In (Moiseeva andArkharova, 2019), a comprehensive analysis of the organizations' costs of technological innovation as one of the indicators characterizing the innovation spillover within a country is undertaken and an increase in the share of R&D costs and costs of development new products and production methods against a background of reduced acquisition costs of machinery and equipment purchasing is denoted. Thus, the emphasis is on the development of innovation, rather than their scaling.

Data and Methods

The analysis is based on the regional data on total production, innovative production and costs of technological innovation for 2016-2018 represented in the website of Federal Statistics of Russian Federation (gks.ru).

To measure the strength and depth of the transformation, which manifests in structural changes, special methods are used in statistics, specific indicators are calculated. Within the research, to assess structural shifts Ryabtsev indices (Ryabtsev and Chudilin, 2001) were calculated. These indices make it possible to conclude about the sustainability of the economic system's development and allow economic interpretation without the use of comparative analysis (Elkhina, 2015) due to the presence of a scale for assessing the significance of structural changes and applicability to any set of statistical data. The meaning of the Ryabtsev index consists in the ratio of the actual measure of the discrepancy between the components of two structures with its maximum possible value. The index is calculated by the formula:

$$R = \sqrt{\frac{\sum_{i=1}^{N}(d_i^2 - d_i^1)^2}{\sum_{i=1}^{N}(d_i^2 + d_i^1)^2}},$$

where N – the number of components in the structures under comparison, d_i^j –component i of the structure j, j=1,2.

The scale for assessing the significance of differences between structures allowing recognizing the shifts is given in Table 1. 8 grades of structural difference are distinguished starting from the identity near to complete to the exact opposite. The changes in the structural difference allow concluding about the directions of changes occurring. The sharpness and strength of structural changes depend on the fluctuations (variations) of the absolute growth indices and specific gravity growth rates.

Table 1: Scale for assessing the significance of structural differences by Ryabtsev index

Interval of index values	Measure of structural differences
0,000 – 0,030	Identity Structures
0,031 – 0,070	Extremely low structural differences
0,071 – 0,150	Low structural differences
0,151 – 0,3	Significant structural differences
0,301 – 0,5	Medium significant structural differences
0,501 – 0,7	High significant structural differences
0,701 – 0,9	Opposite type of structures
0,901 and more	The exact opposite of structures

Source: (Ryabtsev and Chudilin, 2001, p. 46-47)

To evaluate the effectiveness of capital expenditures on technological innovations, the incremental capital output ratio (ICOR) was calculated:

$$ICOR_t = \frac{\Delta K_t}{\Delta V_t} = \frac{I_t}{V_t - V_{t-k}},$$

where ΔK_t is the growth of capital (investment) in the year t, ΔV_t is the growth of production in the year t, k is the number of years in the analyzed period..

It should be clarified that this indicator is commonly used in assessment the investments influence on gross product (Hayes, 2019). Given that capital expenditures do not always give effect in the current year, the analyzed period can be several years (m). In (Gulhati and Datta, 1983) it is noted that ICOR

depends on the pace of scientific and technological progress, the development of professional and managerial skills. ICOR is influenced not only by income from new investments, but also by income from existing assets. Since existing assets usually exceed capital investment, the performance of existing assets has a greater effect on ICOR than the quality of new investments. Thus, a decrease in capacity utilization will raise the ICOR, even if new investments are highly productive.

ICOR can be interpreted as the capital intensity of the increase in the volume of production, therefore it is a kind of "measure of ineffectiveness" - the lower is the indicator's value with an equal value of the increase in production volume, the more effective is the investment (Wai, 1985).

Results

The results of the analysis of structural shifts in the context of federal districts (FD) are represented in Table 2. It can be seen that the structure of shipped products in 2018 remained virtually unchanged compared to 2016. The Central FD is the leader in volume of production, the Volga FD is in second place, the Ural FD is the third, followed by the North-Western, Siberian, Southern, Far Eastern and North Caucasian FDs in descending order of production. To the 2018 the changes had place in the structure of innovative production: the leader has changed - the Volga FD took the largest share in the volume of innovative products, and the Central FD, the leader of 2016, took second place. In 2018, the difference between the structures of the volume of total production and the volume of innovative products which was already significant in 2016, increased.

Table 2: Coefficients of structural shifts by FDs of Russian Federation

Structures compared	Value	Interpretation
Correspondence of the structure of the volume of total products in 2016 and 2018	0,020	Identity Structures
Correspondence of the structure of the volume of innovative products in 2016 and 2018	0,147	Low structural differences
Correspondence of the structure of the volume of total products and the volume of innovative products in 2016	0,219	Significant structural differences
Correspondence of the structure of the volume of total shipped products and the volume of innovative products in 2018	0,249	Significant structural differences

Source: calculated by authors

Russian statistics do not allocate data on capital costs as a part of technological innovation costs. Therefore, to calculate ICOR, it's necessary to refer the structure of technological innovation costs by type of activity. This structure is presented in Table 3, where the costs that can definitely be attributed to capital are shown in bold. Thus, the lower estimate of the average share of capital costs in the total amount of costs on technological innovation may be taken equal to 37.2%.

Table 3: Cost structure for technological innovation in 2017

Types of innovation	Share, %
Research and development of new products, services and methods for their production (transfer), new production processes	42,3
Industrial design, design and other developments (not related to scientific research and development) of new products, services and methods of their production (transfer), new production processes	1,2
Acquisition of machinery and equipment related to technological innovation	34,1
The acquisition of new technologies	1,1
Software Acquisition	2,0
Other types of production preparation for the release of new products, the introduction of	10,1

new services or methods of their production (transfer)	
Education and training related to innovation	0,1
Marketing research	0,3
Other technological innovation costs	8,8

Source: (Moiseeva, Arkharova, 2019)

Figure 2 shows the ICOR values for 2 years. The only FD, where in the period under consideration, the indicator is less than 1, which means the excess of product growth over investment, is the North-West FD. In three districts - Siberian, Southern, and Central - the indicator values are negative, which is associated with a decrease in the volume of innovative products despite the fact of capital expenditures on technological innovations carried out.

Combined with a high aggregate share of these regions in the total volume of innovative products, this led to a very large ICOR value for the country as a whole.

Fig. 2: ICOR for the FDs of Russia for 2016-2018

Similar estimates were made for the only effective North-Western FD in the period under consideration. As is evident from Table 4, over two years, no significant changes in the structure of innovative products had place in North-Western FD. The differences between the structures of total products and innovative products are significant, and in 2018, the differences intensified compared to 2016.

Table 4: Coefficients of structural shifts by region of the North-West FD

Structures compared	Value	Interpretation
Correspondence of the structure of the volume of total products in 2016 and 2018	0,028	Identity Structures
Correspondence of the structure of the volume of innovative products in 2016 and 2018	0,057	Extremely low structural differences
Correspondence of the structure of the volume of total shipped products and the volume of innovative products in 2016	0,271	Significant structural differences
Correspondence of the structure of the volume of total products and the volume of innovative products in 2018	0,279	Significant structural differences

Source: calculated by authors

The ICOR for the particular regions are shown in the Figure 3. In the North-West region, the Arkhangelsk region, the Republic of Karelia, the Pskov region and St. Petersburg were efficient in ensuring growth in the volume of innovative products greater than that of capital costs of technological innovations. In 2018, their total contribution to the production of innovative products constituted 87%. A decrease in the production of innovative products was observed in the Murmansk region, Novgorod region, Komi Republic and Vologda regions.

In the Kaliningrad and Leningrad regions, the volume of innovative products did not exceed the volume of capital costs for technological innovations.

Figure 3: ICOR for the regions of North-Western FD for 2016-2018

Conclusions

The analysis undertaken made it possible to draw a number of conclusions significant to understand the investment situation in the regions of Russia.

1. The structure of production in total remains almost unchanged both in the context of FDs and in the regions of the North-West FD.

2. There is a tendency to shift the structure of innovative products by FDs, manifested in particular in the leadership in innovative products of the Volga FD in 2018 instead Central FD in 2016. The shift in the structure of innovation production in FDs is more pronounced than the shift in total output.

3. The values of the ICOR in the context of federal districts vary widely, and a deeper analysis is needed to explain the reasons. The decrease in the volume of innovative products can be attributed to the following reasons: 1) the general economic crisis, which undermined the demand for products and caused the departure of a number of innovative enterprises from the market; 2) the expiration of the period after which products manufactured by new technologies are considered as innovative in statistics; 3) against the background of the reasons mentioned above in certain combination, the capital expenditures on technological innovations have not yet reached the stage of payback.

4. In the North-West FD, there is a tendency to shift the structure of the output of innovative products, the discrepancy between the structure of total products and that of innovative products is intensifying.

5. In the North-West FD, there are 4 out of 10 regions where, in the period under consideration, capital expenditures on technological innovations were effective in terms of the growth of innovative products. Such a situation gives these regions the opportunity to expand capital expenditures in

technological innovations, provided they are carefully substantiated and the availability of promising projects, as well as make investments in science and education.

6. There is no homogeneous innovative space in the Russian Federation neither in the terms of FDs, nor within North-Western FD. The incremental analysis shows the significant difference in the effectiveness of the capital costs in technological innovation between the components to the moment and this confirms their being in different stages of innovative process.

Abstract

Globalization has had a significant impact on all businesses and industries including construction. It reduced distance and time between all points of the world in near real-time which stimulated international projects. Lebanon plays an important role in international business activity due to its strategic location on the Mediterranean Sea. Lebanese engineers and construction companies for example, work in different countries throughout the Middle East and the Arab world. Working with people from different cultures can present a unique set of problems and challenges. The concept of Cultural Intelligence (CQ) looks at the ability of effectively adapting to different cultures. On the surface, it would seem the Lebanese people and industries should have a high CQ due to Lebanon's culturally diverse population and its history as a trade portal between Europe and the Middle East. The aim of this paper is to understand the level of awareness of CQ and determine if it is being used to solve cross-cultural complexities in Lebanon's construction industry. An online survey was developed and administered to project managers who have worked in Lebanon. The paper concluded that Lebanese project managers (PMs) have a high level of CQ and they have experienced the need for CQ awareness and training.

