bearing, like fault states (inner, outer, ball) states or a normal state. Finally, we will test the performance of the models on other data sets, different from the one we trained and then save the results to make some statistics regarding the accuracy of the models.

Keywords: Condition Monitoring, Machine Learning, Frequency, Mel-Frequency Cepstral Coefficients, Short Time Fourier Transform.

Introduction

Ball bearings represent the essential component of any rotary machine, making the application range of this hardware huge. Any type of failure can slow down, put pressure on other components or even cause the machine to fail. Due to the widespread applicability of bearings, any malfunction is an expensive task, especially in the case of large machinery (e.g. wind turbines, planes, production machines, etc.) and may even involve further safety risks (e.g. plane and car bearings) for the people who are in charge with their control. Condition monitoring comes as a valid solution to these problems. Wind turbines are a valuable example, since without any predictive maintenance turbine bearings may fail, resulting in complete halt of the system, and thus, costing the responsible maintenance company a fortune to troubleshoot the mechanism in due time. With condition monitoring, the maintenance company has real-time access to the health state of the bearing, and so they can schedule remedial works/component replacement dates prior to a possible, yet inevitable failure, hence reducing the expediting expenses for repairs and loss of profit caused by the defective machinery.

Different popular methods which have been applied to handle and analyses data on the parts of any rotary machine cover traditional computation methods, close to simple thresholding techniques and statistical methods, see the research study by Vanem (2018). Nevertheless, all these solutions are conditioned by the fact that they require a specialist with expertise in the field for a correct system diagnosis. This is the main reason why it is important to acknowledge the value of artificial intelligence therein.

Though until the present days, a wide variety of computational intelligence techniques have been used for condition monitoring, in this paper we aim at presenting an effective condition monitoring technique which can be achieved in only a few steps - by using a data acquisition sensor, applying a suitable method to interpret and pre-process data (feature extraction) and setting a type of neural network for result classification.

Data acquisition can be achieved in multiple ways: by means of a vibration sensor, a microphone with electrical signals measured directly on the engine/ or a turbine which spins the bearing. By far the most popular method of data acquisition is using a vibration sensor, because the data is relatively easy to measure and it provides plenty of useful health state information. Raw data is measured in time/amplitude domain, making it almost impossible to generalize over a wide range of bearings, since the predictive accuracy is influenced by multiple test dependent variables (the rotation speed and size of the ball bearing). This kind of raw data predictive test was already tested by creating a 20 X 20 vibration image from 400 data signals and classifying results by means of a CNN (Convolutional Neural Network), see the study of Hoang et al (2019). In order to generalize our prediction model (to remove bearing size, and rotation) we needed to transform the time/amplitude domain into a frequency/amplitude domain, and so we started using Digital Signal Processing (DSP) methods.

Feature extraction is accomplished by DSP methods, to generate a valid input for artificial intelligence models. Most well-known DSP methods are Fast Fourier Transform (FFT), Short Time Fourier Transform (STFT), Mel-frequency Cepstral Coefficient (MFCC). For classifying the health state of the bearing, different types of machine learning procedures were used, due to the powerful pattern recognition that such algorithms have.

The first objective of this enterprise is to provide an accurate prediction for the health state of a bearing using DSP techniques. From the vast literature available in the field, we chose to begin by replicating the work from Hoang et al (2019) research, where an approach with CNN was tested using a method for creating vibration images from raw signal data.

In this paper, we focused on providing diversity to condition monitoring (namely, we chose to test the multiple scenarios of the suggested methods), and on recommending different approaches to the source study. Our aim was to study the reaction of various traditional machine learning classification methods in updated contexts, such as condition monitoring.

Distribution of bearing classes on different data sets

Real-life applications often come with incomplete, imprecise or fluctuating data sets. Therefore, within our test, we focused on different datasets characterized by distinct and specific features.

Our testing approach involved three data sets: Case Western Reserve University Bearing Data, for different details see Case Western Reserve University Bearing Data Center Website, NASA Ames Prognostics Data Repository, see the work of Lee et al (2007), and Bearing vibration data collected under time-varying rotational speed conditions, details in Huang et al (2018) research. These data sets which provide vibration data at different sample rates, bearing sizes and testing conditions, served at seeking to generalize the classification efficiency of our models.

The Case Western Reserve University Bearing Data is our main data set. The fact that within the data set there are four classes of possible health states and behavior with four bearing stress (load) tests, make our NN training efficient, and provide us with a better understanding of possible frequencies generated by a bearing. This data set description is as follows, the testing bench 1 with a 2hp motor on the left, a encoder in the center and a dynamometer on right, two SKF bearings, FE (Fan End) and DE (Drive End). Faults were introduced using electro-discharge machining with fault diameters of 7, 14, 21, 28, and 40 mm, detailed on Case Western Reserve University Bearing Data Center Website. The bearings were tested under different load conditions (0, 1, 2, 3hp) with each fault type that was induced (ball, inner raceway, outer raceway and healthy). Each test of this type was sampled by the acquisition sensor (vibration sensor) at 12k and 48k samples for about 20 seconds (normal) and 40 seconds (fault types). The first round of tests were conducted with the four possible health states on DE bearing with the FE bearing healthy, and the second round was with DE bearing healthy and FE bearing with all four possible health states. More than that, Case Western Reserve University Bearing Data is a clean data set with no NaN values, the data files contain the vibration values for DE and FE bearings. The normal health state has registered over 240.000 values (approximately 20 seconds of acquisition) and for the 3 fault states over 480.000 values (approximately 40 seconds) for each state.

Introduction in Digital Signal Processing

Machine condition monitoring is the technology which consists in measurements (by sensors for obtaining necessary data), followed by the data pre-processing stage (which can be missing in some cases), feature extraction (the mechanism of presenting a signal as a set of characteristics that easily discriminates between pattern classes of the original signal; this is also the fundamental component of any classification procedure) and the classification question (or the identification of the operating state of the machine and the type of failure).

Aspects about the Fourier Transform

The Fourier Transform is a mathematical method that it is used to transform a signal from time to frequency domain. This process usually makes the signal easier to understand, see different characteristics in the article of Siemens community, 'What is the Fourier Transform?'.

The idea behind this theory is that any signal can be decomposed as a series of sine waves with different amplitude and phase. For example, in the Fig 1. is shown how a signal (purple) is decomposed in three sine waves (red, gray and green) with different amplitude. The vertical lines represent the frequency.

Fig. 1: Decomposing a signal into a series of sine waves

From a mathematical way of looking at it, the Fourier Transform is:

$$S_x(f) = \int_{-\infty}^{+\infty} x(t)e^{-j2\pi ft}dt$$

where $S_x(f)$ is the result in frequency, $x(t)$ is the input in time domain. The result comes in complex number (ex. $a + bj$ where a is the real part and b imaginary part). The complex numbers contain information about the amplitude and phase of the related frequency.

Using the following formula:

$$ampl = \sqrt{a^2 + b^2}$$

we can find resourceful information about the signal.

In practice, we used STFT which is a Fourier-related operation. The main difference is that a signal is framed into smaller segments (usually the size of a segment is a power of two, for computation reason). Each frame then is converted into the frequency domain by using the Fourier formula. Another big difference is the appearance of overlap term. Each window has some information from the passed windows. As a result, we will have more information about the signal, more resolution and accuracy.

Mel-frequency Cepstral Coefficient

Looking in 'Mel Frequency Cepstral Coefficient (MFCC) tutorial' you can see that MFCC is a feature extraction technique used in speech recognition. Cepstrum represent a sequence of numbers that gives information about a frame, being similar to an auto-correlation sequence. It is the result of process where the power signal is log compressed (Inverse Discrete Fourier Transform of the log power signal).

$$IDFT\left(log\left(P(k)\right)\right) \longrightarrow C(n)$$

An important aspect is going in the Mel Scale. This new scale perceives the frequency to in a logarithmic way, being similar to the way humans understand sound. We are far better at discerning small changes at low frequencies rather than at high frequencies.

Using the below formula, we can convert to Mel scale:

$$M(f) = 1125 * \ln\left(1 + \frac{f}{700}\right)$$

The MFCC feature extraction technique basically includes:

- Divide the signal in windows.

  This step is about framing the signal into smaller segments because on short periods, the information doesn't variate too much, making us able to retain as much information as we can.

- Estimate the periodogram of each frame.
- Filter the result using Mel filters.

  These two steps are motivated by the way a human perceives the sound. A human doesn't discern the difference between two closely spaced information. Here comes handy the Mel-filterbank. This filter is very narrow at low frequency, meaning we will have more information on this kind of frequencies and less details as it gets higher (the filter will become wide).

- Apply log on the filtered data.

Applying logarithm on the filtered result is motivated by the human hearing (humans don't perceive sound linearly). In the final step, the sequence is correlated because of the overlap in the filter bank.

- Decorrelate the data using DCT (Discrete Cosine Transform).

  Therefore, we apply Discrete Cosine Transform to decorrelate the data (have more information about the signal).

- Keep 2-13 coefficients from the DCT and discard the rest.

  We store only a small part of this result because it has fast changes as the sound degrades.

  This is the step that we've done for our approach as well.

Condition classification problem. Overview of artificial neural network.

Data-based models are the most elastic approach to automated condition monitoring. Data-based models apply when the process model is not known in the analytical form and expert knowledge of the process performance under faults is not available. Designing successful machine learning technique for a here and now problem might only be possible by incorporating the knowledge acquisition flexibility from each new consideration. This is possible by entirely reproducing a new knowledge base from the new observation to which all previous considerations are added. It is constructive that the system should learn from each newly available observation, while preserving the already acquired knowledge.

Artificial neural network are highly capable data processing systems, able to learn elaborate input - output connections from given data. Any typical neural network incorporates a great amount of simple processing elements called neurons which are interconnected in an architectural structure.

As an artificial neural network, we’ve selected Multilayer Perceptron (MLP) which is “feed-forward neural network”, also see details in Wikipedia website, meaning that the data only goes in a single way through the network. In a nutshell, from an architectural point of view an MLP is built with minimum three layers: input layer, minim one hidden layer and one output layer.

- The input layer where the data is mapped as features in neurons.
- The hidden layers where the weights are updated.
- The output layer where the class/result is predicted.

In this section, we are going to describe the flow of MLP that we used. First of all, as input data we had two different kinds of features: the frequency extracted from STFT and the coefficients from MFCC. To note that we didn't combined these two kinds of data because they're totally different. Having this data, the activation function RELU (Rectified Linear Unit), see the next formula:

$$y = max(0, x)$$

was used to activate the most "excited" neurons and go forward through the hidden layers. After applying loss function (Cross Entropy):

$$los = -\frac{1}{n}\sum \log y' \, y$$

where n = number of entry data, y' = predicted label and y = true label) we use backpropagation to calculate the gradient and update the weights of each neuron according to the true label. In the end, on the output layer, the predicted label (types of fault on the bearing) are the results of activating the neurons using SoftMax function:

$$softmax(x) = \frac{e^x}{\sum e^x}$$

The detailed architecture of the ANN for our tests is shown in Fig. 2, where:

- dense_1_input: represents the first input layer (13 is the number of MFCC coefficients obtained with digital signal processing techniques after preprocessing the vibrations emitted by the bearing). For our STFT tests we used a different input layer (2048 coefficients);
- dense_1: is a 32 neurons hidden layer, the rectifier neuron function is ReLu;
- dropout_1: is a layer under dropout, which randomly cutting 0.2 (20%) network connections between layers during each iteration. The function of dropout is to increase the robustness of the model and also to remove any basic dependencies between the neurons;
- dense_1: is a 64 neurons layer, with ReLu activation function;
- dropout_2: is a layer under dropout, cutting again 0.2 network connections between layers;
- dense_3: The last/output layer, with 4 neurons (healthy, inner_race, outer_race, ball). We used softmax function, regarded as the probability of belonging to a certain class.

Fig. 2: The detailed network graph of the ANN tuned for MFCC, Keras's API

Since we have a classification problem, in terms of cost function, we chose categorical_crossentropy. The used optimizer was Adam due to the 'adaptive' way of changing the learning rate.

Experimental Results and Discussion

As mentioned in the introduction, the starting point for our research was the study of Hoang et al (2019), so firstly, we tried to replicate the experiment. Our results were in some measure successful, Table 1.

Table 1: Our results when we've repeated the experiments from Hoang et al (2019). Trained on DE bearing and tested FE bearing using Raw Vibration Images on a CNN

Trained/Tested	0hp FE	1hp FE	2hp FE	3hp FE	0, 1, 2, 3hp FE
0hp DE	61%	63%	62%	63%	70%
1hp DE	71.93%	72.45%	67%	78%	77%
2hp DE	70.97%	81.35%	71%	77%	76%
3hp DE	69.48%	71.32%	69%	78%	74%
0, 1, 2, 3hp DE	69.32%	70.87%	68.39%	67.34%	70.12%

The method used for creating the necessary input for a neural network was the following: split the raw vibration sensor data into 400 samples chunks, create a 20 X 20 image based on each 400-sample chunk, feed the CNN directly with this image. There are some limitations to this pre-processing method of. First of all, this technique is heavily dependent on the rotation speed of the bearing, and secondly, it depends on the sample rate of the acquisition sensor. This means that the method described in Hoang et al (2019) works only on the current type of bearing, the same that the CNN is trained. Using this method will provide unsatisfactory results when tested with a different configuration (e.g. bearing, rotation speed or sample rate).

A test strategy (I) – STFT

In this approach, as a preprocess tool, we used STFT to frame the signal into smaller segments in order to train a machine learning model, in our case MLP, to recognize the states of a bearing. Our idea to generalize was by looking at the fundamental frequencies of a ball bearing, see 'Rolling element bearing components and failing frequencies'. We noticed that there are specific frequencies emitted by the inner/outer cage and the ball. Thus, we tried to see if we can extract a recurrent pattern from raw vibration data from Fig 3 and Fig 3' using DSP methods, more precisely FFT, STFT, see Fig 4 and Fig 4'.

Fig. 3: Signal plots of raw data in amplitude/time domain (Normal signal - left, Ball fault state signal - right)

Fig. 3': Signal plots of raw data in amplitude/time domain
(Inner race fault state signal - left, Outer race fault state signal - right)

Fig. 4: The same signals transformed with STFT in amplitude/frequency domain
(Normal state spectrogram - left, Ball fault state spectrogram - right)

Fig. 4': The same signals transformed with STFT in amplitude/frequency domain
(Inner race fault state spectrogram - left, Outer race fault state spectrogram - right)

Obviously, a pattern emerged, a pattern that is not dependent of the sample rate, nor the rotational speed (since the Fourier Transform changes the domain into amplitude/frequency), in contrast with the starting article, Hoang et al (2019), their method of creating the data heavily depends on the sample rate and rotational speed of the bearing (e.g. if the sample rate or the rotation speed increases, the vibration image will get distorted and the ANN won't be able to recognize the pattern). The pattern is persistent on all load types (0, 1, 2 and 3hp). Afterwards, we started to analyze the data set using most popular DSP methods. To see explicitly if the health state (prediction classes) are separable we used Principal Component Analysis (PCA), a statistical procedure that reduces the dimensionality of the given data to project it in a lower dimensional space, thus, it resulted Fig 4 for Fourier Transform.

Fig. 5: FFT components resulted using PCA
(PCA of FFT for DE bearing - left, PCA of FFT for the FE bearing - right)

Consider that using the FFT/STFT extraction method from Fig 5, the PCA components and training accuracy depend on the FFT size and window, see results in Table 2.

Table 2: Trained on DE bearing and tested FE bearings with STFT frames

Trained/Tested	0hp FE	1hp FE	2hp FE	3hp FE	0, 1, 2, 3hp FE
0hp DE	80.13%	71.56%	71.46%	71.70%	70.46%
1hp DE	70.26%	74.93%	71.70%	71.70%	72.05%
2hp DE	80.13%	72.28%	70.98%	71.70%	72.44%
3hp DE	80.13%	74.45%	84.24%	71.80%	72.89%
0, 1, 2, 3hp DE	80.63%	75.42%	72.66%	71.22%	71.86%

With this data, we trained our neural network, having, much of the same success, around 98% when training and testing on the same bearing, where with ANN method described in Hoang et al (2019) gave in our tests around 80% accuracy on training and testing on the same bearing.

Some clusters from Fig 5 are overlapped so the training on one bearing and testing on another will not have a perfect prediction on faults as it can be seen in the confusion matrix in Fig 6 (last class represents the "healthy" state), but will have very good prediction on classifying if the bearing is anything other than the "normal state".

```
[[ 52   0 185   0]
 [  0   0 236   0]
 [ 11   0 226   0]
 [  0   0   0 836]]
```

Fig. 6: Confusion matrix of the results (test strategy (I))

Most certainly, the results can be improved using a variable Fourier Transform window size with frequency tracking (when there is a variable RPM for the bearing).

A test strategy (II) – Mel Frequency Cepstral Coefficients

In the second approach, we exploited MFCC as a preprocess DSP tool because it emphasizes the bearing sound in a logarithmic scale (more closely to the way a human perceives sound) and also giving us a reduced input for our model (MLP) due to a small number of decorrelated features extracted. As indicated in Fig 7, using PCA technique on the MFCC features, the classes of bearings faults can be identified as clusters.

Fig. 7: MFCC components resulted using PCA
(PCA of MFCC for DE bearing - left, PCA of MFCC for the FE bearing - right)

From the input signal of bearing, we kept an average of 12 MFCC, because of the degradation sound mentioned in the MFCC section and then normalized the data. Another important aspect of our testing is that the FE (Fan-End) and DE (Drive-End) bearing are different models (the size is not the same), but even with that condition, the PCA on MFCC has the same components in roughly the same place, making our ideal of generalizing neural network on classifying bearing faults closer to reality.

At the start, we trained our AI model on one kind of bearing and tested on the same but with different loads(hp). We had very good results, accuracy around 98% (comparing to the vibration image method that has an accuracy of about 80% in our testing) because the MFCC rather it is based on the extraction of features from the way a bearing sounds while STFT extracts the prominent frequencies. Following this, we trained our MLP with normalized data of a bearing and tested on the other bearing (situated in opposite parts of the working bench), see Table 3.

Table 3: Trained on DE bearing and tested on FE bearing using MFCC features

Trained/Tested	0hp FE	1hp FE	2hp FE	3hp FE	0, 1, 2, 3hp FE
0hp DE	80.67%	85.45%	83.11%	84.13%	83.14%
1hp DE	79.92%	85.35%	84.69%	85.03%	84.83%
2hp DE	79.89%	83.03%	82.15%	82.28%	84.63%
3hp DE	74.39%	84.66%	80.48%	82.37%	76.65%
0, 1, 2, 3hp DE	79.97%	82.11%	78.77%	80.91%	83.71%

The results could have been better, but the main reason of this accuracy is that two classes are confused between them. It's about the inner race and outer race. This type of behavior can also be observed in Fig 7. The green and blue label representing these two classes are switched between them. This act can also be seen in the confusion matrix from Fig 8.

```
[[ 929    9   10    0]
 [   3    0  949    0]
 [  53    0  898    0]
 [   0    0    0 3320]]
```

Fig. 8: Confusion matrix of the results (test strategy (II))

This is not a problem to say the least, our neural network will still identify the inner/outer race condition as "not normal" even with the confusion of these two classes. Having in mind the fact that a prediction requires as input low number of samples (in order of milliseconds), we can repeat the test many times (predict more parts of the signal) in order to give a confident result on the health state.

A test strategy (III) – Evaluation on NASA bearings set

As a way of final testing for the proposed criteria of "reaching a general prediction of the state with any given ball bearing" we did the following test: we trained a neural network using MFCC from first data set from Case Western Reserve University Bearing Data Center Website, and tested on some parts of NASA Ames Prognostics Data Repository, research details of Lee et al (2007). We took two large samples based on their description of health state, one chunk of is comprised of healthy bearing data, the second chunk is based on faulty bearing data (must pe precised that the fault type was not given). We processed those chunks using MFCC and then feed it to our neural network. The results were unexpected, when the state of bearing was stated as healthy, our neural network gave a prediction as "normal" state, and when the state was given as faulty our network gave the "outer cage" state (which is a fault state).

Apparently processing with MFCC got rid of all working variables and successfully predicted a normal and fault state (based on their description of data set) on other data with a completely different bearing and rotational speed.

Conclusion

Due to digital drive technology, a great amount of data is available, and it allows operators to keep the state of a drive or machine under constant observation. When combined with the fitting analytical tools, it may also be used for predictive maintenance. Traditional maintenance methods, in which systems are monitored at regularly set intervals, are not based on the actual condition of the systems in question. This means that the inspection of the systems may be scheduled too early or too late for proper intervention.

While premature maintenance is acceptable and has little effect on expenses, belated maintenance could involve serious machinery damage or even failure. In other words, it could have consequences which are both risky and costly. Thus, condition-based maintenance of drives is necessary in order to avoid such perilous outcomes.

While mixing DSP and neural networks is not yet popular technology, it could be a solution to problems that cannot be resolved in any other way. Condition monitoring on mechanical components is possible, since most, if not all components exhibit a behavior that fluctuates when faults arise, and such behaviour can be registered with a microphone or a vibration sensor. Data recorded in such manner can be transformed into patterns using techniques from DSP field and then classified by means of neural networks. The result is a quick and efficient response on the real-time state of the component.

When taking into account the condition monitoring problem, we must bear in mind the necessary prediction that a bearing is "healthy" or has a fault, but what we obtained in our tests before is much more than just that. We tried to specify the defect cause of the bearing, with good results in the configuration train and test on the same kind of bearing with mild success on other configuration train on one type of bearing and testing on another. The results in Table 1, Table 2 and Table 3 were obtained with tests with the train on one type and the test on different type.

In the end what is emphasized by our tests is the fact that we can truly predict between "healthy" and "faulty" states of a bearing using Digital Signal Processing field and Neural Networks.

Abstract

In the literature concerning stock exchanges authors often refer to the concept of market development. At the same time, in most cases they do not provide a precise definition of this term and measures for distinguishing between developed and emerging markets. In fact, there is no single criterion that can be used to measure and assess stock market development. We provide a list of indicators capturing its different aspects and apply them in a comparative analysis of the European stock exchanges. For this purpose, we apply two clustering methods – the *K*-means and the Ward hierarchical algorithms. We conduct the study aimed at reducing the set of the proposed indicators to the most informative ones and find the optimal clusterization.

Keywords: Stock Markets Development, Clustering, Development Indicators.

Introduction

In times of increasing financialization, effective financial markets are one of the most important factors for economic growth. They help to efficiently direct savings and investment in the economy, enabling optimization of the accumulation of capital and the production of goods and services. One of the most critical to modern financial market is a well-developed stock market. The term "developed stock market" is often used in the literature, although in most cases it is not precisely defined. Broadly speaking, it can be understood as a stock market's ability to fulfill its main functions in an economy. It means that there is no single criterion that can be used to measure stock market development. Consequently, only one or two indicators will not be enough to capture all of its aspects (El-Wassal, 2013). For this reason, in the literature one can find several propositions of such indicators, which can be grouped according to some specified main aspects of stock markets development they capture, including market size, liquidity, volatility and concentration, however other attributes can be additionally considered as well (cf. Demirgüç-Kunt and Levine, 1996; El-Wassal, 2013; Bayraktar, 2014 and references therein).

To compare objects in terms of several different indicators which characterize their features, one can apply cluster analysis. Clustering can be considered one of the most important unsupervised learning problems. It involves multivariate methods which aim to classify individuals on the basis of a set of measured variables into subsets (clusters), such that those within each cluster are more closely related

to one another than objects assigned to different clusters. The result of clustering is satisfactory if obtained groups are homogenic and well-separated.

The purpose of this paper is to cluster European stock markets in terms of their development level. In the study we apply two clustering methods – the *K*-means and the Ward hierarchical algorithms. We provide a list of indicators capturing different aspects of stock markets development and conduct the study aimed at reducing the set of the proposed indicators to the most informative ones.

The rest of the paper is organized as follows. Section 2 provides an outline of the cluster analysis and describes the *K*-means and the Ward clustering methods. Section 3 presents the empirical research – data applied, detailed description of the study and its results. Section 4 provides the conclusions.

Clustering Methods

Most clustering methods are based on two popular techniques known as hierarchical and partitional clustering. Algorithms of hierarchical clustering generate a cluster tree (dendrogram) by using heuristic splitting or merging techniques. By contrast, partitional methods usually require that the number of clusters and an initial clustering be specified as an input to the procedure (cf. Omran et al., 2007; Clarke et al., 2009).

In the paper we apply two clustering algorithms: the *K*-means and the Ward methods. The *K*-means method is one of the most popular partitional clustering technique. It is designed to find clusters that minimize the intra-cluster distances, calculated using the within-cluster sum-of-squares:

$$\sum_{k=1}^{K} \sum_{i:x_i \in C_k} (\|x_i - \mu_k\|^2), \tag{1}$$

where K is the number of clusters, C_k $(k = 1,2,\dots,K)$ denote clusters, μ_k are centroids (usually described by the mean of points in the cluster C_k). In order to find the best clustering, the iterative algorithm is performed. It starts with randomly selected (or derived from *a priori* information) initial *K* centroids. Then each point in the data set is assigned to the closest cluster (i.e. to the closest centroid), based on the distance function. Next, based on the absorbed cases, new centroids are calculated. This process is repeated until convergence is achieved.

The Ward method is a technique of hierarchical clustering. Like other agglomerative technique, it builds nested clusters by merging them successively. The obtained hierarchy of clusters is represented as a tree (dendrogram). This method starts with all the data points assigned to their own clusters. Then two clusters are merged into the same cluster. To find which clusters should be merged on each step, the criterion of minimization of the error sums of squares (1) with $\mu_k = \bar{x}_k$ is applied. In the end, the algorithm terminates when there is only one cluster left.

Obviously, the results of clustering depend on the applied method and the values of its parameters (e.g. the analyzed number of clusters). For this reason, the validation measures should be applied to assess obtained clusters. Such measures not only validate clustering but additionally can be used as the tool for choosing the best clustering method and its parameters. One of such method, often used in the literature, is the silhouettes analysis (Rousseeuw, 1987). Silhouettes measure similarity of each point to its own cluster compared to other clusters. For each point x_i they are defined by:

$$s(i) = \frac{b(i) - a(i)}{\max(a(i), b(i))}, \tag{2}$$

where $a(i)$ is the mean dissimilarity between x_i and the points in the cluster C that contains x_i, i.e.:

$$a(i) = \frac{1}{|C|-1} \sum_{x_j \in C, j \neq i} d(i,j) \tag{3}$$

and $b(i)$ is the smallest average dissimilarity between x_i and all points in any other clusters, i.e.:

$$b(i) = \min_{C_k \neq C} \frac{1}{|C_k|} \sum_{x_j \in C_k} d(i,j). \tag{4}$$

If $|C| = 1$ then Eq. (3) cannot be calculated, therefore in such cases it is assumed that $s(i) = 0$.

By definition, silhouettes have a range of $\langle -1,1 \rangle$. A large value of $s(i)$ (close to 1) means that the point x_i is well classified, i.e. it has been assigned to an appropriate cluster. A value of 0 indicates that x_i is close to the decision boundary between two neighboring clusters and negative value indicates that it might have been assigned to the wrong cluster.

The Eq. (2) allows to calculate the silhouettes for single points. However, to assess the quality of all K clusters, one should calculate the average coefficient for the entire data set:

$$\bar{s}(K) = \frac{1}{N}\sum_{i=1}^{N} s(i), \tag{5}$$

where N is the number of points. The value SC given as the maximum value of $\bar{s}(K)$, taken over all K for which the silhouettes can be constructed, is called the silhouette coefficient. According to Kaufman and Rousseeuw (2005) the silhouette coefficient can be interpreted in the following way:

- $SC \leq 0{,}25$: no substantial structure has been found,
- $0{,}26 \leq SC \leq 0{,}50$: the structure is weak and could be artificial,
- $0{,}51 \leq SC \leq 0{,}70$: a reasonable structure has been found,
- $0{,}71 \leq SC \leq 1$: a strong structure has been found.

Empirical Study

In our study we performed a comparative analysis of European stock exchanges to identify markets with a similar level of development. Twenty-three European stock exchanges were examined, including stock exchanges of individual countries as well as exchanges resulting from the merger of stock exchanges of several countries (see Table 1).

Table 1: List of stock exchanges used in the study

Stock exchange	Country/Countries
Athens Stock Exchange	Greece
BME Spanish Exchanges	Spain
Borsa Istanbul	Turkey
Bucharest Stock Exchange	Romania
Budapest Stock Exchange	Hungary
Bulgarian Stock Exchange	Bulgaria
Prague Stock Exchange	Czechia
Vienna Stock Exchange	Austria
Cyprus Stock Exchange	Cyprus
Deutsche Börse AG	Germany
Euronext	Belgium, France, Ireland, Netherlands, Portugal
Kazakhstan Stock Exchange	Kazakhstan
Ljubljana Stock Exchange	Slovenia
LSE Group	United Kingdom, Italy
Malta Stock Exchange	Malta
Moscow Exchange	Russia
Nasdaq Nordic and Baltics	Sweden, Denmark, Finland, Iceland, Estonia, Latvia, Lithuania
Oslo Stock Exchange	Norway
SIX Swiss Exchange	Switzerland
Ukrainian Exchange	Ukraine
Warsaw Stock Exchange	Poland
Zagreb Stock Exchange	Croatia
Luxembourg Stock Exchange	Luxembourg

Two clustering methods, the *K*-means and the Ward hierarchical methods were used to conduct the study. In both these methods, the selection of the appropriate number of clusters into which data should be divided, consisted of maximizing the silhouette coefficient, calculated for the number of clusters from 2 to 10. All calculations were made using own computer codes written in Python. For clustering algorithms and the silhouette coefficient, the Scikit-learn library was used.

The level of development of the examined stock exchanges was described by means of various indicators (explanatory variables) closely related to the stock market and macroeconomic data of individual countries (see Table 2). The data used come from the end of 2019 and were compiled on the basis of statistical databases of the following institutions:

- World Federation of Exchanges (WFE),
- Federation of European Securities Exchanges (FESE),
- European Statistical Office (Eurostat),
- Organization for Economic Cooperation and Development (OECD).

Table 2: Indicators used in the study

Indicator	Description
Market capitalization	The sum of the total market capitalization of each domestic company and exclusively listed foreign companies. Indicator type: monetary. Source: WFE, FESE.
Market capitalization to GDP	The total capitalization of the stock market in relation to the country's GDP. In the case of stock exchanges covering several countries, the sum of GDPs from all component countries is applied. Indicator type: percentage. Source: own calculations based on WFE, FESE (Market capitalization) and Eurostat, OECD (GDP).
Total value traded	The total number of shares traded (domestic and foreign companies) multiplied by their prices. Trades effected automatically through the exchange's electronic order book (EOB). Indicator type: monetary. Source: WFE, FESE.
Turnover ratio	Total value traded to market capitalization (see above). Indicator type: percentage. Source: own calculations based on WFE, FESE data.
Total value traded to GDP	The total value traded in relation to the country's GDP. In the case of stock exchanges covering several countries, the sum of GDPs from all component countries is applied. Indicator type: percentage. Source: own calculations based on WFE, FESE (Total value traded) and Eurostat, OECD (GDP) data.
Foreign value traded to total value traded	The percentage of total value traded generated by foreign companies. Indicator type: percentage. Source: own calculations based on WFE, FESE data.
Total number of listed companies	The number of domestic and foreign companies that have shares (including several classes) listed on the stock exchange. The number does not include investment funds, unit trusts, ETFs and companies whose sole business purpose is to hold shares of

	other listed companies, such as holding companies and investment companies. Indicator type: full number. Source: WFE, FESE.
Foreign listed companies to total number of listed companies	The percentage of foreign listed companies in the total number of listed companies. Indicator type: percentage. Source: own calculations based on WFE, FESE data.
Average company capitalization	Market capitalization to total number of listed companies. Indicator type: monetary. Source: own calculations based on WFE, FESE data.
Number of listed companies per million of population	The total number of listed companies per million inhabitants. Indicator type: decimal. Source: own calculations based on WFE, FESE (Number of listed companies) and Eurostat, OECD (Population) data.
Total number of trades	The actual number of transactions (domestic and foreign companies) which have occurred during the year. Trades effected automatically through the exchange's electronic order book (EOB). Indicator type: full number. Source: WFE.
Number of initial public offerings (IPO) to total number of listed companies	The total number of companies whose shares were admitted to listing during the year through an offer of subscription or sales of shares divided by total number of currently listed companies. Indicator type: percentage. Source: own calculations based on WFE, FESE data.
Capital raised from initial public offerings to market capitalization	The aggregate value of the money raised through IPO divided by market capitalization. Indicator type: percentage. Source: own calculations based on WFE, FESE data.

To ensure a balanced effect of all variables on the grouping result, the data has been standardized prior to clustering. Lack of standardization gives a greater impact on the result obtained by variables expressed in larger numbers. For this purpose, all the variables were normalized using the *Z*-score formula, defined as:

$$z = \frac{x-\mu}{\sigma}, \tag{6}$$

where μ is the mean and σ is the standard deviation (Jain and Dubes, 1988). After the normalization process, all the transformed variables have the mean of 0 and the variance of 1.

First, we investigated stock exchanges using all variables listed in the Table 2. In this case, both the *K*-means and the Ward methods led to low values of the silhouette coefficient (see Fig. 1). In the case of the *K*-means algorithm the silhouette coefficient had the highest value (0.357) when dividing the stock exchanges into two groups. As the number of groups increased, the silhouette coefficient deteriorated. In the case of the Ward method, it took the highest value (0.337) for ten groups. According to Kaufman and Rousseeuw (2005) the structures indicated by both methods should be considered as weak and can be artificial.

Fig. 1: Silhouette coefficients for the *K*-means and Ward methods – all variables

Poor clusterizations obtained can be caused by the excessive number of variables, which can contain spurious or duplicated information. Such variables may prevent providing a good division of the investigated stock exchanges into homogenic and well-separated groups. To avoid this problem, additional steps have been taken to eliminate part of the variables. First, we decided to incorporate to the reduced set of indicators three variables which are most often used in the literature to quantify stock exchanges development, i.e.: market capitalization to GDP, the turnover ratio and total value traded to GDP (cf. Demirgüç-Kunt and Levine, 2004; Lakštutienė, 2008; Beck et al., 2010; Nyasha and Odhiambo, 2016; Tasmaganbetov et al., 2018). Then all other combinations of additional explanatory variables were consecutively added to these three basic ones and the corresponding silhouette coefficient was calculated. According to the criterion of the silhouette coefficient maximization, the following six explanatory variables were selected that made up the final model:

- market capitalization to GDP,
- turnover ratio,
- total value traded to GDP,
- foreign listed companies to total number of listed companies,
- average company capitalization,
- total number of trades.

It turned out that this reduced set of indicators led to the much better clusterization. For both the *K*-means and Ward methods, the silhouette coefficient indicated the split of the investigated markets into five groups. In this optimal case, both methods resulted in the same allocation of the individual stock exchanges to obtained clusters. Figure 2 presents the way in which the silhouette coefficient for both methods was shaped depending on the different number of clusters. The maximum silhouette coefficient (obtained for five clusters) equaled 0.545.

Fig. 2: Silhouette coefficients for the *K*-means and Ward methods – six selected variables

The obtained optimal division of the investigated stock exchanges into groups is presented in Table 2. The silhouette for each stock exchange has been shown in brackets - next to the stock exchange name.

Table 3: Results of clustering for six best performing variables

Group 1	Group 2	Group 3	Group 4	Group 5
SIX Swiss Exchange (0.000)	Borsa Istanbul (0.000)	Deutsche Börse AG (0.403)	Prague Stock Exchange (0.608)	Athens Stock Exchange (0.729)
		Euronext (0.557)	Vienna Stock Exchange (0.719)	BME Spanish Exchanges (0.366)
		LSE Group (0.454)	Luxembourg Stock Exchange (0.664)	Bucharest Stock Exchange (0.760)
		Moscow Exchange (0.185)		Budapest Stock Exchange (0.729)
		Nasdaq Nordic and Baltics (0.347)		Bulgarian Stock Exchange (0.762)
				Cyprus Stock Exchange (0.684)
				Kazakhstan Stock Exchange (0.539)
				Ljubljana Stock Exchange (0.762)
				Malta Stock Exchange (0.756)
				Oslo Stock Exchange (0.319)
				Ukrainian Stock Exchange (0.722)
				Warsaw Stock Exchange (0.729)
				Zagreb Stock Exchange (0.751)

Two investigated markets, namely the Swiss and the Turkish stock exchanges were indicated as outliers. The SIX Swiss Exchange was placed in the single group because it clearly stands out from the other stock exchanges. It has the highest capitalization ratio, the highest total value traded to GDP and is also distinguished by the highest average capitalization of listed companies. Therefore, it can be assumed that the Swiss stock exchange presents the highest level of development among all the analyzed European stock exchanges. The second identified outlier is the Turkish stock exchange, which is characterized by the highest turnover ratio, therefore Borsa Istanbul can be considered the most liquid market.

The third group consists of highly developed five stock exchanges, including: Deutsche Börse AG, Euronext, LSE Group, Moscow Exchange and Nasdaq Nordic and Baltics. The stock exchanges representing this group are distinguished by the highest values of most of the explanatory variables used. It should be noted that Euronext, LSE Group and Nasdaq Nordic and Baltics consist of more than one stock exchange. These are all three markets of this type in our study and all of them they have been placed in the same group. This shows that the merger of stock exchanges can contribute to their growth

and market position. The market that is on the verge of this group is the Russian stock exchange, which has the lowest value of the silhouette coefficient comparing to other markets forming this group.

The fourth group consists of three stock exchanges, which aspire to be highly developed stock exchanges. They are characterized by the highest share of foreign listed companies in the total number of listed companies. All these three stock exchanges have high and relatively similar silhouettes, which means that they constitute the homogenic and well-separated group.

The fifth group consists of the exchanges that can be treated as emerging markets. Most of them are characterized by a high silhouette, which indicates that they are well suited to this group. However, there are two exchanges with outlying silhouettes – BME Spanish Exchanges and Oslo Stock Exchange. In consequence, both these stock exchanges can be regarded as slightly standing out from this group.

Summary

In the study two clustering methods were used to assess the level of development of European stock exchanges: *K*-means and Ward hierarchical methods. In the first stage, both methods were applied using all prepared indicators. However, the use of so many indicators resulted in a poor division of the examined stock exchanges into groups, which was reflected by the low value of the silhouette coefficient. For this reason, in the second stage, the elimination of redundant variables was performed to identify the set of indicators which maximizes the silhouette coefficient. Based on the identified variables we were able to substantially increase the quality of obtained clusters.

The conducted study allowed to indicate the division of European stock exchanges into groups in terms of their level of development. Apart from two outlying stock exchanges, they can be divided into three groups, i.e.: highly developed, aspiring to the status of highly developed and emerging ones. The study also clearly confirmed the impact of merging stock exchanges of different countries on their level of development. This consolidation has a very good impact on the level of development and on the position of the stock market on the international stage. Merging exchanges is a very good opportunity for all exchanges that are at the development stage, so that in the near future they can aspire to a group of highly developed exchanges. This would undoubtedly bring a lot of benefits for a given stock exchange as well as for the participants of a given market.

Social Factors Supporting the Image of The Organisation on The Example of TOP 500 Companies – Poland

Aleksandra CZARNECKA

Czestochowa University of Technology, Czestochowa, Poland
aleksandra.czarnecka@wz.pcz.pl

Abstract

In the economic situation of today, businesses are required to take various actions to increase their attractiveness or to distinguish them from the competition. The need for competition affects typical marketing areas, as well as those related to the acquisition and maintenance of the company's strategic resources, in particular – employees. Companies build and cater to their image, not only as an attractive products or services provider, but also a reliable employer. An employer branding strategy can be a tool supporting the organisations in these activities. The organisations, aware of their impact on society and the environment, increasingly take into account the principles of corporate social responsibility (CSR) in connection with their business.

The aim of the study is to draw attention to issues related to shaping the image of the organisation as an attractive employer, particularly with the use of social factors.

Keywords: Organisation Image, Employer Branding, Corporate Social Responsibility

Introduction

The economic situation of today, including the growing need to compete for a place on the market, means that organisations must consciously and purposefully cater to their own image. The need for competition affects typical marketing areas (recognizing and satisfying the needs of customers, increasing sales, making profit), as well as those related to the acquisition and maintenance of the company's strategic resources, in particular – employees. Therefore, it becomes crucial for the organisation not only to take care of its image as a provider of products or services, but also (and perhaps even most importantly) to shape the image of the company as an attractive employer. As a result of such activities, we increase the attachment, commitment and loyalty of employees, who become promoters of the organisation on the outside. The image of a good employer is also important at the recruitment stage, as it can effectively help to attract the best and most appropriate candidates for the company.

One effective tool that comprehensively supports companies in building and maintaining such a desired image may be the employer branding (EB) strategy. Human Resources (HR) specialists consider it important to build such an employer's position to not only attract the desired employees, but also to retain them for longer periods. To intensify competition for talent, organisations must distinguish their messages from those of their competitors. This is why EB is becoming such an important element of human resources management and success of the organisation. In all this, organisations must not forget that their activities have a significant impact on society and the environment. Businesses aware of these relationships should take into account the principles of corporate social responsibility (CSR) in their decision-making processes.

The aim of the study is to draw attention to issues related to shaping the image of the organisation as an attractive employer, particularly with the use of social factors. Therefore, the following main research problem was adopted: Do the surveyed companies from the TOP 500 – Poland list perceive a need to support the organisation’s image with social factors?

The Image of An Organisation – Concept and Essence

Each organisation carrying out activities on the market is perceived and evaluated by other entities, also operating on the market, in a subjective and complex manner. The impressions and feelings created in the consciousness of market players, forming a certain image of a given company, are referred to as an image. In the literature on the subject, an image is defined as "a collection of beliefs, thoughts and impressions of a given subject (person or group) about an object, whereby an object can be understood as a company, product and its brand, location or person" (Kotler 1994, p. 549). On the other hand, an integrated image of a company is a notion and feeling which is aroused in the consciousness of various entities (both external customers, i.e. market ones, and internal customers, i.e. employees), and can be used as a tool of competition between organisations (Dewalska-Opitek 2010, p. 221). Therefore, the image of an organisation is a subjective notion of this organisation in other persons – it is exactly what others think about it (Budzyński 1998, p.73). The nature of the image is heterogeneous, it includes many different elements, depending on the context, sphere of activity of the organisation and its audience (Wójcik 2005, p.73).

Employer image should be separated from its familiarity, realization, awareness and reputation. The employer familiarity and awareness are essential and fundamental elements to initiate employer image and reputation. This is because these elements make it possible to perform a cognitive assessment of whether or not particular job seekers are aware of the existence of the organisation (Cable and Turban 2001, pp. 115-163, Collins and Kanar 2013, pp. 284–297).

Looking through reputation definitions in different domains, an article proposed by Highhouse et al. (2009, pp. 782-789) can be found that referred to employer reputation as an universal, temporally stable, critical assessment about an organization that is common to the general public. Thus, reputation differs from image in that reputation mainly involves the affective aspects. The other, but not less important, differences are that reputation is a more lasting judgment, which is reflected, among other things, what is the general public's opinion about the organisation. Therefore, it is possible that the general public has positive opinions about an organisation (positive reputation) but that an individual applicant may have a more negative opinion based on concrete experiences (negative image), or vice versa. Rynes et al. (1991, pp. 487–521) emphasized that there is a possibility that a company having a good reputation among jobseekers suddenly loses its positive image through inadequately conducted recruitment or rude employees of the HR department.

A concept associated with reputation is the phenomenon of a firm celebrity defined as a company that meets with great interest from the public opinion with a positive response. It is characterized by having an evaluative and even often emotional component (Rindova et al., 2006, pp. 50–71). Despite these differences, employer familiarity, employer reputation, and employer image are also related. Hence, Cable and Turban (2001, pp. 115–163) placed them under the general concept of employer knowledge.

In accordance to Highhouse et al. (2009 pp. 782-789), employer image is determined as an combination of transient perceptions about specific aspects of an organisation as an employer who has particular components. This definition refers primarily to the four most important elements such as:

- the image is stored by individuals instead of the public,
- the image may fluctuate instead of being relatively stable,
- the image only applies to certain aspects instead of the overall view,
- the image is characterized by cognition in nature.

In general, HR practice also uses the terms of employer's brand and employer branding. At this point, constructing clarity is a purposeful tool. It is suggested to link the employer's brand constructions with the definition framework set out above instead of using other terms for similar constructions. Then it allows to link the external employer brand with the organisation's employer image (outsider's mental representations of qualities linked to the organisation as an employer) while the internal employer brand is associated with an organisation's identity (insider's mental representations of qualities linked to the organisation as an employer). Thus, the external employer branding is considered to be a synonym for employer image management and the internal employer branding for identity management. (Lievens and Slaughter 2016, pp.407-440)

Activities undertaken by companies to build their image as employers are referred to in the literature as employer branding (EB). EB is a fairly new (introduced in the 1990s) concept of organisation management, related to the practice of talent management, as well as the need to ensure and maintain talented employees in contemporary organisations. (Ober 2016, pp. 345-356)

Kozłowski (2012, p. 14) defines employer branding as: "all activities undertaken by the organisation, addressed to current and potential employees, aimed at building its image as an attractive employer and supporting its strategic business goals".

A broader definition is proposed by Francis and Reddington, according to whom EB is an attempt to better specify the terms of the psychological contract between the employee and the organisation in terms of the values provided to the employees. The expression of the employer's image provides employees with practical cognitive structures that give meaning to their employment in the organisation. The importance of the employer's image can be seen in the context of the social exchange theory, according to which employees make carry out a form of a profit and loss account of their employment with a particular employer. (Francis, Reddington 2012, p. 269)

The concept of EB is based on the assumption that the company, as an employer, is treated as a product to be sold. However, it is worth noting that EB is significantly different from recruitment marketing. (Albrychiewicz-Słocińska, Robak 2017, pp. 147-161)

The implementation of EB programmes supports the recruitment process as it attracts valuable candidates to the organisation, reduces turnover and positively motivates employees to work. This, in turn, translates into an increase in commitment and, as a result, contributes to the quality of work and generating a competitive advantage. As a result, the company enjoys financial benefits, in particular resulting from lower employee turnover due to their satisfaction, efficient communication within the organisation, as well as good relationships with superiors. (Barrow, Mosley 2006)

The image of an organisation is greatly influenced by both internal activities (for example, those related to investing in human capital, caring for a healthy work environment and good interpersonal relations or work ethics) as well as those directed to the outside and related to broadly-defined advertising and PR areas. Both are important parts of the concept of Corporate Social Responsibility (CSR).

Basics of the concept of Corporate Social Responsibility

The activity of an organisation and the business decisions it makes not only have an economic or efficiency dimension, but also a social and ethical one. This is why we observe a constantly growing interest in the concept of Corporate Social Responsibility (CSR). The terms used to describe an organisation within this paradigm include: responsible organisation; ethical business; civic organisation, or social environment of the organisation (Bevan et al. 2004, p. 13).

Since CSR affects all aspects of the functioning of an organisation – financial, technical and human, it can be described as a management philosophy. According to the assumptions of the concept of

CSR, an organisation takes responsibility for its impact on society and the environment. CSR is, therefore, a form of awareness, acceptance, as well as management of the implications and results of decision-making processes in organisations. (Skiba et al. 2017, p. 669-671)

The concept of CSR makes it possible to make the unknown known and achieve balance in the organisation, both in relations with the environment and its own employees (Debeljak et al. 2011, pp. 5-22). The social dimension of the activity of the organisation in the area of human resources refers, among others, to: ability to adapt, empathy, openness, integrity and honesty in mutual relations between the management, employees and stakeholders; models and standards of employee behaviour towards customers, consumers and all entities participating in the company's activities; shaping the image of the organisation on local community level through employee narrations, as well as declared and actual value systems forming the basis for the operation of the employees (Bevan et al. 2004, p. 18; Turner 2004)

Corporate Social Responsibility as defined by the European Commission means that organisations take responsibility for their impact on society (European Commission 2011). CSR in the modern economy should mean: conducting activities based on similar values, taking into account persons in the processes of production, distribution and consumption, as well as implementing the principles of social responsibility in all areas of business operations (Kacprzak). Various programmes, guidelines or initiatives that set out the directions of responsible business activity are used to implement these principles. CSR is a voluntary strategy taking into account the social, economic, ethical and ecological aspects in business activity and in contacts with the environment (e.g. with employees, customers, shareholders, suppliers, local community). In practice, this concept is most frequently manifested in such activities as: social campaigns, employee volunteering, sponsoring cultural events, sales products combined with allocating a part of profit for a specific social purpose, creating codes of ethics or eco-labelling the products.

There are many benefits in including the idea of CSR in business activities, however these advantages should be considered in a long-term perspective. These are, above all:

- increased interest by investors;
- increased loyalty of consumers and stakeholders;
- improved relationships with the community and local authorities;
- increased competitiveness;
- improved level of the organisational culture of the company;
- shaping a positive image of the company among employees;
- attracting and retaining the best employees (CSR Encyclopedia).

Social responsibility becomes a sign of the times, an element desired in the image of the company, a distinguishing feature which serves as proof of modernity, maintaining the standard of activity reserved for the best companies which emphasise comprehensive partnerships in their activities. (Pisz 2010, p. 13)

Methodology

The research results presented in the study are part of a nationwide quantitative survey of the representatives of businesses carried out under the project “New trends in human resources

management in large companies". The project was implemented in 2019 with the participation of a specialist third party company – MRW Market Research World. The objective of the survey was to identify:

- social and psychological factors supporting staff development in organisations,
- intangible assets in the organisation,
- processes of management of social capital and trust in organisations.

The study was conducted using quantitative research methods using mixed techniques: CAWI (Computer Assisted Web Interview) and CATI (Computer Assisted Telephone Interview). The combination of these two quantitative methods served to increase the response data. The study group consisted of the largest companies in Poland, the so-called TOP 500 group (according to the ranking of the Rzeczpospolita portal for 2018). The survey company used random sample selection. If a company refused to participate in the study, another business was selected at random. The survey was conducted on a representative sample, with the following parameters: general population size 500, estimation error 6%, confidence level 95%.

The applied research tool is a standardised questionnaire consisting of questions and statements, both closed and semi-open. The Likert scale was used in the answers (so-called Likert scaling), which enables measuring the relative intensity of the answers (Babbie, 2004, p.192). The personal information questions were proprietary, formulated by members of the research team – employees of the Department of Psychology, Sociology and Communication in Management of the Faculty of Management of the Czestochowa University of Technology.

The respondents (companies that took part in the survey) were: 179 companies including the following business activity profiles: 41.8% production, 14.5% production and service, 27.4% service, 8.4% trade and 7.8% production and trade. The revenues of the majority of the surveyed organisations ranged from PLN 51 to 200 million (68.1%), followed by companies with revenues of PLN 5 to 50 million (17.9%); the least numerous were those with revenues exceeding PLN 200 million (14%). Companies also differed in terms of size, measured by the number of employees. Employment at the level of 201-500 employees was demonstrated by the majority surveyed companies (73.18%), the remaining organisations (26.82%) demonstrated employment at the level of over 500 employees.

STATISTICA software was used to examine and describe the significance of differences with respect to the aforementioned independent variables, as well as the remaining correlation variables. The evaluation of the strength of the correlations occurring between the variables was made using Spearman's rank correlation coefficient. The analysis of the obtained statistical data was based on the publication by A. Stanisz (2006, pp.369-391).

The following problem was raised within the framework of the study: Do the surveyed companies from the TOP 500 list perceive a need to support the organisation's image with social factors?

The following three detailed research assumptions were formulated:

A1 In building their image, the surveyed organisations emphasise work ethics.

A2 Whisper marketing concerning relations with superiors is very important for building EB.

A3 A healthy work environment is an important part of the organisation's emotional message concerning EB.

The study adopted numerous statistical hypotheses examining the relations between selected indicators describing the organisation on the market (these included: comparison with the competition in terms of: implementation of new technologies (I1) and increasing the company's resources (I2)) and the social factors supporting the organisation's image (A1, A2 and A3).

Results and Discussion

In the course of the survey, the respondents were asked to respond to the proposed statements, which in this study were used as detailed research assumptions – Z1, Z2 and Z3. A five-step scale was used for the responses: 1 – I strongly disagree, 2 – I rather disagree, 3 – I neither agree nor disagree, 4 – I rather agree, 5 – I strongly agree. For the purpose of the analysis, the responses were grouped into three main categories indicating the respondent's attitude to the proposed statement: negative – sum of responses 1 and 2, neutral – sum of responses 3 and positive – sum of responses 4 and 5. Tables 1–3 contain the lists of responses in the survey.

Table 1: Results of the survey regarding the Z1 assumption

	responses quantity	responses cumulative quantity	responses percentages	responses cumulative percentage
I strongly disagree	9	9	5.02793	5.0279
I rather disagree	12	21	6.70391	11.7318
I neither agree nor disagree	28	49	15.64246	27.3743
I rather agree	53	102	29.60894	56.9832
I strongly agree	77	179	43.01676	100.0000
no answer	0	179	0.00000	100.0000

Source: own study

The analysis of the data (table 1) clearly demonstrates that the respondents, as entrepreneurs aware of the labour market trends, pay attention to work ethics when building their image (over 70% of positive responses). They realise that being ethical is not only an obligation imposed by certain laws and norms, but also an obligation of a moral nature. An ethical business is a more attractive employer on the labour market.

Table 2: Results of the survey regarding the Z2 assumption

	responses quantity	responses cumulative quantity	responses percentages	responses cumulative percentage
I strongly disagree	7	7	3.91061	3.9106
I rather disagree	27	34	15.08380	18.9944
I neither agree nor disagree	50	84	27.93296	46.9274
I rather agree	61	145	34.07821	81.0056
I strongly agree	34	179	18.99441	100.0000
no answer	0	179	0.00000	100.0000

Source: own study

The responses presented in table 2 also indicate a positive approach of the respondents to the studied issue. More than half of the representatives of businesses from the TOP-500 Poland list participating in the survey (53.07%) admit that it is important for the EB message to use whisper marketing to disseminate information on employee-supervisor relations in their companies. Reaching the recipient with the information through a direct and seemingly "spontaneous" verbal message makes the image of an attractive employer even more credible.

Table 3: Results of the survey regarding the Z3 assumption

	responses quantity	responses cumulative quantity	responses percentages	responses cumulative percentage
I strongly disagree	7	7	3.91061	3.9106
I rather disagree	9	16	5.02793	8.9385
I neither agree nor disagree	27	43	15.08380	24.0223
I rather agree	52	95	29.05028	53.0726
I strongly agree	84	179	46.92737	100.0000
no answer	0	179	0.00000	100.0000

Source: own study

The last of the analysed statements received strong positive confirmation in the opinions of respondents (table 3). As many as 75% of entrepreneurs believe that a healthy work environment is an important part of the organisation's emotional message related to EB. A friendly atmosphere at work can translate into increased employee satisfaction and, as a result, an increase in the level of their loyalty and commitment, or reduced staff turnover. Positive feelings and emotions of the employees also positively affect the productivity and efficiency of performed tasks.

As a result of the conducted statistical analyses, a significant statistical dependence was confirmed for only four hypotheses (Table 4).

Table 4: Relationships found between the indicators

Elements of the EB offer supporting the organisation's image	Selected indicators describing the organisation on the market	
	I1	I2
A1	-	Yes
A2	Yes	-
A3	Yes	Yes

Source: own study

Table 5 presents the value of Spearman's rank correlation coefficient (R) for the pairs of variables selected for analysis. Although the values of indicators do not show strong relationships between variables (the value of R is between 0.199698 and 0.218103), the analysis of the p-values of statistical significance indicates the occurrence of statistically significant relationships.

Table 5: The value of Spearman's rank correlation coefficient (R) for the pairs of variables selected for analysis

Pairs of variables selected for analysis	Spearman's rank-order correlation for p<0.05 N=179		
	R	t(N-2)	p
A1 – I2	0.216449	2.94959	0.003612
A2 – I1	0.218103	2.97325	0.003357
A3 – I1	0.199698	2.71143	0.007360
A3 – I2	0.207222	2.81807	0.005381

Source: Own study

The following part of the article shall only present those hypotheses for which statistical verification enables the rejection of the zero hypothesis concerning the lack of dependence between variables and adoption of an alternative hypothesis.

The first of the analysed hypotheses assumes that:

H_0: no correlation is found between increasing the company's resources and the assumption that an organisation emphasises work ethics when building its image,

H_1: a correlation is found between increasing the company's resources and the assumption that an organisation emphasises work ethics when building its image.

With regard to the defined statistical hypothesis, it was found that the value of Spearman's rank correlation coefficient R=0.216449 and the test probability level p=0.003612 enable the rejection of

the zero hypothesis and concluding that the companies which increased their resources by building their image emphasise work ethics.

The next statistical hypothesis assumes that:

H_0: no correlation is found between the implementation of new technologies and the assumption that whisper marketing concerning the relations with superiors in the organisation is very important for shaping the EB offer,

H_1: a correlation is found between the implementation of new technologies and the assumption that whisper marketing concerning the relations with superiors in the organisation is very important for shaping the EB offer.

The value of Spearman's rank correlation coefficient R=0.218103 and the test probability level p=0.003357 enable the rejection of zero hypothesis and adoption of an alternative hypothesis about the occurrence of relationships between the indicated variables. The analysis shows that modern companies are convinced that whisper marketing concerning relations with superiors in the organisation is of great importance for shaping the EB offer.

The following hypothesis was also adopted:

H_0: no correlation is found between the implementation of new technologies and the assumption that healthy work environment is an important element of the emotional message within the EB offer,

H_1: a correlation is found between the implementation of new technologies and the assumption that healthy work environment is an important element of the emotional message within the EB offer.

Spearman's rank correlation coefficient R=0.199698 and test probability level p=0.007360 warrant the rejection of another zero hypothesis and accepting the alternative. Thus, it can be concluded that there is a statistically significant correlation between the implementation of new technologies and caring for good work environment, as an important element of the emotional message contained in the EB offer.

The last of the hypotheses assumes that:

H_0: no correlation is found between increasing the company's resources and the assumption that healthy work environment is an important element of the emotional message within the EB offer,

H_1: a correlation is found between increasing the company's resources and the assumption that healthy work environment is an important element of the emotional message within the EB offer.

Once more, Spearman’s rank correlation coefficient R=0.207222 and test probability level p=0.005381 enable us to reject the zero hypothesis and adopt an alternative hypothesis regarding the relationship between increasing the company's resources and the impact of a healthy work environment on the emotional message contained in the EB offer.

Conclusion

As a result of the research and analysis of the collected material, it should be stated that the businesses from the TOP 500 Poland list consider building the image of the organisation to be an important and often demanding task. It requires a comprehensive approach and a strong commitment of the entire staff. Awareness of the market situation and the need to compete for a place on it makes it necessary for entrepreneurs to fight for their position all the time. For this purpose, companies use

various tools that comprehensively support them in building and maintaining their desired image. Such instruments can be the employer branding (EB) strategy as well as the Corporate Social Responsibility (CSR) concept.

Creating a strong and consistent employer's brand enables attracting and retaining the most suitable candidates and employees. It is worth remembering that creating and utilising unique brand values as well as building a positive employer image leads to very specific benefits.

The success and prosperity of a modern organisation is to a large extent related to such factors as commitment, satisfaction and contentment of its employees. On the other hand, lack of trust among employees, poor communication, unhealthy work environment or unethical attitudes and behaviours lead to employees not identifying themselves with the organisation.

Reliability and honesty are crucial in building the image of an organisation, and those responsible for creating and communicating this image must not forget about this.

Impact of Socioeconomic Inequalities on Social Cohesion – Theoretical Approach

Patrycja ZWIECH

University of Szczecin, Szczecin, Poland
E-mail: patrycja.zwiech@usz.edu.pl

Abstract

The purpose of this paper is to examine the relationship between socioeconomic inequalities and social cohesion. The paper consists of three parts. The first part introduces the subject matter of social cohesion. The second part outlines different approaches to socioeconomic inequalities. The final part demonstrates how the two issues overlap and examines the relationship between socioeconomic inequalities and social cohesion. The paper is theoretical and is based on a critical literature review.

Keywords: Socioeconomic Inequalities, Social Cohesion.

Introduction

Sustainable development is development that seeks to balance the economic, social and environmental needs. Sustainable development aims to achieve a permanent improvement in the quality of life. However, in practice, the social dimension is less discussed and researched than the economic and environmental dimensions. The essence of sustainable development is to ensure a continuous improvement in the quality of life for the present and future generations. Sustainable development entails the lessening of social inequalities on the one hand, and on the other, increasing social cohesion. What is important, we should not treat social cohesion as another pompous but empty word, but rather accept and cherish the mindset underlying this concept, and do our best to implement it.

The discussion about the relationship between social cohesion and socioeconomic inequalities springs from the assessment of potential development mechanisms which enable convergence of socioeconomic systems. Deepening of social and economic disparities, observed all around the globe, is one of the biggest obstacles on the path to sustainable development. At the same time, as inequalities rise, social cohesion is decreasing. Passing on of social and economic inequalities across generations hinders the achievement of sustainable development goals set by the European Union.

The pursuit of social cohesion is rooted in a conceptual framework that defies the excessive competition, individualization, disintegration of communities, social exclusion, marginalization and the *homo oeconomicus* approach, and the effects of incorporating business values into other areas of life. The pursuit of social cohesion is also driven by the need to counteract the effects of the ever-growing social and economic divides.

The paper explores the issue of social cohesion in the context of socioeconomic inequalities. The main goal of the paper is to identify the relationship between social cohesion and socioeconomic disparities. The paper provides a review of theoretical literature on the subject.

Social cohesion as the EU's Statutory Goal

The concept of "cohesion" gained more prominence in international politics of the European Union towards the end of the 20th century. The concept was used for the first time in the Single European Act adopted in 1986, i.e. in the Economic and Social Cohesion Charter which expressly pointed to the need to reduce disparities between various regions of the European Community. This goal became enshrined in the 1992 Treaty of Maastricht, in particular, in Art. 130a which postulates that in

order to promote overall harmonious development, the Community shall develop and pursue its actions leading to the strengthening of its economic and social cohesion. The 1997 Treaty of Amsterdam reinforced the adopted provisions and widened their scope. It provided that the Community will promote high level of employment and social protection, gender equality, the raising of the standard of living and quality of life, and economic and social cohesion. (Gawlikowska-Hueckel, 2002; Głąbicka, 2004; Gawlikowska-Hueckel & Zielińska-Głębocka, 2004).

In result of the Treaty provisions, instruments and policies aimed at reducing developmental disparities were established. A good example here of the systemic efforts made is the Cohesion Fund and cohesion policy.

The EU documents from late 1980s list the following reasons:

- need for harmonious development of the EU regions,
- pursuit of economic integration of the entire Community,
- development of multicultural identities of individual EU member states (the need to integrate immigrants),

for distinguishing the three kinds of cohesion:

- social cohesion,
- economic cohesion.
- territorial cohesion.

In the late 1990s these three dimensions of cohesion merged and started to be treated as one, referred to as "social cohesion" or "cohesion policy" in the EU documents. Social cohesion understood in such a broad way encompasses the following dimensions (Golinowska, 2011):

- social – it emphasizes the importance of leveling disparities in the standard of living and quality of life of EU citizens, and providing adequate standard of public services for populations,
- economic – it underscores the importance of reducing territorial inequalities for promoting sustainable development of the EU,
- environmental – it focuses on the concern for natural resources and environmental health factors,
- political – it focuses on political stability, further development of democracy and promotion of European integration,
- cultural – it underlines respect for Europe's common cultural roots and heritage, and at the same time promotes openness towards universal values.

Approaches to socioeconomic inequalities in economic theory

Socioeconomic inequality, depending on the conceptual premises, is treated either as a way a social system operates or as an undesirable problem (Zwiech, 2013). Conceptual premises derived from the elitist, meritocratic and egalitarian theoretical strands give rise to three different approaches to inequality (Zwiech, 2016):

- legitimization of inequality as an inherent element of free market economy accompanied by acceptance of inequalities at any level and scale,
- no acceptance of inequality (in particular its effects) based on an assumption that systemic solutions are necessary to eliminate such divides,
- conditional acceptance of inequality accompanied by establishing conditions that limit the rise of inequality and determining what is the acceptable threshold of inequality.

Theories that legitimize economic disparities suggest that economy should be desocialized and argue that inequalities are ethically legitimate, although we cannot assess ethical legitimacy without putting aside the norms and values adopted by society. In this case, expectations of social justice are boiled down to entitlements and property rights, therefore legitimization of inequality favours well-to-do people as it justifies the wealth they have accumulated.

Theories based on the lack of acceptance of unequal economic and social outcomes did not hold up and were discredited after the collapse of communist systems. They turned out to be utopian, and definitely did not bring more social justice to the world.

The approach based on conditional acceptance of economic disparities contends that inequalities can be accepted only to a certain extent, as long as certain conditions are fulfilled, such as: guaranteed minimum income, equal opportunities, efforts to maximize the welfare of the least privileged individuals. These theories draw attention to the inequality of wealth and distribution of wealth, and concentrate on an individual's responsibility for their own decisions, commitment, talents or efforts. What emerges in this approach is the lack of acceptance of the ever-growing income inequalities. Existence of excessive economic inequalities hinders socioeconomic development and makes it impossible to increase (or maintain) social cohesion (Zwiech, 2016).

Conditional acceptance of economic inequalities within societies forces us to determine what are the conditions that limit the growth of inequality, what are the acceptable thresholds of these inequalities and what is their optimal size. This issue has been approached in different ways:

- acceptance of inequality accompanied by respect for the principle of guaranteed minimum income (decent, dignified or biological, existential) for every member of the society (e.g. L. Hobhouse's theory (Hobhouse, 1922));
- acceptance of such level of inequality that makes the less privileged group as rich as possible, that is acceptance of inequality as long as it maximizes the position of the less privileged group in the situation of inequality (e.g. J. Rawls' maximin principle (Rawls, 1994));
- acceptance of inequality under the condition that equal opportunities are guaranteed, including an equal starting point for everyone (e.g. J. Roemer's theory (Roemer, 2000));
- acceptance of inequality under the condition that every member of the society has equal capabilities (real opportunities) (e.g. A. Sen's conception of capabilities (Sen, 2000)).

Legitimization of social inequality and Social Cohesion

Pursuant to fundamental assumptions of classical economy, allocation of resources comes first. The issues of distribution and equality are pushed aside and marginalized. Pareto argued that regardless of the distinct difference between efficiency and equality, economic policy can be formulated just on the basis efficiency (Blaug, 2000), without the need to consider the issues of equality and distribution. Pareto optimum, that is a situation when no further improvements as to the allocation can be made, allows to skip the question of income distribution in economic considerations on the assumption that the achievement of maximum welfare is possible with a certain set of production factors and certain income distribution, and changes in the structure of demand and adjustment changes in the structure of supply will occur until the moment comes when no market entity is able to make its situation better off without making at least one other entity worse off. A situation in which the status of wealthy people improves significantly and the situation of poor people does not change is understood as a benefit by Pareto. This approach puts aside the issues of social cohesion and growing inequalities.

In turn, utilitarianism contended that actions are morally right if they maximize utility understood as welfare or pleasure of a community. Such an approach is also based on the belief that distribution of benefits is irrelevant. It is not important which individual gains more benefits and which gains less if only the overall welfare is maximized (Rawls, 1994). The utilitarian approach operates from an aggregate perspective in which aggregate welfare maximization is equated with efficiency. Any

values other than efficiency are significant only to the extent in which they contribute to the maximization of social welfare. According to Brandt (1996), in the utilitarian agenda equality is subordinate to welfare and should be sacrificed in exchange for even the smallest increase in general welfare.

On the other hand, Kuznets claimed that rising income inequality is inevitable. Kuznets suggested that income inequality is inevitably expected to follow an inverse U-curve, first rising with industrialization and then declining at a higher level of social welfare. He argued that in the first period of accelerated economic growth income inequality rises very fast, and then, with the increase of income *per capita*, it declines (Kuznets, 1955). Increase in income inequality is a prerequisite of economic growth since it enables accumulation of capital necessary to stimulate GDP growth. Accumulation of capital happens through concentration of income, in consequence of which income inequality rises (Domański, 2009).

The Washington Consensus also pointed to increasing inequality as an inevitable consequence of modern technology, international competition and globalization. The Washington Consensus policy agenda minimized the role of the state and emphasized privatization, trade liberalization (import in particular) and capital market, deregulation and guarantees for private property. The role of the government was narrowed down to maintaining macroeconomic stability and price stability, with no responsibility for the stability of production, employment and growth. In reality, the Washington Consensus underplayed the issues of social inequality and social cohesion (Stiglitz, 2007; Stiglitz, 2006).

Another conception that legitimizes the growing inequalities is Nozick's theory of justice. Nozick claimed that a fair distribution takes place when every member of the society is entitled to what he has. It is important how the distribution happened, and not the final results it brings about. Hence, economic inequalities result from entitlement and belong to the past. According to Nozick, neither social justice not social cohesion can justify any violation of absolute rights to private property (Morawski, 2001). Nozick legitimized inequality as a natural phenomenon and pointed out that a transfer of property from rich to poor constitutes a violation of entitlements and there is no justification for redistribution of goods. The only redistribution admissible is one that rectifies past injustices arising from a crime or offense.

Hayek, a libertarian ideologue, defined equality from the perspective of individualism. He claimed that equality can only be conceived as equality before the law. However, natural differences between people justify the existence of economic disparities. Economic differences are thus a natural and desirable phenomenon (Rutkowski, 2009). In contrast, Friedman argued that freedom is more important than equality, and economic policies should focus on freedom as a primary value and be careful never to jeopardize it. He claimed that growing economic inequalities are necessary and are the inevitable result of exercising freedom.

Income and wealth inequality is also legitimized by the theory of public choice which claims that redirecting individual's activity from production to redistribution activities generates additional social costs. Economic disparities are thus legitimized with the use of such arguments as the need to avoid additional costs. The redistribution process is perceived as a socially costly race of various social groups to take over income and property belonging to others. According to Buchanan, the issues of wealth and income distribution between people can be solved through a "constitutional contract" subject to "continuous renegotiation" which would redefine the rights of an individual.

Various conflict theories that explain socioeconomic inequalities are jointly referred to as the Social Conflict Theory or, to quote Sztompka (2004), as theory of "cumulative advantage". According to this theory, once a social agent gains a small advantage over other agents, that advantage will compound over time into a larger advantage, i.e. the high-status holders will continue to climb up the ladder while the less fortunate ones will continue to be degraded. In other words, privileges tend to multiply. This theory refers to, on the one hand, the "Biblical truth" or "Mathew effect" which is embodied in the adage "the rich get richer and the poor get poorer", and on the other hand, to the

inheritance of social status. Inheritance of social position between generations, i.e. the passing on of advantages and privileges on the one hand, and disadvantages and poverty on the other, depends on access to education. In modern societies education is perceived as the main means of securing better jobs, higher earnings, influence or prestige. Costs of education can be borne with ease by wealthy families, but not the poor ones, which perpetuates the mechanism of inheritance. Apart from economic inheritance, there is also cultural inheritance (cultural capital) and social inheritance (social capital).

The power elite theory claims that in every society there is a single elite (power elite), not a multiplicity of competing groups, that holds the highest positions and decides life-and-death issues for the entire nation. The first power elite theories (Paveto's and Mosca's) claimed that power elites appear regardless of a society's structure and organization, and that men differ in their capabilities and skills. Historically, hereditary aristocracies were the most talented and gifted people, and as such were the governing elite. However, new sociological conceptions rejected this point of view and treat elites as an offshoot of social structure and socioeconomic inequalities. How power is organized depends on institutional structures rather than personal traits or skills, and it is the system of social organization that decides on who belongs to the elite and what criteria they have to meet. Mills argued that elites emerge in the wake of a specific economic, social and political situation, in result of internal workings of these institutions (Mills, 1961). Status of an individual in the society depends on his access to institutions and the position he holds in the institutions, and not on his personal traits.

To recapitulate, theories that legitimize economic inequality (or increase thereof) argue that such inequality is inevitable on the grounds of neoliberal paradigms. Free market economy seems to carry in itself some inherent economic inequality and the division of society (and resulting inequality and lack of cohesion) plays a secondary role to production and allocation, or even, is completely insignificant. These theories claim that inequality is a natural phenomenon, hence, any limitation of inequality is unjustified. Inequality is perceived as the effect of "tough" economic laws, treated almost as natural law. According to the aforementioned theories, there are values (e.g. freedom) that are more important than equality and cohesion, and limitation of socioeconomic disparities could also restrict these values. Theories that legitimize economic inequality focus on such factors as efficiency, motivational action, additional costs related to redistribution, the functionality of inequality and the society's operating principles.

Theories seeking to legitimize economic inequality argue that, on the one hand, economy should be desocialized, and on the other hand, that inequality is morally right (overlooking the fact that when assessing ethical righteousness we cannot put aside societal norms and models). In this light, it is important to pay attention to how these norms and models are established and shaped. One may venture to say that legitimization of inequality is convenient for the well-to-do people as it justifies the wealth they accumulated, allowing them to easily reduce the expectations of social justice to a discussion about entitlements and property rights. Concurrently, it should be added that the optimistic belief in the gradual upward social mobility in the context of free market has turned out to be extremely naive (Woźniak, 2014).

Lack of acceptance of economic inequality understood as inequality of outcomes and social cohesion

Another approach postulates no acceptance of economic disparities in societies. From the economic perspective such standpoint can be understood in many ways – also, in the extreme, as contention of outcome inequality. Understanding of economic inequality as outcome inequality is typical of utopian socialists. When expanding the famous labour theory of value, Marx developed a theory of additional value and the concept of exploitation of labour power by capital, or the labourer by the capitalist. Analysis of the views of utopian socialists inspired his idea of a classless society in which the value of private means of production being the source of conflicts and antinomies will be done away with. In result of labour, goods of a certain value are produced, which then become objects for sale for a specific price. The issue with transformation lies in the difficulty of explaining the transition from the mode of production when a value is created, to the mode of distribution, when the price is

determined. According to Marx, the amount of labour that goes into producing a good is the source of the good's value, in short, labour is the source of value. If so, the profit gained by the capitalist comes *de facto* from the value produced by a labourer, i.e. the labourer is exploited. The additional value, also called the "surplus value", appropriated by the capitalist is the difference between the value of the good produced and the value of labour force used to produce the good (Sobiech, Woźniak, 2007). Marx emphasized how little of the labour value itself was taken into account in income distribution, exposing ideological reasons behind the income distribution gap. For capitalists, the accumulation of capitals and technological progress become primary goals. The consequence of accumulation is concentration of capitals and wealth in the hands of a few which leads to increasing economic inequality and meltdowns driven by the contradiction between the social nature of production and private appropriation of the surplus value. Therefore, it is necessary to create new economic relationships based on social ownership of the means of production and fair income distribution.

Friedman tried to refute the view that capitalism and free market economy contribute to the increase of economic inequality by arguing that the more capitalist a country is, the less has to be paid for the use of capital and the more income is allocated to the financing of services provided by people. Friedman believed that the capitalist system generates a relatively small divide between the rich and the poor, and that the development of capitalism lessens the inequality gap. As it comes to changes over time, he argued that economic development of capitalist countries was clearly accompanied by continuous, significant reduction of social differences. What can be observed in capitalist societies is rather short-term inequalities which are caused by dynamic changes and social mobility, as well as inequality of opportunities. In economies other than capitalist, one may observe a more frequent occurrence of long-term inequalities which shape the social status of individuals in a more permanent way. Hence, capitalism gives more opportunities to change the social status of individuals (Friedman, 2008). Also Hayek (2007) pointed out that socialism is not the solution to growing inequalities as it does not lead to higher social justice but rather gives rise to a new, arbitrary and rigid social hierarchy. In theory we may envisage a classless society, however, the most radical attempt to create such a society (USSR) was a failure. In spite of the efforts to create a classless society, classes just changed places, with one replacing the other (Lane, 1984).

To recapitulate, for theorists who do not accept economic inequality understood as outcome inequality, capitalism and free market economy enhance economic disparities, whereas socialism lessens them. Marxist economics questioned the liberal conviction that the workings of market forces guarantee equality. Marx believed that the biggest problem was the conflicting economic interests of different social groups.

Theories concentrated on inequality of outcome did not prove right, and after the collapse of the communist systems, they were discredited – therefore, in this paper they have only been mentioned in passing, without focusing on the solutions they proposed. They turned out to be a utopia, and they failed to produce more social justice or social cohesion.

Conditional acceptance of economic inequality and social cohesion

At present, lack of societal acceptance of economic equality is not understood as disapproval of inequality of outcome, but rather as disapproval of inequality of opportunity (or of an "equal starting point in life") and possibility. Inequality of opportunity and possibility create such institutional conditions in which elimination of the economic divide is simply not possible. A society cannot get rid of inequalities without allowing the least advantaged people access to certain offices or positions. Fair Equality of Opportunity theory requires that social positions be open and meritocratically allocated, but also that each individual should have a fair chance to attain these positions. In other words, economic inequality is acceptable only if every individual has a fair chance, and their success in the pursuit of social position is a function of their talent and willingness to use the talents, and not a function of social class. Economy should be supported by a system of political and legal institutions that would ensure fair prospects for success and participation of individuals with similar talents and motivation (Rawls, 1994).

Yet another theory proposes a guaranteed minimum income for all people, regardless of their welfare status. That minimum income should be decided by the society.

In this approach, theorists focus on the least advantaged individuals. They believe that the only type of economic inequality that can be accepted and justified is one that leads to life for the worst off being made better (Rawls, 1994). In brief, this view allows for economic inequality under certain conditions.

It was the Theory of Justice authored by John Rawls that drew economists' attention to conditional acceptance of economic inequality in societies (1994). According to this theory all primary social goods (liberty and opportunity, income and wealth, and the bases of self-respect) should be distributed equally unless an unequal distribution of any, or all of these goods are to the benefit of the least advantaged. Basic points of Rawls' theory can be summed up as follows (Kowalik, 2002):

- the principle is equality of all primary goods (not just the income, but also wealth). So it is not about income redistribution, but the primary distribution. Hence, property owning is also one of the primary social goods which should be distributed equally;
- each deviation from the principle of equality (of both income and health, as well as basic liberties and opportunities) must take into account the benefit of the least privileged individuals.

In short, according to Rawls, inequality is acceptable as long as it brings benefits to the worst off part of the society.

Sen tried to form a bridge between Rawls' Theory of Justice and a perception of inequality defined in economic terms. Amartya Sen's works show no acceptance of the inexorably rising inequality. Sen made a break with the traditional notion of *homo oeconomicus* driven by self-interest, and brought to light the ethical dimensions of economy and the malfunctions of "moral economy". He emphasized that market economy can bring various outcomes depending on how material goods are distributed. Market is only one among many institutions that contribute to the final situation. The starting point of Sen's reflections was the assumption that people are not equal in their capacities and they differ is many respects. Sen wasn't concerned so much with the distribution of goods (as Rawls), but focused on the equality of possibility. He pointed out that negative socioeconomic phenomena (e.g. famine, poverty) are not the result of shortage of goods, but of inappropriate distribution. Sen promoted the notion of "*entitlement*" understood as the right to goods and services or the right to access (Sen, 2000). The rights to have access determine distribution of goods and depend on incomes, social position or education. Sen expanded the theory of equality by adding two concepts: "*capabilities*" which manifest themselves in "*functionings*" (possibilities to realize the capabilities), shifting the focus from resources that define capabilities to the possibilities of using them. He also formalizes that reasoning by means of a conversion function which converts resources into functionings, and stresses that this conversion rate should be equal. Sen advocated that economic decisions should be taken by as many different social groups as possible to ensure development and prosperity. In his belief, poverty was the result of bad governance, in particular bad governance of these few social groups that hold the power and abuse it by having no concern for the interests of other groups.

Dworkin (2002) claimed that "fair" economic distribution has to be ambition-sensitive and at the same time, endowment-insensitive. When discussing equality of resources as an egalitarian distributive mechanism, he emphasized the importance of external and internal resources and pointed to an alternative to the equality of resources – equality of welfare. Dworkin contended that full equality of opportunity for welfare is not possible. In turn, Roemer (1998, 2000) believed that inequality of assets was the key culprit in existing inequality and that the fundamental cause of exploitation was inequality of ownership of productive assets. Roemer formulated a theory of equal opportunity which postulated to compensate persons for "bad luck in the birth lottery", and at the same time hold them responsible for their choices and efforts. Equal opportunity is achieved if the society protects people from bad outcomes that happen because of certain circumstances or bad luck, but does not release them from the responsibility for their autonomous choices and their consequences. Thus, an equal opportunity policy has to equalize outcomes in so far as they are the

consequences of causes beyond a person's control, but allow differential outcomes in so far as they result from autonomous choice.

To recapitulate, conditional acceptance of economic inequality justifies the existence of inequality provided that some threshold conditions are met. These conditions are: guaranteed minimum income, equality of opportunity, equality of capability or the right to social position of a weaker individual. These theories emphasize inequality of assets, inequality of ownership of means of production or unequal distribution of goods, and at the same time shift the focus from resources to the possibility of using them. On the other hand, they assert the responsibility of an individual for his decisions, commitment, talents and efforts. They underline that market is only one of many institutions able to either eliminate economic disparities or deepen them.
It is clear that in this approach there is no acceptance for growing inequality and social divide. In this approach, inequality is accepted conditionally, which means that the conditions of acceptance (threshold conditions) and the acceptable amount of economic inequality are defined. This approach buys into the assumption that excessive economic inequality hampers socioeconomic growth.

Impact of socioeconomic inequality on social cohesion

The term "social cohesion" is not a unanimous concept, and it has no single, commonly approved definition. The notion of "cohesion" is usually used to determine the level of inequality and is understood as degree to which socioeconomic disparities between different regions or socioeconomic groups are politically and socially tolerable (Molle, 2000; Amin&Tomaney (ed.), 1995).
Jenson (1998) identified five dimensions of cohesion that enabled social cohesion:

- affiliation – social isolation,
- insertion – exclusion,
- participation – passivity,
- acceptance – rejection,
- legitimacy – illegitimacy.

In Jenson's theory there is no reference to inequality. However, in a work published a year later Bernard (1999) completed Jenson's proposal by introducing the dimension of quality – inequality which is essential to social cohesion.

The definition of "social cohesion" provided by the European Committee for Social Cohesion (2004) in the Revised Social Cohesion Strategy links it to the elimination of socioeconomic disparities. According to the Committee, social cohesion is defined as a society's capacity to ensure wellbeing to all its members, minimize disparities and avoid polarization.

Hence, to ensure wellbeing to all members of society the following objectives must be achieved: almost full employment, decent wages, social security benefits in case of sickness, poverty and temporary unemployment, assistance in achieving minimum wages, consumption subsidies for people below a certain income level, free use of public goods (Pfaller, 2000). Nevertheless, minimizing economic disparities between members of society manifests itself in the attempts to reduce the gap between the extreme poles of wealth and poverty. This means that economic inequalities in both areas, that is income and expense inequality, as well as asset inequality should be eliminated (Zwiech, 2016). Wealthiness can be analyzed from different points of view. A wealthy person is a person considered wealthy by others, a person who considers himself wealthy and his opinion is confirmed by symbols of wealth or is a person who meets some specific economic criteria (with regard to the wealth threshold). The wealth threshold (in contrast to the poverty threshold) has not yet been unequivocally determined. Wealth has not been studied exhaustively in literature (although lists of wealthy people are available, the wealth indicator being the total value of assets or annual income). It is just the contrary in the case of poverty. There are many definitions and classifications which try to capture poverty and provide a multifaceted understanding of the issue. The answer to the question of what poverty is depends, to a large extent, on a researcher's perspective. It is a multidimensional phenomenon which cannot be described with the use of a single

indicator. On the one hand, poverty is a condition in which a person lacks the essentials and financial resources for a minimal standard of living, thus it is a material deprivation, and on the other hand, poverty is also the lack of opportunity conducive to development (Zabielska, 2007). There are many different measures that try to capture poverty (social minimum, poverty line, Sen's poverty index) in its different dimensions (absolute, relative, subjective, secondary etc.). It must also be underlined that attempts to avoid polarization in the way poverty is perceived are reflected in efforts to refrain from bipolar terms. Polarization means a division (of groups, systems, forces) into two sharply contrasting parts (Kuttner, 1983; Thurow, 1984). On the grounds of economic inequality theories this concept refers to the reduction of the percentage share of "middle class" for the benefit of the "poor class" and/or "rich class" (Kot, 2008).

Analyzing social cohesion through the lens of the society's capacity to ensure welfare to all its members, minimize disparities between them and avoid polarization, socioeconomic inequalities gain special significance as – apart from the prerequisite of social cohesion being to raise the standard of living – the remaining aspects indicated in the *definiens* are to limit inequality and social exclusion.

In addition, the EU Committee for Social Cohesion enumerated factors that threaten social cohesion – income disparity, poverty, unemployment, social exclusion and marginalization, and exclusion from information. All these factors are embedded in a social order according to which some people have limited access to different types of goods, whereas others use them without any limitations. Thus, in short, such phenomena result from asymmetric access to various areas of human activity, i.e. from socioeconomic inequalities.

It should be emphasized that socioeconomic inequality weakens social cohesion not only with regard to the social aspect (divides that are too big entail social costs and negative social phenomena) and economic aspect (too big inequalities adversely affect economic growth, economic efficiency and welfare) (Zwiech, 2016), but also affect the environmental aspects of sustainable development since inequalities put more pressure on the limited resources of the natural environment.

Conclusion

The paper presents the links between social cohesion and socioeconomic inequality, and proves that socioeconomic disparities are one of the key dimensions of social cohesion. In other words, for social cohesion to be achieved, excessive socioeconomic equalities must be eliminated. Socioeconomic disparities weaken social cohesion in its social, economic and environmental aspect.

Moreover, when one looks at social cohesion through the lens of a society's capacity to ensure welfare to all its members, to minimize disparities between them and avoid polarization, elimination of socioeconomic inequalities gains special significance as it limits two out of three aspects that definitely require limitation.

Abstract

The purpose of this paper is to present the issues of equal treatment in employment and of discrimination of employees in companies. The layout of the paper is dictated by the implementation of the objective. The first part introduces the subject matter of equal treatment and basic kinds of discrimination in employment. The study characterizes basic dimensions of unequal treatment and discrimination in companies, in particular: wage, employment, profession-related, post-related and training discrimination. Then results of a research conducted on 601 employees from the West Pomeranian Voivodship in Poland are described.

Keywords: Equal Treatment, Discrimination, Poland

Introduction

Equal treatment in employment assumes that an entrepreneur will take into account the good of his own employees in his activity, having regard to social justice and absolute prohibition of infringing human dignity. A derivative of the obligation to implement the indicated values in economic activity involves equal treatment of various categories of employees and counteracting discrimination, both direct and indirect.

These rules also refer to creating such conditions for work (Zwiech, 2013a; Zwiech, 2013c), in which employees would have the opportunity to fully use their different skills and diverse potential for the implementation of the company's objectives and mission. Thus it seems very important to eliminate existing inequalities and potential discriminatory behaviours which take the form of both direct and indirect discrimination, towards different categories of employees in companies.

The problems of non-equality and discrimination occur in companies on a daily basis. For instance, women, migrants, youngest and older people, national, sexual or religious minorities or disabled persons face a more difficult and worse position on work's ground.

The aim of this study is to present basic problems that may arise in companies, associated with equality policy. The study characterizes basic dimensions of inequality and discrimination in companies, in particular: wage, employment, profession-related, post-related and training discrimination and it presents results of research conducted in Poland concerning discrimination of individual employee-related discrimination.

The question of equal treatment in companies - current state of knowledge

International institutions have been dealing with issues of employee equality on the labour market for over 70 years (Zwiech, 2011a). The mere expanding of anti-discriminatory legislation, however, is not enough to change the differentiation of positions of individual categories of employees on the labour market, and in companies themselves. Therefore, it is necessary not only to pass adequate legal solutions and transplant provisions of the law onto the ground of community life, but to raise social awareness, too.

The United Nations was one of the first international organizations that took up the question of discrimination. The UN took a stand on equality issues in the *Universal Declaration of Human Rights* as early as in 1948. Then the UN announced in Article 26 of the *International Covenant on Civil and Political Rights* of 19 December 1966 that "*the law shall prohibit any discrimination ... on any ground such as race, colour, sex, language, religion, political or other opinion, national or social origin, property, birth or other status*".