Keywords: Cultural Intelligence, Project Management, Construction, Middle East.

Introduction

Messner (2008) explained that project-based industries including construction are becoming more and more globalized. That is caused by different reasons and mainly because firms are now seeking to acquire and implement international specialized knowledge from around the globe as per MacDuffie (2007). For such companies, effective interactions that are meant to facilitate the flow of geographically distributed information and knowledge, are the main requirements behind project success as mentioned by Ioro et al. (2014). For globalized firms, successful project outcomes require effective work interactions that can facilitate the transfer of geographically distributed information and knowledge.

Lebanon has been and still is a socially and economically liberal country. The service sector is the most developed of Lebanon's economic sectors. It is known that Lebanon has always been a prime location for most of the Arab countries investments, tourism and personal recreation for several reasons. Lebanon has beautiful scenery with its mountains, valleys and the ocean which aren't available in most Arab countries. It has a well-developed banking sector. Culturally it is a hybrid of the East and the West. Finally, and most importantly, its geographic location allows it to serve as a trade key portal between Europe and the Middle East.

After gaining independence in 1943, the country implemented a liberal economic system giving it a huge competitive advantage over other countries in the region. Shehadi et al. (1988) mentioned that new trade agreements with Arabian countries helped the economy grow faster. During the Lebanese civil war (1975-1990) the country was destroyed and the economy collapsed including the construction sector. After 1990, the government started a huge construction wave in order to rebuild what was destroyed. This construction plan was catalyzed by the governments plan that was based on foreign

investment and the Lebanese diaspora money. Therefore, the construction industry grew rapidly and soon it boomed in all of the country.

Throughout its history, Lebanon has been the destination for people migrating from poorer countries such as Egypt, Syria, Ethiopia, the Philippines, Bangladesh and others. Despite its small size, Lebanon has a large number of people from different cultures, religions and ethnicities living within its borders. According to the UNDP's 2016 report, "A labor needs assessment for Lebanon", stated that the percentage of foreign workers in the construction industry, outside the managerial and professional positions, is around 55% and most of them are Syrians. The report presented statistics retrieved from the Lebanese Contractors' Union and Syndicate of Construction Contractors showing the total number of workers, including all occupational levels, in the construction sector was 460,600 of which 350,000, 75%, were Syrians.

The objective of this paper is to investigate the awareness of cultural differences and the level of cultural intelligence among Lebanese project managers.

Literature Review

Cultural Intelligence

Project management can be traced back historically to ancient times. It can be logically deduced that the successful completion of ancient mega-projects must have required activities such as planning, managing, coordinating, controlling and others. Wu (2010) stated that projects such as the Pyramids of Egypt, the Great Wall of China, the Taj Mahal of India and others, couldn't have been delivered without project management skills. From another angle, ancient civilizations such huge structures in order to express their power and were often built by culturally mixt labor force, formed by the conquered civilizations. Although they might have never been culturally sensitive, yet they definitely operated in multicultural settings. Culture comprises the different behaviors, beliefs and concepts (e.g., music, cuisine, religion, interpersonal relationships, ethics, habits, business practices) unique to a specific group of people. People working in multicultural settings must understand these factors can positively and negatively affect communications and interpersonal relationships. According to Ang et al. (2008, 2015), Cultural Intelligence is the capability to function effectively across various cultural contexts (e.g., national, ethnic, organizational). Ng et al. (2006) refers to CQ as the ability to effectively adapt to new cultural settings. According to Livermore (2010), CQ is an acquired skill and not innate.

As businesses enter the globalized economic and industrial world, their employees must learn how to manage and relate to multiethnic team members and contacts. For example, a firm in China may be designing or managing a project in South America with team members from both, or even other, countries. Globalization has created a critical need for competencies and skills to help people deal with those from different cultures and backgrounds and to effectively and efficiently manage these differences in order to insure project success.

Cultural Intelligence in Engineering & Construction:

Just as any other profession or field, the engineering and construction fields need cultural intelligence skills to achieve success. For instance, the American Society of Civil Engineers' Civil Engineering Body of Knowledge for the 21st century stated that civil engineers must be trained to "work alongside and report to people from other cultures" (Page 134) and "meet challenges that cross cultural, language, legal and political boundaries while respecting critical cultural limitations and differences" (page 144). Parkinson (2009) stated that for engineering graduates to be globally competent, they must be able to "communicate across cultures", "appreciate other cultures" and "work in teams of ethnic and cultural diversity". In an important study by Warnick (2010), representatives from the engineering industry were asked to rank by importance several qualities to hire engineers. Among the top eight global qualities, were: "communicate cross-culturally", "work in international teams" and "appreciate and understand different cultures".

Cultural Intelligence Structure:

Du Plessis (2011), looked at articles on CQ (Early et al. 2003; Van Dyne et al. 2005 and Ng et al. 2006) and identified four components of CQ:

- Meta-cognitive CQ: the person's awareness of the differences during intercultural interactions. It is a high class mental ability to think about others and to anticipate the outcome of cross-cultural interactions which helps the person to amend his mental model during the experience.
- Cognitive CQ: the person's knowledge of resemblances and differences between cultures. It includes the norms, practices and conventions in different cultures which can be learned by experience or education. It is a very important prerequisite as it helps the person to adapt effectively.
- Motivational CQ: the person's willingness to adapt and learn about other cultures. In other words, it can be explained as the reason why the person is doing the interaction. It can be cause by personal enjoyment to interact with different cultures or by a tangible benefit that will come out of this interaction.
- Behavioral CQ: the person's ability to change his verbal and nonverbal behavior during intercultural interactions. Most importantly, adapting a behavior that is acceptable by other cultures, especially that behaviors are interpreted differently between cultures.

Methodology

A survey was prepared and shared with project managers (PM) who had hands-on experience in managing construction projects in Lebanon. The survey consisted of 25 questions divided into two categories: 6 questions covered general demographic profiling of the participant, 19 questions dealt with CQ. The questions were formulated based on previous questionnaires available online, the researcher's experience and the Cultural Intelligence Scale (CQS), a CQ measuring tool developed by the Cultural Intelligence Center. A seven-point Likert scale was used as recommended in the literature. Lewis (1993) found that a seven-point scale resulted in a stronger correlation with t-test results. Symonds (1924) was the first to suggest using a 7-points scale as it optimizes reliability.

An online survey was used given that it reaches a bigger audience and gather data more quickly. The online survey was sent to 285 professionals from Lebanon and the Arab Gulf. Out of the 81 responses only 41 worked in Lebanon. These 41 were accepted as respondents in this study. The survey was validated using pilot testing and trustworthiness. In addition, resulting data reliability was validated using SPSS software.

Results Presentation & Discussion

Population Demographics

The first six questions covered the demographics of the respondents (e.g., gender, age, education, experience. Five respondents (12.2%) were female and the remaining were male (87.8%). This clearly indicated that project management was mainly a male occupation in Lebanon. The lack of gender equity was also apparent during the original online search for respondents. While there can be many reasons for the gender disparity, two main reasons were proposed. First, Lebanese social structures reflected those of male dominated Arab communities. Second, Lebanon retained gender stereotypes in (e.g., women should only raise families, the engineering profession is only restricted to males).

Table 3 – Respondents' age brackets

Q2 - Age Brackets		
Category	Frequency	Percentage
18 - 24	2	4.88%
25 - 34	25	60.98%
35 - 44	7	17.07%
45 - 54	3	7.32%
55 - 64	4	9.76%

Participant age was divided into 5 groups (Graph 1). Twenty-five respondents (61%) were between the ages of 25 and 34. The remaining 39% were scattered between the other groups.

Graph 1: Respondents' age brackets

Education level varied with 46.34% having a Bachelor Degree, 46.34% a Master's degree, 2.44% a PhD and 4.88% a high school diploma. Five respondents (12.2%) acquired a Project Management Professional (PMP) certificate (Graph 2).

Graph 2: Respondents' level of education

Experience was assessed by two variables: number of years on the job and approximate total value (in million dollars) of the jobs each participant had managed. Two different factors were used to examine experience in order to reflect the complexity of bigger projects and how they affect experience. For example, a manager with only five years' experience could have spent these years working on a project with a value of $50 million. Another manager with 10 years' experience could have spent this time on smaller projects with a total value around $15 million. In other words, a PM can work on a megaproject (worth billions of dollars) for 3 years while another can work on much smaller projects for 10 years.

Table 2: Respondents' years of experience frequencies and percentages

Q4 - Years of experience		
Category	Frequency	Percentage
1 - 3 years	8	19.51%
3 - 5 years	6	14.63%
5 - 10 years	9	21.95%
10 - 15 years	7	17.07%
15 + years	11	26.83%

Years of experience was divided into 5 categories. Table 2 and Graph 3 provides the results: 1-3 years, 8 respondents (19.51%); 3-5 years, 6 respondents (14.63%); 5-10 years, 9 respondents (21.95%); 10-15 years, 7 respondents (17.07%); more than 15 years, 11 respondents (26.83%).

Graph 3: Respondents' years of experience

Total value of jobs was divided into five categories. Table 3 and Graph 4 provides the results for question five: less than 5 million $, 6 respondents (14.63%); 5 to 10 million $, 6 respondents (14.63%); 10 to 25 million $, 3 respondents (7.32%); 25 to 50 million $, 3 respondents (7.32%); more than 50 million $, 23 respondents (56.10%).

Table 3: Respondents' projects total value frequencies and percentages

Q5 - Projects Total Value		
Category	Frequency	Percentage
Less than 5 million $	6	14.63%
5 - 10 million $	6	14.63%
10 - 25 million $	3	7.32%
25 - 50 million $	3	7.32%
More than 50 million $	23	56.10%

Results were close in each category for years of experience. This was not true for total value of jobs where more than half of the respondents (56.1%) had worked on more than $50 million dollars' worth of projects.