Given the guaranteed employee rights, one can identify the following forms of discrimination which may occur in companies causing the emergence, anchoring or deepening of inequalities in the sphere of work (Zwiech, 2011b):

- wage discrimination – referring to the right to equal remuneration for work of the same value;
- employment discrimination – referring to the right to the same opportunities of employment and equal criteria of selection;
- profession-related discrimination – referring to the right of choice of a profession and employment and to permanent work and equal work conditions;
- post-related discrimination – referring to the right to take top positions and to the right to be promoted;
- discrimination in access to training – referring to the right of access to training.

Wage discrimination involves differentiating remuneration of persons performing the same tasks or tasks of the same value. We are dealing with it when wage differentiation results from premises other than the employee's performance. Most often this concerns the difference in the pay of men and women. Focusing attention on equal pay of men and women results from the fact that it is in this classification where the disproportions between sexes occur most vividly. Differences in the pay of men and women less frequently occur on the same posts as it is contrary to the law, they often concern work of the same value.

The Eurobarometer survey conducted in September and October 2009 in 27 countries of the European Union among 26,663 respondents showed that in the Europeans' opinion removing the pay gap between men and women is, next to counteracting violence against women, the main priority of combating gender inequality. 82% of respondents believed that urgent action needs to be taken to remove the pay gap between men and women. At the same time, 62% of respondents believed that gender inequality is common in their country (Eurobarometer, Report 326).

Differentiation in remuneration may be substantiated by reasons referring to market factors since the employer has the right to pay more to employees who provide work for which there is demand. The employer may also differentiate remuneration due to work quality and efficiency. The differentiation due to special requirements towards employees also has an objective character. Length of service may be treated as an objective criterion only in the case of work in which such experience is required. In other cases, it leads to discrimination of an employee on grounds of gender since women enter the labour market later than men or interrupt their employment for maternity reasons (Gick, Tarczyńska, 1999). The above objective factors cannot, however, in any way directly or indirectly refer to attributes that directly characterize individual employees, such as gender, age, race, nationality, marital status, having children, religious or political views, etc.

Wage inequalities and wage discrimination expressed in a significant difference in pay, occur e.g. as a result of professional segregation (Zwiech, 2013b), inadequate valuation and biased assessment of work and as a result of socialization and existing stereotypes and cultural norms.

Valuation of work is a systematic process of establishing a relative value of individual posts. In other words, it is a process of analysis and assessment according to set criteria, allowing a comparison of the difficulty of work and its valuation (Czajka, Jacukowicz, Juchnowicz, 1998). Valuation at the same time involves gathering information that allows the establishment of the post's contribution to the implementation of the company's objectives and the establishment of related qualifications

requirements or the post's profile (Sajkiewicz, 2002). From the point of view of wage discrimination, it is important to compare posts in order to ensure equal pay for work of the same value. Particular emphasis must be given to the principle of not judging the value of the post through the lens of the person holding it.

The range of professional segregation often hinders the comparison between different types of work, though roughly of the same value, performed by different categories of employees. Besides, the very methods of valuation of work may be discriminatory in the selection of criteria and weight attributed to them, as well as in the process of appointing people to posts which may reflect the discrimination happening in the company. Valuation of posts should not attach false objectivity to the existing state of affairs.

Employment assessment may also entail discriminatory problems. The very criteria of employment assessment should not have the nature of indirect discrimination and therefore should not be applied to "universal" criteria which cannot be met by a large group of individual categories of employees. Selection of adequate methods of employment assessment should be free of discriminatory prejudices.

Pay inequalities also result from socialization and existing stereotypes and cultural norms. For example, different socialization of boys and girls is a consequence of the division of spheres of activity accepted in society into male and female activity. These stereotypes are passed on by i.a. one's family, school or mass media. In the socialization process men and women are being prepared to holding specific roles associated with gender, mainly traditional ones. Consequences of different socialization of both sexes involve different professional choices. They weaken women's professional opportunities, at the same time lowering their wages. One cannot omit either the cultural norms and values or beliefs and stereotypes on femininity and masculinity. Thanks to these beliefs, gender inequalities and discrimination of women seem right and the resulting differentiation of social roles and positions according to gender in the sphere of professional work seems to be a "natural state of affairs" (Reszke, 1991).

Employment discrimination means lesser opportunities of employment for discriminated groups and occurs when all qualifications- and profession-related and demographic features are comparable and the discriminated persons have a greater share in unemployment. This type of discrimination entails greater difficulty in finding work and greater risk of losing a job.

In the employee selection process employment discrimination may concern inadequate specification of post-related requirements (inadequately prepared descriptions of posts, including posts' qualifications profiles), inadequate specification of personal requirements, inadequate arrangement of conditions and principles of employment and selection criteria, asking certain categories of employees additional discriminatory questions, being guided by stereotypes in recruitment and selection documents and absence of the opportunity to demonstrate one's skills.

Washington State Human Rights Commission has identified thematic areas which should not be addressed in the process of staff selection for it is deemed to be discriminatory activity. These areas include, i.a., change of surname (it may reveal nationality, marital status); place of birth of the candidate, spouse, parents (it may reveal nationality); religious orientation; political orientation; candidate's skin, eye or hair colour (it may reveal nationality, race); affiliation with organizations, clubs and associations (it may reveal political or religious interests, sexual orientation); age; childcare system (it reveals having children); requirement to provide a photo (it may reveal race, nationality, age); question about criminal record (unless required by work's special character); gender (unless a given type of work may be performed by only one of the sexes); current pregnancy, history of previous pregnancies; spouse's surname, his or her place of work (it reveals marital status) (Aldag, Stearn, 1987).

Another issue associated with employment discrimination involves greater exposure to the risk of losing a job. Unjustified dismissal occurs when the employer is not able to prove that the main reason for dismissal is one of those enumerated below (Armstrong, 2002):

- insufficient skills, talents, health status (which does not allow one to continue working in a given post);
- inappropriate behaviour;
- lack of qualifications crucial to a given post;
- legal reasons making it impossible for a given person to continue work (e.g. a court judgement);
- employment surplus – provided laying off is conducted in accordance with a specified legal procedure and all employees are subject to the same rules;
- employee's participation in an unofficial strike.

Profession-related discrimination occurs where there are arbitrary limitations of access to certain professions as a result of which certain groups are crowded in other professions and where there is differentiation of situations of different categories of employees in the field of employment terms. Profession-related discrimination entails the phenomenon of professional segregation (Zwiech, 2013b), which may take the form of horizontal segregation involving, for example, a fact that in the case of gender discrimination professional activity of women focuses mainly on a few fields of employment (e.g. education, services, health care), whereas men's activity is spread evenly in much more fields. Women are allocated mainly to low-paid professions with little opportunity for career progression and with low status. Such a situation is called "sticky floor". Profession-related segregation leads to relative handicapping of women in awards for work and contributes to discrimination of women in the sphere of professional work (Gawrycka, Wasilczuk, Zwiech, 2007).

Apart from this, discriminated groups encounter one more problem. As fewer in certain professions and in certain posts, they are noticed more and as a result of which they must work harder and their failures are more noticed and observed. As people with a "token" status they feel greater pressure to demonstrate their competences (World Bank Report no. 29205, 2004).

Discriminated groups, being aware that they stereotyped and that others perceive them through the lens of prejudices and negative stereotypes, are at risk of a stereotype which makes them not be able to fully focus on their tasks. A threat of a stereotype, that is fear of confirming negative stereotypes on one's own group, makes it difficult for them to use their potential and to achieve maximum performance. A threat of a stereotype may also affect de-identification with fields in which society stereotypically expects them to fail (Kenrick, Neuberg, Cialdini, 2002).

Post-related discrimination occurs when there are arbitrary limitations to access to managerial or decision-making positions. Post-related discrimination entails profession-related segregation on a vertical plane, which is expressed by the fact that the proportion of persons from discriminated groups is lower in managerial and other decision-making positions. In gender discrimination, this phenomenon is defined as a "glass ceiling" through which women can only observe the higher storeys of power practically inaccessible to them.

Vertical profession-related segregation concerns hierarchy of positions according to levels of qualifications, professional autonomy and knowledge. It involves the fact that employees from discriminated categories reach higher professional positions, that is hold managerial positions (especially top ones), much less frequently and less frequently work in posts requiring higher level of qualifications and reflecting greater professional autonomy which is automatically associated with higher pay.

Post-related discrimination entails lesser opportunities for promotion and movement in the hierarchy of posts in companies for discriminated categories. Such a phenomenon can also be observed in feminized professions – the few men can count on quicker career advancement, which is defined as a "glass escalator".

Another problem associated with inequalities and discrimination in companies is training policy. Professional training is a basic tool of staff development. This covers the processes of learning adopted in a company directed at supplementing qualifications with new elements of knowledge, skills and behaviours. Thus, it ensures an adequate standard of performing one's work, raises flexibility and availability of human resources, facilitates implementation of new techniques and technologies, encourages integration and involvement of staff and understanding of values which the organization pursues and of changes it implements.

Discrimination in access to training may involve application of inadequate criteria when selecting training candidates (which is demonstrated in more frequent delegation to training of young people and men than older employees and women, which is explained by economic reasons since a possible gap in employment may result in the effects of this training being impossible to put to use) and subject-matter of this training. Such an approach reveals discriminatory practices and leads to the emergence of inequalities between various categories of employees in companies.

Research Methodology

This paper presents results of a survey of human resources management systems in companies of the West Pomeranian Voivodship in Poland carried out in the Institute of Human Capital Management of the University of Szczecin on a sample of 601 employees of the surveyed companies (primary sources; for the adopted significance level (0.05) and admissible maximum error of estimation (+/- 4%) it was established that 598 units were the minimum sample size ensuring reliability of research). The time frame for the research covered the period between March and May 2017, and the territorial scope – the West Pomeranian Voivodship in Poland. The subject of the survey involved company employees. An individual company employee was the sample unit where the questionnaire could reach many employees in individual companies. Data from units qualified to the sample was gathered by means of a questionnaire consisting of 78 questions, including 10 in the demographics segment. A random sample unit selection method was applied. In the analyses of differentiation of declarations in selected groups of respondents, four categories of differentiation were identified for the purpose of this study: size of the entity, gender, position and length of service. Respondents' answers to survey questions referring to the implementation of an equal treatment policy in employment were used in this paper. The following six manifestations of implementation of this policy were selected for an in-depth analysis:

- do job candidates have the same employability?
- do employees get similar pay for work of the same value?
- do employees have similar chances for being promoted?
- is employee assessment free of discriminatory prejudices?
- do companies implement programmes that facilitate reconciling work with private life?
- do companies implement a gender equality policy?

Equal treatment in companies of the West Pomeranian Voivodship – research results

Referring to **employment discrimination**, the survey presented in this paper, carried out in companies of the West Pomeranian Voivodship in Poland, asked respondents whether different employee categories in their companies have equal employability. The factors significantly differentiating respondents' declarations turned out to be gender, position and length of service. Table 1 presents the structure of respondents' answers in reference to these criteria.

Table 1: Structure of respondents' answers to the question whether all candidates have identical employability in general and in groups of entities distinguished due to size and in groups of respondents according to their post, length of service and gender (in %)

The same employability	yes	no, employment was down to connections	no, there were discriminatory criteria (age, gender, nationality)	I don't know
total	33.2	28.0	11.6	27.2
criterion: entity size				
micro	36.4	24.6	7.6	29.7
small	32.6	28.2	15.5	23.8
medium-sized	27.5	33.6	10.7	28.2
large	36.9	27.0	10.6	25.5
criterion: post held				
regular worker	31.3	28.9	11.2	28.6
lower-level manager	45.5	15.2	10.6	28.8
mid-level manager	31.4	39.2	13.7	15.7
higher-level manager	46.4	32.1	10.7	10.7
criterion: length of service				
up to 0.5 year	36.1	29.5	6.6	24.6
0.5 to 1 year	34.1	25.9	14.1	25.9
1 to 2 years	37.6	25.9	8.2	28.2
2 to 5 years	34.2	19.2	17.8	28.8
5 to 10 years	33.3	30.9	11.1	24.7
more than 10 years	28.3	36.3	7.1	28.3
criterion: gender				
man	32.6	39.9	12.3	15.2
woman	33.4	24.7	11.0	30.9

Source: author's own compilation on the basis of research results.

Employment dependent on connections was pointed out by 28%, discriminatory criteria – 11.6% of the respondents. At the same time men more often than women pointed to importance of connections in the employment process. Similarly, people with the longest and the shortest length of service pointed to this factor. As regards the post held, connections were attributed great weight by managers of the higher and medium level. For discriminatory criteria, their role in the employment process was pointed out mainly by persons with the length of service between 2 to 5 years.

In reference to **wage discrimination**, a question about remuneration for work of the same value was asked. Table 2 presents the structure of respondents' answers to the question about remuneration for work of the same value. The size of the company was a factor that statistically differentiated respondents' declarations.

Table 2: Structure of respondents' answers to the question whether employees get similar pay for work of the same value in general and in groups of entities distinguished due to size and in groups of respondents according to their post, length of service and gender (in %)

work of the same value – similar remuneration	yes	no
total	60.5	39.5
criterion: entity size		
micro	61.5	38.5
small	68.1	31.9
medium-sized	48.8	51.2
large	60.6	39.4

up to 0.5 year	52.6	47.4
0.5 to 1 year	62.0	38.0
1 to 2 years	59.7	40.3
2 to 5 years	64.9	35.1
5 to 10 years	60.8	39.2
more than 10 years	58.7	41.3
criterion: gender		
man	59.1	40.9
woman	61.2	38.8

Source: author's own compilation on the basis of research results.

Almost 40% of the respondents pointed out that work of the same value is not paid similarly. It is unlawful under Polish law and requires in-depth research. This question is assessed worst in medium-sized companies – in such entities over half of the respondents declared existence of this practice. Similarly high percentages were observed for mid-level managers.

Analysing **post-related discrimination** two issues were investigated – chances for promotion and criteria of work assessment. Table 3 presents the structure of respondents' answers to the question whether all employees have the same chances for being promoted. The size of the company and the post held were factors that statistically differentiated respondents' declarations.

Table 3: Structure of respondents' answers to the question whether all employees have the same chances for being promoted in general and in groups of entities distinguished due to size and in groups of respondents according to their post, length of service and gender (in %)

The same chances for promotion	yes	no	No possibility of promotion
total	32.5	52.0	15.5
criterion: entity size			
micro	37.9	34.5	27.6
small	33.1	55.6	11.2
medium-sized	29.1	55.2	15.7

1 to 2 years	30.6	54.1	15.3
2 to 5 years	30.3	53.1	16.6
5 to 10 years	28.0	54.9	17.1
more than 10 years	29.2	48.7	22.1
criterion: gender			
man	29.4	56.6	14.0
woman	33.1	50.9	16.0

Source: author's own compilation on the basis of research results.

As many as 52% of the respondents pointed to lack of equal chances for promotion. Taking into account the division of the investigated population according to the criterion of entity size, similar percentage can be identified for answers pointing to lack of equal chances for promotion in small, medium-sized and large companies. Besides, such lack was most often noted by regular workers and mid-level managers – by over 25 pp more often than higher-level managers.

In turn, Table 4 presents the structure of respondents' answers to the question whether criteria for employee assessment are free of prejudices. None of the factors differentiating respondents' declarations proved statistically significant.

Table 4: Structure of respondents' answers to the question whether assessment criteria are free of discriminatory prejudices in general and in groups of entities distinguished due to size and in groups of respondents according to their post, length of service and gender (in %)

Assessment criteria free of discriminatory prejudices	yes	no
total	72.7	27.3
criterion: entity size		
micro	75.2	24.8
small	71.1	28.9
medium-sized	75.0	25.0

5 to 10 years	71.6	28.4
more than 10 years	62.7	37.3
criterion: gender		
man	76.0	24.0
woman	71.7	28.3

Source: author's own compilation on the basis of research results.

In general terms, 27.3% of the surveyed respondents declared that employee assessment was not free of prejudices in their organization. In small and medium-sized entities the percentage was slightly higher – it exceeded 28%. Besides, the lower the post, the greater the extent to which respondents declared the existence of discriminatory criteria in assessment. Also, persons with the longest service most often pointed to the existence of such criteria.

In addition, the research focused on whether companies are trying to **solve discriminatory problems** offering organizational solutions such as programmes facilitating reconciliation of work with private life or implementation of a gender equality policy. Table 5 presents the structure of respondents' answers to the question whether their companies implement programmes facilitating reconciliation of work with private life None of the factors differentiating respondents' declarations proved statistically significant.

Table 5: Structure of respondents' answers to the question whether their companies implement programmes facilitating reconciliation of work with private life in general and in groups of entities distinguished due to size and in groups of respondents according to their post, length of service and gender (in %)

Implementation of programmes that facilitate reconciling work with private life	yes	no
total	51.3	48.7
criterion: entity size		
micro	54.1	45.9
small	52.1	47.9
medium-sized	49.2	50.8
large	50.7	49.3
criterion: post held		
regular worker	51.3	48.7
lower-level manager	56.1	43.9
mid-level manager	46.8	53.2
higher-level manager	52.2	47.8
criterion: length of service		
up to 0.5 year	48.3	51.7
0.5 to 1 year	55.7	44.3
1 to 2 years	53.8	46.2

5 to 10 years	51.9	48.1
more than 10 years	49.5	50.5
criterion: gender		
man	48.5	51.5
woman	52.2	47.8

Source: author's own compilation on the basis of research results.

About half of the respondents admitted that their companies implemented programmes that facilitate reconciliation of work with private life, with women pointing to it marginally more frequently than men (52.2% and 48.5%, respectively). Implementation of such programmes was also statistically more often pointed to by employees of micro-companies, lower-level managers and employees with the length of service between 0.5 to 1 year.

Respondents of the research in the companies of the West Pomeranian Voivodship presented in this study were also asked whether their organization implemented a **gender equality policy**. None of the factors differentiating respondents' declarations proved statistically significant. Table 6 presents the structure of respondents' answers in reference to the analysed criteria.

Table 6: Structure of respondents' answers to the question about implementation of a gender equality policy in general and in groups of entities distinguished due to size and in groups of respondents according to their post, length of service and gender (in %)

Implementation of a gender equality policy	yes	no
total	78.8	21.2
criterion: entity size		
micro	81.7	18.3
small	76.8	23.2
medium-sized	72.7	27.3
large	85.1	14.9
criterion: post held		
regular worker	81.0	19.0
lower-level manager	76.6	23.4
mid-level manager	64.4	35.6
higher-level manager	80.8	19.2
criterion: length of service		
up to 0.5 year	81.7	18.3
0.5 to 1 year	82.5	17.5
1 to 2 years	77.9	22.1
2 to 5 years	80.3	19.7
5 to 10 years	83.5	16.5
more than 10 years	69.8	30.2
criterion: gender		
man	82.7	17.3
woman	77.4	22.6

Source: author's own compilation on the basis of research results.

In general, 78.8% of the respondents declared that a gender equality policy was implemented in their companies, where this percentage was slightly higher among men than women (82.7% and 77.4%, respectively). The highest percentage of people declaring their companies implemented this policy was noted for large companies and micro-companies. As regards the post held, regular employees and higher-level managers noticed implementation of this policy to a similar degree, while mid-level managers noticed it to the smallest degree – the difference was as big as 15 pp. As regards the length of service, the percentage of employees with the longest service confirming such a policy was approximately 10 pp higher than among other groups.

Conclusion

Companies whose principal objective is, by definition, to gain profit or to maximise their own value should take measures for their employees, treating them not as cost but investment which will result in the achievement of the above goals. Building appropriate employment relations, including combating inequality and discrimination, should play a key role in operating an economic activity.

The research shows that an equality policy must be constantly implemented as the assessment of the current state in companies of the West Pomeranian Voivodship does not inspire optimism. 40% of the respondents pointed to unequal treatment in pay for work of the same value, unequal treatment in employment was pointed out by approximately 40% (28% of employees pointed to the importance of connections in the employment process and 12% to discriminatory factors) and the lack of equal opportunities for promotion was pointed to by as many as 52% of the respondents. Employee

assessment turned out best against this background – in this case only 27% of the respondents pointed to irregularities in this regard.

Abstract

The article presents the results of a study of the relationship between the development of the urban living environment and the influx of human capital at the level of regional systems in the center of Russia. It is established that regions that have sufficient financial security and developed infrastructure, socio-cultural and educational facilities are more attractive for life. Urban agglomerations is a complex socio-economic system, the development of which must take into account the preferences of all groups of the population. The closest cause-and-effect relationship is between the influx of population and the volume of construction of residential real estate, hospitals, schools, and other socio-cultural facilities. To a lesser degree, the influx of people into regional systems is associated with the development of the commercial real estate market. To assess the development of the urban living environment at the regional level, it is advisable to use ratings and indexes. The urban environment development index, which takes into account the most significant areas of urban agglomerations, can be used as a tool for providing an objective comprehensive assessment of the regions of the Russian Federation.

Keywords: Urban Environment, Human Capital, Region, Assessment

Introduction

The problem of creating a modern urban environment that meets all the requirements of modern society is currently relevant both for Russia and for all developed and developing countries. Today people are the least attached to a particular place of residence and are ready to move to other cities and even countries if they see the potential for such move. Wages and good working conditions attract people, but the habitat is also important. Large corporations are mostly looking for places where human capital is concentrated.

Migration flows are directed to large cities with developed infrastructure, with a need for skilled labor, low crime, lack of barriers for doing business, and accessible urban space for all people, regardless of age, race or gender.

Thus, the centers of human capital become cities that are adapted to human needs and contribute to the generation of new knowledge, technologies, and comprehensive development of the individual. In cities are mostly concentrated people with higher incomes, higher education level, and with higher human and social capital.

A new type of economic system imposes new requirements on the urban environment as a space for the population to live and conduct business. In the conditions of a market economy and increase of digitalization, one of the priority goals of the state should be to attract educated professionals from all over the world. The largest Western companies Google, Apple, GM, Facebook, Uber are no longer

mono-national companies, but their success is ensured by citizens of various countries and continents, and due to the integration of different people, cultures, and different forms of education, they continue to be leaders of the world economy.

The main capital of these companies are not lands, real estate or fixed assets, it is not even technology itself (because they are constantly outdated) or the brand – it is human capital. At the same time, companies, trying to retain and increase human capital, expand the range of additional amenities for their employees – from medical services and insurance to comfortable living for their employees. At the same time, a comfortable urban environment is a necessary condition for ensuring the quality of life and attractiveness of the city. The purpose of the research is to analyze the impact of externalities of urban agglomerations development processes on the inflow of human capital to the regional systems of Russia.

Methods

The study used methods for calculating and comparing the quality of the urban living environment, which is based on the collection, description and evaluation of quantitative and qualitative indicators. The source of information was the official data of statistical yearbooks for the regions of the Russian Federation on such indicators as: the volume of housing construction, commissioning of commercial real estate, highways, etc.

The study uses a rating method of assessment in order to compare urban agglomerations with each other, as well as to identify strengths and weaknesses in the development of the urban environment of the regions.

Results and Discussion

The manifestation of externalities of human capital within the urban environment occurs due to the fact that the city is the "habitat" of the economically active population and it is the activity of this set of economic entities that mediates the boundaries of urban space. Urbanized territories have more developed infrastructure (education, health, information, and finance), so the formation of human capital and its redistribution occurs more intensively in the urban environment.

In Russia, there is a slight increase in the population (Fig. 1), while the maximum number is in the Central Federal district. The population of Russia has been increasing in recent years due to both natural and migration growth. The amount of natural growth is insignificant (no more than 0.2%), and the main growth factor is migration growth, which provides about 90% of the total growth.

Fig. 1: Population dynamics in Russia and the Central Federal district

Russia is characterized by significant regional differences in population trends. By population size, the Central and Volga Federal districts are distinguished, where almost half of the inhabitants of Russia live (Fig. 2). the population of the North Caucasus Federal district increased mostly in 2011-2019, while the population of the North-Western, Ural, Central and southern Federal districts increased to a lesser extent. The population of the Siberian Federal district has increased the least.

Fig.2: Population by Federal districts as of 01.01.2019

The Central Federal district, which includes the largest agglomeration of the country, Moscow and the Moscow region, is the most numerous, followed by the Volga Federal district is not far behind. The remaining Federal districts generally have a comparable population.

It is characteristic that the population of the Central and southern Federal districts is growing due to migration growth, which not only compensates for the natural decline, but also provides a General increase. As a result of Russia's urbanization, its urban population has grown rapidly both absolutely and relatively, while the rural population has steadily declined since the mid-1920s. The Total population of Russia as of January 1, 2019 is 146,780,720 according to data, with 109.4 million people living in Russian cities. The impact of urban agglomerations on human capital is twofold.

On the one hand, the city is an innovative environment due to its inherent concentration of socio-cultural organizations and institutions, rich social and information environments, which in general creates more favorable conditions for human socialization, the formation of its labor and human capital.

On the other hand, urbanization leads to a deterioration of the environmental situation, an increase in air pollution, and a shortage of green areas and land. It is statistically proven that with the increase in the overall well-being of cities, the population is sharply stratified by income level, which is the reason for the growth of social conflicts and is a brake on economic development. In this part, it is justified to form new approaches to the organization of urban development.

The experience of developed countries shows that in order to achieve these goals, all city stakeholders (government, business, science, ordinary citizens, etc.) should take an active part in the development of the city. For example, we have an impact of the construction industry on the environment due to many factors. Stakeholder theory suggests that stakeholder pressure is one of the most important forces that determines the implementation of CSR and can provide organizations with motivation to adopt a corporate social responsibility strategy. In Russia there is a different situation at the moment, when most of the responsibilities for shaping the image of urban space are assigned to the mayor's office. Which in turn leads to lack of transparency of decisions of the bureaucracy and a large number of constraints. However, the task of the city authorities in this process is not to limit, but rather to create opportunities for expressing constructive, and sometimes not so much opinions and implementing the best of them in practice, and sometimes simply not to interfere in the already developing processes. This tells us that in order to build a successful sustainable city, we need to invest in effective partnerships. Such partnerships will depend on the sense and willingness of all sectors to engage in genuine social entrepreneurship and dialogue, while also recognizing the independent roles, responsibilities and special capabilities of each of them.

In this case, the city will become attractive for life, citizens will have incentives to realize themselves in this agglomeration, there will be less reason to think about both internal migration and emigration from the country as a whole. On the contrary, a comfortable urban environment can become an important stimulus for economic growth of the city and as a result, the city will become a magnet for educated, qualified citizens from other regions and countries.

Sometimes, the implementation of even one successful project, for example, significant architectural project, can lead to significant economic growth and increase the attractiveness of the city. There are plenty of such examples in urban studies, including the construction of the Museum of modern art in Bilbao, the Sydney theatre in Australia, the Eiffel tower, Times Square, and many others. The example of these agglomerations shows that it is not necessary to have huge resources for the development of urban space, it is important to invest in promising areas of urban development.

This example is significant for Russian cities and regional systems that, due to their historical specifics, tax legislation, and high levels of government centralization, do not have a large number of resources. The poor quality of the urban environment in Russian cities is largely due to the consequences of the Soviet model of urbanization.

More broadly, the reasons for migration should be looked on the level of the Federal districts of the Russian Federation. The analysis of the population dynamics of the regional systems of the Central Federal district made it possible to establish that in the period from 1995 to 2005 in all regions of the Central Federal district there was a decrease in the population. However, in the following years, a number of areas experienced population growth. The Belgorod, Voronezh and Kaluga regions have the highest growth rates (Fig. 3). Below there are considerations regarding the factors that contribute to the influx of population into these regional systems.

Fig. 3: Dynamics of population changes by region of the Central Federal district

It should be noted that the attractiveness of an urban agglomeration requires not only the presence of attractive urban objects, but also high-quality infrastructure, logistics and the presence of socio-cultural objects.

Different attractiveness of cities and of regional systems reflects the changes occurring in their economies and construction. Transport infrastructure is the most important component in assessing the quality of the environment. The influence of the location and development of the road network is significant for all urban centers, but an example of divergence in the development trajectories of Northern cities, whose remoteness acts as a barrier to economic modernization, is indicative. The top three regions with the highest level of provided roads are Belgorod, Voronezh, and Smolensk regions.

Fig.4: Length in km. Roads in dynamics, paved by region of the Central Federal district.

In terms of the number of areas for housing per 1000 people, the leading position is also maintained by Belgorod, Lipetsk, and Kaluga regions.

Fig.5: Average value of entering residential real estate per 1000 people for 2006-2018 by region of the Central Federal district

The top three in terms of commercial real estate are Yaroslavl, Kursk and Voronezh regions.

Fig.6: Volume of commercial real estate commissioning in thousand square meters by region of the Central Federal district

In terms of the volume of construction of health facilities and schools, following regions can be identified: Belgorod, Voronezh and Ryazan (fig. 7).

Fig.7: The volume of commissioning of health facilities and educational institutions in thousand square meters by region of the Central Federal district.

The given graphs and diagrams allow us to conclude that there is a close connection between the influx and consolidation of the population and the development of the urban environment. Under the urban living environment, we understand the totality of conditions created by man and nature within the boundaries of a locality, which affect the level and quality of life.

To confirm this, we calculated the level of development of the urban living environment and ranked the regions of the Central Federal district by the level of development of the urban living environment (table 1).

The level of development of the urban living environment was defined as:

$$\text{Угсо} = \frac{\sum P}{\sum n} \quad ,$$

P – place in regional systems in the rating by a separate indicator;

n – an indicator that is used to assess the level of development of the urban living environment.

The indices of urban environment development in the regions of the Central Federal district which are shown in the table, allows to build a rating on such important indicators as the length of highways, the introduction of residential and commercial real estate, the volume of construction of health facilities and schools. Note that the largest volumes and, as a result, the highest rating have Belgorod, Voronezh and Lipetsk regions. In the number of outsiders can be attributed to Tula, Ivanovo and Kostroma region.

Fig. 8: Ratings of regions of the Central Federal district on the provision of the population with a living environment

Using official statistics, we have distributed regions according to the degree of development of the urban environment, but for a full assessment, we need to take into account not only absolute values, but also relative values that characterize the population's housing supply, socio-cultural purpose, etc.

To do this, we calculated the coefficients of provision of the region's population with paved roads, residential and commercial real estate, hospitals, schools, and other socio-cultural facilities (table 1).

Table 1: Rating of the Central Federal district regions by the level of urban environment development

Region	Numerator – coefficient of provision of a resident of a region with construction objects Denominator - place in the ranking						The level of development of the urban living environment	Ranking place
	Paved roads	Residential real estate	Commercial real estate	Hospital Area	School area	Provided paid services		
Belgorod	0,12/3	0,8/1	0,65/5	0,11/3	0,30/3	53,8/2	2,8	1
Lipetsk	0,11/4	0,73/2	0,64/6	0,07/6	0,22/5	57,4/1	4	2
Kursk	0,10/5	0,42/7	1,2/2	0,08/5	0,23/6	49,2/5	5	3
Voronezh	0,08/9	0,55/4	0,47/7	0,13/1	0,21/7	55,3/3	5,1	4
Oryol	0,12/3	0,43/6	0,45/8	0,11/3	0,32/2	46,5/10	5,3	5
Kaluga	0,097/6	0,60/3	0,86/3	0,07/6	0,18/9	48,7/7	5,7	6
Tambov	0,10/5	0,6/3	0,43/9	0,10/4	0,19/8	48,6/8	6,1	7
Ryazan	0,09/8	0,49/5	0,27/11	0,12/2	0,24/4	44,2/14	7,3	8
Yaroslavl	0,076/10	0,40/8	1,27/1	0,07/6	0,13/11	47,2/9	7,5	9
Bryansk	0,093/7	0,35/10	0,33/10	0,12/2	0,14/10	44,0/11	8,3	10
Tula	0,07/13	0,31/11	0,15/14	0,01/10	0,48/1	49,0/6	9,2	11
Smolensk	0,16/1	0,40/8	0,087/15	0,08/5	0,10/12	36,7/15	9,3	12
Vladimir	0,074/11	0,36/9	0,24/12	0,03/8	0,08/13	50,8/4	9,5	13
Ivanovo	0,071/12	0,21/13	0,74/4	0,04/7	0,08/13	43,4/12	10,2	14
Kostroma	0,13/2	0,3/12	0,16/13	0,02/9	0,06/14	42,3/13	10,5	15

These tables allow you to identify the leading regions in terms of population availability of paved roads, residential and commercial real estate, hospitals, schools, and other socio-cultural facilities. Such regions are Belgorod, Lipetsk, and Kursk regions, while Vladimir, Ivanovo, and Kostroma regions have become outsiders to a greater or lesser extent.

The data obtained have a high convergence with the graph in figure 3. It is Belgorod region that has been the center of migration attraction in the Central Federal district for a number of years. The above data shows that regions that have sufficient financial security and develop infrastructure, socio-cultural and educational facilities are attractive to live in. This is also confirmed by expert surveys showing that the worst urban factors for Russian cities are congestion of the road network and provision of kindergartens and schools.

Conclusions and Recommendations

Thus, in the Russian Federation, the development of the urban environment determines the influx and consolidation of the population in urban agglomerations. At the same time, urban agglomerations are a complex socio-economic system, the development of which must take into account the preferences of all groups of the population.

The saturation of real estate supply in developed regions of Russia, such as Moscow, Saint Petersburg, Ekaterinburg and Krasnodar, is an incentive for the construction organizations of these regions to change their business models. Increasing competition and a wide choice of real estate on the market forces companies to look at the real estate market from a different angle.

The closest correlation is between the influx of population and the volume of construction of residential real estate, hospitals, schools, and other socio-cultural facilities. To a lesser extent, the influx of people into regional systems is associated with the development of the commercial real estate market.

To assess the development of the urban living environment at the regional level, it is advisable to use ratings and indexes. The urban environment development index, which takes into account the most important spheres of life in urban agglomerations, can be used as a tool for providing an objective comprehensive assessment of the regions of the Russian Federation.

Importance of the Sales Force for Effective Communication of SME in the B2B Sector

Christian ENZ

University of South Bohemia, Budweis, Tschech Republic

christian.enz@np-rbg.de

Abstract

SMEs today operate in an increasingly demanding environment. Societal and economic changes are creating more dynamics, complexity and stronger competition. One cause is globalisation, which is generating increasing competitive pressure. Another reason is the new expectations that legislators and stakeholders are placing on companies. Small and medium-sized companies, in particular, are at risk of being squeezed out by large market players. This forces SMEs to increase their competitiveness. In this context, the sales structure is of particular importance. On the one hand, it must ensure that the market's potential is fully exploited. In doing so, all relevant customer groups must be developed and an economic margin must be achieved in the sale of products and services. On the other hand, it is important to make sales as efficient as possible by minimizing costs. In the course of progressive digitalisation, SMEs are also increasingly relying on direct sales. Nevertheless, there are still numerous companies, especially among family-run SMEs, which continue to rely on a personal sales force. The present research study uses the example of a financial services provider to clarify whether significantly better sales figures can be achieved in the B2B sector with field sales representatives. To this end, the sales successes intended by sales representatives are examined on a three-month basis with the help of a one-sided t-test. The method is based on the author's assumption that better sales results are achieved with field sales representatives than with mere direct sales.

Keywords: SME, Sales Management, Marketing, Marketing Communications

Introduction

Distribution, i.e. the sale of products or services, is a discipline of business administration. The sales policy makes all design decisions on the way from supplier to customer. (Schmalen & Pechtl, 2019, p. 411) One of the decisive tasks of distribution policy is the selection of distribution channels. (Bagusat, Schlangenotto, & Büteröwe, 2016, p. 165) Homburg (2017) (Homburg, 2017, p. 865) and Winkelmann (2013) (Winkelmann, 2013) unanimously assign two functions to sales policy. These are logistical activities on the one hand. On the other hand, market-oriented, acquisition-related activities. Bruhn attributes to corporate communications the task of influencing decisions of target group members in the interests of the company. (Bruhn, 2010, 3 ff) Based on this, Homburg (2017) specifies that marketing communication is geared to the realization of sales transactions. At the same time, he emphasizes the special corporate significance of marketing communication. After all, interaction with potential customers or existing customers is of central importance for sales. (Homburg, 2017, p. 865)

At the same time, the rapidly advancing digitalization is changing customer relationships. Car manufacturers, for example, are now able to send messages to the multi-media systems of vehicles. Without the involvement of an authorised workshop, drivers can be reminded of a necessary inspection. (Helmrich, 2017, p. 92) In agreement with Helmrich, Schmitt/Hitschler state that digitalisation has led to a change in purchasing behaviour. Customers today increasingly decide for themselves via which contact points they find a product, brand or company. (Schmitt & Hitschler, 2020, p. 19) This changed behaviour is increasingly leading to a redistribution of advertising budgets. (Holtkamp & Bange, 2020, p. 388) While established communication channels are suffering losses, advertisers are increasingly investing money in digital advertising. (Gründel, 2017) Nielsen, for

example, predicts that online advertising will grow by 7.3 % year-on-year in 2020. The losers, on the other hand, include newspapers, magazines and cinema. (Weidenbach, 2020) These shifts are based on scientifically sound communication strategies. (Schildhauer et al., 2019, 9 ff) Their focus, as Zerfass/Volk (Zerfass & Volk, 2019, p. 9)and Kainz/Haupt/Schnaderbeck (Kainz, Haupt, Herberth, & Schnaderbeck, 2018)and Haas/Bowen (Haas & Bowen, 2016, p. 29) agree, is often on achieving cost savings.

Meanwhile, the counterpart to digital distribution is personal sales. According to Zupancic, this is the most expensive communication channel. (Zupancic, 2012) At the same time, there are traditionalists like Reinhold Würth who still attributes 90 % of the company's success to the sales force. (dpa, 2020)

In general, it can be said that communication research is currently mainly concerned with the marketing communication of large companies and corporations. The special needs of SMEs are not taken into account. They rarely have large communication budgets in which reallocations are possible. Furthermore, SMEs often operate in geographically limited business areas where not all communication channels are available.

This research aims to examine whether a sales force for SMEs can still be useful in today's world. This would be the case if regions served by a sales force could deliver significantly better sales results than sales units without personal support. The clarification of this question is particularly important because the management of SMEs is faced with constant changes. It is important to react quickly and flexibly to changes. Without, however, losing any advantages or unique selling points. (Maříková, Rolínek, Vrchota, & Řehoř, 2018) More effective sales communication can be one such advantage, otherwise, a sales force in the field means a large cost pool.

Methodology

According to Bruhn, a company's sales policy deals with all decisions relating to the supply of corporate services to customers. (Bruhn, 2019, p. 253) Against this background, sales policy is defined as an instrument of marketing. (Zerres, 2017, p. 10) However, according to Binckebanck, previous research results suggest that the importance of sales in comparison to the other instruments communication, product and price is higher than often assumed. (Binckebanck, 2018, p. 654) To optimally influence the target group's actions, it is necessary to integrate all marketing activities. (Bruhn, 2017, p. 5) Against this background, all communication channels of a company can be defined as sales policy instruments. (Gartner, 2018, p. 158)

The salesforce plays a special role in the round of communication channels. On the one hand, because they are considered to be particularly cost-intensive. (Meffert, 2017, p. 1012; Nold, 2020, p. 123) On the other hand, the sales force enables face-to-face communication. This is interactive and enables a higher level of involvement than impersonal or asynchronous communication. Moreover, personal interaction enables immediate sales. In contrast, the effect of other channels generally sets in with a delay. (Dan, 2018, p. 89; Moriarty, Mitchell, & Wells, 2015)

The focus of quantitative methodology is on making objective statements about the acceptance or rejection of hypotheses (Kuss, Wildner, & Kreis, 2014, p. 52). The research project presented here is based on the following hypothesis:

Hypothesis 1: Distribution performance is not dependent on the season.

Hypothesis 2: The sales performance is significantly higher after the visit of a sales representative.

In the context of this research project, the effect of field sales force visits on the sales performance of different regions is examined. For the results to be used later as a basis for decision-making in SME management, a precise description of the setting is required. (Foran & Lebel, 2012; Škodová Parmová, Líšková, Sdrolias, & Kain, 2017) By describing observable facts it should be possible to make assumptions about connections, relationships, typical and untypical. Through the targeted search for confirmations and refutations, it is possible to recognize on an abstract theoretical level under which conditions certain statements are true and which limitations exist. (Akremi, 2019, p.

328) This theoretical generalization is also called logical inference. (Beierle & Kern-Isberner, 2019, 20 ff; Seale, 2000, p. 109)

Object of Observation

The object of the present research project is a company from the financial services sector operating throughout Germany. Measured by the number of employees and annual turnover, it is to be assigned to the group of SMEs. However, there is no international agreement on how the SME group is to be defined in concrete terms. (Dar, Shafique, & Raziq, 2017, p. 48) The European Union recommends its member states to measure the size of a company according to the number of employees and turnover or balance sheet total. According to the current interpretation for SMEs with between 11 and 250 employees and turnover between EUR 2 and 50 million. (European Commission, 2003) The author of this paper agrees with the EU definition. Specifically, the company under investigation is to be classified as medium-sized, as it has more than 50 employees and annual turnover is above EUR 10 million. The sales force of this company looks after 2,500 independent agents. (VW editorial office, 2017) These are divided into 34 sales regions.

Data Basis

Primary data can be obtained and evaluated to test the hypotheses made. (RAUCH, 2019, 88 f) Alternatively, secondary data can also be used. However, these must be available and must meet specific requirements for a particular research project. (Zeh, 2017, p. 147) For the planned research project, the effect of the sales force on the distribution power of the sales force partners will be investigated. The necessary data will not be collected specifically for the research project. Instead, existing data from sales controlling will be accessed. This means that secondary data is evaluated.

For the present research work, all financial statements from 2016 to 2019 inclusive are analysed. Also, all dates of the sales force introduced in 2017 are examined. Since all units of the population are taken into account, this is a full survey. (Handl & Kuhlenkasper, 2018, p. 306) This allows the hypotheses to be examined directly for durability using descriptive statistics. (Tachtsoglou & König, 2017, p. 259) The evaluation aims to identify deviations in the sales performance of units serviced by sales representatives and units not serviced. Quantitative methods must be applied for this purpose. (Liebig, Matiaske, & Rosenbohm, 2017, p. 5)

Results

The task of every company is to achieve goals that will enable the company's long-term existence through economic success. (George, Labros, & Sotiris, 2014, 11 f) It should be noted that companies are closely linked to the companies in which they are active. (Koukoumpliakos, Řehoř, Sdrolias, & Škodová Parmová, 2019, p. 81) This economic and social environment is increasingly characterised by complexity, dynamism and, ultimately, competition. (North, 2007, p. 167) The reason for this is globalisation, the consequences of which are causing increasing competitive pressure. (Schomaker, Bernstorff, & Nachtwei, 2013, p. 320) Lee/Wainwright/Glassman (2017) (Lee, Wainwright, & Glassman, 2017) Falvey/Greenaway/Silva (2018) (Falvey, Greenaway, & Silva, 2018) Schymik (2018) (Schymik, 2018) But also increasing stakeholder expectations concerning social responsibility (Koukoumpliakos et al., 2019, p. 81), the sustainable development of habitats and the careful use of natural resources make unpleasant work more demanding. (Škodová Parmová, Dvořáková Líšková, Sdrolias, & Aspridis, 2019, p. 177) SMEs, in particular, run the risk of being squeezed out of the market by large companies, as they usually have sufficient financial resources to survive in cut-throat competition. This pushes SMEs to optimise their processes and use existing potential to improve their productivity and thus their competitiveness. (Hanzal & Beranek, 2016, 161 f) Neacşu (Neacşu, 2017, p. 108) Gunduz (2018) (Gunduz & Yetisir, 2018)

At the same time, it can be observed that the share of business processes supported by information technology is continuously increasing. (Brettreich-Teichmann & Grötecke, 2016, p. 1) Against this background, Rump/Eilers even attest digitization a central role in the canon of trends and developments that will shape the future world of work. (Rump & Eilers, 2017, p. 78) According to Lister, this even leads to a situation where the development of new products is geared to the

restrictions of digitization. Suppliers strive for a lean product range and simple offers that require little explanation. (Lister, 2020, p. 26) At the same time, however, it has been proven that customer focus is essential for sales success. (Reichmann, 2019, XV; Teuchert, 2019) This is the area of conflict in which the sales force finds itself. Therefore, it must be clarified whether the high personnel and financial expenditure can still be justified today.

Literature Review

The literature review makes it clear that the sales organisations at SMEs are facing a structural change. (Schweiger & Kump, 2018, p. 293) However, family businesses, which make up a large part of SMEs, are often unwilling to adapt existing sales structures. (Kammerlander & Prügl, 2016, p. 11) Kammerlander/Ganter see this as a decisive competitive disadvantage for family-run SMEs. After all, sticking with old sales structures can result in the loss of margins as well as the loss of entire customer groups. (Kammerlander & Ganter, 2015) Young customers, in particular, expect digital shopping opportunities. The lack of suitable online offers harms the purchase decision. (Gieselmann & Gremmer, 2018, p. 433) Eggers/Hollmann and Sonntag agree that the informed customer already prefers to buy online. (Eggers & Hollmann, 2018, p. 244; Sonntag, 2011, 19 f) Overall, the trend toward online purchases has been steadily increasing since 2000. While e-commerce sales in Germany amounted to EUR 1 billion, the figure in 2018 was EUR 65.1 billion. In 2019 the previous record of EUR 72.6 bn was finally reached. (Furchheim, Wenk-Fischer, & Groß-Albenhausen, 2020) A development that can also be observed in other countries. In the Czech Republic, for example, e-commerce sales rose from EUR 2.4 billion in 2017 to EUR 2.8 billion in 2019, with a volume of EUR 3.6 billion forecast by 2024. (Statista GmbH, 2020)

In the future, however, aligning the entire sales force to virtual channels does not necessarily have to be target-oriented. After all, new generations of customers will not commit themselves to one channel. Rather, as Barnes/Correia (Barnes & Pavao, 2017, p. 7) and Mosquera/Ayensa/Pascual/Murillo (Mosquera, Juaneda Ayensa, Pascual, & Murillo, 2019) agree, they behave as multi-channel shoppers and want to be addressed as such. At the same time, changes in the economy, as can be expected after the Corona crisis, are likely to result in changes in household spending and consumer habits. Thus, a recession can lead to a reduction in income. As a result of the associated restructuring of consumer spending, impersonal or digital distribution channels may become increasingly important for consumers who have preferred personal contact in the past. This happens when alternative distribution channels offer more favourable conditions. (Faltová Leitmanová, Petrách, & Beran, 2019)

From these imponderables, Eggers/Hollmann feels the need to distribute the sales budget sensibly. (Eggers & Hollmann, 2018, p. 243) Up to now, Wollenburg/Holzapfel/Hübner/Kuhn criticize, the evaluation of the meaningfulness of distribution channels is mainly done from the marketing perspective. They advocate steering the customer into distribution channels that make sense from a business perspective. (Wollenburg, Holzapfel, Hübner, & Kuhn, 2018)

Whether the use of a channel makes sense for a company is not a general question. It is not a question of integrating new CRM tools, social media or data analytics. It is also not decided whether a customer feels the channel is modern or whether all industry trends are followed. (Bokeria, Biehl, & Radloff, 2020) From a business perspective, the only question that matters is what contribution margin a channel of marketing communication can deliver. For example, a channel can be superficially effective because it has low contact costs. However, if additional sales potential is lost, for example, because needs remain undiscovered or cross-selling does not succeed, efficiency also suffers. The same applies to market exploitation. If a communication channel has a significantly higher closing rate, this option can pay off, even if it initially appears cost-intensive.

Data Analysis

As explained in 2.2, the present research work is based on the analysis of secondary data. Secondary data are all data that were not collected by the researcher himself. (Bergener, Clever, & Stein, 2019, p. 57) This is possible because all positions required for the analysis are available in sales controlling. In general, as Hausmann and Hartmann/Amine/Klier/Vorwerk (Hartmann, Amine, Klier, & Vorwerk,

2019, p. 48) agree, the use of secondary data is only possible if it meets the concrete information requirements. (Hausmann, 2019, p. 36)

In principle, the present research work pursues the goal of identifying or rejecting the existence of differences between regions serviced by the sales force and those not serviced. For this purpose, the sales successes of the years 2016, 2017, 2018 and 2019 are analysed. The measured values originate from different sales regions, which, however, were assigned by a third party variable. The criterion month could be considered as a third variable that is not the focus of the analysis. Dependent samples would, therefore, be available. (University of Zurich UZH, 2018) For a hypothesis test in such a setting, the t-test for paired samples has established itself as a generally accepted procedure. (White, Redford, & MacDonald, 2020)

Dependence of sales performance on the season

The sales performance is recorded monthly. If the season affected sales performance, the sales results would depend on the month in question. Since the date "month" is not a numerical value, a numerical coding is necessary. An evaluable nominal scaling is then available. (University of Zurich UZH, 2016) This allows the verification of correlations utilizing cross-table analysis. (Leibinger & Sander, 2017, p. 262)

The analysis of correlations for two characteristics is defined as bivariate data analysis. A crosstab table provides a simple and illustrative option for examining the relationships between two variables. (Thousand pounds, 2019, p. 58) On the x-axis of the cross table, often referred to as the contingency table, (Perret, 2019, p. 51), the present years are plotted. On the y-axis, the months January to December are deducted. The absolute sales figures are noted in the table itself. There are regularly particularly high final figures in certain months and particularly low final figures in certain other months. This indicates a correlation between the closing rate and month. Whether this is a coincidental association or a systematic correlation must be examined within the framework of a contingency analysis. The most popular instrument for this is the Pearson's chi-square test. (Backhaus, Erichson, Weiber, & Plinke, 2016, p. 358; Leibinger & Sander, 2017, p. 263)

The Chi-square test checks whether two random variables are stochastically independent. If the absolute frequencies in the population are the same as the expected frequencies in the population in the case of independence, there is no correlation between the two variables X and Y. (Kosfeld, Eckey, & Türck, 2019, 342 ff) The derivation of the expected distribution is based on the idea of a squared standard normally distributed random variables. Accordingly, the square of an N(0;1) distributed random variable follows a chi-square distribution with one degree of freedom (Cleff, 2019, p. 78):

$$Z^2 \sim X_1^2.$$

According to Cleff, the sum of the squares of two independent and standard-normally distributed random variables Z1 and Z2 follows a x^2 distribution with two degrees of freedom: (Cleff, 2019, p. 78)

$$Z_1^2 + Z_2^2 \sim X_2^2.$$

In general, the sum of the squares of n independent and standard-normally distributed random variables, an x^2-distribution with n degrees of freedom can be observed: (Cleff, 2019, p. 79)

$$Z_1^2 + Z_2^2 + \cdots + Z_n^2 \sim X_n^2.$$

The hypothesis test utilizing the chi-square test goes back to Pearson and is generally accepted. However, the reliability of the chi-square test depends on various conditions. Reliability only exists if no more than 20 per cent of the cells have an expected frequency of less than 5. Besides, the smallest expected frequency must not be less than 1 (Backhaus, Erichson, Plinke, & Weiber, 2016, p. 315; Bühl, 2016, p. 306; Hartung, Elpelt, & Klösener, 2009, p. 416) If these prerequisites are not met,

further procedures such as the exact test according to Fisher are to be preferred. The exact test according to Fisher is based on simulations and does not know any prerequisites. Therefore, it can also be used for very small samples and low expected frequencies. (University of Zurich, 2017) This is not necessary for the present research project since the decisive basic conditions are fulfilled. This is shown in Table 1.

Dec	1081,048	1180,477	1283,371	10405,000
Total	9046	9878	10739	87067

This allows the dependence of the distribution capacity on the season to be tested. The established hypothesis (H0) states that there is no dependence between the achieved sales performance and the

month in which it was achieved. This hypothesis is tested with Microsoft Excel using the XLSTAT statistical plug-in. A chi-square test is performed automatically. The results of this test are shown in table 2.

Table 2

Chi-Quadrat (Observed Value)	1190,343
Chi-Quadrat (Critical value)	110,898
FG	88
p-Value	< 0,0001
alpha	0,05

Since the calculated p-value is smaller than the significance level alpha = 0.05, the null hypothesis must be rejected. Instead, the alternative hypothesis (Ha) must be accepted. This states that the two variables are dependent.

Increase of the sales performance by a field service

The primary objective of the present research work is to examine whether a significant increase in sales figures is possible through a sales force. For this purpose, the sales results in regions with field sales force support (region A) are compared with the performance of regions without field sales force support (region OA). As demonstrated in 3.3, sales performance is dependent on the season. For this question, a t-test for two dependent samples is suitable for testing a hypothesis. The elements of the two groups Region A and Region OA are assigned to each other in pairs. Thus, the two groups are not considered independently of each other. The pairs of measured values or their differences are examined. (Witte, 2019, 67 f) Thus, for the t-value:

$$t = \frac{\overline{x_\Delta} - \mu_{d\,\Delta}}{\hat{\sigma}_{x\,\Delta}}$$

For the hypothesis test of the null hypothesis, the simplification results as a quotient from the mean value of the differences and the expected value of the difference mean: (Witte, 2019, p. 68)

$$t = \frac{\overline{x_\Delta}}{\hat{\sigma}_{x\,\Delta}}$$

For smaller samples, the t-test can only be applied if the differences in the population are normally distributed. For Bortz, this condition is already given if an approximately normal distribution is given. Such a small sample is given if n is smaller than 30. (Bortz, 1993) Since the present research project has 47 pairs of cases for this question, this problem can be disregarded.

A special feature of the company under investigation is that the sales force is not directly involved in sales. Rather, it fulfils the role of a sales trainer to enable the customers it serves to sell more. This concept is based on the insight that sales success is no coincidence. Good results result rather from necessary sales and product knowledge. (Unger, 2020, p. 1) The performance of a salesperson is not determined by him or her alone. (Wunderlich, Hinsch, & Olthoff, 2019, p. 184) Jensen & Pfaff see even 70 per cent of sales performance as being dependent on sales management. (Jensen & Pfaff, 2013) The concept of coaching independent sales staff via the sales force to increase productivity makes sense from a scientific point of view. For Zupancic, real coaching requires a certain distance and independence from the responsibility for results. (Zupancic, 2019, p. 125)

However, product-oriented financial distribution has now given way to a demand-oriented approach. This is also actively demanded by legislators and regulatory authorities. (Sommese & Eberhard,

2020, 53 f) A salesperson activated by the field sales force must therefore first identify suitable customers and arrange appropriate appointments.

Besides, the sales territory of the investigated company covers the whole of the Federal Republic of Germany. Different school holidays and the associated vacation periods make it difficult to directly compare sales regions. Also, the sales regions differ greatly in terms of their size and the number of customers served.

Because of the above, the observation period for sales performance is set at three months. The three months following a training date by the sales force are taken into account. The comparison is not made based on actual sales. Instead, the percentage share of the observed months in the annual sales performance of the respective sales region is considered. This setting allows the limiting factors of "holiday periods" and "varying customer base" to be effectively compensated for.

The hypothesis test is performed as a t-test for dependent samples and is calculated with the analysis tools of Microsoft Excel. Data pairs must be formed for this purpose. On the one hand, the average percentage sales performance of a region in the three months following salesforce training is used. On the other hand, the average percentage sales performance of a region without a date in the same period is used.

The null hypothesis (H0) says that there is no dependency between a sales force appointment and the later sales success. However, the author assumes that there is a dependency. For this reason, the analysis is carried out using a one-sided t-test for dependent samples. The significance level is set at 0.05. The result of the analysis is shown in Table 4.

Table 4

Two-sample t-test for dependent samples (pair comparison test)		
	Without FS	*FS*
Mean value	7,350086974	8,365296926
Variance	6,119094591	8,916401113
Observations	47	47
Pearson correlation	0,797925263	
The hypothetical difference in the mean values	0	
Degrees of freedom (df)	46	
T statistics	-3,86200827	
P(T<=t) one sided	0,00017496	
Critical t-Value for one-sided t-Test	1,678660414	
P(T<=t) second sided	0,000349921	
Critical t-Value for second sided t-Test	2,012895599	

The one-sided P-value is 0.00017496 and thus significantly below the significance level of 0.05. The value of the t-statistic is 3.86200827. It is, therefore, greater than the critical t value for the one-sided t-test. This is shown with an amount of 1.678660414. The null hypothesis (H0) must, therefore, be rejected. Instead, the alternative hypothesis (Ha) must be accepted. This says that there is a connection between appointments of the sales force and an increased sales performance by the customer advisors.

Conclusion

The literature analysis in the context of the research work presented shows that more and more business processes are also being digitised in SMEs. (Ristuccia, 2019; Stentoft, Jensen, Philipsen, & Haug, 2019, p. 5155) The driving force is the quest for greater efficiency. This is necessary because globalisation and sustainable thinking are putting increasing pressure on local actors. (Stejskalová, Štrach, & Rolinek, 2018) Connected with digitisation is the hope of achieving an advantageous position in the market through cost-effective organisational structures. (FRANK, Schumacher, & Tamm, 2019, p. 127) This also leads to changes in the distribution structure. (Asheq & Hossain, 2019; Hennart, Majocchi, & Forlani, 2019, p. 761) For example, technical innovations are increasingly being used to replace cost-intensive personnel sales. (Schröder, Schlepphorst, & Kay, 2015, p. 9) The aim is to distinguish oneself positively from competitors in an environment where it is becoming more difficult to create and maintain competitive advantages. (Fuka, Vrchota, & Rolínek, 2018)

Using the example of an SME in the financial services sector, this paper shows that the use of a traditional sales force in the B2B sector can still make sense. Using descriptive statistical methods, it was shown that sales areas with a sales force achieve significantly better sales results than unsupported sections. Thus, traditional sales are not automatically inferior to new, digital channels.

The investigation only covered the number of units sold. Contribution margins were not taken into account, nor was the value of the better sales performance concerning the costs associated with the sales structure. Thus, the present research work provides evidence that established sales structures in SMEs should not be abolished without further ado. Rather, the different channels of marketing communication must be carefully weighed up before making adjustments. The present paper shows

that there is a need for further criteria for the entrepreneurial evaluation of the sales force - and thus provides the impetus for further research projects.

The subject of the present study is an SME in the financial services sector operating throughout Germany. The result cannot be easily transferred to companies with a geographically limited business area or other industries. On the one hand, because financial products usually require a lot of explanation. On the other hand, because financial products are not visible - which places special demands on sales. Against this background, the present paper can also serve as a suggestion to examine the effect of personnel sales in other industries.

ORCID ID: 0000-0002-4129-045X

Abstract

Staff turnover is the inflow and outflow of employees in an enterprise. Many enterprises have problems not only with finding suitable employees but also with retaining them. The objective of the article is to present an impact of staff turnover on the operation of hotel enterprises. Method: A theoretical part of the study is a result of the use of the desk research method. Unique entity's influence (i.e. hotel enterprise's personnel) and the executed processes of human resource management mean that human resource dysfunction has to be assessed individually for each entity. Therefore, the author used case studies in the empirical part aiming at exemplifying human resource activities in the hotel industry. There are results from surveys and interviews with human resource managers conducted in 250 hotels in Poland. The research has shown that high staff turnover rate is a significant problem for hotel managers in Poland. Due to a limited number of research entities, the research findings cannot be generalized with regard to the whole industry. However, they can serve as the basis for a discussion on the phenomenon of human resource management dysfunction in the hotel industry and its impact on work efficiency, thus the functioning of the whole organization.

Keywords: Hospitality, Human Resources Management, Threats

Introduction

Cooperation and commitment of the whole staff are needed for the survival and development of a hotel enterprise's in an increasingly more competitive environment. The way how the personnel treat their duties depends on motivational activities undertaken by a hotel enterprise. Wrong decisions in terms of motivation may lead to a high employment fluctuation rate. Staff turnover (fluctuation) is the inflow and outflow of employees in an enterprise. In practice, the issue of employment fluctuation is still valid. Many hotel enterprises have problems not only with finding suitable employees but also with retaining them.

The aim of the article is to present the reasons for staff turnover in hotel enterprises and their potential effects. The main problem in the functioning of modern hotel enterprise's is the fact that there is no certainty with regard to activities. Threats that occur when conducting business activity may lead a company to bankruptcy and the list of dysfunction factors is long and diverse. Their common characteristic is the fact that they directly affect the financial situation of an entity. By contributing to generating specific types of costs or increasing sales revenue, they imply the level of effectiveness of human resource and investment decisions which is reflected in the company's situation. Therefore, it is of great significance to identify dysfunction factors which may affect the functioning of enterprise (Becker & Smidt, 2016; Bhattacharya &Wright, 2005).
One of the types of threats is the dysfunction connected with an organization's social system. It can be defined as "involvement under conditions of uncertainty in activities concerning personnel which may

prove unsuccessful" (Lipka, 2002). Depending on speed and accuracy of the undertaken human resource activities, it can pose a threat (loss for) to or be an opportunity for business activity (Dionne, 2013; Elahi, 2013).

Dysfunction of human resource management is not a homogenous category which means that many types of dysfunction can be distinguished, namely (Tokarz-Kocik 2012;):

- recruitment dysfunction - failure to adjust labour demand and supply in quantitative and qualitative terms;
- selection dysfunction - is a decision-making situation which involves threats arising from employing a given person on the basis of wrong criteria of selection;
- evaluation dysfunction connected with the process of developing employee's behaviour at work and the results they obtain;
- dysfunction of investment in employees' development, including: the of the lack of expenditure on human capital; the threat of leaving work by employees who the company invested in; the dysfunction of a gap between personnel's knowledge and skills;
- motivational dysfunction – consequences for a company resulting from a wrong selection of motivational tools towards particular employees.

Human resource activities are subject to the threats arising from the changeability of phenomena in the labour market. The above phenomena build up due to the growing mobility of society, and thus recruitment threats become increasingly multidimensional and changes dynamically over time. Labour market expansion due to the Polish membership in the European Union provides more possibilities of searching an attractive job by employees and intensifies economic migration. For Polish companies, it is a challenge in terms of a growth of competitiveness which goes beyond national borders and also makes it necessary to open up to immigrants from other countries (Bizon-Górecka, 2009).

Selection dysfunction is connected with the lack of certainty in terms of the choice of employees as people who should enrich the human resources of a hotel enterprise's. Therefore, it includes a threat that instead of multiplying human capital qualitatively it will lead to its impoverishment with all related consequences.

The next function of human resource management, that is evaluation, is subject to a special threats due to difficulties with a selection of relevant evaluation techniques. Nevertheless, resigning from evaluation to not make mistakes is not a right solution as evaluation results are known to constitute a starting point for various human resource decisions. When determining the level of evaluation dysfunction , the level of objectivity of evaluation procedures performed in a company should be taken into account.

Motivating may also be dysfunctional. The highest dysfunction level corresponds with obtaining a result which is the opposite of motivational activities, that is the state of employees' demotivation, despite particular expenditure on satisfying employees' needs in a better way. Leading to that may result from well as improperly targeted managers' efforts aiming at developing attitudes and behaviours of employees may be harmful. An incentive scheme should be not only consistent with the general strategy of a company (including: sub-strategy of cost development), but also compatible with the requirements of the company's environment (i.e. attracting right job candidates). Failure to meet any of the above requirements that modern incentive schemes face increases motivational dysfunction, thus the threats for hotel enterprise's as an employer (McGee, Rennie, 2012).

Nature of work in Hotel Enterprises

A hotel enterprise consists of a team of people, as well as tangible and financial assets that form a separate entity with its own economic, technical, spatial and legal nature, and is engaged in professional business activities of offering accommodation (rooms) against payment and providing services related to it. The work process in a hotel enterprise is of a different nature than the one found in production enterprises. This dissimilarity is mainly a result of the specific nature of hotel services as they cannot be made-to-stock, stored or delivered to clients' places of living.
Hotel services are quite specific services and providing them often poses a great challenge for hotel staff. Guests who spend longer periods of time outside home expect that many of their needs will be satisfied, i.e.:

- subsistence needs (food, hygiene, sleep),
- additional needs (entertainment, recreation, sightseeing),
- emergency needs (medical assistance, change of plans).

Such numerous types of guests' expectations require from hotel staff to be highly available and engaged.
The simultaneity of production and consumption of services is a factor that influences the employment structure and work organization in hotel enterprises. This characteristic means that work in the hotel enterprise's is continuous, multi-shift and includes the whole week, with Sundays and holidays. Thus, it is hard to standardize the work time and limit it to 8 hours a day. Hotel enterprise's must operate 24 hours a day and, additionally, the tourism movement is intensified during the tourism season, what increases the workload of operational staff. Despite the technological development, machines cannot replace humans in the process of providing hotel services. The essence of hotel work is still a direct contact of a staff member with a tourist and this entails the necessity of employing relatively large personnel.

Attitude and predispositions of guest service employees have a decisive influence on the quality of a hotel product. Therefore, it is of a vital importance that personnel carry out their duties with the utmost engagement. This will be possible if they are properly motivated.

Motivational activities limiting a Staff Turnover Rate

The basic aim of a motivation system is to stimulate people to fulfil their company missions and reach the company goals, while taking account of the needs and expectations of employees. People are motivated to work if they expect that their actions will lead to achieving a goal and getting a valuable reward – one that will satisfy their needs.

Effective employee management in a hotel enterprise requires many activities. The most important is motivating and training employees.

Motivating employees to work involves a range of individually personalized motivational instruments. Salary is considered to be one of the most important and often dominating motivator. Therefore, developing a salary structure is one of the basic processes through which motivational function is being implemented in hotel enterprise's. Apart from direct compensation, the effectiveness of a motivation system is determined by offered perks and benefit packages. They may include such elements as a corporate mobile phone, laptop, private health insurance, additional life insurance, coupons for free lunch in a hotel restaurant, holiday vouchers, coupons for free stay at one of hotels of the chain. Nonfinancial motivating tools also include: intangible rewards (letters of commendation, diplomas, commemorative medals and cups), in-kind rewards (albums, books with dedications), work-life-balance (Grobelna & Tokarz-Kocik, 2016). These instruments are most often less expensive than financial incentives and, under some conditions, they are more effective. Creating opportunities for employees to develop their qualifications is also part of efficient motivation. As a result, it is essential to develop a comprehensive

training programme that is tailored to the expectations of workers and the goals of a hotel enterprise. Proper motivation of employees contributes to their satisfaction with work.

Voluntary redundancy is a symptom of lack of job satisfaction. Job satisfaction is most commonly understood as positive attitude and emotions towards the work environment and professional duties performed by a person. Research on direct relations between job satisfaction and employee behaviour allowed determining the correlation between an increase in job satisfaction and staff turnover at the level of -0.40, which means that the increase in job satisfaction lowers a staff turnover rate (Tokarz-Kocik, 2017; Grobelna et al., 2016). Job satisfaction depends on the balance between what a person invests in their work (e.g. time, engagement), and what they receive in return (promotion, development opportunities, friendly relations), which are a motivational activities (Staples & Higgins, 1998).
In order for them to be efficient, it is necessary that managers in a hotel enterprises recognize the employees' needs and adapt the motivation methods to them (Grobelna et al., 2016). The feedback to this will be increased employee engagement in the process of carrying out duties and staff loyalty. The main benefits of employee loyalty for a company are:

- employment retention,
- increased work efficiency,
- customer retention.

The advantage of employee loyalty is that the longer an employee works in a given company, the more work experience they gain. Staff with more experience in a hotel enterprises have a unique knowledge about the individual customer preferences or product characteristics, thus they provide better customer care. Employee loyalty also determines customer loyalty. Employment stability is significant for positions which require from employees to know individual client needs and preferences. The result of changing staff in a hotel enterprises (e.g. receptionists, waiters, chefs, masseurs) is a gap in customer service, which leads to customer dissatisfaction and a discrepancy between the client expectations and real experience (Hill & Alexander, 2003).

Therefore, it is of the utmost importance to properly develop employee loyalty through the use of appropriate motivating stimuli. These should be adjusted to the needs and expectations of employees. A hotel enterprises should take into account that not only needs evolve due to age, new qualifications or occupied position, but also their hierarchy and the preferred method of satisfying them.

The multitude of factors that differentiate personal goals of each employee in a company requires that a company develops such a motivation system that enables all employees to fulfil their individual personal needs and simultaneously ensures that an organization reaches its own goals.

Employers have to change their approach to building relationships with employees. One solution may be to personalize the career path and replace the so-called corporate ladder with a corporate network. A corporate ladder includes traditional hierarchy, promotion path and assumes that employees' needs do not change with time. On the other hand, corporate network gives employees multiple career paths that allow them to maintain work-life balance (Grobelna & Tokarz-Kocik, 2016). Career path personalization, which is based on an individual career development pace of an employee, gives a possibility to choose workload and work time, as well as a position and the scope of responsibilities.

Staff turnover in Hotel Enterprises in Poland

The nature of work in hotel enterprises means that the high staff turnover makes its operation very difficult, is a significant problem for hotel managers. In 2019, was conducted surveys on staff turnover in hotel enterprises. Managers from 250 hotels, across all sixteen voivodships, participated in this research. The largest group of survey respondents (85%) consisted of managers from three-star hotels.

The next group size-wise (12%) managed four-star hotels. Other respondents represented one-, two- and five-star hotels. The research shoved, that rate at which employees resign from work varies depending on the position held (Fig. 1).

Fig. 1: Hotel departments in which the staff turnover rate is the highest

Source: own work

According to 36% respondents, a high turnover rate (over 50%) can be most often found at the Front Desk. Other hotel departments with high staff fluctuation rates are Kitchen and Restaurant (32% and 14% of responses, respectively). It is also quite common in hotels that housekeeping employees resign (8% of responses). A rather high retention (loyalty) rate is observed on the managerial positions, as only 1% of the researched businesses indicated a high turnover rate in that workforce group. None of the surveyed hotels registered voluntary turnover among the administration employees.

We may look at staff fluctuation as an involuntary phenomenon, which results from legal regulations or employer's will (e.g. contract expiration, reduction in force, retirement), or a voluntary one. There are much more reasons behind voluntary resignation and they mainly depend on an individual approach of an employee or may be a sign of mistakes in the human resources management process (Fig. 2.).

Figure 2: The reasons for staff turnover

Source: own work

The research showed that the main reason behind resignation from work for 50% respondents is unsatisfactory compensation. Among other factors indicated by respondents were personal reasons, economic migration or lack of development possibilities.

Employee salary is one of the most neglected motivational functions in hotel businesses. Salaries in the hotel enterprises in Poland are lower than the average ones in this economy. Median salary in the hotel enterprises in 2018 was PLN 3300 gross in comparison to PLN 4500 gross in the national economy (Report, 2018). In addition to the fact that salaries in the hotel enterprises are relatively low, one may find dysfunctional activities occurring in terms of compensation in hotel enterprises. These are connected with not informing employees about the compensation methods. Other problems related to a pay policy are:

- delayed salary payment,
- disproportionately high compensation of relatives and their acquaintances in relation to workload;
- no payment for overtime.

Apart from low salaries, the research findings point to the limited promotion and career development opportunities as well as lack of respect and support from a superior as significant reasons for employees leaving a company. All of these factors demotivate and contribute to high staff fluctuation in hotel enterprises.

A high staff fluctuation rate brings a range of negative consequences for a hotel enterprises and its workforce (Taylor, 2006; Clausen & Borg, 2010), namely:

- additional responsibilities for remaining hotel personnel,
- costs of a new recruitment and selection process,
- loss of employee's knowledge and experience for the benefit of competition,
- negative image of a hotel enterprises as an employer,

- lower quality of service,
- loss of regular customers.

If an employee resigns from work, it reflects negatively on the hotel remaining personnel who have to deal with additional responsibilities while simultaneously carry out tasks planned earlier. Some workers see this as an opportunity to stand out, but others cannot cope with the new situation and are unhappy. It is often the case that these employees are required, irrespective to their regular responsibilities, to help with training new staff. If this only happens occasionally, the necessity of taking up additional workload does not become a problem. However, if a staff turnover rate is too high and results in an almost permanent workforce deficiency than the morale of staff may go down and they might be less engaged in their work.

The staff fluctuation phenomenon involves the need to hire new employees and this in turn means additional costs for a business. Their largest component is most often expenses related to the recruitment process, which are fees and charges for placing job advertisements in the press or work agency fee. Another element is work time cost of managers involved in the recruitment and selection process for the replacement of a departing employee. It may turn out that several job interviews have to be conducted or the Assessment Centre method have to be used in order to fill some positions. There are also costs of induction to a position and proper training of a new employee, as well as administrative costs related to introducing a new person in the organization (preparing a job contract, setting up personal files, etc.). While the abovementioned procedures are being executed, the position remains vacant. For a company, it means that productivity will be lower for a few weeks. Furthermore, workers need to be paid for overtime. That is why it is difficult to estimate a total cost of this process. The scale may vary a lot and depends on the position.

Besides generating direct costs, employment fluctuation causes loss of other resources, especially if an employee undergoes intensive training in a hotel enterprises and resigns from the position before the employer gets return on this investment. The situation is even worse when this employee resigns in order to be hired by the competition. In such a case, a hotel enterprises not only loses such resources as knowledge and experience, which an employee usually obtains at the hotel's expense, but it must also consider that they will be used by another employer to gain a competitive advantage

A high staff turnover rate is also disadvantageous for a company because of the competition on the labour market. If a hotel enterprises cannot retain employees, it will quickly gain a reputation of a bad employer. As a result, job-seeking professionals will not consider a particular hotel enterprises as a viable option in their career plan (Helm, 2011).

It should be noted that employment fluctuation may be also negatively perceived by customers. This aspect may be very important for positions which require from employees to know individual clients' needs and preferences as it has a key impact on the reputation of an organization. If staff are dismissed or changed too often in a hotel enterprises (e.g. front desk staff, waiters, kitchen staff, masseurs), in the best case scenario, it will result in lower customer loyalty but, in the worst case, it will lead to a general opinion that the service levels are significantly lower, which in turn means a negative company image on the market.

Conclusion

The presented research findings confirm that human resource activities in hotel enterprises are not always conducted properly. Instead of making full use of employees' potential, they result in excessive turnover. It poses a serious threat to the smooth functioning of hotel enterprises.

A high staff turnover rate remains one of the fundamental problems of the hotel enterprises. It is partly caused by a high increase in numbers of hotel enterprises and demand for experienced employees. However, the main reason behind this phenomenon is not competitive enough remuneration and motivational rules applied by hotel enterprises.

Usually, only some general human behaviour patterns are taken into consideration when building a motivation system in a hotel enterprises, while it is necessary to analyse many different conditions related to the characteristics of a person to whom various motivators are applied.

A variety of motivational tools may be used to influence employee engagement. It is important that they are accurately selected, tailored to the type of employee's tasks and value system and that cohesion of motivational activities is ensured, or even that they enhance each other. Employee motivation and engagement in achieving company goals is most efficient when employee and organization goals are identified. In order to increase the efficiency of a motivation system in a hotel enterprises, it is necessary to regularly verify motivational activities connected with identifying irregularities. Therefore, hotel enterprises should:

- devise individual procedures for assessment of the efficiency of a motivation process,
- identify dysfunctionalities of a motivation process using the results of periodic employee evaluation,
- conduct a regular analysis of employees' expectations and aspirations.

It is obvious that employees' expectations are changing, while the principles of a motivation system are formal and are of a static nature. Therefore, the assessment of a motivation system should be conducted on a regular basis and its principles and enforcement should be adjusted by correlating them with the changing expectations of employees.

One should remember that there are differences between employees in terms of their qualifications and engagement within each company. That is why the repercussions of their resignation from work may vary. Some people can be easily and cheaply replaced, while others are difficult to replace, especially if the same level of efficiency is to be achieved. For that reason, each group of employees should be treated differently. Motivational activities should be focused on employees that possess extensive professional knowledge and whose resignation may cause most problems for an organization and generate high costs.

Real Estate Mortgage Risk Management on The Eve of The Global Covid-19 Coronavirus Pandemic

Marcin SITEK

Częstochowa University of Technology, Częstochowa, Poland
marcin.sitek@wz.pcz.pl

Abstract

The purpose of this paper was to analyse the risk of mortgage loans that finance the real estate market for management purposes. It presents an analysis of Poland's economic situation in the years 2014-2018 and its macroeconomic indicators as well as a forecast for the years 2020-2022 (the study was conducted from 8 November 2019 to 6 December 2019). They showed that the situation on the mortgage market reflected the good economic situation of the country and its banking system. The profile of an average borrower with respect to mortgage loans in the period 2016-2018 is presented against the background of the promising macroeconomic situation and the economic standing of the country, considering data on the structure of mortgage loans and borrowers. For the purposes of this paper, it has been calculated that in relation to the total value of residential mortgage loan agreements active in 2019, the share of loans in default amounted to PLN 15.51 billion. This initiated the research on mortgage loans risk analysis presented in this paper. It indicates the impact of the main factors determining credit risk as well as ways of its reduction and minimisation. It was concluded that banks need to introduce modern methods of risk management that involve risk modelling, including based on derivatives, which may suggest the direction of further research. Due to the current situation of the global health and economic crisis related to in this paper refer to February 2020 only. It was also pointed out that the crisis triggered and the deepening recession COVID-19 it should be emphasized that the analyses of the economic and macroeconomic situation as well as forecasts of macroeconomic indicators of Poland's economic situation presented by the coronavirus would result in banks introducing restrictions with respect to mortgage.

Introduction

In recent years, Poland has seen a very dynamic increase in household debt on account of loans taken out for residential purposes, which due to the type of collateral that is used are commonly referred to as residential mortgage loans (or residential mortgages) (Nalepka, 2011).

The banks' lending activities are accompanied by risks. As regards risk, particularly noteworthy are the works of Knight (1921), who published the theory of measurable uncertainty (as risk) and unmeasurable uncertainty (as uncertainty in a strict sense). Systematic research on risk led Harry Markowitz (1952) to propose the first modern measure of risk. In his 1952 essay *Portfolio Selection*, he presented a mathematical concept of the modern portfolio theory (MPT), that is a mean-variance analysis of the asset portfolio so that the expected return is maximised for a given level of risk. For this essay he later received the Nobel Prize in Economics. Terje Aven (2010), on the other hand, devoted almost his entire book *Misconceptions of Risk* to presenting and discussing a dozen incorrect, imprecise and inaccurate definitions of risk.
In order to minimise risk, effective risk management uses various statistical tools or econometric models (Deloitte, 2018; Eurostat, 2018; Gorzeń-Mitka, et al., 2016).

The credit risk assessment is concerned with the financial credibility of the borrower (scoring method) and the quality of the real estate to be purchased with the loan (loan monitoring) (Gąsowska, 2000). Moreover, in order to limit the risk of losses, before issuing a credit approval, banks often use publicly available statistical data about the real estate market (European Federation of ..., 2017; Eurostat, 2018; Zasoby..., 2018).

The main factors influencing the security of the bank's operations related to mortgage lending are the degree of development and knowledge of the real estate market. and related risk with them (Główka, 2008).

Due to the risks associated with mortgage loans for residential investments, which stem from:

- the persistently low level of interest rates,
- the systematic increase in wages and social transfers,
- and the increase in apartment prices (Geng, 2018),

it becomes necessary to effectively manage the risk of mortgage-backed receivables. Therefore, the purpose of this paper is to analyse the risk of mortgage loans that finance the real estate market for management purposes. It presents an analysis of Poland's economic situation in the years 2014-2018 and its macroeconomic indicators as well as a forecast for the years 2020-2022. The paper also analyses the mortgage loan as an instrument for funding residential investments in the real estate market. Based on borrowers' preference for mortgage, it presents the profile of an average borrower in 2016-2018. It also mentions the share of defaulted loans, which in 2019 amounted to PLN 15.51 billion. The Author’s research points to the analysis of the role of mortgage loans and the risk associated with them, the economic situation and the macroeconomic conditions in which they are granted as strong motivators for the introduction of modern methods of risk management in order to minimise it.

Research Methodology

The paper analyses the role of mortgage loans in investment management in the real estate market in Poland in 2016-2019. It is motivated by the assessment of the economic situation and the banking sector in Poland in terms of residential mortgages.

This study aims at analysing the risk of mortgage loans that finance the real estate market. Its objective was achieved using especially data of Statistics Poland, EFC, EMF, HRE, reports of ZBP and KNF, as well as current literature. The analysis of the existing data made it possible to present the economic situation of Poland and the banking sector in Poland in 2016-2019 and residential mortgage loans as instruments of financing investments in the real estate market. The data concerning the mortgage loan portfolio come from two banks and take the form of randomly selected information concerning loan applications and borrowers' information cards and interviews with bank employees.

Based on the economic situation in Poland and the analysis of the mortgage loan market, the paper presents some threats related to the growing level of credit risk. It also points out to the need of effective risk management, especially in order to minimise it.

Real Estate Market Situation

Nearly 23 years have passed since the transformation of Poland’s economy, including its real estate sector, into a market economy.

Real estate, as compared to other goods, is characterised by considerable uniqueness, having a number of different essential attributes, such as physical, economic and institutional-legal features, important for understanding its essence. Among the economic characteristics that are essential in a market economy, high capital intensity and low liquidity should be especially emphasised. Particularly high capital intensity dictates the necessity of financing investments in real estate

especially through external sources, i.e. loans. In the Polish reality, with a shortage of flats (about 2.1 million (ZBP, 2019)), their deficit is one of the strongest factors supporting the high demand for real estate.

Not long ago (in 2016 and 2017), in terms of growing housing prices, Poland was a stable country in a dynamic (in terms of housing price increases) Europe. At present, Poland stands out from Europe in terms of their relatively rapid growth. The policy of the European Central Bank resulted in a significant reduction of credit costs through low interest rates, encouraging western investors to buy flats in Central European countries (including Poland). Rapid price increases of houses and apartments also resulted from of individual factors specific to a given country. Table 1 presents a ranking of the rate of housing price changes in selected European countries in Q2 2018 - Q2 2019.

Table 1: Ranking of selected European countries in terms of housing prices growth rate (Q2 2018 – Q2 2019)

Country	Rate of change in housing prices (including inflation)	Rate of change in housing prices (without inflation)	Average change in housing prices caused solely by inflation
Hungary	increase by 14%	increase by 10%	4.0 %
Latvia	increase by 9%	increase by 5.5%	3.5 %
Poland	**increase by 8.2%**	**increase by 5.6%**	**2.6 %**
Netherlands	increase by 8.3%	increase by 5.8%	2.5 %
Belgium	increase by 3.1%	increase by 1.4%	1.7 %
Ireland	increase by 2.5%	increase by 0.2%	2.3 %
Sweden	increase by 2.2%	increase by 0.1%%	2.1 %
United Kingdom	increase by 1.4%	increase by 0.3%	1.1 %
France	increase by 3.2%	increase by 2.1%	1.1 %
Italy	decrease by 0.2%	decrease by 0.8%	- 0.6 %

Source Author's own elaboration based on data of ZBP (2019), EFC (2019), EMF (2019)

As shown in Table 1, Hungary can serve as an example of a country where prices of flats and houses significantly increased due to the shape of its social policies. Because of high state subsidies for flats and houses, in terms of the housing prices growth rate, Hungary occupies the leading position. Table 1 also shows that a large part of the increase in housing prices in different countries has been caused by inflation (Hungary - 4%; Latvia – 3,5%).

According to AMRON-SARFIN Report 41 (ZBP, 2019), in Poland only in Q3 2019 the average transaction prices (an increase in the average price of 1 m2 of residential units) in the largest Polish cities increased significantly by more than 4%. However, since 2014 these increases have reached almost 10% (depending on the agglomeration).

Therefore, it should be recognized that in the period of Q2 2018 - Q2 2019, the increase in apartment prices was mainly stimulated by a high domestic demand (which in 2018 amounted to 5.3%) - including the demand for residential real estate, the improvement of the financial situation of families and, in particular, the good economic situation of Poland and most other countries.

Changes in economic activity are manifested in changes of basic economic indicators that describe the condition of the economy. Therefore, Table 2 presents selected indicators of Poland's economic situation together with indicators characterising the condition of the banking sector in terms of mortgage loans for the years 2014 – 2018.
Table 3 presents selected macroeconomic indicators for 2018. These indicators were based on data included in Table 2 and EFC data (2019), and can be used in attempts to forecast the prospects for Poland's further development.

Table 2: Selected indicators of the economic situation in Poland and the banking sector for 2014-2018

	Poland 2014	Poland 2015	Poland 2016	Poland 2017	Poland 2018
Real GDP growth (%)	3.3	3.8	2.7	4.6	5.1
Unemployment rate (LSF) annual average (%)	9.0	7.5	6.2	4.9	3.9
Inflation measured by HICP (%)	0.1	- 0.7	- 0.2	1.6	1.2
Outstanding housing loans (€ million)	82 500	90 901	92 015	93 111	100 579
Outstanding housing loans per person above 18 (€)	2 656	2 921	2 957	2 991	3 234
Outstanding housing loans per person to disposable income (%)	33.3	35.8	35.8	33.6	246.0
Gross annual growth of housing loans (%)	3.7	3.7	23.1	13.9	10.4
Average annual mortgage rate (%)	4.1	4.4	4.4	4.4	4.4

Source: EFC (2019), HRE (2019).

The analysis of the data presented in Tables 2 and 3 and the information contained in EMF, EFC and HRE publications allows for a summary of the situation of the Polish economy and the banking sector as well as the mortgage financing. The data submitted include:

- EMF estimates (2019) and data estimates of Eurostat show an increase in real GDP in 2018 by 5.1% compared to 2017,
- according to the EFC (2019), among all components of domestic demand, is was investment expenditure that recorded the highest increase in gross fixed capital formation - it increased by 7.3% in 2018.

- construction is one of the main branches of the economy, aimed at meeting the basic material needs
of citizens. The sector recorded a 17% increase in gross value added compared to the previous year, when an increase of only 6.5% was recorded,
- the average annual unemployment rate in Poland amounted to 3.9% in 2018, compared to 4.9% in 2017,
- at the end of December 2018, the inflation rate in Poland was 1.1% compared to 2.1% in December 2017. The average annual inflation rate was 1.2% y/y in 2018, compared to 1.6% in 2017,
- as regards the banking sector, the main source of funding for mortgage loans, even in the long term, are especially deposits,
- the situation on the mortgage loan market reflects the good situation in the economy, the increase in wages, low unemployment and low NBP interest rates, which result in a low cost of mortgage loans,
- EFC experts' forecasts for GDP, domestic demand, investment expenditure, unemployment rate and inflation for the period 2020-2022 clearly indicate that the rate economic growth would slow down.

The forecasts presented by EFC experts are the result of a study carried out between 8 November and 6 December 2019 (Pawłowicz et al., 2019). However, a global COVID-19 pandemic was declared in February 2020, and has been developing very dynamically since then. In view of this situation and the deepening recession both in terms of human health and economy, all the studies and analyses presented can only be considered relevant for the period up to February 2020.

As a result of the global changes related to the pandemic, so far the following has been observed:
- a rapid deterioration of the health condition of citizens,
- an increase in unemployment,
- closures of businesses,
- a strong inflation,
- an expected significant reduction in GDP and gross expenditure,
- significant restrictions by mortgage banks,
- restrictions on economic freedom.

Mortgage Loan as an Instrument of Funding Housing Investments in the Real Estate Market

Poland's accession to the European Union has awakened the housing needs of Polish families. In this period, an important part was played by the rapid development of the sector that would finance housing construction. Apart from people’s own capital, a residential loan became a common instrument enabling households to purchase their own flat. And the housing deficit (calculated at about 2.1 million by the HRE (2019)) is one of the strongest factors sustaining high demand for real estate.

Banks engage in financing the real estate market by granting loans for the purchase of real estate, financing developers and large construction companies, using real estate as collaterals for loans or investing directly in real estate. A mortgage loan is a liability incurred to finance the purchase or renovation of a property. It differs from other loans in that it is secured by real estate.

A residential loan is a typical loan earmarked for the purchase of a flat, house or garage. A residential loan is always a mortgage. A residential loan is a sub-type of mortgage loan. It is one of the cheapest and most popular ones on the market.
As a result of a strong drop in NBP base interest rates to 4.75% at the end of 2005, a profitable offer of mortgage loans appeared and was followed by a rapidly growing demand for this type of loans. Moreover, a significant economic revival, a drop-in unemployment (Table 2) and a real increase in salaries (Table 3) resulted in a strong increase in the number and volume of mortgage loans granted,

especially mortgage housing loans. Table 4 and Table 5 present the indebtedness of households to the banking sector in recent years.