Graph 4 : Respondents' projects approximate total value

When comparing the results of questions 4 and 5, it can be seen that 23 respondents (56.10%) have worked on projects of more than 50 million dollars while only 11 respondents (26.83%) have more than 15 years of experience. This implies that the 7 respondents (17.07%) having between 10 and 15 years of experience and some of the respondents having between 5 and 10 years have worked on projects of value more than 50 million dollars. This proves the validity of using both questions to examine experience that was previously explained.

In addition, when comparing the age brackets (question 2) and the years of experience (question 4), we can also identify a discrepancy. 11 respondents (26.83%) have more than 15 years of experience against only 4 respondents (9.76%) being between 55 and 64 years old. This implies that all of the respondents between the ages of 45 and 54 have more than 15 years of experience and 4 of the respondents between the age of 35 and 44 have more than 15 years of experience. The biggest percentage of respondents were between 25 and 34 years old and were scattered between 1 and 15 years of experience.

Cultural Intelligence

The remaining 19 questions covered the concept of Cultural Intelligence through yes or no questions and questions using seven=point Likert scales.

General knowledge

Questions seven through nine looked at general knowledge of CQ (Graph 5). In other words, general knowledge describes if the respondents understood the concept of CQ, if they have solved any problem using CQ and if they were able to easily identify cultural differences.

Graph 5 : CQ general knowledge, Q7 to Q9

Q7 indicated 82.93% of the respondents understood the concept of CQ while 17.07% did not.
Q8 showed 85.73% had solved at least one problem at work using CQ at some point in their career while 17.07% hadn't solved any problems using CQ. While some of the respondents recognized the term Cultural Intelligence, some of them confirmed that they do understand and apply the concept without knowing its name and the fact that it became a well-established line of research.

Q8 indicated some of the respondents had unknowingly used CQ solutions based on their experience in working with different cultures.

Q9 showed that 92.68% of the respondents could clearly identify cultural differences in their jobs while 7.32% were unaware of them (Graph 5). The differences in the results of Q8 and Q9 posed an interesting question. If the majority of respondents were able to identify cultural differences what prevented them from using culturally related solutions to solve problems? Most likely, this difference in percentages is due to the lack of professional training for PMs in CQ.

Graph 6: Metacognitive CQ (Q10, Q11) and Cognitive CQ (Q12 to Q14)

Metacognitive CQ

Q10 and Q11 covered metacognitive CQ by looking at the cultural knowledge of PMs (Graph 6). 97.56% of the respondents fell on the positive side of the Likert scale when asked if they adjust their cultural knowledge in cross-cultural interactions in Q10. 26.83% strongly agreed, 53.66% agreed, 17.07% slightly agreed and only 2.44% slightly disagreed. When asked in Q11 if they checked the accuracy of their knowledge during interactions with new cultures, 26.83% strongly agreed, 41.46% agreed, 24.39% slightly agreed, 4.88% were neutral while 2.44% slightly disagreed. These numbers indicated that PMs in Lebanon were well aware of the existence of differences between cultures and were aware of their cultural knowledge.

Cognitive CQ

Three questions (Q12, Q13, and Q14) covered cognitive CQ (Graph 6). Q12 asked if they were familiar with cultural values, religious beliefs, traditions and arts of other countries. 14.63% strongly agreed, 43.9% agreed, 24.39% slightly agreed, 12.2% were neutral and 4.88% slightly disagreed. In Q13, respondents were asked if they were familiar with the rules of verbal expression in different cultures. 7.32% strongly agreed, 43.9% agreed, 19.51% slightly agreed, 21.95% were neutral, 4.88% slightly disagreed and 2.44% disagreed. Q14 asked if respondents were familiar with the rules of nonverbal expression in other cultures and if they changed their expression when necessary. 12.2% strongly agreed, 51.22% agreed, 19.51% slightly agreed, 7.32% were neutral, 2.44% slightly disagreed, 4.88% disagreed and 2.44% strongly disagreed. The results of these three questions indicate that the majority of the PMs in Lebanon are culturally educated and try to use their knowledge as much as possible. In other words, the respondents try to add to improve their cultural knowledge and data base as needed. For example, when encountering people from unfamiliar culture on a job, Lebanese PMs tend to engage with them in cultural discussions to further understand their background and culture.

Motivational CQ

Two questions, Q 15 and Q16, studied the motive behind the CQ (Graph 7). Some people succeed in multicultural settings because they enjoy it, others because they are obliged to do it and others do not succeed. Q15 asked if the PM enjoyed living and interacting with different cultures. 31.71% strongly agreed, 29.27% agreed, 17.07% slightly agreed while 19.51% were neutral and 2.44% slightly disagreed.

Graph 7: Motivational CQ (Q15, Q16) and Behavioral CQ (Q17 to Q19)

Q16 asked if the PM was confident in his or her ability to socialize with people from different cultures. 24.39% strongly agreed, 48.78% agreed, 24.39% slightly agreed and only 2.44% (1 person) was neutral. These numbers indicate PMs in Lebanon enjoy interaction with different cultures and are willing to adapt and learn about them.

Behavioral CQ

Three questions (Q17, Q18, and Q19) looked at behavioral CQ by asking about participants' behavior in cultural interactions (Graph 7). Q17 asked if they changed their verbal behavior (e.g., accent, tone) in cross-cultural interactions. 29.27% strongly agreed, 21.95% agreed, 17.07% slightly agreed, 17.07% were neutral while only 2.44% slightly disagreed. Q18 asked if they changed their speed of speaking and used pauses and silence in cross-cultural interactions. 41.46% strongly agreed, 29.27% agreed, 17.07% slightly agreed while only 12.2% were neutral. Q19 asked if they changed their facial expressions during cross-cultural interactions. 7.32% strongly agreed, 21.95% agreed, 31.71% slightly agreed, 24.39% were neutral, 4.88% slightly disagreed and 9.76% disagreed. These responses showed a marked difference from the previous questions. Although the majority changed their facial expressions the distribution of responses was very different. The results of the behavioral CQ questions indicate PMs can adapt their verbal and nonverbal expressions as needed during interactions with people from different cultures.

CQ Training

This section looked at CQ training (Graph 8). Q20 asked if they were trained on the importance of CQ and the importance of their roles in cultural interactions. 32 were self-trained, 7 had professional training and 9 were never trained. Q21 asked if they were trained to develop an open mind towards cultural differences. 37 were self-trained, 6 were professionally trained and 3 were never trained. Q22 asked if they were trained to appropriately address people from different cultures. 38 were self-trained. 5 were professionally trained and 2 were never trained. Q23 asked if they were trained to learn basic terms or new languages to easily interact. 30 were personally trained, 7 were professionally trained and 9 were never trained.

Graph 8: CQ training questions, Q20 to Q23

It is very important to point out that a person can be professionally AND/OR self-trained. The questions were formulated in such way in order to understand if PMs are self-trained on CQ, professionally trained or never trained. The reason behind this examination is that PMs could've experienced cultural differences and the need for CQ however they were never trained by their company. As a result, they resorted to self-training in order to keep up with the workplace challenges.

Graph 9: Overall CQ experience questions, Q24 and Q25

The most interesting finding in this section was the high number of self-trained PMs versus the low number of professionally trained PMs. This indicates that people have experienced cultural differences and felt the need to educate themselves in order to succeed in the multicultural workplace. At the same time, it points to a lack of professional acknowledgement of the need for training on CQ requiring PMs to find the information on their own.

The final section looked at how CQ affected participants' careers (Graph 9). Q24 asked if they learned that people from different cultures have different orientations and expectations; 100%, 41 respondents,

responded yes. Q25 asked if CQ improved their own productivity and the overall performance; 95.12%, 39 respondents, agreed.

Conclusion

This paper indicates CQ's importance based on the experience and feedback of PMs with hands-on experience in Lebanon's construction and engineering industries. The concept of CQ was familiar to the PMs although some of them understood the concept without knowing the term. Second, the findings indicate that PMs in Lebanon have a high level of CQ. PMs have experienced cultural differences and, therefore, the need for CQ training. Since they were not provided with training through their professional organizations, they often trained themselves. Finally, it was evident that CQ was a very important factor in improving the overall productivity and professional performance of PMs.
In conclusion, CQ is a relatively new but extremely important concept in business and industry practice. As with any other new topic, it can suffer from a lack of credibility. This study shows the need for CQ training and education in the construction industry. It also indicates the positive impact CQ training can have on individuals' performance, project management and therefore, project success. For companies, project success is highly related to company profits. For this simple reason, companies should look more into CQ and include it in their professional training programs.

Conceptual Model of An IoT-Based Enhanced Living Environment for Elderly

Ovidiu BICA[1] and Ion Alexandru MARINESCU[1]

[1]National Institute for Research and Development in Informatics, Bucharest, Romania

E-mail address: {ovidiu.bica, ion.marinescu}@ici.ro

Abstract

The world's population is aging and the number of elderly people is constantly growing. Healthcare systems need to be rethought to meet these challenges. With IoT technology, systems for monitoring the health of the elderly can be developed. RO-SmartAgeing, a remote health monitoring system based on IoT, is presented as a case study for the development of a smart living environment for elderly. There is no global standardization yet, thus developers have trouble setting up an efficient way to transmit, store, administer, secure and provide data from this smart environment. An IoT platform would solve these difficulties through the efficient and adequate management of medical devices, implemented with several technologies, protocols, microcontrollers, sensors, actuators belonging to different entities.

Keywords: IoT, enhanced living environment, health monitoring, IoT platform.