Table 4: Situation in the market of residential loans in 2015-2019

	2015	2016	2017	2018	2019
Number of active mortgage loan agreements (in thousands).	1994.677	2057.170	2140.896	2246.296	2389.311
Total debt on account of residential loans (in billion PLN)	374.082	393.367	388.795	415.538	444.121
Number of new residential loans granted annually	181 325	178 409	190 634	212 596	225 073
Value of new residential loans granted annually (in billion PLN)	39.320	39.496	44.574	53.852	62.629

Source: ZBP (2019, pp. 9, 10)

The analysis of data presented in Table 4 shows that in relation to the result recorded at the end of 2018, the portfolio of housing loans in Poland increased by 143,015 agreements, i.e. 6.37%. In comparison to the result recorded at the end of 2018, it was higher by 6.74% (nominally PLN 27.963 billion). In addition, 225,073 new residential loans were granted throughout 2019 with a total value of PLN 62.629 billion, i.e. 5.87% more (12,477 agreements) in terms of quantity and 16.30% more (nominal PLN 8.777 billion) in terms of value as compared to the results in 2018.

Table 5: LTV structure for newly granted residential loans per year (2015-2019)

	2015	2016	2017	2018	2019
below 30%	7.64	12.45	14.22	13.92	15.00
from 30% to 50%	7.22	6.76	6.90	6.27	6.19
from 50% to 80%	36.02	35.44	33.08	38.15	35.45
above 80%	49.12	45.35	45.80	41.66	43.36

Source: ZBP (2019, p. 17)

Comparing the structure of the LTV ratio of newly granted loans on an annual basis (Table 5), one can see a slight increase in the share of loans with an LTV ratio up to 30% and above 80% by 1.08 and 1.70 percentage points respectively. On the other hand, the popularity of mortgage loans with LTV between 50% and 80% decreased - the share of this segment in 2019 amounted to 35.45%, which represents a decrease by 2.70 pp. as compared to 2018. The criteria currently applied by the bank were consistent with the economic situation until February 2020.

In the great global health and economic crisis (COVID-19), banks are likely to take new, binding decisions with regard to managing mortgage-backed credit exposures. According to Recommendation S (KNF, 2019), those applying for a mortgage loan in the largest Polish bank will have to present a standard own contribution of at least 20%. As of 1 April 2020, PKO BP changed the terms and conditions of mortgage loans and no longer offers the possibility to increase LTV over 80% by meeting additional conditions, e.g. insurance of the missing own contribution (HRE, 2018).
The data from tables 2 and 3 show a stable growth rate of economic processes in Poland and favourable macroeconomic situation. The borrower's preferences were previously presented at work (Sitek, 2019).

Assuming that the highest borrowing activity was reported for borrowers aged 30-35 years, (considering only data from 2019):

- considering Table 4,
- and information on the share of non-performing loans (ZBP, 2019, pp. 10-12)

calculated that in four quarters of 2019 the share of loans in arrears reached 3.35%.
Only for newly granted loans this represents a value of PLN 1.485 billion in 2019. In relation to the total number of active residential mortgage agreements, the share of loans in arrears in 2019 will amount to PLN 15.509235 billion.
And this is already a clear signal to undertake research into the hazard associated with growing credit risk levels and the need for effective management to minimise it.

While the dominant demographic of borrowers is aged 25-35 and a significant part of them migrates for work, they are still the group with the least financial possibilities to invest in their own housing (Zadłużenia..,2017; Kredyt hipoteczny, 2019). In this situation, the need to support the borrowers in solving their housing problems stimulates the search for new, alternative sources of funding.

In a very good economic and macroeconomic situation of the national economy, a change in formal requirements for the assessment of creditworthiness will not suffice to popularise residential mortgage loans,especially for the generation of young people in the 30-35 age group. With the current restrictions imposed on the execution of residential mortgage activity, even the best strategy of managing residential mortgages will not result in their popularisation to satisfy people's housing needs (Skibiński, 2019).

The risk analysis of mortgage loans in the real estate market presented in this paper only refers to the period until February 2020. Due to the present COVID-19 pandemic, a global economic crisis is to be expected. It is estimated that around 5-25 million people worldwide could lose employment as a result of its economic consequences. Job losses for some 25 million people would mean that in terms of its effects the pandemic has surpassed the 2008-2009 financial crisis, and it is estimated that, like the 2008-2009 crisis, some 30 million people will find themselves below the poverty line. In view of such prospects, one should stress that this is not only a global health crisis, but also a huge global labour market crisis and economic crisis, which will have enormous consequences.

In Poland, we are witnessing a significant recession related to the threat to citizens' health, a significant economic downturn, the suspension of micro and small businesses, a sharp rise in unemployment, inflation and restrictions on economic freedom. Currently, the main objective of the government is to prevent the spread of the pandemic, and for the economy, the rapid introduction of the so-called antivirus shield, which translates into credit holidays, support for entrepreneurs and farmers to maintain employment, and especially support for the Social Dialogue Council.

Management of Mortgage Loan Risk

Description of the bank's loan portfolio, considering their impact on risk and its minimisation, has been prepared on the basis of such features as: type of loan, lending period, type of real estate, loan amount, LTV ratio, repayment method, amount of liabilities, age, education, years of employment, number of people in the household and income. Additional information was obtained on the basis of interviews with employees of the bank. The information gathered has led to the following conclusions:

- purpose of the loan. The majority of loans taken out by customers were intended for the purchase of a flat.
- loan duration. Loans are taken out for an average period of 30 years, but there is a clear decreasing trend.
- the average amount of credit granted since 2008 has been systematically decreasing, currently ranging from 200 to 300 thousand PLN. (KNF, 2019; HRE, 2018).
- for a bank, a potential borrower's creditworthiness is particularly affected by their income and the value of their liabilities.

- collaterals used in mortgage loans granted by banks are especially: mortgage entered in the mortgage register as the basic collateral of the loan, civil surety, bill of exchange or insurance as a form of collateral.
- by changing the parameters of the main factors that influence credit risk (age, loan amount, loan duration, loan purpose, available resources, LTV ratio), the bank achieves its reduction and minimisation.

In addition (Jajuga et al., 2017; Tofil, 2007; Wagner, 2016) the correlation of the real estate market and the loan system in terms of risk, indicates that the main problem of the housing market is short and medium-term demand (as a result of demographic growth, changes in the number of households, migration and income changes) in combination with inelastic supply (as a result of a long construction and administrative cycle, attachment to location - as a consequence of the lack of mobility, capital intensity of the project, the necessity of collecting the capital as a long-term savings or moving the construction process forward when funds inflow), with a large share of

- strong links with the financial (banking) system,
- low liquidity of properties,
- high susceptibility to external factors such as the economic situation, interest rates or the capital market.

From the bank's point of view, the consequence of these interactions is the risk of pledge value. This applies to overly optimistic valuation of properties as the subject of loan security. Also too liberal banking practice in the field of investment project evaluation, based on the value of property and not taking into account micro- and macroeconomic threats. These threats relate to the income generated by these properties. For example, in the case of real estate for rent, a carefully determined ratio of debt service to income generated by the property, and not the ratio of debt to the value of property, is of fundamental importance for the bank's security.

In light of the above, effective management of the mortgage market requires constant monitoring of risk-taking determinants of both the real estate market and the banking sector.
In view of the above, effective mortgage market management requires constant monitoring of risk-taking determinants of both the real estate market and the banking sector

It can be concluded that a residential mortgage loan, its size and the associated risk, as well as the economic situation and the macroeconomic conditions in which it is granted, can be treated as a strong incentive to introduce modern methods of risk management in order to minimise it (Sitek, 2016). With a fixed risk weight and probability of loan default it is possible to model the risk (Miles, Pillonca, 2008) based on derivatives (credit derivatives hedging against credit risk, interest rate derivatives hedging against interest rate changes and foreign exchange derivatives, which may constitute an important element of risk management). These can complement mortgage insurance (own contribution), constituting an important element of risk management (California Department..., 2018; Zasoby..., 2018).

Summary

Due to the considerable shortage of flats in Poland and the fact that mortgage loans are the main source of external funding for the purchase of residential properties in Poland, the development of the mortgage loan market is an important instrument supporting residential construction and stable development of this market. The aim of this paper is to analyse the risk of mortgage loans financing the real estate market for management purposes. It attempts to determine the role of mortgage loans in the management of investments in the real estate market.

Analysing Poland's economic situation in the years 2014-2018 and macroeconomic indicators of the economic situation as well as its forecast for the years 2020-2022, it shows that the situation of the mortgage market reflects the good economic situation of the country and its banking system.
The analysis of the role of mortgage loans in the management of housing investments and the impact of the main credit risk factors on its reduction and minimisation showed that:

- borrower’s profile (age, education, years of employment, income),

- loan type, loan duration, loan amount,
- type of collateral such as mortgage and insurance,
- LTV level,
- type of property and amount of liabilities,

as features of a bank's loan portfolio, describe it and have a significant impact on risk reduction and minimisation.

The analysis of the role of mortgage loans in the management of investments in the real estate market clearly points to the need of introducing modern risk management methods by modelling them on the basis of derivatives. At the same time, it is stressed that derivatives such as loan, interest rate and foreign exchange derivatives may complement mortgage loan insurance and become an important element of mortgage loan risk management. In light of the above, we view the objective of this study as achieved.

The paper underlines that all the analyses and deliberations on housing loans only refer to mortgages until the COVID-19 pandemic emerged (February 2020).

Human Resources Management in The Light of The Changes in The External Environment Based on The Example of Chosen EU Countries

Andrzej Skibiński

Czestochowa University of Technology, Faculty of Management, Poland,
E-mail address: skibinskia@tlen.pl

Abstract

Due to the COVID-19 pandemic, a great number of enterprises worldwide were forced to limit its activity. In the lifecycle of every organization, a crisis is an exceptional situation. On the one hand, the risk of a crisis may cause damaging threats and, as consequence, the fall of the organization; on the other hand, however, a crisis may boost a positive renewal and bring further growth opportunities. Undoubtedly, the volatility of the environment and crisis situations such as ageing and shrinking of potential labour resources, a global financial crisis, or epidemiological threats are determinant in terms of a change of approach in modern organizations, in particular with regard to human resources management. Therefore, the principal goal of this publication is to present selected risk factors in the external environment and their influence on today's organizations in terms of HR, based on the example of countries in the Visegrad Group. Quantitative and qualitative analyses presented herein were conducted based on Eurostat's existing data. Dynamic row change methods were applied, for example a dynamics index. In turn, the pace of ageing of the population was defined based on the demographic ageing index (DAI) based on scoring differences between younger and older population shares.

Keywords: COVID-19, Population Ageing, Labour Market, External Environment, Economic Crisis

Introduction

This paper was inspired by the outbreak of the COVID-19 pandemic, which is being battled by governments of almost all countries in the world. Pandemics are one of the potentially largest negative global risks, in particular in the contemporary highly globalized world. They may result in high morbidity and mortality rates, and trigger adverse social and economic effects, which cannot be estimated at the moment. Undoubtedly, the outbreak of the coronavirus pandemic brought an increased probability of a global economic recession, including tensions and dynamic changes in the external environment. Almost every single organization is facing a dilemma concerning running personnel processes that will affect the state and structure of HR resources in the organization. Considering that the human capital is the most valuable intangible resource, it is of utmost importance to maintain high-level resource management, observe quality standards in this regard, and appropriately react to crisis situations because a high quality of management processes decreases the possibility of adverse risk effects. Therefore, the public is asking about the date of organizations returning to their normal functioning after the pandemic. In addition, the author of this publication will attempt to assess the period of „recovery" of macroeconomic indices relating to the labour market, in consideration of the 2007-2009 global financial crisis, although aware that economic effects of the present humanitarian crisis cannot be easily quantities, especially since the historical sample is small.

Study Methodology

At the EU level, statistical data registers are harmonized to a large extent; this allowed achieving a certain degree of their comparability. Therefore, quantitative and qualitative analyses presented in this publication were conducted based on Eurostat's existing data (the *Population and Social Conditions*

section). The author would like to emphasize that this article is an introduction to more detailed research as soon as current quantitative data are published to ensure their comparability. Dynamic row change methods were applied, including the dynamics index. In addition, in the context of the influence of the external environment on the functioning of an organization, most highly developed countries – including countries in the Visegrad Group – are facing a real demographic crisis related with decreasing population (depopulation) and ageing of the society. Therefore, the dynamics of the population ageing process was defined in accordance with the Demographic Ageing Index based on scoring differences between younger and older population share (Długosz, 1998):

$$\mathbf{DAI = [U(0\text{-}14)t - U(0\text{-}14)t{+}n] + [U(\geq 65)t{+}n - U(\geq 65)t],} \qquad (1)$$

where:

U(0-14)t – share of population aged 0–14 at the beginning of the analysed period;
U(0-14)t+n – share of population aged 0–14 at the end of the analysed period;
U(≥65)t – share of population aged 65 and over at the beginning of the analysed period;
U(≥65)t+n – share of population aged 65 and over at the end of the analysed period.

The starting point of the comparison is the year 2007 – the occurrence of the global financial crisis. Presented analyses and obtained study results were derived from a critical review of source literature and the author's side marks.

Theoretical Background

Every organization operates in a defined environment. Environment means both the organization's external and internal environment including all dependencies therein (Griffin, 2017; Gupta, 2013; Wong et al., 2014). For the purpose of this publication, the author concentrates on the external environment, characterized by significant dynamics of changes, which, on the one hand, constitute the drive to develop, but, on the other hand, they pose a certain threat for the organization's functioning. In this context, significant is both the economic dimension as well as the social/cultural dimension of the external environment, which includes: the unemployment rate, prosperity, and demographic characteristics of the population. The functioning of modern organizations in turbulent conditions and permanent uncertainty forces an increase in their flexibility and adaptability, in particular during a crisis (Legg et al., 2012; Kuraś, 2013; Sitek, 2019). According to P. Drucker, a crisis in an enterprise is a consequence of life-cycle phases of individual sectors, in particular in regard to specialized companies; investments in clinical trials, which are assumed to ensure innovation, do not constitute a guarantee of the crisis disappearing and the company holding through (Drucker, 1999). In turn, Oldcorn emphasizes that a crisis is a result of unplanned events, which hinder or threaten normal functioning of an organization (Oldcorn, 1989). In Barton's opinion, a crisis means an unforeseeable event, which has potential negative effects that may substantially restrict the company's operation in the areas of production, services, employment, financial condition, or reputation (Barton, 2001). In connection with the above, it may be concluded that human resources management may be considered from both the perspective of situational conditions as well as a context perspective, which takes account of environmental factors, including the effects of social, economic, institutional and political environment on HR processes (Urbaniak, 2019, Vardialier, 2016). Therefore, the HR system depends, amongst others, on the environmental context often understood as a combination of factors determining the external and the internal situation of the organization, which affects HR management policies and practices in the organization. In this regard, it seems important to pay special attention to the influence of global changes, such as, amongst others, the particularly intense ageing of the population occurring in Visegrad countries. In the light of the dynamic changes on the labour market, caused by demographic processes amongst others, there is a strong need to adjust activities in the area of human resources management (Zeuch, 2016; Cowling and Mailer, 2013; Listwan et al., 2016) Two important concepts were developed in the context of human resources management, namely diversity and age management. The first concept relates to the diversities and individual differences of employees, as well as preventing situations where employees would be discriminated due to their diversity. The second concept concerns undertaking defined activities and initiatives allowing rational and effective management of human resources available in the organization, including in regard to employees in older age groups, in such

manner so that individual works brings profit to the organization and satisfaction for the employee regardless of age (Walker, 2005, Negele and Walker, 2006). Referring to the influence of currently observed demographic trends on contemporary organizations, special attention should be paid to the organization's HR policy; human resources managers face a challenge relating to generation diversity. Undoubtedly, the above-mentioned demographic factors of the external environment (e.g. ageing of the population), as well as economic factors (e.g. economic fluctuations, the situation on the labour market), or random factors (e.g. epidemics) force the application of adjustment processes in the light of changes occurring in the environment. Table 1 presents the chosen typology of changes and the criteria for their distinguishment in the context of crisis situations such as a pandemic or a financial crisis.

Table 1: Typology of changes, conducted on various levels in the organization

Criterion	Types and characteristics of changes
Co-dependence of the time of organizational changes and environment changes	**Reactive change** – a reaction to a change in the environment, conducted when needed, thus often fairly ineffective; **Changes in advance** – in anticipation of future changes of conditions; prepare the organization before the need for organizational changes arises; this gives the organization an opportunity to eliminate the time-distance between the occurrence of the need for change, and the reaction to change.
Change strategy	**Changes directed at the structure** – for example a change of the mode of work, decentralization, a change of the level of formality; **Changes of technology –** working operations, procedures, technical equipment etc.; **Changes regarding people** – their qualifications, approaches, motivations, relations.

Source: own materials based on: K. Kmiotek, T. Piecuch, Zachowania organizacyjne teoria i przykłady. Wyd. Difin, Warsaw 2012, p. 131

It may seem that the concept of change has two dimensions. The first one is the result of the change – its content. This refers to human resources and tangible resources, including technique and technology, as well as various types of social, economic or political relations. The second dimension is the manner of conducting the change, which is closely related with execution methods and techniques and it is defined as the change process (Mikołajczyk, 2005). Therefore, it should be noted that the external environment of the given organization plays the key role in crisis to trigger change-related activities, and the forces derived at its source determine the flow and the final success of these activities.

Result of Research

It seems that an important context factor in human resources management is the changeability of demographic conditions, in which organizations operate and will operate. These conditions determine the changes on the demand side of the labour market in particular. The effectiveness of the execution of the organization's strategic goals will depend on the manner, in which managers will be able to face the challenges resulting from demographic changes (Urbaniak, 2019). Demographic changes, in particular ageing of the population and its consequences, received a lot of attention in the previous years (Reher, 2011; Wellekens, 2015; Mason, 2005; Van de Kaa, 1987). It may be concluded that a visible decrease of working-age population may be expected in the coming years, in particular in Visegrad Group countries, along with an increase in the percentage of post-working age population. Table 2 presents the changes in the working-age population and indicates the pace of general population ageing.

Table 2: Changes in population according to economic age groups in the Visegrad Group countries

	Population share by economic age groups [in%]			DAI
	0-14	15-64	65+	
	Poland			
2007	15.8	**70.8**	13.4	-
2009	15.3	**71.2**	13.5	**+0.58**
2018	15.2	**67.6**	17.2	**+4.25**

	Czech Rep.

Source: own calculations based on: Eurostat database (access: 10.04.2020)

Data presented in Table 2 indicate that during the analysed period from 2007 to 2018 the share of 65+ population has increased substantially, along with a decrease in the share of working-age population in the analysed countries, in particular after the year 2009. The pace of population ageing may be assessed using the DAI. If DAI numbers are positive, then this means a very intense flow of the population ageing process. In turn, negative DAI values mean rejuvenation. The DAI analysis confirms that in the Visegrad Group countries DAI was positive during the period covered by the analysis (2007-2018), which means that the process of population ageing is progressing. However, in Poland and Slovakia this process is more intensive, as proven by higher DAI numbers. Differences in DAI values in these countries may result from the changes in the shares of subpopulations of children and older citizens, which may be occurring in a slightly different manner. In this context, it should be expected that employers would be likely to reach for employees in older age groups. For them, the determining factor in making decisions about engaging and retaining such employees would be unit labour costs, meaning the relations of nominal costs of employment vs. performance. The observed reluctance to employ older people strongly affects the connection, assigned to this subpopulation, between the average growing remuneration and the alleged decreasing productivity related, amongst others, with an increased risk of diseases thus greater absence at work (Skibiński, 2018; Sipa, 2018; Gorzeń – Mitka, 2018). In this context, it is essential to take account of migration processes because intensified migration constituted a significant factor affecting the shrinking of potential labour resources. This process was especially visible after the accession of the Visegrad Group countries to the EU and during the 2007-2009 financial crisis, as confirmed by the data presented in Table 3.

Table 3: Balance of migration and changes in emigration

Country	**Emigration**							
	Year						**Dynamic Index**	
	2007	2009	2010	2011	2012	2018	**[2009/2007]**	**[2018/2009]**

Source: as in Table 2

The above table suggests that the largest increase in migration in the years 2007-2009 was reported in Poland and the Czech Republic, and the smallest in Slovakia and Hungary. The decreasing trend of emigration was reported in countries other than Hungary post 2009. It should be noted that labour

migration and the dynamic growth of demand for labour, especially in the post-crisis period, resulted in intensified shortages of labour in most Central and Eastern Europe countries, e.g. in Poland and in Slovakia. Therefore, the sector of small, medium and large enterprises is experiencing increasing problems with recruitment despite opening the labour market for immigrants from Eastern Europe or Asia. In this context, the role of migration policy is extremely important, and its main aim is to take actions to mitigate effects of population ageing, among other things.

Table 4: Selected characteristics of migration in the Visegrad Group countries

Country	Effects of migration	Migration type	Net migration	Selected causes
Czech Republic	In-flow of immigrants with high qualifications. Mitigation of population ageing effects.	Dominating economic migration	Prevalence of immigrants - increased share of immigrant work force in employment	Favourable situation on the labour market. Salary relation Economic situation Liberal migration policy Population policy. Dominant role of attracting factors.
Hungary	In-flow of immigrants with different level of education. Selective outflow of highly qualified human capital. Filling the gap in work force in the different sectors of the economy. Mitigation of population ageing effects. Strengthening of the position of immigrants of Hungarian origin Improving the labour market situation and filling in shortages of work force.	Dominating economic migration Repatriation prevalence of immigrants of Hungarian origin Reemigrations	Prevalence of immigrants - increased share of immigrated work force in employment	Dominating role of administrative and political pull factors Lack of a coherent migration policy, partly connected with migration crisis Economic situation
Poland	In-flow of immigrants to fill in shortages of workers on the labour market in the different sectors of the economy industry, construction, agriculture, medical services. Improving situation on the labour market. Selective outflow of human capital with varied level of skills and education. Emigration of medical staff	Dominating economic migration, reemigrations	Increasing share of immigrant work force	Economic situation. Salary relation. Structural mismatches on the labour market Migration policy
Slovakia	In-flow of immigrants to mitigate effects of population ageing and fill in employee shortages in the different sectors of the economy, industry, agriculture Selective outflow of human capital with varied level of education.	Dominating economic migration Reemigrations to a lesser degree	Increasing share of immigrant work force	Economic situation. Migration policy. Salary relation

Source: own work based on: Skibiński A. (2017). The migration processes and their consequences for the labour market in the Visegrad Group Countries - selected aspects. Olsztyn Economic Journal 12 (1/2017)

Thus, migration processes are a very complex issue, and none of the existing migration theories is able to explain the changeability of complex migration processes in a fully convincing way. Due to the interdisciplinarity of migration analyses as a research subject and complexity of this phenomenon, there is no one unambiguous research method or a common way of explanation. Therefore, works on migration show multitude of approaches to and interpretations of this process.

Migration processes become more intense usually in situations of crisis (Van Mol, 2016). This is well illustrated on the labour market, which reflects the economic situation of the given country or region. Table 5 presents the basic macroeconomic indices, which diagnose the situation on the labour market for the selected group of EU countries.

Table 5: Registered unemployment rate and employment indices

Country	Total employment (resident population concept - LFS)								
	Year						Dynamic index		
	2007	2009	2010	2011	2012	2018	**2009/2007**	**2010/2007**	**2011/2007**
Poland	57.0	59.3	58.9	59.3	59.7	67.4	**1.04**	**1.03**	**1.04**
Czech Rep.	66.1	65.4	65.0	65.7	66.5	74.8	**0.99**	**0.98**	**0.99**
Hungary	57.0	55.0	54.9	55.4	56.7	69.2	**0.96**	**0.96**	**0.97**
Slovakia	60.7	60.2	58.8	59.3	59.7	67.6	**0.99**	**0.97**	**0.98**
	Unemployment (Percentage of active population)								
Poland	9.6	8.1	9.7	9.7	10.1	3.9	**0.84**	**1.01**	**1.01**
Czech Rep.	5.3	6.7	7.3	6.7	7.0	2.2	**1.26**	**1.38**	**1.26**
Hungary	7.4	10.0	11.2	11.0	11.0	3.7	**1.35**	**1.51**	**1.49**
Slovakia	11.2	12.1	14.5	13.7	14.0	6.5	**1.08**	**1.29**	**1.22**

Source: as in Table 2

Two significant detailed conclusions may be drawn from the data presented in Table 5. Firstly, during the 2007-2009 crisis employment indices dropped in Hungary (4%), Slovakia, and the Czech Republic (1%), which was reflected in an increase of the registered unemployment rate in this group of countries. In turn, in Poland the situation was slightly different because the decrease in the employment dynamics and a clear increase of the unemployment rate occurred post 2009 due to, amongst others, intensified external migration. Secondly, an improvement of the situation on the labour market, reflected in growing employment indices and a drop of the registered unemployment rate occurred after two years from the end of the crisis, i.e. in 2011, in all analysed countries. Considering that the labour market somehow constitutes a barometer of economy, it may be stated that the economies of these countries started to emerge after the economic slow-down two years after the crisis, as opposed to certain southern EU economies such as Greece or Portugal, which were affected by the 2007-2009 financial crisis for much longer.

In regard to the global COVID-19 pandemic, it may be observed that there is a lack of current quantitative data from the labour market, which could be used to estimate the approximate date of moving to recover. This results, amongst others, from the fact that the current crisis caused by the coronavirus pandemic does not derive from the banking sector as the 2007-2009 financial crisis, but it is an effect of the influence of an external shock on the economy. Although the banks in many countries in, for example, the Visegrad Group, are much better prepared to support the economy, the scale of the problem is definitely greater and forces organizations to start preventive actions and modify their strategies in the areas such as human resources management. Table 6 presents exemplary crisis strategies in organizations.

Table 6: Exemplary crisis strategies

Strategy of survival	**Strategy of decreased profitability**
General characteristics	
Temporary solutions aimed at quick cost reduction and maintaining financial liquidity. Decrease of salaries, technological breaks, budget freezing	Long-term solutions aimed at operating in conditions of decreased profitability. Cutting costs to ensure minimum profitability.
Employment policy	
Employment maintenance policy. Terminating civil law contracts, outsourcing contracts or consulting contracts. Personnel movement freeze.	Redundancy limited to the minimum ensuring profitability. Outplacement. Personnel movement freeze. Reduction of the skills overpotential.
Salaries	
Decrease of salaries – usually equal decreases for everyone. Blocking any and all salary raise.	Suspending salary raise. Very rare salary raise, only to retain key employees. In case of a very difficult situation – decrease of salaries.
Role and situation of the HR in the company	
The HR role in the area of development decreases. The role of the personnel director as a management	The HR role in the company decreases. HR is responsible for the process of reducing personnel costs.

adviser increases. HR is responsible for the process of reducing personnel costs.	
Personnel shortages	
Assessment of demographic threats in the organization: - assessment of physical fitness and monitoring the health of employees, in particular in older age groups - identification of areas in the organization threatened by a labour force deficit, in particular in younger age groups	Assessment of the level of inter-generation cooperation in the organization through a diagnosis of: - the transfer of knowledge between employees from various age groups; - inter-generation relations.

Source: own material based on: Smolska M. (2009). Kapitał ludzki w dobie kryzysu. Ekonomiczne problemy usług nr 46, pp. 289-300, Skibiński A. (2019) The Concept of Demographic Management as an Element of Human Resources Management in Organizations. IBIMA Business Review. Vol.2019 p. 9

Conclusion

The dynamic changes in the external environment in contemporary enterprises are the generators of crisis situations and have substantial influence on operation of these enterprises as well as their human resources policy and human capital. Undoubtedly present demographic trends which increase the heterogeneity of work resources, and changes of structures and relations between demand and supply for work substantially increase the unforeseeability of the environment, thus increase the situational uncertainty. Therefore, the principal threat faced by organizations is related with personnel problems due to the ageing and shrinking of potential labour resources in the countries where increased emigration and population ageing were observed in the last years. The analysis of existing data also demonstrated that economies of developing countries such as those in the Visegrad Group were quite effective in recovering after the 2007-2009 financial crisis. Will the situation be similar in case of the crisis triggered by the COVID-19 pandemic? In the author's opinion, there are many uncertainties because all sectors of economy, particularly services and production, will be negatively affected in the coming months. According to the estimates of experts from the European Commission, economics of some UE countries may shrink even to approximately 5% GDP. Therefore, the pace and efficiency with which organizations will react to the approaching threat and implement appropriate preventive mechanisms, amongst others in the area of human resources management, will be the decisive factors in recovering after the crisis. Summing up, it is worth to invest in human resources because they are most valuable for the organization, especially in situation of a crisis when many business try to reduce the costs of operation. It must be remembered that every crisis is followed by economic recovery, and it is then that the employer's image and its ability to handle crisis will decide about the company's success.

Abstract

Outsourcing can greatly contribute to the efficiency of business processes and generate multiple benefits. However, it requires a detailed business case for a change of the pursued operational model. As is evident from the literature, especially in relation to small-sized businesses, such decisions are often made imprudently, based on general trends and recommendations. Businesses tend to make individual, very subjective analyses of their conditions, to implement a concept of outsourcing almost instinctively, not always choosing the right criteria. This is is made worse as there are no readily available methods and tools dedicated to such businesses. Most of the research relates to large corporations and is based on advanced methods and techniques that are difficult to implement in smaller establishments. This problem became the starting point for this publication, which presents considerations regarding the justification for implementing of transport service outsourcing in a small-sized manufacturing plant. The method of assessment and analysis of possible scenarios as well as universal recommendations for all enterprises are presented.

Keywords: Financial Security, Outsourcing, Transport, Logistics

Introduction

The term “outsourcing” means the use of external resources. Is an abbreviation for outside-resource-using. Outsourcing has also been defined as a procedure involving the separation of certain functions of a business from its organizational structure and their transfer to other economic operators (Setamanit, 2018). The basic benefits of outsourcing selected business functions suppliers include (Zhu et al., 2017):

- cost minimization and control,
- business focus on the core activity,
- quality improvement of outsourced functions,
- access to resources that the customer does not have,
- capital increase,
- transfer of functions that are difficult to implement, operate or control,
- transfer of risk to the service provider.

The literature distinguishes between two forms of outsourcing, internal sourcing (insourcing) and external sourcing (outsourcing). Insourcing consists in the assignment of part of the functions to a business partner, a subsidiary or a company, a shareholder of which the enterprise is. These companies are separate and independent but share capital with the service provider. On the other hand, external sourcing is about delegating some of the business functions to an outside enterprise (Zhu et al., 2017).

The function areas outsourced most often include:

- IT technologies and systems,
- customer service,
- marketing,
- finance and accounting,
- HR management,
- logistics,
- manufacturing.

The area covered in this paper is logistics. Logistics services outsourced by enterprises include, among others:

- transport,
- storage,
- shipping,
- palletization, packaging,
- customs procedures,
- waste and returnable packaging management,
- finance and accounting services (invoicing, insurance, payment services)
- supply chain management,
- distribution,
- sales.

The options to boost competitiveness through the use of resources, knowledge, experience and professionalism of a logistics operator, to increase the quality of services or reduce employment and costs are undoubtedly an advantage that outsourcing offers (Setamanit, 2018). It also lets the company to focus on managing its core business. However, it is not an ideal solution and brings with it some difficulties, which can include:

- problems with selection of the right business partner,
- difficulties in communication and coordination of activities at the initial project stages,
- risk that the expected requirements and the conditions for cooperation are not met,
- consequences of partnership: control of access to all information and insight into company data, loss of full control over certain key processes, organizational changes.

Logistics outsourcing generates benefits from cooperation not only for the outsourcing company but also for the service provider. The outsourcing company can get a lot of profits, such as the cost reduction, increased quality of services or more efficiency in the core business, as mentioned above. On the other hand, the service provider can make profits from its operations, build its knowledge and experience, and thus enter a higher segment in the market.

In the literature, outsourcing is presented from various perspectives. As regards transport, these include, for example, route optimization (Tang, 2018, 2020), supply chain network design (Cortinhal et al., 2018), service provider assessment (Zhu et al., 2017) or risk assessment for outsourcing of such functions (Zhu, 2016; Tian & Guo, 2019). Most of the research relates to large enterprises; for example, the efficiency of the supply chain is analyzed in terms of outsourced functions in a group of large companies (Kalinzi, 2016), multisourcing in the telecommunications (Mehmet, 2013) or healthcare sectors (Jeremy et al., 2013).

Publications concerning small-sized enterprises are available (Agburu et al., 2017; Mageto et al., 2018), but these are few. In contrast, those dealing with large companies most often use advanced tools, such as simulation models (Yang & Chen, 2019), fuzzy logic (Ljubojević et al. 2019), multi-criteria models (Bidani & Frikha, 2018) or time series (Papana, 2013). These can be difficult to implement in companies with a smaller vehicle fleet. Therefore, such businesses often carry out individual analysis

of their own conditions and make almost instinctive decisions regarding the benefits of outsourcing, not always to choose the right criteria for the adopted business strategy (Baeza et al., 2019).

In recent years, entrepreneurs have understood the need to separate extra functions from the organizational structure and transfer these to outside economic operators, which will take care of them more efficiently and effectively. The concept of outsourcing, including transport services, can be an important factor in the projects for minimization of costs while increasing the company's economic potential. However, outsourcing of transport services alone does not guarantee a better financial performance and can seriously affect the company's financial cash flows. Therefore, the profitability of such decisions must be assessed in each company before deployment. Only once the results are available, the question can be answered whether outsourcing of transport services will fulfil its role in the company and contribute to the cost and process optimization.

This paper presents such an analysis. Based on collected empirical data regarding transport processes, the operations of the transport department in a manufacturing company were assessed, to make a proposal with a view to increasing its profitability through the use of external service providers. Also, the paper demonstrates the importance and role of outsourcing in the enterprise, its advantages and disadvantages, as well as the factors that most affect profitability.

The aim of this paper is primarily to indicate a method of testing a small-sized enterprise, in response to the deficiency found in the literature, as well as to emphasize the importance of analyses preceding any outsourcing project and to show how any changing factors (in this case, lease agreement fees) can affect the final decision.

Research object and methodology

The analysis was based on data obtained from a manufacturing company whose business covers the production and assembly of furniture, based in Poland, in the eastern part of the Mazowieckie Province. Innovative ideas, customer satisfaction and continuous development of production technology all let the company to deliver orders in a comprehensive manner. The company has created furniture systems and solutions mainly designed for chain stores. Many years of experience in the industry allows the company to meet customers' expectations from the design and visualization stage, through the selection of appropriate materials, to the attractive lead time and professional assembly on the site. A sample project is presented in Fig. 1.

Fig. 1: Furniture manufactured by the assessed company
Source: Company's materials

The company experienced a dynamic growth in 2011. Automation of the manufacturing plant and provision of capacities for comprehensive order delivery, including the processing of raw wood, furniture board, glass, plexiglass, metal and stone, and upgrading of the machinery, which increased the scope of possible material processing, including printing and varnishing, allowed the company to

enter new markets. In view of this, in order to improve transport efficiency, a decision was made in 2017 to replace the transport fleet. Until then, the company had vehicles made in 2008 and in 2009, with mileage ranging from 400,000 km to 640,000 km, which was associated with high unreliability rates due to frequent failures. This not only generated extra cost but also affected the company's reputation especially where deliveries were late.

New vehicles were highly reliable and additionally met the stringent ecological and safety criteria, showcasing the values of the company. In this way, the company established a fleet of 12 light-duty trucks and one tractor unit with a semi-trailer.

The data collected by the company concerning the transport tasks, the revenues generated by them and the costs incurred allow not only to consider the functioning and profitability of the company but also to assess the improvements which can be implemented. The method of analysis, comparison and finally synthesis used in the article does not require any advanced mathematical or IT tools and therefore can be implemented in any company. Determining the seasonality of the process, assessing expenses, development opportunities and calculating profitability of potential improvements ought to be incorporated into management of every company.

Assessment of the Transport Department Operations

The first aspect of the analysis was the assessment of transport intensity expressed in the number of kilometres travelled. Fig. 2 presents a monthly summary of orders delivered in 2019 by LDVs and the tractor unit. As is evident, it fluctuates by calendar month.

Fig. 2 : Number of kilometres travelled by vehicles by month 2019

The shortest distance travelled was in December, while May and June, as well as October were the most favourable months. Next, the financial situation of the transport department was analyzed in 2019, taking into account:

- all costs of transport orders delivered, including: fuel expenses; road tolls; insurance costs; driver salaries; lease costs; repair and spare part costs; consumable fluid costs; technical inspections; and office costs, which included: salaries of office employees, electricity, Internet connection, telephone subscriptions, insurance, taxes and accounting;

- revenues from transport services rendered, calculated as the product of the number of kilometers travelled and the rate of 3.3 PLN/km for the tractor unit and 1.9 PLN/km for LDVs. The summary is presented in Table 1

Table 1: Balance sheet of the company for 2019

Month	Revenues [PLN]	Costs [PLN]	Profit/loss [PLN]
January	172,532.20	195,141.93	-22,609.73
February	189,599.50	200,510.62	-10,911.12
March	212,606.90	214,055.39	-1,448.49
April	211,958.10	211,192.12	765.98
May	222,544.90	219,346.77	3,198.13
June	235,295.70	223,819.87	11,475.83
July	195,119.30	200,442.25	-5,322.95
August	215,483.30	211,631.45	3,851.85
September	214,516.10	213,016.80	1,499.30
October	219,392.20	218,327.23	1,064.97
November	192,912.70	203,840.51	-10,927.81
December	151,827.00	192,903.29	-41,076.29
Total	2,433,787.90	2,504,228.21	-70,440.31

As the table above shows, the transport department of the analysed company posted a loss of PLN 70,440.31 in 2019. However, it is also clear that negative results are not posted in every month. There are periods such as June, in which profit amounted to PLN 11,475.83. The above financial picture was conditioned by the number of kilometers travelled in the delivery of transport services and the high value of costs incurred, the percentage share of which is shown in Fig. 3.

Fig. 3: Percentage share of cost types.

Fig. 3 shows that apart from fuel, the second largest group among all expenses consists of lease fees. As this cost item significantly influences the assessment of the transport department operations, in Table 2 the summary is presented without lease fees.

Table 2: Profit in 2019 by month excluding lease fees

Month	Revenues [PLN]	Costs [PLN]	Profit/loss [PLN]
January	172,532.20	156,499.53	16,032.67
February	189,599.50	161,868.22	27,731.28
March	212,606.90	175,412.99	37,193.91
April	211,958.10	172,549.72	39,408.38
May	222,544.90	180,704.37	41,840.53
June	235,295.70	185,177.47	50,118.23
July	195,119.30	161,799.85	33,319.45
August	215,483.30	172,989.05	42,494.25
September	214,516.10	174,374.40	40,141.70
October	219,392.20	179,684.83	39,707.37
November	192,912.70	165,198.11	27,714.59
December	151,827.00	154,260.89	-2,433.89
Total	2,433,787.90	2,040,519.41	393,268.49

The summary shows that the transport department of the analysed company is able to generate profits. Additional costs resulting from the use of lease arrangements in the company have a huge impact on annual profit. As this is a cost that can be avoided when using outsourcing, a decision was made to analyze this option by looking at how it would impact the company's financial cash flows.

Analysis and assessment of the profitability of transport service outsourcing

A robust business case for outsourcing of transport services requires that the profitability of such a solution is examined. To this end, current profits from the transport department were compared to an outsourced-transport scenario. It was assumed (based on a review of offers posted on the Internet) that the cost of an external service for LDVs is PLN 1.8 and for the tractor unit PLN 3.6. The results obtained are presented in Table 3.

Table 3: Monthly profit statement with outsourced services for the two transport vehicle types

Month	January	February	March	April	May	June
Total profit	4,127.80	4,199.50	6,802.10	5,742.90	7,704.10	7,941.30
July	**August**	**September**	**October**	**November**	**December**	**Total**
3,505.70	5,491.70	6,158.90	7,679.80	5,122.30	5,739.00	70,215.10

The calculations show that using an external service provider would let the company to generate profits in each month, with the total figure for 2019 with outsource transport services amounting to PLN 70,215.1, which, compared to the loss incurred, is an impressive result. However, as the high lease payments have a significant impact on this result, a comparison of profits without these costs would be more useful, as shown in Table 4.

Table 4: Monthly profit statement 2019 for outsourced transport services and use of own transport excluding lease fees.

Month	Profit with outsourcing [PLN]	Profit with own transport [PLN]	Difference [PLN]
January	4,127.80	16,032.67	11,904.87
February	4,199.50	27,731.28	23,531.78
March	6,802.10	37,193.91	30,391.81
April	5,742.90	39,408.38	33,665.48
May	7,704.10	41,840.53	34,136.43
June	7,941.30	50,118.23	42,176.93
July	3,505.70	33,319.45	29,813.75
August	5,491.70	42,494.25	37,002.55
September	6,158.90	40,141.70	33,982.80
October	7,679.80	39,707.37	32,027.57
November	5,122.30	27,714.59	22,592.29
December	5,739.00	-2,433.89	-8,172.89
Total	70,215.10	393,268.49	323,053.39

Table 4 shows that profit in 2019 would be higher by as much as PLN 323,053.39 in the case of using own transport if the company had not been burdened with lease payments compared with outsourced transport services. It is also clear that both options would generate profit in 2019 for the analysed company.

Summary

The aim of this paper was to present the aspects of decision making regarding the form of transport services based on the example of a selected manufacturing company. The analysis showed that these decisions must be preceded by a detailed profitability analysis, taking into account multiple factors. For the selected company, the decision to use outsourcing seemed favorable, compared with the loss incurred in 2019 in the amount of PLN 70,440.31. However, lease fees, which amounted to PLN 463,704 had a huge impact on the result. In this scenario, outsourcing of transport services compared with transport orders delivered by own means would bring the company a profit of PLN 140,655.41. With the knowledge on the share of lease costs in the total costs, another analysis was made. The potential profit with outsourced transport services was compared with the option of own transport, but after excluding lease fees, which showed how high a profit can be generated by the transport department using its own fleet of vehicles. In view of the research carried out and the fact that the analysed manufacturing plant will pay the last lease fees in May 2020, it can be concluded that the company would not profit from outsourcing transport services.

However, it should be noted that the results obtained can only be applied to this specific company. Nevertheless, the method of analysis, comparison and synthesis used is universal. Simple calculations that can be done in any spreadsheet software should precede the implementation of new solutions in any company. The method of conducting such analysis may be implemented in any given company. Moreover, the decision to outsource is influenced by other factors in addition to the discussed revenues.

The use of own transport offers more flexibility and freedom from issues related to coordination and communication with an external service provider. Moreover, the business owner has a strict control over the transport process. An essential disadvantage of outsourcing is the risk of errors on the part of the service provider, which may result in a detriment to the principal's reputation and loss of customers.

Therefore, such a decision must be thoroughly considered on a case-by-case basis, also in the long-term, and supported by reliable calculations, as presented in this paper.

Abstract

Domestic wastewater management in Jakarta pays special attention to the faecal sludge management. Millions of inhabitants in Jakarta still use septic tank technology as on-site household domestic wastewater treatment system. Considering that most of the population in Jakarta still uses septic tank technology, providing good operational standard of faecal sludge infrastructure is an effort that must be done by the Jakarta Provincial Government to reduce pollution of domestic wastewater. Actions taken to reduce environmental pollution caused by domestic wastewater in the community with local system management. Based on existing standards in Indonesia, septic tanks must be routinely desludging every 2-5 years for those which meet the SNI 2398-2017. The scheduled desludging aims to pollution prevention due to septic tanks because it has a proper range of desludging period. This study was conducted with a quantitative approach using descriptive methods. Involves as many as 1,322 respondents filling out closed questionnaires. The results of this study, 60.8% of respondents knew of the existence of a suction hole in their septic tank, and the rest don't know. Most of the respondent's houses or buildings in Kelurahan Pademangan Barat (67.2%) had never desludged their septic tanks at all. As much as 51.9% of respondents have septic tank suction holes that cannot be opened and only 48.1% can be opened. For desludging according to standard, there are 13.8% of houses or buildings in the Kelurahan Pademangan Barat that have implemented it while the remaining 19% are still using designs are not in accordance with standard.

Keywords*:* Faecal Sludge Management; Desludging Period; Septic Tank; Water Pollution

Introduction

In several studies conducted by Il (1989), Tilman and Lehman (2001), Miller & Spoolman (2015) show that activities carried out by humans produce a variety of influences on the main systems of life when viewed in terms of social, political, economic and cultural. Rani and Dahiya (2008), Putri et al (2016) and Wijaya et al (2018) mentioned increasing population and development is one indicator of the economic success of urban communities but the use of resources will produce new problems, namely the presence of waste. Another research by Tchobanoglous et al (1977), Salvato (1982) and Metcalf & Eddy (2014)'s book state in addition to industrial waste, domestic household liquid waste is a major contributor to urban waste and triggers a variety of water problems. The domestic wastewater management system in urban areas is one of the important indicators related to the development of proper community sanitation, because poor sanitation can have an impact on the economic system and the running government. BPS DKI Jakarta (2018) mentioned Jakarta has 10.46 million inhabitants. As many as 85% of those number still use septic tank technology as a local scale household wastewater treatment system.

The regional government has prepared significant facilities and infrastructure to meet the target of universal access for the community, one of which is to provide a local wastewater treatment system that starts from the disposal of feces in facilities such as septic tanks and then faecal sludge is aspirated and transported for further processing in the faecal sludge treatment plant known as *Instalasi Pengolahan Lumpur Tinja* (IPLT). According to Worldbank (2016) as many as 67.5% of Indonesia's population in 2025 will live in cities. ASEAN Secretariat (2019) give a view Jakarta as the first most populous city in Indonesia contributes to the count of 30.7% in areas that do not yet have proper sanitation management. Urban domestic wastewater management in Jakarta pays special attention to the faecal sludge management.

Based on data shown by the DKI Jakarta Provincial Statistics Agency (2018), the city of Jakarta has an area of 662.33 km^2 and has a population density of at least 158.04 inhabitants/hectare. The increase in population figures accompanied by a rapid growth in settlements has made the city of Jakarta experience a drastic reduction in environmental status. From a total of 10.46 million inhabitants in Jakarta, according to the DKI Jakarta Provincial Government's Regional Wastewater Management Company (PD PAL Jaya) in 2018, only 3% are served by sewerage or domestic sewage piping systems. commonly called a centralized system (off site system), 12% through access to sanitation with local individual processing systems (on site system) and the remaining 85% still use *sepiteng* which refers to the existence of septic tank technology. The rest are still practicing open defecation so there are various triggering factors for river pollution and the inadequate quality of ground water in Jakarta. Although almost 100% of the people of Jakarta have access to sanitation, data from the Ministry of Health (2020) show there are 25 *kelurahan* that have been verified by Open Defecation Free (ODF), but 535.62 thousand people are still doing open defecation.

A fact that most of the people in Jakarta still use septic tank technology, so providing a good operational standard IPLT infrastructure is one of the efforts that must be effort by the Jakarta Provincial Government to reduce pollution of domestic wastewater in the community. Contribution of pollution from faecal sludge can be estimated from the rate of pollution load that can be reduced per unit time in g/day or kg/day or tons/year, so that according to Anggraini and Nuraeni (2016) after multiplying the daily sludge volume that is processed (m^3/day) with the content of the pollution load (mg/L) in the faecal sludge will get the rate of reduction of the pollution load. Looking at the data on the number of residents in Jakarta who still use septic tanks, the potential quantity of faecal sludge entering the IPLT should be quite high, but in fact the PD PAL Jaya (2019) mentioned daily average volume of sludge is very small ie 104.4 m^3/day and cause IPLT to have a significant iddle capacity, like research conducted by Subhan U et al (2017), due to desludging based on community demand (on-call based) so as to monitor the performance of septic tanks and improve operations IPLT, a faecal sludge management activity is made regularly. Regular desludging is aimed at reducing pollution due to domestic wastewater.

Based on existing standards in Indonesia, septic tanks must have desludging period. It should be routinely desludging every 2-5 years. The determination was carried out on septic tanks that meet the SNI 2398-2017 specifications with an estimated septic tank having a combined and separated systems. It is also mentioned in the previous standard i.e. SNI 03-2398-2202, a septic tank with a separate system measuring about 1 m3 is intended for one house or building with only 5 inhabitants. Sludge desludging of septic tanks is carried out more frequently than the standard range of periods generally due to the inclusion of household wastewater other than feces into the septic tank, or the capacity of the septic tank is too small. Whereas desludging is performed less frequently than the standard period range, it is likely that damage to the septic tank will seep out and pollute the soil so that the impact on active groundwater used. In addition, if the tank capacity used is too large, the desludging will have a long time span, but this rarely happens.

Study from BPLHD on 2015 shows several points in Jakarta groundwater pollution caused by coli bacteria. As a case study, the coli bacteria value in groundwater samples in Kelurahan Pademangan Barat, North Jakarta reached a pretty high number of coli bacteria values, ie 370,000 MPN/100 ml. The general aims of this research is to provide a new perspective that controlling pollution caused by domestic wastewater can not only be done by optimizing the treatment of faecal sludge in the IPLT

like previous study by Oktiawan and Priyambada (2007) but also by conducting local system management (on-site) domestic wastewater by having a good desludging period. An analysis of social problems was carried out through collecting respondent data so that the frequency of community sludge desludging and emptying of septic tanks could be generated.

Methods

The study was conducted in Kelurahan Pademangan Barat, North Jakarta, Indonesia in 2016. It was conducted with a quantitative approach using descriptive methods through a survey of respondents by distributing closed questionnaires so that the percentage of suctioning frequency data was obtained. In this study closed questionnaires were distributed to 1,322 respondents who were a list of questions in the form of multiple choice. Hypothesis testing is not carried out but only describes the state of some variables, symptoms or conditions that occur in the study area. The survey included questions about the technical specifications of the local wastewater treatment system owned by respondents to determine the conditions of fulfilling the requirements if desludging is to be done. The case study in this research was carried out in Kelurahan Pademangan, where in this case the city government was assisted by the working group at the kelurahan level to implement the Scheduled Sludge Service program. The results can be used as capital for the city government to control the sustainability performance of the management of sludge in the future.

Result and Discussions

Existing Conditions

The community has understanding that septic tanks that are not managed or desludged regularly for years mean that they have no problems, even though according to data released by the *Dinas Lingkungan Hidup* in 2018, most rivers in Jakarta have been contaminated with faecal bacteria Eschericia coli (E. coli). Delinom (2008), Kosasih BR et al (2009), and Kooy et al (2016) mentioned biological contamination have an impact also on the quality of ground water in the city of Jakarta. Cases of septic tanks leaking to the ground, direct disposal of greywater or non-toilet domestic wastewater resulting from washing baths into drains and water bodies are the main factors of water pollution. Through the total coliform parameter which is an indication that the water is contaminated with feces, water pollution in Jakarta has exceeded the 99,000 MPN/100 ml sample of the maximum allowable level of 0 MPN/100 ml, which is regulated in Permenkes No. 492/Menkes/Per/IV/2010 concerning Drinking Water Quality Requirements.

Table 1: drinking water quality requirements are regulated in Permenkes No. 492 of 2010

Parameter	Units	Maximum allowable number
E. Coli	Number per 100 ml sample	0
Total coliform bacteria	Number per 100 ml sample	0

Jakarta's groundwater pollution is dominated by manganese, iron, organic, coliform, and faecal bacteria. The high concentration of these pollutants indicates that there is still a lot of ground water in Jakarta that is polluted by domestic wastewater from septic tanks. Based on research by BPLHD Jakarta (2015), that has been conducted twice at various sample points in 197 *Kelurahan* in Jakarta, the biological contamination rate of Coli bacteria parameters in ground water in Kelurahan Pademangan Barat, North Jakarta is in the range of 0-370,000 MPN/100 ml and is the area with the highest pollution compared to other municipalities.

Analysis of Respondents' Survey

In this research, data obtained from a survey of 1,322 respondents regarding the ownership status of on-site domestic wastewater treatment namely septic tank at the research location, the existence of

suction holes in the septic tank and the conditions can be opened or not to then be connected to the range of desludging periods carried out by each house or building. The existence of suction holes facilitates the implementation of septic tank desludging.

Fig. 1: Respondents desludging period in Kelurahan Pademangan Barat

Ignorance of the position of the desludging hole will require searching and dismantling the estimated location of the septic tank so that desludging can be carried out, leading to additional costs and effort in addition to desludging. The survey found that only 60.8% of respondents knew of the existence of a suction hole in their septic tank, the rest don't know. The existence of suction holes is not enough, because many suction holes are rarely or even almost never used, making it difficult to open. If the desludging hole cannot be opened, it must be dismantled so that the septic tank below can be accessed for desludging. The demolition requires additional time, money and energy outside the desludging activity. Based on the survey results obtained as much as 51.9% of respondents in the Pademangan Barat Kelurahan have septic tank suction holes that cannot be opened and only 48.1% can be opened.

Regulation Requirement

Technical requirements for septic tank systems are combined and separated systems commonly used at the household scale are for a minimum number of users of 5 people per household, detention time (td) or residence time is 2-3 days with an estimated sludge basin of 30-40 L/person/year and drainage period 2-5 years. To avoid the case of sepiteng seeped in the middle of community settlements, the Research and Development Center for Housing and Settlements, the Research and Development Agency of the Ministry of Public Works and Housing recommends a percolation test to determine the soil's absorption capacity. This needs to be done before the infiltration pipeline or well from the septic tank is built so that it can be carefully estimated the area of infiltration needed.

Sludge desludging in septic tanks which is carried out more frequently than the period of 2-5 years is generally caused by the entry of household wastewater other than feces into the septic tank, or the capacity of the septic tank is too small. Whereas desludging is carried out less often than 2-5 years generally due to damage to the septic tank so that wastewater seeps out and contaminates ground water, or the capacity of the septic tank used is too large. It can be seen (see Fig. 1) that the majority of respondents' houses or buildings in Kelurahan Pademangan Barat, which is 67.2%, have never desludged their septic tank at all. For the desludging period according to SNI, there are 13.8% of houses

or buildings in the Kelurahan Pademangan Barat that have implemented it. While the remaining 19% are still using septic tanks whose designs are not in accordance with SNI so that it requires replacement and further socialization of information about the necessity of desludging regularly in accordance with established standards.

Field studies show that the status of a house or building in Kelurahan Pademangan Barat is self-ownership so it is considered easier to do desludging compared to houses or buildings with contract, lease, and joint ownership status. Houses or buildings with contract and rental status require coordination and approval from the official owner, whereas joint ownership status requires agreement between co-residents consisting of various families and backgrounds. But in reality this is not in line with the amount of desludging. The location of the septic tank is one of the determinants of whether or not routine septic tank desludging is carried out. Septic tanks will be easily accessed if they are located in the front or yard, while septic tanks located inside the house and backyard require special effort because there is a possibility of being blocked by a room or an object.

Find out the availability and exact position of the septic tank will facilitate the implementation of desludging. Do not know the position of the desludging hole resulted in the need for searching and dismantling the estimated location of the septic tank, causing additional costs and effort in addition to desludging. USAID Indonesia in *Pedoman LLTT* (2016) announced the condition of septic tanks that are not suitable for desludging or emptying by truck units provided and the position of houses that are difficult to reach by the suction hose due to the dense living space becomes an obstacle for implementing scheduled desludging. To facilitate desludging, it is recommended to make a manhole, the aim is not only for physical control but also for routinely desludging, so that the septic tank does not need to be wrecked.

Conclusion

It can be concluded according to the research conducted, from a survey of 1,322 respondents regarding the ownership status of on-site domestic wastewater treatment namely septic tank at the research location, found that only 60.8% of respondents in Kelurahan Pademangan Barat knew of the existence of a suction hole in their septic tank, the rest don't know. The survey also shows that 51.9% of respondents have septic tank suction holes that cannot be opened and only 48.1% can be opened, so wrecking of the septic tank must be done when desludging implemented. Majority of respondent's houses or buildings in Kelurahan Pademangan Barat, which is 67.2%, have never desludged their septic tank at all. For the desludging period according to SNI, there are 13.8% of houses or buildings in the Kelurahan Pademangan Barat that have implemented it. While the remaining 19% are still using septic tanks whose designs are not in accordance with SNI so that it requires replacement and further socialization of information about the necessity of desludging regularly in accordance with established standards.

Abstract

The research objective of the article is to examine the extent to which various characteristics of household are related to income inequality and to verify whether the decline in overall inequality is accompanied by the decrease in inter-group inequality. The contribution of our article consists in employing recently available microdata from EU-SILC to the analysis of income inequality for three types of income. In this study, we use the Theil index and its property of being additively decomposable. The following six factors have been chosen as the possible drivers of income inequality: the type and size of the household, labour market status and educational level of the household head as well as the degree of urbanisation and region of its residence. Our results indicate that the characteristics related to the labour market are the most influential factors of income inequality in Poland. The characteristics describing the household composition contribute to the overall level of inequality but to a smaller extent. Our study also revealed that the relatively low overall inequality hides more serious income inequality between household groups.

Keywords: Income Inequality, Inter-Group Inequality, Theil Index

Introduction

The issue of income inequality that started to take shape during the economic transformation in Poland has been clearly visible after Poland's accession to EU in 2004. In 2005, Poland belonged to the EU countries with the highest income inequality. Since 2007 a gradual decrease in inequality of income before and after social transfers has been observed in Poland. Looking at these overall inequality patterns, the relative stability in the level of inequality over the past decade can be seen. This allows us to assume that inequality in Poland is not a pressing problem.

At the same time, Poland has experienced significant changes in the socio-demographic situation and stands apart when compared to the rest of the EU countries in terms of demographic changes. Poland is a country with one of the lowest total fertility rates, one of the largest increases in life expectancy, extremely intense population aging and a very large emigration abroad (Gołata and Kuropka 2016). Furthermore, a sharp increase in education attainment and a significant decrease in the unemployment rate to its lowest levels since 1991 has been observed during the last decades.

The research objective of the article is to examine the extent to which the socio-demographic characteristics of household and personal attributes could help explain income inequality in Poland. Moreover, the paper attempts to answer the following questions: does the impact of social transfers on the reduction in income inequality respond to the diminishing differences between average incomes of household subgroups? How does the inter-group inequality and the driving forces behind it vary over time? We employ a Theil decomposition to examine the impact of various factors on the level of income

inequality. The contribution of our paper consists in employing recently available microdata from EU-SILC to the analysis of income inequality for three types of income.

Studying inequality between different socio-demographic groups and its determinants is highly relevant. We focus on dimensions of inequality suggested in the existing subject literature as important sources of income inequality and social discontent. The choice of these dimensions is based on a classification of socio-demographic categories, as well as on the hypothetical characteristics of disadvantaged households described in the literature.

A study that is pretty close to our investigation is that of Papatheodorou (2000), who applied the decomposition of income inequality by subgroups of Greek household classified by characteristics such as, for instance, the type and size of the household, the occupational status and the educational level of the household head, region of residence and the degree of urbanisation. Medgyesi (2014) analysed the contribution of population characteristics (*e.g.*, education level, household composition) to income inequality and its change during the 2004-2010 period in EU countries, including Poland. He evidenced that the importance of education tends to be relatively high in EU12 countries and relatively low in EU15 Member States. Chongvilaivan and Kim (2016) and Biddle and Montaigne (2017) used decomposition analysis to study the role of the degree of urbanisation in explaining the income disparities between household groups.

Data and Methodology

In order to empirically explore the sources of income inequality, our study employs data from the EU-SILC survey conducted by Eurostat. The micro-data were obtained under a project entitled 'Income and inequality of income of European households' (RPP 162/2018-EU-SILC) and cover information about incomes achieved by individual members of Polish households in 2006, 2012 and 2018. In the first year of the study, the sample consisted of 14,914 households, *i.e.,* 45,122 individuals. For 2012 and 2018 the samples included 13,116 households (with 37,123 persons) and 15,214 households (39,922 persons), respectively.

The study reports on three concepts of income: household disposable income (abbreviated to DPI), household disposable income before social transfers except old-age benefits (abbreviated to IWB), and household disposable income before social transfers (abbreviated to IBT).

IBT consists of the sum of gross personal income components for all household members and gross income components achieved at the household level. It mainly covers earnings, incomes from self-employment, incomes from rental of a property or land as well as interests, dividends, profit from capital investments, so IBT can be identified with market income.

In comparison with IBT, IWB includes also old age benefits and survivor' benefits, while DPI covers all of the above-mentioned incomes and benefits as well as unemployment, sickness and disability benefits, education and family/children related allowances, social exclusion and housing allowances. In the study, all incomes were reduced by taxes on wealth, inter-household cash transfer paid and tax on income and social insurance contributions.

In our analysis, household is used as a unit of the study. Therefore, in order to take into account differences in the household size, all of the above-mentioned incomes were adjusted using the equivalence scales. Income was divided by the number of equivalent adults in the household, and then equivalised value was assigned to each household members. When adjusting, we used the OECD-modified equivalence scale.

All inequality measures presented in the paper were calculated using the personal cross-sectional weights thus they are equivalent to an extrapolation of the measures to the whole population.

When analysing income inequality, we assume that the inequality in a population split into groups can result from the unequal distribution of income 'between' the groups as well as from the unequal

distribution of income 'within' each group. We consider six household attributes that constituted the basis for identifying groups of households as possible drivers of income inequality, *i.e.,* the type and size of the household, the labour market status, the educational level of the household head, the degree of urbanisation, and the region of residence of the household.

Based on the household type, we have created seven household subgroups, distinguished based on the composition of the household, *i.e.,* the number of adults and dependent children.

When analysing the size of the household, we consider six subgroups separated on the basis of the number of household members - from one to six persons. Households consisting of more than six members were included in the last subgroup.

According to the EU-SILC methodology, the head of the household is a person whose income creates the dominant source of household income. Based on the personal characteristics of household head, such as the labour market status or the level of education, we have divided all households into subgroups.

Considering the prevailing source of income of a household head, we recognised the following subgroups of household:

- employees,
- the self-employed,
- the unemployed,
- retirees living on old-age benefits,
- pensioners living on survivor's and sickness benefits.
- persons living on disability benefits.

When creating subgroups of households based on the highest educational attainment of the household head, we have considered the following six levels of education: pre-primary, primary, lower secondary, upper secondary, post-secondary non-tertiary, and tertiary.

In the study, we analysed income inequality in regions identified at NUTS1 level and classified households into six groups.

In our analysis, we also take into account the degree of urbanisation of the household location area. Based on this feature, according to the EU-SILC methodology, we have distinguished households situated in a densely populated area, moderately-populated area and thinly-populated area.

To assess income inequality, our study employs the Theil coefficient, which represents a special case of the Generalised Entropy (GE) type measure. The class of GE measures can be described by the formula:

$$GE(\alpha) = \frac{1}{n(\alpha^2-\alpha)} \sum_{i=1}^{n} \left[\left(\frac{y_i}{\bar{y}} \right)^{\alpha} - 1 \right], \qquad (1)$$

where y_i is the equivalised disposable income of household i, $\bar{y}$ is the population mean income, and n is the number of households in the population. The parameter α indexes the members of the class and summarises the sensitivity of $GE(\alpha)$ to income differences in different parts of the income distribution (Cowell, 2006, p.5).

GE(α), for $\alpha = 1$, is called the Theil index. Since the expression (1) is not defined for $\alpha = 1$, because the denominator $n(\alpha^2 - \alpha)$ equals 0, the Theil index is obtained using the *de l'Hôpital rule* and can be described by the formula:

$$T = \mathrm{GE}(1) = \frac{1}{n} \sum_{i=1}^{n} \frac{y_i}{\bar{y}} ln \frac{y_i}{\bar{y}}. \qquad (2)$$

The values of the Theil index ranges between 0 and $ln(n)$, where 0 represents complete equality and $ln(n)$ points to complete inequality (Chongvilaivan and Kim, 2016, p.85).

Our choice of the Theil index is justified by two facts. Firstly, it satisfies the four main principles that any inequality metric should meet in order to be considered a reliable measure, namely: anonymity, mean independence (or income-zero-homogeneity), the principle of population replication (or population-size independence) and the Pigou-Dalton principle of transfers (Bourguignon 1979;

Shorrocks 1980, 1984). Secondly, an appealing feature of the Theil index is its property of being additively decomposable.

According to Bourguignon (1979), an inequality measure is considered to be additively decomposable if total (overall) inequality can be expressed as the sum of between groups inequality and within a group of inequality.

Assuming that all households are partitioned into *m* non-overlapping groups, the Theil index can be decomposed into the two components as follows:

$$T = \sum_{j=1}^{m} s_j T_j + \sum_{j=1}^{m} s_j \, ln\left(\frac{s_j}{p_j}\right) = T_w + \mathrm{T_b}\,, \qquad (3)$$

where s_j is the income share of a group *j* in total population income, p_j is the population share of a group *j* in total population. T_j is the Theil index corresponding to a group *j*, T_w and T_b denote within-group and between group components, respectively.

The first sum in the expression (3) measures a part of overall inequality that results from inequality within subgroups. The within-group term is a weighted average of group inequalities where the weights depend on income shares. The between-group component states the extent of inequality due to differences in the group mean income. It expresses the level of inequality that would be observed if the income of each household is replaced by the mean income of the respective subgroup. T_b can be interpreted as income inequality between the groups separated on the basis of household attributes, which comprise the total inequality, and this allows to appoint the nature of the causes of income inequality. The importance of attributes in explaining income inequality is assessed as a ratio of the inequality between subgroups to overall inequality.

Trends in Income Inequality in Poland

Our empirical analysis focuses on income inequality in Poland for the period 2006–2018. In order to present the dynamics of inequality we decided to use various proxies of income inequality: the Theil index, which is the basis measure of our analysis, the Gini coefficient, and the percentile ratio P90/P10. The Gini coefficient was chosen because it seems to be the most commonly used measure of income inequality and can easily be found in official statistics. The selection of P90/P10 ratio was determined by the fact that it describes the relation of the income of the richest households to that of the poorest. More precisely, it presents the relation of the minimum level of income attained by 10% of the richest households to the maximum level of income achieved by 10% of the poorest ones. Table 1 reports the above-mentioned inequality measures for three types of income.

Table 1: Measures of income inequality in Poland

IBT	Gini	Theil	P90/P10
2006	0.530	0.364	17.598
2012	0.475	0.284	8.238
2018	0.463	0.244	7.289
IWB			
2006	0.387	0.243	6.406
2012	0.342	0.197	4.792
2018	0.327	0.171	4.612
DPI			
2006	0.333	0.190	4.579
2012	0.309	0.169	4.001
2018	0.278	0.132	3.514

Source: Authors' own calculation using EU-SILC data.

When analysing the measures of income inequality presented in Table 1, two main conclusions can be drawn: about a regular decline in income inequality in Poland and about the equalising effect of transfers.

Firstly, all measures of income inequality reflect the trend of decreasing income inequality in subsequent years. The most striking example can be the P90/P10 ratio for IBT in 2006, when the minimum income of 10% of the richest households was almost eighteen times higher than the maximum income of 10% of the poorest. In 2012 and 2018 this relation was much lower.

The highest level of inequality was observed in IBT, mainly consisting of wages, self-employment income and capital income. This can be the confirmation of wages and self-employment income being the main source of income inequality.

Secondly, all of the measures consistently indicate that the level of inequality in Poland is decreasing when household receive further social transfers. However, it should be noticed that the equalising effect of old-age and survivors' benefits is stronger than the effect of other transfers.

Since 2007, the income inequality in Poland has been decreasing monotonically. However, it seems important to examine whether the decline in overall inequality is accorded with the decrease in inequality between groups of households.

Decomposition of income inequality by population subgroups

Decomposition of IBT inequality

This section presents and analyses the results of the decomposition of income inequality by subgroups. In the first step of our discussion of the results we focus on the inequality of equivalised disposable income before social transfers including old-age and survivor's benefits (IBT). Income IBT can be equated to market income reduced by taxes and social insurance contributions, which consists of salaries, self-employment income as well as savings, property and investment income. Therefore, the level of inequality on IBT income is shaped mainly by salaries and self-employment income inequality. As mentioned in the previous section, inequality on IBT income decreased substantially between 2006 and 2018. We observe that there has been a decrease in inequality on total IBT together with a corresponding drop in within-groups inequality (Table 2).

Table 2: Decomposition of income inequality by subgroups

		IBT		IWB		DPI

Source: Authors' own calculation using EU-SILC data.

The main causes of income inequality were the educational level of the household head and the labour market status of the household head. Between 2006 and 2018 the ratio of the inequality between subgroups to overall inequality decreased in both cases from 25.4% to 15.5% and from 25.4% to 18.9%, respectively (Figure 1). Our research shows that there is a positive correlation between the level of education of the household head and the level of household income. The fall of the effect of differences in household income based on the education level of household head resulted, among others, from the rising education level of Poles. Likewise, the fall of the effect of differences in household income based on the labour market status of the household head resulted, among others, from the decrease in the unemployment rate. Out of the six analysed factors, income inequality due to the labour market status of the household head contributed most significantly to overall IBT inequality in 2018.

Fig. 1: The ratio of inequality between subgroups to overall IWT inequality
Source: Authors' own calculation using EU-SILC data.

Chongvilaivan and Kim (2016) suggest that the urban versus rural income inequality is central to the debates on increases in income inequality. In Poland, as can be seen in Table 2, the degree of urbanisation had some importance. The breakdown by degree of urbanisation produced somewhat identical results in the years 2006-2018. This factor explained roughly 7.5–6.5 % of overall income inequality.

The household size and household type are further demographic variables used in this study. The share of the inequality between subgroups in total inequality was equal to 5.1% - 6.1% and 5.6% - 6.0%, respectively. This appears to indicate that, the type and size of household were less significant. As shown by the differences of the above mentioned characteristics between the analysed years, the basic pattern of the contribution of household size and household type remained unchanged.

Intuitively, economic inequality among different regions may serve as a driving force of income inequality. The central region in Poland tends to experience a faster pace of economic and social development. However, our results show that differences in income between households in different regions of residence contributed insignificant to the overall inequality and it is of negligible importance

in Poland. Only about 1.4-2.8% of the income inequality can be explained by the location of the household.

Decomposition of IWB Inequality

In the second step, the study covers six variables for different social and demographic household characteristics with a possible influence on IWB inequality. Table 2 and Figure 2 show how between groups inequality, within a group inequality and total inequality changed over the 2006-2018 period for total disposable household income before social transfers other than old-age and survivor's benefits.

Differences in the level of education had the highest impact on the extent of IWB inequality during the 2006-2018 period. The level of education of the household head was particularly important in 2006, where it accounted for around one fourth of overall inequality. It should be highlighted that the addition of old age and survivor's benefits to IBT did not reduce the ratio of the inequality between subgroups to overall inequality. This is due to the fact that the level of education affects not only labour income but also pensions.

The labour market status of the household head contributed to the overall inequality to a smaller extent than education attainment during the period 2006-2018 (Figure 2). The addition of old-age and survivor's benefits to IBT significantly reduced the effect of differences in household income based on the labour market status. In 2006 the labour market status of the household head accounted for 10.8% of overall IWB inequality. Our results showed that 93.4% and 91.8% of inequality, in 2012 and 2018 respectively, could be explained by within-groups disparities, while the rest could be attributed to differences between groups.

The income sources related to the degree of urbanisation were quite significant determinants of household income inequality. Between 2006 and 2018 the degree of urbanisation accounted for 7.0%-8.7% of the overall IWB inequality and this effect was larger than the effect on IBT's distribution. It can be discerned that the average annual pension in the urban areas was higher than that in the rural territories. Therefore, the inclusion of old-age and survivor's benefits did not diminish the ratio of the inequality between subgroups to overall inequality.

As for household structure, it had a minor impact. For the household size and household type the results are less impressive and similar to the obtained ones for the previous decomposition. More specifically, the observed inequality comes overwhelmingly (from 93.2% to 94.8%) from heterogeneity within the groups based on the household size and from 5.0% to 6.6% of the overall inequality can be attributed to the differences in the type of the households. It is also interesting to note that the inclusion of old-age and survivor's benefits did not change the ratio of the inequality between subgroups to overall IWB inequality.

Fig. 2: The ratio of inequality between subgroups to overall IWB inequality
Source: Authors' own calculation using EU-SILC data.

As in the case of decomposing IBT inequality, the region of residence factor was the least significant in explaining IWB inequality. The decomposition of the Theil indices by region of residence predicts that the contribution of region inequality to IWB inequality was low since the between-group component constituted merely 1.6% and 2.9% of overall income inequality.

Decomposition of DPI Inequality

In the next step we investigate whether the inclusion of social transfers (*e.g.,* unemployment benefits, family/children related allowances, housing allowances, sickness and disability benefits) changed the fraction of total inequality that results from the differences between average incomes of different subgroups of households. In order to evaluate the impact of different household characteristics we decomposed the Theil index of equivalised disposable income (DPI).

As with the two previous types of income, the main cause of income inequality concerned the educational level of the household head (Figure 3). The between-group component attributed to 17.0%-24.5% of the observed inequality in differences in household income based on the education level of household head, which is larger than what we obtained for the two previous decompositions. Social transfers reduce market income inequality, but the Theil gap is not enough to explain income redistribution since it says little about the extent to which social transfers accrue to the least affluent households. Not all kinds of social transfers (*e.g.,* family/children related allowances) accrue to the low-income households headed by a person with a lower level of education.

The degree of urbanisation was the next significant household characteristic related to income inequality. The evidence reveals that between 2006 and 2018, the impact of degree of urbanisation on DPI inequality diminished from 8.9% to 6.5%. The decline in the inequality within the subgroups distinguished based on the degree of urbanisation coincided with the reduction in inequality between the subgroups. It is also interesting to note that the ratio of the inequality between subgroups to overall inequality increased as a result of the inclusion of social transfers in household income.

The inclusion of social transfers significantly reduced the differences in income between subgroups distinguished on the labour market status of the household head. Between 2006 and 2018 the differences in income between subgroups accounted for from 5.7% to 8.7% of overall DPI inequality. It is also clear that inter-groups inequality contributed less to total inequality when looking at equivalised household income (DPI) than at disposable household income before social transfers (IBT and IWB). The decrease in the ratio of the inequality between subgroups to overall DPI inequality makes sense since social transfers such as unemployment benefits and disability benefits accrue to the poorer households.

Fig. 3: The ratio of inequality between subgroups to overall DPI inequality

Source: Authors' own calculation using EU-SILC data.

The breakdowns by household size and household type produced the somewhat identical results. Between 2006 and 2018, the contribution of differences in the household size and household type to overall DPI inequality decreased monotonically from 6.6% to 3.7% and from 6.8% to 4.1%, respectively. Moreover, the inclusion of social transfers had an equalising effect on the differences in income between the subgroups distinguished based on the household size factor in 2018. The ratio of the inequality between subgroups to overall IBT inequality was equal 6.1%, while the ratio of the inequality between subgroups to overall DPI inequality was equal to 3.7%. This result points to the likelihood that the differences in income between subgroups decreased as a result of the additional transfers of family benefits (*e.g.,* The 'Family 500+' programme).

Evidence suggests that between 2006 and 2018 there were no significant differences between average incomes of different subgroups of households based on the region of residence factor. The observed DPI inequality came overwhelmingly (97.1%-98.4%) from heterogeneity within the subgroups; the between-component accounted for a modest part (1.6%-2.9%) of the total. This finding points to the relatively limited contribution of the region of residence dimension to overall DPI inequality.

Conclusions

Previous studies, which analysed the distribution of income inequality in Poland, most often concerned only one type of income. In this article, we made use of the additively decomposable nature of the Theil index and recently available detailed survey data to look at to analyse how different social and demographic factors are related to the extent of income inequality for three income types. Old-age and survivors' benefits as well as social transfers decrease income inequality. Our intention was to verify whether the equalising effect of transfers corresponds to the diminishing differences between average incomes of household subgroups.

IBT inequality decreased significantly between 2006 and 2018 when measured by the Theil index and by the Gini coefficient. The educational level of the household head was the main cause of IBT inequality during the 2006-2018 period. This conclusion is clearly in line with theoretical (see, for instance, Green *et. al.* 2016) and empirical research regarding the existence of important differences between average incomes of education subgroups (Muszyńska and Wędrowska 2018), (Medgyesi 2014). Income gaps between different education groups narrowed in the years 2006-2018 but the income inequality among households within each education groups increased. The labour market status of the household head also played a greater-than-average role in shaping the level of inequality. However the contribution of differences in this factor to overall income inequality decreased in 2012 and 2018 compared to 2006.

IWB inequality decreased between 2006 and 2018. Therefore, the decline in within-group inequality was an expected result, since the inclusion of old-age and survivor's benefits had an equalising effect on income distribution. While within-group inequality declined, inter-group inequality also decreased, however the change in the within-group inequality was much larger in magnitude than the change in the inter-group inequality. Studies analysing the impact of benefit instruments on the reduction in income inequality find that public pensions are responsible for most of the reduction in income inequality (Fuest *et. al.* 2010), (Amarante 2016). However, the inclusion of old-age and survivor's benefits reduced the ratio of the inequality between subgroups to overall IWB inequality only for the subgroups identified based on the labour market status of the household head.

Social transfers such as unemployment benefits, family/children related allowances, housing allowances, sickness and disability benefits constitute an important source of household income inequality reduction. The most striking result to emerge from our study is that the inclusion of social transfers had an equalising effect on the differences in income between the subgroups identified based on the size and type of household in 2018. The addition of social transfers to IWB income significantly reduced the effect of differences in household income based on the labour market status in 2006. The differences in the level of education had the largest impact on the extent of DPI inequality. Green (2016, p.34) suggests that a key difference between a low- and higher-income household may be the extent to which they value education.

In conclusion, between 2006 and 2018 the dispersion of salaries and self-employment income as well as disposable income inequality declined in Poland. However, the relatively low overall inequality hides more serious income inequality between various social and demographic groups.

Integrated Approach to Risk Analysis and Mitigation in Polish Construction Industry Capital Groups

Dorota TENETA-SKWIERCZ

Wroclaw University of Economics and Business, Wroclaw, Poland
E-mail: dorota.teneta@ue.wroc.pl

Abstract

The main objective of this study was to identify factors influencing the effectiveness of application of the integrated approach to risk analysis and mitigation, the so-called GRC (Governance, Risk management, Compliance) and to assess the degree of preparation of Polish construction companies to implement this approach. In the research, an idiographic approach, a case study procedure, were used. The analysis was carried out on the two largest Polish capital groups in the construction sector, BUDIMEX and UNIBEP. The carried out case studies made it possible to describe the practices applied by construction companies which are important for the effectiveness of the GRC. These practices were shown in five groups of factors, such as: corporate policies and procedures/supervision, communication and training, ethical organizational culture, responding to and preventing future incidents, risk management. The research shows that although BUDIMEX and UNIBEP's approaches to the GRC differ in several respects (BUDIMEX shows greater diligence in fraud prevention), in general the degree of preparedness of both groups to implement the GRC can be considered as satisfactory.

Keywords: Risk Management, Compliance, Construction Industry, Governance.

Introduction

Nowadays, it is hard to disagree with the viewpoint that any organization that cares about achieving its goals and building a competitive advantage must pay attention to the needs and expectations of its stakeholders, respond flexibly to changes in the environment, create an effective system of internal and external communication and set the boundaries of its operations. These boundaries will be determined not only by the external regulations, established by the state, international institutions (e.g. the European Union) or trade associations, but also by internal regulations in the form of policies, procedures, a set of key standards and values, often included in codes of conduct. Moreover, it should also consider the risks and uncertainties that can be a source of both business losses and benefits. The concept that integrates all these aspects is GRC (Governance, Risk management, Compliance).

The main objective of this study was to identify factors influencing the effectiveness of application of the integrated approach to risk analysis and mitigation in a company (GRC) and to assess the degree of preparation of Polish construction companies to implement this approach. In the study, the idiographic approach and case study procedure were used. The analysis was carried out on the two largest capital groups in the Polish construction sector whose parent companies are listed on the Warsaw Stock Exchange and included in the WIG-Budownictwo Index. The choice of the qualitative approach was dictated by the intention not only to state the fact of occurrence but also a synthetic description of selected practices, important for the effectiveness of GRC.

The essence and conditions for the effectiveness of the GRC approach - literature review

Until recently, a silo approach to management, risk and compliance activities prevailed, which, as a result of their considerable dispersion within the organization, negatively affected the transparency and effectiveness of the decision-making process (Vicente, Mira da Silva 2011). Nowadays, the need to integrate these three functions is increasingly recognized, due to their strong interdependence. This is the birth of the GRC, which is an integrated approach focused on risk analysis and mitigation in

line with internal and external regulatory requirements (Salido, Voon 2010). According to N. Racz et al. (2011) the GRC is a holistic approach to governance, risk and compliance across the organization, ensuring that the organization acts ethically and in accordance with its risk appetite, internal policies and external regulations . The Open Compliance and Ethics Group - OCEG (2009) defines the GRC as a system of people, processes and technologies that enables an organization to: understand and prioritise stakeholder expectations; set business objectives that are consistent with values and risks; achieve objectives while optimizing its risk profile and protecting values; operate within the boundaries of external and internal, legal, social and ethical regulations; provide relevant, reliable and timely information to relevant stakeholders. As C.S. Switzer and his team (2015) rightly concluded, the GRC provides the right people with the right information at the right time, the right goals are set and the right actions are taken, including controlling activities, necessary to solve the problem of fraudulent behavior.

For the GRC to live up to its hopes, appropriate conditions must be created. Thus, people who are responsible for compliance management should be able to participate in the development of the strategy of action. All members of the organization, regardless of their position in the organizational structure, should be aware of the importance of applying not only the relevant legal standards but also ethical criteria in the decision-making process. McNulty (2007) believes it is necessary to establish corporate governance mechanisms, such as independent audits of corporate activities, and to design an information and reporting system that provides management with timely and accurate information sufficient to make informed decisions about the organization's compliance.

Table 1: Factors affecting the effectiveness of the GRC

Factors affecting the effectiveness of the GRC	Description
Policies and procedures/corporate governance	written policies and procedures to prevent and deter fraud; they should provide guidance to staff on how to deal with potential compliance problems, the process of communicating and reporting compliance issues and the conduct of investigations by regulators; they may take the form of codes of conduct;
Communication and training	regular communication of standards and procedures throughout the organization; regular training and evaluation of their results through e.g. knowledge testing
Ethical organizational culture	placing ethics at the centre of the organization; fraud is not tolerated; whistleblowers will not be punished; risks are systematically reduced by established controls; promotion of an ethical organizational culture
Responding to and preventing future incidents	Update rules to prevent abuse on an ongoing basis; document procedures to prevent, detect and respond effectively to incidents; review incidents and threats and develop corrective action plans; having suitably qualified human resources (e.g. compliance officer, compliance team), technical resources (e.g. GRC software, confidential internal reporting of breaches of compliance in the form of a staff hotline)
Risk management	identifying regulations that affect the organization; reviewing internal policies and procedures; identifying, analyzing and monitoring risks with the approval and support of senior management

Source: Own study based on (McNulty 2007), (Mulugeta 2016)

The analysis of the literature on the subject, in particular B.M. Mulugeta (2016) and McNulty's (2007) studies on the effectiveness of compliance management systems, allowed the author of this study to create a reference list of five groups of factors which, in her opinion, are of key importance for ensuring the effectiveness of GRC. These will be: appropriate corporate policies and procedures/supervision, communication and training, an ethical organizational culture, responding to and preventing incidents in the future (including having the resources to exercise due diligence in preventing and detecting misconduct) and risk management (Table 1). This list was used by the authors as a reference point in the process of collecting and analyzing empirical data.

Own Research Methodology

The research was conducted in January and February 2020. The largest Polish capital groups from the construction industry in terms of revenues were selected for the research. The selection of entities was based on Deloitte's report (2019) "Polish Construction Companies 2019 - the most important players, key growth factors and prospects for the industry". It seems that the top players in terms of capitalization and revenues, and in addition the listed companies, will be particularly well placed to apply the GRC approach effectively. The basis for such an assumption is the observation that they have adequate resources (human, material, financial and informational) to invest in mechanisms for this effectiveness. What is more, the growing number of regulations to which they are subject and the transparency of their activities, resulting from information obligations, provide a strong incentive to respect both legal obligations and the so-called soft low in the form of various self-regulatory solutions.

The research was carried out in two main stages. The first stage consisted of in-depth studies of the literature in order to identify the key factors of GRC effectiveness. In the second stage, the content of the 2018 reports was analyzed. These were management reports on the activities of BUDIMEX and UNIBEP groups, BUDIMEX's integrated report and UNIBEP group's sustainability report.

The rationale for undertaking the research was to see a research gap. Most studies currently available focus on one of the three functions of the GRC, without showing systemic interdependencies between them. Moreover, the analysis of the literature on the subject has revealed a deficit of industry analyses concerning the GRC, in particular those devoted to the construction industry. Existing analyses usually concern the financial and IT sector, while construction is of great importance for the development of the economy. In Poland, the direct and indirect impact of the activity of the building materials sector accounts for 3.5% of GDP, and in the case of construction services it is even 16.8%. Almost every fifth working Pole finds employment thanks to the construction sector. The total impact of the construction materials and services sector creates 20.3% of GDP and almost 2.6 million jobs (Deloitte 2016).

Problems of The Construction Industry in Poland

Construction in Poland is very fragmented. The engineering construction industry is dominated by large companies, while the majority of construction works on the specialist construction market (plumbing, electrical works, etc.) are performed by companies with less than 9 employees. According to EMIS Company Database (2018), the sales of the 10 largest companies in this sector in 2016 accounted for just under 17% of the sector's sales. In the non-residential construction sector, several large entities such as BUDIMEX, Strabag, Skanska, PORR, ERBUD and UNIBEP (Deloitte 2019) dominate. WIG Budownictwo, one of the Warsaw Stock Exchange's largest construction companies indexes, has been in a downward trend for over a year. Decreases do not only apply to those companies which have a diversified business profile or are suppliers of construction materials. There are many reasons for this. One of them is the mismatch between the tender system and the changing market situation. Large construction companies, which are faced with a tender for a construction that will last several years, usually bear the risk of an increase in the cost of labour and construction materials and, as a result, a reduction in the final margin realized on the contract.

Undoubtedly, the indexation system, i.e. the dependence of payments on changing market conditions, could be a security for their interests; however, in the Polish conditions, it is not very widespread. Another problem is the lack of qualified employees. Problems with obtaining employees translate into an increased risk of delays in the execution of construction contracts. The Polish Association of Construction Industry Employers drew attention to such problems that afflict the construction industry in Poland as the growing reluctance of financial institutions to provide construction guarantees, lack of postponement - record-breaking since 2012. - The Polish Association of Construction Industry Employers pointed to such problems as the growing reluctance of financial institutions to provide construction guarantees, the lack of translation of the record-breaking revenues into increased profitability of enterprises and problems with financial liquidity or payment bottlenecks (Rozkrut, Kowalczyk, Boguszewski 2020).

The construction market in Poland is regulated in quite a detailed way. In the opinion of the companies that operate on it, the legal regulations that apply to it are often ambiguous, which leads to their different interpretation. The amendments to the Construction Law and to the Act on Planning and Spatial Development, which were announced for a long time and were supposed to speed up and facilitate the execution of construction investments, have not been implemented. At the same time, new regulations have appeared recently, which made it difficult for some construction companies to operate. These include, among others, payments in the split payment system (the so-called split payment mechanism - MPP), Employee Capital Programmes, which generate additional costs or an increase in the minimum wage in 2020.

The Results of Surveys

Budimex Group

The identification of factors affecting the effectiveness of GRC in the BUDIMEX Group was carried out on the basis of the Report of Activities for 2018 (*Sprawozdanie zarządu z działalności 2018 Budimex*) and the Integrated Report for 2018 (*Budimex zmieniaj świat. Zintegrowany Raport Roczny 2018 Budimex*) in GRI Standards version, verified by an independent auditor.

Policies and Procedures / Corporate Governance

The key areas for the group are: life and health protection, ethical behavior, environmental protection and energy performance improvement, high quality of works and services, responsible information and prudent decision making, integration of management systems. The BUDIMEX Group and its member companies operate on the basis of the Integrated Management System, consisting of the following standards and certificates: PN-ISO 26000: 2012 - Social and environmental responsibility management system in the company; ISO 9001:2015 - quality management system; ISO 14001:2015 - environmental management system; PN-N-18001:2004 and OHSAS 18000:2007 - occupational health and safety management system; ISO/IEC 27007:2013 - information security management system; AQAP 2011: 2009 - Quality management system; SO 50001 - Energy management system; ISO 10001 - Management system for codes of conduct related to customer satisfaction; ISO 20000-1 - IT services quality management system; NCAGE2 - NATO Commercial and Government Entity - awarded to entities whose activities are related to the range of defense products or services.