Introduction

The continuous evolution of medical sciences and related technologies is one of the main growth factors of life expectancy worldwide, a phenomenon that is expected to continue in the future (World health statistics, 2019). This tendency is a trigger for profound societal changes due to an expected growth, with a rapid rate in the number of elderly people (World population prospects, 2019). These demographic projections are often correlated with an inevitable multiplication of health issues and impairments that older adults will have to face in the daily life. Based on these perspectives, the increase in medical expenses puts a strong pressure on traditional centralized healthcare systems, affecting their level of sustainability in the medium and long term, with predictable negative consequences on the quality of life (QoL) for the elderly and people with disabilities. Therefore, there exists an increasing demand for developing elderly care services utilizing novel assistive technologies, with the aim of providing efficient remote elderly monitoring services to support an active and independent living (Azimi et al. 2016).

Starting from the necessity to maintain and foster the autonomy of elderly people and, thus, to improve their QoL, various research programs were operationalized, ambient assisted living (AAL) being the most important initiative at UE level. AAL represents an emerging multi-disciplinary field and is strictly related to an ecosystem of different technologies and applications for personal healthcare monitoring and pervasive and ubiquitous computing (Dohr et al., 2010). In this sense, AAL encompass all of the new assistive technologies that underpin the development of intelligent systems, capable of providing integrated services not only for data collection, event monitoring, or environmental sensing, but also for healthcare assistance through supporting smart decision and recommendation, based on the user behavior understanding (Koleva et al., 2015).

Enhanced Living Environments (ELE) is another concept closely related to AAL area, mainly associated with all information and communication technologies (ICTs) used in maintaining an active and independent life for a wide category of people (e.g. elderly people, people with disabilities, etc.). For this purpose, ELEs promote a broad range of healthcare services and applications that help to maintain these vulnerable categories more autonomous as long as possible within their preferable living environment (Marques et al., 2019). Currently, most efforts are converging towards the

development of ELE / AAL solutions able to provide continuous monitoring and control of the environment, based on pervasive devices and use of ambient intelligence to mix these devices. This ecosystem offers the possibility for an increasing quality of life (QoL) and better living conditions for elderly and disabled people, improving their health and safety in an effective and often pervasive manner (Goleva et al., 2017).

According to different analysis (Dimitrievski, et al., 2016), (Zdravevski et al. 2019) there are several research directions falling within this scope. Most of the efforts are directed towards the development of ALE / ELE systems that aim to monitor daily activities, detect specific events (e.g. falls, or false alarms), automate assistance, and decrease caregiver burden (Trajkovik et al., 2015). Another important area of application, but insufficiently explored, refers to the continuous monitoring and supervision of some more serious health issues, such as accidents and vital signs by means of sensors especially developed for this purpose. Sensor devices are supported by various algorithms and computational techniques, context modeling, location identification, and anomaly detection (Poon et al., 2015). Thus, ELE incorporates the latest technological achievements related to the sensor design and material science: wireless communications and data processing, as well as machine learning, cloud, IoT, edge, and fog technologies, which extend traditional sensing and monitoring systems, opening the way to the implementation of cost-effective and easy to use remote health, activity and environment parameters monitoring, as an efficient method to improve individuals' independence and facilitate healthcare assistance for elderly people at home (Angelov et al., 2019; Pombo et al., 2015).

In line with different AAL/ELE perspectives regarding the use of new and innovative solutions for an active and independent ageing, this paper proposes a complementary approach in this field, by proposing a conceptual model of an IoT-based enhanced living environment for elderly and disabled people, as a useful reference for future practical development of a AAL/ELE system for continuous health monitoring and supervision. Next, the paper is organized as follows. Section II presents a state-of-the art of different ELE technologies aiming to construct safe environment and provide better healthcare services for elderly and disabled people. Section III presents a conceptual model of an IoT-based enhanced living environment for elderly and disabled people, viewed as a support for a new architectural development of a healthcare, environment parameters and activity monitoring system. Section IV briefly presents some of the results obtained by the research team of the project "Non-invasive monitoring system and health assessment of seniors in an intelligent environment (RO-SmartAgeing)", which demonstrates the potential, efficiency and usefulness of advanced IoT based ICT solutions in the field of healthcare. The final section presents the conclusions and subsequent approaches.

Related Work

In the last decade, the development and integration in consumer devices of a wide range of sensors for healthcare, well-being, and fitness, have led to the availability of a vast amount of personal health data (Suciu et al., 2015). This has generated a huge opportunity in both healthcare and healthy lifestyle, to provide cost-effective, personalized, and real-time monitoring, detection and recommendations services. In this context, many of the AAL/ELE research and development initiatives aim to support these efforts, both for the end users and healthcare providers.

Despite the progress made in development of sensing technologies, vital signs monitoring techniques, risk and accident detection methods, activity recognition techniques, communications technologies, etc., there are several open issues in implementing efficient solutions, especially in the field of active and independent aging. Most of the current efforts still do not fully meet the general needs of the older adult for safety in carrying out daily activities, social connections, or more personalized healthcare assistance. Other issues concern the implementation of these solutions and are related to usability, user interface, data structure, ubiquitous design, ergonomics, and data access (Koleva et al., 2015), while others are related to ethical and social aspects such as user acceptance, privacy and confidentiality of information (Azimi et al., 2016).

As part of the effort to address these challenges, Karvinen et al. (2019) explore the RDF storage solutions with the aim of finding a specialized database, capable of storing and processing RDF data,

which sufficiently meets the ELE storage needs. More specifically, they focus on a Smart Space platform aimed at running on a cluster setup of low-power hardware that can be run locally entirely at home with the purpose of logging data for a reactive assistive system involving activity recognition or domotics. Based on literature analysis of RDF stores, the authors suggest different relevant aspects of RDF storage systems that need to be considered in AAL/ELE environments and provide a comparison of available solutions.

Vogiatzaki et al. (2019) focuses on finding cost-efficient solutions to support mental well-being as methods for physical and mental rehabilitation for the elderly at home, combining progress in applied clinical "know-how" with stimulating engagement through entertainment and "real feeling" of gaming environment. For this, an automated home ICT system is envisaged by the authors for utilization by patients, care providers, and family members for the effective use of rehabilitation procedures in familiar environment. The authors propose a full system solution that integrates a set of state-of-the-art technologies, such as augmented/virtual reality gaming, multi-modal user interfaces, and innovative embedded micro-sensor devices, combined together in a Personal Health Record (PHR) system, supporting the delivery of individual, patient-centered electronic health (eHealth) services both at home, at hospital, or on the move.

In the context of anticipated demographic changes, Angelov et al. (2019) emphasize the necessity for development of cost-effective, real-time, remote sensing and health-status monitoring solutions for elderly and disabled people, in order to support their QoL improving and create better living conditions in the environment of their choice. The authors provide an overview of relevant sensing technologies, vital signs monitoring techniques, risk and accident detection methods, activity recognition techniques, communications technologies, etc., and conclude that new types of network paradigms, such as the Internet of Things (IoT), will extend traditional sensing and monitoring systems giving an advantage to control the environment.

Zgheib et al. (2019) address some interoperability issues in IoT-based AAL/ELE heterogeneous environments, suggesting the use of semantic middleware architectures (consisting of both technical and semantic components) as a complete interoperable solution. The authors present an overview of the existing semantic middleware proposals that address many of the research challenges regarding the interoperability in IoT systems that still remain open, such as scalability, real-time reasoning, provision of a simple application programming interface (API) usable in various application domains, provision of a complete ontology that is able to describe both domains and sensors in IoT, etc. The authors consider the recently proposed Web of Things (WoT) architecture as one of the major candidates for solving the interoperability issues in IoT in general.

Koleva et al. (2015) provide a comprehensive overview of the main challenges in the design and realization of an effective Ambient Assisted Living (AAL) system. Authors propose solutions to overcome those challenges during the development of "eWall for Active Long Living" (eWALL) project. The goal of the eWALL system is to offer a personal health monitoring system combined with positive reinforcement, medical reminders, connection to social networks for enhancement of social relations, in addition to home security and alerts for medical personnel in case of emergency.

Rajini (2019) presents the advancements in the IoT based healthcare methodologies and investigates the individual IoT security and privacy characteristics such as security needs and threat models from the health care aspects. Additionally, the author explains the way how various technologies like big data, ambient intellect, and wearable can be influenced in a healthcare framework; it resolves different eHealth policies and IoT guidelines globally to identify how they support economy and society with respect to sustainable development; and allows new research directions on IoT based healthcare sector.

Xu et al. (2019) propose a framework concept that support behavior monitoring through noninvasive and privacy preserving sensing. Collecting data are transmitted and used for analyzing sensing information with low richness. This framework aims to increase the users' perceived privacy in existing monitoring systems, avoiding data over-collection and over exposure of problems.

Conceptual model for an Enhanced Living Environment

IoT devices give direct, all time access to the patient in a less intrusive way than other alternatives. They empower individuals in attending to their own health, and allow providers to deliver better care to patients. This results in fewer accidents from miscommunication, improved patient satisfaction, and better preventive care (Tutorials Point, 2016). Continuous monitoring offers an analysis of real-time vital parameters of the patient, which proactively uses IT tools to associate data from many sensors, estimate risk levels (Alexandru, Ianculescu, 2017). Given the global aging of the population, it is necessary to objectively identify the specific health problems, living conditions and life experiences of the elderly and to ensure effective and safe real-time communication between health professionals and patients. The active and healthy ageing domain includes the following services and activities:

- Continuous monitoring of the activity with the purpose of detecting conditions or risk events;
- Emergency detection;
- Early detection of cognitive fall;
- Social connection assistance;
- Physical activity and home rehabilitation consultant;
- Attendant for outdoors activity.

The physical environment where these services are taking place are known with the name of Smart Living Environments. The functional architecture of this conceptual model is presented in the figure 1.