The following policies have been implemented in the BUDIMEX Group: risk management policy, anti-corruption policy and anti-monopoly policy, which are binding in all companies. The strategic approach to corporate social responsibility is defined in the responsibility policy and CSR strategy.

Communication and Training

All information about the Code of Ethics and Compliance Policy is available on the BUDIMEX Group's BUDIMEX intranet. Each new employee of the Group is familiarized with the Code of Ethics as part of the introduction, and since 2016, ethics has been an element of cyclical trainings for employees.

The Group applies the principle of conducting dialogue in a decentralized manner, which means that direct relations with stakeholders prevail. The frequency of contact depends on the nature of a given group and its needs. Communication channels with stakeholders are adjusted to a given target group. These include supplier surveys, meetings and conferences, social media, chat bot, social projects, participation in external initiatives, e.g. Agreement for Safety in Construction. The Communication Department and Press Spokesman and the Strategic Analysis Office are responsible for dialogue with the external environment. All employees will familiarize themselves with the applicable anti-corruption procedures during regular trainings.

Ethical Organizational Culture

BUDIMEX's mission is to carry out construction investments - including real estate development projects - in a manner worthy of the market leader, with respect for the natural environment and principles of ethics, care for customer satisfaction and user comfort, which the company wants to achieve thanks to professionalism and passion for building, high efficiency of operation, as well as partnership relations with suppliers and subcontractors. The key values of the group include: ethics, cooperation, responsibility and ambition. BUDIMEX operates under conditions of extended responsibility. When concluding a cooperation agreement, each contractor of the BUDIMEX Group is obliged to comply with: occupational health and safety requirements, environmental protection requirements and the "Code of Conduct for Contractors". During the cooperation, constant monitoring of subcontractors is carried out, and finally a summary evaluation takes place.

The BUDIMEX Group is bound by the Code of Ethics and the compliance policy is implemented. The main principles of this policy are: respect for the law, ethics and honesty in the conduct of business, transparency of the activities of the companies in the Group, zero tolerance for activities that do not comply with the applicable law or the Compliance System. As part of its efforts to promote diversity, in November 2016 the BUDIMEX Group signed the Diversity Charter. For many years, BUDIMEX has been a signatory to the "Agreement for Safety in the Construction Industry", whose mission is to reduce the number of accidents on construction sites by promoting a safety culture, raising awareness of the dangers associated with work on the site and preventing risks and accidents.

Responding to And Preventing Future Incidents

All employees of the BUDIMEX Group have access to information and tools enabling them to report violations of the Code of Ethics or Compliance Policy. The report can be made in person or anonymously, in writing, by e-mail. Everyone is assured of the lack of professional consequences related to the fact of reporting. Employees also have an emergency phone at their disposal. Upon detection of irregularities, they immediately take corrective action. The implementation of the IMS Policy, as well as other policies, procedures and processes, are subject to regular external audits from the economic, social and environmental point of view, so that their effectiveness can be continuously monitored. Annual internal audits are also carried out by the so-called internal auditors - employees of the BUDIMEX Group, with appropriate competences and experience. Each time internal audits are additionally confirmed by an external audit.

The Ethics Committee is responsible for compliance with the Code of Ethics and monitoring the compliance of the standards of professional ethics with the Code of Ethics. Each year the Ethics Committee prepares a report on its activities, which is then forwarded to the Management Board and the Audit Committee of the Supervisory Board. The Internal Audit Office is responsible for identifying and analyzing risks in the Group and preventing factors that cause them. The role of the Office is also to take preventive measures and build awareness of BUDIMEX employees about the risk itself and the actions that may lead to it. The correct application of the Compliance Policy is supervised by the Chief Compliance Officer appointed for this purpose by the Management Board of the Company, the Deputy Compliance Coordinator and the Compliance Committee established at the request of the Compliance Coordinator. It consists of representatives of each organizational division of the Company. The CSR Committee is responsible for the implementation of the principles of corporate responsibility, consisting of representatives of the Company's Management Board and representatives of organizational units.

Risk Management

The companies of the BUDIMEX Group providing construction services monitor technical, organizational, legal and financial risks related to the planning and current progress of works on individual contracts. The business model and its implementation are related to business risks which have been defined for each of the six capitals (financial, human, organizational, intellectual, social

and natural capital). In order to eliminate the risk in the management area, the Group's parent company - BUDIMEX Co. - uses a set of corporate governance principles entitled "The Corporate Governance of the Group". "This set of rules defines, among others, the principles of information and communication policy with investors, internal systems and functions, relations with shareholders. As part of risk monitoring in the supply chain, BUDIMEX audits its subcontractors.

The UNIBEP Group

The identification of factors affecting the effectiveness of the GRC in UNIBEP Group was carried out on the basis of the 2018 Activity Report (*Sprawozdanie zarządu z działalności 2018 UNIBEP*) and the 2018 Sustainability Report (*Raport zrównoważonego rozwoju 2018 UNIBEP*). This report was prepared in accordance with GRI guidelines in the core version. It was verified internally by the Company's Management Board and individual organizational units directly involved in its preparation. The report was not subjected to the external verification.

Policies and Procedures/Corporate Governance

Priority areas of interest for UNIBEP Co. are: customer needs, employee competence, work safety, environmental protection, compliance with applicable laws and ethical standards and cooperation with the local environment. The UNIBEP Group manages its environmental aspects, occupational safety, quality of construction works and manufactured construction products using the Integrated Management System including ISO 14001, OHSAS 18001, ISO 9001 and PN-EN 13108-21. Seven procedures of conduct in the area of occupational health and safety have been introduced within the IMS. These procedures are defining roles and responsibilities and the manner of conduct in the area of occupational risk assessment at workstations, accidents and potential accidents, employee prophylaxis, occupational health and safety training, occupational diseases, and assessment of compliance with legal regulations in the area of health and safety. The Group has an environmental declaration stating that UNIBEP Co. not only meets the legal requirements but also takes additional voluntary actions to minimize its impact on the environment. In order to create and maintain a comprehensive and effective risk management system, UNIBEP applies a Risk Management Policy.

Communication and Training

In 2018, nine trainings on environmental issues were conducted. These were both practical training courses, such as environmental simulations, as well as theoretical training related to the implementation of ISO 14001. There is an internal intranet in the group, where all the necessary pieces information about the current activities of the company are posted and a quarterly magazine entitled "The environmental simulations" is published. The quarterly "Uniwieści", in which news related to the current activity of the company, are posted, profiles of employees are presented, reports from company events are described, etc. The periodical is available in paper and digital versions. All members of the management bodies of the UNIBEP Group have been informed and trained on anti-corruption procedures and responsibilities. Each newly hired employee is required to pass the e-learning training and become familiar with the applicable regulations. Procedures, internal regulations and the most important health and safety documents are posted on unibep.net.

Ethical Organizational Culture

UNIBEP has a document called „A Community of Principles and Objectives" document which defines the identity of the group and its three main values (which indicate specific values). These values are knowledge (specific values are professionalism, quality and openness), passion (specific values are commitment, pride, courage and consideration) and trust (specific values are teamwork, responsibility, society). Each newly hired employee signs a commitment to comply with the rules and procedures in force in the UNIBEP Group, including a declaration of respect for human rights. A policy of partnership has been developed in the management of subcontractors. All contracts (100% of construction sites) are monitored on an ongoing basis for proper implementation, including the risk

of corruption. The progress of construction works is monitored on a monthly, bi-weekly or sometimes weekly basis. Training courses are conducted, during which procedures and internal instructions are discussed. So far, the Group has not developed a formalized diversity policy document, nor does it have a code of ethics. UNIBEP is a signatory of the "Agreement for Safety in Construction".

Responding to And Preventing Future Incidents

In the case of sudden environmental incidents, an appropriate procedure is launched, which verifies the environmental aspects of a given activity and immediate remedial and corrective actions are taken in order to avoid future environmental incidents. The buildings are controlled by external bodies, including the Voivodship Inspectorate of Environmental Protection, the Municipal Guard, and the Municipal Offices. During the inspection, the person representing the company is the Site Manager, who is in possession of relevant environmental documentation. In case of any infringements, immediate actions are taken in order to comply with the recommendations of the inspection body. The employees of the Audit and Internal Control Office continuously verify the IMS by performing audits and internal controls according to annual plans. IMS is also periodically reviewed by top management. As part of the Integrated Management System, the group carries out monitoring of non-conformity and corrective actions.

Risk Management

In order to systematize and facilitate the risk management process, areas for which separate risk registers and maps have been created and maintained have been defined. These are: offering, production, bituminous mixtures, house production, IT, finance and accounting, legal team, export, purchasing and logistics, HR, quality and health and safety and warranty service. In UNIBEP cyclical risk reviews are held using the following risk identification techniques: review of existing risk registers for a given area, analysis of the course of internal organizational processes on the basis of previously prepared descriptions and process maps, analysis of information and reports on events that occurred in the past. Current risk identification is performed by all UNIBEP employees regardless of their position in the organizational structure and function. They identify internal and external factors of the nature of threats or opportunities that may significantly affect the possibility of achieving the set goals.

The Conclusions of The Study

The research shows that both capital groups consider safety at work, compliance with law and ethics and environmental protection as their priority. This is evidenced by their integrated management systems, which include standards of effective management of the social and environmental responsibility of the company. Both groups have written policies and procedures aimed at preventing abuse, and maintain an open dialogue with internal and external stakeholders using modern information and communication technologies (social media, intranet, web portals). Senior management exercises appropriate oversight of compliance and attaches great importance to identifying and meeting the needs and expectations of key stakeholders. Both BUDIMEX and UNIBEP define the key risks and then monitor them. They introduce systemic solutions in the field of occupational health and safety and conduct intensive training activities in this area. They also develop an ethical organizational culture by defining clear and explicit ethical principles, setting the framework for fair and responsible behavior of all their members.

What makes them different is the extent of the responsibilities they assume, the approach to the institutionalization of management ethics and the type of audits carried out. Thus, responsibility at BUDIMEX is extended, i.e. it includes not only subsidiaries but also external suppliers and sub-suppliers. This demonstrates the responsible management of the supply chain by BUDIMEX. The responsibility practiced in UNIBEP has the characteristics of direct responsibility, covering mainly subsidiaries. BUDIMEX has a CSR policy and strategy, a code of ethics, a compliance and diversity policy. UNIBEP has not yet developed such documents. Only BUDIMEX has a practice of confirming internal audits with external audits. Conducting an independent external evaluation gives

it the opportunity to verify the compliance of the internal audit function not only with international and national standards and recommendations, but also with best market practices. What distinguishes BUDIMEX is also the establishment of numerous committees (Ethics Committee, Audit Committee, CSR Committee, and Compliance Committee) to develop awareness of the importance of compliance and prevent any abuse.

Summary

The conducted case studies made it possible to describe the practices applied by large Polish construction companies, important from the point of view of GRC effectiveness. These practices were shown in five groups of factors, such as: corporate policies and procedures/supervision, communication and training, ethical organizational culture, responding to and preventing future incidents, risk management. The research shows that although the approaches to the GRC of BUDIMEX and UNIBEP differ in several aspects (BUDIMEX shows greater diligence in fraud prevention), in general the degree of preparedness of both groups to implement the GRC can be considered satisfactory. Their solutions can provide a solid foundation for the effective implementation of an integrated approach to risk analysis and mitigation. What they have in common is a specific culture of responsibility, whereby the achievement of business objectives respects the limits set by law and ethical standards.

The author is aware of the limitations of the empirical research. These include, for example, the static nature of the conducted analyses, which does not allow to identify trends in time appropriate for the groups or industries under investigation. Moreover, due to the fact that the research covered only two largest construction groups, generalization of conclusions for the entire industry, in particular for the SME sector, might be taken as a serious abuse. Moreover, the fact that the parent companies of the analyzed groups are public companies certainly influenced the nature of applied practices in the GRC area. The use of the GRC approach by companies from other industries and sectors could be a further aim and direction of the future research. An interesting area of exploration seems to be the set of similarities and differences in approach to GRC between construction industry players and financial sector companies.

Acknowledgment

Abstract

The aim of the research presented in the article was to develop a new approach to the implementation of the topic "The role and place of controlling in a business unit" in the classes about controlling implemented at economic universities in Poland. During the lecture, as well as computer exercises, students were presented with various aspects related to controlling that are important for the functioning of the enterprise's information system. The presentation uses a simple and short example of the task of allocating costs in a construction and service enterprise. Based on the example, the following issues were presented: cooperation between controlling and accounting services in the field of building cost recording systems, the process of analysing and reporting cost data, the role of controlling in modifications of the organisational structure and cost objects (including cost centres), support by controlling accounting services in cost allocation for cost objects, and improvement of accounting and accounting processes. The example and its solution were implemented into the spreadsheet environment. To assess the adopted approach, there was employed a questionnaire whose task was to determine the degree of mastery of the issues presented, as well as opinions on the form of conducting classes and the presentation of content. Based on the results of the survey, it was possible to confirm the thesis stating that the issue of the place and role of controlling in a business unit can be effectively presented using the example of cost calculation and computer techniques.

Keywords: controlling, the role and place of controlling in business, teaching at economic universities.

Introduction

Controlling is one of the concepts supporting the management of an enterprise. According to Szychta and Dobroszek (2017), "the concept of controlling is ambiguously interpreted, and for a synthetic expression of what controlling is, there are used terms such as 'management system', 'management subsystem', 'management method', 'management tool', 'management model', 'supra-functional management instrument', 'element of the management system', 'management support system', 'control process', 'coordination system'." Due to the scope of the issues of this study, its authors propose to assume that controlling is the same as the concept of management accounting. Its origin dates back to distant times. According to Nesterak, the basics of controlling date back to the 15th century (Nesterak 2002). Due to the dynamically changing environment and current trends in the global economy, controlling tools still constitute significant support for the management. This tendency may be manifested by a considerable interest in programs of studies / specialisations related to supporting the management process.

Teaching controlling at the higher education level takes place for full-time and part-time studies at all levels: bachelor's, master's and post-graduate. Due to the links between controlling and accounting, finance, management and economics, the main area of interest for the authors of this study is the educational process taking place at Polish economic universities. Syllabuses of subjects related to controlling contain various issues implemented in auditoriums and computer laboratories. The analysis of the content, the taught forms and hourly dimensions of these syllabuses became a reason to pose a research question regarding the ways and possibilities of improving the educational process of controlling at Polish economic universities.

A number of students have difficulties in grasping the concepts of controlling. This paper assumes that it is not the subject matter that is dry, but rather the methods in which controlling fundamentals are usually presented. Departing from traditional approaches such as standard lectures and engaging computer-based learning environments can result in a higher level of students' understanding of the subject. Presenting controlling principles with the use of computer simulations can help demonstrate the practicality and necessity of the subject. This should both make controlling attractive and enlightening for students, as well as improve their knowledge on the subject.

Hence, the purpose of the research presented in this article was to develop a new approach to the subject of "the role and place of controlling in an economic unit" in class with students, and to examine the level of mastery of the presented issues, as well as opinions on the form of conducting classes and content presentation using a questionnaire.

The authors of this study drew attention to the issues raised during classes about the role and place of controlling in a business unit. Due to the specifics of this topic as well as its multithreading, a case study was prepared in which there was used an example of the cost calculation of a construction and service enterprise. Based on this example, there were presented issues which showed the role and place of controlling in relation to cost information processing.

Due to the need to implement modern teaching measures, individual study points were developed in a spreadsheet environment. This means that the classes can be conducted as lectures (using a multimedia projector) or in the form of exercises in a computer laboratory.

In the adopted research procedure, there was adopted a thesis which stated that the issue of the place and role of controlling in an economic unit can be effectively presented using the example of cost calculation and computer techniques. Surveys and quantitative methods were used in the study. The study was conducted in 2019 at public economic universities among students from the fields in which controlling classes were conducted.

Changes in Learning Accounting

The twenty-first century can be called a century of continuous change (McGrath and Bates, 2013). Changes are also related to education and teaching methods used (Singer and Wiesner, 2013). Educators can no longer rely only on traditional, passive forms of teaching; they need to do more to keep up with the rapid change in business. One of the solutions is to modernise traditional teaching methods to provide students with a rich and meaningful learning experience and thus keep them engaged (Jaijairam 2012).

Accounting has traditionally been a rather conservative discipline (Leventis, Dimitropoulos and Owusu-Ansah, 2013), which includes the utilisation of standard lectures and exercises. Students are not taught to apply their acquired accounting knowledge to managerial decision-making in business, even though it can be successfully applied in the decision-making process (Hall, 2010; Silviu-Virgil, 2014). This is confirmed in the study by Burnett (2003), who furthermore underlines that accounting education programs must innovate the employed methods (Stejskalova et al. 2019). Alternative teaching techniques and methodologies for accounting include the use of Twitter (Osgerby and Rush,

2015) or IT technology in accounting courses, which include digital games (Carenys and Moya, 2016) and educational computer learning programs (Chan et al., 2016). Štrach and Stejskalová (2015) advocate the concept of real-life case studies in teaching accounting.

While adopting a new teaching method, it is important to note how educators introduce the new approach to students. Duhigg (2013; 2016) emphasizes that the new procedures cannot be simply ordered. The rules should be accepted by participants. Some students who are already familiar with a certain way of teaching may not be inclined towards a change in the teaching process. They may need a different explanation to see the new method as a chance and not a barrier to studying accounting.

Teaching of the Controlling Subject at Polish Universities

The beginnings of teaching controlling at home universities coincide with the implementation of this concept in Polish enterprises during the transformation period in the 1990s. A lot of work was devoted to the educational issues of controlling at Polish universities. The evolution of the teaching of this subject at economic universities is recognised by such works as (Kes 2017), (Kes 2008). The thematic scope of subjects related to controlling implemented at post-graduate studies was presented by Z. Kes at the conference on Didactics in economic sciences, organised by the Agricultural University in Szczecin in 2005. The presented study was entitled "Selected aspects of the organization of post-graduate studies << Management Accounting and Controlling >> at the Wroclaw University of Economics." Regarding the use of computer techniques, Z. Kes and M. Kotłowska determined the level of work skills in a spreadsheet of finance and accounting students as well as computer science in business. Based on the research, the authors concluded that students know the functions and tools that are used during classes, at least at a basic level (Kes and Kotłowska 2013).

The evidence of this convergence are the results of Z. Kes' research on subjects conducted at the Department of Cost Accounting and Management Accounting at the Wroclaw University of Economics. The collected information shows that the subject named "Controlling" appeared in the field of finance and banking at extramural studies of the Faculty of Management and Computer Science in the years 1994/95, with eight hours of lectures and fourteen hours of practical classes. In contrast, 1996 should be considered the peak year when it comes to the presence of controlling topics in the full-time curriculum of the Faculty of Management and Computer Science. A mandatory block was introduced to the program of finance and banking, and it was entitled "Information support for controlling". The subjects implemented under this block included: accounting in the controlling information system, and operational controlling, both consisting of 30 hours of lectures and 30 hours of classes conducted in a computer laboratory.

Currently, many universities in Poland have faculties or specialisations which teach subjects covering operational, strategic or functional controlling. As part of collecting materials for this research, there was conducted an internet query to determine the thematic scope of subjects related to controlling, forms of classes, and hourly dimensions. Due to the relationship between controlling and the economic, management and accounting areas, the analysis covered Polish public economic universities. The query was carried out in 2019. Due to the possibility of conducting classes at three-year studies, the researched period is 2017-2019.

As part of the preliminary research, it was found that the name of the vast majority of items related to the subject of the query contains additional terms. For example, there were found items such as: operational controlling, strategic controlling, production controlling, incentive and bonus systems in controlling, IT tools in controlling, controlling and finance of enterprises, controlling logistics, controlling marketing, sales controlling, personnel controlling, value controlling, project controlling and investment, eco-controlling etc. Due to the fact that the issue of the place and role of controlling in an economic unit should be included in the basics of the analysed area of knowledge, only subjects which were called "controlling", "operational controlling" or "operative controlling" were further evaluated. Assuming that Master's studies are an extension of undergraduate studies, it was

additionally assumed that, in order to analyse the content of syllabuses, only subjects realised at the first degree of study were taken into account.

The analysis of the content of individual syllabuses shows that the first classes are devoted to, among others, the origin, essence and role of controlling in an economic unit. This means that the origins, definitions, tasks and functions of the concept need to be presented to students. In order to present what controlling does, it is possible to use examples of implementations or case studies of controlling systems. Since students who took part in controlling classes had previously completed accounting and cost accounting courses, tasks which have already been processed can be used for this purpose. Such a scenario was prepared as part of the search for directions for improving didactics in controlling classes. Detailed information on the prepared example is provided in the next section of this study.

Description of The Case Study "Role and Place of Controlling in A Business Unit"

The purpose of the study was to show the role and place of controlling in a business unit as part of one of the first classes on controlling. These classes are directed to full-time and part-time undergraduate students who have had previous classes in accounting and cost accounting. The presented case is adapted to both lectures (90 min) and classes in a computer laboratory (120 min). The canvas for this example was an item from a set of tasks (Kowalak 2013) regarding cost grouping in a construction and service enterprise.

The company described in the task carries out the activity of laying fibre optic lines using its own resources. The following cells were separated in the organisational structure:

1) construction department,
2) equipment and transport base,
3) fibre optic lines department,
4) supply department,
5) production preparation and costing department,
6) analysis department,
7) human resources and organisation department,
8) the company's management board.

The task is to allocate functional and subjective costs determined by 11 distributors. The operations included in the content relate to the costs of material consumption, energy, external services, salaries, employee benefits, and other costs by type. As mentioned earlier, the task, which is known to students and whose solution should be considered short and simple, allows to focus the attention of listeners on the important elements of controlling functioning in the field of cost information processing. Table 1 lists individual issues developed in the case study.

Table 1: The role and place of controlling in the processing of cost information

No.	Role and place of controlling	Implementation in lectures and practical classes
1	Acquiring data from the financial and accounting system (AS)	Import of data from txt and xlsx files using the text import wizard and Power Query.
2	Cooperation in the construction of generic cost records	Presentation and discussion of the contents of the table with the numbers and names of generic cost accounts appearing in the task.
3	Analyses by type costs	Based on the data from item 1, a pivot table is generated showing the percentage structure of costs by type.

No.	Role and place of controlling	Implementation in lectures and practical classes
4	Cooperation in creating organisational structure	Presentation and discussion of the contents of the table with the numbers and names of organisational units appearing in the task.
5	Cost allocation by organisational unit	In the table with transactional data (from item 1) a column with a selection list containing the names of organisational cells (from item 4) is inserted. Subsequently, individual cost items are assigned to the appropriate entities.
6	Cost analysis by subject	Based on the data from point 5, a pivot table is generated, showing the percentage structure of costs in the subject system.
7	Participation in creating cost centre structure	Presentation and discussion of the contents of the table with the numbers and names of cost centres related to the objects present in the task.
8	Improving recording processes	In the table with transaction data (from item 1), a column with cost centre numbers and the appropriate formula is added, allowing for automatic reading of the cost centre number based on the content of business operations.
9	Cost analysis in cross-section of cost centres	Based on the data from point 8, a pivot table is generated, showing the costs according to cost centres.
10	Participation in the creation and modification of billing procedures	Based on the content of the task, a list of costs to be settled is created along with the definition of the order of settlements and distribution keys.
11	Construction and modification of the information base constituting the basis for calculation and settlement procedures	There is prepared a presentation of tables containing the data needed for the settlement of common costs, e.g. for the purposes of settling the costs of the transport base, a table containing a record of the working time of individual vehicles.
12	Carrying out settlement procedures not covered by the AS system	Based on the table with transaction data regarding the costs of the transport base (point 1) and the recording of the working time of individual vehicles (point 9), the cost mark-ups for individual carriers are calculated.
13	Participation in the costing process	Based on all collected and processed data, direct and indirect costs related to the calculation objects presented in the task are presented.
14	Cost analysis in a spreadsheet system	Based on the data from point 13 a pivot table is generated, showing direct and indirect costs according to the carried out orders.

Source: own

The aspects of controlling operation in an enterprise presented in Table 3 can constitute both the content of the lecture and the exercises in the computer laboratory. Thanks to this, it is possible to present an important part of controlling during classes, focused on cost data. Showing how controlling is involved in the processing of cost data, by using a simple and short numerical example, allows to easily understand its role and place in a business unit.

The use of a spreadsheet in the presentation and exercises provides the opportunity to visualise accounting issues, as well as to remind students of the algorithms used in the cost calculation process. Additionally, it is possible to draw attention to the fact that the amount and diversity of data processed by controlling requires efficient use of IT tools.

The Analysis of Answers Regarding the Improvement of The Educational Process

While attempting to use new content in controlling classes, the authors of the article decided to conduct a survey on student opinions on the implementation of the topic "place and role of controlling in a business unit" in accordance with the assumptions presented in the previous section.

The classes were addressed to the 3rd year students of the first degree full-time and part-time studies in finance and accounting, as well as post-graduate studies in accounting. At the first meeting about controlling, there was prepared the topic entitled "The role and place of controlling in a business unit". The topic was introduced both during the lecture (part-time and post-graduate studies) and during practical classes (full-time studies).

Due to the need for continuous improvement of the teaching process, students were asked to complete a short anonymous survey whose purpose was to collect opinions and suggestions about the classes. The survey was prepared in Google Forms and included four questions plus a question about the study mode. Table 2 presents the sample size and answers, including the form and mode of classes.

Table 2: Sample size and response structure

Type of studies	Number of students enrolled	Number of completed surveys	Return rate
[1]	[2]	[3]	[4]=[3]/[2]
part-time studies	181	68	38%
full-time studies	85	72	85%
Post-graduate studies	36	26	72%
Total	302	166	55%

Source: own

As presented in Table 2, the majority of students participating in controlling classes attended part-time studies. The return of surveys was also the lowest in this group. The average score for the return ratio was 55%. The structure of the survey questionnaire is presented in Table 3.

Table 3: The structure of the questionnaire

No.	Question	Type of answer
1)	How do you assess your knowledge about the topic "place and role of controlling in a business unit" after the class?	5-point Likert scale: 1 – no understanding of the topic 5 – extensive understanding of the topic
2)	After completing the class, can you take a stand regarding the place and role of controlling in a business unit?	5-point Likert scale: 1 - I can't say anything about this topic 5 - I can explain exactly what this topic is about
3)	Assess individual issues raised in class from the point of view of the level of your understanding of their content:	
a.	role of controlling in cooperation with the accounting department	5 percentage ranges presenting different degrees of understanding the topic of the class: 0% - 20% 20% - 40% 40% - 60%
b.	the role of controlling in building data access	
c.	the role of controlling in the construction of data processing systems	

No.	Question	Type of answer
d.	the role of controlling in conducting settlement and calculation procedures	60% - 80% 80% - 100%
e.	the role of controlling in providing data to managers	
4)	How do you assess the usefulness of MS Excel during classes on "Place and role of controlling in a business unit" in relation to other forms of teaching, e.g. MS PowerPoint presentations or lectures using a blackboard?	5-point Likert scale: 1 - Very bad 5 - Very good
5)	Provide comments and suggestions regarding your expectations related to these classes.	Open question
6)	Choose your form of studies.	Single choice question full-time studies part-time studies post-graduate studies

Source: own.

Based on the collected responses, it was established how the students assessed their level of knowledge after classes conducted in accordance with the presented case study. The first question concerned the assessment of knowledge regarding the topic – "Place and role of controlling in a business unit" after the classes. Figure 1 presents the distribution of answers to this question together and by type of study.

Figure 1: Distribution of answers to the question "How do you assess your knowledge about the subject of 'place and role of controlling in a business unit' after the classes have been completed, in total and for each type of studies

Source: own.

The graphs presented in Figure 1 show that the average level of knowledge about the role and place of controlling in a business unit after classes was indicated by 41% of respondents, with a good and very good level being indicated by 38%. Only six students marked the answer indicating a lack of understanding of the topic. Regarding the distribution of answers depending on the type of study, it should be noted that part-time students indicated a good understanding of the topic (40%) at higher levels than the respondents from full-time (24%) and post-graduate (35%) studies.

In order to determine the impact of the type of study on the assessment of the degree of knowledge, statistics χ^2, its theoretical value for the significance level of 0.05, p-critical value and Cramér's V contingency coefficient were determined. The results are presented in Table 4.

Table 4: Assessment of the relationship between the type of studies and the assessment of the level of knowledge

Parameter	Value
χ^2 coefficient	6.73
χ^2 theoretical	15.51
Critical level of significance	0.57
Cramér's V	0.14

Source: own

The results presented in Table 6 indicate no relationship between the type of studies and the assessment of the level of knowledge. Thanks to this, it can be concluded that the presentation of the role and place of controlling in a business unit, by means of the case study described in point 3 of this study, is similarly assimilated by students of all types of studies.

The second question in the survey concerned the respondents' answers regarding the possibility of expressing a position on the place and role of controlling in a business unit after classes. Figure 2 presents the distribution of answers to this question in total and for each type of studies.

Figure 2: Distribution of answers to the question of whether the student can take a stand regarding the place and role of controlling in a business unit after classes, in total and for each type of studies

Source: own.

The data presented in Figure 2 show that 46% of respondents can take a position on the place and role of controlling in a business unit at a good level (4), with the average level being marked by 34% of students. In contrast, the answer "I cannot say anything about it" was marked by four students, of which three attended full-time studies. Regarding the distribution of answers depending on the type of study, there is no differentiation among full-time and post-graduate students. A good level was selected by 43% of all respondents, while 53% of those answers belonged to part-time students.

In order to determine the impact of the type of study on the assessment of the possibility of taking a position on the topic discussed in class, $\chi 2$ statistics, its theoretical value for the significance level of 0.05, p-critical value, and Cramér's V contingency coefficient were determined. The results are shown in Table 5.

Table 5: Assessment of the relationship between the type of studies and the assessment of the possibility of taking a stand regarding the topics covered in class

Parameter	Value
χ^2 coefficient	14.52
χ^2 theoretical	15.51
Critical level of significance	0.07
Cramér's V	0.21

Source: own.

The results presented in Table 5 indicate no relationship between the type of studies and the assessment of the possibility of taking a stand regarding the topics covered by the case study. Following the assessment in the previous question, it can be concluded that the presentation of the role and place of controlling in an economic unit, using the case study described in point 3 of this study, is similarly remembered by students of all types of studies.

Since the role and place of controlling can be considered in various aspects, students were asked to indicate the degree of understanding of the role of controlling:

- in cooperation with the accounting department,
- in the construction of the access to data,
- in the construction of data processing systems,
- in the scope of conducting settlement and calculation procedures,
- in the field of providing data to managers.

Answers in individual aspects have a similar distribution (Figure 3).

Figure 3: Distribution of students' understanding of individual issues

Source: own.

From the point of view of the form of conducting classes and directions for their improvement, an important issue is the assessment by students of the usefulness of MS Excel during classes in relation to other forms of teaching, e.g. MS PowerPoint presentations or lectures using a blackboard. Figure 4 presents the distribution of answers to this question in total and for each type of study.

Figure 4: Distribution of student assessments regarding the usefulness of MS Excel during classes in relation to other forms of teaching in total and for each type of studies

Source: own.

The data presented in Figure 4 show that over 70% of students consider the usefulness of Excel in controlling classes to be good and very good. Distributions of answers to the question about the usefulness of a spreadsheet show diversity. For part-time studies, 57% of respondents gave good and very good reviews; 49% was the result for post-graduate studies, and 93% for full-time studies. These results are confirmed by the analysis of the impact of the type of study on the opinion on the usefulness of Excel (see Table 6).

Table 6: Assessment of the relationship between the type of studies and the opinion on the usefulness of MS Excel during classes in relation to other forms of teaching

Parameter	Value
χ^2 coefficient	53.76
χ^2 theoretical	15.51
Critical level of significance	0.00
Cramér's V	0.40

Source: own.

Data presented in Table 6 indicate a significant relationship between the type of studies and student opinions regarding the usefulness of MS Excel during the classes described in this study. Cramér's V coefficient of 0.4 means a strong correlation between variables. The lowest average grade was given by post-graduate students and the highest by full-time students.

Among the comments and suggestions made by students, there were repeated voices suggesting that it would be beneficial to do the presentation of Excel-based solutions at a slower pace. This means that more time should be allocated to this kind of class. One opinion of the students was particularly noted by the authors of the survey. It is reflected in the following quote: "An Excel file is a very good alternative to a presentation – this form has conveyed the theory in a much more attractive way than a presentation which is read. In this way, it is possible to remember many more elements than from the presentation. In addition, it emphasizes that controlling is not only knowledge in the field of finance (which was my previous conviction), but also the skill, cleverness of data organisation, and the need to cooperate with the IT department".

Conclusion

The aim of the research presented in this article was to develop a new approach to the implementation of the topic "The role and place of controlling in a business unit" in the classes on controlling implemented in higher education. To assess the adopted approach, there was employed a questionnaire whose task was to determine the degree of mastery of the presented issues, as well as opinions on the form of conducting classes and content presentation.

The new approach to the implementation of the course was to show students various aspects of controlling relevant to the functioning of the enterprise's information system processing cost data. For this purpose, there was used a short and simple example of the task of allocating costs in a construction and service company. Using the example, it was possible to present the following issues related to the role and place of controlling:

- cooperation with accounting services in the construction of cost recording systems
- creating and sharing cost analyses,
- participation in modifications of the organisational structure, cost objects (including marginal capital product),
- support for accounting services in the allocation of costs to cost facilities and improvement of accounting processes.

The above-mentioned process of data processing and organisation for management needs is an important role of controlling. However, as the place of controlling in an economic unit, it indicates the location between transactional systems (e.g. financial and accounting system, production, warehouse, personnel system, etc.) and managers at various levels.

The presented example was implemented into a spreadsheet, where it was possible to illustrate the individual stages of the data processing process. The prepared file in MS Excel format also created the possibility of performing the calculation process by students in computer rooms.

Based on the results of surveys conducted among students of various degrees and teaching modes who participated in the classes using the discussed approach, the thesis was confirmed that the issue of the place and role of controlling in an enterprise can be effectively presented using the example of cost calculation and computer techniques.

The presented method helps students understand how controlling interacts with the daily world of business. Students will learn that its principles can be applied to each company, both formally and informally. Preparing a family budget or a corporate one are both examples of controlling put into practice. Computer techniques can help grow this understanding by relating material to common situations.

The Relationship between BATNA and the Choice of Strategy in Trade Negotiations

Joanna KRZYWDA

Czestochowa University of Technology (CUT), Poland
joanna.krzywda@pcz.pl

Abstract

The BATNA, i.e. the Best Alternative to a Negotiated Agreement, is - besides issues such as hierarchy, mental strength and resources - an element that can determine power in negotiations and thus determine their course and outcome. "Plan B", as BATNA can be otherwise called, can actually be given a decisive role, which means that correcting it can provide a significant advantage and can often lead to a better outcome. Due to its importance and the links with the various components of the negotiations, the BATNA is a frequent subject of research in the literature on the subject. This paper attempts to identify the relationship between three different types of the BATNA (strong, weak, non-existent) and the negotiating strategies chosen by negotiators during trade negotiations. The conclusions were drawn from an experiment conducted under university conditions with the participation of those students who, due to their experience and knowledge and in line with the consensus reached among researchers on this issue, were granted the status of experts for the purposes of the study. The concept of the experiment was taken from the literature on negotiation. The study confirmed some of the initial research hypotheses on the impact of BATNA on the choice of one of the two known negotiation strategies, namely the strategies of cooperation and competition. It was found that there is a link between the strategy chosen by the negotiator and - not so much the BATNA itself as - the difference in the assessment of the BATNA by the two negotiating parties.

Keywords: trade negotiations, BATNA, negotiation strategies

Introduction

The concept of BATNA is one of the central concepts in theoretical research on negotiation and is well known to practitioners. It was first used by Fisher and Ury in 1981 in their fundamental work on negotiations, i.e. *Getting to Yes: Negotiating Without Giving In*. They defined it as a best alternative to a negotiated agreement, which is the answer to the question of how I would achieve my interests if the negotiated agreement did not meet expectations. (Fisher and Ury, 1981). Since then, research on BATNA has been one of the main themes of research on negotiation. This paper attempts to identify the relationship between three different types of the BATNA (strong, weak, non-existent) and the negotiating strategies chosen by negotiators during trade negotiations. An experiment method was used, the concept of which was taken from the literature on negotiation.

BATNA is extremely important in trade negotiations because it is closely linked to the powers of the parties. In such negotiations, the power of the parties is measured primarily by their economic potential (Rządca 2003). However, it can be increased by developing good alternatives. BATNA is also a tool for evaluating a potential agreement. If a BATNA is very good, there may be no need for negotiations, because an agreement may not give anything better than the available alternative. For the authors of this concept, BATNA is a benchmark against which every negotiation result is compared.

The knowledge about BATNA is crucial for the negotiation processes conducted by companies. On a global scale, economic practice shows an increase in the scope and dynamics of cooperation and competition. Economic negotiations are becoming increasingly important and their scope is

expanding, and the risk in terms of assumptions, conditions, tools and negotiation results is increasing, which consequently places very high demands on managers. (Kozina, 2012, p. 10). Since negotiations have become an important tool in company management (Biesaga-Słomczewska, 2009), they should be considered in a broader context, as an element of a longer relationship, and not as a one-off event. Managers may be interested in increasing their negotiating power in order to increase their effectiveness in reaching negotiated agreements. This is particularly the case where power is unevenly distributed on both sides, which may be due, for example, to the different sizes of companies negotiating with each other. Knowledge of the mechanisms that govern BATNAs can help to balance the powers and avoid reaching agreements that are rather unfavourable to either party.

Literature Review

The beginnings of research on BATNA and its relationship with the behaviour of negotiators date back to the 1990s. In particular, they confirmed that it affects the power and position in the negotiations and that these values are directly proportional and that the stronger the BATNA, the more extreme the negotiator's expectations of an acceptable outcome will be. If the negotiator has a weak BATNA, he or she will be reluctant to give up negotiations. Having a weak BATNA or none at all results in less negotiating power and more dependence on the outcome of the negotiations, and thus in a greater willingness to accept a less favourable outcome. (Pinkley et al., 1994)

Research into the link between BATNA and a negotiating strategy adopted by negotiators has a certain tradition already, although consensus has not been reached on all issues. The research has focused mainly on recommendations on the strategy to be followed by buyers and suppliers. (Patton et. al. 2010) Negotiating strategy means "interaction patterns used by parties in conflict to achieve resolution". (Ganesan, 1993, p. 184). The theory of negotiation assumes that there are two fundamental negotiating strategies, i.e. strategies of cooperation and competition (Krause et al., 2006; Zachariassen 2008), also known as a cooperative and competitive attitudes (Necki, 2005) The strategy of cooperation in negotiations is meant to achieve a result that is mutually beneficial, while the negotiator pursuing a competitive strategy seeks to maximise his or her profits and secure a winning result. It is generally believed that a cooperative, i.e. collaborative strategy is more effective in building longer and more sustainable supplier-buyer relationships in supply chains, although there is no empirical evidence to support this thesis, yet (Thomas et al. 2015). The choice of negotiation strategy depends on the importance of the negotiation issue, the existing relationship between the parties but also, to a large extent, on the availability of other solutions, i.e. one's BATNA. (Habib et. al., 2015)

However, there are still conflicting views on how BATNAs affect the outcome of negotiations. McAlister et al. have proved that negotiators who have equal power in negotiations more often reach integrative agreements (i.e. agreements that maximize the joint profit of the two parties by taking advantage of trade-offs between differently prioritized issues) than those secured under conditions of unequal power among disputants. (McAlister et. al., 1986). An opposite conclusion was reached by Rolof and Daliley, who have shown that pairs of negotiators with unequal power reach agreements based on a greater mutual benefit than pairs with equal power. (Roloff, and Dailey, 1987). In view of the fact that the results quoted are the result of studies that have become rather distant in time and the fact that there are no studies on the impact of BATNAs on the choice of negotiating strategy, a certain research gap can be said to be present here.

Research Hypotheses and Methodology

The aim of the study was to draw a conclusion on the relationship between BATNA and one of the two strategies chosen by negotiators - cooperation or competition. The hypothesis was formulated that a too good BATNA causes a competitive attitude in negotiators, while a weak BATNA makes them cooperate. In other words, there is a relationship between BATNA and strategy.

The essence of the study was an experiment with the participation of students based on previously prepared scenarios, in which the participants were supposed to predict the behaviour of negotiators.

Both the concept of the experiment and the participation of students in the experiment were taken from the literature on the subject, in which this method is very often used and accepted as a method of research on negotiations. It is very well suited to isolating cause and effect relationships and provides a great deal of control over variables, and is also particularly useful in the case of negotiations which, due to their specific nature, are difficult to study in "natural" conditions and for which it is difficult to obtain information, due to managers being frequently reluctant to share such knowledge. (Thomas et al., 2006). Moreover, in research on negotiation, students with some experience in negotiations and who have done a negotiation course are regarded as comparable to professionals and many questions in the field of negotiation research can be effectively tested by using trained students as experimental subjects. (Herbst, Schwarz, 2011). Due to a large size of the experiment, for the purposes of this study, it was decided to present here only part of the results that prove one of the hypotheses formulated a priori on the basis of the literature on the subject. According to this hypothesis, a strong BATNA results in the choice of a competitive strategy in trade negotiations.

With reference to the literature on the subject, scenarios of situations with dyads i.e. with the participation of two negotiators were prepared. In each situation, each negotiator was free to use one of the three types of BATNAs, which - in line with the assumptions made by Ury and Fisher - determined the strength of the negotiator. Thus, for each of the two negotiators it was possible to have a "strong BATNA", a "weak BATNA" or to remain "without a BATNA", which consequently generated 9 different situations.

Table 1: The situations in the experiments in terms of the strength of the negotiators' BATNAs

		Negotiator no. 1		
		STRONG BATNA	WEAK BATNA	NO BATNA
Negotiator no. 2	STRONG BATNA	situation 1	situation 2	situation 3
	WEAK BATNA	situation 4	situation 5	situation 6
	NO BATNA	situation 7	situation 8	situation 9

Source: author's own compilation

The scenarios were descriptions of situations invented by the author of this study in relation to authentic situations occurring in economic life known to her from practice in enterprises known to her, so they contained a large element of realism and were presented for review to two persons experienced in negotiations. In each scenario, the situation of the two parties, i.e. the negotiators who were preparing for trade negotiations, is described. Based on the description of the situation (e.g. a restaurateur looking for a supplier of products for their restaurant vs. a thriving local cold meat supplier, a retail company preparing to talk to its supplier about an inevitable price increase, a representative of a large retail chain looking for a supplier of organic vegetables among local producers, etc.), the participants in the experiment were expected to determine the powers of both parties on a scale of 1-5 and then determine which of the two strategies - cooperation or competition - would be chosen by the first negotiator justifying their answer.

The survey involved 56 students of a university in southern Poland in the last year of their Master's studies in logistics in both full-time and extramural studies. The average age of participants was 26.5. Of all the participants, 11 declared that they had no experience of any kind in negotiations. Out of the remaining 45 students, 15 declared a job-related negotiation experience of almost 2.5 years on

average and the remaining 30 students had some occasional experience, i.e. negotiating a sale or purchase for private purposes. All the participants in the experiment had completed a course in negotiation, included in the curriculum of their studies as an obligatory subject called Commercial Negotiations. As part of the experiment, the participants received a description of 9 situations with the questions about the power of the negotiators and predictions about the strategy to be chosen by negotiator no. 1. On average, it took the students about 45 minutes to provide answers to all the questions.

For the analysis and verification of the hypothesis made, answers were chosen for situations 1, 4 and 7, i.e. those in which, according to the assumption of the experiment, negotiator no. 1 had a strong BATNA, while the second negotiator had - respectively - a strong BATNA (situation 1), a weak BATNA (situation 4) and no BATNA (situation 7), leaving the remaining situations to further consideration due to the limited size of the present study. In this way, 168 responses from the participants (56 participants x 3 situations) were obtained for the analysis. The responses to the three situations were then grouped in a matrix in which the starting point was the negotiating strategy chosen by the participant and an assessment of the powers of the two negotiators, which could be either prevailing in negotiator no. 1, equal in both negotiators or prevailing in negotiator no. 2.

Table 2: Matrix of the arguments in the choice of the negotiating strategy and assessment of power of both negotiating parties

	prevailing power of negotiator no. 1	**With the balance of powers**	**prevailing power of negotiator no. 2**
Collaborative strategy chosen	- argument 1 - argument 2 - argument 3 - …	- argument 1 - argument 2 - argument 3 - …	- argument 1 - argument 2 - argument 3 - …
Competitive strategy chosen	- argument 1 - argument 2 - argument 3 - …	- argument 1 - argument 2 - argument 3 - …	- argument 1 - argument 2 - argument 3 - …

Source: author's own compilation

In each of the six groups of the responses given, on the basis of the explanations and rationale provided by the participants, a list of arguments used to justify the choice of strategy was made on the basis of a semantic analysis. Further analysis was of a qualitative nature.

Results and Discussion

The participants in the majority of cases interpreted all three situations similar to the intention of the author of the experiment, i.e. with the exception of 9 participants, they all stated that in the situations described, negotiator no. 1 has a strong negotiating position. On a scale of 1-5 they rated it on average at 4.05; 4.6; and 4.23, respectively, while the power of negotiator no. 2 was rated at 3.4, 2.56 and 3.17, respectively. When asked to specify the type of the strategy chosen by negotiator no. 1, most of the participants (66%) indicated a cooperative strategy in situation no. 1, in the case of situation no. 4 - a competitive strategy predominated (87.5%) and in the case of situation no. 7 it was also a competitive strategy that prevailed (59%). For a better clarity, the results are shown in Table 3.

Table 3: Average powers of negotiators nos. 1 and 2 on a scale of 1-5 in the opinion of the participants of the experiment and indications of the participants as to the expected negotiation strategy

		Negotiator no.1 STRONG BATNA
Negotiatior no. 2	STRONG BATNA	Situation no.1 1. Negotiator: 4.05 2. Negotiator: 3.4 Difference: 0.96 anticipated strategy: **cooperation 66%,** competition: 34%
	WEAK BATNA	Situation no. 4 1. Negotiator: 4.6 2. Negotiator: 2.56 Difference: 2.04 anticipated strategy : **competition 87.5%,** cooperation 12.5%
	NO BATNA	Situation no. 7 1. Negotiator: 4.23 2. Negotiator: 3.17 Difference: 1.39 anticipated strategy : **competition 59%,** cooperation 41%

Source: author's own compilation

For a deeper analysis of the relationship between the anticipated strategy and the negotiating power of both sides, a difference in the perception of the negotiators' powers seems to be important. It turns out that the greater the difference, the more frequently a competitive strategy was indicated as the one chosen by the negotiator with a stronger position. This means that when a negotiator is convinced that he or she has the upper hand over the negotiating partner, he or she is more likely to adopt a competitive strategy.

This conclusion is confirmed by the analysis of the arguments that the participants in the experiment gave as the explanation and rationale for the choice made by negotiator no. 1 (the one with a strong negotiating position) of a cooperative strategy or competitive strategy, respectively. The willingness to choose a cooperative strategy when negotiator no. 1 has the upper hand or his or her power is equal to that of negotiator no. 2 was justified by the students in a number of ways. The graph shows, respectively, the arguments and the number of times a given argument appeared in the participants' answers (some people provided more than one argument).

Fig. 1: Arguments supporting the choice of a cooperation strategy with a subjectively perceived stronger or equal negotiating position of negotiator no. 1.
Source: author's own compilation

The most frequent motive given for choosing a cooperative strategy proved to be the expected joint success of both negotiating parties, which can be regarded as the same as the provided motives including awareness of the common interest and expected benefits for both parties. This means that the choice of a cooperative strategy is based on "noble" motives, a "we" perspective and a problem solving approach in which both sides identify themselves with each other and are inclined to see the negotiating partner as a partner in an attempt to solve a given problem. Slightly less emphasis was given to the argument of a general willingness to find a consensus and expected future benefits in the form of reduced prices and discounts - the latter may be expected as a "reward" for engaging in a cooperative strategy when holding a stronger position. These were followed by arguments and motives such as caring for the future prosperity of one's own interest or having BATNAs. The latter motive may seem a little surprising, because - as will be shown below - a strong BATNA leads rather to choosing the strategy of competition. Further revision of the list of reasons why negotiators should choose a cooperative strategy makes it possible, above all, to draw conclusions as to their number and diversity. It can be noted that there are arguments resulting from both business practice, such as uncertainty of other solutions, willingness to avoid risk, or care for having a better opinion and image of the company, which can be achieved by using a cooperative strategy, as well as "social" arguments, such as the desire to get to know the other party, respect for the opposing side or mutual dependence.

Meanwhile, the explanations for choosing a competitive strategy form a short list, in which the possession of a strong BATNA, also called by the participants the possession of an alternative, appears as the main motive, and the resulting opportunity to set conditions in negotiations - this argument appeared as a justification 61 times, which means that it appeared in 36.3% of all justifications (168 situations examined). This does not mean, of course, that in other cases the participants did not see negotiator no. 1's good BATNA. This may mean that they did not give a decisive importance to the BATNA in the negotiations. In 4 cases, the participants actually pointed to a good BATNA as a basis for choosing a cooperative strategy.

Fig. 2: Arguments justifying the choice of the competitive strategy with a subjectively perceived stronger or equal negotiating position of negotiator no. 1.
Source: author's own compilation

However, a vast majority of participants, anticipating the negotiators to follow the strategy of competition, believed that this choice will be dictated by having good alternatives and the very possibility of making tough demands - or else - the negotiators will play hard, because they simply can afford to do so. Any failure of the negotiations and failure to reach an agreement will not be a great loss for them, as they will then have to choose one of several good alternatives. The motive driven by the desire to be granted low prices and maximize profit, which did not appear too many times, but still frequently enough to be regarded as relatively numerous (14 times), was given as an argument that was supposed to encourage negotiators to adopt a competitive strategy. This is interesting because a related argument of expectation of future benefits in the form of reduced prices and discounts appeared as a motive for choosing a cooperative strategy. It should be noted, however, that in the case of the competitive strategy, the profit motive refers to one-off negotiations and means focusing on achieving profit in a given negotiation process, while in the case of the cooperative strategy, profit appears as a reward that can be expected only in the future. A short list of motives for adopting a competitive strategy is completed successively by various types of advantage, e.g. that related to knowledge, experience, size, as well as being independent of the negotiating partner and the outcome of negotiations, which in a sense may also be associated with having alternatives, i.e. BATNAs.

Conclusions

A short list of reasons with a significant dominance of the strong BATNA as an argument justifying the choice of a competitive strategy and a long and varied list of arguments supporting the choice of a collaborative strategy allow to draw several conclusions concerning the mutual dependence of the negotiation strategy on the type of motives that drive the negotiators. The choice of collaboration strategy is dictated by an attitude which, according to the literature on the subject, can be called cooperative. This involves seeing the negotiation process as part of a longer relationship, not as a discrete event, and then the negotiating partner is seen as an ally in achieving a common goal. This finding is known in the literature on the subject.

The conclusions concerning a competitive strategy allow for positive verification of the research hypothesis presented in the introduction. This means that a list of well understood alternatives to a possible unfavourable agreement (BATNA) leads to the choice of a competitive strategy. In other words, not only may the negotiator's awareness of various good alternatives result in a lack of motivation to enter into negotiations, as has already been shown in earlier studies, but also in the choice of a competitive strategy based on a lack of willingness to make concessions, on high demands and closed positions and a lack of flexibility. Negotiations may then take the form of a competition or lead to a win-lose outcome. A good, i.e. strong BATNA gives the power and willingness to make use of it through a competitive attitude. This power does not have to be objectively large at all - the strategy chosen depends on the perception of one's position in relation to the other, as well as the perception of the difference between one's position and that of the opponent: the greater the subjectively perceived advantage of the negotiator, the more confrontational his or her approach might be.

Knowledge of this relationship has some useful implications for the management of relationships, particularly in the area of business negotiations. For if numerous and good alternatives to the possible outcome of negotiations (i.e. a strong BATNA) cause the adoption of a competitive strategy, the question should be asked about the scope of knowledge that the negotiator should have on this subject. On the one hand, preparation for negotiations requires good preparation of alternatives to the negotiated agreement, which is common knowledge and practice among negotiators. On the other hand, good alternatives compromise the capacity for cooperation. For this very reason, negotiating companies should consider whether negotiators should actually be fully aware of all possible alternatives and thus of the power that the negotiating company has at its disposal. If the negotiator has an extensive and in-depth knowledge of the BATNA, one could also consider raising his or her awareness of acceptable strategies and preparing himself or herself more carefully for negotiations also in terms of techniques facilitating cooperation so that he or she could represent a cooperative approach. It is also possible not to equip the negotiator with the awareness of a strong negotiating

power, which should make him or her more cooperative and encourage him or her to adopt a strategy of collaboration in negotiations. Nevertheless, knowledge of how the BATNA influences the behaviour of negotiators requires greater understanding and preparation on the part of the company, extending beyond their negotiators and including senior managers. This should be particularly emphasised in situations where the company intends to treat negotiations as a tool to create long-term business relationships.

Abstract

The matter of the article is the issue of management of history in public space through activities directed for support of reenactment in Poland in the mission of preserving its historical and educational values. Historical reconstruction is an element of *public histor*y which has enormous educational power due to huge contribution of humans' passion as well as an attractive and engaging form of disseminating knowledge. Adequate management guarantees the experience of emotions that are bought by modern consumer and also transfers knowledge in such a way which creates engaged recipient, not only a passive observer. Education is one of the lifebloods of initiatives undertaken by these organizations, and its lack completely precludes reconstruction from the area of popularizing knowledge. The professionalization of groups is a guarantee of reliable knowledge transfer. It would allow to go beyond the boundaries of amateur hobby and start professional activities. It will make you to learn the history according to your own original scenario.

Keywords: Management, Public History, Education, Reenactment

Introduction

Interest in the concept of Public History in Polish research has been becoming more and more noticeable for several years. The most important ones should be highlighted research works: J. Wojdon (2015) and (2018); T. Szlendak, J. Nowiński, K. Olechnicki, A. Karwacki, W.J. Burszta (2012); W. J. Burszta (2016); R. Traba (2014); K. Deskur (2009); M. Řeznik, M. Saryusz Wolska, S. Stach, K. Stoll (Kraków 2017). Thus, it reflects the development of this phenomenon abroad, where there is an increase in initiatives to promote historical themes: F. Sayer (2015); D. Dean (Hoboken 2018); T. Cauvin (2016) The story becomes present in social media, where it is disseminated to a wide range of interested parties in various interesting ways via websites such as YouTube. As an example of programs that are associated with the dissemination of history it should be mentioned, especially popular among young audiences channel ”History without censorship”, ”History in 5 minutes”, as well as professional programs referring to the discipline such as, for example, ”Good Idea. Radosław Gajda & Natalia Szcześniak”. In many cases, these channels are very professional and successfully serve as additional educational material. In this case, especially young people are the main and demanding reception that postulates for an interesting, multimedia and interactive form of communication. At the same time, history becomes present in many TV programs and channels. Increasingly, the lot of many TV series and movies is set in the past. Internet own productions in some gaining popularity stations and rentals such as HBO, Netflix Inc., Showtime, Amazon Prime Video etc. again and again fund their viewers educational entertainment in the form of historical documents or production, or whose script is based on actual events, biographies of famous people whose actions take place in the former historical space. An example could be "Chernobyl" popular among Polish audiences, the Golden Globe winner in the best limited series or television movie category, and Emmy Awards for the best limited series. On the largest and most visited Polish film site Filmweb (https://www.filmweb.pl/) it was rated by consumers at 9.0. on a scale of 1.0-10.0. History's activity in the media and in the virtual world also applies to computer games (there are

many titles here: Assasin's Creed (serie Europa Universalis since 2001), *Civilization* (serie since 1991), *Total War* (serie since 2000), *Europa Universalis* (serie since 2001), in which the created world, often, even if it does not reflect historical facts directly, is built on solid foundations, which provide historical knowledge, and what's more, it makes sense. One of the best Polish products of recent years can be used as an example: the game *The Witcher 3 The Wild Hunt*, the label of the CD Project Home capital group. Its success was so huge that in 2019 CD Project was one of the highest-rated Polish companies on the Warsaw Stock Exchange. The game is a creation of a fantastic world, however, following the article by P. Jankowski (2018) on historical foundations in relation to the fiction of the virtual universe, the fact that its foundations create representations of real world societies from the past is clearly visible. The gam eis based on the cultural specificity of the European Middle Ages, as well as progressive pre-industrial eras. They draw inspiration from both Slavic and Norse mythology as well as real political events. In the public space, the nature of places related to collecting and distributing knowledge about the past among recipients is also changing. Until recently, ossified and not very public friendly places are turning into real centers of culture and education. Museums, archives and libraries are experiencing renaissance today. A world that our parents' generation still admired only through the glass, or which they often did not have access to, becomes available not only digitally, but also at your fingertips. Museums and libraries have become specialized places of not only historical education for contemporary recipients (an example would be: Museum of the History of Polish Jews POLIN in Warsaw, Wroclaw City Museum, Silesian Museum in Katowice, History Center Zajezdnia).

The origins of *public history* can be traced in the 70s in the USA. According to the contemporary opinions the history "for the public, by the public, with the public, of the public" was completely different from the stubbornly stuck one in stiff scientific debates academic history – J. Wojdon (Warszawa 2018). In addition, it quickly turned out that university studies are not fully sufficient in the process of transferring knowledge in the form of popular science, available to the society whose needs were completely different than meticulous scientific analysis. For the first time the question arose: how skillfully manage history in public space so as to convey knowledge that was previously focused on a small group of specialists in a competent, attractive and accessible way. Public history (german historiography is inclined towards the term "applied history", but recently there are also publications that use the name public history in some publications the term is even treated as a synonym) undertakes the problem of examining historical consciousness primarily in order to address society's demand for historical education and, in accordance with this analysis, compose the means and content of the message in a flexible and methodical way that will allow effective reach to the recipient. The task of history in public space is to shape and educate society. In this case, one can also successfully refer to R. Traba's (2014) opinion on applied history and use its elements to define the intention of public history. In his opinion, the fundamental task of applied history is to shape historical imagination and acquire workshop competences consisting in the critical analysis of various and extensive source material. Thanks to this, using new research methods and technologies, people operating in the field of history, acquire new competences and are able to respond appropriately to the changing needs of recipients. That ability to respond flexibly, to transform in the way society expects, has given the opportunity to enter history into the sphere of management and marketing activities. Previous history graduates have become not only scientists, but managers managing original projects. The scale and type of these projects vary enormously. However, their main goal is to contribute, through developing historical marketing, to education as well as to the protection and saving of endangered cultural heritage. However, not only historians are responsible for the public presence of the past in our surroundings. History reaches us through the aforementioned most popular forms, which are entertainment games, movies, TV series. In addition, games, outdoor events, reconstructions. It is present in applications dedicated to urban tourism, and more and more often also related to exhibitions or historical objects often on an impressive scale. Actually, you don't need much to see it in every element of space. It is accompanied by reflection on the purpose and role of history in social life. Not only historians, but also publicists, politicians, people involved in promoting culture, but also citizens – enthusiasts take the floor in this matter. This group will interest us above all.

As a A. Mikos v. Rohrscheidt (2008) wrote one of the common and unconventional forms of leisure travel is living history tourism which is a variation of historical tourism and is included in the forms of universal cultural tourism. The phenomenon of reenactment has good literature abroad, e.g.: V. Agnew, *(*2007); L. McCalman, P.A. Pickering (2010); C. Schroeder (2013). In Poland, it is also increasingly described in publications that are happy to deal with related problems, including e.g.: A. Mikos v. Rohrscheidt (2011); M. Bogacki (2008), (2010) and (2018); K. Majtas (2012); K. Baraniecka-Olszewska (2015); L. Gardeła (2016); P. Wojnarowicz, J. Małysiak (2018); P.T. Kwiatkowski (Warszawa 2008); As M. Widzicka (2015) and K. Rojek (2009) wrote the origins of the historical reconstruction movement in Poland, one should look in the actions of Zygmunt Kwiatkowski, the president of the local branch of the Polish Tourist and Sightseeing Society (Polskiego Towarzystwo Turystyczno-Krajoznawcze), who from 1977 organized knight tournaments at the castle in Golub-Dobrzyń. The breakthrough moment was certainly the organization of the first staging of the Battle of Grunwald in 1998, which resulted in the increased interest of Poles in this type of events. As with stack history and public history, a terminological problem also arises in the case of the concept of historical reconstruction. Researchers such as M. Bogacki (2010), referring to the translation of the English term historical reenactment, opted to use the concept of ”historical reproduction” and not ”historical reconstruction”, because the latter should be reserved for those groups that actually tend to most faithfully reconstructing the past, a fragment of it. Therefore, in this case, the essence of knowledge and relevant education for the quality of these productions cannot be avoided. However, not every researcher approaches this problem so rigorously. Examples include A. Mikos v. Rohrscheidt and K. Rojek, who often use these terms interchangeably. Observations made among survey respondents who work in historical reconstruction groups (which is often important for many years) show that activists themselves do not pay too much attention to this. In their opinion, those who have been dealing with reconstruction for a long time, devoting it to participation in shows, activities for their group, spent a lot of money on the best possible reproduction of the character being reproduced, and also intensively explored literature and historical sources in order to best know the area what they are like are professionals. Perhaps a compromise should be sought here. However, it is undeniable that the group’s expertise can often be seen at first glance. The most reliable in terms of the workshop are much more often considered as a partner for cooperation with cultural institutions, they receive an offer to engage in films etc. It should be emphasized that historical reconstruction or reproduction is not a cheap occupation. Professionalisation often takes years. People are always the most important foundation. Only a properly managed team is able to engage in increasingly ambitious forms of activity and jointly achieve these long-term goals. Most historical reconstruction groups focus on doing hobbies, but in each of them there will be people whose activity takes on the character of paid work. As M. Pstrocka-Rak and M. Nowacińska (2013) rightly observed, the exact Polish scale of historical reenactment in Poland is unknown. Researchers A. Mikos v. Rohrscheidt and T. Jędrysiak (2011) estimate that it concerns 600 reconstruction groups covering about 12.5 thousand people. However, it is difficult to refer to these data as definitive and certain. Also in the often quoted by the authors of the publication ”The Great List of Robert Bagrit” (www.bagrit.pl) there is information that from 2001 about 600 groups of historical reconstruction have registered. However, it does not take into account both the activity of these groups and the profile of their activities. The opinions of reconstructors tend to double this sum, because not every organization operates on the basis of professional marketing, promotes itself in the media, participates in historical reconstruction events or even wants to go beyond the sphere of hobby. As noted A. Mikos v. Rohrscheidt (2011) reconstruction groups usually function as registered associations or informal groups whose regulations are based on internal arrangements. The most common source of learning about the reconstruction environment are websites and internet forums. Among the numerous should be mentioned among others (in Polish): ”FREHA. Forum Rekreacji Historycznych”, ”dobroni.pl Portal historii ożywionej”, ”HALLA Forum wikińskie” ”militarni.pl Portal-militarno-historyczny”, ”reenacting.eu”, or appointed via Facebook ”Rekonstrukcja Historyczna”, ”Odtwórstwo historyczne”, ”Odtwórstwo historyczne – Historical reenactment”.

Events with historical reconstruction groups have undoubtedly gained popularity over the past few years. Events involving ”live history shows” in their program have become an attractive spectacle for recipients, both intellectually and emotionally. The number of various events, shows or festivals referring to history is growing dynamically, and both the private sector and cultural institutions have

noticed the huge potential of this form of marketing. The scale and impact of these events on public space are beginning to be further analyzed. A recent article about one of the most popular events from the 14th to 15th centuries in Poland and one of the most recognizable medieval festivals in Europe – the ”Siege of Malbork” (http://oblezenie.zamek.malbork.pl) perfectly showed how through efficient management of museum events one can lead lively education and effective promotion aiming at building a long-term loyalty relationship – J. Hochleitner, I. Rekuć (2017). It turns out that it is education that is emphasized each time as the primary goal of all, even the most commercial shows. The problem of historical education in the field of historical reconstruction was raised, among others in the book: K. Olechnicki, T. Szlendak, A. Karwacki (2016). In research co-financed by the Ministry of Culture and National Heritage regarding activities for the promotion of national culture, carried out in 2016 and published in a specially prepared report (Warszawa 2016), the phenomenon of historical reconstructions and their impact on public space as well as their function in the process of propagating patriotism were just looked at. One of the study segments was to raise the issue of education. The first respondents surveyed were a group of viewers participating in these events. The study involved 400 people during events from July 10, 2016 to August 27, 2017 in events in 15 cities in Poland. Respondents were asked to provide goals, which in their opinion are the main reason for organizing historical reconstructions (In this and other questions more than one answer could be chosen, therefore the answers do not add up to 100%). Practically ¾ of the respondents (73.1%) indicated education. Over half (52.8%) said that the purpose of the reconstruction is to popularize history. However (30.6%) of the respondents indicated entertainment. Only (4.7%) of the respondents indicated the function of motivating organizing these undertakings. In addition, the respondents were also asked to assess the phenomenon of reenactment. (79.2%) of respondents considered them to be one of the most interesting forms of history teaching. For (57.5%) historical reconstruction is a combination of science and education, for (30.8%) an element of historical politics, and for (25.4%) an interesting entertainment event. Similarly, similar questions were asked to historical reconstructors / performers. It turned out that in their opinion, the phenomenon of reconstruction primarily serves education and promoting history. The subjects were asked to define the right purpose of historical reconstructions in their opinion. The survey was conducted on a group of 204 people representing various groups of historical reconstruction. As many as (61%) respondents indicated the mission of popularizing history and (60.5%) education. (38.5%) of the respondents were in favor of entertainment. Indeed, from the perspective of the public history mission, education is of the greatest importance here. This truth makes us aware of one basic problem that should be considered key in the effective management of history in public space. Namely, the question of how to support contemporary reenactment in Poland to preserve its historical and educational value? Many authors in their publications on historical reconstructions pointed out that the level of education was very different, often unfortunately dramatically poor. At the time, as the lesson was showing, the show whether the historical festival was quickly turning into an entertainment festival, and thus its educational value was losing importance. It is not surprising, therefore, that M. Bogacki’s opinion on the suggested naming of most projects that instead of ”reconstruction” should be called ”reproduction”.

Certainly, the professionalization of groups promotes a more reliable message and makes the image look professional, arousing greater confidence of the recipient as to the correctness of the transmitted content. Also, cooperation with cultural institutions affects the viewers' conviction as to the right substantive competence. Financial issues and the possibility of support from local authorities and other sources that would enable the development of historical reconstruction groups are also significant here. In Poland, as rightly noted by M. Bogacki, the group of "reconstructors – professionals" is small and consists mainly of people with extensive experience and experience in reproduction. These include groups such as: Legio XXI Rapax (http://www.legioxxirapax.com), Association Kaperska Kompania (http://kompania-kaperska.pl) Smocza Kompania (http://www.smoczakompania.pl) Jomsborg Vikings Hird (http://wioskawikingow.pl) or Opolskie Bractwo Rycerskie (https://opolskiebractworycerskie.pl.tl) whose members participated in the study carried out for the purposes of this article. These groups are involved in the reconstruction of various historical periods from antiquity to Napoleonic times. However, their activity is over 5 years of activity ”in the industry”. In total, 234 respondents from at least 62 historical reconstruction groups took part in the study (providing the name of the group in the survey was not mandatory):

Source: own elaboration

The majority of respondents were men, a total of 74.8% of respondents (175 respondents), women 25.2% (52 respondents). In the aforementioned research report (Warszawa 2016) in part of the quantitative study, the percentage of men constituted 72% of respondents, women 28%, which is a very similar statement to the one presented today. According to the interviewers, this diversity could be due to the fact that the phenomenon of reconstruction is more popular among men, which they believe: "It is conditioned culturally and historically. Part of the reconstruction concerns battles, wars or historical periods in which the role of women was not dominant. Therefore, they less often participate in reconstructions. " This phenomenon is not fully researched, therefore this opinion does not prejudge the fact that it is mainly a male occupation. It is worth noting that in this environment there are several groups consisting of women themselves, such as: Morskie Suki – female crew Orła Jumne, which are not necessarily engaged in the craft of ”typical for a woman” (https://www.facebook.com/femeagle), also many women take active part in battle shows (most often as light infantry, archers etc.).

The largest group among the respondents were people aged 27-35 (50%), respectively between 35-51 years (21.8%) and (20.5%), between 18-26 years of age. People between the ages of 52-60

constituted (6%) of the respondents, and only (1.7%) of the respondents gave the age above 61 years. It follows that historical reconstruction groups are mainly made up of young people up to the age of 35, i.e. in the most creative and leisure-free period that can be spent on hobbies, or attempts to implement original or innovative ventures. The low participation of people over 61 in historical reconstruction can be explained by the fairly short period of presence of this form of activity in Poland, which was not so popular in past generations, as well as its very nature. Camping in the open, increased physical activity, activity in the group's life: trainings, trips (several days, monthly) etc. are not particularly attractive for older people.

The vast majority of respondents have been working in historical reconstruction groups for a long time. Membership in the group over 5 years declared (70.1%) 164 people, (21.4%) 50 people belong to the group from 2-5 years, (6%) 14 people from one year to 2 years, and only (2.6%) 6 people under one year. The group of respondents therefore concentrates mainly people who have been involved in reconstruction for a long time, thanks to which, as you can suppose, they can better define their needs and correctly emphasize the principle of problems that the reconstruction environment must face in Poland.

Regarding the professional situation, as many as (86.1%) or 199 people declared themselves as working persons. Only 22 people (9.5%) as learners. And only (3%) 7 people as unemployed and (1.3%) 3 people as pensioners. This result can be compared with the question about the extent to which belonging to historical reconstruction groups is related to practicing hobby. As many (38.5%) 90 people indicated hobby as the only motivation and exactly the same number of respondents (38.5%) 90 people as one of the main reasons for engaging in this form of spending free time. (13.2%) 31 people indicated that this is not the only interest they engage in so much (6.8%) 16 people definitely do not see their activities as hobby, and only (3%) 7 people see in it a hobby and additional gain value. The combination of these two answers to the questions asked shows that the reconstruction community is primarily people seeking development for their passions. Most of the respondents are professionally employed who are not forced to maintain reconstruction activity. This is very important because the group of these people, constituting 86.1% in this case, will not necessarily motivate funds, and what is more, they will not necessarily engage in education-oriented activities, and even if it results only from their individual desires or beliefs. Interesting is the same question 5 from the survey, in which respondents were asked about how much belonging to historical reconstruction groups is related to the desire to educate society. 15% of respondents said that this is the basic value of what they do. 37.6% were in favor of the fact that education is largely important in their activities, but it is not expansive. 34.2% admitted that they readily educate recipients, but only if they see their interest. 12.4% of respondents said that they do this to a small extent because they do not feel predisposition in this regard. However, only 0.9% admitted that they did. It does not have sufficient historical knowledge. It follows that the reconstructors rather belong to people willing to share knowledge, and what they expect from the recipient is primarily interest. This comparison shows that the reenactors will respond to the needs of the recipients in a positive and willing way, but they will not rather be the initiators of this activity. Rather, it is expected from the participant and the viewer. This is important in composing the event space, its narrative, and script to plan a place for the recipient's emotions, whose enthusiasm and desire to acquire detailed knowledge would motivate the reconstructor to get involved and want to draw the viewer into a more specialized area of knowledge.

Chart 1 : How much my belonging to historical reconstruction groups is related to the desire to educate society?

Source: Own elaboration based on the research results

In the next question, respondents were asked whether they perceive the need for intensified educational activities on the part of historical reconstruction groups that would complement the performances at historical festivals. As many as 52.6% of respondents said that this form of education is very important, while 32.9% – rather yes. 8.1% have no opinion on this subject, 6% said that they are rather not. Only 0.4% of people were of the opinion that they definitely did not see such a need. The high percentage of people who were in favor of intensifying education to which historical reconstruction groups would be the sender shows that, according to the reenactors, it is needed. For recipients, these additional initiatives, enriching larger events such as historical festivals, could become an opportunity to deepen knowledge not only in relation to the main staging (usually a battle scene show), but to learn about the era, social history, cultural history, and above all with microhistory. Shifting the center of gravity to the latter could greatly contribute to developing the concept of modern man about the past. A microhistory bypassing great processes and addressing the problems of everyday life could become a narrative and more accessible narrative than discussing only the main issues, the understanding of which requires knowledge of a series of political or social events (this is not possible to achieve in the time allocated for the presentation).

Chart 2 : Do you see the need to intensify educational activities (exhibitions, lectures, etc.) on the part of historical reconstruction groups that would complement the performances at historical festivals?

Source: Own elaboration based on the research results

The process of professionalizing historical reconstruction groups is long and often very difficult. As a result, many groups only stop for hobby activities. A barrier to development is primarily a problem

with financing activities, as well as a lack of support from cultural institutions or local authorities (this is especially visible in small towns where groups often have a problem finding a cooperator, e.g. a museum located in a historic building, behind through which you can easily start long-term operations). Most of the money that goes to the budget of historical reconstruction groups is obtained independently. Groups usually set up associations for this purpose. On the other hand, many group members decide to run their own business, which allows them to sell services in the form of event services, demonstrations, or sale of craft products, etc. Respondents asked about whether they receive external support for conducting reconstruction activities for the most part, because as many as (59.4%) replied that they did not – they do not receive such support. (26.1%) of the respondents answered yes. However, 14.5% that they do not have such information. Another question was directed to people who answered yes to the question about receiving financial support. Respondents indicated three main sources of such financing. These include the municipalities (49.4%), self-government cultural institutions (48.3%) and independent sponsors (44.9%). Co-financing of actions by foreign capital is only (6.7%). Thus, it turns out that historical reconstruction groups are mainly supported by Polish capital, including institutions and local authorities focused on the development of culture and local promotion. Unfortunately, the problem of lack of co-financing may concern more than 2/3 of historical reconstruction groups.

Chart 3 : Does my group receive external support for reconstruction activities?

Source: Own elaboration based on the research results

Chart 4 : If yes, what are the most common sources of funding?

Source: Own elaboration based on the research results

Another question concerned the exploration of ways of obtaining financing for historical reconstruction groups by themselves. First, the respondents were asked whether the groups of which

they are members obtain external financial support for conducting reconstruction activities? (44.9%) of respondents replied that they obtained money in this way for actions. (43.6%) admitted that they did not. However (11.5%) admitted that they did not have information on this subject. In the second supplementary question, the respondents were asked to indicate the most common sources for such financing. The vast majority, as much as 65.2% indicated the sale of services (organization of paid shows) and goods produced by the group (jewelry, clothes, tools). Subsequently (38.5%) own proprietary project submitted by the group, e.g. as an association, business entity as part of competitions related to the development of culture. (20%) respondents indicated independent sponsors, (11.9%) other sources, only (11.1%) co-financing from European Union funds. Most groups seek sources of financing on their own, focusing primarily on selling services. The commercialization of historical shows may be partly the result of the reconstruction groups' pursuit of development, which in this way can easily offer a "product" that provides them with cash. Unfortunately, the choice of this form carries many dangers related to the quality of the message focused on educational value.

Chart 5: Does my group get external financial support for reconstruction activities?

Source: Own elaboration based on the research results

Chart 6 : If yes, what are the most common sources of such funding?

Source: Own elaboration based on the research results

Lack of financing in the process of professionalizing the group is undeniably one of the main barriers. In the question in which the respondents were asked to indicate the basic problems in the process of forming a group of historical reconstruction and to start action not only in the private – hobby, but

public sphere – the largest number of respondents, as many as 57.7% of those surveyed. Another significant problem, according to respondents, is the lack of places that the commune would make available free of charge for groups to organize trainings, workshops, lectures and meetings (48.3%). The third is the ratio of financing bodies treating reconstruction groups as a product providing entertainment for the masses (38.5%). In addition, the respondents pointed out problems such as: seasonality of reconstruction festivals or the unattractiveness of the place of action, the group preventing the development of activities and making it the main gainful activity (21.8%), other (16.2%) and: inability to receive a good contract due to the lack of experience in organizing shows (6%).

Chart 7 What is the basic problem in the process of forming a group of historical reconstruction and starting its operation not only in the private (hobby) and above all public sphere? (indicate the two most important)

Source: Own elaboration based on the research results

An important question addressed to reenactors was a request to indicate the greatest barrier to cooperation between cultural institutions and historical reconstruction groups. Their role in the process of introducing groups into public education-oriented public spaces is enormous. Actually, thanks to mutual cooperation, it is possible to carry out many projects, which for museums, cultural centers or libraries are an excellent promotion, a strategy to attract customers and tourists, and often a way to attract lucrative financing. The main problem that accompanies this cooperation is the issue of remuneration for demonstrations or museum lessons (33.3%). Cultural institutions are poorly funded, which is why gratification is often only symbolic. The second barrier indicated by the respondents was: lack of agreement on participation in the education process, treating historical reconstruction groups only as curiosities for enriching the program, ignoring the competences, knowledge and education of its members (32.9%). On the other hand, the third problem pointed out by the respondents was the form of the institution, which is non-progressive and is not interested in new forms of disseminating history (28.6%). The perception of historical reconstruction groups as a competition that is prevented from establishing lasting cooperation was indicated only by (5.1%) people.

Chart 8 : What in my opinion is the biggest barrier to cooperation between cultural institutions and historical reconstruction groups?

Source: Own elaboration based on the research results

The last two questions served as an attempt to indicate areas of cooperation that would allow support for historical reconstruction groups in their public education-oriented activities by a) cultural institutions (Figure 9) and b) local authorities (Figure 10). In the case of the former, the reenactors would most likely see their role in cooperation as guides or storytellers providing additional, professional service for exhibitions (they have experience about what they are talking about, they used objects known from exhibitions, etc.). 37.6% of the respondents were in favor of this solution. Another interesting solution would be the possibility for the institution to provide a place that groups could use for their own needs (shows, workshops) (29.5%). Interesting to the respondents was also the offer to create a database shared between institutions in order to use groups for the needs of current festivals, exhibitions, etc. enabling the transfer of historical reconstruction groups within a cultural institution (18.8%). The proposal to create channels in social media in cooperation of historical reconstruction groups and cultural institutions promoting each other only interested (6%) respondents. (8.1%) also indicated ”other” solutions. For the second chart, the most interesting way to support local authorities would be to create a program dedicated to historical reconstruction groups that would provide funding for educational activities (32.5%). As the second most attractive form of support, respondents indicated promoting the participation of historical reconstruction groups in education by organizing and financing meetings with school youth (27.4%). The third - free access to rooms in community centers / communal premises etc., where meetings for historical reconstruction groups could be held with open access for those interested (22.2%). Only (4.3%) of respondents indicated the possibility of co-financing groups dealing with ancient crafts and promoting them in museums by dedicating dedicated exhibitions. However, a small percentage in this case may be related to the fact that only a small percentage of reenactors deal with real craftsmanship. On the other hand (2.1%) the respondents chose the answer ”other”.

Chart 9 : How can cultural institutions contribute today to support historical reconstruction groups in their public education-oriented activities?

Source: Own elaboration based on the research results

Chart 10 : How do you think local authorities could best contribute to supporting historical reconstruction groups in their education-oriented public activities?

Source: Own elaboration based on the research results

The activity of history in public space is not only more and more visible, but most importantly, this phenomenon is subject to in-depth reflection on the further possible perspectives of its acceleration and the necessary evolution. Efficient management of history in public space guarantees the experience of emotions that the modern consumer willingly becomes a buyer, and also transfers knowledge in such a way that a person becomes an engaged recipient, and not just a passive observer. Historical reconstruction (activities around reconstruction is an element of public history, which has definitely a huge educational potential thanks to both the huge contribution of passion of the members of the reconstruction movement, as well as an attractive and engaging form of disseminating knowledge. The only condition that must be met for this education to work properly is support for reconstruction groups in the process of their professionalization, as well as increasing confidence in their competences. Research carried out on members of reconstruction groups showed that education is one of the basic foundations of initiatives undertaken by these organizations, and that the lack of this foundation completely excludes reconstructive activity in the area of science popularization. Cultural institutions and local authorities are of particular importance in the process of professionalizing groups, because it is primarily their initiative and openness that favor cooperation ensuring the possibility of obtaining funding and facilities necessary for further development. The area of cooperation is very extensive, ranging from the most anticipated financial

assistance to the proposal of cooperative activities or free rental of rooms to support independent initiatives.

Leadership in Crisis – A Practical Approach

Katarzyna M. PUSZKO

General Tadeusz Kosciuszko Military University of Land Forces Faculty of Management, Wroclaw, Poland, katarzyna.puszko@awl.edu.pl

Justyna MAŁYSIAK

General Tadeusz Kosciuszko Military University of Land Forces Faculty of Management, Wroclaw, Poland, justyna.malysiak@awl.edu.pl

Abstract

In general, the concept of crisis is attributed to a negative value, most often perceiving threats only, and the opportunities associated with positive change are not recognized. In addition to the difficulties of functioning, the crisis can be a source of significant changes and unexpected benefits. Skalik (1990) mentioned. When an organization is in crisis, there is a need for consistent leadership. Russel E. Pallmer (2010) mentioned. There is not much time to deliberate and endlessly discuss what decisions to make. The leader must take the lead and take personal responsibility for what is happening. It is known that managers are people who properly perform tasks, while leaders perform the right tasks. In the book by Kotter (1990) While managers acquire the ability to perform tasks well, leaders are focused on doing good tasks. The article presents the structural leadership framework in the face of crisis and a model of leadership maturity in the empirical dimension. Due to the cyclical nature of the research process, further research in the area of interest could be heading in the below mentione directions: developing a leadership model using the deductive method (i.e. by deriving from their one or more sentences some of their succession, i.e. a logically derived sentence) in a research study by Nachmias Ch.F., Nachmias D.(2001), building a leadership model using quantitative methods, identify other leadership contexts, shaping leadership flexibility ,measuring changes in leadership.

Keywords: Leadership, Crisis, Company

Introduction

Although interest in practice and developing leadership skills has been going on for thousands of years, leadership is nowadays both the most widely studied and the least understood issue in social sciences. In the book by Kosy, Ksiażek (2014), Książek, V. Motzko, Ch. Motzko, S. Kaiser, D. Schmitz (2014). According to Ph. Kotter, leadership is about coping with change. It has become so important, among others, because companies operate in a turbulent environment, i.e. an environment in which changes are disordered, chaotic, multidirectional and multilevel. Lichtarski (1992) mentioned. This environment is characterized by complexity and variability. Complexityis determined by the amount and variety of elements that make them up, which the company should consider in the course of its activity. In a research study by Puszko-Machowczyk (2007) The variability of the environment occurs as a result of changes occurring within individual components of the environment as well as as a result of relationships (connections) between them. Changes occurring in the modern enterprises environment: are caused by many reasons (they can come from various sources), are rapid, discontinuous, both in structure and directions of activity, have a wide range, are difficult to predict, identify, can affect the whole enterprise or its individual parts, may be an opportunity or a threat to the other enterprises, are of great intensity, depth and multitude. And the more changes, the greater need for leadership. In the book by Galata (2007) The need for leadership is relatively important in a crisis situation. The aim of the article is to identify the possibilities of

implementing the leadership demand and to develop a leadership model in the face of the crisis in the light of economic practice.

Characteristics of the research

Empirical research covered companies representing the construction industry. The aim of the study was to recognize the current state of leadership and leadership maturity in terms of crisis. In the course of research, verification of the following hypotheses was assumed:

1.The larger the size of the company and the broader scope of activity, the greater the propensity to resolve protective problems in leadership in a crisis through adaptation.
2.The smaller the size of the company and the narrower the scope of activity, the greater the tendency to take up anticipative transgressive leadership problems in the face of crisis.

The choice of enterprises was conditioned by the specifics of the construction industry (e.g. product real estate, product and crew mobility, participation of the contracting authority in the production process, employment fluctuation, climatic seasonality of production, aesthetic significance of the product, artistic qualifications of the designer and parts of contractors, longevity and capital intensity of structures, complexity of the production process) and industry characteristics from the market demand side. In a research study by Gorynski (1981), Jerzak (1990), Pabian (2001), Smialowski (2000), Uchma (1998), Puszko-Machowczyk (2007). Empirical research was conducted with the useof the survey method. Surveys were conducted in enterprises located in Lower Silesia in the first half of 2020. The scope of research included: recognition of the essence, current state and mechanism of the leadership phenomenon in the light of the crisis. The time horizon of the research covered the years 2000-2020 (i.e. it was equal to the period of the company's operation on the market). Nominated leaders answered the questions in the survey. 12 leaders were examined to obtain research material. The criterion for selecting a sample was the consent of the respondent. The sample thus formed does not meet the criterion of a statistical sample. It is also not a random sample.In the light of the above presented conditions, the study should be treated as a case study. Detailed information on the methodology of empirical research is presented in Ledzianowski (2012).

Leaders represented enterprises classified according to the following criteria:

1.Enterprise size**:** Ustawa z dnia 2 lipca 2004 o swobodzie działalnosci gospodarczej, (2004) mentioned. From the point of view of size, the research was attended by: 8% of large enterprises (marked as D in the remainder of the article), 17% of medium-sized enterprises (**S**), 33% of small enterprises (M) and 42% of micro enterprises (Mi) (Table 1).

Table 1: Structure of enterprises in terms of their size

Enterprise number	Enterprise size
8	Largeenterprise
4, 10	Middle sizeenterprise
1, 5, 6, 7	Smallenterprise
2, 3, 9, 11, 12	Micro-enterprise

2.Basic type of activity. From the point of view of the basic type of activity, the research was attended by: 100% of enterprises whose basic type of activity is the erection of complete buildings or their parts; civil engineering (P). The structure of enterprises from the basic type of activity point of view is presented in Table 2.

Table 2: Structure of enterprises from the basic type of activity point of view

Enterprise No.	Basic type of activity
1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12	Enterprises whose main activity is the construction of complete buildings or parts of them; civil engineering.

Results of the Empirical Research

Leadership is: the actions or behavior of a leader to change a group (16% including 8% of D, 8% of Ś; 16% of P), interpersonal relationships with others based on willingness, not on forms of pressure Merton (1969) mentioned (8% including 8% of S; 8% of P), the ability to go beyond a specific organizational culture and then initiate the process of evolutionary changes generating an increase in adaptability Shein (1992) mentioned (8% including 8% of M; 8% of P), the process of creating the sense of cooperation necessary to understand the essence of action In the book by Drath and Palus (1994) (32% including 16% of M, 16% of Mi; 32% of P), using non-compulsory influence to shape the goals of the group or organization, motivating behaviors focused on achieving those goals and helping to define the culture of the group or organization (16% including 8% of M, 8% of Mi; 16% of P) and the term of dealing with change Griffin (2002) mentioned (16% including 16% of Mi, 16% of P) (Table 3).

Table 3: Defining leadership

Definition	Leader No
1. Leader's actions or behavior aimed at introducing changes in a given group	8,4
2. Interpersonal relationships with others based on willingness, not pressure	10
3. The ability to go beyond the specific organizational culture and then initiate the process of evolutionary change generating an increase in adaptability	1
4. The process of creating a sense of cooperation necessary to understand the essence of action	2,3,5,6
5. Using non-compulsory influence to shape the goals of a group or organization, motivating behaviors focused on achieving those goals and helping to define the culture of the group or organization	7,9
6. Leadership is dealing with change	11,12

Based on the information presented in Table 3, it can be seen that understanding the concept of leadership in empirical terms correlates with the definition of this term in the literature. Leadership is both a process and a certain property. As a process, leadership relies on the use of influence skills, without resorting to coercive measures, with the intention of shaping the goals of the group or organization, motivating behaviors focused on achieving those goals, and helping to specify internal procedures for implementing the project. On the other hand, leadership defined as properties can be treated as a set of unique and specific features attributed to individuals that are perceived by the environment as the qualities of a leader. Leadership understood this way is relatively important in the face of the crisis.

The concept of crisis in relation to leadership in an organization is difficult to define due to its multidimensionality and various subject references. Zakrzewska-Bielawska (2008), Zawila-Niedzwiecki (2008) mentioned.

This is confirmed by economic practice, which understands the crisis as:

1. The main, unpredictable event that has potentially negative effects, significantly limiting the organization's activities in the field of production, services, employment, financial condition and reputation: (8% including 8% of M; 8% of P),
2. The state of internal imbalance caused by a critical event. He is characterized by very high emotional tension, fear of losing control, a feeling of terror and a sense of helplessness, as well as various forms of behavior disorganization and somatic symptoms. It is a turning point requiring appropriate action to be taken: (8% including 8% of M; 8% of P),
3. Any event or activity that may have a potentially negative impact on the credibility and efficiency of a business and which is typical remains or will soon be beyond the control of that business: (8% including 8% of D; 8% of P);
4. Consequence of the sectors life cyclephases, especially for specialized enterprises, while innovationsare not a guarantee for the disappearance of the crisis and the survival of the enterprise: (8% including 8% of Mi; 8% of P);
5. A situation or condition in which, as a result of accumulation of difficulties, the implementation of the basic functions of the enterprise is at risk, while limiting the organization'sability to eliminate the existing situations or condition: (8% including 8% of Mi; 8% of P);
6. A condition that threatens the survival of the company and the achievement of its goals, limits the time available for remedialaction and surprises decision makers with its appearance, thuscreating conditions of strong pressure: (8% including 8% of Mi; 8% of P);
7. The effect of the appearance of unexpected disruptions in the organization'soperations, including internal and external factors of a randomnature: (8% including 8% of S; 8% of P);
8. A situation in which the organization (s) found them selves face to face with critical problems and in which they experience unrelenting external pressure and deep internal pressure: (8% including 8% of Mi; 8% of P);
9. Result of unplanned events disturbing or threatening the normal functioning of the company: (8% including 8% of Mi; 8% of P);
10. A certainpathology in enterprise development, often caused by the disproportion between the goals and resourcesused to achievethem. It is a specific decision-making situation: (8% including 8% of S; 8% of P);
11. The situation of a greatthreat to the organization as a whole, in which due to the accumulation of various difficulties and intensification of conflictphenomena, the implementation of its basic functions is at risk: (8%, including 8% of M; 8% of P);
12. The consequence of disturbances in the existence or implementation of one orseveral factors determining the existence and development of an enterprise, boththose with external and internalimpact, depending on the efficiency of management: (8% including 8% M; 8% P) (Table 4).

Table 4: Defining the crisis

Definition	Leader No
1. The main, unpredictable event that has potentially negative effects, significantly limiting the organization's activities in the field of production, services, employment, financial condition and reputation	1
2. The state of internal imbalance caused by a critical event. He is characterized by very high emotional tension, fear of losing control, a feeling of terror and a sense of helplessness, as well as various forms of behavior disorganization and somatic symptoms. It is a turning point requiring appropriate action to be taken	5
3. Any event or activity that may have a potentially negative impact on the credibility and efficiency of a business and which is typical remains or will soon be beyond the control of that business	8
4. Consequence of the sectors life cycle phases, especially for specialized enterprises, while innovations are not a guarantee for the disappearance of the crisis and the survival of the enterprise	2

5. A situation or condition in which, as a result of accumulation of difficulties, the implementation of the basic functions of the enterprise is at risk, while limiting the organization's ability to eliminate the existing situations or condition	3
6. A condition that threatens the survival of the company and the achievement of its goals, limits the time available for remedial action and surprises decision makers with its appearance, thus creating conditions of strong pressure	9
7. The effect of the appearance of unexpected disruptions in the organization's operations, including internal and external factors of a random nature	4
8. A situation in which the organization (s) found themselves face to face with critical problems and in which they experience unrelenting external pressure and deep internal pressure: (8% including	11
9. Result of unplanned events disturbing or threatening the normal functioning of the company	12
10. A certain pathology in enterprise development, often caused by the disproportion between the goals and resources used to achieve them. It is a specific decision-making situation	10
11. The situation of a great threat to the organization as a whole, in which due to the accumulation of various difficulties and intensification of conflict phenomena, the implementation of its basic functions is at risk	6
12. The consequence of disturbances in the existence or implementation of one or several factors determining the existence and development of an enterprise, both those with external and internal impact, depending on the efficiency of management	7

The causes of the crisis are exogenous and endogenous. External causes of the crisis mainly come from the micro-environment and concern: adverse changes in commodity prices (100% including 42% of Mi, 33% M, 17% of Ś, 8% of D; 100% of P), adverse changes in the condition of business partners (48% including 16% of Mi, 16% of M, 8% of Ś, 8% of D; 48% of P) and a decrease in demand for the company's products or changes in its structure (48% including 16% of Mi, 24% of M, 8% of Ś; 48% of P). On the other hand, macro-environment is caused by changes in legal regulations (16% including 16% of Mi; 16% of P) and random factors (8% including 8% of Ś; 8% of P).Internal causes are seen as:

•In terms of people: no identification of employees with the enterprise, which limits their activity, entrepreneurship and the strength of the incentive effect of incentives (8% including 8% of Mi; 8% of P), indecisiveness in management and decision making (16% including 8% of Mi, 8% of M; 16% of P), other (i.e. lack of qualified laborforce) (16% including 8% of Mi, 8% of M; 16% of P);
•In relation to the organizational structure: deficiencies in organization management (8% including 8% of S; 8% of P), incorrect organizational solutions (8% including 8% of M; 8% P), mismatch with the strategy (8% including 8% of M; 8% of P) and poor information flow (16% including 8% of M, 8% of Ś; 16% of P).

In turn, the low quality of the material and production base (8% including 8% of Mi; 8% of P) is the cause of the crisis in the domain of technology.

Tables 5 and 6 presents the most important causes of the crisis.

Table 5: External causes of the crisis

External causes	Leader No.
Macro-environment	
• changes in legal regulations,	2,9
• random factors.	10
Microenvironment (competitive environment)	
•adverse changes in the condition of business partners,	2,4,5,6,8,11
• decrease in demand for the company's products or changes in its structure,	1, 3, 4, 6, 7, 12
• adverse changes in commodity prices.	1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11

Table 6: Internal causes of the crisis

Internal factors	Leader No.
1. People	
• lack of identification of employees with the enterprise, which limits their activity, entrepreneurship and the strength of the incentive effect of incentives,	11
• indecision in management and decision making,	5,9
• other (i.e. lack of skilled labor).	1,2
2.Organizationalstructure	
• deficiencies in management organization,	10
• incorrect organizational solutions,	6
•strategy mismatch,	7
• bad information flow.	7,4
3.Technique	
•low quality of the material and production base.	3

Most leaders agree that an organization's crisis is a difficult situation. This concept is characterized by actual or apparent loss of control over its activities, disturbance of the internal balance of the organization, threat to the existence of the organization or its part (function), deterioration of the financial condition of the organization, limiting its development opportunities, threat to the company's strategic goals, ambivalence of development and repair opportunities, possibility violation or loss of public confidence and internal faith in the organization, which deteriorates its image, short decision-making time, high risk, a high degree of uncertainty causing employees' fears and fear, low predictability, disrupted organization's activities. It means a state in which action may face serious obstacles, which undoubtedly causes a special decision-making situation for them (leaders).

Considering the information presented so far, it can be expected that as a result of leadership actions overcoming the symptoms of the crisis, there will be a return that will prolong the functioning of the enterprise or the enterprise will be liquidated.

Figure 1 in a research study by Gopinath (1991) shows how to overcome the crisis in the enterprise.

Fig. 1: Overcoming the crisis in the enterprise

Model of leadership maturity in the face of a crisis

Taking into account the difficulties associated with measuring leadership and the attributes of a crisis and the basic criteria accompanying crisis phenomena such as time and risk, the authors propose a model of leadership maturity in the light of the crisis. Considering the problems that leadership faces in a crisis and taking into account the classification proposed by J. Kozielecki (1991) mentioned, there can be distinguished:

- protective problems, i.e. those which–resolved as part of decision-making processes–take the form of a set of alternatives and their results do not go beyond the normal limits of previous activities (accomplishments). They are so-called routine choices that are every day problems,
- transgressive problems, i.e. those requiring the search for a set of alternatives whose effects go far beyond the limits of previous activities and achievements. These problems are unique, unrepeatable, poorly identified, but encouraging reforms and at the same time causing resistance to change.

Risk should be treated not only as a threat but also as a chance of success. The essence of the risk is taking action, the effects of which may be different. It is a dynamic element because it is related to human activity. However, human activity is caused by something. Therefore, risk must create some opportunities so that human action can be inspired. Risk, in fact, is something positive and causes a person to try to improve their knowledge so that the actions and decisions they make are innovative and effective. The necessity to make a choice requires the acceptance of a risk take or rejection criterion (cost-effectiveness criterion). Such a criterion should take into account all factors affecting the quality of the decision taken. Therefore, the cost-effectiveness criterion should be as uniform as possible for all the decisions. Uniform character should be understood as a technique common to various situations in the area of constructing the criterion from components specific for those situations. The formulation of the risk profit ability criterion will be different in the case of a one-way effect (loss) and different in the case of the possibility of a multidirectional effect (profit, loss). For the first situation, the main criterion for the cost-effectiveness of risk will be the minimization of the consequences of a loss. In the seconds situation, the decisive criterion will be the choice of the option with the largest positive surplus of profit over loss. Next to the profitability of risk, another factor very important for the leader is the belief that the actions taken are right. Fairness means absolute conviction about the optimal choice in given conditions. The concept of equity therefore requires knowledge of the circumstances and possible effects of using alternative solutions. The feeling of equity is, however, a reward in dealing with risk and usually acquires an objectified character only in retrospect. At the same time, equity is important because it gives more faith in the sense of own risk analysis and a positive attitude to the situation related to the lack of absolute certainty. Risk should be useful. The usefulness of risk means its positive role that it plays in achieving positive results from activities associated with it. The postulate of taking advantage of the risk is not enough, however, for the risk to become practically useful. An indispensable condition for the usefulness of risk is the

ability to control and control its elements and the risk as a whole. In a research study by Jedynak, Szydło (1997).

Science does not yet fully understand the nature of time. It is known that it can be considered in the categories of objective, measurable, and subjective in the sense of experiencing specific periods of time as acceleration or delay (depending on individuals and situations experienced) Szewczuk (1979) mentioned. In a free market economy, time is considered from a financial point of view. Improper use of working time as an important instrumental value in companies (i.e. being a necessary condition for the implementation of tasks) is treated as a potential crisis factor. In turn, appreciating time means that it can become not only anally, but even an advantage Lipka (2001) mentioned. The leader may underestimate the basic ownership of time, namely its unidirectionality (”time passes, never stepping back”), may not plan time at all (considering that it kills his creativity), not differentiate between working time, time off work and leisure time, set priorities in correctly (dealing with many, often marginal and not achieving the main goal matters) or fail to keept imearrangements or take into account the necessary reserves (or on the contrary: set them too broadly). Therefore, he does not comply with the principles of: economy of operation, division of labor, intensification of work or complexity of the organization. This takes revenge on the economic (resulting from non-performance of tasks in various fields of activity) and psychological (in the form of so-called time stress, i.e. stress, the source of which is ”he lack of time necessary to perform specific tasks”). Leadership in the light of the crisis should here fore be seen in terms of the degree of anticipation and the pace of implementation.

Developed leadership maturity in the face of crisis is shown in Figure2.

Leadership maturity model		Self-assessment of the maturity level
0: unconsciousness	Not realizing the existence of crisis and risk.	
1: skeptical	Disbelief, doubt on the occurrence of crisis, crisis phenomena; underestimating the crisis and risk.	
2: neutral	Awareness of the crisis and indifference in eliminating the crisis, avoiding risk by choice and necessity.	
3: diagnostic	Recognition of the crisis and emergency response; risk avoidance of choice, acceptance of risk out of necessity.	1,2,3,5,6,12
4: diagnostic	Extinguishing the symptoms of a crisis; dealing with difficulties that may threaten the functioning of the enterprise; defensive actions and reaction to vents that have already occurred; using compensation and repressive methods of risk manipulation (hedging in terms of covering the value of possible losses by creating a specific amount of financial reserves in the event of adverse fortuitous events, such as self-insurance and insurance).	4,7,8,9,10,11
5: proactive	Crisis prediction, actions aimed at avoiding crises; shaping active attitudes in catching phenomena that can lead to a crisis and seeking the best solutions to counteract the crisis; the use of preventive risk manipulation methods (which are intended to prevent and prevent random events), risk catalog, point analysis of threats, point analysis of potential opportunities and benefits.	

6: feedback	Crisis turning point; treating the crisis as an opportunity to take revitalizing activities, enabling the survival and development of the company and achieving economic results even better than before the crisis; risk manipulation through risk transfer to entities other than the insurer (risk transfer, for example, factor), risk sharing and risk community (involvement of a partner who, along with a profit perspective, accepts the possibility of loss or risk reduction through its segmentation), risk compensation (statement of the company's activities in such a way that during a possible lost here would also be a relatively high probability of profit that would cover these losses).	

Fig. 2: Leadership maturity model

The developed model enables the option of choosing a leadership ceiling. On the basis of self-evaluation, it enables placing leadership at an optimal level. It can be a kind of signpost to help you orient yourself on what to do to improve leadership. The proposed model was developed by the inductive method (i.e. by reaching general laws based on experiments and experimentally established facts). In the book by Nachmias and Nachmias (2001).

Self-assessment of the level of leadership maturity shows that the majority of respondents said that they are at level 3, i.e. crisis recognition and immediate response in a crisis situation, avoiding risk of choice, which appears as a brake on the initiative of the leader and accepting the risk of necessity, which it shows his excellence by accepting risk out of necessity.

Half of the respondents rated their maturity at level 4, i.e. extinguishing the symptoms of the crisis; dealing with difficulties that may threaten the functioning of the enterprise; using defense activities and responding to events that have already occurred, using the opportunities offered by compensation and repressive methods of risk manipulation.

It can therefore be concluded that the hypothesis 1 (the larger the size of the company and the broaderscope of activity, the greater the propensity to resolve protective problems in the field of leadership in a crisis through adaptation activities), hypothesis 2 (the smaller the size of the company and the narrowerscope of activity, the greater the tendency to take up anticipative problems of transgressive leadership (facing the crisis) has not been confirmed.

luiza.piersiala@wz.pcz.pl

Abstract

The air transport industry has undergone a lot of changes over the years. These changes were primarily caused by rapidly progressing globalisation. Customer preferences and needs change year to year, hence, the struggle is constant to achieve ever better quality of the provided services. The aviation services market must be considered as a multi-stratum aspect. The objective of the present article is a diagnosis the revenue of airports and the identification of costs that airports must bear to optimise customer services and to fight global competition. The empirical analysis uses statistical data collected by airlines and airports. The data was processed and is presented using tables and diagrams.

Keywords: Aviation Infrastructure, Air Transport, Airport, Costs, Revenue

Introduction

The air transport services market is one of the fastest-growing branches across the entire transport industry of the world. In a time of dynamic globalisation and the so-called „distance reduction" we are seeking ever greater problems related to transport. The air transport services market is evolving very quickly, and thanks to this we are able to deliver cargo to the most distant places on Earth (Kabus, Srtulak-Wójcikiewicz et al. 2016: 156-157).

The operation of airports is very complex. A very high number of factors influences their operation. Two types of airports may be discerned between in the air transport market. The first are commercial airports, which are profit-oriented and operate in the industry successfully. The second are also commercial ones, but operate with government aid, operating around breakeven or not generating profit at all.

Airports around the world operate using certain organisational and management structures. According to data of the ACI (Airport Council International), ca. 14% of all airports in the world are, to some extent, privatised, beginning with corporate management all the way to various kinds of public-private contracts (Glaeser and Gotlieb 2008: 158-159). The steady rise of passenger counts in the world and numerous development trends make the option of privatisation of airports ever more attractive. Year after year, the pressure grows on airport managers to adapt to developments in the air industry and to invest more and more in infrastructure expansion (Precoco 2010: 2428) . This is steadily becoming less and less possible for local budgets and fore the state sector, which continue to represent the vast majority within airport management structures. Currently, over 50% of all European airports are privatised in some form, and this trend is developing (Pels, Njegovan et. al 2009: 341).

Airports, like all enterprises, generate revenue and costs. Naturally, in economy, revenue should be higher than costs, however, this is not always possible [1. Online]. For the most part, revenue generation by airports depends on such factors as: directions of air traffic routes, passenger flow volumes, the volume and type of handled air craft, local legal provisions and world economic trends [10. Online].

The objective of this article is to diagnose the development of revenue at airports and to identify costs that airports must bear in order to optimise customer services and fight global competition.

Research Methodology and Sample Description

Globalisation and digitalisation influence endless possibilities of travel and movement around the world. The continuous development of large air carriers such as small, *low cost* types, make ever more people choose air transport as the means of getting from A to B. Continuously increasing competition influences the innovativeness of the services offered, the establishment of a carrier brand and market services availability. These components determine the level of development (Piersiala, 2018, p. 790). Air transport is referred to as the direct entity that causes globalisation and at the same time, undergoes processes of globalisation. Very quickly-developing air transport and innovative technical solutions that are quickly introduced into daily use determine that aviation participated in the main stream of globalisation from the very beginning. Aviation companies that still want to develop, increase passenger numbers, the quality of provided services and, what is more, improve their turnover, must actively participate in globalisation processes, hence transforming their globalisation strategies.

The issues presented in the paper focus on the characteristics of profits and costs of airports. The authors of the paper attempted to analyse strategies used by airports to improve their revenue, all the while minimising the costs borne.

The paper was prepared on the basis of foreign-language literature studies concerning management, logistical infrastructure as well as air transport, Polish and European documents in this area, analyses of statistical data collected by airports and airlines.

The present paper uses the following research tools and methods:

- analysis of available knowledge on the basis of management and logistics literature;
- analysis of acts of law;
- statistical data of airports;
- statistical data collected by airlines.

Results

On the basis of business models, research and prognoses, airlines develop very quickly. The market includes carriers that aspire to be giants, other airlines must continuously develop to stay on top. In the year 2018, the largest airline by passengers served was the carrier American Airlines. This is an example of a big player in the air industry who, despite their achieved position, must continuously watch out for the competition. The largest low-cost carrier turned out to be Southwest Airlines, only offering flights within the United States. Europe's largest carrier is also a low-cost operator, Ireland's Ryanair [16. Online]

Table 1: Ten largest air carriers in the year 2018.

Rank	Airline	Seat	Passengers served
1	American Airlines	United States	198.700.000
2	Delta Airlines	United States	183.700.000
3	Southwest Airlines	United States	151.800.000
4	United Airlines	United States	143.200.000
5	Ryanair	Ireland	119.800.000
6	China Southern Airlines	China	84.900.000
7	China Eastern Airlines	China	80.900.000
8	easyJet	UK	73.100.000
9	Turkish Airlines	Turkey	62.800.000
10	Lufthansa	Germany	62.400.000

Table no. 1 shows the list of the largest passenger air carriers in the world. The data clearly shows that the United States are the market where the largest number of passengers is transported, with the first four places belonging to airlines from the United States. There is a clear difference in terms of passenger counts between the largest airline, American Airlines, and even Europe's largest carrier or airlines from emerging markets.

The aviation services market could not exist without modern and developed airports. There is an enormous number of airports in the world, managed by state or private bodies. All categories of airports, however, are generally aimed at making profit due to very high competition. Airports must be attractive with their offer, not only for passengers, but also for airlines and other entities supporting the activity of the entire industry. The world's largest airports have for years been struggling to be the largest in terms of passengers served. This is influenced by several factors, e. g. the location of the largest urban centres, demographics and attractiveness of the region for tourists (Grothaus and Helmes 2009: 4-5).

The air transport services market sees so-called commercialisation of activities and services. Airlines, airports and other entities in the industry are mainly aimed at generating profit and growing. The company Airbus expects for the aviation services market to grow over the next 20 years to the value of USD 4.6 trillion. Airbus divides the segmentation of the entire market into three parts:

- aircraft-focused lifecycle services, incl. technical service;
- flight operations services – airlines and their services;
- passenger experience.

Commercial operations of aviation entities are, however, burdened by certain regulations and provisions. An example of broad and extensive legal provisions is the profession of the commercial aircraft pilot. In order to become a commercial pilot, one goes through a range of training seminars, tests and exams. For instance, in the UK, one can discern between four basic licences that are acquired in order to finally reach the status of pilot and to be able to fly commercial routes. These are [10. Online]:

- Commercial Pilot Licence – CPL-A aeroplanes;
- Commercial Pilot Licence – aeroplanes with a CPL-A IR instrument rating – concerning aircraft able to fly according to on-board instrument readouts;
- Airline Transport Pilot Licence – ATPL-A aeroplanes – licence to handle commercial aircraft in airlines;
- Multi Pilot Licence – MPL – licence to work as pilot in a multi-person crew.

Studies on commercial aviation show the trend, in which aviation industry companies are primarily aimed at the improvement of passenger comfort and amenities. Airlines focus on improving the equipment on both their short-range as well as long-range aircraft, training of on-board personnel so that the customer would be as satisfied as possible from the service [16. Online].

In terms of economic operation of airports, one can list two fundamental sources that contribute to the revenue of an airport as an enterprise. These are (Bruecner 2003: 1147):

- Aeronautical activity
- Auxiliary activity

Sources of revenue in aeronautical activity are mainly influenced by operation fees, fees per aircraft parking on the tarmac according to the airport tariff, fees per departing passenger, tariff fees per aircraft landing at the airport, fees for terminal navigation and other airport fees related to operations, meaning, lighting or additional services (Schlenker and Walker 2016: 774-775). Auxiliary activity is made up of revenue sources such as: licence fees, fees for land lease by the airport, rental of office, storage and hanger space, fees for services at the airport, meaning, restaurants, stores, parking lot fees, fees for the display of advertisements and posters at the airport, fees for other types of activity such as hotels or the rental of conference space (Halpern, Graham 2013: 115-116). Every airport has their own rates and fees for diverse services that are provided. This is mainly governed by the location of the airport, by its popularity, competitive capacity and the amount of taxes that the airport has to pay for their operation (Graham 2018: 144).

Fig. 1: Revenue structure using the example of the Kuala Lumpur airport

Fig. no. 1. the revenue structure for aeronautical and auxiliary operations for the Kuala Lumpur airport. The figure shows that main revenue from aeronautical activity are landing, standby and aircraft handling fees, while in terms of auxiliary activity revenue is mainly generated by services, sale and relevant management of the airport space.

Discussion

Every airport in the world, however, has its own details of revenue amounts. The most revenue is, of course, generated by the handled passengers; the amount of this revenue is based on the number of passengers served and the fees per passenger. One of the largest airports in the world, London Heathrow Airport, generates a profit per passenger of ca. USD 13.32 (Graham 2018: 178). To compare, Washington Dulles airport makes USD 5.68 per passenger, with Paris' Charles de Gaulle airport making USD 10.92 for handling a single passenger (Cidell 2015:1136). A large part of revenue for aeronautical activity are, of course, flights. The fees depend on the aircraft size and the time the aircraft will be using the ground services at the airport. At Heathrow Airport, for instance, a small Bombardier Dash-8 craft will pay USD 999 for operations, and a Boeing 747 – USD 11,600 (Vasigh and Fleming 2016: 278-280). Departing aircraft is also burdened by fees, depending on passenger counts.

Fig. 2: Airport revenue structure, %.

Figure no. 2. shows the percentage share of revenue by generation source. The diagram shows that most revenue of an airport is generated by aeronautical activity.

Table 2: Sample table of fees for certain operations at Wrocław Airport

AIRCRAFT LANDING	MAXIMUM AIRCRAFT TAKEOFF MASS (MTOM)	RATE, PLN
Domestic and international traffic	Up to 3 t	80.00
	Over 3 to 10 t	275.00
	Over 10 to 30 t	600.00
	Over 30 to 50 t	975.00
	Over 50 to 100 t	1,560.00
	Over 100 to 150 t	3,000.00
	Over 150 to 200 t	7,000.00
	Over 200 to 250 t	12,000.00
	Over 250 t	20,000.00

PARKING FEE (For each commenced ton of maximum takeoff mass (MTOM)	RATE, PLN
First four hours of parking	0.00
Every commenced 24 hour period	6.00
DEPARTING PASSENGER at passenger terminal	RATE, PLN
Domestic and international traffic	32.00
DEPARTING PASSENGER from General Aviation terminal	RATE, PLN
Domestic and international traffic	150.00
ADDITIONAL FEES	RATE, PLN
Aircraft security by a selected guard for each commenced hour of work of each guard	150.00
Special lighting of parking space for each commenced 24-hour period for one light source	50.00
Fence for parking space	500.00
Security by the airport fire service for fuel filling/ drainage from the plane during passenger boarding/ disembarking or when passengers are on board, per operation	100.00

Table no. 2 shows the rates for basic services, take-offs and parking of an aircraft, as well as additional services provided on the tarmac at the international airport in Wrocław.

The financial structure of airports is not just revenue, but also costs that it must bear for its operation. One can discern between basic costs borne by the airport, and these are: personnel costs, rental of operational space, telecommunications and media costs, repairs and maintenance, administrative costs, material and supply costs, depreciation, security costs, energy and heating costs and other operating costs (Barett and De Vita 2015: 49-50). At an airport, the largest part of the costs are those related to personnel. They are related to the number of passengers that keeps rising year after year. Technological development shall most probably never allow the complete elimination of the human factor from airports, hence, a continuously rising number of passengers shall also cause in creases in personnel counts.

Over the years, airports have become ever better managed, and one sees this in depreciation costs, which, in official statistics, are dropping year on year (Graham 2018: 210). A rising tendency over the years is seen in security costs, which are mainly the result of the New York attacks of September 11, 2001 (Vasigh and Fleming 2016: 267-268). Airports around the world will in the coming years face energy source diversification so as to reduce costs borne in this regard. Energy costs vary for airports depending on size and geographic and administrative location in the world. Energy costs are generally different than fuel costs as most airports in the world use conventional energy sources, meaning, power plants (De Vos, Cumming, Moore et al. 2016: 137). Simulations of use of renewable sources such as hydroelectric plants, wind power plants or biomass combustion energy continue to be attempted, however, these technologies still do not secure the generation of sufficient amounts of power to provide uninterrupted operation of a gigantic airport 24 hours a day, seven days a week (Barett and De Vito 2015: 50-52).

Administrative costs also belong to the category of costs dependent on an airport's location. An airport is burdened by various taxes and fees imposed by local authorities and legal provisions in a given country. In order to attract customers and new passengers, every airport must be appropriately

present in the media. For this purpose, qualified marketing specialists are employed to design advertisements (Halpern and Graham 2013: 113). An airport must in this case bear costs related to the promotion of the enterprise. An airport would not be able to function without suitable maintenance and cleaning personnel for places such as terminals. In the operating structure of an airport, a lot of pressure is put on passenger comfort, and every airport must bear relevant costs in order for terminals and buildings within the airport infrastructure to always be clean and well-maintained [1. Online].

Fig. 3: Example percentage share of costs of an airport

Figure no. 2. presents the example costs at an airport. The diagram shows that clearly over half of the costs, up to 55%, are aviation operations, meaning aircraft landings, costs related to passengers and service costs. 45% are non-aeronautical costs, such as rent or licences related to the operation of the airport.

Airports in the world are primarily aimed at improving profit and reducing costs related to operations, however, this is not always possible for instance due to the world market situation or the fuel price increase trend.

Fig. 4: Financial analysis of London Heathrow airport for the years 2017 and 2018.

Figure no. 4. shows changes in revenue and costs over the span of one year at one of the largest airports in the world, London Heathrow. The above data shows that both revenue and costs increased, however, revenue increased by much more – good news for the company. Revenue in the year 2018 increased by 3% year on year. The costs borne increased by just 0.8%, rather the result of increases in prices of raw materials in the world than of mismanagement.

Operating in such a highly competitive market, airports must maintain very good management of the structure of their expenditures and revenue. Properly balanced and smart investments provide for the largest airports in the world higher profits than expenditures year after year.

Summary

One can note a continued increase in the popularity of aviation in all respects in the air services market for several years now. Ever more people are choosing aircraft as their preferred mode of transport, causing new airlines to emerge and the offers to be ever better adapted to customer needs. It is estimated that until the year 2050, the population of the world could reach nine billion, doubtless a challenge for air carriers. Ever more airports are being constructed around the world. The financial structure of airports is not only revenue, but also costs that the airport must bear for its operation. Airports, operating on such a competitive market, must manage their expenditures and revenue very well. Proper balancing and smart investments enable the world's largest airports to register higher profits than losses.

Green Controlling in Enterprise Management – Perspective of Reporting in Polish Construction Companies

Helena KOŚCIELNIAK

Czestochowa University of Technology, Faculty of Management, Poland

Abstract

Green controlling in modern management conditions is growing in importance; in general terms, it relates to reporting the impact of the company's operations on the environment. The main objective of the theoretical and empirical investigations of this study is to analyze and assess the applied meters and indicators of sustainable development within the framework of controlling and to build the path of their system to support management in this field. In order to achieve the intended objectives, the methodology of measurement of green controlling areas was used and leading meters in green controlling were determined. The value of the research consists in the presentation of the areas of environmental controlling of Polish enterprises and their potential to achieve the success of future results. Moreover, the postulated system of eco-controlling meters represents a new quality in information resources of enterprises for efficient and effective management of their activities.

Keywords: Controlling, Green Controlling, Business Model, Enterprise Management, Performance Measurement.

Introduction

The growing complexity and dynamics of the environment in connection with globalization imply the search for and implementation of tools supporting management processes, appropriate for this environment. One of these tools is controlling, which ought to be adjusted to the business model conducted by the company. The concept of the business model in management science comes from the 1950s and 1960s; the dynamic growth in the interest in this concept in the subject literature was recorded at the beginning of the 21st century. In this study, the genesis of the 1st stage of development of the business model concept is omitted; it is extensively and comprehensively presented in the foreign and Polish literature (Lindner, Cantrell, 2004), (Rappa, 2004), Cyfert, Krzakiewicz, 2011), Floden, Sorkina, 2014),(Fehrer, Wieland, 2020). In this study, the attention is drawn to environmental reporting using the tools of controlling (Nesterac, 2019),(Broadbent et al, 2008).

Modern enterprises increasingly need to possess not only the ability to deal with market mechanisms, direct regulations but also to disclose information concerning environmental and social issues (Rossignoli and Lionzo,2018).. The observation of changes taking place in the environment of enterprises increasingly implies the qualitative development, i.e. the one in which environmental and social loses will be limited (Zalewska-Turzyńska, 2018). In the activities of enterprises, planning, control and information supply systems should be implemented, particularly in order to prevent the components of the natural environment from destruction to eliminate unproductive use of natural resources, furthermore, to be able to reuse waste, to prevent working conditions that are excessively hazardous for health in connection with the reduction in the investment attractiveness of the enterprise and the region in the area of which the company operates (Kochalski, 2016).

According to the International Group Controlling (IGC), controlling is a tool accompanying economic activities; it is an information service for managers directed to planning and monitoring their activities (Nowak, 2011),(Nowak and Nita, 2010), (Serfling, 1993). It is pinpointed that the primary function of controlling is coordination. Furthermore, coordination as a controlling function relates to secondary coordination aimed at, i.e. mutual adjustment of individual management subsystems, i.e. planning, control and supplying information. According to J. Weber, the basic function of controlling is to ensure

rationality in enterprise management (Weber, 2002, cited after: Skoczylas, 2009),(Baum, 1999), (Szulte, 1998),(Ziegenbein, 2001). In general, it should be stated that the task of controlling is to mutually agree upon the system of planning and control as well as supplying information (Giraud, 2011). This coordination is essential, it is impossible to provide, through the information system, the demand for information reported by the planning and control systems of individual enterprises (Schultz, 2015). The subject of the concept of controlling may be generalized and its segments may be indicated, which include:

- uncertainty in decision-making due to the extent and diversity of the company's activities and an increase in own complexity in connection with the dynamics and complexity of the business environment,
- external and internal supervision of the company's activities,
- ability to adapt to the variable environment and to anticipate,
- overcoming external and internal complexity using information processing, planning and control as well as
- maintaining flexibility by ensuring the ability of adaptation and anticipation (Hopfenbeck, 2000, cited after: Skoczylas, 2009), (Nowak, 2018).

The system of planning, control and supplying information in order to preserve environmental and social benefits and the one which is oriented to the accomplishment of broadly understood environmental tasks is green controlling, known as environmental and/or eco-controlling. As it is emphasized in the subject literature, green controlling is the latest type of controlling; its main task is to establish environmental objectives of enterprises, planning and control of the use of resources and any burdens for the environment and society and to provide managers with information on environmental and social aspects (Nesterak, 2015), Balicka, 2015), (Meyer, 2005).

In economic practice, enterprises have a different approach to bearing responsibility for the use of the natural environment; they consider the observance of the rules of environmental protection as a necessity arising from, imposed by state and EU authorities, principles of environmental protection due to the imposed legal regulations or social pressures. However, there are enterprises which take a range of actions aimed at increasing the rational management of natural resources and reducing their environmental impact on the natural environment(Bucholc, 2010), (Langevin, 2013).

The issue of controlling pro-environmental activities will be verified in construction companies operating in Poland. On the basis of the EU research, it should be stated that the impact of construction on the natural environment is substantial. The construction sector directly uses about 1.8 billion tons of primary raw materials; thus using 25% of a total demand for primary raw materials. About 40% of energy is consumed indirectly or directly in the construction sector, mainly when using buildings. As a result of the energy demand of construction, 36% of total carbon dioxide emissions in the European Union is generated. It is also noteworthy that construction generates more than 0.6 billion of waste, i.e. 36% of a total amount of waste. In the light of the above data, conducting the empirical research in the field of eco-controlling in this group of enterprises is fully justified.

Theoretical Background

Controlling Dimension of Environmental Issues in Activities of Enterprises

In economic practice, one may come across different solutions in terms of environmental reporting. Having analyzed the available empirical materials, three basic groups of reporting can be distinguished in this field, such as:

- description of pro-environmental activities; reports contain the description of the environmental policy and the activity of enterprises in terms of emissions, control and energy saving,

- numerical information about the impact on the environment where, in addition to the environmental policy, the market share of environmentally friendly products is given or the size of resources used by the company and their efficiency,
- financial environmental reporting where, in addition to the environmental policy and quantitative information concerning the impact of the company on the environment, financial data in this field are reported in the form of: the value of environmental commitment, environmental protection costs with the indication of, among others: disposal and pollution reduction costs, pollution prevention costs and environmental charges, investment expenditure on ventures in the field of environmental protection (Schaltegger and Muller, 1996), (Desai, 2009), (Paszkiewicz, Szadziewska, 2011), (Michalak, 2016).

Table 1: Historical review of environmental reporting by enterprises

Years	Activities of companies	Extent of reporting
1970s and 1980s	Enterprises present what is available within the framework of their information systems	Presenting primarily qualitative information; information systems of enterprises contained very few disclosures on environmental activities. The first environmental reports
Mid 1990s Late 1990s	Business managers ask stakeholders what they ought to present in reports Business managers begin to use reporting standards	Extending environmental reporting using indicators in environmental performance imaging; enterprises gain greater experience in reporting social activities; environmental reports are much more extensive and contain the analysis of the results. Environmental and social reports
Early 2020s Future	Business managers address their requests to others to verify what has been presented in the reports Managers are convinced of the benefits due to more rigorous comparison and evaluation of the results.	A significant proportion of indicators and reports are of high quality and they may be subjected to the external verification of attestation; however, there is still the need to provide benchmarks for comparing activities with other companies. Environmental and social reports. Sustainability reports. Sustainability reports included in the annual report.

Source: Own study based on A.M. Fet, J.K. Staniskis, V. Arbaciauskas, (2009), Indicators and reporting as a driving tool for environmental activities in the region, 'Environmental Research Engineering and Management', 2009, No.1 (47), p.70, cit. in: A. Paszkiewicz, A. Szadziewska, (2011). Reporting on ecological aspects of operations in energy and chemical enterprises, Scientific Notebooks of the University of Szczecin, No 625, Finance, Financial Markets, Insurance No 32..

The first guidelines providing the global framework for reporting on sustainable development – the so called GRI Guidelines – were published in 2000. Two years later, GRI G2 arose as well as the concept of the partner network and the status of the organizational stakeholder (OS). In 2005 the organization already had 225 partners (OS), also including the Association of Chartered Certified Accountants (ACCA) 11. Since the activities conducted by GRI are the subject of the research and constant improvement, in years 2006–2013 the subsequent versions of the guidelines entered into force – respectively G3, G3.1 and G4 (Bucholc, 2010). In November 2016 the Global Sustainability Standards Board (GSSB) announced the latest version of the guidelines – the so called GRI Standards. It is worth

pinpointing that 2017 was transitory in its nature. Since the guidelines GRI G4 were no longer in force only on 1 July 2018, the reports for 2017 could be compiled according to both new and "old" guidelines(Dumay and Guthrie, 2010).

The global development of the framework for reporting published by GRI in chronological order is presented in Table 1.

Table 1: Global framework for reporting in a historical order published by GRI

Year	Name of the reporting framework
2000	GR 1 Guidelines
2002	GRI G2 Guidelines
2006	GRI G3 Guidelines
2011	GRI G.3.1 Guidelines
2013	GRI G4 Guidelines
2016	GRI Standards- the latest version of guidelines
2017	Transitional period, GRI G4 were no longer in force on 1 July 2018; the reports for 2017 could be compiled according to both new and old guidelines

Source: Own study based on information available at: https://www.globalreporting.org, accessed on 07.04.2020.

In the subject literature, it is widely emphasized that green controlling leading to the compilation of environmental reports by entities operating in the market and their publication is to:

- disclose information being the basis for the evaluation of enterprises from the point of view of their social responsibility,
- provide useful data to the owners to take appropriate decision as a result of the response to the reported information,
- popularization of environmental initiatives taken by enterprises,
- conduct activities to improve the environmental policy, objectives and planned activities in designated areas for the benefit of the natural environment in enterprises,
- motivate both managers and employees to take decisions for the benefit of the environment. (Raines, 2002), (Hopfenbeck, 2000).

Green controlling based on the controlling paradigm, which combines the idea of management by goal with management by deviations, uses the basic principles and functions of management, is compatible with other types / types / types of controlling and gives the possibility of wide application from the point of view of practical diversification of ecological issues in individual sectors of the economy.(Vollmuth, 2007),(

In the literature, it is pinpointed that green controlling raises a number of objections. It has both supporters and opponents. It is usually emphasized that green controlling is responsible for growing expectations of stakeholders and supports the company in the dialogue with the environment by showing specific effects of its involvement. Moreover, environmental controlling makes it easy to satisfy future demands in terms of eco-friendliness and thus contributes to the reduction in the future environmental commitments. The attention is also paid to the activities against green controlling. They mostly include incurring significant costs associated with the preparation of this type of information; the organization of green controlling requires the involvement of specialists, the change in the company's organizational structure. The opponents of reporting question their suitability in the

processes of communicating with the environment: the poorly prepared report may bring effects opposed to the intended one. The one which is too extensive will be found too difficult to verify, having exclusively the marketing direction (Bartels, Iansen-Roger, 2008, cited after: Paszkiewicz, Szadziewska, 2011), (Rowbotton and Schroeder, 2014),

Hypothesis Development

These considerations are the voice in the discussion and, in the course of the above, the following research hypothesis was formulated: green controlling can bring a number of benefits to the construction companies, and it determines their business model.

In the conducted empirical research, it is assumed that environmental reporting provides an opportunity of confronting own achievements of individual enterprises with the achievements of the best enterprises in the analyzed sector. Furthermore, it allows for providing a wide group of stakeholders with the information on the impact of decisions and actions taken by managers on the society and the environment. The implementation of the assumed goal required a review of source materials, which are literature on controlling, enterprise management and internal materials of the surveyed construction enterprises.

Methodology and the Sample

The implementation of the research tasks formulated in this way imposed the use of the following research methods: literature studies, case study analysis, surveys, content analysis as well as induction and synthesis methods used when formulating the conclusions.

It should be pinpointed that content analysis belongs to the most frequent methods used in the measurement of environmental and corporate social responsibility of enterprises (Stray, 2007) and (Jose, Lee, 2006). In this research method, there is a multifaceted interaction between: a set of knowledge of the subject, previous beliefs.(Yin,2003). The research model on green controlling in enterprises results from the adopted research mode. The first stage was the critical analysis of foreign subject literature. The literature primarily related to green controlling, meters and indicators used in it for the purposes of management. On the basis of the above, the problem areas, relevant from the point of view of the analyzed research topic, were identified. The second stage of the research model was the selection of the research subject as well as characterization of the research sample, determination of the scope of the research and an attempt to measure research areas. In total, 35 enterprises were subjected to the analysis: 70% of the respondents amounted to large enterprises, the other 30% amounted to small and medium enterprises. The research period was the 4th quarter of 2019. The reasoning was based on the objective and systematic assessment of the content of the identified environmental areas of the activities of enterprises. The respondents of the survey on green controlling reporting were the managers of the surveyed enterprises. The number of the surveys corresponded to the number of the surveyed enterprises; their feedback amounted to 91%.

The empirical research relates to construction companies. According to the studies presented in the documents “Lead Market Initiative for Europe”, prepared by the European Commission, the construction market is responsible for 42% of the final energy consumption in the EU, 35% of the total greenhouse gas emissions to the atmosphere; it is also responsible for the significant consumption of non-renewable raw materials, such as water or aggregate. A significant problem in construction is also the demolition of old buildings: cleaning them up. Thus, the need to develop innovative products and technologies in construction is pinpointed. The European Commission defines four attributes of sustainable construction, such as:

- ✓ innovativeness,
- ✓ responding to social needs,
- ✓ environmental friendliness,
- ✓ economic efficiency (see also Teece, 2010).

For the needs of management in eco-controlling, the attention was drawn to analytical meters and indicators used for these purposes; the concepts of *meter* and *indicator* are often used interchangeably but their range of meaning is not the same. The meter is a nominated number expressed in any unit. The indicator is a nominated number compared to another and the one which is the basis for the reference of a nominated number. Therefore, indicators may take both nominated and non-nominated values (Kochalski, 2011), (Bode, 2008). In environmental activities, meters and indicators ought to meet a number of requirements, such as: low costs of data collection, simplicity of calculation and interpretation of results, significance for management decision-making, temporal and spatial comparability, understandability for different groups of recipients, usability for individual areas of the company's operation, information capacity adjusted to the policy of disclosure of confidential information and consistency with applicable legal requirements (Schwarz et al., 2002; Bossel, 1999). The correctly constructed meters and indicators allow for reliable identification of events and building a forecast of future volumes and trends. In green controlling, they allow for the presentation and assessment of activities occurring at individual stages of management along with the relationships between them and their strength.

Analysis of the meters and indicators of green controlling in Polish construction companies

The considerations in this part of the study will be preceded by the general characteristics, assessment of the development and barriers encountered by construction companies in Poland. In the overall assessment, the construction sector indicates an upward trend. The representatives of construction companies, however, see the situation of the construction sector rather unfavorably. About 59% of those questioned assess that the situation in the sector is bad, and only 26% that it is good; 15% of the respondents have no opinion concerning this issue. The ratings vary, however, depending on the size of the company. The situation is particularly negatively assessed by enterprises operating in the road and railway segment (about 60% of negative ratings) and large enterprises (about 55% of negative ratings). Interestingly, 51% of the respondents admit that in 2019 the value of sales revenues increased; it should be pinpointed that, in the whole construction sector, the level of the value of sales revenues was the highest in the six years and it amounted to PLN 115 billion. As indicated by the conducted research, there was a very high level of capacity utilization in the surveyed enterprises until the fourth quarter of 2019 (about 90% in November 2019). The previously recorded sales revenues do not translate, however, into an increase in the profitability of the construction sector which has indicated a downward trend since 2018. About 80% of the respondents claim that an increase in the prices of building services provided by enterprises is accompanied by a decrease in gross profit; 57% of those questioned recorded a decline in gross profit. This decline was mainly due to an increase in prices of aggregates, asphalts, steel and steel products and concrete products. It was not, however, the only factor determining the economic situation in the construction sector. The group of negative factors also included the issues such as: unprofitable contracts, rising labor costs, difficulty in maintaining financial liquidity and difficult access to external financing. One of more important challenges for construction companies is employees; more than 75% of the surveyed companies experienced problems with recruitment of new and/or outflow of existing workers in 2019, primarily specialists and unskilled workers. In terms of ad hoc measures, in the light of the problems with staff, managers raise wages and employ foreign workers, mainly from Ukraine and Belarus. Construction companies are coping with maintaining financial liquidity (74% of indications). The main reasons for problems in this area are primarily: long payment terms from investors, difficulty in claiming remuneration for additional work (more than 70% of indications). The surveyed enterprises also indicate difficulties in access to external financing, both in the form of credits and loans (respectively about 80% and 70%).

The analysis of the environmental and energy policy of large construction companies indicates that they show the awareness of the improvement in their environmental activities; they see commercial

and economic benefits in this area. Most construction companies from this group, for the purposes of success of their business activities and satisfaction of their stakeholders, define environmental responsibility as a priority area of their strategy. Furthermore, they take actions to reduce the negative impact of their activities on the environment to the extent which is technically possible and economically justified (Adner, 2017).
It should be pinpointed that there is always the control of the environmental and energy policy by management staff in order to establish its relevance and effectiveness and to ensure its observance (Brillinger, 2018). In general terms, construction companies emphasize the following issues in their environmental reporting:

- implementation and maintenance of an effective environmental and energy management system,
- avoiding environmental pollution by analyzing both indirect and direct impacts affected by their activities,
- minimizing the consumption of natural resources, energy, raw materials,
- avoiding waste,
- supporting recycling whenever it is possible.

Large construction companies implement the Environmental and Energy Management System based on ISO14001 and/or ISO 50001 and/or EMAS or other regulations and maintain this system. Their activity in terms of environmental reporting is already at the stage of planning. Enterprises fully support the environment as well as prudent and economical use of natural environment. Moreover, consistent rules and definitions of minimum standards in terms of fuel management are created to allow responsible operational units at all levels and the departments of central concerns for efficient and effective monitoring of fuel consumption. To ensure the further development of the environmental management system, in the enterprises of the analyzed sector, the people in charge are appointed as well as their agents. Generally, it should be noted that, in large construction companies, environmental reporting is based on the certified management system (Berllinger, 2020).

A number of subcontractors are employed in construction, thus large construction companies using their services, provide training for subcontractors in terms of the observance of principles of environmental protection; the attention is also drawn to the observance of procedures, having experience and well-functioning equipment.

In the survey, managers indicate environmentally friendly activities, such as:

- minimizing tree felling as much as possible, removing plants to other locations as well as planting new trees and other plant species,
- protecting trees in the area of the impact of construction against mechanical damage,
- organizing the construction camp mainly in the already developed and transformed areas, away from housing developments and valuable natural areas,
- water tanks are protected against pollution from construction,
- monitoring the construction by environmentalists,
- the construction cycle is correlated with the natural cycle,
- striving to ensure that the top layer used for finishing works is of local origin,
- preparing construction sites for unforeseen emergent situations and equipping them with the necessary equipment in the event of contamination.

Environmental reporting is very extensive, and it is difficult to present it comprehensively in one study. From the point of view of environmental controlling, the aforementioned areas of environmental activities in construction require quantification in the form of specific meters and indicators (Table 2).

Table 2: Selected meters and indicators of green controlling in Polish enterprises of the construction sector

Specification	Stages in management cycle in environmental controlling of enterprises			
	Initiating	Planning	Implementation	Control
Cost meters	x	x	x	x
Benefit meters	x	x	x	x
Resource meters	x	x	x	x
Variance Analysis				
Eco-efficiency meters: resource consumption to value of production and/or sales	x	x	x	x
Indicators of water/ energy consumption	x	x	x	x
Amount of waste taken to landfills	x	x	x	x
Volume of consumption of recycled materials	x	x	x	*
Amount of renewable energy used	x	x	x	*
Degree of water, soil, air pollution	x	x	x	x
Impact on biodiversity	x	x	x	x
Environmental management systems	x	x	x	x
Packaging reduction meters	x	x	x	x
Level of contamination and erosion of soil	x	x	x	x
Ocean of suppliers in environmental terms		x	x	x
Number of environmental complaints	x	x	x	x
Value of investment in environmental protection	x	x	x	*
Value engineering	x	x	x	*

The presented scope of green controlling in the surveyed enterprises is diversified and identifies economic, environmental and social activities (Chow, 2006). At the stage of initiating and planning,

the meters and indicators of green controlling give the grounds for planning, setting objectives or conditions of their implementation; they help to operationalize financial and non-financial objectives. They provide the basis for the construction of the business model.

At the implementation stage, meters and indicators of green controlling perform the communication function. At this stage of management, it is important to promptly and accurately transfer specific tasks in the field of environmental activities for the effective use in relevant decision-making situations; they also relate to the verification and implementation of works on the compliance with time, schedule and scope while monitoring financial discipline according to the adopted budget records.

At the control stage, meters and indicators allow for the assessment of the degree of the accomplishment of objectives in relation to the applicable standards or activities of competitors. The results of this comparison are the basis for the submission of proposals of necessary measures to avoid or reduce adverse deviations or to use favorable deviations. On the whole, the results of this analysis are the basis for the adjustment of implementation or even the adopted plans. Meters and indicators trigger learning processes. The control is related to the supervision function; it is particularly important in large enterprises, where managers participate in management. Meters and indicators enable decision-making and monitoring the behavior of employees.

The conducted empirical research on green controlling in the surveyed enterprises indicates that there is no coordination of information in this field. The problem concerns the issue of waste management, so important in construction. It could take the form of the so called reports on problems; they are created as independent reports in a situation where managers recognize that the problem of waste violates the budgetary discipline of the implemented tasks, the level of contingency reserves or generates the problem associated with the financial liquidity of the company (Bukłacha, 2019).

In green controlling, it is essential to constantly search for new, more effective forms of measurement to increase the reliability of information enabling the management of this aspect of enterprise activity in relation to the determinants of construction of the future; they include the issues associated with eco-construction. Eco-construction consists of a number of issues. They include the issues, such as: increasing the energy efficiency of facilities, searching for new building materials, applying alternative sources of energy. Moreover, the environmental construction of the future is to reduce the amount of building waste, which is indicate in this study in the light of the conducted empirical research, and to minimize the consumption of energy related to the production and transport of building materials. All in all, it should be stated that energy saving, environmental science and humans are the main factors which will determine the development of the construction sector by 2025, which gives an incentive for further and continuous optimization of green controlling functioning in construction companies (Raport, 2019).

Discussion

The conducted empirical research concerning meters and indicators of green controlling in construction companies indicate that they are multicriteria. In fact, they were identified at all stages of the implementation of construction ventures.

An open problem is, however, the controlling concerning waste. In the case of construction, it is the key aspect adversely affecting the local biosphere. Waste arising from the construction site, coming from renovation and dismantling of buildings and road infrastructure (brick debris, asbestos) is an important environmental problem. The surveyed enterprises, in their statements, guarantee that the works related to the disposal of waste are carried out with due diligence, and hazardous waste is properly managed. The managers of the surveyed enterprises in general descriptions of the environmental activity, indicate that about 65% of waste is transferred to natural persons for reuse in accordance with the principles specified by the provisions; however, there is no accurate reporting in this field.

In the surveyed enterprises, the process of value engineering is used, which allows for the optimization of the use of materials and reduction in their negative impact on the environment. The scale of processing and reuse of raw materials, which are production waste in the construction sector and other sectors of the economy, such as mining, energy and metallurgy, is not reported, though. An important discussion problem is currently the cooperation of construction companies with municipalities in the area of which various investments are being realized. This would make it possible to achieve individual objectives and also allow synergies in terms of environmental and social issues.

Conclusions, Limitations and Directions for Further Research

The assessment of the content and the system of green controlling of construction companies was one of the main theoretical empirical aspects of the conducted research.

The environmental reporting enables long-term strategic decision-making, measurement and increasing the efficiency of operations in important areas not analyzed so far; the inclusion of management boards in important issues of sustainable development also takes place. The area of green controlling is an integral part of more extensive reports, concerning sustainable development.

The analysis of the applied meters and indicators of green controlling in construction companies indicates the necessity of their use also at the stage of controlling. This problem, due to the specificity of the analyzed sector, primarily concerns waste management. The conducted identification of the meters and indicators of the economic, social and environmental development does not constitute their complete list; however, this may be the basis for their further improvement and orientation, taking into account a broader diagnosis of waste management, which would be very useful from the point of view of the controlling services of enterprises of the analyzed sector. Moreover, environmental reporting at the stage of initiating and planning cannot be merely the component of building the image of enterprises in relation to their stakeholders.

In the further research in the field of green controlling, the attention should be drawn to the holistic approach to their system (Epstein et al, 2014), (Stal and Corvellec, 2018), (Kochalski, 2019). The integration of all areas of sustainable development in the system of meters and indicators is necessary for the enterprises which intend to use green controlling in the processes of planning, control and supplying information supporting management and also the future business model.

Artificial Intelligence for Cognitive Competitive Purposes

Allal MOKEDDEM

Lecturer, University of Alger 3, Department of Management and Technology, Algiers, Algeria, mokeddem.allal@yahoo.fr

Abstract

The businesses transmit not only products and services, but also other resources presented by beliefs, perceptions and ideologies... These resources enrich competition through constantly evolving business models. In this article, we analyze this new competitive regulation based on cognition. Then we study the business model and its evolution in favour of an intelligent competitive environment.

Keywords: Artificial intelligence (AI), cognitive competition, business model, competitive intelligence.

Introduction

In a constantly changing competitive environment, the company is faced with the obligation to set up an environmental monitoring system, which measures the innovative strategic actions carried out by the company and its competitors. At this stage, the development of an effective competitive strategy must be consistent with the different dimensions of the strategy, namely structure, leadership, culture and technology.

In the 21st century, the businesses are seen as a center of innovation and wealth creation. In this context, each company is supposed to understand the movements of competitors. Any action, whether strategic, such as a joint venture or operational action, such as a massive recruitment, downsizing of staff or a publicly announced change of management that could be exploited by competitors to bring out valuable information.

In a highly competitive environment, it is almost impossible to monitor all kinds of information. For example, competitors' product pages, customer reviews of competing products, product review sites, success stories and customer testimonials, social media channels, scheduled blogs and webinars. All of these resources can also create a wealth of information about the products or marketing resources that your competitors are using.

In this context, according to Alsheibani et al (2020) in-depth analysis techniques serve businesses as a strategic technology for organizations. The world's leading producers of technology Google, Amazon, IBM, Apple and others have all taken advantage of artificial intelligence (AI) to deliver a better customer experience Brynjolfsson and Mcafee (2017), improve productivity Varian (2018), and developing commercial collaboration methods Hunter (2018).

Faced with this new competitive environment, the rules of competition are constantly evolving. A new environmental state based on cognitive resources which makes it possible to understand this environment. In this article, we analyze the foundations of cognitive competition and how will the competition be intelligent in the era of AI?

This paper is divided into three parts. The first is a staging on the concept of cognitive competition. The second part presents the permanent changes planned in the business plan following the integration of AI. The last part presents how companies can make competition smarter.

Motivation

The business is looking for the ways to reach a strategic position that ensures its survival and growth. A competitive status that brings opportunities must be reinforced by an effective strategic decision system. In this regard, the companies seeking a position must develop their means of investigation and competitiveness by introducing in-depth analysis methods.
This study opens the doors for Small and medium-sized enterprises to fight in this competition by exploiting their cognitive capacities. The companies using the advanced technological means will be able to dissect each competitive action by highlighting any cognitive resources developed during the competition.

Cognitive Competition: What Is It About?

Today, the competition is not limited only to managerial or organizational theorems, beyond sociology; social psychology and psychoanalysis also see their importance in the competitive world. In this stage, the company has become a cognitive development entity. The cognition is mainly based on a set of theorems such as the theory of strategy based on resources and competences Penrose (1959); Hamel and Prahalad (1990); Barney (1995), also the organizational learning theorem Argyris and Schön (1978) which emphasizes on the cognitive capabilities of organizations.

A competitive environment based on cognition, is an environment that transfers not only products and services, but also other resources such as ideologies, perceptions, values and beliefs… In this context, highly competitive companies are looking for ways to take into account the cognitive phenomena of competition. This type of business brings together research and development centers as well as institutional players around innovation projects with regional, national and international vocation Laroche and Nioche (2015).

The cognitive competition is measured in terms of the cause and effect relationship between phenomena. At this level, the decision maker analyzes each cognitive action, in order to highlight information that enriches the identification and deliberation phases of the strategy. Contrary the traditional approach, the cognition looking to detect what initiates strategic change, not just strategic outcome. The decision maker can understand the strategy as a set of connected actions which reveals a set of information and knowledge on the state of competition which can be converted to competitive opportunities.

A competitive environment brings together all atomic competitors, homogeneous products Cabral (2000), incomplete information on the environment and all companies will have equal access to technology and resources. The position in a competitive environment will not happen outside of a unique and distinctive resource base. Certainly, some benefit from unique resources, such as patents, and others can win the competition through strategic actions such as merger, absorption and alliances. In this context, two types of cognitive skills essential to compete (see Figure 1).

Fig. 1: The foundations of cognitive competence, Source Levine et al (2017)

The competing companies measure their potentials via two types of skills, namely analytical skills defined according to the ability to reason through abstract problems. The second is presented with intelligence strategic which favors companies to anticipate the behavior of competitors. In a first plan, the analytical skills carry two dimensions of use. The inside dimension, seems likely to make better decisions during the optimization and the coordination between the different activities. This has been confirmed by Helfat and Martin (2015) the companies that have a reservoir of analytical skills are those that can achieve better management and synchronization of its activities. In this context, better management and optimization of the company's value chain are reflected in the control of how and by what means individuals perceive and think during the design and implementation of the strategy. This strategic reasoning is achieved through a set of skills known as social cognition Frith and Singer (2008).

The external analysis dimension is used to detect threats and seize opportunities. This possibility is materialized by the dynamic capacities defined by Teece (2007) 'the capacity of the company to integrate, develop and reconfigure its internal and external skills to cope with a rapidly changing environment'. Such an expression can be measured by direct observation of the individual behavior of each actor involved in the competition. This facilitates the environmental analysis process and therefore clearly defines the competitive model that will be adopted by the company.

The strategic intelligence is the second basic resource in a competitive market based on cognition. The strategic intelligence is a set of actions and activities used to find, analyze and evaluate all commercial information in order to achieve a competitive objective Abd et al (2019). According to the Intelligence Report (2020), the strategic intelligence is designed to provide leaders with critical information to effectively define and adjust strategy. The concept of strategic intelligence is close to other concepts such as economic intelligence and competitive intelligence. According to Huyghe (2010), strategic intelligence is based on methods intended to clarify reality and discover projects and resources in a situation of competition or conflict. On the contrary, the economic intelligence is based on research, processing, dissemination and protection of information useful to economic actors. In a nutshell, the economic intelligence is a subcategory of strategic intelligence. All of these mechanisms make competition smarter and use open source of information management techniques to gain an advantage over the competition.

The strategic intelligence process is based on an effective strategic intelligence system. The company does not only seek to collect information on the competition, but also to create a competitive network based on resources. This is in order to clarify the facts of competition Levine et al (2017). The following figure illustrates the structure of an industry that uses the strategic intelligence profiling tool during the implementation of the strategy.

Fig. 2: Strategic Intelligence Maturity Model, Source : Bleoju and Capatina (2015)

- ***Intelligence Provider***

The intelligence providers are those who demonstrate their ability to harness strategic intelligence and transfer it into new methods and technological tools. The suppliers who feed the managerial context with new organizational, cultural and human approaches aim to involve all employees in

technical, social and environmental performance. This privilege offers the option to present knowledge in models intended to understand, solve and analyze new environmental situations.

- ***Vigilant Learner***

The learning companies present the second style of companies that contradict spy practices. This type of business is more flexible to deal with new competitive situations. At this level, learning companies are those that constantly challenge their business models, in order to clarify and deepen the overall vision of the organization. In this context, any decision processed becomes a space for sharing and collaboration.

The learning companies can set up collaboration and sharing channels with the various environmental players. The channels are presented by a network which encourages the business actors to engage in the process of developing the competitive environment. In this context, the organizations are also able to react quickly and in a timely manner to a rapidly changing environment. According to Hassan et al (2017), the organizations engage in the search for new knowledge (exploration) in order to ensure current viability, in parallel while devoting our resources to the development of things already known (exploitation). In this regard, learning increases competition via two learning modes, adaptive and generative Luo, (2020); Escrig et al (2019). The first generally increases performance in the form of increased profitability, return on investment and growth in the market share. The second increases reliability by enabling companies to develop sustainable business models, thereby providing products and services that are superior to the competition.

- ***Opportunity Captor***

The third category of companies is presented by companies that capture opportunities. An opportunity is a favourable circumstance. The concept of opportunities bring together a set of companies around different approaches: Loilier and Tellier (2020); Germain, (2010)

- ***Strategic Approach***

In the Harvard model, the notion of opportunity takes into account any external factor likely to favourably influence the prospects for growth and the trajectory of an organization. In a strategic context, the managers are more sensitive to the search for threats and have a strong feeling of mastery of the environment. The strategic approach makes it possible to analyze the competition by using the competition rule which says: "behind every promising opportunity lies a destructive threat".

- ***Praxeological Approach***

In the praxeological approach, the discovery and construction of opportunities are integrated with the strategic process. According to Andrews' approach, the opportunity makes it possible to identify strategic and operational actions. These actions make it possible to exploit the strategic potential of the organization. Once the business idea is issued, the exploration and evaluation process is displayed.

The process of discovering and building of opportunities is divided into two phases. A phase of reflection focused on determining the goals and general orientation and a more operational phase focused on the seizure of opportunities. The reflection phase is included in the strategy formulation approach which leads to identify the distinctive skills of the company. In this phase, the discovery of opportunities requires a better combination of resources.

- ***Generating Approach***

The identification of opportunities requires strategic resources that aim either to strengthen the organization's capacity to resist in the face of unprecedented disruptions, or to build the capture of strategic opportunities. In this context, the companies project themselves into an evolving and

proactive competitive status. The realization of such an approach consists in making innovation a determining factor of competition. At this stage, the companies define competition according to exogenous and endogenous parameters. For example, the technology which defines the new efficient conditions of production imposed on firm. Likewise, the inspirational approaches indicate that competition is accentuated by the effect of internal factors. For example, the organizational performance, in particular the quality of organizational routines that have been developed to compete in an innovative context.

- ***Opportunity Defender***

The latest style is presented by the protectors of opportunities. At this level, the companies defend their interests against proactive spies. The concept of redirecting competition only functions with a good diagnosis of the internal and external environment. In this context, the opportunities defender uses different ways of circumvention in order to protect their benefits and develop others. First, false alarms distort competition. The companies disclose misleading information about their strategic protocols to competitors in order to contradict the behavior of competitors. The second strategic action very heavily used by protective companies is to invest well in micro niches which require very specific and sometimes scarce resources and means. The third aspect frequently used by companies is to explain part of their business plan in order to create interoperability channels between the operating systems of competitors and that of the company.

In similar circumstances, the competitive environment takes on a more rigorous dimension. In this context, many companies are looking for ways to explore all the information from different data sources by manipulating and directing very precise information on the environment and on the behavior of each actor. But how can businesses succeed in the same competitive environment?

AI For Competitive Purposes

With the advent of advanced technologies that increase the ability of companies to respond proactively to competition, the strategic and operational system of companies is growing and becoming more complex. A competitive decision-making system is based on technological tools that carry the strategic dimension. The strategic dimension is presented through an analysis of the movements of each player where, why, what, how and by what means this competitive action will be carried out.

The competitive trends have transformed the competitive methods and protocols adopted by companies. The companies are oriented towards the angle which sees AI as a support for the development of business capacities of the company Davenport and Ronanki (2018). In this context, Tripathi and Parmar (2019) indicate that AI projects the company to a higher level of thinking. From a decisional point of view, AI transforms and makes machines, procedure and decisions more intelligent.

AI-Based Business Plans

According to Wright and Schultz (2018), the recent advances in robotics, artificial intelligence and machine learning allow machines to automate activities that once seemed immune to disturbance. These activities including tasks based on thinking, tacit learning, detecting emotions and even deciphering the behavior of competitors. Overall, AI can meet three important managerial needs: automate business processes, obtain competitive information through data analysis and interaction with customers and employees Davenport and Ronanki (2018). Generally, the automation of the activities is related to the most complex tasks are which requires a resource base which is constantly developing.

The technology with its different variants is no longer used as a tool for sharing and transferring knowledge, but rather considered as an instrument of cognitive investigation. From an operational tool to a strategic tool that can make the company smarter in managing its business portfolio. A study

was conducted with 250 business leaders who knew perfectly how to use AI in businesses. More than half said their main goal was to continually improve the product line to offer the best products to their customers. (See Fig 3).

Fig. 3: The Business Benefits of AI, Source: Deloitte (2017)

According to studies conducted by Vinogradova et al (2019), the exploitation of advanced technologies in the business world has contributed to the development of innovative manufacturing approaches. This new situation is the consequence of the development of new trades, new knowledge and new skills that will be increasingly requested by business leaders. In fact, according to Global Revenue for Enterprise Applications (2019) the annual revenues from the use of artificial intelligence applications will increase from $ 7.6 billion in 2018 to $ 107.3 billion in 2025 and by 2030, the global economy could reach $ 15.7 trillion.

All are based on information; the design of an intelligent industrial system is a process which not only includes the production procedure with its possible requirements such as quality standards, production measurements, flow measurement, logistics flow and capital flow ... Etc, but requires an automatic detection of each change affecting competition, collaboration, learning, analysis, cognition, decision-making and control of the decisions process.

According to Li et al (2017), AI technology presented by deep learning techniques, automatic natural language processing, partitioning and automatic classification, learning machines, pattern recognition and predictive techniques ... etc., has changed the concept and the way which a business can be classified as a competitive business. A business model refers to a set of interdependent activities covering the whole of the company Gassmann et al (2017). A business model will never be fully explained to the public. Leaders are looking for the ways to innovate and differentiate themselves from the competition. An innovative multidisciplinary business model is one that creates significant change in strategy, organization, culture and leadership. The manifested interest in AI has been underscored by the business community. The study conducted by Columbus (2017) with more than 3000 interviews with business leaders. As a result, the study found that 84% believe that AI will allow the company to acquire and maintain its competitive advantage and 75% said that AI will have access to new business concepts. In this context, we need to think about how AI could invent a distinctive business model?

The development of advanced technologies has opened up commercial channels that can act anywhere with anyone, anything, anytime and on any medium, be it physical, digital or virtual Lindgren and Rasmussen (2016). Indeed, the companies must constantly know how their business plan works and how is it built? In this part, we travel in the world of AI and we analyze how to do and act when advanced technological tools are integrated into the strategic system of the company.

First, the companies need to familiarize themselves with the language of the business world in order to feel in harmony with the expected technological developments Lindgren (2017). In this regard, Valter et al (2018) presents a conceptual model that examines the relationship that connects four integral parts, namely: the human intermediary; the machine intermediary; analysis of business models and the business plan ecosystem. (See Fig 4)

Fig. 4: The montage of an AI-assisted business plan, Source: Valter et al (2018)

The development of a business model is a mission by a thousand miles. First, the human action which brings together any interaction that joins the business reality to the business model Valter et al (2018). The business model is a perceptual representation of business reality. The human factor updates the model with his understanding how things act in business reality. This interpretation will never be put outside the business environment. The model has undergone interactions that generate a new knowledge from different areas of expertise. This situation opens the door to new styles of potential understanding that offer opportunities for exploring cross-border knowledge.

The technology slides provide opportunities during developing a transparent and effective business plan. A machine presented by data entry robots, heat maps…Etc, which continuously observes the reality of business. We cite devices that analyze customer behavior via machines installed in sales areas. In this context, a business model triggers one or more events on the intermediate machine. If a business owner wants to have a number of customers in his store within a specific period of time, then this event triggers a business model that at one time treats a limited number of customers in the store. The business model considers price as a determining factor, contributing to the decrease or increase in the prices of specialized offers displayed via automatic display panels.

The third impact factor describes the relationship between artificial intelligence via deep learning models that reflect the intersection between the human factor, the machine and the desired business plan. The AI and deep learning algorithms analyze the ecosystems of business models in order to optimize existing business models and suggest new models based on the success of others that operate in various competitive contexts. The deep learning algorithms offer the possibility of building improved business models using an artificial intelligence tools. For this purpose, each design phase corresponds to a particular state of competition. Consequently, the deep learning algorithms transform business plans into hierarchical structures. For example, the lowest level consisted only of lower-class customers versus the higher levels reserved for the most important customers in terms of quantity of purchases and who require specific negotiation approaches.

In the section below, we describe perfectly how the company can transform the competition and make it more intelligent?

How to Make Competition Intelligent?

The company is looking for a way to strengthen its competitiveness through better quality provided, better delivery times and greater flexibility in adjusting costs. In this context, the development of an effective operational strategy that reflects the planning, design and implementation of strategic decisions is the only path to the development of a distinctive competitive status. At this level, the analysis of the competitor's behavior offers a precious opportunity to develop a competitive intelligence system. This system based on a strategic method which constantly anticipates the movements of competitors Guo et al (2017).

The competitive analysis is powered by advanced technologies allowing efficient access and analysis of large data sets. According to Kraus et al (2020) the deep learning and deep neural networks

promise to maintain improvements, performance and make better predictions compared to traditional methods. However, the neural networks have changed the way we compete in a market. Accordingly, hundreds of layers and millions of complex neurons He et al (2016) hide sophisticated information and resources about the competition.

The deep learning has not only been very successful in natural language processing, but also in image classification, object detection, object localization and image generation Kraus et al (2020). As a result, large companies around the world like Google in 2016 launched an update to its translation system that uses deep learning to improve the translation accuracy that accompanies the human performance approach. Moreover, Amazon and Netflix use deep neural networks in their recommendation system. In this respect, each competitive action carried out receives treatment based on the competitive intelligence approach (see Fig 5).

Fig. 5: The three pillars of competitive intelligence system, Source: Sassi et al (2016)

- ***Collection of actions***

The competitive actions are made by the competition. Its actions are reflected in the company's decision-making system. Often, the company's strategic decision-making system is encrypted, which makes the collection process quite difficult. In this context, the identification of the strategic source of information requires fairly powerful means of collection. The WebRadar is a powerful tool that offers companies the ability to follow market trends. For example, we cite the WebRadar that assess the reputation of the company. Several advantages on the horizon namely: I) it discovers the influences that impact the reputation of the company; II) it monitors your image in real time and III) analyzes your image with the public. Especially since, according to Chaveesuk et al (2019) in the digital age, companies leave behind so much information regarding their online activities such as research, purchases and reading articles, etc. These informations are produced daily and used by companies for commercial purposes.

For this reason, several applications have been developed to provide information and news about the competition. Adthena (2018) continuously monitors millions of keywords around the world. This technology allows you to see on what terms your competitors are bidding and the resulting impact on your campaigns. With Adthena (2018) Greenlight was able to instantly analyze the performance of competitors via a device that quickly scans advertising copies, a task that used to take hours and days. Therefore, by eliminating these delays, Greenlight was able to provide information to customers earlier and spend more time in the design and execution of their plan.

- ***Actions association***

The actions collected must be grouped in such a way that the reactions of competitors to the launched offer are in the same cluster. The competitors' reactions focus on internal and external competitive criteria. We cite the cluster that combine both internal and external factors, namely the style of marketing communication and the perceived of higher quality. The companies are oriented towards the use of a brand communication method that disseminates imaginary concepts about the product. This creates specificity in the use of this product and a difference in its brand and its nature.

- ***Rule generation***

This step is reserved for the generation of competition rules in the form of an algorithm (if… .. then). In this respect, the rough set theory which can be considered as an intelligent mathematical tool offers

the option of extracting and defining competitive rules from the observation of approximate and inaccurate data. The rough set theory is applied to generate rules and predict the actions of competitors based on the history of the competition (see Fig 6).

Fig. 6: The system generating the competition rules, source: Author developed

The generation of a competition rule is subject to an algorithm which instantly connects to the competitive archive store. As an example, we simulate the rule of "confrontation by services" in a telecommunications market structured by a set of companies (C1, C2 ... C8). The system generator of competition rules acts according to the algorithm presented below:

Rule 1: A1: If (actor= Concurrent 1) and (actor= Concurrent 2) and (Type of service=2Go communication bonus line) and (target= Actual customer, Prepaid line) then (Owen company will react with action A5 and A8 respectively).

Conclusion

The competition is defined by a set of actions presented in a business plan. The Knowing of the state of competition is the unique way to develop an effective competitive system. At this stage, the cognition and the perception of competition have been accompanied by the development of methods and big data techniques analysis. In this regard, the combination between the human factor (thinking), machine (power) and the business plan ecosystem (environment) presents the three basic foundations for the development of the intelligent competitive system. The latter is put into operation as soon as a competitive action appears. This action is the subject of an advanced strategic analysis in order to generate new competition rules.

Abstract

With the recent economic crisis in Brazil, many local authorities found it difficult to balance their budgets, pay employees' salaries and make payment to suppliers. Curitiba, a local authority in the south of Brazil, faced similar problems in this period. This study analyses two electoral cycles that coincided with the national crisis. The aim is to analyse whether the Curitiba's Financial Recovery Plan, launched to contain the increasing imbalance of municipal finance, had a positive impact. For the analysis, a quantitative approach was adopted corresponding to two electoral cycles (2013-2016 and 2017-2020). The measures sought to raise municipal income from taxes, contain expanding expenditure on staff and consider the civil servant welfare system. Measures to raise income were positive, although coinciding with a period of national economic recovery. Those to restrain the growth of payments were found to be effective.

Keywords: Financial Recovery Pan, Financial Management, Fiscal Responsibility, Local Finance.

Introduction

Following the Brazilian Federal Constitution of 1988, Brazilian local authorities were elevated to a third federate entity and benefited from political decentralization, as opposed to the previous period marked by authoritarian centralization and concentration of income with the military regime. The autonomy granted allowed local authorities to establish their own governments (Soares and Melo, 2016).

Recently, Brazilian local authorities have experienced an economic crisis caused partly by the economic depression affecting the whole country. The effects of this crisis were shown in a study elaborated by the National Confederation of Local Authorities (2018), where 35,3% of local authorities claimed they were not able to finalize their accounts in 2017, with 77,1% depending on the Financial Support for Local Authorities (FSLA) to do so. The study also showed that delays in paying employees and suppliers were the aspects most affected and many local authorities were not able to finalize their accounts in the accounting year.

However, local authorities' expenditure on investment grew by 41,6% between 2017 and 2018 according to the "Financial Report of Sub-National Entities" from the National Treasury Department (2019), which could represent financial recovery. In addition, it is worth noting that 2018 was an election year, when there tends to be increased expenditure (Vasconcelos and Nogueira, 2013).

In the context of a national crisis, this study reveals the situation of Curitiba where the management in charge of the local authority in the period between 2017 and 2020 claimed that municipal finance was severely jeopardized and with an imminent risk of paralysis of various services and inability to meet

payments (Curitiba, 2019). Therefore, a financial recovery plan was established, which will be analysed in this study. Curitiba is situated in the Southern Region of Brazil and is the capital of the State of Paraná. According to IBGE[1] it has an estimated population of 1,9 million, has one of the best quality of life indices in the country (10th position) and has the 5th highest Gross Domestic Product (GDP) in the country, estimated at approximately 84 billion *reais* (base year 2016).

The question this study aims to answer is the following. Which measures adopted (by Curitiba) to achieve financial balance can be relevant for adoption by other local authorities also experiencing financial stress? The intended contribution is to present such measures and how they can help other cities to balance local finances.

Financial Recovery Mechanisms

Financial recovery plans generally emerge from the need to balance accounts due to excessive debt and governments' consequent inability to meet their financial commitments. Some studies by various authors identifying possible causes of municipal debt are presented below:

- The electoral cycle can contribute to municipal debt, as election years can raise municipal expenditure. However, laws passed to restrict such action, as in the case of the Law of Budget Stability in 2001 in Spain, have contributed to lessening the impact of the electoral cycle on local finances (Bastida, Beyaert and Benito, 2013).
- In a study of Portuguese local authorities, alternation of the executive, governance by right-wing parties, high expenditure on staff and having a greater amount of capital revenue can contribute to municipal imbalance (Nogueira, Basílio and Ribeiro, 2019).
- Over-budgeting, i.e., when much greater income than what is actually taken in is forecast, can also be a reason for debt. When this difference is significant, and occurs in successive years as an intentional practice that allows local authorities to increase their expenditure without the capacity to support this, budget imbalance can be the outcome (Furtado, 2016)
- National crises also have a direct effect on local authorities, since public finance is subject to major restrictions due to the reduction in taxes collected, these being the main source of income. For that reason, the Brazilian Federal Government reduced the funding for all sectors (Silvestre, 2019), jeopardizing local authorities' economic situation.

The term fiscal responsibility is generally associated with governments' prudence in limiting expenditure and managing public debt, but it is also related to governments' measures and processes in managing fiscal matters (Cruz, 2015). Financial recovery mechanisms are understood to be financial rebalancing measures in order to increase income, reduce expenditure and restructure debt (Nogueira et al 2019).

A study by Jimenez (2019) showed that planning is associated with greater budget solvency, but its effectiveness can vary from one city to another, since planning helps most cities with financial difficulties but not those facing extreme fiscal decline.

The first alternative for municipal administrations is improvement of their management indices. Leite Filho and Fialho (2015) and Ribeiro and Jorge (2015) concluded on a positive and significant relation between indicators of municipal public management and those of municipal development. Here, Netto and Monaco (2017) indicate that the adoption of indicators is fundamental, as these can quantify the result of public policies, helping the manager to make decisions to improve them. The same authors (2017) also indicate that management by results, effective communication and the structuring of a controlling authority are important to increase the efficiency and rationalization of public expenditure.

For Carvalho Junior (2018), in a scenario of great dependence on transfers, it is fundamental for local authorities to widen the base of their own income to ensure service provision and investment in infrastructure. In this context, the Urban Building and Land Tax (UBLT) is indicated as having the potential to extend that income, since it is a tax that causes few economic distortions and can be

progressive. The author (2018) made an assessment based on an equation of property tax performance, concluding that average income could increase from 0,48% to 0,83% of municipal GDP, which would correspond to an average increase of 10,8% in local authorities' current income.

Among the main measures evaluated in the study by Carvalho Junior (2018) to be adopted to widen the income base are those of a legislative and administrative nature: (i) modernize and update the physical base and that of property tax payers; (ii) carry out technical property assessments close to the market value; (iii) minimize exemptions and review the level of tax rates, opting for selective, progressive tax rates when the aim is to protect the poorest; (iv) adapt tax rates to budget needs and the results of administrative reforms, principally when they are very low or very high; and (v) incentivise tax-payers' voluntary compliance through financial assistance and strongly restrain non-compliance by recording the outstanding debt at the registry office.

Therefore, faced with the financial and economic crisis experienced worldwide, it is increasingly fundamental for management to find partners to combat the effects caused on the control of public accounts (Santin, Pereira and Camargo, 2017).

One of the main mechanisms to control public accounts in Brazil is the Law of Fiscal Responsibility[2] (LFR), passed in 2000 with a view to controlling public expenditure and providing transparency in financial management. At the same time, it aimed to avoid opportunistic behaviour at the end of a period in power (Araújo, Santos Filho and Gomes, 2015; Linhares, Penna and Borges, 2013; Santolin, Jayme Junior and Reis, 2009). This law defined 60% of Net Current Income (NCI) as the limit of expenditure on staff and the relation between net consolidated debt and current income should not exceed 1,2. In addition, sanctions were established for those not complying with the norms.

Santolin, Jayme Jr. and Reis (2009) concluded that the LFR was important in reducing municipal deficits. However, imposing rules can lead to limiting the government's effective participation in anti-cyclical fiscal policy. In addition, by allowing high expenditure on staff (up to 60%), this led various local authorities to increase this type of expenditure and reducing the relation between investment expenditure and income through taxes. The authors concluded that in a climate of macro-economic depression, the strict rules and severe sanctions foreseen in the LFR end up limiting expenditure on public investment, as this is the area most susceptible to cuts in order to achieve financial limits. Other expenditure presents a more rigid structure and is not so easily changed. Araújo et al (2015) reached similar conclusions in a study on the impact of LFR on local authorities in Alagoas, also finding that local authorities most dependent on transfers are the ones that suffer most impacts on investment capacity to carry out public works and provide residents with services.

For Cruz (2015), although the LFR states that planned, transparent action and efficient control mechanisms are necessary to achieve balanced public accounts, most empirical studies are based on the pillar of responsibility as regards complying with the goals and limits imposed. Other mechanisms of financial responsibility contained in the LFR are little explored in these studies, namely: planning, transparency and control.

Methodology

Analysis of the methods adopted in Curitiba's Financial Recovery Plan (FRP) was carried out through a quantitative approach referring to two electoral cycles (2013-2016 and 2017-2020). The aim was to determine the impacts of municipal budgetary measures coinciding with a period when the Brazilian economy changed from positive growth in 2013 and 2014, to recession in 2015 and 2016 and a slow recovery from 2017 (IBGE, 2019). Currently, in 2020, due to the COVID-19 pandemic, the economic scenario is not yet clear, although many publications indicate another world recession.

The secondary data collected are based on material available on the Curitiba Local Authority Transparency portal[3], having selected files containing the Annual Budget Law (ABL) of each year studied, besides the "Budget balance sheets", "Statements of Expenditure by Function/Sub-Function" and "Statement of Net Current Income" relating to the 6th two-monthly period of each year due to these

contemplating evolution of real income and expenditure for that year, allowing comparison with the budget forecast by the ABL. The basis for comparison did not consider intra-budget income[4]. To update budget values, the General Consumer Price Index (GCPI) was used, between December 2012 and December 2019. This index was considered in other studies for this purpose, as it is the Federal Government's official price index, used even to define and control the goals for inflation in Brazil's monetary and fiscal policy (Farias, 2009; Teresinha and Souza, 2012). The budgets were standardized so that the database would always consider the same sources of income and expenditure, for example, to calculate the comparison of Service Tax (ST), up to 2017 income from fines, interest, current debt, discounts and deductions were considered separately from the actual ST collected, whereas from 2018 a single amount of income was considered. This study follows the methodology adopted from 2018. All the actions of the FRP were implemented according to specific legislation.

Results and Discussion

This section will discuss some points of Curitiba's FRP contained in the Curitiba Prefecture Report (2019), such as:

- Creation of the Municipal Fiscal Responsibility Law– MFRL;
- Launch of the "Curitiba Receipt" programme, updating of the Service Tax (ST) Law;
- Simplification and adaptation of the tax rate on the Inter-Personal Transmission of Fixed Property and Real Rights (ITFP);
- Alterations to the civil servant welfare regime.

Evolution of the municipal budget in the period 2013-2019

In the period analysed, between 2013 and 2019 and with correction of values according to the GCPI, Figure 1 reveals that forecast income was practically stable growing by 1,5% in the period, consolidated income increased with a positive variation of 6,8% and expenditure grew with a positive variation of 4,9% in the same period.

Fig. 1: Evolution of Income and Expenditure in Curitiba Between 2013 and 2019
Source: Own elaboration based on data Curitiba Prefecture Transparency portal

Without considering updated figures for 2019, in the period analysed income increased by 46,5% and expenditure by 40,9%. The difference between income and expenditure was compensated for by intra-budgetary income that is not analysed in this study. However, it is important to note that since 2014 the budget forecast has been falling in the search for balance and seeking to avoid the phenomenon of over-budgeting, and even in the years of national recession (2015 and 2016) there is growth in consolidated income.

Municipal Fiscal Responsibility Law

The MFRL approved in the domain of municipal legislation, tends to be more restrictive than the Federal FRL, referred to in the previous section, with differentiation, for example, in relation to the following aspects:

- Civil servants' welfare is now included in the local authority's financial management;
- The MFRL introduced a mechanism limiting the growth of expenditure on staff, linking that growth to levels of income. Article 17 of Law 101/2017 stipulates that the nominal variation of total expenditure on staff employed, in each period, cannot exceed 80% of the nominal variation of net current income received in the previous period;
- The Council of Fiscal Management and Responsibility was set up, responsible for decisions of optimizing and classifying public expenditure. The Council is for consultancy and deliberation and should advise on various matters, among them career planning, forming agreements, arranging credit, granting salary increases and re-adjustments. The council is formed of various municipal departments.
- Obligatory reduction of expenditure on staff when this reaches 50% of the NCI, preventing the local authority from exceeding legal limits. This reduction refers to expenditure on the executive authority, with the FRL stipulating a limit of 54% for this authority and 6% for the municipal legislative authority. Article 19 of the MFRL stipulates that if "total expenditure on staff in each authority exceeds 92,6% (ninety-two point six percent) of the limits established in this Complementary Law", there must be a reduction in expenditure on commissions and remunerated functions, overtime granted, Full-Time Work (FTW) contracts and contracting services from third parties. This measure is particularly interesting given what has been observed by various authors regarding the high limit allowed by the FRL for mayors to use on expenditure on staff – 60% of the NCI (Araújo et al 2015; Linhares et al 2013; Santolin et al 2009). Then again, the reduction of expenditure on staff and contracts with third parties can jeopardize the provision of services to the community.
- The MFRL limited expenditure on publicity to 0,6% of the NCI, which in 2019 would represent 46,5 million *reais*. However, in the two periods analysed, only in 2014 was an amount greater than 0,6% of the NCI allocated to expenditure on "social communication". After approval of the MFRL, average expenditure was 0,267% of the NCI, indicating that the limit of 0,6% adopted could be reduced.
- The requirement to provide costing resources for the implementation of new public equipment.

Review of taxes and incentive to extend income

Service Tax (ST) formed the main income of Curitiba Local Authority and between 2013 and 2019 on average accounted for 16,41% of its sources of income. Launching the "Curitiba Receipt"[5] programme, as part of Complementary Law 102/2017, aimed mainly to encourage residents to request the Tax Receipt for the services they use in the city hoping to diminish tax evasion and contributing to increased income from ST. This is encouraged by holding monthly lotteries with prizes that can reach 150 thousand *reais* and allow a reduction of up to 30% of the annual amount of UBLT. Analysis of the income from this tax between 2013 and 2019 revealed whether the measure resulted in benefits for local finances. Figure 2 presents the evolution of income regarding the amount forecast and received. A fall is noted between 2015 and 2017 and recovery between 2017 and 2019. Considering the figures without using the GCPI, between 2017 and 2019 there was a growth of 12,1% in this period, but

considering the updated figure, the amount collected in 2019 did not exceed that of 2013 (first year of analysis), i.e., the programme contributed to recovery, as the growth is greater than the growth in Brazil's GDP (between 2017 and 2019 GDP grew by 3,6%), but the level of income collected has not yet exceeded the figure recorded in 2013.

Fig. 2: Evolution of ST in the Period 2013-2019

Source: Own elaboration through analysis of the budget balance sheets provided by Curitiba Local Authority.

Concerning the Urban Building and Land Tax (UBLT) in the period between 2013 and 2019, there was an average annual growth of 5,86% (considering correction of the values by the GCPI), which is slightly greater than average inflation in the period, which was 5,76% per year.

Curitiba's Fiscal Recovery Plan (FRP) simplified and applied correction to the tax rates of the ITFP, as income from this tax had fallen significantly before the Plan, as demonstrated in Figure 3. From 2017, the year of implementing the FRP, the tax started to grow, but only in 2018 did it exceed the forecast. This tax's participation in total municipal income declines until 2016, representing 3,58%, and grows thereafter, reaching 3,95% of total income in 2019. Therefore, the tax is seen to have recovered, albeit slowly, its share of the contribution to municipal income.

Fig. 3: Evolution of ITFP Between 2013-2019
Source: Own elaboration from analysis of the budget balance sheets provided by Curitiba Local Authority.

Alteration to Civil Servant Welfare and Freezing of Career Plans

With payment of salaries being the main local authority expenditure, the FRP acted consistently in this area (Curitiba, 2019). Considering the limits imposed by the Federal LFR, from 2017 the local authority adopted a series of adjustments to restrain the growth of payment on salaries, these measures including the freezing of career plans (Law 15.043/2017) and temporary suspension of staffing re-adjustments, which occurred again from 2018. The Federal LFR indicates that expenditure on staff should not exceed 60% of the local authority's Net Current Income (NCI), with 54% being for the Executive and 6% for the Legislative Authority. The situation of the executive's salary sheet generates most discussion and for that reason Figure 5 presents the relations between expenditure on staff (Executive Authority) and NCI.