Fig. 1: Functional architecture of conceptual model for an enhanced living environment

The perception layer is the place where the smart things interact with the physical world. In this layer, intelligent sensors are used to gather real time data. Medical sensors measure patient's vital signs while environmental sensors (ambient devices, humidity, temperature, proximity, light, smoke sensors) measure indicators, which influence patient's condition, such as room temperature, smoke, light, movement (Angelov et al., 2019). This layer has a main task in collecting data from sensors. Afterwards, the data is transmitted to the network layer. For instance, many sensors may be connected to the patient's body to make sure that there is a monitoring to the patient's condition and provide help when its needed (Azza, 2019).

The network layer works as a communication layer, where data coming from the sensors are compressed, prepared, secured, and transferred via the Internet to the cloud domain. This Level includes hardware equipment and network software that make possible any type of connection with the cloud. The devices used in this layer are: Wi-Fi systems, radio communication devices with low power that are using radio spectrums like 3G, LTE and Bluetooth. For more computing power it can be intercalate EDGE layer between network layer and cloud. This layer brings more benefits: reducing data sent to the cloud, data analytics execute at the edge, quicker intervention for risk situations and enhance data protection.

The processing layer is found in the cloud. The cloud computing infrastructure is dedicated to provide Internet access, to process, to analyze and to store the data.

The application layer provides tools for data management, security, data access control to upper layers applications, data analysis, big data. In this layer is found the IoT platform, that is a mediator between the smart devices /sensors and edge computing and application layers. The IoT technology enables to connect all types of things to the network and develop applications to control and manage smart devices using Internet transfer protocols. All the complexity of enabling connectivity, services and cloud commuting for these devices is the job of the IoT platform (AIOTI, 2019). IoT platforms include the integration of sensors with different communication protocols (HTTP, MQTT, CoAP), abstract all those intricacies and make available simple APIs to communicate with any sensor over any network. Via, APIs, data management, and algorithms, an IoT platform allows elements of a network to connect, monitor, and communicate with each other with more flexibility. The platform can enable also data prioritization, a feature of highest importance at one time when sensors and other physical objects starts to generate new amounts of data.

The interoperability layer contains several application programming interfaces (APIs). The data is stored through cloud technologies providing access to patient's health data and health records.

The application layer acts as an interface for interaction for end users (caregivers, physicians). Based on the data that is collected different methods and analysis can be applied in order to evaluate the quality factors of IoT-based smart wearable devices (e.g. DANP method), this contributing to the better understanding of users' needs with regard to design criteria and also to develop strategies to improve the quality of IoT-based smart wearable devices (Balog, Bajenaru, Cristescu, 2019). This layer uses the results of the data analysis processed and stored in the cloud domain. Application layer is also responsible for sending abnormality alerts. This layer converts extracted knowledge into visualization using real-time dashboards. Monitoring the daily activity routine can be used to achieve active aging service models.

The conceptual model for an enhanced living environment is used for the RO-SmartAgeing project. In **smart living environment** we have on the one hand the medical sensors connected to e-Health Sensor Shield V2.0 together with Arduino and Raspberry Pi and on the other hand we have environmental sensors. Cloud operations for processing, viewing and sending alerts for data collected from sensors are performed by the Thingsboard platform. Collected data from sensors is pushed via MQTT over WiFi to ThingsBoard for storage and visualization (real-time web dashboard). The environmental sensors are connected to Wifi microchip ESP8266, that push data to ThingsBoard server via MQTT protocol by using PubSubClient (Pubsubclient, 2019) library for Arduino. ThingsBoard has data collection API and visualization capabilities for almost any IoT device.

IoT based ICT solutions for RO-Smartageing System

Creating an *enhanced living environment* at home for elderly people ensures optimal conditions to continue life in an independent and active way, with maximum benefits in terms of preventing and limiting degenerations and diseases associated with aging. This involves taking into account a number of challenges throughout the development process. Such challenges address different categories of issues related to remote health and environment monitoring (acquisition of data and information about the elderly, housing, etc.), communication technology (reliability of real-time data transmission), choosing optimal intelligent processing technologies (analysis, relevant decisions, etc.) and the provision of personalized services.

The project *"Non-invasive monitoring system and assessment of the health of the elderly in an intelligent environment" (RO-SmartAgeing)"* is a research effort funded by the Romanian Ministry of Research and Innovation whose main objective is to demonstrate the potential of ICT (Internet of Things - IoT, Instant Data Computing - Edge, Dew, Fog computing, Cloud computing, Big Data, predictive analytics) to transform the way which health care services are provided to the elderly people.

The main objectives of the project refer to the development and validation of a *health monitoring and evaluating system* for elderly people that integrates non-invasive motion and physiological sensors for collecting medical parameters, as well as an *intelligent environment* based on discrete environmental sensors for monitoring daily activities and lifestyle. In support of these results, a dedicated cloud solution is developed for data storage and aggregation, including for the presentation of the results obtained from the advanced data analysis.

Achieving the proposed objectives will lead to the following benefits:

- Increasing the quality of life of the elderly and their family members by providing intelligent non-invasive remote services such as monitoring, diagnosis, assistance for daily activities, alert in case of accident;
- New scientific knowledge in the field of non-invasive intelligent services for the elderly, health and quality of life analysis and modeling, evaluating the acceptance and usefulness of proposed healthcare technological solutions.

The IoT environment used to monitor the elderly health consists of four main components: things (medical sensors, smart medical devices), connectivity (allows connection between things and applications; in most cases it is a gateway), software (located in cloud and responsible for data collection, device management, configurations, security, identity management, etc.) and applications (real-time dashboard, rule engine, analytics, alerting). IoT platforms are called middleware because they manage interactions between the hardware and the application. An open source IoT platform will support the components described above.

This type of platform is essential for the provision and processing of data, around which business models can be developed, such as IoT-based environments for aging well. The platform allows the collection, processing and viewing of data from medical sensors or other monitoring devices as well as their remote management. In figure 2 are depicted the main technologies considered for the realization of the RO-SmartAgeing ecosystem.

Fig. 2:RO-SmartAgeing ecosystem

e-Health Sensor Platform, Microcontrollers and Microcomputers

ThingsBoard is an open-source IoT platform, used to collect, process, view and manage data collected by smart devices (ThingsBoard: Open-source IoT Platform, 2020). This platform supports device connectivity using standard IoT protocols, such as MQTT, CoAP, and HTTP. ThingsBoard is a multi-tenant solution with multiple customers who have multiple users with multiple devices. The

product has a set of ready to use widgets and dashboards that can be easily customized. The platform is installed in a Docker container located in the cloud (Bica, 2019; Docker, 2020).

The sensors analyze various medical parameters that are connected to the Arduino Uno and Raspberry Pi via MySignals, an e-Health Sensor Platform. MySignals platform supports the following analog sensors we use: temperature, skin conductivity (Galvanic Skin Response—GSR), position detection, and breathing airflow sensor, electrocardiogram (ECG) and electromyogram (EMG). The board connects to an Arduino UNO like a shield and uses the Arduino SDK IDE. (e-Health Sensor Platform V2.0 for Arduino and Raspberry Pi, 2020). The Raspberry Pi microcomputer is connected to the Internet and acts as a server that sends the data received from the Arduino Uno to the ThingsBoard platform installed in the cloud.

Wearable Monitoring Sensors

A wide range of sensors, both wearable and environmental will be used in the RO-SmartAgeing system. Wearable sensors are smart electronic devices (electronic device with micro-controllers) that are worn close to and/or on the surface of the skin, where they detect, analyze, and transmit information concerning e.g. body signals such as vital signs, and/or ambient data and which allow in some cases immediate biofeedback to the wearer (Düking et. al, 2018). Through a range of over 16 sensors, RO-SmartAgeing offers the possibility to detect biomedical parameters and transmitting values to IoT health monitoring platforms through microcontrollers and microcomputers: Pulse oximeter; ECG; AirFlow sensor; Blood Pressure monitor sensor; Glucometer; Body temperature sensors; Electromyography Sensor; Spirometer sensors; Galvanic skin response; Body position sensor; Snore sensor; Body parameters sensors (body mass, body fat, bone mass, muscle mass, visceral fat, body water, BMI - body mass index and BMR - basal metabolic rate).

Environmental Monitoring Sensors

Sensors from this category provide various types of information: location, position, the individual's movements and contextual elements which can be compared to data collected via sensors embedded on or implanted in the individual, including the validation of alarms, like in the case of falls (Noury et. al., 2018; Coardos et al., 2020). The RO-SmartAgeing system is designed to manage the following range of environmental sensors: dust, temperature and humidity, motion, depth, distance.

Conclusion

Remote health monitoring in an IoT-based smart living environment will improve the assessment of physical parameters of elderly and will eliminate many visits to hospital. Conceptual model of an IoT-based enhanced living environment in which the elderly can be monitored remotely, while carrying out their daily activities safely at home serve as the basis for the development and implementation of the RO-SmartAgeing project. The data provided to healthcare professionals will allow them to adjust their treatment correctly. Physicians will be able to accurately diagnose the patient's health to improve emergency response. IoT offers new techniques, architectures, and platforms for enhanced healthcare systems with the chance to improve medical treatments for personalized healthcare.

Thingsboard platform ensure security features, scalability, and capacity for collecting, storing, and analysing data. This platform can be integrated to develop a conceptual model based on the convergence of care objectives and processes along the healthcare process.

Acknowledgement

The authors gratefully acknowledge the contribution of Ministry of Research and Innovation for funding the project RO-SmartAgeing - "Non-invasive Monitoring System and Health Assessment of the Elderly in a Smart Environment" for the period 2019-2022.

Agricultural Policies and Risk Management Strategies: What Solution for Guarantee Food Security?