Fig. 5: Relation Between Expenditure on Staff (Executive) and NCI
Source: Own elaboration based on budget balance sheets provided by Curitiba Local Authority

Figure 5 shows that expenditure on staff grew from 2013 and reached a peak of 45,80% of NCI in 2016. The forecast for 2017 was for that tax rate to increase to 47,44%, but with the implementation of the FRP in that year the amount spent on staff represented 41,19% and fell to 37,57% in 2018. There was a slight increase in 2019 and the forecast was exceeded. An ascending curve is noted in the expenditure on staff/NCI relation, but the local authority never reached the Warning Limit of 48,60%. Besides the amounts forecast and spent, Figure 5 presents the relation considering the new methodology applied by the local authority, which deducts from the amounts the service income from the public transport system of the Curitiba Urbanization Fund (CUF) according to Municipal Complementary Law n° 101/17 (MFRL). With this new methodology, the NCI is less than that considered previously (in 2013-2016) and therefore the local authority would have exceeded the precautionary limit in 2016. However, Net Current Income, defined by both the MFRL and the FRL is the same, and the justification for withdrawing the income quoted in the NCI calculations would be greater fiscal accountability. Irrespective of the methodology applied, it is noted that expenditure on staff was growing and that the measures adopted by the plan were important in rebalancing and improving the path of expenditure. The year 2019 should be assessed over time as to whether this is a new expansion of expenditure on staff or an isolated point in the curve. The reduction in expenditure on staff is also related to the increased number of employees requesting retirement and not replacing them at the same rate.

The question of welfare was worked on in two ways: the increase of the percentage contribution to the welfare regime and the creation of a complementary welfare system. With the approval of Law 15.042/2017, for civil servants who were already within the Administration framework, the percentage contribution changed from 11% to 14%, with an annual increase of 0,5% until reaching the new limit (14%). This measure took into consideration the deficit in the municipal welfare system (Curitiba, 2019).

Through Law 15.072/2017, for new employees entering from September 2017 a Complementary Welfare Foundation was created, CuritibaPREV. In this regime, classified as hybrid by the FRP, civil servants were now protected by Curitiba Municipal Welfare Institute (CMWI) up to the limit of the General Regime of Social Welfare, and above that, the complementary welfare system came into effect (financed by capitalization). "That means that for every real you invest in your welfare account, the local authority will invest one more real. It is an indirect salary, going towards your pension"[1]. As the

changes in the welfare system are recent, it was not possible to evaluate the impact on local authority finance.

Conclusions

This study aimed to answer to the question: Which measures adopted (by Curitiba) to achieve financial balance can be relevant for adoption by other local authorities also experiencing financial stress? This study aimed to assess some measures implemented by Curitiba's Fiscal Recovery Plan. Considering the fall in municipal income, increased expenditure on staff and the crisis affecting the country from 2014, in fact the adoption of some measures were important in rebalancing municipal accounts and avoiding some situations found in other local authorities, such as delayed payment of salaries. In updated figures, income and expenditure grew at a similar rate, according to the data analysed and available on the balance sheets provided by the local authority on its Transparency Portal.

Of the measures analysed, increased ST and ITFP taxes are found to be important in improving income and that charging taxes on transport applications, although a small proportion of the budget, contributed to municipal income.

Implementation of the MFRL with mechanisms for stricter control of expenditure on staff than the Federal FRL agrees with what various authors presented in their studies and can be an important measure to be replicated in other local authorities. Despite a change in the calculation methodology to establish net current income, the growth tendency of this item was significantly reduced from implementation of the FRP. Considering that expenditure on staff represents a large share of the municipal budget, the adoption of measures in this area is fundamental for any government seeking to balance its books. Not replacing civil servants at the same rate as they retire is a factor to analyse in maintaining the public service provided to the population.

Other mechanisms of the FRP were not analysed in this study, such as the Municipal Information Record (CADIN) and the Fiscal Recovery and Stability Fund (FUNREC), approved in June 2019, which aims to use budget surpluses to create financial reserves for use in emergencies, as well as checking whether the measures already implemented continue to provide results for the local authority.

Notes

[1] Data provided by IBGE at https://cidades.ibge.gov.br/brasil/pr/curitiba/pesquisa/38/47001?tipo=rankingandano=2016

[2] The Brazilian LFR refers to Complementary Law nº 101, of 4 May 2000 – It establishes norms of public finance directed to accountability in financial management and makes other provisions.

[3] Curitiba local authority has a Transparency portal containing financial and other information, accessible at https://www.transparencia.curitiba.pr.gov.br/

[4] According to the Treasury of the State of São Paulo, intra-budget income includes current income from organs, local authorities, foundations, dependent companies and other entities belonging to financial budgets and social security, when the income originates from expenditure of the organ, local authority, foundation, dependent company or other entity involved in those budgets, in the same sphere of government.

[5] "Curitiba Receipt" is the local authority's programme to encourage people to request a tax receipt whenever they "consume" any service related to the Service Tax (ST). The most common ones are those provided by schools and nursery schools, further education and language courses, gymnasiums, health plans, beauty salons, mechanical workshops, car parks, pet shops and several others.

Abstract

Russia has a high concentration of population and consumer demand concentrated in several large metropolises. This is reflected in the current state of the transport sharing market, many of whose services have gained widespread use in large urban areas. The development of the Russian transport sharing market allows solving environmental issues, helps reduce transport infrastructure costs and reduce transportation costs in general. At the same time, international experience has shown that the sharing economy provides favorable conditions for startups and attracts venture investors, recognized players in the transport industry. And the combination of consumer trends and technology has allowed the transport industry in developed countries to become one of the leaders of the global economy. However, the analysis performed showed that the Russian transport sharing market is not competitive if compared to foreign counterparts. This is prevented by a number of constraining factors. The paper identifies these risks, detects the factors and causes behind them, and also gives helpful suggestions on how to mitigate their adverse effects.

Keywords: world transport sector, transport sharing, risk matrix.

Introduction

Transport plays a special role in the development of the global economy and people's lives in a diverse and multifaceted fashion. Supporting and accelerating the vigorous interaction of all branches of the economy, the transport sector is inevitably in a state of continuous development and improvement. The systemic changes that are characteristic of the processes of global production and international trade exist due to evolutionary leaps in the world transport sector. The trends of this market follow their own laws. Nevertheless, the laws of this economic sector tend to constantly change under the influence of an endless number of various factors.

At the current stage of economic development, the transport sector is one of the key globalization factors for both international trade and the international division of labor, mass tourism and cultural exchange. Transport affects favorably changes in the world economy as a whole, culture and international relations.

Understanding such a close interaction of the transport sector with many economic sectors, we cannot help but note the influence of many contradictory trends on it, since as an infrastructure sector, transport has a overwhelming ascendancy on the regional and international distribution of production

capacities, is involved in the global reproduction process and assumes the role of one of the most important parts of the economic relationship system.

The urgency and variety of problems that arise due to certain laws and current trends in the development of the world transport services market, and their direct impact on the Russian economy, have determined the research topic.

Lots of research papers that are focused on this area of the world economy pay great attention to the fundamental principles and basics of the transport market, its impact on a variety of macroeconomic processes, and the impact on the country's internal welfare (M.P. Gordon, 1993) (J.C. Johnson, D.F. Wood, D.L. Wardlow, 2002) (A.U. Albekov, 2002). We cannot help but note that these papers also considered the actions of governments aimed at increasing the competitiveness of their countries in the world market of this economy sector (D.S. Nikolaev, 1984) (V.S. Lukinsky, V.I. Berezhnoy, E.V. Berezhnaya, 2004) (L.B. Mirotin, 2003) (V.S. Novitsky, 2016).

It is worth noting that, despite the plurality of various research in this area, significant changes in the development of the world transport services market have not yet been fully and comprehensively covered in the papers of modern researchers. At this stage in the development of the global economy, the transport services market is changing and supplemented based on the emergence of new trends in economic development.

One of the trends in the modern economy that has embraced the transport services market is sharing. The sharing economy could get widespread use due to the emergence of specific services that combine resource owners with those in need of this resource. A weighty argument in favor of the sharing economy is that people in the 21st century desire greater mobility, understand that temporary access to a certain good is much more convenient and profitable than owning it permanently and personally. However, it will not be entirely correct to say that the phenomenon of sharing is a modern trend of the economy only.

This area was rather common and popular in the Soviet Union. On the other hand, the Internet could make it possible to monetize and achieve such a large scale, which makes us describe the sharing economy as a competitive economic model. The sharing model itself has created entire areas in the sectors of goods and services, making money from which was previously considered impossible.

Based on the above, there is a need to choose an optimal development strategy for Russia, which will increase the overall competitiveness of the domestic economy, its long-term and sustainable growth, which means the inevitable enhancement of the sharing economic system. The latter, in turn, is prevented by a number of barriers.

In view of the above, this paper is aimed at determining the constraining factors and risks in the development of the transport sharing market in Russia, as well as searching for tools to mitigate their adverse impact on the Russian transport sharing market.

Methodology

During the study, the following general scientific methods were used: a content analysis method intended to analyze the semantic content of text arrays and products of communicative correspondence related to the subject of the study, as well as tools for inductive and deductive analysis, which allowed combining the authors' individual conclusions on this issue and state the authors' vision of the issue. During the study, we also used special methods: absolute and relative statistical indicators, behavior indicators, methods of visualization for the results of the study. When constructing and describing models, the authors tried to follow the principles of a package approach, which allows establishing the most significant relationships and trends of phenomena and processes in the transport sharing market and formalizing the most significant effects.

The information base of the study consisted of formal statistical and analytical materials of the Russian Ministry of Internal Affairs, RosBusinessConsulting, TADviser, and the Organization of Economic Cooperation and Development.

Results

The results of the study of Russia's position in the transport sharing market makes it possible to conclude that the transport rental market in the Russian Federation has stupendous potential for further development. Most of the transport sharing service platforms are in million-plus cities and in large Russian tourist centers.

And the Russian transport sharing market faces high competition and good consumer demand. One of the growth drivers characterizing the vehicle sharing market in the Russian Federation is high Internet connectivity (Skripkin, 2019). Large distances between cities and the non-uniform development of rail services makes the Russian road carriage market really outstanding in the world transport services market, indicating great potential for growth.

In 2018, the Russian transport sharing market amounted to 7 billion rubles (US$ 107.7 million) versus US$ 3 billion on the world transport sharing market (Samsonova, 2019) (Makarenko, 2018).

The main constraining factors to the development of the transport sharing market in Russia are:

1. Damage or complete destruction of vehicles by users
2. Fraud at the registration
3. Traffic accidents
4. Low level of user engagement
5. High operating expenses
6. Poorly developed urban infrastructure
7. Intoxicated drivers
8. Acts of vandalism by transport sharing users

To better understand the issues affecting the containment of the transport sharing market, we propose to matrix risk information as a “risk matrix”, allowing us to list the risks in descending order of characteristics of their importance.

It is worth noting that the importance of risks in transport sharing is determined not only by one specific parameter, such as, for example, large financial losses, but also by the probability (frequency) of adverse effects.

		Scale of the effects of risk realization				
	Description	Minor	Small	Medium	High	Extremely high
Probability of adverse effects	Almost reliable	5				
	Very likely	4	8	2		3
	Possible		7		1	
	Unlikely					
	Extremely unlikely				6	

Low risk	Medium risk	High risk	Extremely high risk

Fig. 1: Risk matrix of the Russian transport sharing market (Source: compiled by the author).

Consider each of the presented risks in more detail.

1. Damage or complete destruction of a vehicle by the user.

This problem of sharing companies falls into the high-risk category involving financial costs for the lessor. Damage to a vehicle during its operation is rather common in the transport sharing market. This can happen not only through the fault of the renter, but also due to circumstances beyond their control. For example, damage to vehicles by a third party or weather events (Novitsky, 2016). However, these are isolated cases; most often it is the user's negligence that carries the direct risk of damage to the rented vehicle. Here, the lack of rental culture among Russian consumers of services plays an adverse role.

The mind of the Russian user viscerally reckons that we bear less responsibility for other people's property than for our own property. Therefore, sharing companies often note the negligence of national users towards damage to rental vehicles. (see Fig. 2).

Fig. 2: Statistics of accidented transport in Russia (Source: compiled by the author).

Quite often, aggregators noted cases of dodging responsibility for damage to vehicles caused during rental. And even tightening the terms of the rental contract does not help minimize the financial costs of remedying the consequences of such damage. There are several causes behind this: from the mere

inability to recover the amount of damage from a particular user to the underdeveloped legislative and regulatory framework.

2. Fraud at user registration on the platform.

The existence of a black market of accounts for using rental cars with other people's particulars is a problem not so much of a financial nature as of a reputational one for aggregators. Indeed, the violator does not bear any responsibility either to the sharing platform, or to other road users.

According to Konstantin Semenov, the head of technical audit at Group-IB, there are two main ways for violators to use fraudulent data when using rental vehicles: firstly, when registering on a sharing platform, the user uses other people's data acquired on external Internet resources. Secondly, fraudsters use already existing accounts, records of people who have been successfully verified, but did not secure their personal data (Moskalenko, 2016).

With such access, violators can feel free to drive a rental vehicle at other people's expense, cannibalize vehicles, and not bother with abidance by traffic regulations. (see Fig. 3).

Fig. 3: Statistics of traffic accidents involving sharing transport in 2019 (Source: Compiled by TASS News Agency according to the Ministry of Internal Affairs).

According to data published by Dr Web, it has been known that Russian aggregators have different levels of protection, but each of them has the same weakness, namely, poor protection from MITM attacks, which are used to received the contents of sharing platforms' databases.

3. Traffic accidents. Vehicles provided by sharing platforms are one of the most dangerous road users, both in terms of the frequency of accidents users get into, and in terms of the severity of financial losses for aggregators. Complete destruction of a vehicle happens much more often in this segment than in other areas of transport services in the Russian region.

Insurance claims are mainly due to traffic accidents, where the guilty party is most often a sharing platform customer. On average, the frequency of losses is 3-4 times higher than the average one. This is due to several reasons: firstly, due to the high usage rate of sharing vehicles, with an average mileage of more than 45 thousand km in year; secondly, from the demographic data of Russian users of transport sharing, it becomes clear that the average age of the customer is 18-25 years, which means they have small real driving experience, which adversely affects the driving pattern (Vavilin, 2005).

4. Low level of engagement of transport sharing user.

The Russian transport sharing market is short of users of its services. On average, there are 1,082 users per vehicle, which is very few with a fleet of 120,000 vehicles. Since the sharing industry in the transport segment of the Russian market is at the start, people are poorly informed about this service. Most of the Russian people still believe that the sole car ownership is more profitable and comfortable compared to sharing (Ulitskaya, 2014).

However, according to the Ministry of Transport, major metropolises in the country are experiencing an overload of the transport system by about 30%; in view of this, a number of actions are being taken to limit the number of private vehicles. A perfect example of these measures is the introduction of paid parking areas in major cities of the country, an increase in property taxes and other fees and levies.

In addition, according to statistics, vehicles are used by owners during only 5% of the time, they are simply idle during the remaining 95% (Semenikhin, 2011), which involves enormous financial costs in the form of taxes, maintenance, payment of insurance premiums, fuel costs, payment of parking areas.

In addition, for most Russian people, the cost of transport sharing services is unbelievably high (the average monthly cost of car rental is about 4 thousand rubles), lots of people who have no private vehicle would like to use rental ones, but reject this due to high rates and high liability for damage to the vehicle (the average amount of liability for damage to the vehicle in an insured event is 50 thousand rubles) this.

5. High operating expenses.

Most of sharing companies in transport services in the Russian region incur huge financial costs due to high operating expenses (Gordon, 1993). They include leasing costs related to the acquisition of the required number of vehicles in the aggregator's fleet, since a small number of vehicles will not allow the operator to profit from its services and occupy a market share necessary for this. (see Fig. 4).

Fig. 4: Shares of transport sharing services in Russia by the number of vehicles (Source: compiled by the author).

Another source of costs for transport sharing aggregators is vehicle maintenance. The Russian laws clearly regulate the timeframe for technical checkup and violation of these standards entails considerable penalties. In addition, the maintenance and repair of vehicles is very costly: it includes both the replacement of consumables and the purchase of the necessary spare parts to replace already worn-out parts.

Costs related to purchase of fuel and payment for parking facilities are also included in the operating expenses of sharing services (Sutyagin, 2009). This also includes the costs related to insurance policies, without which it is simply impossible to provide services in transport rental.

6. Underdeveloped transport infrastructure.

As noted earlier, large distances between cities and the non-uniform development of rail services makes the Russian road carriage market really outstanding in the global transport services market, indicating great potential for growth. However, Russia's transport infrastructure is underdeveloped compared to the European market (Ulitskaya, 2014). About 70% of road pavements in the Russian region are in disrepair and require major repairs. In addition to the technical state, the system of traffic interchanges and connections is also a problem. It is not designed for such a number of vehicles, which results in a periodic overload of traffic arteries leading to large financial and tourist regions. (see Fig. 5).

Fig. 5: Load on the transport infrastructure of Russia in 2019 (Source: Based on the research data from RBC)

As noted earlier, urban infrastructure is currently experiencing an overload of vehicles of about 30% in large metropolises. Poor integration of urban and public transport does not allow sharing transport aggregators to function optimally within a city (Afontsev, Belova, 2019).

7. Intoxicated drivers. This problem falls within the group of medium risks of sharing services and is within the tolerance limits.

Despite this, intoxicated drivers create certain reputation risks for sharing aggregators. Such extent of driving under the influence is, perhaps, characteristic of the Russian region only. The high level of irresponsibility of such users is often dangerous not only for the road users around them, but also for themselves.

Russian transport sharing services include into their rental agreements a ban on driving under the influence and on carriage of intoxicated passengers, violation of this clause of the contract entails large punitive measures up to blocking the user by the aggregator.

In addition to the service fines provided for by the service company, where a traffic accident occurs through the fault of an intoxicated driver, the insurance policy of the company does not cover the losses incurred and such a user pays all costs by themselves.

8. Acts of vandalism by transport sharing users.

Cases of vandalism by users in relation to the aggregator's property fall within the group of medium risks and cause minor financial losses to companies. However, with a small scale of the consequences of such actions, there is another risk parameter – their frequency, which places this financial risk to the area of increased control by the aggregator (see Fig. 6).

Fig. 6: Statistics of small thefts from rental vehicles in 2019 (Source: Compiled by TASS News Agency according to the Ministry of Internal Affairs).

With an insufficient culture of rental, most of the Russian users of transport sharing services feel free to inflict small-scale damage to the property of the service.

Conclusions

Based on generalized assessments of the above adverse factors, it may be concluded that the Russian transport sharing market is low competitive as a whole. As of today, Russia has no opportunity to change its position in the system of the world transport sharing market, since a number of identified problems should be solved in order to switch to an innovative development path.

Conclusion

Despite the fact that currently, the development model of the Russian transport sharing market can hardly be called ideal, based on the analysis of the identified risks and constraining factors of the Russian transport sharing market, recommendations on strengthening Russia's position in the global transport sharing market can be made:

1. The general culture of rental should be increased among the people of Russia by influencing users through a package of measures aimed at improving the quality and safety of the service;

2. It is necessary to ensure that vehicles are equipped with telematics sensors, devices for control of user road behavior and actions with the property of the rental company; the introduction of the

gamification process and the deep penetration of digitalization in the infrastructure of cities with a population of over 1 million people should be considered as priority tasks for Russian transport sharing market;

3. It is worth paying attention to the decrease of the number of personal vehicles or to the attraction of a bigger number of these vehicles in the sharing system within 5-10 years in order to decrease the adverse impact on the environment, as well as in connection with the trend of universal urbanization to decrease the load on transport infrastructure.

Role and Significance of Crisis Management in Enterprises

Magdalena BSOUL- KOPOWSKA

m.bsoul@vp.pl,

Abstract

Dynamically changing environment, necessity to adjust to the growing demands of customers and emerging crises in the organisation force the enterprises to verify their hitherto modes of operation. A crisis is a unique situation which determines the mode of functioning of an organisation. A crisis is often perceived as a pejorative phenomenon, which adversely affects the organisation's development and is a threat for the meeting of its goals and, in case no steps or incorrect steps are taken, may lead to the fall of the enterprise. However, it may also be a stimulus to act and it may constructively affect the company's operation. A company, reacting to a crisis, has to assess the conditions both in its environment, as well as internally and verify the artefacts, the system of values and the major principles which form the basis of building its organisational culture. Therefore the management, apart from taking steps related to current operation, should also act in the area of crisis management. This article attempts to present complex issues of crisis management in the micro-, small and medium-sized enterprises taking into account the fact that the situation of crisis is inseparable element of the operation of each enterprise. While conducting the research (from December 2019 to February 2020), 33 companies were surveyed. The statistical analysis of the data showed statistically significant differences between the size of the enterprise and getting the company into crisis. The results of the conducted research indicate, among others, that the susceptibility to crisis situations decreases as the size of the enterprise increases.

Keywords: Crisis Management, Enterprise, Crisis in Organisation, Crisis Situation Management

Introduction

Theoretical Bases of Crisis Management

The issue of crisis management involves the necessity of discussing the aspects which are the source of organised thinking and acting with respect to this matter. This source is a crisis-type situation, i.e. crisis situations and crises which may have an adverse effect on the operation of an enterprise. They may also include phenomena that have a positive impact on the organisation, yet on account of their sudden, unexpected and thus difficult character, they disrupt the continuity of social, political, economic and other processes (Kitler, Wiśniewski, Prońko, 2000, p. 133).

Literature devoted to the issues related to management in crisis situations contains numerous endeavours at defining the phenomenon known as a crisis. A crisis is identified as a quite unexpected and strong phenomenon, changing the hitherto state of affairs and processes occurring within an organisation in an unexpected and undesired direction, thus threatening the hitherto transformations. Etymology of the of the verb krinein, which derives from Greek, means to separate, to sieve off, to decide, to judge, whereas the noun krisis that stems from it means a choice or a decision. Thus, in the most common understanding, a crisis is a breakthrough moment, a turning point at a time most dangerous to an organisation in the current situation, which is the least advantageous for it among any other possible ones. It is generally believed that a crisis situation emerges as a result of a specific state of threat. Its culminating moment is materialisation of a possibility of realisation of specific threats, should it be impossible to counteract the intensification of individual elements that co-determine it. The beginning of a crisis situation takes place at the moment of appearance of signs

indicating rapid materialisation of actual threats which, in general, are perceptible in a given organisation.

Therefore, the goal of crisis management is to counteract the potential, as well as the actual threats and to get prepared for their occurrence, along with keeping or restoring the original status. The intention of crisis management is to ensure safety for an organisation by fostering conditions for all entities within a specific area of possibilities to develop and to accomplish a sense of certain control over the potential threats, including their monitoring, early detection and accumulating measures to counteract them.

The principles of counter-measures may encompass procedures and incentives prepared by the management of a given organisation to grasp control over the already existing crisis, reducing its effects, which is called crisis reaction (Sienkiewicz, Górny, 2001, p. 28). This may also be a process of actions undertaken by an organisation which is aimed at preventing a crisis situation and, in case of its materialisation, at attempts intended to counteract dangerous phenomena. Such actions are commonly known as crisis situation management (Wróblewski, 1996, p. 39).

Review of Crisis Management Definitions in Organizations

In the life of every organisation, crisis is a unique phenomenon. On the one hand, the possibility of its occurrence may become the source of destructive threats and, in consequence, lead to the collapse of the organisation, yet on the other hand, it may stimulate it to positive renewal and offer it an opportunity for further development. The inevitability of crises phenomena in the modern organisations gives rise to the necessity of their early detection, diagnosis and subsequently overcoming. This, in turn, induces the necessity of understanding the core of the crisis phenomenon and its premises.

The concept of a crisis in an organisation is difficult to define on account of its multidimensionality and various subjective references. This term may be referred not only to economic phenomena, but also to social, technical, organisational and legal aspects, to individual persons and communities with pre-defined internal organisation and management systems. In the common understanding, a crisis in general means a difficult situation which either exists or may happen. In the universal sense, the term crisis is understood as a turning point in any course of events, a decisive moment, a breakthrough moment, a stage or an event after which a change happens.

Reference books on the subject include a number of definitions of crisis management. An interesting definition of crisis management is provided in a study entitled “Generic Crisis Management Handbook” in line with which crisis management is to be perceived in a broad perspective, taking into account such procedures and activities that are intended to take-over control over a crisis situation by crisis managers and which allow them to shape the course of the crisis via preparatory activities (Wiśniewski, 1014, p. 79).

According to M. Madej (2010, p.102), “in the world of business where crisis management is understood in line with the definition deriving from its cradle - the United States - it constitutes a set of organisational, logistic and financial measures the aim of which is to prevent emergence of crisis situations, ensure efficiency of decision-making structures on all levels of management, continuous readiness of authorities and measures to take action, efficiently react to and liquidate the effects of the existing situation”. Thus, crisis management consists in: counteracting the threats, both potential and current ones; preparing for the occurrence of threats or reacting to the existing crisis situations and subsequently preserving or restoring the original status. On the other hand, R. Barton (1993) believes that a crisis is a major, unpredictable event which has potentially adverse effects, significantly limiting the operation of an organisation in the area of production, services, employment, financial condition and reputation. In turn, according to J.R. Caponigro (1998), a crisis is any event or action that may have a potentially negative impact on the reliability and efficiency of business and - typically - remains or will soon get out of control of such business. I. I. Mitroff (2001) defines a

crisis as an effect of emergence of unexpected disturbances in the operation of an organisation, including internal and external (fortuitous type) factors. For Ch. F. Herman (1963), a crisis is a status that threatens the survival of a company, meeting the company's goals, reduces time available for commencement of repair actions and surprises the decision-makers with its emergence, thus creating the conditions of strong pressure.

A crisis may also be examined as a stage in the cycle of an enterprise. And thus, P. F. Drucker (1992, p.138) believes that a crisis is an inevitable and ineluctable event accompanying organisations. According to him, a crisis in an organisation is a consequence of stages in the life cycle of sectors, in particular specialist companies, whereas innovations cannot offer a guarantee for disappearance of crisis and survival of a company. In turn, R. Oldcorn (1989, p. 237) defines a crisis as an ineluctable, repetitive process resulting from stages in an organisation's cycle. He presents it as the "product of unplanned events, which may disrupt or threaten the normal operation of a company".

Based on the review of crisis concepts, a crisis definition was adopted for the needs of this paper where a crisis is understood as a state of threat, where - as a result of accumulation of various difficulties - performance of basic functions of an organisation is at risk.

Crises have various sources, their impact encompasses both individual parts and entire organisations. Their duration may vary, along with their effects. However, it may be noted that they always affect the organisation, either indirectly or directly. Only the company can determine whether a crisis will have a positive or adverse impact on it. A. Zelek (2003, p. 40) attracts attention to the fact that in spite of the variety, the multiple meanings and the ambiguity in interpreting crisis phenomena in an organisation, it is possible to indicate their basic features, which include: durable disturbed operation of the organisation; actual or alleged loss of control over the operation; disrupted internal balance of the organisation; threat to the existence of the organisation or its part (function); aggravation of financial condition of the organisation; threat to the meeting of strategic objectives of the company; ambivalence of the possibilities of development and repair; possibility of infringement or loss of public trust and inner faith in the organisation, which aggravates its image; reduced time of decision making; high degree of uncertainty causing fear and anxiety among the employees and low level of predictability - an element of surprise.

The analysis of the researches of crisis situations in Polish enterprises lead to the conclusion that their causes lie both in the environment and in improper management (Wawrzyniak, 2002, pp. 53-56). Surveys conducted by A. Zelek (2002) on a sample of 117 West Pomeranian enterprises in 2002 indicate that the main causes of the external crises in Polish enterprises include: the recession in the Polish economy (67.6%); the increase in competition level (65.0%); the recession in a given industry (44.2%); payment gridlocks (42.5%); the unemployment rate (41.3%); high interest rate (35.2%); inflation (11.5%) or frequent changes in managerial positions (8.8%). On the other hand, the internal causes include the following: mismanagement (38.2%); lack of capital (35.3%); low efficiency (18.5%); lack of development strategy (18.0%); personnel conflicts (17.5%); random events (14.7%) or wrong pricing policy (11.8%). Hence, the most common reasons for the emergence of the crisis in Polish enterprises were: recession in the national economy and a given industry, growing domestic and international competition, lack of capital and payment gridlocks as well as poor management. In contrast, the results of the surveys conducted by A. Zakrzewska-Bielawska (2008, pp. 65-92) on a sample of 65 large (employing over 249 people) enterprises from all over Poland in 2001 show that the enterprises which have undertaken restructuring activities also indicate such internal reasons as: excessive employment and too high labor costs, changing customer expectations and the need to introduce new products, excess of fixed assets and the resulting high financial burdens, while also insufficiently developed marketing activity. Therefore, presented considerations show that there are numerous reasons for the crisis of enterprises. In general, it can be stated that any negative phenomena for an organization, regardless of the area which they concern, may constitute a reason for crisis.

The purpose of crisis management is thus striving to minimise the potential threats and efficient performance of activities in case of their occurrence, the efficiency of which depends, to a significant degree, on skills, competence and rights both of persons managing such activities, as well as units taking part in a crisis situation. In this case, capacity means the ability to accomplish the goals that were set, whereas efficiency - the degree of accomplishing them (Sienkiewicz-Małyjurek, Krynojewski, 2010). In relation to this, the complexity of the issue of crisis management results from the necessity of taking actions that are adequate to the threat before its emergence, i.e. such actions that do not allow for the materialisation of a crisis situation. On this account, crisis management attaches significant attention to proper identification of materialisation of potential threats and, in case of their occurrence, planning of activities, making a division of obligations and areas of competence of entities participating in it, preparation of measures and technologies for using them, distribution of activities in the field that are adequate to the needs, spatial management and monitoring of existing security systems.

Study Methodology

In the modern economy, enterprises must implement proper action strategies in the conditions of risk and uncertainty, create management scenarios with respect to unpredictable crisis situations and rapid response programmes, as well as reinforce internal mechanisms for balance restoration.

The purpose of this paper is an attempt at showing a complex problem of managing a crisis situation in an enterprise, taking into account the fact that a crisis situation is an indispensable element of operation of every company.

The author of this paper tried to find answers to the following questions:

1. Can a crisis situation be managed, in particular in the conditions of uncertainty and chaos?
2. Is managerial personnel capable of managing a crisis situation when it is difficult to foresee the potential threats?
3. Are companies susceptible to crisis situations?
4. What are the causes of crisis situations in companies?
5. How do companies react to crisis situations?
6. What is the assessment of utility of tools for managing a crisis situation in the opinion of persons managing a small and medium-sized enterprise?

The following hypotheses were adopted for survey purposes in this paper:

1. The awareness of the necessity of managing a crisis situation grows along with the size of an enterprise.
2. Susceptibility to crisis situations is reduced along with the growth of awareness of the necessity of managing a crisis situation.
3. Managing a crisis situation allows for faster identification of problems and, in consequence, for the existing changes.
4. The awareness of the necessity of managing a crisis situations increases with the size of an enterprise.

To receive answers to these questions and research hypotheses, a questionnaire survey was used. The main survey was preceded by a pilot one, thanks to which less significant questions for the examined problem were eliminated. The final version of the questionnaire included: a description of the survey and 23 closed-ended questions with an option of individual response in case the respondent did not find a fitting answer. The questionnaire was divided into four parts. The first part of the questionnaire referred to enterprises which were in a crisis situation. The questions were meant to describe the characteristics of crisis situations which small and medium-sized enterprises encountered and check the degree of preparation with respect to a given crisis situation. The second part referred to the issues of managing a crisis situation. The third part focused on the management of a crisis situation at the stage of current operation. The last part included demographics questions. The questionnaire was carried out by means of telephone interviews and categorised interviews among owners of micro,

small and medium-sized enterprises or their managers. During the survey (from December 2019 to February 2020), 47 interviews were carried out among small and medium-sized enterprises conducting their business in the area of the Silesian Province, out of which 33 companies decided to undergo the survey and passed positive verification.

Microsoft's EXCEL and Word programmes, along with the statistical package, STATISTICA 13.3, were used to analyse the collected research material and graphic presentations.

Survey Results

In the surveyed group of companies, micro-companies (employing up to 9 persons) and small companies (employing between 10 and 49 persons) had the largest share, which amounted to 72.2%. In the discussed group, small companies were definitely dominant, which made up 61.5%. Micro-companies were only 10.7%. On the other hand, the group of medium-sized enterprises (employing from 50 to 245 persons) constituted 27.8%. The largest group of surveyed companied was involved in services (49.2%), subsequently production (27.7%), retail sale (24.6%) and wholesale trade (24.4%). The results of the author's own survey show that almost a half of surveyed companies (48.7%) experienced a crisis situation at least once. Statistical analysis of data showed statistically significant variation with respect to the size of a company and the experience of a crisis situation. In the case of micro-companies, susceptibility to crisis situations was as follows: 67.4% were susceptible, 32.6% were not susceptible; in the case of small companies: 56.2% were susceptible, 43.8% were not susceptible; in the case medium-sized companies: 38.5% were susceptible and 61.5% were not susceptible. Thus, an assumption can be made that the smaller the company, the greater its susceptibility to crisis situations.

In the group of surveyed companies, a crisis situation was most often manifested by a drop in sale (36.5% in the case of micro-companies, 30.2% in the case of small companies, and 27.6% in the case of medium-sized companies), a drop in the market share (18.2% in the case of micro-companies, 17% in the case of small companies and 21.4% in the case of medium-sized companies), aggravating atmosphere at work (19.1% in the case of micro-companies, 15.2% in the case of small companies and 19.8% in the case of medium-sized companies) or loss of financial liquidity (15.2% in the case of micro-companies, 13.4% in the case of small companies and 14.3% in the case of medium-sized enterprises). Only 7.4% of the surveyed companies indicated aggravating company image.

A further part of the survey referred to the determination of the causes of the existing crisis situations in the surveyed companies. The analysis of the author's own survey has shown that as many as over 70% of small and medium-sized enterprises covered by the survey indicated changes in the external environment of the enterprise as the causes of a crisis situation, which included: amount of taxes, rate of economic growth, state policy with respect to entrepreneurs and competitors' activities. On the other hand, internal causes included conflicts among employees, incorrect management, errors made by employees and lack of an adequate strategy.

In turn, the surveyed micro-companies listed the following factors as the external causes of crisis situations: incorrect state policy with respect to entrepreneurs, competitors' activities and problems with business partners. Internal causes listed most often included improper company management, conflicts at work place and lack of capital.

The surveyed companies reacted to a crisis situation most often by implementing the following repair activities: organisational changes: micro-companies 52%, small enterprises: 59% and medium-sized enterprises: 78%; overall cost reduction: micro-companies 75%, small enterprises 68% and medium-sized enterprises 69%; improvement of financial control: micro-companies 32%; small enterprises 39% and medium-sized enterprises 31%; market restructuring: micro-companies 33%, small enterprises 49% and medium-sized enterprises 34%; reduction in marketing expenditure: micro-companies 5%, small enterprises 27% and medium-sized enterprises 34% and replacement of managing personnel: micro-companies 7%, small enterprises 15% and medium-sized enterprises

28%. The received results show that the larger the company, the more often it introduced organisational changes in order to be able to get out of a crisis situation. The above-listed organisational changes often referred to a reduction in employment.

As part the performed survey, the companies taking part in it also took a stance with respect to the applied tools for managing a crisis situation, such as: anti-crisis teams, procedures of conduct in crisis situations, emergency plans in case of a crisis situation or a communication system during a crisis situation. The analysis of received responses has shown that the degree of utility of some tools increased along with the growth of the company's size. The surveyed companies most often apply emergency plans in case of a crisis situation (over 61%); the second element used most frequently are the prepared procedures of conduct during a crisis situation (58%); the third position is taken up by a communication system during a crisis situation (32%). In the last place, the surveyed companies indicated the necessity of using anti-crisis teams (19%). Such teams are most often used in small and medium-sized companies: 46% and 59%, respectively.

On the other hand, factors that according to the surveyed companies most often hinder preparation for a crisis situation include limited possibilities of foreseeing a crisis situation: micro-companies 47%, small enterprises 49% and medium-sized enterprises 56%; external factors of the enterprise: micro-companies 46%, small enterprises 48% and medium-sized enterprises 52%; no experience in managing a crisis situation: micro-companies 44%, small enterprises 42% and medium-sized enterprises 36%; and lack of funds and proper resources: micro-companies 36%, small enterprises 38% and medium-sized enterprises 39%.

Bearing in mind that 48.7% of enterprises experienced a crisis situation at least once, 62% of respondents among small and 61% among medium-sized enterprises declare preparation for a crisis situation at the stage of current operation. Preparation for a crisis situation is different in the case of micro-companies, among which only 39% declared preparation for a crisis situation.

Discussion

Dynamically changing environment, necessity of adjusting to the growing demands of customers and emerging crises in the organisation force the enterprises to verify their hitherto modes of operation. Sources and causes of crisis phenomena may derive from inside the company, as well as from its environment. Crisis situations affect companies in varied degrees. Some enterprises are affected directly and a crisis has burdensome consequences; it has an indirect impact on others, whereas few companies do not feel its influence. A crisis makes companies more aware of the problem of uncertainty, unpredictability and instability of the economic situation (Orłowski et al. 2010, p. 28).

In relation to the fact that every crisis is usually unique on account of its course in reference to a specific company, it is difficult to have ready-made solutions. Therefore, every crisis requires an individual approach.

On account of the broad range of the author's survey, only selected results are presented for the purpose of this paper, which were meant to provide answers to the questions referring to the subject matter discussed in it. And thus, in response to the following questions: can a crisis situation be managed, in particular in the conditions of uncertainty and chaos? The answer is affirmative in reference to these companies that are more aware of the significance of a crisis situation and its potential effects and with respect to the ones which undertake a number of actions as part of a broadly understood process of crisis management. On the other hand, in the case of companies that do not manifest great activity or do not handle the existing situation well, improper management of a crisis situation had adverse effects.

Whilst discussing the management of a crisis situation, it must be remembered that managerial personnel plays a key role in this process. Such personnel is under the obligation of management in

an efficient and professional manner in the existing crisis situation. According to K. Krzakiewicz (2005, s. 22), managerial personnel is required to make professional decisions, the goal of which should be to counteract crisis situations and to focus efforts on selected priorities in order to overcome them and to avoid the consequences of adverse crisis phenomena.. Thus, is managerial personnel capable of managing a crisis situation when it is difficult to foresee the potential threats? The conducted survey shows that over 60% of both small and medium-sized enterprises declare preparation for a crisis situation. It is worth noting that these are the companies that had already dealt with a crisis situation before. On the other hand, micro-companies have a problem. Only 39% declared such preparation. Difficulties with evaluating preparation of micro-companies may result from insufficient knowledge not only within the range of crisis situation management, but also weak awareness of bases of functioning of an enterprise which, as already mentioned, is confirmed by the PARP (Polish Agency for Enterprise Development) study results (Orłowski et al. 2010, p. 17). It should also be remembered that there are no universal solutions and verified reactions to all crisis situations that could be applied as a pattern. Awareness of small and medium-sized enterprises that proper preparation for a crisis situation will allow them to reduce the risk of occurrence of serious consequences is vital. Thus, are the surveyed companies susceptible to crisis situations? Statistical analysis of data showed statistically significant variation with respect to the size of a company and the experience of a crisis situation. The results of the conducted survey show that susceptibility to crisis situations decreases along with the growth of a company.

In the case of small and medium-sized enterprises, the external causes most often included the amount of taxes, the rate of economic growth, the state policy and competition. On the other hand, micro-companies indicate - as external causes of crisis situations - incorrect state policy towards entrepreneurs in the first place; in the second place - often unfair practices of competitors and, in the third place - problems with business partners. On the other hand, as internal factors, small and medium-sized companies most often listed: conflicts among employees, improper management, errors made by employees and lack of a proper strategy. In the case of micro-companies, internal causes indicated most often included improper company management, conflicts at work place and lack of capital.

The surveyed companies reacted to a crisis situation by implementing the following repair activities: organisational changes, overall reduction of costs, improved financial control, market restructuring and reduction in marketing expenditure. The larger the company, the more frequent introduction of organisational changes in order to get out of the crisis situation. It is also worth noting that companies that had experienced a crisis situation before more often consider crisis situation management useful in comparison to companies which had not experienced such situation. Thus, crisis situation management consists in taking specific steps that allow for avoiding crisis and in case of its occurrence enable reduction of its adverse consequences.

Therefore, what is the assessment of utility of tools for managing a crisis situation in the opinion of persons managing a small and medium-sized enterprise? The received results show that larger companies assess the utility of tools used in crisis situation management better. The conducted survey confirmed doubts related to weak preparation of companies for potential crisis situations and a slight percentage of companies using all tools to manage a crisis situation. It showed that slightly over a half of surveyed companies (61%) had emergency plans. Only over a half (58%) of surveyed companies implemented procedures that had to be followed in case of potential crisis situations. Least popular was having anti-crisis teams: only 19% of companied had such teams.

Thus, it may be declared that all of the hypotheses set in this survey were positively verified.

Conclusions

A crisis adversely affects the organisation's development and is a threat for the meeting of its goals and, in case no or incorrect steps are taken, it may lead to the fall of the enterprise. However, it may also be a stimulus to act and it may constructively affect the company’s operation. Managers of small

and medium-sized enterprises believe that crisis situation management, including planning, is less important from their point of view. Some of them assume that insuring a company is going to protect it against any crisis and in relation to this, no additional activities are necessary. Another reason for which some small and medium-sized enterprises do not manage a crisis situation is the absence of proper tangible and intangible resources which facilitate adequate preparation. Furthermore, entrepreneurs indicate lack of time for preparing emergency plans and other activities that are related to the preparation for a crisis situation and do not see the necessity for setting up crisis teams. They explain it by lack of finances and the fact that the future is too uncertain in order to foresee it. Managers of surveyed companies also believe that serious crises happen so rarely that they do not require special procedures and that one has to react to the crisis when it materialises.

On March 4th, after the above-mentioned studies had been completed, the first case of COVID-19 infection appeared in Poland, which significantly affected functioning of the SME enterprises, including those who participated in the above research. In recent days, the large amount of entrepreneurs have been suspending business activity and have been informing labor offices about planned collective redundancies. As a result of the outbreak of the coronavirus pandemic and the restrictions introduced by the government only on March 31st, as many as 9,151 entrepreneurs suspended business activity in Poland and 1,353 closed them down. This is twice as much as in the same period a year ago. According to the Polska Press Information Agency, in March 2020 a total of 58.7 thousand applications were submitted to the Central Registration and Information on Business (CEIDG) regarding suspension and closing down of business activity. The survey conducted among the entrepreneurs by Employers of Poland (Pracodawcy RP) shows that in April the scale of terminations of employment will be enormous. Every fifth company plans to lay off 20% of employees, and every tenth - 30%. In total, up to 66% of companies plan some kind of reductions of personnel. Moreover, the entrepreneurs do not count on the government's so called anti-crisis shield because, according to many experts, it does not solve the most urgent problems which entrepreneurs currently have to face. As many as 78% of entrepreneurs assess the solutions adopted in the anti-crisis shield as very bad (54%) or bad (24%). Only 7% of them judge the solutions positively (https://polskatimes.pl/przedsiebiorcy-masowo-zawieszaja-dzialalnosc-gospodarcza-tysiace-firm-nie-moze-funkcjonowac-przez-koronawirusa-raport-polska/ar/c1-14893619). The pandemic threat has not been taken into account in the area of threats to the small, medium and large enterprises, therefore I believe that this research should be repeated after the end of the COVID-19 pandemic.

Measuring the Goals of Lean Management Concept Implementation

Nicoletta BASKIEWICZ

Czestochowa University of Technology, Czestochowa, Poland
nicoletta.baskiewicz@pcz.pl

Abstract

The purpose of this paper is to elaborate on the issues of efficient implementation of the Lean Management concept in enterprises. Such efficiency was treated very comprehensively; on the basis of several dozen papers available on-line, quantitative measures were identified and thanks to them, areas of implementation were determined, along with objective assessment of progress in implementation and subsequently application of the Lean Management concept. Furthermore, these measures were thematically grouped and assigned to one out of four areas of Lean Management maturity areas. Literature studies carried out as part of this paper seem to be of key importance for the assessment of the functioning of companies in general (not only the ones applying Lean Management), as they indicate gaps and deficiencies along with directions of changes aimed at improvement of efficiency in operating activities in almost every area of the company's operation.

Keywords: Lean Management concept, Lean Management implementation process, Lean Management implementation efficiency, Lean Management efficiency measures, Lean Management maturity.

Introduction

Already at the pre-implementation stage, i.e. initiation and conceptualisation of the implementation process of Lean Management, activities aimed at transforming the needs and benefits into specific and thought-through goals seem to be important; they are going to constitute a point of reference with respect to the monitoring and control activities of both the implementation process as such, as well as the outcomes of such implementation and measurements of the degree of maturity in the application of the Lean Management concept. The role of every well-defined goal is to transform the needs or the expected benefits into specific and clear results. Most frequently, guidelines of the SMART approach are used for correct identification of goals, which assumes that goals should define specific results described with the use of precise measurable indices, which enable evaluation of the degree of success accomplishment; in this case, it is going to be the level of maturity of Lean Management, expressed by the advancement in the application of Lean Management. A vital issue from the point of view of goal determination is the choice of parameters which, in the fullest mode, illustrate the level of goal accomplishment. Thus, a situation must be ruled out where measurement is only made because such possibility exists and not because it is necessary. Basili, Caldiera and Rombach prepared a methodology for identifying and determining goal parameters by asking a set of questions and group answers given to them. Such conduct led to the separation of activities only in areas of key importance for the implementation of Lean (Basili, Caldiera, Rombach, 1994, p. 98). Another feature of a well-defined goal is its feasibility within the scope of cost and implementation time. This feature is particularly important, as lack of faith in the possibility of meeting the goal weakens the employees' morals and reduces faith in the operation of the company as a whole. Overly ambitious goals, instead of being a challenge, too often become the cause of reduced self-confidence of organisation members, thus becoming a basic source of resistance against implementation of Lean Management.

Literature Review

At the implementation stage, monitoring and control processes seem to be of key importance for the efficiency of undertaken activities (Darońń, Górska 2019). Monitoring and control of the implementation process of Lean consists in identifying and subsequently tracing divergences from the plan and taking the necessary corrective actions (Azharul, Kazi 2013, pp. 169-196). In this place, it is worth noting that the ongoing control of implementation determines the planned implementation of the Lean system and allows for identification of all factors (Sanjay 2011 pp. 55-74; Jagdeep, Harwinder 2012, pp. 88-111) affecting its implementation (PMI, 2008). Based on the studies of Kumar and Phrommathed (Kumar, Phrommathed 2006, pp. 104-132), it may be ascertained that lack of specification of measurable outcomes of the implementation process (Podobiński 2015, pp. 5-15), as well as the lack of the continuous monitoring of the process of implementation of Lean Management result in a chaotic transformation (Peter, Anders, Per, Pia 2012, pp. 829-849). Furthermore, broadly conducted control activities ensure maintenance of Lean effects in an extended perspective of time (Todd, Maike, Ian 2011, pp. 587-603). Additionally, continuous control of both the implementation, as well as the subsequent application of the Lean concepts and tools prevents return to previous practice (Mohamad, Hom, Ashraf, Nick 2013, pp. 280-320). Both the implementation and the subsequent application of the Lean Management concepts is supported by a broad array of tools, prepared in the greatest degree by Japanese employees of the automotive industry (Lokman, Lanita, 2014, pp. 83-115). Analytical and control tools that form a basis of such set allow for analysis of the implemented processes (Shah, Ward 2007, pp. 785-805).

Research Question

However, one should be aware that the Lean Management concept, stemming from the Lean Management philosophy, is characterised by a holistic approach (Bhasin 2011, p. 56). Nevertheless, in spite of the fact that there are a number of tools, they are often inadequately used - one tool is used to solve all problems or all tools are used to solve one problem, alternatively the knowledge and experience are missing in the precise matching of a tool to the problem (Pavnaskar, Gershenson, Jambekar 2003, p. 16).

Taking the above into account, the following research questions were set:

1. What are the areas of maturity in the implementation (application) of the Lean Management concept?
2. What are the principles used in the application of the Lean Management concept and how do they correspond to the maturity areas?
3. What are the factors determining the implementation of the identified principles of applying the Lean Management concept?
4. What measures can be distinguished that allow for the verification and assessment of implementation of individual factors that determine the application of the LM principles?
5. What should be the direction of changes in the values of individual measures in order to accomplish maturity in the application of the Lean Management concepts?

Research Design and Methodology

With the aim of answering the research questions that were set, analysis of reference books was carried out, on the basis of which four areas of maturity in the application of the Lean Management concept were distinguished (leadership, people, processes and outcomes). Subsequently, also based on the scientific knowledge, principles guiding the enterprises that apply the Lean Management concept in practice were identified. Another step was determination of factors that allow for the application of the previously identified principles and finally, the factors were assigned to measures along with target values.

In this place, it is worth noting that in spite of the fact that the literature on conceptual premises, determinants of implementation and implementation as such, along with benefits resulting from it, is extensive, yet a systematic approach to such knowledge was missing, along with a breakdown which could be broadly used in the economic practice.

Results

Proper identification of factors determining the implementation of goals that were set is crucial for the formulation of measures. Similarly to goals, measures verifying their accomplishment were also divided into four areas in line with the maturity theory (Pieńkowski 2016, p. 158) in the application of the Lean Management concept (Table No. 1).

Table 1: Measures and desired directions of their formation

Area	LM Principle	Determinant	Measure	Desired directions of measure formation
LEADERSHIP	Decentralisation of liability	Supervisory tasks performed by teams	Leadership in a team is entrusted to its member (e.g. a foreman) Supervisory tasks are performed by a team Separated supervisory level in an organisation	↑
		Leadership in a team	Percentage of employees who are capable of performing leader functions	↑
			Percentage of employees accepting internal leaders	↑
		Hierarchy in organisation	Number of organisational levels in a production organisation	↓
		Area of liability	Number of functional areas for which a team is responsible	↑
	Vertical information system	Manner of information communication	1. Information is displayed in a continuous mode in separate and visible places located directly by the production line 2. Oral and written information is regularly communicated to employees 3. Written information is communicated regularly 4. No information for employees	↑
		Strategic content included in information	Scope of information (number of areas to which the information refers) communicated to the employees	↑
			Time perspective of communicated information	↑
		Operating content included in information	Number of measures used to assess the capacity of teams and their size	↑

		Frequency of information communication	Frequency with which the information is communicated to employees (diversification of content communicated in information)	↑

PEOPLE	**Function integration**	Scope of work performed by a team	Number of task areas implemented by a team	↑
		Support functions (auxiliary processes)	Relation of direct to indirect employees (non-production to production)	↓
	Interdisciplinary teams	Team structure	Percentage of employees working in teams	↑
		Task structure	Number of tasks in a production process performed by teams	↑
		Work position classification	Number of work positions	↓
		Diversity of tasks (rotation)	Employees change tasks in a team 1. Continually 2. Every hour 3. Every day 4. Once a week 5. Once a month 6. Once a year 7. Less frequently than once a year	↑
		Trainings	Number of diverse tasks in which the employees are trained	↑
			Number of functions in which the employees are trained	↑
			Number of training hours per newly-hired employee	↑
	Decentralisation of liability	Supervisory tasks performed by teams	Leadership in a team is entrusted to its member (e.g. a foreman) Supervisory tasks are performed by a team Separate supervisory level in an organisation	↑

		Leadership in a team	Percentage of employees who are capable of performing leader functions	↑
			Percentage of employees accepting internal leaders	↑
		Hierarchy in organisation	Number of organisational levels in a production organisation	↓
		Area of liability	Number of functional areas for which a team is responsible	↑

PROCESSES	**Pull instead of push**	Use of the pull system in relation to the push system	Number of stages in the flow of materials where the pull system is used in relation to all stages of flow of materials	↑
		Degree of implementation of the pull strategy	Percentage of annual value planned for implementation in the pull system	↑
	Reduction of costs that do not add value	Work in progress	Value of work in progress in relation to sale	↓
		Size of batch	Work time between change-overs	↓
		Change-over time	Amount of time necessary for change-over	↓
		Machine downtime	Number of machine downtime hours due to incorrect operation in relation to total machine time	↓
		Transport Parts Waste Manufacturing defects	Frequency of parts transport	↓
			Physical distance (transport path)	↓
			Value of waste in relation to sale	↓
			Value of manufacturing defects in relation to sale	↓

	Just in time	Size of batch	Production time between change-overs	↓
		Work in progress	Value of work in progress in relation to sale value	↓
		Order processing	Time necessary to process every order	↓
		Just in time level	Sequential introduction of JIT Possibility of processing specific supplies in the JIT mode Batches are delivered just in time	↓

RESULTS	**Zero defects**	Liability for identification of defective products	Employees identifying deficiencies and stopping the production line	↑
			Employees identifying deficiencies but not stopping the production line	
			Quality control division identifying deficiencies and informing the production managers	
		Liability for correction of deficiencies	Defective products are handed over to a person responsible for their materialisation Employees identify defective products and repair them Repair division repairs defective products	↑
		Quality control division	Number of persons working in a quality control division	↓
		Process control degree	Processes are controlled by measurements during the process performance Measurement is carried out after every process Measurement is carried out only on the ready-made product	↑

		Autonomous control of defects	Percentage of inspections carried out by an autonomous defect control unit	↓
		Area of repairs and corrections of production defects	Size of the area of repairs and corrections of manufacturing defects	↓

Legend: directions of changes in the value of indices in the organisation's transition towards Lean:

↑ *- should grow*
↑ *- should be reduced*
↑*- practice should change in the indicated direction*

Discussion

In the area of leadership, the fundamental principle is liability decentralisation. The direction of changes towards decentralisation may be determined by identification of places in the organisational hierarchy where supervisory tasks are performed (similarly to measures that refer to the principles of constant improvement and zero defects). The necessity of minimising the organisational levels and maximisation of areas for which a team is responsible is assumed, along with the percentage of employees who are capable of performing leadership functions and, importantly, a growing percentage of employees accepting internal leaders. The last issue subject to measurement in the area of implementation of the Lean principles is application of the vertical information system; in line with this principle, every member of the organisation, starting from the lowest position, should have access to information, both operating and strategic. Therefore, it is necessary to examine and to analyse how individual pieces of information are communicated; the best option would be for the highest percentage of information to be communicated in a continuous mode in places designated for this purpose, directly by the production lines. First and foremost, the information should contain data pertaining to measures used to assess the capacity of teams and their size; in this respect, both the scope of information and the frequency with which the information is communicated are important.

In the area of processes, key principles include application of the pull system instead of the push system and striving for reduction in costs that do not add values to the manufactured products or services which are guaranteed by successive reduction in the value of work in progress in comparison to sale, reduction of the batch size and reduction in the machine change-over time and, in general, the machine downtime as a result of incorrect operation. A significant issue is also reduction in transport (parts, waste,

manufacturing defects), both with respect to distance and the frequency of processed shipments. Whilst determining the level of implementation of the Just in Time principle, it is necessary to primarily focus on successive reduction of the value of measures referring to the units of production time between change-overs, the time necessary for the processing of every order and the level of implementation of Just in Time from sequential introduction of JIT up to delivery of all batches just in time. The Just in Time concept is closely correlated with the application of the pull system in production, which is another principle in companies practically applying the Lean Management concept. The numerical verification of the existence of the pull system consists in presentation of the relation of stages in the flow of materials implemented in line with this principle to all stages of the flow of materials as part of individual processes and the level of annual value planned to its implementation in the pull system.

Within the scope of results, the most significant criterion is the application of the zero defects principle, which consists in continuous improvement perceived as practical application of the Kaizen philosophy. Intensity of ongoing improvement may be defined by analysing and comparing, period by period, the increase in the number of suggestions filed by employees and their implementation, as well as the intensity of pro-quality activity, which may be assessed through identification of the level of organisation of such activity from its complete absence through a formal system of suggestion submission, or existence of multidisciplinary teams up to quality circles. The principle of zero defects is in practice determined as the level of liability for product defectiveness, which is assessed via identification of a person indicating defects (it is assumed that it is optimal when the deficiencies are identified in the place of their emergence), liability for correction of deficiencies (deficiencies should be corrected by persons responsible for their emergence), with such assumptions that the number of employees in the control division should decrease, similarly to the size of the repair area or the percentage of inspections carried out by the autonomous defect control.

The “people” area focuses on creation and operation of interdisciplinary teams, both in the realm of conceptualisation and implementation of projects streamlining the hitherto processes, as well as performance of processes as such. The optimum form of production organisation in Lean organisations is production in manufacturing cells, which should encompass maximally comprehensive parts of the process that may be performed by the minimum number of employees. Thus, the percentage of employees working in teams should be growing; they should be characterised by significant flexibility and competence that authorises them to continually change tasks in the team. At the same time, it is worth emphasising that the number of trainings for organisation members should be growing, both with respect to task diversity, as well as functions. Similarly, indicators refer to the principle that stipulates that integration of functions is significant in the LM organisations, which is also expressed by the number of task areas performed by the team; furthermore, whilst verifying this principle, also the relation of direct employees to indirect ones is identified by indicating that the number of tasks and even auxiliary processes has to be reduced to the minimum.

Study Limitations and Conclusion

A significant limitation in the proposed breakdown is the lack of possibility of comparing it with other similar breakdowns, as they are simply missing in the literature on the subject which, on the other hand, may define its uniqueness. Another limitation is the lack of practical confirmation and practical verification of the proposed solutions, which may constitute tool support for leaders responsible for implementation of the Lean concept in companies that they manage.

Evolution of Korean Direct Investment in CEE since Global Financial Crisis

Pawel PASIERBIAK

Maria Curie-Sklodowska University, Lublin, Poland
pawel.pasierbiak@umcs.pl

Abstract

Korean direct investment has been developing quite intensively since the last decade of the 20th century, and Europe has become one of the major investment areas. In the 1990s, Korean investors also became interested in the markets of Central and Eastern Europe (CEE). Gradually, the value of Korean investments in CEE countries increased. The global financial and economic crisis of 2008 became a significant turning point for investment activity. The author of this study focuses on the analysis of changes that have taken place in the investments of South Korean corporations in Central and Eastern Europe after the crisis. The study aims to indicate the characteristic trends occurring in the inflow of Korean FDI to CEE and their interpretation. To achieve the goal, the method of statistical data analysis, inference method, and analytical-descriptive method were used.

Keywords: FDI, South Korea, Central and Eastern Europe, Transnational corporations

Introduction

Korean direct investment in Central and Eastern Europe appeared on a larger scale in the 1990s. As a result of establishing diplomatic relations with the transforming post-socialist countries, the conditions in which South Korean corporations could function have improved. The first enterprises focused their activities mainly in industries related to manufacturing, the electrical and electronic industries as well as the automotive industry. In subsequent years, along with the growing strength of the country's economy, Korean investments developed even more intensively, and Europe was one of the most important investment locations. The global financial and economic crisis initiated in the United States in 2007 was a significant turning point for investment activity in the world.

Therefore, some questions about changes taking place in the investments of Korean corporations arise. Has the level of their investment decreased after the 2008 crisis? Has Central and Eastern Europe become a more/less critical area of investment? What factors influenced the activities of Korean corporations in CEE? The author of this study tries to answer the above questions. The primary purpose of the study is to present changes and indicate the main tendencies that took place in Korean direct investment in the CEE countries. The structure of the study was subordinated to the achievement of the above objective. The second section presents an outline of the basic theories explaining foreign investments. The analysis of the development of Korean FDI in Central and Eastern Europe is covered by section three. Part four presents selected conditions for the development of investments in Central and Eastern Europe. The study ends with a summary section.

Several research methods were used in the study: a method of analyzing statistical data (UNCTAD, Korea Eximbank, World Bank), an inference method, and an analytical and descriptive method. The subject scope of the study concerns foreign direct investment. The time range generally covers the period 2007-2018, but wherever possible, the latest data were used.

Theoretical Debates on Foreign Direct Investment

The evolution of foreign direct investment theory illustrates the historical process of developing international business operations. The first FDI theories explained investments made by corporations from developed countries, while later, investments made by enterprises from developing countries. Theories of FDI for developed countries emphasize the role of non-price qualitative factors influencing investment decisions. At different stages of economic development, they have a different character. In turn, theories for developing countries emphasize more the importance of the marginal competitiveness of price factors, resulting from the political and institutional environment in developing countries (Kim and Choi, 2018, p. 17). South Korea, which only at the turn of the 1980s and 1990s became more involved in global investment flows, could be treated as a transforming country. On the one hand, it was a developing country, but on the other, it also had the characteristics of a developed country (Tolentino, 2005, p. 264). Consequently, the growth of Korean investments in the world in the 1990s could not be comprehensively explained using traditional theoretical concepts describing the activities of corporations mainly from developed countries. It was particularly evident in the studies of Korean researchers who either critically assessed existing theories or created their own concepts, which they believed were more adapted to South Korean conditions. Nowadays, when Korea is classified as a high-income country (The World Bank, 2020c), the concepts of investments made by corporations from developed countries are more widely used to explain South Korean investments.

Until World War 2, the international production by national enterprises was attempted to explain using neoclassical theories of the international flow of goods and factors of production. However, due to unrealistic assumptions about perfect competition in the markets for factors of production and goods, this concept could not explain satisfactorily international production. Concepts closer to reality, i.e., assuming that international production (investments) is undertaken as a response to market imperfections began to appear in the 1950s and 1960s. In his work, S. Hymer stated that companies operating within imperfect markets can develop an advantage that will give them a competitive advantage over rivals in both domestic and foreign markets (Hymer, 1976, pp. 41–46). Possession of advanced technology or high management skills can be treated as a firm-specific advantage that will overcome the costs of 'foreignness' on the investment location market. In 1966, R. Vernon (1966) formulated the theory of product-cycle, also used to explain foreign direct investment. According to him, some enterprises will be innovators within a given industry, even if all of its competitors would have equal access to knowledge on the basis of which innovations are created. Vernon described the sequential process of product development from the innovation phase to the maturity phase to the standardization phase. In maturity phase, when the company begins to meet with strong competition on domestic market, it decides to invest and start production abroad. In the 1970s and 1980s, attempts were made to have a more holistic approach to explaining FDI. The theory of internalization by P. Buckley and M. Casson claims the company's activity is not only production but the entire range of activities, including research and development, marketing, training, raising funds, or managing financial assets (Cherry, 2013, p. 8). These types of activities are connected by flows of intermediate products, including knowledge, technology, production, and sales experience, as well as materials, parts and components and semi-finished products. Effective coordination of these activities is key to the company's success. Therefore, if organizing and acquiring intermediate products on external markets is difficult, then it is advisable to create internal markets. All this provided that the benefits outweigh the costs (Casson, 1993, p. 361). Nevertheless, like enjoying specific firm-advantage, the mere possibility of internalizing transactions was not a sufficient reason to start production abroad. These issues were researched in the 1980s by J. H. Dunning. According to his Eclectic Paradigm of International Production (2002a, p. 176), the company must possess three types of advantages to engage in FDI: ownership-specific (O), location-specific (L), and internalization incentive advantages (I). The propensity to engage in foreign production will be higher, the greater its comparative advantage over other enterprises, and the more profitable it is to create or add value to existing advantages as a result of choosing a foreign location. Dunning also pointed to the basic categories of motives that guide companies undertaking FDI. These are resource-seeking, market-seeking, efficiency-seeking, and strategic asset or capability seeking motives. An enterprise engaging in FDI can be motivated by the influence of one or more of these factors, changing over time. Without deeper analyzing the exact

motives, it can be concluded that they are mainly of economic nature. However, today, apart from those mentioned above, political and institutional factors are playing an increasingly important role.

One of the theories describing investments made by corporations from developing countries is the concept of the investment development cycle by J. H. Dunning (2002b, pp. 214–216). It argues that along with the country's economic development, its foreign investment position will go through specific phases. At first, there will be no investment activity. In the second phase, along with the improvement of infrastructure, economic structure, and government policy, intermediate products are beginning to be imported to the country. However, high transaction costs mean that foreign investment is flowing into the country, resulting from the ownership advantages of foreign enterprises. In the third stage of development, the country's ability to create its ownership-specific advantage appears. Some companies may already attempt to invest abroad. The fourth phase of investment development means that the country becomes a net investor. Another concept describing the development of investment from developing countries is the theory proposed by Luis T. Wells. Investments from developing countries reflect a product life cycle phase or technological gap. The development of FDI shows an analogy to the development of production and export of countries what depends on the level of technological development. The countries that currently produce goods have an innovative and cost advantage. They export these goods to countries that have not yet established production bases, i.e., they are further down the pecking order.

Similarly, FDI also follows such a pattern (Tolentino, 1993, p. 43). The same author (Wells) also pointed to the motivations that guide corporations from developing countries. He pointed to the policies of governments, and measures aimed at promoting external investment, restrictions on the internal market, expected higher rates of return on investment abroad. Also, companies can invest in securing supplies of raw materials, establish bases for raw material development, circumvent import restrictions, and develop products that meet local conditions (Cherry, 2013, p. 15). The above analysis and review of the literature show that foreign direct investment in developing countries is motivated mainly by institutional and political factors: these are 'push' variables in home countries and 'pull' variables in host countries (Kim and Choi, 2018, p. 22).

Because South Korea was treated as a country in transition from the status of developing economy to that of a developed economy, its foreign direct investment exhibited the features of theory for both developed and developing countries. At the same time, Korean researchers criticized existing concepts, sometimes creating their own (Cherry, 2013, pp. 25–33). Without analyzing these concepts, one can point to such Korean theories as Integrated Theoretical Model (Yun Tong-jin), Structural Market Defence Theory (Jun Yonkwook), Post-Product Cycle Model (Yun Tong-jin) or Competitive Advantage-Representative Specialization Zone Theory (An Se-yong).

At the current stage of South Korea's economic development and based on the analysis of its investment activities, it can be concluded that the investments made by Korean corporations are more in line with the assumptions of theories intended for developed countries. Important factors encouraging the firm to invest abroad are intangible assets, internalization as well as localization. Additionally, government policies can influence positively activities undertaken by corporations.

Development of Korean foreign direct investment in Central and Eastern Europe

The 2008 global economic crisis is a significant turning point for international capital flows around the world. Until then, foreign direct investment developed intensively. In 2007, the annual FDI outflow reached a record high of 2.168 USD billion (UNCTAD, 2020). From that time to the present, the value of world outflowing FDI did not reach the level from 2007. By 2009, the value of investments had fallen to half of the 2007 level (to 1.099 USD billion). In the following years, by 2015, global FDI was slowly growing (1.683 USD billion), but in the next three years, the value was regularly dropping. In 2018, the FDI value was 1.014 USD billion, i.e., 53.2% lower than in 2007.

Against the background of global trends, quite positive changes took place in investments made by Korean corporations. In the years 2007-2018, the value of investments increased from 21.8 to 38.9 USD billion, which meant an increase of 78.3% (UNCTAD, 2020, p. 55). In general, Korea showed a positive upward trend. After a slowdown in 2012-2015, since 2016, Korean corporations have again undertaken intensive foreign activities. In 2016, the value of Korean FDI increased by 26.2%, the following year by 14%, and in 2018 by 14.2%. Over the entire period, the average growth dynamics of Korean FDI exceeded that for the world, which allowed increasing the country's share in the global FDI outflow from 1% to 3.84%, i.e., almost four times (UNCTAD, 2020). This is an achievement that should be assessed positively.

Fig. 1: Outgoing Foreign Direct Investment in the World and Korea, USD billion

Source: Own preparations based on (UNCTAD, 2020).

Korean investments were located mainly in Asia, North America, and Europe, although significant structural changes occurred in the analyzed period. In 2007, the total share of these three destinations stood at the level of 89.2%, which was due to the high share of Asia (53.6%) and smaller Europe (19.6%) and North America (16.3%) (Korea Eximbank, 2020). In 2019, the total share decreased to 80%, but the share of Asia dropped significantly to 32.3%, while North America and Europe increased to 25.8 and 21.9%, respectively. The importance of Europe fluctuated because, in 2008, the share dropped to 14.1%, while in 2009 and 2010, it was around 25%. In subsequent years, a decline in the importance of this continent could be observed (to even 11.4% in 2016). This was partly due to a negative assessment of the volume of demand in the EU affected by the sovereign debt crisis. At that time, corporations such as Hyundai were considering an increase in production in non-European countries (UNCTAD, 2013, p. 55). Since then, Europe's share has increased, which was seen in 2018 (23.1%) and 2019 (21.9%). It can, therefore, be concluded that Europe was a relatively attractive place for Korean investors, which was confirmed by the growing number of Korean companies operating in Europe (Korea Eximbank, 2020). According to data from the Korean Eximbank, the value of investments in the European Union in 2007 amounted to 3.322 USD billion, to increase to 10.899 USD billion by 2019. Most of the investments were directed to the EU15, while investments in CEE ranged from 2.9 to 24.5% of the total Korean investment to the EU.

Fig. 2: Korean FDI in Central and Eastern Europe, 2007-2019, USD million

Source: Own calculations based on (Korea Eximbank, 2020).

According to the data (Figure 2), in 2007, Korean investments in CEE did not exceed 1 USD billion. However, in subsequent years they fell quite sharply to the level of 185.6 USD million in 2009, which was in line with the global downward trend. In 2010, Korean companies invested only 171.2 USD million in CEE. In subsequent years, until 2015, the value of investments did not exceed 200 USD million, except for 2012, when inflows increased to the level of 352.6 USD million. Investments began to grow from 2016, particularly intensively in 2018 (by 176%) and 2019 (by 65.8%). This was associated with large investments in Poland, Hungary, and, to a lesser extent, Czechia. The geographical structure of Korean investments in CEE countries is shown in Table 1.

Table 1: Korean direct investment in CEE countries, geographical breakdown, %

Country	2007	2008	2009	2010	2011	2012	2013	2014	2015	2016	2017	2018	2019

Source: Own calculations based on (Korea Eximbank, 2020).

Based on the data from Table 1, it can be stated that Korean corporations are strongly focused on selected markets. The primary investment location countries were: Poland, Czechia, Slovakia as well

as Hungary, and Romania. Depending on the year, investments in these five countries reached as much as 99.9% of total Korean investments in the group of eleven CEE countries. In 2018-19, when the total value of investments increased significantly, the main recipients were Poland (44% in 2018 and 53.2% in 2019), Hungary (32.4% and 36.7 %), and Czechia (20.1% and 3.2%). This situation resulted from, among other factors, the high popularity of these directions as locations for manufacturing investment.

Korean investments in Central and Eastern Europe are concentrated in manufacturing, especially in consumer electronics and in automotive industry. In the years 2007-2019, the share of this sector ranged from 70.1% to 98.3%. In some years, investments were invested in other industries, such as in 2010 and 2011, when investments in Slovakia were made in electricity, gas, steam and air conditioning supply. Another industry that was sometimes chosen by Korean corporations was whole and retail trade. However, here the highest share occurred in 2008 when a one-time investment of 40 USD million in Slovenia gave the industry a share of 8.4%. In the remaining years, the value of investments in whole and retail trade remained at a low level.

Conditions of the Korean direct investment development in CEE countries

Korean direct investments in CEE were undertaken in conditions created by several groups of factors. It is impossible to list and fully describe all of them in such a short study, but the basic ones can be indicated: 1) economic situation in the world, Korea, and CEE markets; 2) investment climate in CEE countries; and 3) Korea's investment policy.

The global economic situation immediately after the outbreak of the crisis in 2008 was unfavorable. The decreases appeared in world production, international trade, and foreign direct investment. The majority of developed countries experienced a sharp recession. GDP fell by 2.5% in the US, 4.3% in the EU, and 5.4% in Japan (The World Bank, 2020b). Against this background, the situation of South Korea was relatively good, because, in the worst year, the country maintained a positive growth rate of 0.7% in 2009. After 2010, the global economic situation improved. The average GDP growth in the world ranged from 2.5 to 4.3%. In 2010, South Korea recorded an increase of 6.5%, and in subsequent years the dynamics also remained positive and relatively high (2.3-3.3%). In the years 2011-2013, the economic situation in the EU became even more complicated. Excessive public finance deficits in some EU countries have led to the sovereign debt crisis, which in 2012 reduced EU GDP by -0.4%. In 2013, the increase was only 0.3%. In the following years, the situation improved slightly, and the highest level of GDP growth in the EU was achieved in 2017 (2.6%).

The analysis of the economic situation in the countries of Central and Eastern Europe gives quite differentiated results. Among the analyzed group of countries, only Poland in the whole period showed a positive economic growth rate. Other countries suffered quite severely from the effects of the 2008 crisis. All countries recorded a decline in absolute GDP, and in the Baltic republics, a decrease exceeded 14% (The World Bank, 2020b). The sovereign debt crisis in the following years affected Croatia, Slovenia, and Czechia profoundly, as these countries recorded a negative GDP growth rate in 2012-2013. Other countries survived the crisis relatively well.

The changing economic situation in the CEE countries did not have the same impact on Korean FDI since Korean corporations' investments were focused on selected markets only. The dynamics of economic growth and the inflow of Korean FDI to the five most essential destinations in CEE are presented in Table 2.

Table 2: GDP growth and inflow of Korean FDI to Czechia, Hungary, Poland, Romania, and Slovakia, 2007-2018, % and USD millions

Source: Own preparations based on (The World Bank, 2020b) and (Korea Eximbank, 2020).

Calculated linear correlation coefficients indicate weak relationships between the inflow of Korean FDI and GDP dynamics, even in the case of the most important investment markets in CEE. The highest statistical correlation was recorded for Poland (0.49, which means moderate correlation). In other cases, the correlation was even lower and amounted to 0.37 for Hungary; 0.34 for Czechia; 0.34 for Romania, and 0.21 for Slovakia. Based on the above description, it can be concluded that in the analyzed period, the dynamic of economic growth was not the most important determinant in Korean FDI development in Central and Eastern Europe. The economic situation of the country is only one of the elements of the investment climate. The others are social, administrative, and political climates.

The assessment of investment climate by investors gives a basis for decisions about a localization. The annual assessment of the climate for business is presented in the annual Doing Business Report. Figure 3 presents the transformed ranking covering only Central and Eastern Europe countries.

Fig. 3: Ease of Doing Business Index – ranking within a group of CEE Countries, 2007-2020
Source: Own preparations based on (The World Bank, 2020a).

Figure 3 shows that the highest positions in the ranking were taken by countries whose markets were not priority destinations for Korean corporations. Investments were directed instead to countries with lower positions in the ranking, i.e., Poland, Hungary, Czechia, and Romania. This means that there existed other, more critical factors prompting Korean corporations to be active in selected markets of Central and Eastern Europe. In Poland, the advantages could be a large market, relatively low labor costs, or a favorable location. In Czechia, there were factors related to the condition of the economy and the importance of the country in the export of cars, parts and electronic products (Szunomár and McCaleb, 2015, pp. 13–18; Dorożyński and Kuna-Marszałek, 2016, p. 129).

Other institutional factors related to the investment attractiveness of the CEE countries can be connected to the creation of special economic zones. Almost all countries receiving Korean investments have actively supported the industrial sector through investment incentives and by the opportunity to operate in special economic zones (Dorożyński and Kuna-Marszałek, 2016, p. 130). CEE countries are also the primary beneficiaries of assistance under the EU structural funds, which can positively influence the perception of these countries as an attractive investment destination. Another institutional factor that is worth pointing out is the entry into force (2011) of the free trade agreement between Korea and the European Union (KOREU FTA) (Pasierbiak, 2013). Since trade cooperation between countries is strongly related to capital flows (Michalski, 2018, p. 12), then the development of treaty relations results in a positive assessment of the investment climate. This is particularly important in countries that have recently undergone socio-economic transformation processes.

The last element of conditions for Korean FDI inflow, which will be indicated in this study, is the country's policy towards investments undertaken by Korean corporations. Over time, this policy has strategically evolved to reflect various stages of the country's economic development (Nicolas, Thomsen and Bang, 2013, p. 28). In 2005, there was a reorientation in policy towards outgoing FDI. Since this year, the government has been actively promoting outgoing FDI, encouraging domestic companies to invest abroad and to build business alliances with foreign corporations operating in Korea. In 2007, the Policy for Supporting Koreans Firms to Invest Abroad was initiated, creating the Committee for Global Business Operation. The rank of this committee is evidenced by the fact that the Prime Minister became its chairman. The committee coordinated activities between agencies dealing

with services for Korean investors (including KOTRA), various governmental organizations (including banks), and ministries responsible for FDI outward policy (Nicolas, Thomsen and Bang, 2013, p. 30).

Conclusion

South Korean corporations are active players in the contemporary global economy. Their investment activities cover all major world markets, also those in Central and Eastern Europe. Based on the analysis of this study, several summary conclusions can be drawn.

1. Since Korea was treated as a transforming country, following the path from developing to a developed one, Korean investments were explained by theories specific to both developed and developing countries. Today, factors such as intangible assets, internalization, localization, as well as governmental support, are used to explain Korean investments.
2. Korean investments after 2007 showed different trends than global investments. While the value of global investment outflows did not reach the level of 2007 by 2018, Korean investments increased by 78% to reach 38.9 USD billion. The share of Korea in world outflow grew from 1 to 3.84%.
3. The share of Central and Eastern Europe was relatively small in total investment located in the European Union. In the years 2007-2019, it ranged from 2.9 to 24.5% of the investment value. The value of Korean investments in CEE increased from USD 814 million (2007) to USD 2 billion (2019).
4. Korean investments were very unevenly distributed among the CEE countries both in geographical and sectoral terms. Countries such as Poland, Czechia, Slovakia, Hungary, and Romania played a dominant role, attracting even 99.9% of the total investment in selected years. High concentration was also observed in the sectoral structure of investments. The share of the manufacturing sector ranged from 70.1 to 98.3%. Other sectors were electricity, gas, steam and air conditioning supply, and whole and retail trade, but the value of these investments was low.
5. Analysis of the conditions for Korean direct investment in CEE reveals their differentiated significance. Also, it confirms that a more in-depth analysis of the investment climate is needed.
   - The economic situation does not seem to be the most crucial factor in encouraging corporations to invest in a given location. Among the analyzed countries, only in the case of Poland, the correlation between incoming FDI and GDP dynamics was relatively high (0.49).
   - Korean corporations do not necessarily invest in those countries that demonstrate the highest ease of doing business. The share of Baltic republics in Korean investments in CEE, despite high positions in the Doing Business rankings, is negligible. In turn, such economies as Poland, Czechia, or Hungary, which are on further positions in the ranking, were the more often chosen as investment spots.
   - Korean corporations can enjoy the support of the government and various Korean institutions. The state's activity in this area increased, especially after 2005.

Abstract

In the context of the structural adjustment of the world economy and changes in the balance between economic centers, the increasing role of regional economic unions and the spread of digital technologies, the demand for finding effective tools for managing economic interests and conflicts of the economic activities' participants is growing. Conflicts of interests of various stakeholders' groups arising both in the public and private sectors in many countries are increasingly viewed as direct threats to social stability. To solve the indicated problem, it is necessary to comply with the standards that minimize the risks of conflict appearance and provide high probability of its resolution. Today, in the Russian Federation, the provisions on the accounting policies of organizations can be used as a base for such standards because in accordance with the current legislation, their adoption is mandatory. The article presents the evidence base for the inconsistency of the strategic intentions of corporate organizations and the socio-economic policy of Russia, which gives rise to conflicts of interest for various groups of stakeholders. The authors' vision of the goals and objectives of accounting policies as a tool for managing conflicts of interest of Russian corporations is demonstrated. The content of control and analytical procedures at the main stages of the accounting policies formation in order to effectively manage conflicts of interest is disclosed.

Keywords: Accounting Policies, Stakeholders, Conflict of Interests, Corporate Management.

Introduction

Amid structural transformation of the world's business and changed balance between economic centers, increased role of regional economic alliances and spread of digital technologies, there is a higher demand for the search of efficient tools to manage economic interests and conflicts of players involved into the reproduction process and the process of added value generation. It is known that such players belong to different social groups and trade unions.

Conflicts of interest of different stakeholders occurring in the public sector of economics and private business in many countries of the world are more often considered as direct threats to the social stability. It is no coincidence that today the issues of managing conflicts of interest at the level of corporate structures become subject to the state policy and legislation.

Considering the need to overcome the effects of new threats and challenges of the planet, today it is more important to solve the problems of protecting economic interests not only of stakeholders, prospective investors, banking agents, senior executives and employees of the business, but also there is a higher

demand for instruments and mechanisms of non-infringement of the interests of other social groups whose living depends on the government's budget revenues.

Unsolved problems in the management of conflicts of interest deepen social opposition in the society and give rise to corruption. In this respect, it is extremely relevant to develop tools and mechanisms to prevent conflicts of economic interest between the participants of the process of the added value generation. To solve this issue, in our opinion, it is important to follow certain rules and comply with the standards eliminating risks of emerging conflicts and ensuring high probability of their resolution. Today accounting policies of Russian organizations which must be adopted according to the current legislation of the Russian Federation (RF, 2011) can be used as such standards. By adopting certain provisions of the accounting policy of the corporate structure, its management can deliver an optimal balance of economic interests of the following social groups: shareholders, bank agents, government, employees, suppliers of resources and services, senior executives.

Development of the accounting policy is a complex and diversified process, the results of which influence the choice of methodological approaches to the corporation's reporting procedure for, at least, the next year. This brings up the question: what are the goals of the corporation's management and to what extent do they correspond to the innovative scenario of the Russian development outlined by the Russian Government which assumes that our country quite rapidly becomes the world's leading power?

Literature Review

Kotler, Maon and Lindgreen (2016) emphasize that the circle of modern corporation stakeholders is much wider than the circle of its shareholders, and also includes all those who are interested in the success of the corporation - owners, employees, customers and the public.

Demski (2003) argues that conflicts of interest in corporations are usual and cannot be completely eradicated, so the question should be raised primarily about tools and mechanisms for conflict management, and, emphasizing the importance of understanding the roles of the parties, he believes that the system of counterbalances cannot to be absolutely effective. In this study, as well as in (Barrya, Lepetita, Strobelb and Trana, 2017), attention is focused on the organizational mechanisms for managing conflicts of interest, but not on their sources reflected in the financial statements.
In (Carney, Gedajlovic and Sur, .2011) the authors note that stakeholder value concept and inclusive stakeholder approach predominate in the conflict management literature.

The issues of the interest conflict management and the accounting policies are tied through many logical relations and are inherently embedded into the economic activity of the organization.

IAS 8 (IAS 8, 2003) determines the accounting policies as the specific principles, bases, conventions, rules and practices applied by an entity in preparing and presenting financial statements and states that changes in the accounting policies is an adjustment of the carrying amount of an asset or liability, or related expense, resulting from reassessing the expected future benefits and obligations associated with that asset or liability.

Nevertheless Len and Glivenko (2019, p. 26) argue that till the moment “the research has not led to an unambiguous interpretation of the concept of "accounting policy" and its components” and find it reasonable to include organizational components as well as past and future events into the concept of accounting policies.

Kuznetsov; Demidenko and Malevskaia-Malevich (2019) argue that the substantiated construction of the economic model is a powerful tool for effective organization’s activities management. The appropriate use of resources creates the reliable base for productiveness and efficiency increase (Sokolitsyn, Ivanov

and Sokolitsyna, 2017) and forms the requirements for the adequate accounting policy and representation in the accounting system focused on minimizing the accounting risks (Domnin, Makarova and Martynenko,, 2019) and the errors of audit (Yurevna, Mikhailovna and Robertovna, 2018; Yurevna, Robertovna and Mikhailovna, 2018; Kochinev and Antysheva, 2019).

Dvas and Dubolazova (2019) point out the increasing role of the risk management in the Russian organizations and Iakovleva, Ignatiev; Aksenova, Iakovleva and Vanicheva (2019) highlight the importance of the proper analytical base including, in particular, the accounting policies, for the risk management purpose. The appearance of the new sources of risk multiplies the potential of interest conflict occurrence both inside the organization and in its outer surrounding (Demidenko, Gorovoy and Malevskaia-Malevich, 2017). In (Julianto, Yasa, Pasek, and Ekawati, 2019) the interest conflicts are studied taking into account gender factor of the conflict parties.

The ability of the accounting policies to serve a tool for managing conflict depends on its ability to produce information corresponding to the interests of stakeholders. (Brennan and Merkl-Davies, 2018) consider the issues of providing information to stakeholders in the context of communication channels.

Alayemi (2015), discussing the possibility of adequate financial statement understanding in the context of accounting policies, shows its direct and indirect impact on financial coefficients, ROE and gearing and points out that the difference in the accounting policies constrains the comparability of these indicators. The influence of accounting policies on the financial performance of an enterprise is also studied in (Smokvina, Kavierina and Lihanenko, 2016). Discussing accounting policies in the context of corporate social responsibility (Azim and Ara, 2015) believe that all the stakeholders should perform their best to uphold the accountability.

Studying the listed firms in South Asia, (Ali and Ahmed, 2017) find no significant relation between accounting policies and indicators they investigated, in particular, profitability. However they argue that accounting policies allow shifting income value and insist that diminishing the number of alternatives provided by accounting standard will improve reporting quality. Study of (Zicke and Kiy, 2017) identified that the changes in the German accounting standards gave ambiguous effect on the financial reporting of the companies.

Vergoossen (1997) raises the question about how investment analysts interpret the changes in accounting policies, and connects such interpretation with the type and character of change.

Ding, Jeanjean and Stolowy (2017) write that the decisions on the accounting policy within the boundaries of the standard result from a trade-off between the information needs of various stakeholders. And the findings of the mentioned authors “contradict the conventional wisdom in which shareholders should prefer dynamic conventions of accounting over static conventions while from its inception, the International Accounting Standards Board purposely decided to favor investors over other stakeholders and promoted dynamic options of accounting choices”.

Bowen, DuCharme and Shores (1995) show that long-lasting implicit claims between a company and its customers, suppliers, employees and short-term lenders create incentives for management to choose long-term accounting methods aimed to increase income.

The large importance of the issue in the context of Russian economy was noted and substantiated in the recent works of the authors (Dedyukhina, 2011; Guzikova and Belyakova, 2019).

Methods and Data

Alongside with the analysis of opinions on the issue represented in the scientific publications and requirements of legislation, we surveyed the heads of accounting services and chief financial officers of the corporate structures of St. Petersburg and Leningrad Region to identify the goals that management sets in developing of accounting policies. The survey was conducted in the form of a questionnaire of students of the Training Center for Certification of Professional Accountants. When asked about the goal pursued by the management of your organization in the development of the accounting policy, it was suggested to choose options for possible answers (one or more), or to formulate own point of view that is different from the proposed answer options. 622 respondents were involved in the survey.

Main Provisions and Results

The results of our studies show that, despite the uniform methodological principles for regulating of the accounting policies of Russian corporations, provided by the law (RF. 2011; MF RF, 2008), the goals of its developing are very different. Among them, we highlight the following: restructuring of cash flows, increasing profitability of the remuneration of senior management, reducing complexity of accounting procedures, convergence with International Financial Reporting Standards and others. This situation in Russia has not changed for a sufficiently long time, despite the growth of social tension.

The results of the undertaking survey are represented in the Table and show that today the accounting policy of the organization is not generally considered by its management as a tool for managing conflicts of economic interest of various groups of stakeholders. It is not also aimed at solving of strategic objectives of long-term industrial and regional economic development.

At the same time, 91% of respondents agreed that one of the main reasons for economic crisis phenomena lies precisely in the inconsistency of the development strategy of the organization with the social and economic policy of the government, which is one of the reasons for the conflict of interest. The correct choice of methodological techniques and methods for taking into account the facts of economic life in the process of developing an accounting policy of the corporation not only can, but also should be considered as an efficient means to ensure flexibility and efficiency of managing economic interests of all parties that secure directly or indirectly the organizational health.

A deeper study of the current situation allows us to identify another phenomenon: the accounting policies of Russian corporations are not aimed at determining of the priorities of economic interests of stakeholders and their best balanced combination, which is especially important for achieving the goals of long-term social and economic development of the Russian Federation. This is evidenced by the results of the survey, line 12 of the table.