Francesco ZECCA

Department of Management, Faculty of Economics, La Sapienza University of Rome, Rome, Italy

Abstract

Natural disasters and climate shocks are major factor driving emergency levels of food insecurity. Studies on risks have underlined that poor household are less able to satisfy their basic needs when faced with unexpected shocks. Despite the importance of food security especially in developing countries where large share of population relies on agriculture for their livelihood, the scientific community has not completely considered the role of the resilience capacity in order to curbing the negative impact of natural disasters. This paper contributes to understanding the validity of build a resilient food system to withstand shocks and stresses at different temporal and spatial level. In relation to that it has been necessary to highlight the agricultural concerns of natural disasters and risk management, and to introduce them to the factors determining the needs of build resilience. On these bases the methodology employs content analysis of selected scientific literature and reports of International Organizations in order to bring out the key issues for the adoption of resilience in the frame of strategies for guarantee food security. The results have shown that resilience could be the key, but it is required a holistic approach by reorganizing adapting and evolving into new configuration the adopted plans and policies.

Keywords: Resilience, Food Security, Natural Disasters, Agriculture

Introduction

The purpose of this paper will concentrate on agricultural policies and risk management strategies to increase food security and build natural disasters resilience.

Stating the impact of natural disasters on agriculture and recognizing the rural poor as the most affected and kept by the occurrence of natural disasters itself into poverty traps, the contribution will then identify a possible solution into building resilient livelihoods. This so as to render the affected communities able to recover and eventually escape the poverty trap, in line with the approach endorsed by many actors involved in efforts against natural events consequences, from small Non-Governmental Organisations (NGOs) to United Nations (UN) Organizations.

In the first part the paper introduces natural disasters and their impact on agriculture focusing on the specific effects that such terrific climate variability has on this particular sector.

Then outline levels of intervention on the part of various actors to address the impacts of natural disasters on agriculture: the farmer level in order to describe the risk management strategies they have at their disposal; the national level of governmental intervention, underlying the crucial role of the state in assisting affected communities; the international level in which international organizations perform the key task of providing guidelines and promoting coherence and integration of global actions. The analyses put evidence on the fact that despite constrained to an unequal socio-economic class, disasters still disproportionally affect individuals in the relief and recovery phase.

The third part of the paper will concentrate on approaches and tools for building disasters resilience in agriculture. In the last section, the paper put evidence on several aspects emerged from the investigation led.

The paper concludes that any possible strategy to cope with natural disasters and tackle food insecurity needs a holistic approach that takes into consideration a concentrated effort to build resilient livelihoods and free affected communities from vicious cycles of poverty and hunger. In the conclusion the prevention of disaster is considered to be a matter of managerial administration, rational prediction and organizational readiness.

The method used for the investigation has been based on the use of the information coming from selected literature which satisfy the following eligibility criteria:

- key words: resilience, food security, natural disasters, agriculture;
- type of paper: articles published in international peer-reviewed academic journals and report of International Organisations.

Literature Review

Natural Disasters and Agriculture

The number and frequency of recorded natural disasters, along with the associated impact and damage to livelihoods and economies has increased significantly in the last decades. Natural disasters often destroy critical agricultural assets and infrastructure, disrupting production cycles and trade flows. This affects food security[i] and causes additional disruptions throughout the value chains. In addition, disaster impact on agriculture has a direct effect on livelihoods. In fact, disasters can cause unemployment and/or a decline in wages and therefore income among farmers and farm laborers. They diminish the availability of food commodities in local markets, leading to food inflation. These pressures restrict households' purchasing capacity, limiting the access to food, deplete savings and can force the sale of vital productive assets and erode livelihoods.

The phenomenon wrecking the agricultural world is huge and it seriously jeopardizes development hindering the path towards reaching the Sustainable Development Goals (SDGs) by 2030[ii].

Such disasters may slow overall economic growth, especially where agriculture and food production still account for a large share of gross domestic product and employment.

Even though the phenomena of natural disasters concern all strata of society and involves all different types of actors, the most affected are always developing countries and the poorest people of the world. In particular, those who depend on the agricultural sector and on natural resources for their living are the most severely damaged by disasters and crisis. They make up 75 % of the poor and insecure people in the world (FAO, 2015).

During the last decade, the quantity and quality of food consumption are weakened and food insecurity and malnutrition increase, particularly among the most vulnerable households. Between 2005 and 2014 approximately 93 billion dollars were lost as a result of contractions in crop and livestock production after natural hazards and disasters occurred in developing countries (FAO 2015).

Specifically, floods have been responsible for 37% of the cumulative production losses in crops and livestock, amounting to just under 34 billion dollars.

During the same time span, droughts provoked 19% of agricultural losses, which amounted to over 17 billion dollars, while other climate events such as high temperatures, storms and wildfires, causing damages for over 21.5 billion dollars (FAO 2017).

FAO revealed that in developing countries, the damage to the agricultural sector represents an average of 22% of the total damage and losses caused by disasters triggered by natural[iii] . This percentage rises to 25% if only climate-related disasters, such as droughts, floods, hurricanes, typhoons and cyclones are considered.

Of all-natural disasters, the link between drought and agriculture is particularly significant as 84% of the damage and losses arising from droughts is critical for the agriculture, while the remaining burden is typically, on sectors such as health and nutrition, energy, water and sanitation.

Within the agricultural sector, the crop subsector absorbs over 42% of the total damage and losses caused by disasters, while the livestock subsector sustains nearly 36%. The fisheries subsector is severely affected by tsunamis and storms such as hurricanes and cyclones, while most of the economic impact to forestry is caused by floods and storms. The consequences are that the production losses can cut the agricultural value added or sector growth, with consequences for national GDP (FAO 2015).

Notwithstanding the many efforts at national and international level, there is still limited systematic data and information on the impact of disasters and hazardous events in agriculture and its subsectors (FAO ,2017).

Concerning the specific characteristics of the phenomena a natural disaster is characterized by being both unexpected and overwhelming. Such sudden crises represent a departure from the natural order of everyday life. The artificial separation between everyday life and crises cloak the real nature of disasters which affect vulnerable people who are exposed to a wide range of risks (IFRC, 2006). People, indeed, face risks that are a combination of both vulnerability and hazard (Blaikie et al 1994). The relation between natural and human is so tightly connected in all disaster circumstances which render impossible to consider disasters to be entirely natural in any straightforward way.

People's actions, which have a negative impact on climate change, represent a factor which disproportionally affects farmer communities (Hopkins and Red Cross Red Crescent ,2008). Since agricultural yield is subject to seasonal rainfall and specific climate conditions, farmers are the first actors at risk. As stated by O'Keefe et al. (1976) it would be necessary to take the naturalness out of natural disasters. However, natural disasters have not the arbitrary power to affect people in the same way.

Although climate change is supposed to influence and hit all countries, its impact seems to intensify the vulnerable food security conditions of the more disadvantaged. The vulnerability of such people arises from severe malnutrition, migration, and from diseases coming from dry seasons which might result in loss of livestock, loss of crops, lack of rangeland forage for livestock, and water shortage including water contamination. Vulnerabilities are the characteristics of people and their situation influencing their capacity to anticipate, cope with, resist and recover from the impact of a natural hazard(Wisner et al.,2004). Only by conceiving both vulnerability and natural hazard would it be possible to generate a disaster (Blaikie et al. ,1994). Permanent emergencies in agriculture are hence produced by the connection between risk and adverse weather, together with weather-related plant pests and diseases and fall in the price of commodities, to which a population is exposed(Stubbs, 2018). The production of such constant emergency is produced by the unequal allocation of risk among its citizens by the state. It is the state, indeed, that generates a discriminating social order and a marginalized category of vulnerable people who are mainly represented by the agricultural population which find themselves at the end of the societal order (Bankoff ,2001). Disasters can be interpreted as the extreme situation which is implicit in the everyday condition of the population (Braid et al. 1975; Wisner et al.,1993).

By apportioning income and assets in a disproportional way, welfare creates forms of discrimination among society. As a consequence, natural disasters occur in a political space and mirror the power relations which represent the root causes of the malfunctioning of the economic and political systems(Cohen et al., 2008). This means that if a country is not economically able to cope with a drought for example, herders and farmers – the first and worst hit when drought strikes – will become even more vulnerable. In addition, as previously stated, the economic marginal individuals, who are forced to live in dangerous environments, become to be seen as of marginal significant to those who have political and economic power. Therefore, the question that arises spontaneously is: does natural disaster exists that are not the result of exploitative and economic processes? Some disasters might be considered 'innocent' in nature since they involve a risk which arises from class-neutral socially -

constructed processes (Cannon ,2008). From this perspective, the disaster is not handmade but happens when a vulnerable population gets in the way of a hazard; no one is made vulnerable. The location in which they live, and the possible exposure to risk, is the result of an individual choice. The Indian Ocean tsunami, for instance, might exemplify such narrative.

Being the society relative uniform for what concerns the class-based socio-economic variations, the tsunami can be considered a relatively innocent disaster since inequality had not made some people more vulnerable than others.

The concept of innocence applies to the type of social construction: there is no actor, group, institution or other figure involved towards whom blame can be directed.

However, while this may be true of the immediate impact of the hazard, it is entirely plausible that economic and political forces that differentiate between various groups can have an impact on the relief and recovery phases (Cannon, 2008).

These people's situation and risk exposure is exacerbated in particular by the current climate change situation, due to the connections between climate change and agriculture.

Exposure to more complex, frequent and intense climate extremes is threatening to erode and reverse gains made in ending hunger and malnutrition. In addition to conflict, climate variability and extremes are among the key drivers behind the recent uptick in global hunger and one of the leading causes of severe food crises. The cumulative effect of changes in climate is undermining all dimensions of food security(FAO, IFAD, UNICEF, WFP and WHO 2018).

Countries where large shares of the population rely on agriculture for their livelihoods and with agricultural systems that are significantly affected by climate factors, such as rainfalls, droughts, or temperature variability, are the most affected by hunger and malnutrition.

Risk Management Strategies and Agriculture

Broadly speaking, risk management is the process of identification, evaluation, and prioritization of risks ,defined as the effect of uncertainty on objectives, followed by the development of strategies to govern such risks. Risk reduction instead reduces the severity of the damage or the probability that it will occur. A risk analysis is at the basis of plans of actions to reduce or manage damages caused by adverse events. Disaster risk reduction (DRR) is the policy objective of anticipating and reducing risk, while disaster risk management (DRM) can be considered to be the implementation of DRR, since it is about the actions that attempt to achieve the policy objective (UNSIDR 2015).