On this occasion, Sokolov (2007) notes that “the whole point of the accounting policy is that officially every company is allowed to choose accounting methods and thereby generate both taxable and accounting profit”. That is, the accounting policy of the organization is considered by the scientist, first of all, as a tool that provides a reasonable combination of economic interests of several parties involved: owners, creditors, personnel, government and senior management of the enterprise by achieving the desired indicators of the financial statements at the end of the year.

Table - Questionnaire survey on the goals of developing and regulating accounting policies of Russian organizations

Response wording options for the organization's accounting policy goals	Distribution of respondents by response options	
	number of respondents	specific weight of respondents in their total number, %
1. Optimization of the organization's tax payments	211	33.9
2. Resolution of inconsistencies in the current accounting and tax laws	93	15.0
3. Reducing complexity of accounting procedures	131	21.0
4. Restructuring of cash flows to provide sources of financing for certain processes (activities) of the organization	62	10.0
5. Restructuring of cash flows to achieve the desired figures of the financial statements	37	5.9
6. Ensuring (increasing) of the current return on investment of capital owners	19	3.1
7. Convergence of national reporting approaches with IFRS	19	3.1
8. Ensuring (increasing) of the current solvency of the organization and repayment of obligations to the bank	19	3.1
9. Ensuring of the increase of net assets of the organization and (or) equity	6	1.0
10. Increasing of the market value of the organization	19	3.1
11. Ensuring of the attractiveness of the organization for potential investors (owners and creditors)	6	1.0
12. Optimization (minimization) of the asymmetry of economic interests of the parties involved in the organization's business (capital owners, creditors, government, personnel, administration)	0	0
13. Total	622	100

Source: composed by the authors

It follows that the accounting policy of the organization can be used by its management as an anti-crisis tool for managing agent relations and optimizing economic interests of various groups of stakeholders, ensuring organizational health. The provision that agent relations are carriers of potential contradictions, conflicts of interest and give rise to the crisis phenomena is also determined by the modern theory of agent relations (Agency theory) (Vernimmen, 2010).

Commenting on the development of agent relations and their significance in modern conditions of social and economic development of the society, Sokolov (2007) notes that “the history of this relationship dates back to the end of the 19th century, when joint-stock companies appeared in increasing numbers,” and it was during this period that “the great German lawyer R. Jäger (1818-1892) said that joint-stock companies ruined people much more than all wars together. Our country (Russia, author's note) is no exception”.

Considering the multivariance of modern views on the goals and objectives of the organization’s accounting policy in Russian practice and the severity of social and economic problems, we present in this publication another point of view on this issue. In our opinion, in corporate structures the main goal for delivering an accounting policy cannot be separated from its strategic intentions, including the need to

increase investment attractiveness and ensure new capital inflows. Moreover, all other tasks of the corporation can be considered in the context of this specified goal. An approximate list of such tasks formulated by us is presented in Figure 1.

Note that the highest effect of using accounting policies as a tool for managing conflicts of interest can be achieved if the results achieved are monitored on a regular basis and analytical procedures are used. Depending on the stage of the accounting policy developing, analytical procedures will be used within one of three areas of economic analysis: assessment, diagnostics or (problem-oriented) search (Figure 2).

CORPORATION'S ACCOUNTING POLICY

GOAL
Ensure the investment attractiveness of the corporation
and optimize (minimize) the asymmetry of economic interests
of the parties involved

OBJECTIVES

A. If the market for products (goods, works, services) is saturated:
● Ensure the necessary level (increase) of gross profit and financial strength by minimizing current costs (expenses) and flexible contract (pricing) policies with suppliers and customers, taking into account stabilization of demand for products
● Restructure cash flows aimed at diversifying investment activities

B. If the market for products (goods, works, services) is not saturated:
● Ensure the necessary increase (level) in gross profit and financial strength by increasing sales volumes and flexible product portfolio policy, taking into account the increase in demand for products
● Restructure cash flows aimed at expanding investment activities, increasing economic potential and market share.

C. Other objectives:
● Maximize net profit and ensure the level of financial profitability not lower than the average rate on bank deposits;
● Maximize gross profit and ensure the level of profitability of sales not lower than the industry average
● Increase (maintain) the value of net assets to the value sufficient to provide property guarantees to owners in the event of closing down of the business
● Increase (maintain) equity capital to the size sufficient for on-going financing of the core business of the enterprise and (or) full replacement of loan capital
● Increase market value of the organization
● Maintain the current solvency of the enterprise sufficient to fulfill obligations to creditors
● Minimize information asymmetry and optimize economic interests between the parties involved ensuring the maximum feasibility and high reliability of the financial statements intended for external users

Fig. 1: The goals and objectives of the corporation's accounting policies as a tool for managing conflicts of interest

Fig. 2: Use of control and analytical procedures at the main stages of developing of the accounting policy of the corporation

At the first stage, the assessment and diagnostic analysis provides for a comprehensive examination of the accounting system that has developed in the corporation, including document flow, bookkeeping and reporting, study of business conditions, areas of activity, and organizational structure. Accounting

policies should be developed in parallel with the budgeting process, in which the management forms the main indicators of the business plan for the nearest period and long-term perspective.

Compliance with this condition, in our opinion, is especially important, since the accounting policy is not a formal attribute of the corporate governance, but a document that performs certain functions to justify ways to implement investment decisions and prevent conflicts of interest. Assessment and diagnostic analysis allows us to assess the quality of the procedures for preparing financial, tax and statistical reporting for external users, including assessing compliance with legal requirements, strategic goals and ensuring the balance of interests of various social groups of people.

At the second stage of the accounting policy developing, the Russian legislation is monitored. In case of changes in the legislation governing the accounting procedure, the accounting policy of the corporation is also subject to changes. Such changes are binding in accordance with the Federal Law No. 402-FZ “On Accounting” (RF, 2011). At the same time, the corporation's management can initiate changes in the accounting policy, considering the possibility to choose any accounting methods defined by the law, and thereby generate the desired indicators of the financial statements. Since changes in accounting policies affect the comparability of financial indicators for different periods, the Russian legislation provides for mandatory written notification of such changes for the coming year in an explanatory note to the annual corporate financial statements.

It is known that ensuring the reliability of the financial statements is one of the factors influencing the investment attractiveness of business entities and ratings of investment activity of industrial and geographical segments. In this regard, at the final step of the second stage of developing the corporation's accounting policy, it is planned to use search analysis procedures and at the same time develop internal control standards that will act as corporate financial management tools.

The third stage involves the use of monitoring and control procedures for the implementation of the requirements enshrined in the order "On the accounting policies of the organization".

The main task of the corporation's management and accounting policymakers at this stage is to promptly resolve issues and control reliability of the accounting information if it becomes necessary to choose new accounting methods to balance the interests of the parties involved.

Conclusions

The regulatory legal acts of the Russian Federation determine the basic requirements for the reporting indicators and developing of accounting policies for corporate structures in order to protect the interests of users from inaccurate information about the results of financial and economic activities.

Thus, using the capabilities of the Russian legislation the management of corporate structures has a real opportunity to use the efficient management controls for conflicts of interest of various social groups of people, to hold back extending social contradictions and reduce the risks of irreversible consequences of economic crises.

Abstract

The aim of this paper is to map the current situation in online shopping in Slovakia using secondary data. Consequently, based on primary data, the aim of this paper is to identify the frequency of online shopping via large screens (PC/laptop) and mobile devices in terms of gender and generational characteristics of consumers on a sample of 627 Slovak respondents. The results of this study show that Slovaks prefer to buy through larger screens, but it is not possible to dispute frequent shopping through mobile devices, too. In particular, women and consumers of the Generation Z make purchases several times a month. Although shopping via mobile devices shows a rapidly growing tendency, it is still questionable to what extent online shopping using mobile phones is widespread in the Slovak population. However, it is certain that online shopping is already a common part of lives of most consumers in Slovakia.

Keywords: E-Commerce, M-Commerce, Consumer Behavior, Frequency Of Shopping

Introduction

E-commerce is a revolution in business practices (Ohidujjaman et al. 2013, Bauerová 2019). Khan and Mahapatra (2009) state that information technology can play an important role in the development and improvement of services in the business sector, and that today, after the agricultural and industrial revolution, the Internet is considered the third revolution.

The SWOT analysis of e-commerce by Awais and Samin (2012) highlights ubiquity, low operating costs, improved customer interaction and time savings as unique strengths of e-commerce. The ubiquitous nature of the Internet has allowed e-commerce to overcome geographical boundaries and penetrate different markets to generate demand in peri-urban and rural areas after successfully exploiting its potential in metropolitan cities (Gangeshwer 2013; Weberová et al. 2016). Dobbs et al. (2013), Štefko et al. (2015) noted that online stores often sell products at a low price, which the consumer sees as an advantage. Goldsmith et al. (2005) revealed that some consumers shop online just to avoid direct interaction with sellers. They are more comfortable when dealing with a seller if the contact takes place in a virtual space (Gburová and Marchevská 2017; Mura et al. 2018).

In many studies, researchers have found that mobile commerce is a next step of the development of e-commerce. As m-commerce makes use of the Internet via mobile or tablet, scientists categorized m-commerce as a sub-group of e-commerce. Both concepts are similar to each other and share basic business principles (Fong and Wong 2015; Štefko et al. 2017). In another view, mobile commerce is a new element of e-commerce, where all transactions are connected via mobile devices and use the wireless network. Therefore, it could be stated that mobile commerce is a part of the e-commerce that is carried out through a mobile phone (Li a Dong 2010; Bucko et al. 2015).

M-commerce is an umbrella term encompassing several types of mobile commerce, while m-shopping concerns only those activities related to the purchasing process, especially in B2C and C2C environments. In this case, mobile shopping can be defined as searching, browsing, comparing and purchasing goods and services online via wireless handheld computers or mobile devices, in particular smartphones and tablets (Groß 2014).

The Internet and the rapid development of technology have revealed a new global market where there are no time and space barriers (Hečková et al. 2019). In addition, this progress has led to the emergence of a new consumer called the "online consumer" (Racolta-Paina and Luca 2010, Gavurová et al. 2018). These consumers play an important role in e-commerce and have different purchasing habits compared to traditional consumers. Companies must pay attention to the needs, habits, lifestyles and characteristics of online consumers to meet them in a more global, competitive and dynamic environment (Svatošová 2013).

According to Zhou, Dai and Zhang (2007), online purchasing behavior was defined as the ratio of online buyers to the total population of the nation, and the economic status was measured with GDP per capita. However, such data did not reveal the consumer's intent, which is an extremely important resource for online retailers. Pavlou and Fygenson (2006), Dejan, Bačík and Fedorko (2014) argue that online shopping behavior is very closely related to information technology, because the web system primarily provides the means to make a purchase.

The current state of the issue

The rapid penetration of mobile phones into everyday lives reflects the fact that people browse the Internet mainly on mobile devices. We are social (2019) tracked the time people spend on the mobile Internet and found that while in 2014 26% of the total daily time on the Internet was spent using mobile devices, this share has been increasing steadily year on year. According to the company's data, we conclude that in 2019 we spent almost half of the total time spent on the Internet using a mobile device.

Mobile website statistics also showed great results. More than half (52,48%) of website traffic comes from mobile devices. Worldwide Internet traffic is dominated by mobile devices (Stat Counter 2019).

The situation on the Slovak e-commerce market also reflects the current developments. Today, the vast majority of Slovaks (85%) between the ages of 12 and 79 has access to the Internet. Year-on-year, these numbers continue to grow. In December 2019, IAB (2018) saw a further increase in the overall Internet population to 3,5 million and the mobile Internet population to 2,8 million. Moreover, according to the Ecommerce Foundation (2018), up to 59% of Slovak consumers shop online. One of the measures of the growth of e-commerce in Slovakia is also turnover, which reached EUR 1,130 million in 2018, thus representing a year-on-year increase of up to 23%.

The number of visits made from mobile devices is also provided by the IAB report (2018), according to which the average monthly visit rate by Slovak PC users reached 3,4 million users in 2018, a slight year-on-year increase compared to 2017. This trend mirrors the global trend, while it is evident that people are increasingly using mobile devices to access the Internet. The average monthly traffic via mobile devices in 2018 was 2,6 million users.

In addition to the aforementioned, IAB (2018) reported also the time spent by Slovak users on individual devices browsing media. According to the report, in 2018 Slovaks spent 7 hours a month on average (across all platforms - PC, Mobile, Tablet) on the Slovak media. Men spent 1 hour and 28 minutes more on PCs than women. In 2018, users spent 1 hour and 3 minutes more per month on a mobile phone than on a computer.

Interesting statistics are also provided by a report carried out by Picodi (2018) on how Slovaks shop online. For this report, the internal data of the global e-commerce platform Picodi.com for the year 2018 was used. The statistics mapped 35 countries of the world. For currency conversion, the company used the average exchange rate for March 2019. According to the company's data, while global mobile shopping is on the rise, Slovaks still prefer to make their purchases through computers. Based on Picodi's data, it can be concluded that in 2018 31% of transactions were made by mobile,

which is 25% less compared to transactions carried out using computer. In addition, the average value of an order made via mobile is slightly lower. While Slovaks spend an average of € 54 on mobile purchases, the value of purchases is € 4 higher when shopping using computer.

In terms of mobile trading, m-commerce's share in the total Czech e-commerce was up to 10% in 2014 - almost 300 million euros, as confirmed by Lelák (2016) from the website Pricemania Academy. Slovakia is above average, it is doing even better than the Czech Republic, says Braverman (2016), CEO of Heureka. When comparing the number of mobile visits, according to him, the figure is better for Slovaks - 37% compared to 30% for its western neighbors. In 2018, the share of mobile phone visits of Slovaks was 52%, an increase by 15% (Heureka 2018).

Methodology

The main aim of this paper is to identify the purchasing behavior of Slovak consumers in terms of demographic differences. Specifically, the paper focuses on describing the frequency of online shopping via large screens (PC/laptop) and mobile devices, comparing the frequency of shopping in men and women, as well as comparing the frequency of online shopping across generations. The input data were obtained from a questionnaire survey. The questionnaire was divided into three parts.

The first part of the questionnaire contained items for sorting the research sample according to demographic characteristics, the second part of the questionnaire monitored subjective answers of respondents in connection with shopping using a mobile phone and the last part of the questionnaire examined the frequency of online shopping. We focused on shopping via large screens and shopping via mobile phones. Respondents could indicate one of the options (1 = At least once a week, 2 = At least once a month, 3 = Several times a year, 4 = Maximum 2-3 times a year and 5 = Maximum once a year). Only respondents with at least one online shopping experience were eligible to participate in the research.

The research sample consisted of part-time students regardless of further specifications. We also decomposed the sample of respondents born in 1966-2000 into three generation cohorts: Generation X (1966-1976), Generation Y (1977-1995) and Generation Z (1996-2000) according to Duh and Struwing (2015). After discarding irrelevant responses, we created a data file with sample n = 627. The only condition for participation in the research was the experience with online shopping. The following table describes the characteristics of the research sample.

Table 1: Characteristics of the research sample

Characteristics		Frequency	Percentages
Gender			
	Female	394	62,84%
	Male	233	37,16%
Generation			
	Gen X	45	7,18%
	Gen Y	330	52,63%
	Gen Z	252	40,19%
Economic status			
	Employed (full-time)	383	61,08%

	Employed (part-time)	50	8,97%
	Self-employed/ entrepreneur	73	11,64%
	Unemployed	69	11,00%
	Parental leave	34	5,52%
	Other	18	2,87%

Results

Figure 1 below illustrates the frequency of online shopping, using a desktop or laptop computer, in terms of gender. It is evident that most consumers make online purchases at least once a month. Surprisingly, the numbers of women are twice as high as men at this frequency, but this may also be due to the disproportionate number of respondents in terms of gender. However, the numbers are approximately the same at a higher frequency of purchases (at least once a week).

Fig. 1: The frequency of online shopping via a PC/laptop from a gender perspective

The following part of the paper captures the outcomes of frequency analysis of online shopping via mobile phone from the perspective of generations (Figure 2). In this case too, it is clear that the highest numbers are recorded for the option "at least once a month" in Generation Y (n = 149) and Generation Z (n = 111). The option "several times a year" was chosen by 15% of people aged 1997-1995 (Generation Y) and 13% of people aged 1966-2000 (Generation Z).

Fig. 2: The frequency of online shopping through a PC / laptop from a generational perspective

Figure 3 below shows the frequency of mobile shopping from a gender perspective. It is evident that the numbers in this case are much more proportional than the outcomes of larger screen purchases. The figure shows that most purchases made using mobile phones are done once a month for women (n = 129) while men shop at these frequencies at less frequently. The largest group of mobile shoppers shops via their mobile device at a frequency several times a year (n=79).

Fig. 3: The frequency of online shopping using a mobile phone from a gender perspective

Figure 4 illustrates the frequency of purchases carried out via mobile devices from a generation perspective. Even in this case, the highest numbers for Generation Y (n = 149) and Generation X (n = 111) are recorded for a frequency "at least once a month". Surprisingly, Generation Y shows high numbers even at the lower frequency of purchases – "maximum once a year".

Fig. 4: Frequency of online mobile shopping from a generational perspective

Conclusion and Discussion

Given the huge expansion of the Internet network, it is no surprise that every second person in the world uses the Internet (eMarketer (2017a). At the same time, e-commerce statistics from Statista (2019) point to the fact that there are 1,92 billion digital customers, representing 63% of the total Internet user base and about a quarter of the total global population. Interesting figures are also reported by GSMA Intelligence (2019), according to which in 2018 there were 3,6 billion people using the mobile Internet. At the same time, these figures represent 47% of the total global population.

The above results of various research agencies and website underline the importance of addressing the issue of online shopping. Mobile commerce shows a rapid growth tendency in the global concept, but it is questionable to what extent mobile shopping will be popular among the population of Slovakia. However, the amount of time Slovaks spend on these devices, combined with the current trends, mobile phones can prove to be a powerful tool that should not be left unnoticed by no business.

The main aim of this paper was to identify the frequency of online shopping via large screens (PC/laptop) and mobile devices in terms of gender and generations among Slovak consumers. The survey showed that most women shop online at least once a month, and the same frequency was also seen for women using mobile devices, although the results showed that a large group of women shop at lower frequencies through these devices (several times per year). Conversely, most men shop using a mobile phone several times a year. From the perspective of generations, it is clear that larger screens are still very popular with Slovak consumers. Most often, Slovaks make purchases at a frequency of several times a month, except for the oldest generation. The frequency of mobile purchases for individual generations ranges from several times a month to several times a year.

It should be emphasized that the research is limited, as it focused on a sample of Slovak students. Therefore, the results cannot be generalized to the whole population of Slovakia. Another limitation of the research is the disproportionate representation of respondents from the perspective of generations, especially in relation to Generations X, as these were underrepresented. For future research, it would be useful to target a more heterogeneous group of people, such as all mobile phone users with proportional representation of different age and gender groups, or to monitor the purchasing behavior of consumers from different neighboring countries.

Management of The Aviation Transport Services Market

Judyta KABUS

Częstochowa University of Technology, Poland
judyta.kabus@wz.pcz.pl

Abstract

The aviation transport services market is one of the fastest-growing branches of the entire transport system across the world. The aviation transport services market has undergone many changes over the years. In a time of dynamic globalisation and so-called „distance reduction" we are dealing with ever greater transport-related difficulties. The market for aviation transport services is evolving very quickly, and thanks to it we are able to deliver cargo to the farthest corners of the world. The aviation transport services market has for several years shown continuous increases in the popularity of aviation in all respects. Ever more people are choosing aircraft as their mode of transport, contributing to the establishment of new airlines and offers ever more suited to customer needs. The aviation transport services market must be considered as a multi-layered phenomenon. The objective of the present article is to diagnose development plans of airports and identify the development of key components of the air transport services market. Particular attention is drawn to the influence of globalisation and airline alliances to the character of the air transport services market. The empirical analysis uses statistical data collected by airlines and airports. Data is analysed and presented in the form of tables and diagrams.

Keywords: Aviation Infrastructure, Air Transport, Airport, Services

Introduction

The contemporary aviation market is developing very dynamically, is innovative and modern. Aviation transport is also a fairly young discipline, and its origin reach back to the beginnings of the 20th century. On exactly December 17th, 1904, the event that changed history took place, ushering in true aviation. Aviation pioneer and inventor Wilbur Wright made his first flight that day at Kitty Hawk; even if it did last just 12 seconds, it sounded the beginning of a new era in aviation. Wilbur cooperated with his brother Orfille for years, and they are considered the fathers of aviation (Ruciński, 2013: 13-13).

The period just after World War I is considered the beginning of civil aviation. During the war, aircraft were constructed for military purposes, however they could now be transformed into machines for civilian use. Production also commenced of aircraft meant purely for passenger transport, which could take between six and eight people aboard. Such was e. g. the Junkers F13. This aircraft initiated the first commercial connections. In the 1920s, the first airlines were founded and the first connection networks were developed. The end of the 1920s are also the beginnings of the first large passenger aircraft like the Junkers G38, which flew regular connections between such cities as London, Copenhagen, Rome or Stockholm (Sandela 2009: 13-14). The period after World War II spans dynamic development and evolution of airline connections as well as passenger aircraft and their engines themselves. The first jet airliner was the British De Havilland Comet 1. Ever bigger aircraft and ever greater speeds made the passenger numbers rise year to year, with the aviation services market becoming global. Such quick development and such transport capacities of aircraft allowed aviation to completely displace transatlantic ocean liners, which ferried passengers between the Old Continent and America for years, from transport. The end of the 1960s is the beginning of brief yet very intense history of supersonic flights. There were two representatives: The Russian Tupolev Tu-144 and the British-French Concorde. The first was, however, quickly removed from service following two catastrophes. The Concorde continued to fly over the Atlantic for a quarter century more, until 2003.

It was removed from services due to environment protection, as these planes were fuel-hungry, and for economic reasons. The beginning of the 21st century means the development of large airlines, the emergence of great alliances and the market appearance of so-called low-cost carriers (Ruciński 2013: 17-19).

The objective of the present article is to diagnose the development of airports and to identify the development of key components of the aviation transport services market. Particular attention is drawn to the influence of globalisation and airline alliances on the character of the aviation transport services market.

Research methodology and sample description

The aviation transport services market is made up of intertwined many components. This market is an environment, in which relations occur between entities and resources flow that support distinct structures. The aviation services market must be considered in the regional and global context; it is made up of elements that describe the mutual relations on this market. The market, as the name suggests, is the place where transactions are performed with consent of the participating entities. In the aviation services market, the dominant entities are passengers, travel agencies, airports and, of course, airlines. There also exist external entities that also create the market and influence its functioning; these entitiXs include, among others, marketing advisory agencies, local authorities, banks or insurance companies. In order for the market to develop dynamically, competition must exist between service providers. Two types of competition on the aviation services market may be indicated: inter-branch and intra-branch competition. Interbranch competition occurs between markets that offer substitute products, meaning those that constitute a response to the same kinds of needs. Depending on the country or region, customers will choose various modes of transport. In terms of intrabranch competition, the customer is fought for between service providers within the market, meaning, between aviation transport companies.

The issues presented in the paper focus on the development characteristics of airports and the shaping of key components of the aviation transport services market. Hence, particular attention was also paid to the influence of globalisation and airline alliances on the aviation transport services market.

The paper was prepared on the basis of studies of Polish and foreign-language literature concerning management, logistics infrastructure as well as air transport, domestic and European documents in this area, analyses of statistical data collected by airports and airlines.

The present paper shall utilise the following research tools and methods:

- analysis of available knowledge based on management and logistics literature;
- analysis of acts of law;
- statistical data of airports;
- statistical data collected by airlines

Discussion

Changes on the aviation transport services market proceed very dynamically; this is influenced by diverse competitive instruments. Long-term analytical research estimates that until the year 2037, the aviation services market will see growth of over 5% (US Department of Transportation :Online 14).

Fig. 1: Estimated development of the aviation transport services market until 2037.

Figure no. 1 shows the estimated aviation transport services market development until 2037. The data indicates that the world GDP may rise by 2.8% as compared to the year 2018. The number of passengers transported shoul rise by 4.7%, and the aircraft fleet is to grow by 3.5% as compared to the year 2018. This growth concerns the entire world aviation market (US Department of Transportation :Online 14).

Fig. 2: Estimated growth level of the aviation services market until 2037, subdivided by world regions.

Figure no. 2 shows the estimated growth level of key components of the aviation transport services market subdivided into the individual regions of the world.

According to the data, the largest growth should be seen in Africa, up to 6% compared to the year 2018 in terms of passengers served. Latin America will also see high growth as compared to 2018. of up to 5.9%. The biggest growth of the fleet, or the number of aircraft, will be experienced by the Near East, seeing a value of 4.9% (Albalate, Bel et al. 2015: 167-168). This will be the result of fast-growing airlines such as Emirates or Qatar Airways. Considering the GDP, in turn, the Near East shall also see

biggest growth of 3.5% as compared to 2018. The diagram shows in turn that smallest overall growth of aviation transport services is expected in Latin America (US Department of Transportation: Online 14).

The increases in passenger counts, services and fleet sizes also mean an increase in value of the entire market. It is estimated that until 2037 the entire market value could even reach USD 6.3 trillion.

Fig. 3: Market value broken down by world regions.

The data in fig. no. 3 shows the subdivision of the entire market value estimated for 2037. The above data shows that the highest value of the aviation services market will be shared by Asia and Oceania – USD 2,670 billion. Europe will also have a high market share of USD 1,240 billion. The lowest value is estimated to be reached by Russia and Central Asia, just USD 150 billion (US Department of Transportation :Online 14).

Results

One of the most significant components that influence the growth of the aviation transport services market is continuing globalisation. Globalisation has a real influence on the development of the world and of civilisation, it influences the shape of markets, is the driving force behind the competition and expansion to new markets. The influence of globalisation causes economic and social changes. The dynamics of growth of glbalisation are multidirectional. This development is influenced by aspects such as (Dobruszkes, Giovani et. al. 2017: 52):

- the financial condition of the individual economies;
- the performance capacity of goods and the quality of their technological capacities;
- large management teams and the quality of their knowledge and skill resources;
- broadly understood societal mobility and wealth.

Globalisation and digitalisation influence unlimited capacities of travel and movement across the world. The continued development of large as well as small, *low cost* carriers makes many people choose aviation transport as a mode of getting from A to B. Ever expanding competition influences the

innovation capacity of the services offered, the expansion of carrier brands and the market availability of services. These components determine the growth level. Aviation transport is described as the direct subject that creates globalisation, and that at the same time, undergoes globalisation processes (Kabus, Srtulak-Wójcikiewicz et. all 2016: 156-157).

Fast-growing aviation transport and innovative technological solutions quickly introduced into daily use determine the fact that aviation was the mainstream of globalisation from the very beginning. Aviation companies that want to continue to develop, increase passenger numbers, the quality of the provided services and, hence, that want to increase financial turnover, must be participating factors in globalisation processes, transforming their globalisation strategies. This applies mainly to regional carriers who, failing to participate in globalisation processes, may be pushed to the edge of the market, and, as a consequence, disappear from it altogether (Cidell 2015:1136). Small and regional airlines are starting more and more frequently to initiate long-haul connections, e. g. flights between Europe and North America. It is the already mentioned globalisation that forces minor carriers to undertake activity aimed at testing new trends – whether they are even economical to begin with (Percoco 2010: 2429). The main barrier for transatlantic flights is certainly a certain monopoly developed over the years by large flag carriers such as British Airways, KLM, Lufthansa or even Poland's PLL LOT. Intercontinental flights are, however, burdened with cost. Taxes and diverse fees mainly influence the prices of transcontinental flights. The largest carriers have a mechanism to balance out their prices, with an economy-class ticket being relatively cheap, yet very high in business class. Thanks to such discrepancies, they are able to balance out the costs borne in terms of taxes and fees. Low-cost carriers continue to study the possibility of long-haul connections, however, from the economic point of view this seems uneconomical. *Low cost* carriers earn most on individual connections. Within Europe, a single airplane is able to make even eight flights per day, and each of these generates separate revenue from diverse fees and low operating costs. A transatlantic flight is a single connection performed at the same time, and there is no way to avoid costs related to e. g. fuel or en-route (ENR) fee (Barett and De Vita 2015: 49-50).

The dynamic development of the aviation services market is also stimulated by strategic airline alliances. Alliances are concluded between airlines mainly for the purpose of expansion. Airlines operating within an alliances cooperate on certain levels, however, continue to be competitors. Every carrier has their own *know-how*. Cooperation within an alliance allows carriers to implement good solutions of the partner within their company, and to provide their own good practices to others (Schlenker and Walker 2016: 774-775). This creates the possibility of improvement of one's own competitive position on the market and to operate a more dynamic expansion policy to new markets. In order for cooperation to be successful, conditions of balance must be maintained. An example of cooperation and mutual benefits is the Sky Team airline alliance, which developed a collocation system at London Heathrow's terminal four. This entails the sharing of all ticket sales and departure handling desks by all alliance carriers. This helps to improve the flow of passengers and reduces operating costs by alliance members. These desks also allow the passengers to change reservations to any flight with a carrier belonging to Sky Team. Heathrow terminal four also offers the world's first SkyTeam Exclusive Lounge (SKY Team: Online 12). Airline alliances are hence the key mode to ensure most competitive and better services on markets. The expansion of connection networks thanks to alliances allows individual carriers to offer flights to new airports. Airlines have most advantages on their local markets, with respect to which they have knowledge and experience, they know the specifics and expectations of customers in those markets. In order to enter a new market, airlines require knowledge about them, and it is here where local airlines come to aid (U.S. Department of Transportation 1999: 7-11).

Fig. 4: Example development of an alliance using the example of SkyTeam in the years 2013-2018.

Figure no. 4 presents the development of the SkyTeam alliance over five years between 2013 and 2018. The diagram clearly shows that the alliance experienced clear growth at this time. Alliance members created new connections, and as compared to the year 2013 the number of destinations increased by 56. The aircraft fleet of the carriers also expanded by just over 100 units, with a significant increase of operations, up to 17000 in 2018 (SKY Team :Online 12).

The quickly developing aviation transport services market over the years forced the creation of international organisations that would control aviation market activity. The largest such authority is the „International Air Transport Association", or IATA. This organisation was formed in Havana, Cuba, on April 19th, 1945. to promote air services safety, with passengers in mind, naturally. At the moment of formation, the IATA included 57 members from 31 countries of the world, mainly North America and Europe. Over the years, the organisation expanded, and at the end of 2018 it included 290 airlines from 120 countries, giving a share of 82% of the world's entire air transport. It is a vision of the organisation to work to represent and service the world's entire aviation industry. It develops global business standards, on which the entire aviation market is based. This organisation helps aviation

carriers in terms of business and to work on the basis of clear-cut rules. For the year 2019, the IATA has assumed several priorities such as (IATA: Online 13):

- improvement of legal rules;
- reduction of fuel and airport fees and taxes;
- continuation of audits aimed at improving safety;
- increasing member numbers and their satisfaction;
- removal of barriers against commercialisation of alternative fuel and energy sources.

The second largest aviation body is the ICAO, the „International Civil Aviation Organisation". This is a UN agency created during the international convention on civil aviation in Chicago in the year 1944. 54 member states called the ICAO into existence to promote cooperation. The ICAO today cooperates with 192 member states to develop consensus on normative issues in civil aviation, recommended operating practices and in terms of balanced economic development in aviation. The ICAO also develops forecasts for the aviation market and conducts detailed statistics for the entire aviation industry. It monitors diverse safety and performance indicators for the aviation transport sector. The chief vision of the organisation is the permanent development of the world civil aviation (IATA:Online 13).

Summary

Considering the development of humanity, air transport remains a very young area. In reality it has been in existence for just over 100 years. Beginning with the first wooden aircraft, whose flight lasted just a few seconds, all the way to the enormous aircraft able to reach any corner of the world. The development of aviation completely changed the perception of globalisation, and transformed the approach to civilisation development. The aviation services market is nowadays the main driving force behind global development. It is the development of aviation that contributes to the development of „contraction" of time and space. Thanks to aviation services, we can reach the farthest corners of the world within a matter of several hours. New technologies enable the aviation transport services market to continue to develop at a great pace.

Does Share Capital Influence the Success of IPOS?

Tadeusz DUDYCZ

Faculty of Computer Science and Management, Wrocław University of Science and Technology,
Wyb. Wyspiańskiego 27, 50-370 Wrocław, Poland,
tadeusz.dudycz@pwr.edu.pl

Abstract

This paper examines the impact of share capital on the success of new issues during initial public offering (IPO) The study is based on a sample of IPO firms which went public on the Warsaw Stock Exchange from 1998 to 2013. The paper shows that share capital which was created to protect corporate creditors against the "extra" risks associated with limited shareholder liability – interacts with investor behaviour and can be used to improve the success of a share issue.

Keywords: Par value, Share capital, Signalling, Creditor protection, Corporate law, IPO, WSE

Introduction

The concept of par value was conceived in order to counteract fraudulent practices that became widespread after shareholders were released from company obligations (Cook, 1921). These consisted of issues and public sale of shares that were not reflected in assets. Therefore, the concept of par value assigned each share a value reflecting cash payments or assets contributed by each shareholder and reflecting the scope of their liability for the company's obligations (Shares, 1921). The share capital corresponding to the par value of one share multiplied by its quantity reflects the capital that company must maintain in order to satisfy the claims of their creditors. Share capital is the main element of the capital maintenance principle, because shares cannot be sold below par value and the capital accumulated in this way cannot be distributed as long as the company exists. However, the concept of par value has been criticized since its birth. It has been accused of not being able to effectively protect creditors against the defrauding behaviour of shareholders.

Although the concept of par value has become the cornerstone of company law in many countries, nowadays there is a clear tendency to abandon it. The exception to this is the European Union and the European Economic Area. Its strong position in Europe stems from the support that the concept of par value has in the Second Council Directive of 13 December 1976. Subsequent analyses, such as Reforming Capital – Report of the Interdisciplinary Group on Capital Maintenance (Rickford, 2004) and a feasibility study on an alternative to the capital maintenance regime established by KPMG on behalf of the European Commission (KPMG, 2008) did not find unambiguous reasons for abandoning it. Therefore, it should be expected that this concept will continue to function in the company law of many countries, which justifies further research into its functioning in practice.

Although the concept of par value was created to protect society and creditors, it may also have an impact on financing companies (Rickford, 2004). Share capital can be a signalling tool showing the degree of shareholder involvement in the company (Mulbert & Birke, 2002). Therefore, it can be expected that it will be well invested. The purpose of the article is to examine the usefulness of share capital as a signalling tool, which contributes to improving the company's position on the capital market. The contribution of the article to the literature is its examination of the impact of share capital on the success of a new issue during its IPO. According to the author's best knowledge, this aspect has not been studied to date. The concept of par value already has over 200 years of history, but previous considerations of its functioning are theoretical and carried out in the field of law and accounting. This

article enriches this discussion with empirical research which, to the best of my knowledge, is a new aspect.

The remainder of the paper is organized as follows. Section 2 provides a literature review and the hypothesis for my investigation. Section 3 describes the data, variables used in this study, and research methods. In Section 4, I present and discuss the empirical results, and Section 5 concludes the paper.

Literature Review and Research Hypothesis

Background

The concept of par value was conceived over 200 years ago as a response to the fraudulent behaviour of shareholders after their release from personal responsibility for the company's obligations. This exemption was of great importance for economic development, because it created conditions for public sale of shares and accumulation of capital (Cook, 1921). However, it also resulted in the appearance of negative phenomena involving the sale of shares that did not have adequate coverage in assets, which were hence called 'watered stock'. The concept of par value consists of assigning each share a nominal value reflecting cash payments or assets contributed by each shareholder (Ho & Lan, 1999). Due to the fact that the share capital contributed during the establishment of the company is stable and reliable – because companies cannot redistribute it to shareholders as long as the company operates and new shares can not be sold below par value – it is a convenient criterion for measuring the extent of shareholders' liability. Share capital can be considered the first legal capital because it began the maintaining capital principle created to protect the company's creditors against the extra risk related to the limited liability of shareholders for the company's liabilities (Armour, 2000). Par value paid by shareholders for their shares is the price required by law for the advantages of limited liability companies (Mwenda, 1999). Legal capital fulfils a similar role for creditors as a financial cushion which acts in the same way as financial adequacy provisions for financial institutions (Bachner, 2009; Handschin, 2012).

Legal capital has been criticized from its inception. Enriques and Macey (2001) believe that the capital maintaining principle does not bring any benefits to creditors; on the contrary, in some cases it even harms them. Consequently, the accompanying burdens of this principle on companies and societies are completely unjustified. The authors are convinced that maintaining this principle in European law, despite its ineffectiveness, results only from the influence of interest groups that benefit from the functioning of legal capital. These include incumbent management boards representing the interests of controlling shareholders, accounting officers providing required share valuation services, and lawyers assisting managers in navigating the maze of unnecessarily complicated laws regarding legal capital. Also, Ho (2017) claims that the principle of capital maintenance contributes to reducing the flexibility of the financial structure and burdens it with cumbersome procedures that force companies to pay for 'useless expert reports and legal advice' (p. 19). Similarly, Mulbert and Birke (2002) consider that the utility of the capital maintaining principle for the protection of creditors is small and there is a nontrivial likelihood that this principle does more harm than good. In turn, Mwenda (1999) remarks that the value of assets may increase or decrease over time and, for this reason, this value ceases to correspond to the value of the originally contributed share capital. Therefore, any cash-based equity valuations used as a signal for a market about the value of shares in the company's equity are usually fictional and may be both meaningless and misleading. Therefore, in contrast to Bebchuk (1992), Ho (2017) is convinced that in the real world creditors do not pay attention to legally maintained capital which should reflect the value of collateral, because they often protect their interests by covenants.

However, there are also authors who see the benefits of the capital maintaining principle. Bonbright (1924) points out that par value does not reflect the value of a company subject to constant change and cannot be determined on the basis of share certificates; it only reflects the capital that shareholders

agreed to contribute. In addition, Pennington (1990) emphasizes that the concept of par value is useful when declaring dividends in percentage of par value, as well as determining the voting rights at the general meeting or determining the amounts due to privileged shareholders in the event of the company's liquidation. According to Mulbert and Birke (2002), the most important positive effect of the capital maintenance principle is limiting harm actions to creditors by distributing capital, in particular by way of 'hidden distributions'. Therefore, the principle of maintaining capital can be a way to reduce post-contractual opportunism by shareholders (Armour, 2000) and the same mechanism can be used to reduce agency conflict (Panetsos, 2016), because – for example, as reported by Boubakri and Ghouma (2010) – covenants may be ineffective in protecting creditors if the ultimate owners are a family. Cascino et al. (2013) are advocates of a continental accounting model which focuses on creditors and requires highly codified reporting (Joos & Lang, 1994), and empirical evidence from Europe shows that creditors prefer conservative accounting valuations.

Although the purpose of the par value regime is to protect creditors against fraudulent behaviour of shareholders, it can be used as a tool to influence the financing of the company (Rickford, 2004). This impact results both from the properties and mechanism of the par value regime. Generally, two types of interactions can be distinguished. The first behavioural interaction results from the number of shares and the nominal value of the stock determined by it. By appropriately shaping these parameters, there is a possibility to incline investors towards committing perceptual biases. The second type of interaction results from the value of the entire share capital and the consequences of the capital maintenance principle.

The main purpose of this article is to test the impact of the entire share capital on the success of issuance during an IPO.

Hypothesis

Share capital is subject to the principle of capital maintenance, which means that it is inviolable during the functioning of the enterprise. According to Mulbert and Birke (2002), it can serve as a 'seriousness' test and as a signal that shareholders have confidence in their company and intend to work hard towards its success. Therefore, this capital should be located in the most valuable assets, as opposed to other types of equity, such as reserve capital or retained earnings. Reserve capital and retained earnings are more transitory in nature and therefore may be invested in short-term assets with lower efficiency. From this, one could expect that when there is more equity capital in the equity structure, this is a strong positive signal for investors, improving the company's position on the capital market. On this basis the following hypothesis have been formulated: *H: Share capital is an effective signalling tool contributing to the success of the new issue.*

Sample Description and Research Method

Sample

The study is based on a sample of IPO firms which went public on the Warsaw Stock Exchange from 1998 to 2013 (total number of IPOs reported in Panel A of Table 1). This initial sample of 496 IPOs was reduced by excluding:

a) financial institutions (e.g., banks and insurance companies),
b) IPOs which were not connected with new common stock issuance,
c) IPOs for which data was incomplete.

The final sample thus consists of 259 IPOs. Panel A of Table 1 shows the variations in the sample number of IPOs over the 16 years.

The primary source of data used in this study was Notoria Service; however, because there are sometimes incomplete or incorrect data in the database, other sources of data were used to supplement these, such as IPO prospectuses, and annual reports available on the companies' websites and at www.gpwinfostrefa.pl.

The main focus of this study is the impact of share capital on the success of issuance during IPO and profitability after IPO. Panel B of Table 1 reports the basic characteristics of the sample firms one year before IPO, such as total assets, total sales, and financing parameters. The variables used in this study are defined in Table 2.

Research Methods

In the first step, three models were built in which the dependent variables were parameters which characterized the issue success. Three parameters were selected: the relation of the issue price to the book value of the shares, the percentage increase in equity, and the ratio of the percentage increase in equity to the percentage number of shares sold. The following variables were used as control variables: indicators showing the financial condition of the company, such as ROE, ROS, CR, S/A, E/FA, D/A; parameters illustrating the economic situation, such as WIG, WIG percentage change, and GDP growth; and SC/E was used as a measure for the share capital. The sector was added. The number of issued shares was strongly related to the size of the company and the nominal value of the shares. In order to increase the symmetry of the distribution, most parameters were shown as a logarithm. The explanation of the parameters used is presented in Table 2. Therefore, the models used are as follows:

$$Y_t = \alpha + \beta_1 sector + \beta_2 ROE_{t-1} + \beta_3 ROS_{t-1} + \beta_4 Ln\frac{S}{A_{t-1}} + \beta_5 \frac{D}{A_{t-1}} + \beta_6 LnCR + \beta_7 Ln\frac{E}{FA_{t-1}} + \beta_8 GDP + \beta_9 LnWIG + \beta_{10} WIG[\%] + \beta_{11} LnNP + \beta_{12} \frac{SC}{E}_{t-1} + \beta_{13} NrSh + \varepsilon_t$$

Results

In Table 3, Panel A, we can see that IPO companies obtain very large amounts of capital. The trimmed average shows that the capital increase is above 150% (Proceeds/SE_{t-1} [%]), investors pay more than PLN 4.8 for each zloty of the book value (IP/BV_{-1}), and the sale of one percent of shares allows you to increase equity capital more than 6% ((Proceeds/SE_{t-1})/(% shares sold)). It can be concluded that IPO companies generally succeed during the issue, allowing them to multiply their capital. This success is determined by profitability (ROE) (Table 3, Panel B) which was also reported on in previous studies (Dudycz & Brycz, 2017).

A good signal for investors is also the possession of large amounts of cash (CR) and high indebtedness (D/A), which is a signal for investors that the banks, as a third party, have rated the company well (Brycz, Dudycz, & Kowalski, 2017).

Table 2: Variable definitions

Variable	Definition
Ln NP	Natural logarithm of nominal price of share
Ln Assets	Natural logarithm of total assets
Ln Sales	Natural logarithm of net sales
Ln SC/E	Natural logarithm of share capital to the total shareholders' equity ratio
Ln S/A	Sales to total assets ratio
ROE	Return on equity defined as net income divided by shareholders' equity calculated as the difference between total assets and total liabilities
ROS	Return on sales ratio
D/A	Debt ratio defined as total debt (the sum of current liabilities and long-term liabilities) divided by total assets
Ln CR	Natural logarithm of cash ratio defined as short-term investments divided by current liabilities
Ln E/FA	Natural logarithm of shareholders' equity-to-fixed-assets ratio defined as shareholders' equity to total fixed assets
Ln NrSh	Natural logarithm of number share issued
IP/NP	Ratio of issue price to the nominal value of shares
Ln IP/BV	Natural logarithm of ratio of issue price to the book value of shares
Ln WIG	Natural logarithm of value of the Warsaw Stock Exchange Index, which comprises all companies listed on the main market; the initial value of the WIG Index on 16 April 1991 was 1,000 points
WIG [%]	Rate of return on WIG Index
GDP growth	GDP growth rate defined as the percentage change in gross domestic product during one year
Sector	Sector of the economy. A variable used to control for the sector effect, which is coded as: 1 – architecture; 2 – chemical industry; 3 – energy; 4 – mining and metallurgy; 5 – trade; 6 – information technology; 7 – media and telecommunications; 8 – heavy industry; 9 – light industry; 10 – food industry; 11 – services.
Ln NrSh	Natural logarithm of number share issued
Proceeds/SE_{t-1}	Percentage increase in shareholders' equity through the issuance of primary shares calculated as the IPO proceeds from the sale of primary shares divided by total shareholders' equity at the beginning of the IPO year (calculated as the difference between total assets and total liabilities)
(Proceeds/SEt-1)/ (% shares sold)	Percentage increase in shareholders' equity to the percentage of shares sold via the issuance of primary shares

The success of the emission is also influenced by timing, especially measured by GDP growth. However, apart from the financial condition and timing, the impact of which has already been reported in the literature, the success of emissions is also influenced by a triad of factors determining the emission parameters. As we can see in Table 3, Panel B, the impact of the success of the issue is to emit a small number of shares (NrSh) with low NP, the book value of which is characterized by a large share of SC in Equity (SC/E). Issuing a small number of shares increases the probability such that the demand for shares will exceed supply, which will positively affect the price of shares. Low NP means that the remaining types of share values (book value, issue price) are also relatively low, so they induce investors to make perceptual biases such as the 'face value' effect or 'charm price', whereas, the positive impact of SC/E ratio on the success of the issue shows that, for investors, share capital is a measure of investor involvement that promises better management of the company and, consequently, higher efficiency of the company. This confirms the hypothesis that share capital can be used as a signalling tool to improve the company's position on the capital market.

Table 3: Regression analysis of the determinants of IPO success

F	28.388	13.988	23.997

*Panel A reports the mean values of each variable Y_t . Panel B reports the results of the regressions models. The constant term is not reported. The standard errors that are robust to heteroscedasticity are reported in parentheses. *, **, and *** indicate that coefficients are significant at 10, 5, and 1 per cent levels of significance, respectively.*

Conclusions

The par value regime imposes on companies the obligation to create and maintain capital in order to secure the claims of the company's creditors. The effectiveness of such security has been questioned from the inception of the par value concept. However, there are reports in the literature that the par value regime can affect the financing of the company both positively and negatively. A positive impact may result from investors' perceptions of share capital as a measure of shareholder commitment and as a kind of 'seriousness test'. On the other hand, a negative impact may be the result of low flexibility of equity consisting largely of share capital.

The research presented in this article shows that, in fact, equity capital is a positive signal for investors, contributing to the success of a new issue. Apart from good financial results of the company, this success is also determined by issue parameters such as the number of issued shares and their unit value. The number of issued shares of the new issue affects their supply. Too high a number has a negative impact on the success of the issue. The question arises whether this factor is global or only appears in small markets where a limited number of active investors operate. However, answering this question would require expanding the research. The low unit price of shares, in turn, contributes to investors making perceptual biases, which are manifest in the separation of the share price from its fundamentals. In this context, par value can be seen as a manipulation tool contributing to the success of the issue.

Abstract

Today, the car sharing market is gaining global popularity. This service is actively used in all megalopolises of the world countries, and even now experts predict a vast huge evolutionary leap in this innovation. The ability to use any type of vehicles anywhere in the world, without actually owning it and bothering with property costs, is one of the main advantages of the Sharing Economy. Today, there are three main regions of the global car sharing market growth – the Asia-Pacific region, Western Europe and North America. The analysis of the dynamics and key trends in car sharing development in three largest regions in question allowed identifying the key factors of intensive development of the car sharing market in these areas, as well as forecasting further growth opportunities for this segment of the transport market.

Keywords: World Transport Sector, Car Sharing, Maas System.

Introduction

The term "collaborative consumption" was first used by American economists Marcus Felson and Joe Speth, in an article published in 1978 in the American Behavioral Scientist journal entitled "Community Structure and Collaborative Consumption: a Daily Activity Approach." 33 years later, the TIME magazine named the collaborative consumption as one of the ten ideas that will change the world (Komarova I.P., 2017). The Sharing Economy has provoked one of the largest social and economic shifts, comparable in importance to the industrial revolution. As a consequence, a new large-scale business trend of the present time has emerged. It is difficult to imagine a sector or a category of business interests that will not be affected by the sharing economy (Ulitskaya N.M., 2014).

As compared with traditional economic model, the sharing economy of the car sharing has a range of obvious advantages:

1. The openness of the collaborative economy makes the entrance of new participants more accessible. The user sets its priorities depending on the available personal time and resources. Such participants can interact in several areas of activity. The user's ability not to limit itself to a single country or city, to be mobile, while earning income.

2. Increasing the benefits for those who offer the resource and those who need it involves the ability to raise the standard of living, while eliminating the social and physical burden of ownership.

3. In no small way, the sharing economy affects the environment. It is essential to recall that one of the drivers of the sharing economy onset was the constantly growing global population. The car sharing allows limiting the number of vehicles in personal use.

4. Restriction of monopolies leads to consumer benefits, which imply an increase in the quality of services and lower prices.

The use of all advantages of the sharing economy in the transport industry makes it possible to make a revolutionary surge, allowing users to have access to a wide range of vehicles without need to bear the costs and other expenses associated with its ownership (V.S. Lukinsky, V.I. Berezhnoy, E.V. Berezhnaya, 2004). At the same time, the sharing economy provides a favorable environment for startups and entices venture investors, recognized transport industry players, both direct vehicle manufacturers and rental companies, turning on strengthening of their positions, especially in the car sharing sector. The transport industry has acquired momentum to become one of the world's leading economies by combining consumer trends with technology, while providing users with a unique sense of personal use. Therefore, it is not surprising that the transport industry is closely connected to future mobility concepts such as car sharing, association of transport manufacturers, MaaS mobility and electric mobility services, as well as other cutting-edge innovations in digitalization and autonomous driving that are in the offing. Over the past few years, the share of users was constantly on the rise in arithmetical progression, especially in large cities, where more and more people bear the expenses associated with the cost of personal transport ownership (E.S. Zemskova, 2019).

Due to the above, the purpose of this work is to analyze the development trends of the main regional car sharing markets, the spotting of which will allow predicting the dynamics and growth directions of the global car sharing market.

Methodology

During research, the following general scientific methods were used: the content analysis method, designed to analyze the semantic content of text arrays and products of communicative correspondence on the research subject, as well as inductive and deductive analysis tools, which allowed us to combine individual authors' conclusions on this problem and formulate the author's vision of the problem. Special methods were also used during the research: absolute and relative statistical indicators, dynamics indicators, and research finding visualization methods. When constructing and describing models, the authors tried to adhere to the principles of an integrated approach that allows establishing the most significant relationships and trends of events and processes in the car sharing market and formalize the most significant effects.

The research database consisted of official statistical and analytical materials from the University of California, the New York Stock Exchange, and the Brookings Institution.

Results

The key players in the global market for car sharing services are the Asia-Pacific Region, Europe and North America. This is due to the following reasons:

1. due to the growth of population in these regions, the car sharing industry has become one of the most prominent sectors in the transport fleets;

2. the car sharing significantly helps to rein in the pollution level by reducing the volume of sales of business-owned vehicles.

3. with the growth of air traffic and trends of online booking of vehicles, the vehicle rental is the preferred option for travels, since the car sharing becomes the most economical and fastest type of transport services.

4. increase in disposable income of people in such countries as the USA, countries of the Western Europe, and Southeast Asia, as well as improvement of road infrastructure in these regions, contribute to exponential increase in the car sharing industry.

5. another market growth resource is the expansion of the Internet usage trend.

Let's take a closer look at three main transportation regions and their growth dynamics: North America, Europe, and the Asia-Pacific region.

North America is the third world largest transportation market following Asia and Europe, and its vehicle fleet and the number of participants have grown significantly since 2010. The fleet increased by more than 2.5 times, and the number of participants increased by 3.5 times from 2010 to 2018 (see table 1).

Table 1: Regional trends in the car sharing market in North America (Source: Brookings Institute, Global Market Insights, NYSE)

Period	2008	2010	2012	2014	2016	2018
Participants	117,656	318,838	516,100	908,584	1,625,652	1,837,854
Participants' growth rate	0.00%	65.00%	27.00%	33.00%	34.00%	7%
Vehicles	3,337	7,505	10,420	15,795	24,210	26,691
Growth rate of fleets	0.00%	50.00%	18.00%	23.00%	24.00%	5%
Factor	35.3	42.5	49.5	57.5	67.1	68.9

It is estimated that the growth of car sharing in the United States hovers around 17% for companies that manage vehicle fleets over the next 7 years (A. Samsonova, 2019).

The portion of this growth is associated with several incentives implemented by the US Government. Some of these incentives operate at the municipal level, while others have been implemented in different states. The state legislation generally focuses on transport taxation and incentives to use transport fleets. Examples are Washington state tax incentives, special programs increasing co-location between transit hubs and vehicle parking space in California, or partnership relations between public transit operators and car service providers in Oregon, and, in particular, special vehicle parking permits in several states.

While Canada is a smaller market compared to the US, its population is located mainly in metropolitan areas, accounting for more than 85%, and boasts some of the busiest car sharing markets. This is why some CAGR estimates for companies and private users are closer to 20-23%. The example of a thriving car sharing market is Vancouver: it has four operators - 2 based on a fixed service and 2 in free movement, and citizens have access to a fleet of almost 3,000 vehicles. As of 2018, almost 1/3 of the adult population of Vancouver had one or more memberships on car sharing platforms (see table 2). This is about 200,000 people.

Table 2: Growing share of cars in Vancouver (Source: Global Market Insights, Pew Research)

Period	2015	2016	2017	2018
Percentage of Vancouver's adult population using the car sharing, %	13	20	26	29

For both countries, governmental and municipal incentives are expected to increase, especially for programs encouraging the use of electricity and transport in low-income districts or rural neighborhoods.

In fact, in April 2018, the city of Los Angeles, in partnership with the French group Bolloré, has launched an all-electric vehicle separation operation where vehicles were strategically placed in low-income areas. The company expects that 100 cars will be available in 40 locations by the end of the year, and by 2021, the number will triplicate. One more program that is currently in BETA stage is Hui in Hawaii. Hui solves the transportation problems of Honolulu, a city with less dense public transport infrastructure compared to some typical vehicle markets such as Paris, London, New York. This is a partnership between Toyota and the large dealer network Servco. The involvement of dealers to manage the vehicle fleet allows creating a unique system that will open up new opportunities in small provincial localities.

Europe is the second world largest transportation market (following Asia), partly because of its densely populated cities and partly because the European Union pays great attention to the implementation of environmentally friendly technologies and greenhouse gas emission reduction (S.N. Bobylev, P.A. Kiryushina, O.V. Kudryavtseva, 2019). This led to an explosive increase in the number of operators and transportation fleets. In 2018, Europeans had 3.5 times more vehicles available for sharing compared to 2010. This also led to an incredible increase in the number of users: eight times between 2010 and 2018 (see table 3).

Table 3: European development trends in the car sharing (Source: The research was implemented by RAEC together with the TIAR-Center)

Period	2008	2010	2012	2014	2016	2018
Participants	212,124	334,168	552,868	691,943	2,206,884	4,371,151
Participants' growth rate	0.00%	26.00%	29.00%	12.00%	79.00%	49%
Vehicles	7,491	10,833	16,779	20,464	57,947	57,857
Growth rate of fleets	0.00%	20.00%	24.00%	10.00%	68.00%	0%
Factor	28.3	30.8	32.9	33.8	38.1	75.6

According to the CAGR (Compound annual growth rate), the growth of share of transportation business in the UK is 18-20% for companies and private users over 7 years. Partially this growth is related to improved broadband infrastructure and very unstable economy, which leads to the fact that people look for alternatives to owning a vehicle.

Evaluations of market growth dynamics for Germany are slightly higher than for the UK - the CAGR for companies and private users is between 21-23% (Pazderova V.Yu., Thagapso R.A., Hot F.T., 2016). This is not surprising since Germany is currently the largest European transportation market. At the beginning of 2018, more than 2 million people signed up for the car sharing service, and more than 677 cities and localities offer the car sharing service, which is 80 more than in 2017. There are several main reasons why Germany is so quick to accept the car sharing mode. One of the main factors is that some of the largest vehicle manufacturers have submitted their own car sharing offers (Daimler, BMW). One more important factor is that Germany has proposed a unique legal framework to support clean energy solutions. In 2017, the German Bundestag approved the so-called personal car sharing law: initially, it governs the creation of parking spaces specifically for the car sharing throughout Germany (N.A. Maratkanov, 2018).

The law makes it incredibly easy to obtain public parking spaces for a fixed separation of transport, and allows local authorities to reduce or cancel charges for common access transport parking.

The implementation of a large-scale electric vehicle fleet is one of the biggest opportunities in Germany with ongoing investigations of Dieselgate scandals. Currently, 10% of the German fleet consists of electric vehicles. Although this is actually 100 times more than the number of personal vehicles, Gunnar Nehrke, the President of the German Car Sharing Association, believes there is a potential for more growth. However, he also states that support programs and incentives from the Germany are necessary to increase the economic viability of electric vehicles in fleets.

The growth potential for France is within the same range as for Germany, but France is a particularly hot market for peer-to-peer companies. Drivy is a very successful French version of Touro; in fact, France is the most successful P2P market throughout Europe with more than 1 million users. Another major provider of car sharing services in France is Réseau Citiz, which operates in more than 80 cities and has 18 different local platforms. In France, it is profitable to use the services of companies involved in car sharing, whose fleets have electric cars, because this country is particularly strict about the rules for the separation of vehicles, especially with regard to freely moving vehicles. All of them must be fully electric or at least hybrid. As in Germany, the implementation of a large fleet of electric vehicles is a great opportunity for the platforms presented in France. If the operator satisfies this condition - EV/hybrid fleet - it is very easy to get necessary parking permits. However, the problems are also similar - only cities with sufficient infrastructure are financially viable for this model (N.A. Maratkanov, 2018).

As of 2018, Asia is the largest world transportation market (see table 4). In addition, the fleet size more than triplicated in just 2 years, from 2016 to 2018. The number of participants is 8.7 million, which is twice as much as in Europe % (Pazderova V.Yu., Thagapso R.A., Hot F.T., 2016).

Table 4: Growth dynamics of the car sharing in Asia (Source: The research was implemented by RAEC together with the TIAR-Center)

Period	2008	2010	2012	2014	2016	2018
Participants	15,700	12,546	81,817	160,500	955,880	8,722,138
Participants' growth rate	0.00%	-11.00%	155.00%	40.00%	144.00%	406%
Vehicles	608	810	4,315	6,155	20,344	67,329
Growth rate of fleets	0.00%	15.00%	131.00%	19.00%	82.00%	115%
Factor	25.8	15.5	19.0	26.1	47.0	129.5

Rapid industrialization and urbanization were the main factors that contributed to this growth. In addition, such countries as Taiwan and India have underdeveloped transport infrastructure, and China has a high percentage of air pollution. The first means that countries in the Asia-Pacific region exercise very strict control over personal vehicle ownership. The latter encourages governments in these regions to make better use of their road network and add new electric vehicles.

China's motor fleet and its users are ready for further growth. Roland Berger, a German consulting company, which has been involved in transport for many years, estimates an annual growth rate of 45% by 2025. Despite this huge growth prediction, China remains a difficult market to enter, especially for foreign operators. There are several initial conditions that must be met to startup a car sharing business in China, but none of them can be easily achieved, especially in cities with strict restrictions on license plates and a lack of parking space (S. Klein, 2010).

It is not surprising that 90% of all transport companies in China operate locally. Car sharing service providers operating in China can be divided into three groups: OEM owners, third parties supported by OEM, and third-party technology companies. It is also worth noting that most car sharing

operators in China rely on government grants and exclusive partnership relations, which help them to secure a foothold in the market before creating a more profitable business model. All of this proves the difficulty of entering the Chinese car sharing market for foreign companies.

Conclusions

As a result of the research it is possible to draw the following conclusions:

1. The countries of the Asia-Pacific region represent the largest share in the global car sharing market. This is due to the high degree of urbanization of this region, the improvement in the transport infrastructure, the presence of protectionist measures for national sharing companies, and the availability of socio-economic opportunities for its further growth;

2. In all regions reviewed, public transport providers and municipalities are increasingly open for evaluation of MaaS options for their citizens. Mobility as a service means fully integrated mobility, as well as integrated public transport, even in the largest cities. The goal is a seamless user experience that can increase the number of people who have elected not to own vehicles, since MaaS offers the same convenience and freedom. It is still unknown who will be the last MaaS operator and provider: it may be a public transport authority that will ensure the transportation fairness for all. Or it may be the private sector, which will more probably implement innovate faster.

3. despite the fact that the scope of transportation business in all regions of the world has increased significantly over the past few years, experts believe that the car sharing market is only at the beginning of its journey. In North America, this industry is expected to grow due to the development of tourism and Internet technologies, in Europe - due to the active implementation of "green" technologies, in Asia-Pacific countries - due to the transport markets of India and Taiwan that are not yet involved in this process.

Abstract

Through this article, we aimed to analyze the main effects of the global crisis caused by the new coronavirus - Covid 19 in passenger air transport services. Passenger air transport services were one of the first industries to experience the worldwide transmission of Covid-19. Even though the last crisis that also affected this field is about a decade since it ended, no one predicted the financial decline that this industry was going to go through. Major global players have adapted new strategies with immediate application, aimed at limiting the effects of passenger slag, transforming part of the fleet for passenger transport into cargo planes and seeking to operate transports, mainly at the request of governments, from Asian countries to all globe.

Keywords: air transport, Covid-19, financial effects, air routes.

Introduction

Epidemics and diseases have always affected the Earth, differentiating the spread, the number of victims and the effects on economies, more or less advanced. The virus that appeared at the end of 2019 in China had unsuspected implications, spreading in less than two months around the globe. The first effect noted was the slowdown in the global economy and the decline in industrial production, with an imminent crisis expected.

Recessions are not considered by specialists in the field as natural actions of the economy, although most tend to follow a specific type and an inevitable cyclicality. In most situations, periods of recession are preceded by economic growth. At the level of 2020, the researches identified a series of methods meant to anticipate and counteract the occurrence of such situations through risk management.

The freezing of liquidity manifests a first response given to the potential state of recession because both the entities and the population seek to hold as large amounts as possible. This desire helps to block the cash flow, causing bankruptcy or mass layoffs. The result is translated into a series of unprecedented economic measures that the government and central banks are trying to solve by providing liquidity or

spending where they did not do until recently. The main problem is that the economy is starting to grow again, with a boom expected.

Implications of COVID-19 in the Air Transport industry: A Theoretical Approach

The COVID-19 pandemic is shaping up as a crisis and not a financial crisis started by the years of artificial growth of some sectors. Many elements were not foreshadowed, and that may appear in the coming years, being caused by these disasters. The current recession is very different from previous recessions, with exact causes and about which we can say precisely how it happened or how it was caused. The economy is declining because of COVID-19 and its growth potential, but current policies are meant to protect everyone's health. From the perspective of economic policy, unprecedented results have been obtained: all economists - regardless of the degree of confidence given to government policies, have concluded on the measures to be taken in this regard. An exchange usually measures the level of economic activity. People pay in exchange for goods or services, and the purchases of one person become payments of another. The amount of income defines this exchange, and if they are high, by default, the level of exchange will be higher. The situation of the COVID-19 pandemic will cause the economy to decline through lower revenues and lower expenditures. Expenditures tend to make us happier than not; our economic well-being is affected by recessions. The reduction of economic activity is manifested by the decision that we want to spend less on specific services; in this case, the use of air travel to travel on vacation to produce things meant for sale. If that happens, no matter how much they might want those things, there will be shortcomings. If there are fewer people around the payment, there will be fewer payments.

The spread of the new coronavirus COVID-19 globally has had far-reaching effects on the entire economy, but one of the most affected sectors is air transport. A large part of the business trips and all the tourist trips were canceled. With the spread of this pandemic, people were advised to stay in their homes, and the entire economy slowed down. The way money is spent changed radically in just three months. The big online stores recorded record sales, taking advantage of the fact that the population was restricted from travelling.

In the current crisis, economists have an essential role to play in their expertise in shaping management and planning strategies. From the COVID-19 pandemic, it is too early to say definitively what lessons will be learned which from the current mistakes will not be repeated. However, some aspects may be relevant, for example, if we look around the world today, the countries that were closest to previous outbreaks developed plans long before the others. One thing is sure: the global economy is interconnected, the proof being the fact that for many goods, the Asian market was the only supplier. Even if only a few countries properly manage pandemics, this does not prevent a significant drop and a painful recovery.

The global economic crisis caused by COVID-19 has affected all sectors of the economy, but as we well know, one of the most affected sectors is the travel sector. There are several pieces of evidence of cooperation between actors in the air transport industry, both in a particular subsector (eg air industry) and not only (e.g. between airlines and ground airlines) which are dependent on some other. From the experiences of previous events, aspects have highlighted that show that tourism and business travel have led to the full development of the airport's capacity worldwide, developing millions of jobs in developed and developing countries. The global economy is now increasingly dependent on air travel, also with an increasing share of goods, in value, transported by air. In the situation caused by the COVID-19 pandemic, many companies have adapted their strategy, reorganizing their passenger transport fleet into a cargo fleet.

Analyzing in comparison with the economic recession manifested in 2010, it is highlighted that then for the first time; the corporate segment was affected in the air transport whose profit started to decrease.

Then, the travel agencies declared a decrease in turnover of 20%, and the market trend was not at all favourable. Finally, the market tourism crisis has affected the hospitality industry, and that of small private entrepreneurs who have been linked to this area and forecasts do not indicate that the market continues to contract. The crisis caused by COVID-19 did not aim at a slowdown in the economy, in this case of air transport services, for 1-2 years, but a sudden fall by applying government policies to ban most flights and limit exit from homes.

Implications of COVID-19 in the air transport industry: a practical approach

Estimates of the impact of COVID-19 on scheduled international passenger traffic for the period January - September of the year 2020, compared to the reference line (currently planned flights) indicates:

- A general reduction of between 41% and 56% for seats on aircraft traded by airlines;
- A decrease between 705 to 963 million passengers;
- Losses between $ 160 billion and $ 218 billion in airlines' gross operating income;
- If the global economy can recover quickly, in semester three or later, the specialists' estimates are the following;
- A general reduction of between 57% and 67% for seats on aircraft traded by airlines;
- A decrease between 961 to 1.17 million passengers;
- Losses between $ 218 billion and $ 253 billion in airlines' gross operating income;

The impact that this pandemic will have on air transport services depends on the duration and magnitude of the outbreak and retention measures, the degree of consumer confidence in air travel and economic conditions.

Fig.1: The international evolution of passenger traffic between 1945-2020

Source: interpretation according to the IATA 2020 report

Iit It may be noted that globally, since 1945 the number of passengers using air transport ervices has been steadily increasing, with few exceptions in the early 1970s, during the Oil Crisis, in the 1980s during the Iraq War. , in the 2000s after the September 11 attack and in 2020 due to COVID-19. From the decrease

in the number of passengers, the crisis at the beginning of 2020 is the most pronounced with a value between 33% and 74% compared to 2019. The losses suffered by airports reach approximately 76 billion USD, and most have been closed or are operating at a reduced volume. Experts also predict a sharp decline in tourism, as people will no longer travel and spend money on other destinations. 96% of world destinations with travel restrictions. Although freight transport has continued to operate, the volume of world trade in goods is expected to decrease by between 13 and 32% in 2020 compared to 2019.

Fig. 2 : Air traffic 2019

Source: IATA 2020 Report

Fig.3: Passenger traffic in 2019 and 2020

Source: IATA 2020 Report

Analyzing the two traffic structures comparatively, it shows its low level in the first quarter of 2020. Also, except for the decrease in traffic values, there is an intensification of races to Asian countries, large producers of goods in the field of hygiene and care.

Conclusions

The year 2020 is certainly described as a time marked by significant changes, starting from individual attitudes and reaching the changes brought to the global economy. The crisis caused by the slowdown in consumption has been difficult to anticipate, and it is hard to believe that the final moment is known. As in other industries, air transport services have suffered significant losses that can be clearly defined after the global economy recovers. It is expected that the traffic levels that air transport services reached in the first month of 2020 will be comparable to those of mid-2023.

It will be necessary to develop new strategies, meant to cover the new needs of the people, to maintain a level of social distance, reduced prices or various technical adaptations in order to reduce the risk of illness in airports and aircraft.

Abstract

The impact of digital financial instruments on the legalization of illicit financial flows has remained under-investigated so far, which makes this study relevant. The study aims to analyze the impact of the level of cashless payments on the legalization of the tax base for personal income tax in Russia. The study proceeds from a hypothesis that an increase in cashless payments should have a positive impact on the legalization of the tax base for personal income tax. Possible causes of the increase in personal income tax payments were verified. An analysis of statistics showed that wages (including shadow wages) grew insignificantly between 2014 and 2018, so this factor could not have the determining role. The authors supposed that the main trigger of higher tax payments was the shrinking of unreported pay. Further analysis confirmed a correlation between an increase in bank card transactions and a higher assessed amount of personal income tax. The key conclusion of the study is that the legalization of the tax base for personal income tax happened as a result of greater transparency of financial flows thanks to the spread of cashless payments and the adoption of online cash registers.

Keywords: Shadow Economy, Digitalization; Payment Card, Legalization of Tax Base.

Introduction

The shadow economy has been the subject of numerous studies. Economic activities that develop outside the state's control and accounting, and, therefore, are not registered by official statistics causes damage to the real economy. First and foremost, this shows in slower economic growth, lower state tax and non-tax revenues, a deterioration of living standards, growing crime rates. A growing shadow economy affects not only the state of economy but also the social situation.

Today, as digital technology is penetrating economic processes, an opportunity appears to study the impact of digitalization on the level of the shadow economy. Unreported economic activity poses a threat to economic security and has a destructive effect. The impact of digital financial instruments on the legalization of illicit financial flows has not been properly investigated, which makes this study relevant and timely.

The study aims to analyze the impact of the level of cashless payments on the legalization of the tax base for personal income tax in Russia.

The hypothesis of the study is that an increase in cashless payments should have a positive impact on the legalization of the tax base for personal income tax.

The findings should help reduce the level of information uncertainty as to the impact of digital financial instruments on the legalization of tax bases and the state of the shadow economy.

Literature Review

The majority of the reviewed studies focus on the causes behind tax avoidance, methods of measuring the informal economy, the implications of illicit schemes, and impact models for various factors.

For example, F. Schneider and D. Enste (2000) look at the theoretical framework of the problem. Their study describes the causes and implications of the spread of the informal sector, assess its size, and gives a definition of shadow economy.

M. Allingham and A. Sandmo (1972) designed a classical model for assessing the impact of various factors on tax evasion. Among such factors are the likelihood of a tax audit, the size of the penalty, tax rates, the tax payer's income. M. Spicer (1974) designed a behavioral model of tax evasion that considers the influence of several non-economic factors on taxpayers' propensity to evade tax and the impact of penalties on evasion.

Using various methods, researchers assess the volume of the shadow economy in various countries. L. Medina and F. Schneider (2018) present the data on the size of the shadow economy in 158 countries between 1991 and 2015. The authors also explore the causes determining the shadow economy.

R. Goel and M. Nelson (2016) found that the bureaucratic complexity of taxation has a major impact on the size of the shadow economy.

G. Yaniv (2019) studies businesses that generating cash for envelope wages. Among such businesses he investigated so-called cash-intensive businesses (that receive a large portion of its receipts in cash).

A. Kireenko et al. (2019) discovered sector-specific characteristics of tax crime in Russia and showed that fiscal crime is more pronounced in lower-paying industries. These authors (Kireenko A. et al., 2018) also estimate that the level of unconditional voluntary tax compliance varied between 25 and 35%.

Scholars see two development trends in the accelerated digitalization of the economy. On the one hand, digital financial instruments considerably curtail the potential of the unobserved economy to spread further. Such instruments help make transactions more transparent and controllable, thus mitigating the likelihood of the adoption of illicit schemes. On the other hand, scholars look at the digital space as an area of illicit activity. R. Remeikiene et al. (2018) gave a definition of digital shadow economy. As a result of their study, the authors concluded that the digital shadow economy is an unlawful activity that is carried out online in breach of existing legal norms with a pursuit of illegal mutual interest and material benefits. R. Remeikiene and L. Gaspareniene (2016) also drew up the characteristics of entities engaged in the digital shadow economy. In collaboration with V. Navickas (Gaspareniene L. et al., 2016), they described consumers' attitude to that phenomenon.

Some experience has been gained of shadow economy studies, including the design of methods for assessing the size of the shadow sector, causes behind its appearance, as well as the implications of its impact on the real economy and identification of the determinants of the shadow economy. A theoretical framework was created for conducting research under the conditions of economy digitalization.

The problem of tax avoidance is being actively researched, along with the problem of the shadow economy's expansion. We have not found, though, any studies examining the positive impact of financial instrument adoption on the legalization of tax bases.

Methodological Framework

We analyzed assessed personal income tax reports by the Federal Tax Service[1]. The analysis covered data for the years 2014 to 2018. Assessed personal income tax includes income tax at the rates of 13, 30, 9, 35, 15%, as well as at other rates applied by tax agents.

We factored in the influence of income growth on the amount of assessed tax. Income was calculated as total annual wages, including unreported wages between 2014 and 2018. The data was retrieved from reports by the Federal State Statistics Service of the Russian Federation[2]. The impact of income growth on the amount of assessed tax was studied through comparison of the growth in the two indicators.

The volume of payment card transactions was estimated on the basis of data published by the Central Bank of the Russian Federation[3]. The analysis covered the period 2014 through 2018. The analysis of the ratio and growth in cash withdrawals and transfers for the purchase of goods or services in the total volume of transactions over the studied period was also performed on the basis of Central Bank data.

We compared the growth trends in assessed personal income tax and the volume of transactions to purchase goods and services in 2014-18. We also compared the growth in the amount of assessed personal income tax and the growth in payment card transactions in 2014-18.

Analysis of Results

Personal income tax serves as an indicator of trends in the size of the shadow sector as regards wages. This is why revenue from personal income tax can be viewed, with a good deal of reservation, as indicative of the shadow economy situation (Fig. 1).

Fig. 1: Assessed personal income tax in 2014-18, billion rubles

The volume of assessed personal income tax grew by around 33% over the five-year period. The increase might be due to higher personal incomes as well as a larger share of reported wages.

Personal income growth can fully explain the increase in personal income tax revenues over the studied period. To examine the impact of changes in personal income on personal income tax revenues it is necessary to understand the ratio of the growth of personal income relative to the growth in the amount of assessed tax. If personal incomes grow slower than the amount of assessed tax, the increase in personal income tax revenue might be associated with the legalization of the tax base. This allows for a hypothesis that personal income tax revenue has been growing thanks to a bigger share of reported wages in the total amount of wages paid (Fig. 2).

Fig. 2: Wages, including unreported wages in 2014-18, billion rubles

Aggregate personal incomes increased by 20% over the five-year period. The figure is 13% smaller than the growth of assessed personal income tax. Consequently, income growth is not the only factor of influence. At the same time, in 2016, personal incomes decreased by 0.5% year-on-year, while assessed personal income tax did not decrease. On the contrary, personal income tax revenues grew 7%. The accelerated growth in assessed personal income tax against the background of slower personal income growth enables one to suppose that the shadow economy might have shrunk in terms of wages.

Growth in cashless turnover could be one of the reasons for employers to start to pay wages on the books or to decrease the share of unreported wages in the total pay to employees (Fig. 3).

Fig. 3: Volume of payment card transactions in 2014-18, billion rubles

The curve clearly shows a trend towards cashless payments. The growth in such transactions exceeded 57% over the studied period. It has to be observed that the type of cashless transactions must be

analyzed to understand a relationship between cashless transactions and the legalization of the tax base for personal income tax.

Transactions through payment systems are divided into cash withdrawals and payments for goods and services (Fig. 4).

Fig. 4: Shares of payment card transactions in 2014-18, %

In 2014, cash withdrawals made up almost 79% of all transactions, whereas in 2018 the share of such transactions decreased to 59%. There is also an obvious trend towards cashless payments.

We shall compare the growth in assessed personal income tax value with the changing volume of payment card transactions. There is an upward trend in both cases (Table 1).

Table: Changes in volume of payment card transactions and assessed personal income tax in 2014-18, %

Indicator	Relative deviation, %			
	2015 against 2014	2016 against 2015	2017 against 2016	2018 against 2017
Payment card transactions	109,72	114,52	109,98	113,85
Assessed personal income tax	105,12	107,15	105,62	111,77

It is possible to conclude that there is a correlation between the two indicators. On the one hand, an increase in cashless payments has an impact on the shrinking of the shadow sector in terms of wages. On the other hand, a higher share of wages paid on the books results in a bigger volume of payment card payments because officially paid wages are usually transferred to workers' bank cards. Consequently, when the volume of cashless payments for goods, works and services grows,

organizations are left with less money that can potentially be converted into cash. Funds are credited to a current account. They become visible to oversight authorities. A reduction in cash leaves the company with fewer options for withdrawing money to pay underreported wages. When cash is used, it is practically impossible to trace cash flows, while current account transactions and bank card transactions are recorded in files that oversight officers can access.

The mandatory use of online cash registers is a limiting factor for organizations and private entrepreneurs. Online registration of all transaction with the tax authorities together with a transition to cashless payments considerably limits the options for off-book sales. When an online cash register is used for recording payment for goods, works or services, it is impossible not to issue a receipt. When there is little cash on hand, cash withdrawal schemes have to be used in order to pay "envelope" wages to employees. Private entrepreneurs thus remove funds from official money turnover while legal entities use flight-by-night firms or affiliated private entrepreneurs to withdraw cash. In such a case, illicit schemes become a regular occurrence. When all transactions are recorded in bank statements and other documents, the likelihood of being penalized grows, encouraging companies to abandon the practice of paying unreported wages.

Conclusion

The hypothesis that an increase in cashless payments should have a positive impact on the legalization of the tax base for personal income tax in Russia has been confirmed.

The reduction of the shadow sector as regards wages and the legalization of the tax base have been identified as a factor of growth for assessed personal income tax has been identified. Statistical data confirm a trend towards a preference for cashless payment for goods and services over cash withdrawal. A correlation has been detected between payment card growth and an increase in the value of assessed personal income tax.

The key conclusion of the study is that the legalization of the tax base for personal income tax has been the result of greater transparency of financial flows thanks to the spread of cashless payments and the adoption of online cash registers. These processes make it more likely that tax officers will reveal illicit schemes thanks to comprehensive transaction reporting.

Abstract

This research aims to explore hotel brand loyalty by analysing what are the main factors that lead to it and explain the individual's reasons that lead guest decision towards a specific hotel service since operational knowledge indicates that new consumption trends as well as new market segments in tourism have specific consumption behaviours and arises with the evolution of the industry. The main goal of this paper is to provide relevant information to improve hotel marketing strategies and keep the knowledge on consumer habits updated because their motivations and actions will determine and influence the ability of hotels to adapt to new consumption realities. In this context, this research focus on service hotel marketing, quality of service and hotel brand loyalty and allowed the implementation of applied consumer research in scientific methodology, using questionnaires filled out by consumers who made hotel reservations. The authors applied a statistical inferential test, a binary logistic regression model, looking up to understand if customer loyalty behaviour may be explained by our predicted and studied variables, specially emotional and rational factors, the knowledge of guests' preferences and habits, employees' performance and the existence of a loyalty programme.

This research allowed to conclude that there are five main dimensions that influence loyalty behaviour: knowledge of guests' habits and preferences, contact with hotel employees, existence of a loyalty programme, room rate and rational factors, which is an important information to improve hotel marketing strategies as hotel industry becomes more competitive each year.

Keywords: hotel consumer behaviour; hotel management; brand-consumer relationship; brand loyalty; hotel consumption cycle.

Introduction

The most challenging thing when dealing with tourism and the hospitality economy is trying to measure up to the guests' expectations as global demand inspires diversification of supply, expanding into new types of accommodation from luxury resorts to simple apartments or local accommodation. The number of people traveling is increasing, with a variety of motivations ranging from leisure, culture, work, health, family, etc. The movement of people has become easier over the years considering that online information allows us to easily desire any product/service (Pickett & Pritchard, 2015). Another

decisive factor was the globalization of business that boosted the growth of business tourism and incentives, currently known as MI (Meeting Industry).

In recent years, the curiosity of researchers strengthened the relationship between the consumer and the brands, as the daily goal of hotels is to reduce the number of customer defections, allowing the relationship to perpetuate in time, an element that is believed to be essential for brand loyalty (Cohen, Moital & Prayag, 2014). Hospitality organizations that work on customer retention often find it to be a more solid process because they are marketing to customers who already have expressed an interest or experience in their service, facilitating the engagement with the brand and making it easier to capitalize on their experiences with the company. In fact, it is considered that retention is a more sustainable business model that is a key to sustainable growth.

Background and Literature Review

The starting point to investigate hotel buying decision cycle starts with the analysis of the companies as service companies and, therefore, understanding that the tourist/client is an integral part of the service provided, influencing it and being influenced by it, which will automatically affect the quality of that same service. Since the economic success of these hotel companies depends on the above relationship, providing excellence in customer service should be the mission of the entire hotel organization, including its top managers (Hudson & Hudson, 2013). In the past few years, as travelling develops and, consequently, hotels supply increases, a growing number of empirical investigations have shown that satisfaction and repeated business are influenced by consumers' emotional experiences and if it implies a change for a "better emotional state" of the customer – he proceeds from indifference and instability to satisfaction and trust – the provision of service is enhanced and, therefore, an increase in customers' perception of value (Back, Barret & Han, 2008).

Thus, building "intimate" relationships is currently considered as a very profitable and compensatory customer loyalty strategy, regarding the costs that personalization of the service requires to set our brand in the guest mind as a reference in quality of service, measured by the difference between service performance and customers' expectation.

Udofia's research (2019) suggests different scientific research methodologies that include several variables to evaluate and measure quality of service and customer satisfaction. Based on this investigation model and objective, the authors oriented their vision to that variables that match their operational understanding.

Hotel Consumer Behaviour

Nowadays, the client, has numerous tools to check the arguments of the companies in their promotion and to look for alternatives that suit their desires, besides being better informed than ever. The analysis of buying decision process is, thereby, truly important to determine buying behaviour as the first step to understand what's their deep motivation and behavioural triggers that encourage the potential customer to became hotels' next guest. Besides, this attentive and critical thinking allows marketeers to redesign their strategies and by improving their knowledge of the segment they pursuit and guest service.

The purchase decision may go over the service that is able to create positive expectations on the costumer, standing out as a reliable proposal to meet their needs. So, the hotel must present itself as a captivating experience so that the customer realizes our difference to the competitor (Bai & Yoo, 2013; Cohen, Moital & Prayag, 2014).

The literature review indicates that there are three sets of key factors influencing consumer behaviour: cultural, social, and personal factors (Bowen, Kotler & Makens, 2010). In the hospitality industry, due to its variety of reasons that feeds their motivations locations, we describe a global market influenced by several cultural, social and economic factors which include different and correlated processes preventing a individual analysis. So, a complementary approach for hotel behavioural study allows

researchers to build an better understanding, improving sharp and wise business strategies, identifying the internal force that leads to desire and buy and all the mechanism that sustains it – motivation. This theory reinforces that there is no formal categorization of the factors that motivate the tourist to consume and tourist motivations: it results from the combination of several factors and may differ between market segments (Udofia, 2019).

Throughout the process of personality formation, the child absorbs certain values and preferences of his family that will influence his options, including in terms consumption. Regarding to social factors, the authors explain that consumer behaviour can be influenced directly by their reference groups, family and social and professional roles, whether their administer a direct or indirect influence (depending on the intensity and frequency of interaction). Consumer decisions can still be influenced by their personal characteristics, such as age, stage in the life cycle, economic availability, lifestyle, etc. Thereby, consumer needs are at the basis of the marketing work dwelling on the fact that companies do not create needs, only on a few occasions they seek to awaken unnoticed needs and desires in the consumer (Manhas & Tukamushaba, 2015).

Customer Loyalty to the Hotel Brand

When analysing the relationship between brand and consumer loyalty, it is possible to conclude that hotel consumer experience shapes the brand image through associations that are later activated by rational (eg. price) or emotional factors (employees and other symbolic reasons), motivating them to their consumption decisions and influencing brand loyalty. These feelings directly influence customer respect to your brand and drive customer loyalty behaviours (Crosby & Johnson, 2007).

An hotel visit become an experience loaded with expectations when a costumer decide to invest in a company to enjoy a period of quality time. Traditionally, one of the best hotel quality indicator and service variety is the stars classification and rates as a standard reference. However, this system has been losing ground and influence as modern tourists rather trust in on-line opinions based on previous experiences (Buhalis, Law, Leung & van Hoof, 2013). Perception, consumer's feelings and their experience with the brand is something that differentiate it as well as selling quality service and maintaining high price will increase its reputation from a company and also increase brand loyalty (Djati & Rumambi, 2007).

Finally, the literature suggests that loyalty to the brand will be related to the degree of consumer involvement and as satisfaction with the service and its buy-back increases, research on alternatives is reduced, that is, positive and negative emotions have positive and negative effects on consumer satisfaction as well as on their intention to repurchase (Cohen, Moital & Prayag; Grisaffe & Nguyen, 2011; King, So & Sparks, 2013).

Factors That Lead to Hotel Brand

A strong brand may become the most important intangible asset for the company and an important barrier to the entry of new competitors into the market (Manhas & Tukamushaba, 2015). These authors state that perceived service quality directly determines the perception of brand image and service experience is important in establishing performance of different organizations, however, subliminal factors have not been clearly delineated in the existing literature and this study aims to fill this gap.

In Hotel management, there is a direct relationship between marketing strategies and operations. If on one hand marketing reaches the consumer and promises to meet their needs, the operation must be prepared to exceed that promise, otherwise the brand image and consumer perception will be negatively affected. Thus, the strength of a hotel brand lies in the positive image of the customer in relation to their quality of service and facilities, so that it is perceived in the market as "more" than competition, providing customer satisfaction and leading to loyalty behaviour (Crosby & Johnson, 2007; Djati & Rumambi, 2007).

The role of the hotel employee is so loaded with expectations: the promise given by the hotel that the moment that will be with us will be perfect, being committed to provoke unique experiences confirming that your choice was the best (Lee & Ok, 2012). The prestige of the brand is factor of perceived quality and is related to social status, wealth or power because it represents products/services consumed infrequently and that fulfil the need for social fulfilment, influencing the decision to buy the consumer (Grisaffe & Nguyen, 2011; Kim & Yu, 2010).

In order to understand hotel experience, an investigation was developed to identify the factors that guests consider as the most important. Results identify two groups that marketing strategies should focus on (Manhas & Tukamushaba, 2015): *concentrate here* – the first impression, helpful and friendly staff, quality of restaurant food, hotel experience matters in choosing the particular hotel, dealing with complaints-, as extremely important for guests in hotel performance; *keep up the good work* – prompt room service, the room comfort, the quality of service, the value for money of the hotel, value for money of the room service, the overall quality of food, the overall quality of beverages -, as attributes that contributes to a comfortable hotel experience.

In their study, Bai & Yoo (2013), categorized the factors that may allow hospitality companies to influence their consumer loyalty in two groups: internal factors and external factors. Internal factors are described as the set of factors that affect the company in its operation, customer service and the ability to create strategies to reach consumer: product/service (brand), quality of service, marketing mix and costs. External factors are presented as external conditions to the organization and are related to the way that consumers recognize the brand toward competition: the costs that the consumer incurs when changing brands, situational factors, perceived value, satisfaction, commitment and brand trust.

Internal Marketing and Quality of Service

There is never a strong and successful brand without having, on the one hand, a loyal and satisfied customer who is respected and, on the other hand, an employee who believes in the brand and who is motivated to provide the service. Although technological innovation has brought transformations for companies, the human element continues to be a cornerstone (Hwang, Lee & Ok, 2016; Manhas & Tukamushaba, 2015).

The strategic importance of hotel employee lies in the fact that it plays the leading role in consumer-oriented experiences, suggesting special attention from the management to these resources because of the commercial and communication results (WOM or e-WOM) that they can generate, which means that employees with high personal qualities are an important asset for the company and for its profitability (Ginsburg et al., 2014; Lee & Ok, 2012). Hotel staff performance concerns to the ability of hotel employees deliver the expected service and it is indicated that in a long-term service (during a long period of time), the emotional characteristics of the staff gain importance to the guest, having a more intense impact on him (Lee & OK, 2012).

The nature of hotel service may be described and characterized by the intense interaction between hotel staff and guests. Hotel experiences are dynamic and complex systems providing services where they interact with each other in different ways and, thereby, this interaction should be a source of positive and comfortable experiences, pursuing high levels of customer satisfaction. A study by McKinsey and Company shows that a positive experience with our staff results in an 85% likelihood of the customer repurchasing the product or service, while 70% of customers have reduced their intention to buy when displeased with the service (Beaujean, Davidson & Madge, 2006).

Methodology

In the previous section, the conceptual framework for the research was discussed.

The main purpose of this study was to investigate what leads to customer satisfaction and what are the factors that relate to and influence hotel guests' loyalty, focusing on emotional and rational factors. Thus, it becomes necessary to evaluate a selection of variables that

influence customer loyalty in hotel industry as well as other dimensions referred to in the previous section, allowing the authors to continue the work started by Campos & Oliveira (2018).

Based on a standardized methodology, a single questionnaire survey instrument was used as the data gathering technique for this investigation. The questionnaire was tested before publishing.

In this quantitative research, the authors have collected data using a questionnaire survey applied to Portuguese tourists, from August to October 2017, obtaining a total of 302 questionnaires.

It is considered pertinent to use a survey with a selection of closed-ended questions, including different types of questions: dichotomous questions, multiple-choice questions and scaled questions since it may be appropriate when we seek to know the ways of life of the population, their behaviours, opinions and even their attitude towards subjects, emphasizing the descriptive type of the investigation (Mason, 2014).

The questionnaire was divided into three sections. Section one was designed to obtain data relating to individual profile. Section two, sought establish buying decision choices and determine the intensity of the two sets of factors: emotional and rational. section three of the survey intended to identify aspects of the guest preferences using a 4-point Likert item with categories 1 = "totally disagree" to 4 = "strongly agree".

About the sampling method, once authors are not able to access an hotel guests' data base due to ethical questions, an exponential non-discriminative snowball sampling was used. Snowball sampling is the most popular in business studies focusing on a specific company that involve primary data collection (Dudovskiy, 2018).

Collected data were analysed by using SPSS software version 25. This software allows for timely and effective computation of statistical analysis.

To achieve the goal for this investigation, statistical tools were employed in the analysis, namely binary logistic regression and descriptive analysis were used along with testing reliability and validity. Throughout the analysis, a significance level of 5% will be assumed for making decisions about the validation of the research hypotheses. For the calculation of the final sample, account was taken of the non-violation of the assumptions for the application of a multivariate analysis. Thus, a final sampling error of 5.6% was assumed for a 95% confidence level.

To assess and analyse the factors that influence hotel loyalty, a binary logistic regression function was used. We dichotomized the response variable hotel loyalty taking account of the ordering by using cumulative probabilities. In using binary regression, hotel loyalty was used as a dependent variable based on "yes/no" answer to a questionnaire survey. After the analysis of the state of art, hotel loyalty was regressed against a set of independent variables to determine which factors explains guests' behaviour: knowing the guest profile (as his preferences and habits), existence of a loyalty programme, rational factors, emotional factors, contact with hotel employees, price, reservation channel, hotel awards, gender, marital status and travel motivation. The statistics of the output include the odds ratio, z-score and p-value (the significance level of reference for this test was $\alpha = 0.05$).

Results

First, some descriptive statistics are presented regarding the characteristics of the sampling and the independent variables (Table 1).

The sample of this research includes 69.4% female and 30.6% male respondents, an average age close to 35 years (34.66 years, SD = 10.8) and the majority of the respondents were single (57.1%) or married (33.3 %). In terms of travelling habits, the survey respondents travel on average about 3.61 times a year during 6.17 days (SD = 3.52). The majority of the individuals (89.9%) has "Recreation and

holidays" as their main motivation for the trip and when the consumer decides to travel, the first decision he makes is clearly related to the destination which accounts for 71.9% of the answers.

In relation to information to help the consumer to decide, 55.9% of individuals search the hotel's website for information about facilities and services, 41.9% examine online opinions, 40.4% check in social media, 29% ask family and friends for advice, 27.9% follows travel bloggers, 17.6% ask the travel agent for advice and 6.3% trust newspapers and magazines as a source of information.

Regarding the way the reservation is made, we can confirm the tendency to use the internet: 53.3% of the respondents reserves using online travel agencies, 33.4% of the respondents book directly with the hotel unit and 13.2% hire a travel agency.

Table 1: Descriptive Statistics for Independent Variables used in the Logit Model.

	Knowledge of guests' habits and preferences	Existence of a loyalty programme	Emotional Factors	Rational Factors	Contact with hotel employees	Room Rate	Hotel Awards
Mean	2.37	0.01	1.7483	2.8079	2.85	2.73	2.40
Std. Deviation	1.097	0.115	1.2239	1.6086	0.871	0.861	0.941

Source: Own elaboration based on SPSS output

On a descriptive analysis, accordingly to our sample, the respondents based their decision on 1.75 emotional factors (SD = 1.22) and 2.81 rational factors (SD = 1.61), on average and just a really small part of the respondents belongs to a hotel loyalty programme.

The remaining variables were measured using a Likert scale (using a 4-point Likert item with categories 1 = "totally disagree" to 4 = "strongly agree"):

- Knowledge of guests' habits and preferences with a mean on 2.37 indicates that, on average, our sample did not based its decision on that factor;
- Contact with hotel employees reports a mean on 2.85 which means that our sample agrees that this is important to decide on a hotel service;
- On average, our sample disagrees that the room rate is one of the most important factors to decide;
- Hotel awards presenting a mean on 2.4 indicates that this is not a key element that influences their decision.

Logistic Regression Analysis

The logistic regression model was applied to establish the relationships and examine the significant influence of knowledge of guests' habits and preferences, existence of a loyalty programme, emotional factors, rational factors, contact with hotel employees, room rate, reservation channel, travel motivation, hotel awards, gender and marital status on hotel loyalty of the guest.

Some sociodemographic variables were included as independent variables in the model, because it was assumed that the sociodemographic variables of the questionnaire could directly or indirectly influence the hotel loyalty of the customers.

In this model, there are 11 independent variables and the probability of these variables are examined. These probability values are the values of the Wald test to determine whether the parameters are meaningful. The reference category of the qualitative variables was made according to the interpretations determined as the first category.

First of all, we may realize if this Regression Model fits this investigation data. To test the significance of the model adjustment we use the Omnibus Testes of Model Coefficients.

The model is considered a good predictor of "hotel loyalty" as indicated by the Omnibus Tests of Model Coefficients ($\chi^2_{(15)} = 47.889$; $p < 0.001$) and the Hosmer and Lemeshow Test ($\chi^2_{(8)} = 4.769$; $p = 0.782$).

Considering the Omnibus Tests of Model Coefficient, it is possible to conclude that there is at least one independent variable in this model which can predict "hotel loyalty behaviour" and allows to reject the null hypothesis that all of the coefficients are null.

The significance of the adjustment Test of Hosmer & Lameshow admit the authors to verify that the estimated model has an acceptable adjustment quality once the null hypothesis of the model is not rejected. This relation may be confirmed by percentage of the classification capacity of the model which describes that the model classifies 78.2% of the cases correctly.

Since the preconditions to analyse the significance are valid, it is possible to apply our Regression Model which enables to obtain the results presented in Table 2.

Table 2: Binary Logistic Regression of Determinants of "Hotel Loyalty"

Independent variables	B	S.E.	Wald	Df	Sig.	Exp(B)
Knowledge of the guests' habits and preferences	0.512	0.141	13.103	1	0.000	1.669

Hotel Awards	-0.157	0.163	0.925	1	0.336	0.855

Source: Own elaboration based on SPSS output

Results of logistic regression analysis have shown that emotional factors, gender, marital status, reservation channel, travel motivation and hotel awards no statistical significant influence (logistic p-value > 0.05) exists on "hotel loyalty".

On the other hand, the knowledge of hotel guests' habits, hotel loyalty programme, rational factors, previous experiences with hotel employees and room rate statistically explain our dependent variable hotel loyalty (considering a significance level of 5%).

As it was indicated before, the model predicted 74.8% of the hotel loyalty behaviour. However, only four out of the eleven predictor variables were significant in predicting hotel loyalty behaviour at the level of 5% and one at the level of 10%.

This data indicate several interesting conclusions:

- The probability to become loyal to an hotel brand increases 67% if the hotel get to know the preferences and the habits that satisfies its guests;
- The odds of an existence of a loyalty programme encourages a guest to become loyal is approximately 16:1 (1565%);
- Regarding rational factors, the odds decrease 26.2% of bringing a new repeated guest to the hotel;
- The probability of conquering a new loyal guest improves 39% if he/she had already experienced pleasant moments with hotel employees' or had positive recommendations about the staff of the hotel unit.
- An hotel guest becomes 28.4% less likely to a loyal behaviour facing a price increase.

Focusing on rational/emotional factors, it is possible to conclude that the more rational becomes the decision, the less likely it is to the guest become loyal to the hotel. Analysing Figure 1, this information is corroborated once it is possible to identify that loyal guests count rational factors in a significantly inferior way.

Figure 1: Clustered bar chart - Hotel loyalty and Rational Factors

Conclusions

The aim of this paper was to understand what are the different factors that lead Portuguese customers to hotel loyalty based on an investigation built and developed on a descriptive and inferential study: a questionnaire was developed based on the information gathered in the literature review.

Results of the empirical study indicated that there was a five variables that, accordingly to our sample, influence hotel loyalty: knowledge of guests' habits and preferences, contact with hotel employees, existence of a loyalty programme, room rate and rational factors.

Based on literature review, it was said that by consistently delivering a quality of service against those brand expectations at every touch point, you can provide the reinforcement necessary to inspire repeat purchasing decisions and other loyalty behaviours. Besides, and as this research have indicated, individual's expectations also depends on customer's previous experiences in the hotel, based on satisfactory memories of the that period of time once it is possible to find a match between customers interest, profile and preferences and the hotel service. (Crosby & Johnson, 2007; Ariffin & Maghzi, 2012).

This research conclusion on influence of rational/emotional factors, led directly to what was suggested by literature review (and to what it was empirically expected) because it was indicated that the impact of emotional factors on loyalty supplants rational factors at a ratio of about 5 to 3, and surprisingly, this victory of emotional factors is felt in both B2C and B2B markets, suggesting that business operation should be oriented to the consumer experience. In the hotel case, this study indicates that its intangible characteristics are the factors that most affect the emotions of the guests: smile, non-verbal language, facial expression and recognition, tone of voice (Crosby & Johnson, 2007).

This may happen because the intangibility is associated with a greater risk in the purchase of an hotel service. Thus, building a strong brand on the market can become a facilitator of economic profitability by simplifying the consumer decision-making process by providing guarantees of good service.

Hotel operations try to meet guest satisfaction by finding out his expectation, needs and interests but, due to the easiness of information access and other people's opinion, requires an individualized service, special and appropriate to their profile and desires. Besides, it is interesting to understand if future guest decision result from rational or emotional way because, on account of the high competition, the hotel service should trend to engage the customer in an emotional way. Since a hotel service is defined by its intangibility, corporations must understand hotel experience in its whole cycle, since the decision of travelling until they leave the hotel, aiming for a repeated visit by tailoring their marketing strategy to their preferred segment (reflecting on experience, exclusivity, emotion and engagement), reaching the desired success and high customer satisfaction levels (Gustavo, 2013).

Humanization of International Law As Seen in The Example of International Economic Law (Economic Legal Order)

Ewelina CALA-WACINKIEWICZ

University of Szczecin, Szczecin, Poland
ewelina.cala-wacinkiewicz@usz.edu.pl

Abstract

Despite the fundamental influence and multidimensional impact of the phenomenon of humanization on international law, the concept of humanization of international law has not been subject to quantity-wise extended analysis by legal scholars and commentators. As much as T. Meron's findings addressing humanization of international law *explicite* have inspired a broad scholarly discourse in the literature, research focused on the impact of humanization on particular branches of international law remains overwhelmingly in minority. International economic law also called economic legal order is one of the branches which holds the status of the system of the law - international law. And although categories such as "law", "legal order" or "system of the law" do not have an equal scope of reference, linguistic distinctions between them do not have major significance in this study. However, they outline the background of reflections, in their assumptions devoted to the system of international law as such and international (including EU) economic law as the former's component. The discussed humanization of international law, in general terms revealing the impact of human rights on international law and thus outlining the area of research and bringing its scope onto international ground, is a specific binding link of these analyses. The essence of humanization of international law *per se* is a substantive justification of leaving out the subject-matter of internal law in this study.
Referring to the above, the adopted research methodology, proceeding from the general to the detail, with particular emphasis on the case study (international (including EU) economic law), orders one to assume that the main aim of this study is to demonstrate the influence (impact) of humanization of international law on the international economic order. The culmination of the research involves the formulation of the research hypothesis according to which humanization in the context of international economic law should be examined in two dimensions, as humanization of law and humanization in the law. Introduction of these categories is a *novum* in current research addressing this subject-matter and verification of the hypothesis outlines the scope of observations carried out on the basis of the analytical method and the method of interpretation of applicable law.

Keywords: International (EU) Economic Law, Economic Legal Order, Humanization of International Law, Human Rights

Introduction

Despite the fundamental influence and multidimensional impact of the phenomenon of humanization on international law, the concept of humanization of international law has not been subject to quantity-wise extended analysis by legal scholars and commentators. As much as T. Meron's study (Meron, 2006; and also earlier: Meron, 1989; Meron 2000) addressing humanization of international law *explicite* has inspired a broad scholarly discourse in the literature, research focused on the impact of humanization on particular branches of international law, for the needs of this study understood as such sets of legal norms which by being identified due to the subject of regulation govern a specific area of community life, remains overwhelmingly in minority. To simplify, branches of international law understood in such a way, in summary analogies of internal law branches, constitute basic elements of the system of international law, which *a priori* imposes on them a status of sub-regimes in the system of international law.

International economic law, also called economic legal order, is one of the many branches of international law (apart from the above-mentioned international humanitarian law) which without a doubt meets the above criteria. And although categories such as "law", "legal order" or "system of the law" do not have an equal scope of reference (Lang, 2008, p. 13; Wasilewski, 2004, p. 47; Gourgourinis, 2011, pp. 996-997), linguistic distinctions between them do not have major significance in this study. However, they outline the background of reflections, in their assumptions devoted to international law as such and international (including EU) economic law as the former's component. The discussed humanization of international law, in general terms revealing the impact of human rights on international law and thus outlining the area of research and bringing their scope onto international ground, is a specific binding link of these analyses. The essence of humanization of international law *per se* is a substantive justification of leaving out the subject-matter of internal law in this study.

Referring to the above, the adopted research methodology, proceeding from the general to the detail, with particular emphasis on the case study (international (including EU) economic law), orders one to assume that the main aim of this study is to demonstrate the influence (impact) of humanization of international law on international economic order, at the same time confirming or falsifying the research hypothesis according to which humanization in the context of international economic order should be examined in two dimensions, as humanization of law and humanization in the law. Introduction of these categories is a *novum* in current research addressing this subject-matter and verification of this hypothesis will outline the scope of further observations carried out on the basis of the analytical method and the method of interpretation of applicable law.

Humanization of international law and humanization in international law - semantic distinctions

As signalled above, the subject-matter of humanization of international law has been addressed on the one hand in the shadow of research on general international law (The Impact, 2009; Pronto, 2007, pp. 753-765) and on the role human rights play in it (examples here are provided by for instance general courses at the Hague Academy of international judges by B. Simma (Simma, 1993), T. Meron (Meron, 2006) or A.A. Cançado Trindade (Cançado Trindade, 2014, especially the chapter addressing The Humanization of International law, pp. 99-196; Cançado Trindade, 2013) and secondary publications of the same authors), on the other, due to the concept of fragmentation of international law or even its constitutionalization, i.a. on the forum of the International Law Commission (Report of the Study Group of the International Law Commission, 2006; Ajevski, 2014, pp. 87-98). Without going into an in-depth analysis, legal scholars and commentators have attempted to outline the function of human rights in the development of international law, which, by running in parallel to the sets of unrelated legal norms of the system of the law, leads to a change in the structure and nature of the current international legal order. In T. Meron's approach, it is norms and institutions concerning human rights that brought about a revolution in the system of international law, radiating onto other branches (Meron, 2006) and confirming that human rights law is part and parcel of the general law (Pronto, 2007, p. 764).

The review of ways of approaching humanization of international law done for the needs of this study reveals that the concept of humanization of this law is presented in the following semantic contexts, which - by way of ordering - may be approached *sensu largo* and *sensu stricto*.

In the first approach, humanization of international law to a smaller or greater degree in associated with constitutionalization of this law. However, it must be reserved at the outset already, that if constitutionalization of international law were to be identified only with the process aiming to adopt a constitution as an act of fundamental importance to a legal system (which from the international law perspective would have to entail attributing the Charter of the United Nations signed at San Francisco on 26 June 1945 (United Nations, 1945) the status of a constitution of an international community (The United Nations Charter, 2009), the humanization of international law would fit into the discussed approach faintly. The Charter, as is emphasized in the literature, in not a constitutional

primary source of the entire international law, neither is the entire international law subject to law-creating control of the United Nations (Doyle, 2009, p. 113). Moreover, international human rights law is based on other regulations than the said Charter of the United Nations. Pursuant to its provisions (specifying in Article 1 the purposes of the United Nations), even though the need to promote human rights and to encourage respect for these rights and for fundamental freedoms for all without distinction as to race, sex, language, or religion was expressed, this, undeniably significant, normative category was not elaborated on. It was done in a number of other documents adopted under the auspices of this or other international organizations.

The search for the meaning of the concept of humanization of international law, at the same time rejecting the above approach to perceiving constitutionalization of this law - as a process aiming to adopt a constitution in the formal meaning - implores reaching for the root of the word "constitution". This word, deriving from Latin *constituere*, in its verb form means "to arrange", "to order". Adopting this as a basis, constitutionalization of international law should be understood as an introduction (collection or ordering) of the rules of shaping of the system (rules shaping the system) within which various constitutional processes harmonize. Humanization of international law also fits within such a complex of phenomena which in J. Zajadło's approach are proof to certain constitutional processes of the international community (Zajadło, 2011, p. 12). It is enumerated along such processes as e.g. increase in the number of *ius cogens* norms and *erga omnes* obligations, hierarchy of international law or signing international agreements of the nature of a mini-constitution (Widłak, 2010, pp. 53-54). In this meaning, the theory of humanisation can be seen as contiguous or, to a certain extent, complementary to the other relevant 'big' theory, namely, the constitutionalisation of international law (Tzevelekos, 2013, pp. 62-63).

Speaking of rules shaping the system, presenting human rights within the framework of the concept of humanization of international law is particularly important. Human rights, being a source of unity of the international law system, affect this system in a shaping manner. On the one hand, classified as part of general international law, they confirm the systemicity of this law, on the other they reflect the role and significance of general principles of law (including the principle of respect for human rights), which by specification are applicable in individual branches of international law, strongly affecting these branches and combining them into a cohesive whole. In this approach, individual sub-systems of international law are, both substantively and formally-legally (systemically), immanently related to this law.

This last observation points to the second semantic context of humanization of international law suggested above - the *sensu stricto* context. Within this context humanization of international law is nothing more that radiation, impacting or transferring legal-human regulations to other branches of international law. For example, V.P. Tzevelekos sees humanization in this way, highlighting that "in the theory of the humanisation of international law, [one can observe] a narrative purporting to depict 'the law as it is', that is, to identify the ways positive international law is changing because of human rights, to capture the evolution that its humanisation has generated and, mainly, to illustrate the influence the latter has on the international legal order" (Tzevelekos, 2013, p. 63).

However, it is difficult to stop at a statement that the impact of human rights on other branches on international law occurring within one system of the law proceeds in a one-way fashion. The occurring noticeable feedback is described by M. Özkan Borsa who points out that international public law influences human rights and humanitarian law, but these two fields also have a reforming effect on public international law which even extends to its other subdisciplines (Özkan Borsa, p. 83-84). It is because it is impossible to separate within one system of the law the impact the legal norms it is composed of have both on one another and on the common part that is general international law.

Summing up the above findings it needs to be noted that the essence of humanization of international law cannot be understood by narrowing the concept of humanization of this law only to one of the indicated semantic contexts. Therefore, it may be proposed as a postulate that one should see in humanization, which in its essence is a process, state, phenomenon, on the one hand as such an impact of human rights on the system of international law which by shaping this system binds it into

a whole (humanization *sensu largo* - humanization of international law), on the other, as an impact which aims to introduce to individual branches of international law (that is specialized sets of legal norms) legal-human regulations (humanization *sensu stricto* - humanization in international law), taking into account the jurist nature of these branches.

Humanization of international law and humanization in international law versus international (including EU) economic law

Being a domain of the current international law, the specialization of this law occurring in parallel with a multifaceted development of international relations in specific areas of community life, has led to the shaping of international economic law as a branch of international law. This branch is characterized by a far-reaching specific nature (Menkes, 1988, pp. 21-23), translating into difficulties in defining the concept of international economic law. Leaving them out of the scope of these reflections, one needs to conclude that due to the criterion of norms' origin, the legal international economic order is composed of "all norms governing economic affairs as long as their basis is in the sources of law of an international nature, irrespective of between what entities they regulate relations" (Białocerkiewicz, 1987, p. 43). And even though the definition raises some controversies (for example one may encounter a thesis according to which international economic law includes norms regardless of their origin as long as they regulate international economic relations (Ziemblicki, 2014, p. 183), as seen in the example of international economic order the assumption that it is a person and his needs (i.a. those of an economic nature) that should be the subject of protection from an international legislator is emphasized in a particular way. It is because we are talking about a material legal order only in the context of international law, including also European law as law separated due to its regional scope of application of legal norms of the legal order. Remembering that the law of the European Union is the most universally cited exemplification of the latter, the EU economic law *in extenso* fits within the above definitional determinants.

Legal norms creating human rights are an immanent part of any legal order. Noticing currently the rank of economic rights (as second-generation rights), one does not depreciate in any way fundamental rights (forming first-generation human rights) to which economic rights are a specific supplementation with another dimension, i.e. a dimension that is translatable onto the human material existence within the so-called states' positive obligations. However, there is no doubt that both from the perspective of the system of international law and from the perspective of its individual components - branches of this law, human rights (including those of an economic nature) are a collection of legal norms that have a special meaning. It is because the dual character (proposed above) of perceiving humanization of international law is revealed in it, which allows looking through the lens of human rights not only at international law as such (humanization *sensu largo*), but also at individual branches of this law, including international economic law (humanization *sensu stricto*).

In the first of the outlined contexts, human rights forming part of general international law, are reflected in numerous legal international acts. Narrowing the enumeration down to those which directly include economic rights, without a doubt one can point to the International Covenant on Economic, Social and Cultural Rights signed at New York on 16 December 1966 (UN General Assembly, 1966). The catalogue of economic rights included in it covers i.a.: the right to work and the right to decent remuneration (Article 6 and 7 of the Covenant), the right to strike and to form trade unions (Article 8 of the Covenant) or the right to an adequate standard of living (Article 11 of the Covenant). And although the provisions of the Covenant, which forms part of the achievements of the United Nations, are not a *novum* in this scope, they are attributed a leading role in shaping the described category of human rights. Duplicating regulations already known to the international community from the European Convention for the Protection of Human Rights and Fundamental Freedoms signed under the auspices of the Council of Europe on 4 November 1950 (Council of Europe, 1950), the Covenant introduced the so-called sectoral protection according to individual categories of human rights.

In the light of the above, it can be noticed that contemporary international law does not stray away from human rights (including from economic rights) whose main beneficiary is a person - individual. Therefore, it does not surprise, as pointed out by T. Meron, that the humanization of public international law under the impact of human rights has shifted its focus above all from State-centered to individual-centered (Meron, 2006, introduction, p. 1). This shift towards an individual is even more expressly described by Z. Drnas de Clément who writes that "by centralizing the human being as a point of concern and calling for the humanization of international relationships, new international thinking gives relevance to the human being and the role of the individual in the fulfillment of international law principles" (Drnas de Clément, 2010, p. 407). This thought reflects fullest the essence of the process of humanization of international law, making the category of human rights not only a part of law common to all its branches, but also a binding link of the system of international law.

In the second approach to the context, it is worth noting the fact that apart from international economic law "using" general international law and human rights inscribed in its scope (in this meaning, these right of a general nature), primarily it is a branch of international law in which one can observe the phenomenon earlier called humanization in law. This phenomenon is revealed in a particular way in the context of the EU economic law. What is interesting, initially the European Communities and since 1992 also the European Union did not take up the legal-human subject-matter in their treaty provisions, adhering to a general statement that they are based in their functioning on respect for human rights, contributing to their protection. However, the development of this legal order, demonstrated even in signing at Lisbon on 13 December 2007 of the Treaty of Lisbon amending the Treaty on European Union and the Treaty establishing the European Community along with the annexed Charter of Fundamental Rights (O.J. C 306, 17.12.2007, p. 1–271) caused the subject-matter of human rights to permeate on the normative ground of the European Union. For example, in Article 16 of the Charter of Fundamental Rights the freedom to conduct a business was proclaimed and in Article 36 access to services of general economic interest was guaranteed. If additionally one were to take into account that "fundamental rights of citizens of the European Union were considered an integral part of general rules of community law, among which protection of privacy, ownership right, freedom of choice and performance of a profession, economic freedom are of particular importance" (Cieśliński, 2009, p. 16) then the fact that the EU economic law did not stop only at using the legal-human regulations forming part of general international law but by extending the catalogue of these rights they were adapted to its needs, has non-trivial importance for he research hypothesis formulated in the introduction. Then analysing, in the legal-human scope, the structure of the described legal order, one needs to conclude that it includes not only "general human rights", but also rights which through this order were shaped somehow for its own needs, at the same time reflecting the attribute (specific nature) of this order. The rights in question (like the right of access to services of general economic interest) are an expression of far-reaching specialization of the EU economic law.

Conclusion

The above findings allow a look at human rights as a source of unity of international law (Cohen, 2012, p. 382), at the same time giving rise to a conclusion that human rights have given an entirely new, human face to what has traditionally been a sovereignist legal order (Tzevelekos, 2013, p. 75). Without a doubt the above-mentioned "human face" of international law is a consequence of dually understood humanization of international law (humanization of law and humanization in the law), reflecting the order's legal and international development. It is enough to remind that initially the subject-matter of human rights was reserved only to national legislations. Thus transferring it (after World War II) onto an international ground cannot be left underestimated also on the ground of research, proving the unquestionable development of both the international law itself and its legal-human subject-matter under the rule of this law.

Looking at human rights dually as a component of general international law and as a component of individual branches of the system of international law (including the international economic law undertaken as a case study), it is possible to confirm the research hypothesis posed in the introduction

according to which humanization - in the context of this legal order - must be perceived as humanization of law and humanization in the law. On the one hand, human rights (including those of economic nature) shape the system of international law, combining it into a whole under general international law (humanization of international law). On the other, introducing to international (including EU) economic law legal-human regulations, taking into account the specific nature of this branch, proves its far-reaching specialization which is a manifestation of humanization in international law. Noticing this phenomenon is all the more essential since this specialization implicates further development of this branch, not on the general international law plane any more, but on the plane of multiplication of legal norms forming this branch.

The above fully implements the postulate of "human face" of international law, which, especially in the context of economic rights as international economic law, should protect a human-individual as a beneficiary of these rights and values created by the law. It is the individual juxtaposed with the institution of the state that is an entity protected less, whereas economic rights and their development under the international (including EU) economic law are a chance to compensate and level away the individual's weaker position.

Abstract

Today, the Russian Federation needs qualified specialists who can quickly solve professional problems in different ways, find the optimal solution. Therefore, knowledge and skills in the field of mathematical modeling are demanded in the study of natural sciences, technology, economics and most other professional disciplines. As a result, a working hypothesis was put forward: the level of acquisition of knowledge and skills by students of the economic direction determined by the formed competences in the process of studying the discipline "Methods of optimal solutions" will be higher if these skills are formed in the process of solving economic quasi-professional problems by means of mathematical modeling. A large amount of heterogeneous information, uncertainty and ambiguity of mathematical modeling of economic processes, data variation are significant factors in attracting economic problems to research. They can be solved by means of various methods based on probability theory, mathematical statistics, elements of automation theory, as well as software tools for performing accuracy of calculations and automation of operations. One such approach is described in the article. Based on the pedagogical experiment carried out, conclusions can be formulated, stressing the validity of the proposed hypothesis and the possibility to use methods and means of linear programming in mathematical models of quasi-professional tasks. Knowledge of mathematical models contributes to a better understanding by students of the causes of different economic situations, as well as allows them to understand and compare emerging patterns and correctly predict the consequences of economic decisions in professional activity.

Keywords: Mathematical Modeling, Economics, Linear Programming Problem, Information Technologies.

Introduction

Today the graduates of the economic direction will be in demand on the labor market, if, when faced with solving real production problems, they have the ability to make a reasonable optimal solution, based on normative government and local documents and mathematical models of solving this problem.

The term "optimal solution" has a long history in the field of linear programming. It applies to different subject areas. In the modern comprehension, the optimal solution is called a solution based on objective analysis (knowledge, experience, experiments and calculations) and subjective understanding of the value and effectiveness of solutions (Prokhorov, Frolov, 2011).

The Relevance of Research

According to the State policy of the Russian Federation in the fild of improving higher education, one of the priorities of its development is to improve the quality of mathematical education in all areas of students' training.

Therefore, it is no accident that mathematical education is the most important component of the entire system of fundamental training of a graduate of higher education. Much research is devoted to studying the content of training of graduates of economic direction and methods of their professional competencies' formation. Nevertheless, the topic continues to be relevant for modern education, as a unified approach to the problem has not yet been developed. This problem is particularly relevant in the field of formation of ability to solve economic problems by means of mathematical modeling: what kind of technologies, methodologies, software tools are needed by the graduates, what professional competences, methods of their formation and assessment of the level of their development they should possess. The main reasons for this problem, on the one hand, are the sharp increase in the volume of knowledge both in the field of economics and in the computer environment, as well as the rapid change of technology and digitalization of business, and on the other hand, the system of higher education does not always have time to respond to the demands of society and employers.

The analysis of the ability to model economic systems in various organizations showed that the main problem is not insufficient knowledge of young professionals, but the lack of practical skills and experience in modeling economic and socio-economic processes in specific professional activities, transfer of theoretical provisions, methods of information processing to practice (Ural, 2020). Having sufficient knowledge within the professional cycle subjects, graduates are not always ready to solve difficult and extraordinary production problems, which require integration of knowledge and skills from different fields. Therefore, the quality training of students in higher education institutions requires significant improvement of training, especially within the disciplines of the mathematical and general natural science cycle, which allow to train specialists with a wide outlook, able to adapt to changes in technology.

The theoretical-methodological basis of the study was the works of domestic and foreign authors, such as D.L. Andrianov, A.I. Anchishkin, K.A. Bagrynovsky, A.O. Baranov, A.G. Granberg, V.P. Maksimov, R.I. Ostapenko, V.V. Poladova, A.N. One of the directions of increasing the efficiency of formation of ability to solve economic problems in students is methods of mathematical modeling and IT-technology.

Problem statement

The purpose of this study is to select and build components of the methodology of training students of economic direction to solve quasi-professional economic problems by means of mathematical modeling, accompanied by finding an effective solution to their provided data. Such a rule is often called an optimality criterion, and a preference measure is called quality indicators. The best option is possible only if two conditions are met: at least one reasonable criterion; at least two options to compare (selection required) (Prokhorov, Frolov, 2011; Semerikov, 2013).

There is a mismatch in the level of development of the problem of student training in the field of mathematical modeling, as well as a contradiction between the need of society for economists with a sufficient level of digital literacy in solving economic problems. They are the ones that make up the study's problem. The pedagogical opportunity to solve quasi-professional economic problems by

mathematical modeling methods in order to improve the professional training of graduates of economic direction in universities and the scientific justification of its implementation, obviously, requires special study.

The hypothesis of the study is that the process of improving the professional training of future economists when studying the discipline "Methods of optimal solutions" will become more effective if:

- the methodology of mathematical modelling skills will be applied to economic quasi-professional tasks in the educational process;
- the linear programming software of Mathematica, MathCad, Matlab, Maple, Derive and their partial counterparts Scilab, GNU Octave, Maxima, SMath Studio Cloud will be used.

Research Questions

The search for optimal solutions is carried out through mathematical methods of quantitative analysis of variants, which allows to exclude subjective, emotional and psychological factors, thus putting planning and management on a scientific basis. The use of mathematical methods, the introduction of information technologies, the complication of technologies and production processes, the operation of big data for decision-making, the creation of qualitative analysis allows to fully investigate the problem, to study the emerging new additional possibilities in the theory and practice of management decisions.

The analysis of federal educational standards of economic direction showed the absence of mathematical modeling as a necessary component of professional competence of the future specialist.

The object of the study is the process of forming in students of economic direction the ability to use mathematical modeling to find the optimal solution at changing parameters of components of the production process.

The subject of the study is the methodology of teaching students of economic direction to solve quasi-professional problems with economic content in conditions of use of computer mathematical systems.

The nature of the scientific and pedagogical problem, the degree of development of its various aspects, largely determined the goals and objectives of the present study.

Purpose of the study. In order to get acquainted with all possible ways of finding the optimal solution of the problem and forming competences for students in the field of system analysis, we have developed and introduced into the practice of training bachelor 's degrees in the direction 38.03.01 "Economics" profile "Accounting and finance" the discipline work program "Methods of optimal solutions». In the course of pedagogical research we monitored the success of development in students of bachelor's degree of ability to carry out mathematical modeling in solving quasi-professional problems of economic content.

Research Methods

The model, object, modeling, modeling stages, modeling methods, system and system approach act as the basic concepts of discipline "Methods of optimal solutions». The application of mathematical methods implies the use of linear programming models in solving problems of an economic nature, when it is necessary to design and study new systems, abstracting from the insignificant parameters of the system in question, to analyze and systematize the properties of the system, to select and justify optimal conditions for their functioning, etc.

Among the researchers involved in the description of formalized economic and mathematical models, it is worth noting the works of K. Marx (Extended production model), L. Walras (statistical model of

the farm known as the general economic equilibrium system), V. Pareto (pattern of distribution of income of population in capitalist countries in the form of hyperbola ("Pareto curve")), V.K. Dmitriev (cost-output relationship equations), V. Leontiev (Balance of costs and output), L.V. Kantorovich and M.K. Gavurina (mathematical methods of organization and production planning), J.B. Danzinga (study of simplex method), A.N. Tolstoy (optimal transportation plan), F. Hitchcock (transport task), etc. Today, economic and mathematical models are in demand in various theories, including inventory management theory, mass service theory, game theory, statistical decision theory, network planning and management methods, and mathematical programming.

During the system study, several models are created, which leads to the need to identify the best model with qualitative characteristics. This activity allows in-depth study of model properties based on the results obtained. Thus, on the example of solving the transport problem it is possible to distinguish several criteria indicators, which include monetary and time costs for transportation, volume of transport works. In general, the solution is called permissible if it satisfies restrictions: resource, legal, moral and ethical. The solution is called optimal (best) if it provides an extremum (maximum or minimum) of the selection criterion in an individual or satisfies the principle of matching in a group context.

The modeling process creates conditions for the technological development of the activity, when the development of the model is carried out in a step-by-step manner strictly in accordance with the intended purpose, with an adjustment, if necessary, to the existing model (or the development of a new model) with the correlation of the obtained results with the real conditions of the model operation under the specified conditions. If the obtained model meets the set goal, has a complete or sufficient correspondence with the original, then the fields of its application and introduction into theory or practice are determined in the future.

In other words, the generalized characteristic of the solution of an economic-mathematical problem is its efficiency, depending on the proportional degree of achievement of the goals to the cost of the whole solution (the total cost of resources for making and implementing the solution). On this basis, it can be concluded that the solution to such a problem is the more effective, the higher the degree of achievement of the goals and the lower its cost.

The study of mathematical modeling opens up wide opportunities for understanding the connection of computer science with all sciences, including mathematics. Formal and abstract modeling with the help of computers – verbal, informational, mathematical – nowadays became one of the information technologies in the organization of educational and cognitive quasi-professional activities when students master the main educational program (Kraineva, Shefer, 2017).

Any mathematical model reflecting essential features of an object or process can be given by the language of equations and other mathematical means. Based on the theory of description of formal grammars (according to N. Chomsky) (Volkova, Rudenko, 1999), a generalized scheme of solving mathematical problems (Setyaningsih, Nining, Juniati, Dwi, Suwarsono, 2018) and requirements to the formation of a management solution (Sierksma, Zwols, 2015), the linear programming problem (LPP) can be defined in the form of an interconnected chain of the following objects:

$$\text{LPP: } \langle S_o, T, Q \mid S, A, B, Y, f, K, Y_{opt} \rangle,$$

where to the left of the vertical line there are known elements, and to the right there are unknown ones of the task: S_o - the problem situation; T - is the decision time; Q - resources available for decision making; $S = (S_1, ..., S_n)$ – the set of alternative situations clarifying the problem situation S_o; $A = (A_1, ..., A_k)$ – multiple objectives pursued in decision-making; $B = (B_1, ..., B_L)$ – multiple constraints; $Y = (Y_1, ..., Y_m)$ – the set of alternative solutions; f is the preference function; K is the criterion for choosing the best solution; Y_{opt} is the optimal solution.

Verbally, the description of the mathematical model of the SNR can be given in the following: based on the specified operating conditions of a system of some problem situation S_o, time T, and resources

Q, it is necessary to clarify the situation S_o with a plurality of hypothetical situations S, to form the sets of goals A, constraints B, and alternative solutions Y, to evaluate the preferences of solutions f and to find the optimal solution Y_{opt}, based on the formulated selection criterion K (Schrijver, 1998a; Schrijver, 1998b; Aleksandar, Velinov, Vlado, Gicev, 2018; Samuel Chiabom Zelibe, Chika Ugwuanyi, 2019).

Thus, when solving LPP, it is necessary to select a method that will find the largest (or smallest) linear function value of several variables if there are constraints in the form of linear equations and inequalities imposed on these variables.

As methods of LPP are chosen: simple and directed methods of alternative situations, graphic (or geometric) method, simplex method, dual task, potential method, artificial basis method (M-method), "north-west angle" method, minimum cost method, rectangle method (jordan transformations), Vogel and Gomori methods (for integer calculations), Hungarian method (Orlov, 2004; Samarov, 2009; Vanderbei, 2014; E. Klafszky, Tamás Terlaky, 2007; Ahmed, Khan, Ahmed, Uddin, 2016).

The process of solving LPP by the simplex method is reduced to four stages (Fig. 1).

Fig. 1: The process of solving LPP simplex method

By means of information technologies it is possible to carry out modeling at different criterion indicators by means of the optimization solution by means of automation of mathematical calculation, obtaining the final result in numerical, formula, graphical forms (Bimal Das. Effect of graphical method for solving mathematical programming problem. Daffodil International University Journal of Science, 2010).

Currently, there are various computer mathematics systems that have the necessary instrumentation to build mathematical models and solve linear programming problems, such as Mathematica, MathCad, Matlab, Maple, Derive and their partial counterparts (Scilab, GNU Octave, Maxima, SMath Studio Cloud, etc.). Familiarization with licensed and freely distributed packages of programs makes it possible to increase the level of training of students in the field of digital literacy by organizing their own educational and cognitive activities in the study of various disciplines (Kraineva, Shefer, 2017).

Let us give an example of a quasi-professional problem offered to students of economic direction, finding the optimal solution of which is carried out on the basis of linear programming using various means.

The fish shop uses various resources to produce its products. It is known that the production of fish in own juice requires 2 units of fish in Class I, 1 unit in Class II; pate – 1 and 3 units, respectively. The total quantity of each fish species is 400 and 600 tons. Labor intensity of fish production in own juice is 4 units, pate – 5 units. Total amount of labor intensity – 1237 units. It is necessary to determine

how much fish in own juice and pate the plant needs to produce in order to achieve maximum profit from sale of products, if the price of fish in own juice is 6 rubles per unit of product, pate – 9 rubles.

Let us formalize the task condition by specifying a simplex table or function entry and inequality system (Table 1).

Table 1: building a simplex table

Resources	**Resource consumption rates per product**		**Total resources**
	Fish in own juice	**Pate**	
Fish, in Class I	2	1	400
Fish, in Class II	1	3	600
Labor intensity	4	5	1237
Profit from sales of one product	6	9	?

In the construction of the mathematical model, we will designate through x_1 and x_2 the produced units of various types of products (fish in own juice and pate). On a statement of the problem x_1 and x_2 variables are not negative, i.e. $x_1, x_2 \geq 0$.

The profit from the sale of such a number of products will be $F = 6x_1 + 9x_2$ rubles. Need $F = 6x_1 + 9x_2 \rightarrow max$ is necessary.

Let us set restrictions of a task. It is known that to make x_1 fish in own juice and x_2 pate, $2x_1 + x_2$ fish, in Class I, will be required. Stocks of fish in Class I are made by 400 tons, therefore $2x_1 + x_2 \leq 400$.

Similar for fish in Class II: $x_1 + 3x_2 \leq 600$.
Similarly to set labor intensity: $4x_1 + 5x_2 \leq 1237$.

Under the specified constraints, the overall appearance of the linear programming task is as follows:

$$\begin{cases} 2x_1 + x_2 \leq 400 \\ x_1 + 3x_2 \leq 600 \\ 4x_1 + 5x_2 \leq 1237 \\ x_1, x_2 \geq 0 \end{cases}$$

Solving MS Excel, it is necessary to use the built-in analysis and search for solutions by specifying the change cells of the x_1 and x_2 variables and constraints. In this case, the original data of the task should be presented in the form of a table, which contains formulas reflecting the dependencies between the data (Figure 2).

Basic variables and the objective function

	Fish in its own	Paste		Objective function	
Profit	6	8		0	max

=SUMPRODUCT(C4:D4;C5:D5)

Required from production (restrictions)

Fish, in Class I	2	1	<=	400	0
Fish, in Class 2	1	3	<=	600	0
Laboriousness	12	15	<=	3711	0

=SUMPRODUCT($C$4:D4;C11:D11)

Fig. 2: Formulas used in calculations

The greatest difficulty for the user is usually the task substitution itself, i.e. the selection of such inputs and constraints that MS Excel issues a valid solution to the task (Figure 3).

Basic variables and the objective function

	Fish in its own	Paste		Objective function	
	101,5714	166,143			
Profit	6	8		2104,71	max

Set limits

Required from production (restrictions)

Fish, in Class I	2	1	<=	400	389,286
Fish, in Class 2	1	3	<=	600	600
Laboriousness	12	15	<=	3711	3711

$C$4 >= 0
$D$4 >= 0
$G$11:$G$13 <= $F$11:$F$13

Fig. 3: Solution of the LPP in MS Excel

In Figure 3, you can see that the result of these actions is to find x_1 = 101.5717 and x_2 = 166.143 for maximum profit at the specified resources and constraints. By adding another constraint that the resulting x_1 and x_2 vaues are integers, we get 103 and 165 that satisfy the task condition.

B. V. Bukhvalova presents an automated software FinPlus designed to solve problems of linear and quadratic programming (training version), written in the programming language VBA (Bukhvalova, 2019). The package provides the user with additional capabilities (compared to the search for a solution): various ways of entering data, the possibility of saving conditions and solving the task, access to simplex tables, the possibility of performing post-optimal analysis. It is also possible to generate conditions of linear and quadratic programming tasks of given dimension. A detailed solution to the problem with this package is shown in Figure 4.

A report on the decision

Return to the task

c=	6,00	9,00			
				b=	y=
A=	2,00	1,00	<=	400,00	0,00
	1,00	3,00	<=	600,00	0,86

Fig. 4: The decision of LPP means of the FinPlus

For the solution of this task it is also possible to use the Mathematica system (Dyakonov, 2008) in which, having set the Maximize function for the solution of a problem of linear programming, in designations of variables x and y: Maximize [{6x + 9y, 2x + y <= 400 && x + 3y <= 600 && 4x + 5y <= 1237 && x> = 0 && y> = 0}, {x, y}], we will receive the decision in various options – analytical and graphic (Fig. 5).

Fig. 5: The solution of LPP in the «Mathematica» system

The values found for the variables x and y are presented in fractional form. By making changes to the presentation format, you can get a response in the form shown in Figure 6.

Fig. 6: The amendment of the data presentation format in «Mathematica»

A similar result can be obtained by changing the Maximize function to NMaxmize, which is used for integer calculations (Figure 7).

Fig. 7: Using the NMaximize function to solve the LPP using the «Mathematica» package

Online systems of computer mathematics also allow to solve problems of optimization (The World of Mathematics, 2019; an online resource for solving the linear programming problem by the Gomori method, 2019), which allows to perform calculations based on various methods, to save the obtained solutions in MS Word (* .doc) and MS Excel (* .xls) format.

We will use the Gomori method (an online resource for solving the linear programming problem by the Gomori method, 2019) to solve this problem. To do this, we specify the number of variables and constraints, as well as the formula constraints used in the description of the formalized mathematical model (Figure 8).

Fig. 8: Setting task conditions for a Gomory method

The result of the calculations is shown in Figures 9, 10.

Оптимальный план можно записать так:

$x_1 = 101^4/_7$, $x_2 = 166^1/_7$

$F(X) = 6 \cdot 101^4/_7 + 9 \cdot 166^1/_7 = 2104^5/_7$

Fig. 9. Fractional result of calculations

Оптимальный целочисленный план можно записать так:

$x_1 = 103$, $x_2 = 165$

$F(X) = 6 \cdot 103 + 9 \cdot 165 = 2103$

Fig. 10: Integer result of calculations

Findings

To get acquainted with all possible ways to find the optimal solution of the problem and to form competences of students in the direction 38.03.01 "Economics" profile "Accounting and finance" in the field of system analysis, we have developed working programs of discipline "Methods of optimal solutions».

Testing on the implementation of the program was carried out in three stages on the basis of South Ural Institute of Management and Economics, in which 157 students participated in the training direction 38.03.01 "Economics" profile "Accounting and finance" face-to-face and correspondence form of training. The division into control (C) and experimental (E) groups was based on the determination of the mean score in mathematics and computer science, which was 0.1 higher in the control groups than in the experimental ones. Surveys and questionnaires of teachers, students, development of the content of the discipline work program, search of information technologies providing mathematical modeling of economic tasks were carried out at the reporting stage. At the initial stage we tested the content of the topic developed, which reflects the study of the foundations of linear programming, funds of evaluation funds aimed at identifying the level of formation of competences. At the analytical stage, a post-operational analysis of the works of the students of the economic direction was carried out, which allows to determine the success factor of their ability to carry out mathematical modeling in solving economic problems (Table 2), based on the method developed by A.V. Usova (Usova, 1969); formulation of conclusions, formulation of recommendations.

Table 2: the success development rate of the students' ability to perform mathematical modeling in solving economic problems

Number of tests	Groups	Skill Formation Rate $\overline{P} = \frac{\sum_{i=1}^{N} P_i}{NP}$	Skill Success Rate	
			$\bar{j}_Э = \frac{\overline{P}_{Э3}}{\overline{P}_{Э1}}$	$\bar{j}_K = \frac{\overline{P}_{K3}}{\overline{P}_{K1}}$
I	E	0,56	1,38	1,26

	C	0,41		
II	E	0, 68		
	C	0, 46		
III	E	0, 77		
	C	0, 52		

Conclusion

1. The pedagogical experiment confirmed the validity of the hypothesis and showed that students of economic directions of training will have perfect knowledge of mathematical apparatus, be able to analyze and interpret the obtained data, find optimal solutions, changing various parameters of components of the production process.

2. These skills are formed in the process of solving economic quasi-professional problems by means of mathematical modeling and information technologies.

3. The experiment determined the possibility of using linear programming methods in mathematical models, which allow to optimize the decision-making process in economic problems presented in quasi-professional tasks.

4. Solving economic problems by means of mathematical modeling is one of the important conditions of linear programming for solving professional problems, the indicator of which is the transfer of knowledge and skills in the discipline "Methods of optimal solutions" into mastery.

5. The study confirmed the positive impact of our system of economic problems on the degree of formation of students' ability to work with linear programming tools (MS Excel spreadsheet, FinPlus program, Mathematica mathematical packages, MathCad, Matlab, Maple and online services) in solving economic problems and expanding the range of opportunities in the teacher-learner and learner-learner dialogue.

The scientific novelty of the study is that:

1. a methodology for training in solving quasi-professional economic problems in Mathematica, MathCad, Matlab, Maple has been developed in the context of the applied orientation of economic training for students;

2. a set of didactic conditions has been identified, which contribute to the effective expansion and deepening of the applied direction of the discipline "Methods of optimal solutions" by solving quasi-professional economic problems in Mathematical, MathCad, Matlab, Maple environment;

3. a set of methodological techniques has been developed to solve problems with economic content in Mathematica, MathCad, Matlab, Maple environment in the process of students mastering the discipline "Methods of optimal solutions": presentation of educational information according to the levels of formation of digital literacy; the usage of intra and inter-business linkages to effectively solve quasi-professional economic problems using Mathematica, MathCad, Matlab, Maple.

In summary, it is necessary to note the special role of linear programming in mathematical models, as it contributes to the most effective decision-making in serious economic problems. Any modern economist is obliged to understand economic and mathematical methods, as it is knowledge of mathematical models that contributes to a better understanding of the causes of economic situations, as well as allows to understand and compare patterns and correctly predict the consequences of economic decisions.

Abstract

The ESD concept developed by the United Nations should be able to encourage students' skills, perspectives and values for a sustainable future. The purpose of this research is to develop an existing ESD model and combine it with the concept of the authentic experience to produce an ESD model that is adapting to the values and wisdom of the implementation of education in Indonesia. The ESD model developed in this research is a hypothetical model in which the development of the ESD model in this research based on the ESD model developed previously by Shohel and Howes. The results obtained from this research are the ESD model produced by combining the components of the school, ESD awareness circle, local wisdom, service-learning, community engagement, and evaluation. In the future, this model is expecting to be a basic model for sustainable development education that involves local wisdom in Indonesia.

Keywords: ESD, model, education, school

Introduction

In a research study by Dannenberg and Grapentin (2016) mentioned the crucial issues concerning sustainable development are included in ESD to enable people to get used to living and to act sustainably. Skills and knowledge are also needed to build relationships and cultural concerns of the community, democratic values and processes, theories that explain the socio-historical context of learners, and processes of action that continue to reflect on structure and dynamics (Aguilar, 2016), and develop and maintain sustainable society (Laurie et al, 2016).

ESD implementation cannot be done alone by schools. Building partnerships with various parties, value orientation, holistic, complex, and useful is the basic principle of ESD (Fadeeva and Galkute, 2012). Fadeeva and Galkute's (2012) explanation is in line with Bruns et al (2019) that the implementation of SDGs in schools influenced by stakeholders from inside and outside the school, as well as the design and implementation of quality reforms. Potential schools can develop through various positive activities, following the targets and goals of education for sustainable development. The ESD integration approach in the Quality Criteria for ESD-Schools document (Guidelines to enhance the quality of Education for Sustainable Development) (Breiting et al, 2005) explains that involvement in ESD should not be considered as an additional burden on teachers and principals, but instead used as opportunities to enhance learning and teaching activities and increase innovation for all schools. Effective school programs must be able to support students' knowledge, attitudes independently, and skills in real life for complex situations (Cincera and Krajhanzl, 2013). Schools must also create an atmosphere of learning that is authentic, meaningful, creative, and based on students to enable sustainable development practices (Goldman et al, 2018).

Lewin (2019) explain that ESD curriculum must aim at better learning management, cumulative in nature, encouraging changes in consumption and promoting environmental insights, social cohesion, and changes in consumer preferences. ESD implementation in schools requires close-thinking

thinking to think about complexity and overcome uncertainty (Julien et al, 2018) and emphasises participation and interaction between students and their student-centred environment, collaborative, inquiry-based approach (Uitto et al, 2018). Normative competence is also essential to implement, negotiate, and reconcile norms and principles (Ploum, 2018) in addition to developing students' multi-perspective for action taking and supported pedagogically in the practice of sustainability (Kater-Wettstädt, 2017). Explanation of Ploum (2018) and Kater-Wettstädt (2017) in line with Dlouhá and Pospíšilová (2018), which states that students' competencies must be able to be used to improve their skills and potential to be creative, confident, and to engage participants with the community to manage and make a decision. Rogers (2019) also explained that education to achieve sustainable development goals does not only go through the formal sector, but must go through non-formal education with flexible, contextual, and participatory learning programs. Knapp (1980) explains that learning experiences are designed for cognitive and psychomotor purposes, so the development of environmental ethics needs to be considered following the values, planning, and evaluation goals.

Teachers can support student competencies in individual, social, and institutional activities to realise collective action and transformation towards sustainability (Sahakian and Seyfang, 2018). The pedagogical approach must be adapted to the teaching resources so that ESD learning becomes relevant, timely, and useful (Cahill and Warwick, 2019). Vare and Scott (2007) explain that clear learning strategies, openness, and the existence of evaluations are needed to carry out ESD. Teise and Roux (2016) mentions values, critical thinking skills, and conceptual clarity in the implementation of ESD in order to recognise as part of the ethos and culture of education.

Shohel and Howes (2011) grouped the ESD model into three, and each containing three sub-levels of achieving sustainable development, namely education about sustainable development which contains transmitting information, changes attitudes, changes behaviours. Education for sustainable development which contains taking action, builds awareness and practical understanding, results in a practical commitment to sustainable living. Critical education towards sustainable development which contains generating knowledge through critical action, reflection, changes policy, develops active and critical citizenship. This change model from Shohel and Howes was chosen because this model contains three kinds of sub-models which can be adjusted to the conditions of achieving sustainable development in the country concerned. Education about sustainable development can be applied to areas that are just starting to step towards sustainable development, education for sustainable development can be used for countries that already have the initial foundation for implementing sustainable development, but still, need efforts to maximise resources for achieving sustainable development. Education towards sustainable development can be applied to countries that have all elements of society have understood the importance of sustainable development so that they need universal elaboration at the national level.

Indonesia already has a program called Adiwiyata where the Adiwiyata program can be used to develop students' attitudes and responsibilities to protect and manage the natural environment through school governance that supports sustainable development (Prabawa-Sear, 2018). The program, managed by the Ministry of Environment and Forestry in collaboration with the Ministry of Education and Culture, aims to realise schools that care about and are cultured in the environment using participatory principles (all school components are involved) and sustainable with all activities carried out in a planned and comprehensive manner (Chaeruddin as cited in Maryani, 2016). Therefore, education for sustainable development from Shohel and Howes is suitable to be developed in Indonesia, considering that Indonesia has already begun the initial steps towards achieving sustainability with the Adiwiyata program.

The development of the ESD model can use to fill the gap between Environmental Education and ESD itself through ecopedagogy to determine socio-environmental boundary situations and to carry out transformative actions through deep and broad reflection (Misiaszek, 2019). At present, there is no systematically developed ESD model for high schools in Indonesia. Based on these facts, the question arises: How can the ESD Model for SMA in Indonesia be prepared based on the Shohel and Howes models? For this reason, this research aims to develop an ESD model based on the ESD

model from Shohel and Howes by adding components that are appropriate and can be implemented in Indonesia.

Methods

The method used in this research is through a literature study in several related research papers to develop the existing ESD model. Field observations were also carried out by researchers at two Adiwiyata (green school) recipient schools in Jakarta, Adiwiyata School in Indonesia, which is an environmentally friendly school that has started an education that supports environmental awareness. These observations are used to support the preparation of this ESD model.

Result and Discussion

The development of the ESD model by the author is to develop the Shohel and Howes ESD model in Figure 1. The Shohel and Howes ESD model is grouped into three, and the authors develop the ESD model of the Shohel and Howes "*education for sustainable development*". The ESD model change was examined to determine the strengths, weaknesses, and material needed for the development of the ESD model for high schools. The results of the Shohel and Howes ESD change model study are presented in Table 1

Table 1: The result of Shohel and Howes ESD change model study

advantages	disadvantages
1. The interaction between school and community is very beneficial for student development. 2. It can accommodate complexity and incorporate social action into practice. 3. The orientation that is strong on the principle of human welfare. 4. The curriculum problems integration. 5. Lifelong awareness and practices were changing action. 6. It contains practical and contextual learning for a better life.	1. Study results in Bangladesh may not be applicable in other countries, including Indonesia, due to differences in social systems, education systems, budgets, and financing. 2. The application of the model is based on research results in non-formal education and does not explain how this model can also be practised in formal schools, especially in high schools. 3. It does not contain learning strategies.

Based on the study of the strengths and weaknesses of the Shohel and Howes ESD change model, it is necessary to adjust the material requirements for the ESD model to be developed. The material needed is:

1. A clear learning strategy that places the learning process as a process as well as an outcome;
2. Openness to unplanned directions (uncertainty);
3. Evaluation (Vare and Scott, 2007);
4. Settling conditions related to social systems, education systems.

Based on the results of the previous ESD model literature review, the Shohel and Howes Model, the authors make an ESD model development table for high schools in Table 2

Table 2: ESD model for senior high school development

Model ESD Shohel and Howes	Developing a model	ESD model for senior high school
Take action	1. Adjustment to local situations and conditions; 2. Competencies (teachers and students); 3. Environmental awareness.	*1. ESD Awareness* *2. Circle Local wisdom*
builds awareness and practical understanding	1. School interactions with the community 2. School potencies.	*1. Service-learning* *2. Community engagement*
results in a practical commitment to sustainable living	1. Learning as a process and result; 2. Evaluation.	*1. ESD school* *2. Evaluation*

Based on the ESD model development in Table 2, the resulting ESD Model development for SMA is presented in Figure 1.

Fig.1: ESD Model for senior high school

1. *Sustainable Development Awareness Circle*

The Education for Sustainable Development Goals Learning Objectives document by UNESCO in 2017 explains the learning objectives which divide into three domains: cognitive domain, socio-emotional domain, and behavioural domain. These three domains are fundamental to instil environmental awareness. Sustainable Development Awareness Circle is a circular model part which contains the terms Cognitive which are defined as knowledge, Affective which is defined as an attitude, Conative which is defined as a behaviour, three circles that are interconnected with each other that symbolise the three pillars of sustainable development namely Environmental, Social, Economic, and sustainable development. Gatti et al (2019) mentioned that the focus of achieving ESD is cognitive, affective, behavioural learning and the ability to solve compound sustainability-related problems. The opinion of Gatti et al (2019), not in line with the findings of Olsson et al (2019), which states that ESD-certified schools have less impact on students' knowledge, attitudes, and behaviour towards sustainability. The integration of environmental, social, and economic aspects can be adjusted to the ability of the school, meaning that not all aspects are integrated at one time, but can be done according to scope and sequence vertically or horizontally. The intended vertical scope here is between levels ranging from tenth grade to twelfth grade and horizontally is only one level.

2. *Local Wisdom*

Local wisdom in this model is interpreted by the writer as the local wisdom of the local community so that education for development is carried out with the inclusion of insights that include indigenous insights, local culture in environmental management, social life, thinking patterns and behaviour that characterise the local area. Nguyen (2017) explains that the ESD Model adapted to

the conditions, priorities, and educational actions of the countries concerned, in order to get a comprehensive picture of ESD that is in line. Nguyen's explanation (2017) is not in line with the statement of Sandoval-Rivera (2019), which states that ESD does not pay attention to the importance of local and indigenous knowledge even though local knowledge can found incomplete information on environmental management including ecological development and maintenance to strengthen the achievement of SDGs. The direction of the local wisdom arrow that leads to the ESD Awareness Circle is intended that in the ESD learning process, teachers and school leaders include elements of local wisdom or use the concept of local wisdom as a foundation as well as enrichment in this ESD learning model.

3. Service Learning dan Community Engagement

The teacher chooses the most direct learning method in the field in the research location. Direct learning in the field can be interpreted as participatory activities with students being able to practice the theories obtained in the classroom for certain subjects, as well as learning service to the environment and community (service-learning) through direct engagement with the community (community engagement). This activity is in line with Uitto, who stated that ESD emphasises participation and interaction between students and their environment. This participatory activity is also following what was conveyed by Dlouhá and Pospíšilová and Kater-Wettstädt which explained that participation to the community could be used as knowledge development, enhancement of students' skills and potential in sustainable practice efforts. Shohel and Howes mentioned that in the change in the ESD model they developed, namely education for sustainable development, there must be an element of taking action, which is used to build awareness and practical understanding so that it will produce a commitment to live sustainably. (results in a practical commitment to sustainable living). While from the two schools observed, it has not been programmed to build the character of students to think critically so that no awareness and understanding has been built to commit to living sustainably.

4. Education for Sustainable Development School and Evaluation

Education for Sustainable Development School in this model is a school that has run ESD learning and as an output of the ESD learning model developed by the author. This ESD School is not a title given to a school like the Adiwiyata award because there is no official institution in Indonesia that provides an assessment for schools that run ESD. Schools that have reached this stage are expected to be able to carry out the principles of sustainable development and can drive changes in knowledge, skills, values, attitudes, and empower the community and equip present and future generations to meet their needs in a balanced and integrated way. Schools running ESD must meet indicators ESD competence. Assessment must be done to evaluate the understanding of students' big picture (Kopnina, 2012), the application of local wisdom including indigenous knowledge including its development and synthesis in sustainability education (Koehn and Uitto, 2013), and to reflect on the implementation of ESD in schools which raises an argument due to trends and contradictions between goals and implementation on the ground (Kopnina, 2020). The author intends evaluation in this model as a self-evaluation activity or an independent evaluation of one's abilities. This independent evaluation is due to the lack of institutions that carry out assessments for the implementation of ESD in schools. This independent evaluation is carried out by schools related to the implementation of ESD learning in schools at the ESD Awareness Circle and participatory Service Learning and Community Engagement activities.

Conclusion

The ESD model developed by the authors in this research is hypothetical. The model developed by this author is expected to increase environmental, social, and economic awareness to support sustainable development. This model can be used in high schools to raise environmental awareness for the initial stage, followed by incorporating social and economic aspects in learning activities in schools so that it is expected to support the implementation of education for sustainable development for high schools. Specific studies need to carry out to develop learning techniques in the ESD Awareness Circle section so that schools can adapt this model to the conditions and abilities of the school. If schools want to implement this ESD model, then preparations need to be made

appropriately related to the readiness for implementation time, budget, teachers, students, and other school residents. The implementation of the ESD model can be adjusted to the situation and condition of the school concerned.

Abstract

This article analyses the current situation as well as projections for the future of road transport in Poland, as well as setting the appropriate strategy of developing this area of activity. The starting point is the role of transport in the economy. This paper also includes characteristics of forms of shipping according to the transport branch concentrating on road transport, in account of data on carriage, cargo, and average shipping distance.

Keywords: Economic Development, Transport, Transport Management

Introduction

Today, the world is developing in a multidimensional fashion. The highly developed transport infrastructure influences creating a competitive edge. Transport is the social/economic activity, which determines any and all other activities of people and businesses. Transport is characterized by an organizational/legal complexity, diversity of processes relating to movement of cargo and people, as well as a complexity of technical correlations. Transport enables the economic development of every country, foreign trading, and market integration; it ensures accessibility to different regions; efficient transport influences regional and local economies.

The social role of transport is also important. Firstly, we have economic benefits resulting from effective operation on the job market, which, in turn, influence the expansion of this market. This contributes to reduced unemployment, an increase in the wealth of the society and, what follows, a decrease of the level of poverty. The social role of transport also comprises improving all types of services. Additionally, the transport sector play an important role in the area of support – charity activities and humanitarian actions.

Obviously, negative external aspects of the transport sector should also me mentioned. These include: pollution (contamination of water, soil, and air), significant accident rate, costs of congestion, increasing levels of noise and vibrations, over-consumption of energy, and reducing the green areas.
Road transport is the most popular transport branch. Its advantages include: flexibility and fast pace of deliveries, possibility to reach every place on the globe, carriage of various goods, long- and short-distance shipping. Whereas disadvantages include: pollution, significance accident rate, long delivery time on long distances in case of road jams or traffic bans, delays in deliveries.

Literature Review

The universal term of transport is referred by Tarski in his definition (1973, p. 11), according to whom "in the broadest etymological sense, transport means a technological process related with movement at distance, meaning movement of persons, items or energy". In account for the logistic aspect, Kauf (2016, p. 140) defines the transport process as a "group of coordinated activities pertaining to a time- and space-related transformation of articles and information, in accordance with the terms and conditions of a contract between the carrier and the contracting authority". According to Tomanek (2004, p. 11) the work "transport" is used in the three following meanings: subjective – as a separate area of the national economy; activity-related – as the act of moving (in this context, carriage is related with forwarding, logistics, and the transport process); tangible – as material

equipment meant for moving. Transport constitutes an important part of the logistics concept, as it directly contributes to implementation of its primary goal, which is supplying a particular product to a particular place and in specific time (Mesjasz-Lech, Włodarczyk, 2019, p. 93).

Transport affects economic development, division of work, specialization of production, and it increases the reach of the market. It is decisive in terms of success of not only one economic sector but the economic success of the entire country (Button, 2010, p.23). Transport cannot be replaced by other services. Existing and planned transport networks and the volume of shipping constitute important factors for city and region development, and determine the locations of investments and businesses. Transport facilitates exchange of goods and services, realization of social goals (meeting communication needs, ensuring access to education, as well as health, cultural and sports facilities). Transport significantly affects the Gross Domestic Product (GDP) and the development of national economy sectors (Button, 2010, pp.21-23). There is a close correlation between the growth in gross domestic product (PKB) and an increase in the demand for transport, both the transport of goods and passengers. It is predicted that the level of transported goods and thus the level of pollution from transport will increase regularly until 2050. The total demand for freight on a global scale can be up to three times higher than nowadays (ITF Transport Outlook 2017).

Transport cannot be executed without a technical infrastructure. The development of every transport branch and their cooperation depend on this infrastructure. Transport literature defines infrastructure as a group of principal institutions and equipment essential for proper functioning of the economy (Wojewódzka-Król, Rolbiecki, 2018, p.14). It should be noted, on the basis of the presented definitions, that infrastructure plays a substantial role in the execution of transport processes (Benassi et all, 2015, pp. 47-50). It conditions their timeliness, efficiency, effectiveness, reliability, and the level of costs and safety. Infrastructure is to ensure proper flow of merchandise. The level of development of transport infrastructure conditions overcoming time- and space-related deviations between demand and supply (Skorobogatova, Kuzmina-Merlino, 2017, p.319, Maroto, Zofío, 2016, pp. 145, Kadłubek, 2015, 496). Characteristics of infrastructure are presented in table 1.

Table 1: Characteristics of transport infrastructure

Attribute	Description
Technical indivisibility	Occurrence of certain technical characteristics, which prove the usability of the technical infrastructure; executing the undertaking in such manner so that individual elements reach their usable capacity; the need to build additional infrastructural facilities;
Economic indivisibility	Incurring expenses for the development of infrastructure, which leads to recurring fixed costs
Long term of execution of infrastructural facilities	This is affected by the long duration of planning and designing infrastructural facilities; time-consuming project preparation due to taking into account elements such as: compliance with transport and regional policies; environmental effects of the investment; attributes and specificity of the infrastructure of defined transport branches; coherence of transport systems; law regulations
Long term of use	The necessity to conduct a detailed analysis of future transport needs, because improperly conducted forecasts and adopted technical and spatial solutions may prevent the development of transport systems
Priority of transport outlays	Funds assigned to transport infrastructure and other infrastructural elements should have priority over consumption expenses
Immobility	There is no possibility to move the elements of the infrastructure
Effects on the natural environment	Direct or indirect negative effect of facilities and equipment on the environment e.g. exhaust emissions

Source: prepared on the basis of: I. Urbanyi-Popiołek, Podstawy organizacji i ekonomiki transportu – wybrane zagadnienia [in:] edited by I. Urbanyi-Popiołek, Ekonomiczne i organizacyjne aspekty transportu, Wydawnictwo Uczelniane Wyższej Szkoły Gospodarki w Bydgoszczy, Bydgoszcz 2013, pp. 11-13.

The characteristics of the transport infrastructure include economic and technical indivisibility. These characteristics result directly from the high asset and capital absorption of the transport infrastructure. Moreover, transport infrastructure is characterized by functional and spatial immobility, as well as sustainability of use (Rolbiecki, Wojewódzka-Król, 2013, p.37).

Road transport, also referred to as vehicle transport, currently constitutes the dominant method of carriage of persons/ cargo. Shipments are transported by roads using motor vehicles. Road transport in Poland is regulated in the Act on Road Traffic. Road transport is characterized by substantial flexibility and availability, favoured by a developed road network. Every shipment can be delivered door to door. Receipt of shipments may be conducted at any place or time. In addition, duration of transport (in case of short distances) is relatively short (Leończuk, 2011, pp.99-100).

Analysis of The Functioning of Vehicle Transport in Poland

Vehicle transport was developing slowly during the interwar period. This changed after signing a contract with the Italian FIAT in 1932. The production of Ursus trucks and Fiat passenger vehicles has started. After the 2nd World War, truck factories in Lublin and Starachowice were established, as well as bus factories in Sanok and Jelcz, and a passenger car factory in Warsaw; the production of motorcycles was commenced, and this transport branch started developing. The role of transport after 1989 has grown significantly. The vehicle cargo transport became demonopolized. The Polish vehicle transport market constitutes an integral part of the EU transport market. It is subject to numerous EU and national regulations. The market of vehicle transport services is analysed in the context of individual carriers, buyers of transport services, as well as in the sectoral and macroeconomic dimensions.

Based on the level of accessibility and area services, the following categories of roads are distinguished: motorways, public roads, and express ways. Motorways are roads designed for vehicle traffic only. They were specially designed, and equipped with two separated one-way roadways. They have multi-level crossroads with intersecting roads. Express ways are also meant only for motor vehicles; they have two separated one-way roadways. As at the end of 2018, there were 3 730.7 km of express roads in Poland, of which 1638.5 km are motorways and 2092.2 km are express ways. In total, in 2018 the length of roads was at 424 563.9 km. it should be underlined that although the length of this type of roads increased in Poland in the past years, the country is still well behind other European countries. Figure no. 1 presents the network of roads in Poland in 2019.

Fig. 1: Network of trunk roads in Poland in 2019

Sieć dróg krajowych	Network of trunk roads
Stan istniejący	Current status
Wg stanu na dzień 08.11.2019	As at 08.11.2019
Oznaczenia:	Legend:
Autostrada (A)	Motorway (A)
Droga ekspresowa (S) – dwujezdniowa	Express way (S) – two lane road
Droga ekspresowa (S) – jednojezdniowa	Express way (S) – one lane road
Droga krajowa (G, GP) – dwujezdniowa	Public road (G, GP) – two-lane road
Droga krajowa (G, GP) – jednojezdniowa	Public road (G, GP) – one-lane road
Droga wojewódzka	Voivodeship road
Miasta na prawach powiatu	Poviat towns
Granice województw	Voivodeship borders

At the end of 2017 the total length on public roads in Poland amounted to 422.3 ths. km, of which 71% were hard surface roads, and 29% – dirt roads. The proportion of hard surface roads 2018 was 97.2 km/100 km^{2}. Most hard surface roads are located in Silesia, Mazovia, Lower Silesia and Świętokrzyskie. Least hard surface roads are located in voivodeships in the North and in the West of Poland, meaning Lubuskie, West Pomerania, Pomerania, Warmińsko-Mazurskie and Podlaskie. Since 2005 the length of hard surface roads has been gradually growing thanks to continued works aiming at adjusting the road infrastructure to the current needs of road users. The diagram below presents the number of kilometres of motorways and express ways in Poland in the years 1989-2018.

Fig. 2:Number of kilometres of motorways and express ways in Poland in the years 1990-2018

The line infrastructure of road transport is also assessed in terms of quality. The Polish roads network has significantly improved in the last decade, although it is still behind the quality of roads of other European countries. There are no roads enabling unobstructed traffic, in particular transit traffic – bypassing cities. The quality of bridges, flyovers, tunnels, and underpasses is low. In 2017 it was assessed that over a half of roads in Poland was in a good state. However, still over ¼ of road surfaces in the country was unsatisfactory, and 14.5% were in a poor state. 1.4% were under renovation. According to the *Report on the technical status of the surface of public roads at the end of 2017*: unequal course of roads, meaning that there are areas with significant density of roads networks, as well as areas where this network is poor, which hinders fast transportation of cargos, insufficient number of transit roads, too little roads linking individual municipalities, insufficient number of city bypasses, tunnels, bridges, car parks, parking places, pedestrian routes, bicycle lanes, a low technical quality of bridges and surfaces.

Another factor conditioning the development of the transport market in Poland is the number of vehicles. Based on statistical data, Poland is noting a systematic increase in the number of motor vehicles (Table 2).

Table 2: Number of motor vehicles in Poland in the years 2010-2017 [ths.]

Types of vehicles	**2010**	**2011**	**2012**	**2013**	**2014**	**2015**	**2016**	**2017**
Passenger vehicles	17 240	18 125	18 744	19 389	20 004	20 723	21 675	22 504
Trucks and road tractors	2 982	3 131	3 178	3 242	3 341	3 429	3 542	3 640
Buses	97	100	100	103	106	110	113	116
Motorcycles	1 013	1 069	1 107	1 153	1 190	1 272	1 356	1 427
Other	1 706	1 764	1 746	1 796	1 832	1 875	1 915	1 948
Total	23 037	24 189	24 876	25 684	26 472	27 409	28 601	29 635
Mopeds	922	1 033	1 100	1 163	1 217	1 259	1 292	1 328

Source: https://www.pzpm.org.pl/Rynek-motoryzacyjny/Park-pojazdow-zarejestrowanych/Tabele-Park-pojazdow-zarejestrowanych-w-Polsce-1990-2017 [12.04.2020]

The increase of the number of vehicles includes all groups. In comparison to 2010, in 2017 the number of passenger vehicles increased by 30%, trucks and trailers – by 22%. The lowest growth was recorded in buses – 19.6%, and highest in motorcycles – almost 41%. Taking into account all vehicles, their number increased in the analysed period by 28.6%. Significant growth was also noted

in mopeds – 44%. In addition, ¾ of the motor vehicle park in 2017 covered passenger vehicles. 12.3% were trucks and road tractors. Less than 5% of vehicles on Polish roads were motorcycles, and 6.6% - other (including specialist vehicles). The growth in the number of vehicles is also confirmed by the data from the Polish Automotive Association (PZPM) for Q1 2019. In the period from January to the end of March 2019, the following numbers of vehicles were registered (Quarterly report entitled: *Branża motoryzacyjna, Raport kwartalny PZPM i KPMG*, Warsaw 2019, p. 4.): 17 030 passenger vehicles (increase by 11.1% in comparison to 2018); 7 453 trucks (increase by 4.2%); 7 414 semi-trailers and trailers (increas by 7.8%); 532 buses (decrease by 15.2%); 3521 motorcycles (increase by 68.2%), 3 022 mopeds (increase by 83.6%). Analysing the presented data it should be noted that only registration of buses dropped in Q1 2019. In account of percentage values, the largest increase was report in mopeds and motorcycles.

Apart from the line infrastructure, there is also the point infrastructure, which is analysed in terms of passenger services, cargo handling and means of transport. A transport point is a properly equipped place, where movement of persons/cargo may start or end, or where the mean of transport is changed. Whereas a transport hub is every such point, where lines from at least three directions intersect. These are the lines of one or more transport branches (Grzybowska, 2009, p.196).

Carriage of goods by vehicle transport requires an infrastructure that guarantees loading, reloading and unloading of shipped cargo. These works are related with the shipping process. Currently, for vehicle transport, there are public unloading platforms, stations or factory stations, as well as reloading points. In addition, there are business units operating at the verge of the vehicle transport / roads / automotive sector, which are also included in the transport infrastructure. They include gas stations, vehicle service centres, workshops, technical facilities of transport companies (Wojewódzka-Król, 2010, pp. 464).

Subsequently, an analysis of cargo carriage in transport branches was performed based on available statistical data. The analysed data cover the years from 1995 to 2015 and originate from the Main Statistical Office.

Based on the analysis of the volume of cargos in the examined period, it may be confirmed that the volume was systematically growing (apart from the year 2005, when a minor drop in vehicle cargo transport was reported). Considering the structure of cargo carriage according to cargo mass expressed in tons it may be stated that the share was between 75.8% in 2005 up to 84.3% in 2010. This period saw a dynamic growth of shipping. This was caused by a substantial increase in the number of vehicles and the number of shipping companies. In subsequent years, the volume of shipping increased due to construction of new express ways and motorways (they were built because of the EURO2012 championships taking place in Poland and in Ukraine). In the analysed years there was also a constant average increase noted in the distance of shipping 1 ton of cargo (a growing trend with average annual growth of the distance of carriage at 6.8 km). This is an important parameter from the point of view of competitiveness of the given transport branch. Table 3 presents data concerning transport in Poland in account of the distance of cargo carriage.

Table 3: Distance of cargo carriage in Poland

Year	Up to 49 km	From 50 to 149 km	From 150 to 499 km	Above 500 km
2017	606 995.3	325 173.0	262 540.3	22 109.6
2018	548 246.0	293 334.4	261 593.4	20 226.5

Source: Przewozy ładunków i pasażerów w 2018 roku, GUS, Warsaw 2019, p.3.

Presented data demonstrate that most shipments on the national market were executed at a distance of up to 49 kilometres. Least shipments were executed at a distance of over 500 kilometres.

The analysis of the volume of cargo shipments expressed in ton-kilometres, which takes account of both the mass of cargo and the carriage distance, demonstrate that this indicator was also continuously increasing (from 51 000 in 1995 to 273 107 ton-kilometres in 2015). In 2018, cargo

transport expressed in thousands tons increased by 7.2%, and in million tons – over 8%. Most frequently transported cargo includes: extracted minerals (including coal), food products, furniture, agricultural products, construction products, and waste.

When discussing the road infrastructure, an important issue is its excessive overload, which results from various causes. Mostly, we are observing a significant increase of the number of vehicles on roads, and an expansion of road transport. On some roads and transport hubs the infrastructure is overloaded. This happens in particular in urban areas, and on routes linking tourist towns (Borck, 2017). The construction of new bypasses or roads is often protested against by ecologists. In their opinion, exploitation of the transport infrastructure will result in pollution, disintegration of the area, violation of existing ecosystems, security risks, and excessive noise (Cai, Zhou, 2015, pp.1-7). However the progressing globalization and economic development forces the expansion of the transport infrastructure (Levinson et. All, 1996, p. 2-10). There must be new road networks, reloading points and stations, to make transport of cargo and people more efficient.

State's Transport Policy

The main goal of the transport policy is a clear improvement of the quality of the transport system and its expansion according to the principles of sustainable development, the quality of the transport system is one of the key factors affecting the quality of life of residents and the economic development of the country and regions. The development of the country's transport policy means: improvement of transport availability and quality of transport as a factor improving the living conditions and removing economic development barriers, supporting the competitiveness of the Polish economy as an important instrument of economic development, improvement of the effectiveness of the transport system, integration of the transport system in both branch structure and territorial structure, improvement of safety leading to a radical reduction of accidents and eliminating their effects, and – in terms – improvement of personal safety of road users and cargo protection, elimination of the negative effect of transport on the environment and living conditions. In the transport policy, emphasis is placed mainly on the undertakings, the effects of which could significantly influence the economy of the country or a given region, and would be tangible for the largest possible number of transport users. According to the Polish transport policy, priority is given to projects aimed at: improvement of the state of all roads, development of the network of motorways and express ways on most overloaded routes, including links with the trans-European network; railway modernization through an expansion of competition between operators to adjust them to market needs and retain their role in transport, with a simultaneous improvement of the effectiveness; improvement of safety in transport; improvement of the state of the railway infrastructure and limiting the costs of access; improvement of the quality of transport in cities, metropolitan areas and regions, including the conditions of pedestrian and bicycle traffic, and taking account of the needs of the disabled; development of intermodal systems; development of the market of air services, in particular lifting the barriers for small carriers and regional airports; increase of the role of seaports and airports and improvement of access to these ports in local and national scale (Kabus, Strulak-Wójcikiewicz, Nurzyńska, 2016).

The currently valid strategic document relating to transport policy is the strategy prepared in 2017 entitled: "Sustainable Transport Development Strategy up to 2030" (Ministry of Infrastructure, 2017). According to this principal document, the national transport policy aims at increasing the availability of transport and improvement of safety of traffic participants, as well as ensuring the effectiveness of the transport sector by way of creating a coherent, balanced, innovative and user-friendly transport system in national, European and global dimensions. It should be indicated that Poland's link with European and global transport systems as well as the improvement of territorial accessibility in the national scale requires inter-branch integration. Reaching cohesion of the entire transport system is related with both a dynamic expansion of the missing infrastructure elements, to allow completing this system as soon as possible, and using modern technologies, including intelligent transport systems to facilitate the functioning of transport and to improve the safety of not only users of the infrastructure but also traffic participants. The principal goal of the Transport Development Strategy is to create an integrated transport system through, amongst others, investing in transport

infrastructure and creating advantageous conditions for the efficient functioning of transport markets, as well as development of effective transport systems to ensure creating links that allow performing deliveries of products and raw materials to enterprises and facilitate the movement of users of the infrastructure. The main goal of the "Sustainable Transport Development Strategy up to 2030" is presented in Figure 3.

Fig. 3: Main goal and detailed goals of the "Sustainable Transport Development Strategy up to 2030"

Conclusions

Transport affects sustainable development, which refers to social, ecological, economic, spatial and functional factors, and the growth and effective functioning of the transport system allows conducting business operations. Moreover, the level of development of the transport system is the factor, which decides about the availability of transport (so called communication accessibility) in the given area.

The systemic transformation and its resultant economic changes significantly contributed to the improvement of the state of the transport system in Poland. Along with the systemic changes and economic transformations the transport policy has also changed. After the end of the command and control economy in Poland, legal regulations were being loosened, and general business became liberalized. This process also related to transport, which was reflected in the transport policy. Currently, the transport system is regulated by both national and EU laws. In addition, as from 1989 Poland started to prepare and implement (with different effects) strategic documents pertaining to the

transport policy. The Polish transport policy was changed numerous times due to a lack of a coherent concept of long-term transport development, and a lack of systemic solutions relating to financing these investments at the national and self-government level.

Abstract

The article is devoted to assessing the dynamics of innovative productivity of regions and the effectiveness of capital expenditures on technological innovation. The structural shift index and the incremental capital output ratio were used as assessment tools. The assessment was carried out in the context of the federal districts of Russia and the regions of the North-West of the country. The analysis revealed a tendency to relatively small shift the structure of innovative products and a tendency to increase the discrepancy between the structure of products as a whole and the structure of innovative products by regions. Regions were identified where the increase in capital expenditures for technological innovation exceeds the increase in innovative products, which is not clear evidence of the ineffectiveness of capital expenditures, but requires a thorough analysis of the situation. The approach used in the work and the conclusions drawn can be used in innovation management at the regional level.

Keywords: Region, Innovation, Structural Shifts, Incremental Capital Output Ratio.

Introduction

This section In February 2019, the Strategy for Spatial Development of the Russian Federation for the period until 2025 was approved. This document, undoubtedly, should become a significant milestone in the formation of state regional policy. However, in (Valentey, Bakhtizin and Kolchugina, 2019) it is indicated that the Strategy did not actually take into account the differences between the Russian regions both in terms of their socio-economic development and in their innovative potential, and its substantial refinement is necessary to specify its basic provisions and to create the mechanisms for enhancing the role of constituent entities of the Russian Federation in strategic development, taking into account differences in their development levels and potential.

The interconnection of regional development with innovation is currently not in doubt, however, questions of assessing the innovation effectiveness in the regions have not yet received comprehensive answers.

Effectiveness is the most important economic category that allows measuring the results of economic activity in comparison with its implementation costs. Based on the effectiveness indicators, areas for improvement are selected and optimal investment options are determined. The most important indicator of the region's economy effectiveness characterizing its economic power is the annual amount of products, work and services produced in the region and shipped to the consumers.

To assess the effectiveness of the region's economy and its innovative component, often use such characteristics as the amount of innovative products and their change over time, the share of innovative products in the total production, as well as indicators of innovation costs.

The most important type of innovation is technological innovation, which means the final result of innovation, embodied is a new or improved product or service introduced on the market, a new or improved process or method of production (transfer) of services used in practice. The costs of technological innovation are the actual costs represented in money units associated with the implementation of various types of innovative activities carried out at the enterprise's, industry's, region's or country's level. As part of the costs of innovation, statistics take into account current and capital costs. It is capital expenditures that constitute investments forming the material basis for the production of innovative products in the medium and long term, so their effectiveness should be the priority subject for analysis.

According to the methodology adopted in statistical accounting, capital investments (long-term investments) are annual expenses for the creation, increase in size, and the acquisition of non-current long term (over one year) assets not intended for sale, carried out in connection with the development and implementation of technological innovations . They consist of the cost of acquiring machinery, equipment, other fixed assets, as well as constructions, land and nature management facilities necessary for carrying out innovative activities.

This study sets the task of identifying trends in the structure of the regional economic space based on the examining of structural shifts in the indicators of regional innovative products, and assessing the effectiveness of capital costs for technological innovations.

Literature Review

An analysis of the strategic approach to the innovative development of the Russian regions is the content of the work (Aleksandr, Svetlana, Irina abd Elena, 2017). In (Karelina, 2015), significant interregional differences in the main indicators characterizing the innovative activity of the Russian regions are noted, and it is emphasized that in conceptual documents the allocation of specific zones of priority development is considered as an important aspect of the regional policy of the Russian Federation. .

Rodionov and Rudskaya (2017) conclude that the prerequisite for the economic development of Russia as a whole is the creation of an innovative environment in the regions, and in (Rodionov, Rudskaia and Degtereva, 2017) the significance of the regional foresight as the basis for the formation of national development plans is substantiated (Figure 1). Smirnova (2019) believes that regions objectively become a special space that allows an active implementation of innovative process. Gospodarchuk (2006) provides a number of reasons, due to which the regions become such a specific space.

The introduction of innovation in the regions is ensured by regional innovation systems, which should provide the dissemination of new knowledge, skills and best practices in the region (Cooke, 2002; Liu and Chen, 2003; Agrawal, Cockburn, Galasso and Oettl, 2014; Pino and Ortega, 2018).

Fig. 1: The regional foresight in the context of global development

The presence of significant regional differences is demonstrated in (Valentey, Bakhtizin and Kolchugina, 2019). The works (Nosonov, 2014), (Rudskaia, 2017), (Goncharova, Degtereva and Sopilko, 2018), (Nikonova, 2019) are devoted to identifying problems that reduce the innovative activity of Russian regions and proposing measures to overcome them. There are a number of works exploring the problems of innovative development in certain strategically significant regions of Russia, for example, (Komkov, Selin, Tsukerman and Goryachevskaya, 2017), (Shestak, Shcheka and Klochkov, 2019). As possible drivers of innovative development of the regions the following are studied - active foreign trade (Tkacheva, Osadchuk, Kapustina, Kobersy and Litvinova, 2017), strengthening ties between business and science (Dvas, Malinin and Velichenkova, 2019), development of financial institutions and improving access to credit resources (Rozanova and Tishkov, 2019), level of informatization (Guzikova and Panteleev, 2015). The effectiveness of innovation in the context of investment flows was analyzed in (Ruyga, 2016).

An analysis carried out in (Kharitonova, Bondarenko, Yudina and Tanina, 2017) makes it possible to establish the presence of a very close dependence of the gross regional product per capita on innovation factors. The mentioned authors conclude that the possibilities for improving the regional economies' effectiveness determine the development of their innovative potential, the creation and introduction of innovation. At the same time, in (Kharitonova, Bondarenko, Yudina and Tanina, 2017) it is said that effectiveness must be considered from two sides - quantitative and qualitative. In the context of regional development, the quantitative side means saving resources, time for achieving the goals of the region, and the qualitative side reflects the nature of the resources, technologies and production methods used.

It should be noted that the problem of finding indicators adequately reflecting the results of innovation cannot be considered resolved. This is pointed out in (Bortnik, Zinov, Kotsyubynsky and Sorokina, 2013).