In the literature risk management is part of a broader risk governance framework that typically includes at least three stages: risk assessment and evaluation, risk management and risk communication. What should be underlined is that the link between these three components cannot be considered liner. As a result, agricultural risk management is an interconnected structure where both government actions and markets interact with risks and farmers' strategies.

Concerning farmers, they cannot control atmospheric conditions, economic developments and further circumstances even if they have a direct influence on the farming's profits. It is in this framework that the farmer must manage farming risks within a wider plan of farming system (OECD 2009). Without knowing what will happen in the future, farmers must find appropriate actions to deal with risk in order to protect themselves from decisions taken today. This process of reducing the chance of a 'bad' outcome occurring is indeed incorporated into risk management strategies (Kahan 2008). The possible negative effect of these unpredictable occurrences pushes farmers to implement various risk management strategies in the sphere of their production plans, the available portfolio of physical, financial and human capital, and on the degree risk aversion (OECD 2009). Since every factor of climate mutation result into communities' food insecurity, farmers find themselves into the position of managing risks by following a series of steps which unfolds as follows. First of all, they need to

determine the possible sources of risk and comprehend the different consequences. Then they have to choose the various strategies which may be selected and evaluate the effects of each possible result. Finally, they must analyse the trade-offs that might arise between the cost of the risk and the profits that can be made (Bazza et al., 2018). As a result, farmers must try to reduce the happening of an unfavourable outcome or they must prevent the harmful effects of an unfavourable event every time possible (Kahan,2008). It is due to these risks hence that more individuals are herding and farming on smaller plots of land, which leads to both an increase in the use of marginal soils that are sensitive to erosion and to a rise in competition between livestock and cropping (Bazza et al.,2018). Despite it is impossible to predict climate change and natural disasters events, the best actors to assess the availability of various strategies to deal with these risks are the farmers. In more concrete terms, as stated by Holzmann et al. (2001), risk management strategies can be divided into three levels: prevention strategies to diminish the possibility of a destructive event from happening, mitigation strategies to decrease the consequences of an unfavourable event, and coping strategies to alleviate the effects of the risky event once it has occurred (OECD 2009). Within this division, it is possible to analyse generic strategies to reduce risk.

The first one is known as risk sharing which deals with the diffusion' of risk among various agents instead of focusing it on one actor only. For example, share-cropping system is based on the idea of spreading production risk between the tenant/worker and the owner of the property, in order to reduce the total costs of the sum of their risk premiums. The second method is risk pooling which pulls together the returns on risk of two farmers that will then divide the resulting outcome. Insurance firms work by bringing together the risks and then spreading them among different people. The last one is called diversification strategies which follows the same premise. In this context, diversification means that the farmer will not concentrate all his resources on a single activity but will employ them in different ones. Diversification spreads risk and is a successful risk management strategy because not all farm enterprises and operations are likely to be affected in the same way by changing situations (OECD 2009). This approach may consist in administrating and managing different farm enterprises together at the same time , engaging in different physical locations in the same farm business, working in the same farm enterprise over successive periods of time, or generating income from off-farm activities (Kahan, 2008). Another example is intercropping, which is a common form of crop diversification. For instance, in the case of drought soils, more resistant seeds may be planted together with food crops to guarantee that some gains are produced from the effort put into land cultivation. In many cases and in different countries, maize and sorghum are planted together; maize has some probability to fail in a drought situation but is resistant to animal damage, on the other hand sorghum is very resistant to drought but more sensitive to bird damage. Furthermore, in low rainfall areas of Southern Africa, farmers commonly use the mixed broadcast farming which is an example of intercropping. Through this practice, the farmer plants at the same time three or four different seeds on the same plot of land in order to guarantee the domestic food supply in case of drought. Although one or two crops may fail, the other ones might resist and provide food to the household (Kahan, 2008).

Concerning the governmental level, the transformative capacity (governance mechanisms, policies/regulations, infrastructure, community networks and formal safety nets)requires the intervention of governmental actors.

Many countries have national platforms, legislation and policies on disaster risk reduction, but few address agriculture, food security and nutrition with sector specific disaster risk reduction policies and objectives. Several existing global policies provide guidelines to national and regional government in their action to support affected populations. Nevertheless, it is important to bear in mind that different types of environments give rise to different types of disasters across countries and regions, and different types of disasters affect in significantly diverse ways agriculture and its subsectors. Different countries deal with different challenges across the world, and each government must therefore apply precise disaster-tailored interventions.

Despite a consistent increase in average government spending on agriculture in the last decades, such expenditure is far from being adequate to the needs of the sector, especially when it is considered the devastating effects of natural disasters.

Building Resilience

Resilience[iv] has emerged not so much as a new conceptual construct but rather as an organizing framework that integrates humanitarian and development efforts(IFPRI,2014).

Building resilience means helping people, households, communities, organizations and countries, and global institutions prevent, anticipate, prepare for, cope with a recover from shocks and not only bounce back to where they were before the shocks occurred, but become even better-off(Ulrichs et al,2019).

Prevention is the core objective. It addresses the root causes of vulnerabilities, focuses attention on emerging risks and emphasizes early action. It strengthens local capacities to build resilience.

Measures of resilience must distinguish between the *ex-ante* (preshock) capacity of resilience and the *ex post* time path of the outcome (food security, nutrition and so on) after the shock has occurred.

Studies on risk and vulnerability have shown that in general, poorer household are less able to guarantee their basic needs when faced with unexpected events as natural disasters, often disposing of assets to assure consumption, but with negative consequences for future well-being(IFPRI,2014).

Resilience focuses attention on the idea that short-term shocks are malign not just because of their immediate effects but also because of their adverse long-term consequences.

Despite the growing recognition that effective social protection is important to help poor and vulnerable household avoid long-term descent into poverty, there is still relatively little awareness of the differential vulnerabilities of men and women within households. Men and women may be exposed to different types of risk because of a combination of biological, economic, and cultural factors, including gender roles – the socially determined relationships between women and men. Men and women may also have different ways of insuring against and coping with risk. Not only do shocks and stressors such as have immediate effects on preschool children's nutritional status but that these effects persist into adulthood. Children in household with greater resilience are likely to be better nourished and better schooled; in turn, as adults, these children will likely be more resilient to the shocks and stressors the face.

Build resilience in agriculture means diversifying a portfolio of activities: adopt good practices, integrate disaster risk reduction in agricultural interventions and strengthen the governance framework for early warning and action(FAO,2018).

A resilient food system[v] is able to withstand economic and environmental shocks and stresses at different temporal and spatial levels(Misselhorn *et al*,2012).

Resilient food system can help countries transition from a relief stage to a development path(Babu and Blom,2014)
At the same time agricultural and food systems themselves need to be resilient to shocks, both large and small, to help availability and access event when disaster strikes.

Food security level is determined from the resilience level and vice versa . In fact, food security and resilience are strongly interlinked: food security is both an input to and on outcome of strengthened resilience.

Climate resilience requires context-specific interventions aimed at anticipating, limiting, and adapting to the effects of climate variability and extremes and building the resilience of livelihoods, food systems and nutrition to climate shocks and stresses.

Results and Discussion

The recurrence of natural disasters and crisis causes havoc and snares countries – especially developing countries - into poverty traps, undermining their efforts to eradicate hunger and malnutrition and contributing to increased food insecurity, as well as future vulnerability to natural shocks. In fact, a country which has been hit by a natural disaster is more likely to be hit again and with severe consequences. Prolonged or recurrent natural disasters decrease the resilience and coping capacity of affected peoples, provoking mortality as well as livelihoods assets and economic losses. In addition, disasters severely damage not only individuals, but market structures through changing production and consumption patterns, critical public infrastructure and housing - all fundamental factors for economic growth and development.

The focal point is still on how agriculture can recover from a natural disaster rather than on being less sensitive to it.

All this due to inadequate funding, readiness and coordination which is still very constrained.

What is needed then is to modify the perception and management of risks, by shifting the approach from an emergency response towards a more pro-active policy capable of taking into consideration a long-term planning to decrease risks and build better resilience. This means that natural disasters exist, but they might be exacerbated by human actions and inactions which are consequences of climate change. On this line of thought, in order to reduce the vulnerabilities of people – being them socially constructed or not – the different nations and actors are increasingly envisaging a multi-hazard and comprehensive approach to disaster risk reduction.

It is important to underline that, despite there are three dimensions – the individual, the national and the international – constant feedbacks among all the factors lead to both the assessment of risk and to the management of risk strategies and policies.

These three levels must hence work together by identifying sectoral and ecosystem approaches which are adequate for the most vulnerable situations due to natural disaster,
In order to significantly reduce and mitigate the impact that disasters have on the community, farmers' risk management strategies must be accompanied by policies and decisions constructed around farmers and their needs.

In fact, farmers and local communities alone are not able to deal with the effects of natural disasters on their own, and governmental assistance is fundamental in devising the right policies and planning the adequate financial investments in prevention and ex post recovery response.

what actions can be taken against such Reducing risks and building resilience within agriculture requires a policy environment that is conducive to the full mainstreaming of disaster risk reduction within the sector. Sector-specific disaster risk reduction planning is needed to proactively reduce disaster losses in the sector, enable sector growth and protect the food security and nutrition of vulnerable populations

In a holistic approach, disaster risk management and reduction plans need to be incorporated into agriculture sector development plans and policies, and not treated in separated agendas, especially in disaster-prone countries with population that are highly dependent on agriculture for their living.

Through the implementation of a holistic approach is possible optimize actions that can be taken against the climatic variability effects.

Conclusions

Agriculture is fundamental to help communities recover from natural disasters. It plays a critical role in the aftermath of disasters in that it can absorb both economic and environmental shocks and ensure

access to food and livelihoods to affected people, as well as help them recover and adapt over time. It is therefore crucial to invest in agricultural policies and disaster management programs to increase food security and disaster resilience, and action must be taken at various levels: global, regional, national and local, involving a wide range of actors such as governments, international organizations, NGOs and members of local communities. It is fundamental to involve small farmers and local communities living in highly exposed countries in programs dealing with disasters and their consequences, so that they have access to knowledge and technologies, and strengthen their tenacity and resilience to such events. It is fundamental to concentrate investments in preventive action, rather than devoting all resources to measures dealing with the aftermath of events. Contribution demonstrated that preventive action has been deemed to be four times more effective than reactive emergency response.

In view of holistic and comprehensive approach, measures of disaster risk reduction (DRR) should be integrated into agricultural development policies and socio-economic development plans, and vice versa agriculture should be included into DRR programs.

Consistently with the notion of an integrated approach, climate change adaptation plans and policies shall be considered together with disaster risk reduction and management programs, due to the crucial relationship between the two.

What is needed to enable the achievement of sustainable development and ensure food security and nutrition, is to build the disaster resilience, the ability of a socio-ecological system to withstand and overcome stresses due to changes in the earth's climate, as well as respond to such stresses by reorganizing, adapting and evolving into new configurations that can more effectively absorb environmental shocks. Natural disasters resilience building should be integrated by national and local governments into short, medium, and long-term policies.

Implementation of natural disasters resilience means refitting tools and intervention.

In order to bring about actionable results, increased financial resources for DDR and DDM in the agricultural sector and subsectors are needed both at the national and subnational level.

Local and regional governments must therefore increase significantly their investment in the agricultural sector and its subsectors, especially in countries where agriculture is a vital source of livelihood, due to the crucial role the sector has not only in ensuring food security and eradicating hunger, but in sustainable development and economic growth for the country as a whole. In this effort, national governments should be supported by the private sector and development assistance.

The availability of specific databases which thoroughly describe disasters and their impact on the agricultural sector within the Countries is an indispensable necessity for adapting plans to the Country specific strategy.

Improving resilience will require better data and information on risks and responses, better approaches to monitoring and measuring resilience.

In addition to that in order to achieve a development to be climate-resilient, it will require greater access to technologies, markets, information and credit for investment to adapt production systems and practices.

For the future the efforts of investigation must to be concentrated on how to measure resilience by, among other things ,settling on the concept, theory and implications of resilience.

Resilience could be a natural overarching theme of post 2030 agenda, encompassing poverty eradication, food security, and nutrition security. It could also be seen as a way of connecting people-centred development goals with the planet-cantered sustainability goals.

[i] the FAO(Food and Agricultural Organisation) widely accepted definition affirms that food security exists when all people, at all times, have physical and economic access to sufficient, safe and nutritious food that meets their dietary needs and food preferences for an active and healthy life.

[ii] the 2030 Sustainable development agenda ,adopted by the United Nations in September 2015,defines 17 sustainable development goals(SDGs),169 individual targets, and 25 global indicators for monitoring the progress towards the goals and targets.

[iii] the term is used to identify phenomena like droughts, floods, hurricanes, typhoons, cyclones, earthquakes, tsunamis and volcanic eruptions that, because of their geographic location, severity and frequency, have the capabilities to affect humans, their structures, or their activities adversely. The qualifier natural eliminates made phenomena as war, pollution, and chemical contamination.

[iv] comes from the Latin word *resilire*, which means "to rebound or recoil". Its earliest usage was in 19 th. century shipbuilding, and it is used extensively in civil and mechanical engineering.

[v] A food system is the process by which institution, organizations, and individuals transform inputs into food and nutrition outcomes.

Artificial Intelligence and IoT:
The Future of Remote Health Monitoring is in Machine Learning

Abstract

Artificial intelligence (AI) is currently one of the most controversial and discussed topic and the first question that is raised every time is "will it be helpful or not for a human being?". Several types of AI will increasingly be applied in the healthcare domain due to the complexity and rise of data in this field. Machine learning, an important subset of AI, provides a way to make the healthcare system more dynamic and robust. This article presents some applications of machine learning in the healthcare domain. It also provides the role of Internet of Things (IoT) systems through vital signs monitoring for elderly patients and it highlights the impact of machine learning in diagnosis management, treatment prediction or reducing errors with the help of remote health monitoring.

Keywords: Artificial Intelligence, Internet Of Things, Machine Learning, Remote Health Monitoring.

Introduction

Nowadays, a lot of technologies are currently widespread in business or other domains and more and more are being implemented in healthcare. Such technologies, as artificial intelligence (AI) and IoT, have the potential of changing a lot of aspects of patient care, as well as the administrative processes behind it. A lot of studies suggest that, sometimes, AI can perform as well as or even better than most of the doctors at key healthcare tasks, such as diagnosis management or treatment prediction and it can also help radiologists in spotting different types of tumors. However, there will be some years before AI can partly or totally replace humans for most of medical processes, but, at the moment, it surely helps to automate a lot of aspects of healthcare.

The development of medical equipment and the ubiquitous availability of data networks make it possible to monitor more patients through telemedicine and Internet of Things (IoT) systems. The remote healthcare monitoring of a person can be used to identify physiological changes in the human body, therefore, enabling early intervention. Thus, it is necessary to develop a smart healthcare monitoring system capable of observing patients' health, especially the elder ones.

The continuous growing of the elderly population, followed by the increasing exposure to chronic diseases associated with ageing, will have more and more repercussions in the future for the healthcare system (Efraim et al., 2017).

However, the interpretation of the collected data has become a challenging situation. Machine learning, an important subset of artificial intelligence, learns from experience or from the amount of data that is given and predicts events in the future based on the provided instructions. In the healthcare domain, it helps to analyze thousands of different data points and present specific outcomes, provide timely risk scores, precise resource allocation and has a lot of applications.

This paper is intended to present the influence artificial intelligence has in the healthcare domain and it also provides how machine learning can help in predicting certain diseases or treatment specifications based on an IoT system for remote health monitoring.

For demonstrating the added-value brought by machine learning to remote health monitoring, it is introduced a brief presentation of the system that is developed inside RO-SmartAgeing (Ianculescu et al., 2019) project, aiming to monitor and evaluate an elder patient's health and eventually alert the medical professionals if there are any significant changes in his vital signs.

Artificial intelligence in healthcare

When it comes to artificial intelligence, it is assumed that it is not only about one technology, but a collection of them. Their relevance to the healthcare field is really significant, but the processes behind them differ from one another.

The healthcare industry is in a continuous development and artificial intelligence, machine learning and deep learning are helping more and more in increasing the profits. More and more organizations claimed that will implement artificial intelligence solutions as they think AI-driven applications in the healthcare industry are generating revenue (Davenport et al., 2019).

Types of artificial intelligence and their relevance to healthcare

- *Machine Learning – from neural networks to deep learning*

As we live in an era of new computing technologies, machine learning, one of the most important branches of AI, is a method of data analysis in which computers can learn from data, identify patterns and make decisions based on minimal human intervention (Choy et al., 2018).

In the healthcare domain, one of the most common applications of machine learning are prediction and deciding the treatment suitable for the patient based on what the algorithm is learning (data from the patient's health and his medical history). When we are talking about prediction, it is preferably to have more data for training (supervised learning) therefore the accuracy of the outcome would be better as well as the treatment prediction.

A category of machine learning algorithms which has grown faster for the last years is the neural network. Neural networks are a set of algorithms, inspired from the human brain connectivity, designed to recognize patterns and have significant applications in clustering and classification (Howard et al., 2019). Thus, in the healthcare domain, they are used to determine if a patient can get a certain disease or not. Neural networks are based on inputs, outputs and certain weights of variables or "features" that link the inputs with the outputs and the accuracy resulted provides whether the model classifies the input correctly or not.

With the constant growth of AI in the healthcare field, Deep Learning, a more complex form of machine learning has become more and more successful in diagnosis. Deep learning for computer vision provides a more accurate method for medical imaging, cancer diagnosis and treatment. With the help of Electronic Health Record (EHR), a patient's data (demographic information, laboratory results and medical history records) is stored and, using deep learning algorithms, it can provide a correct diagnosis and also reduce the waiting time for this result. Based on the data EHR systems stores, these algorithms detect certain patterns in the patient's health and give some results related to the patterns they identify. Nowadays, researchers use data in EHR systems to build deep learning models to predict some health-related outputs (for example, the probability of a patient to develop a particular disease).

- *Natural Language Processing*

Natural Language Processing (NLP) is a subset of AI which is focused on the interpretation, manipulation and automation of human-generated speech or written data (Velupillai et al., 2018). It includes a lot of applications such as speech recognition, text analysis or different translation methods.

In the healthcare domain, there are a few promising NLP approaches and applications that can be used such as comparing and detecting in clinical guidelines and lab reports, extracting clinical history

(symptoms, diagnoses) from EHR, map clinical history with codified clinical guidelines and develop some machine-to-human natural language systems.

- *Physical robots*

It is well known that physical robots are more and more being used in factories or warehouses and perform a lot of tasks such as lifting, welding, moving or assembling different objects. Recently, robots have become more user-friendly and it is easier for humans to train them into doing a certain task.

As an important application of physical robots into healthcare industry, surgical robots have become a helpful tool for a surgeon as they improve the ability to see, create precise and minimally invasive incisions or stitch wounds (Haidegger et al., 2017). The common procedures done by the surgical robot include gynecologic, prostate or head and neck surgeries.

Applications of Machine Learning for diagnosis and treatment prediction

As the world population is constantly growing and the life expectancy is still increasing, most of the health systems are becoming overwhelmed and less equipped for the challenging tasks they face. More and more researchers have been working on machine learning models that can predict the susceptibility of a disease or help to early diagnose a certain illness so that could help the medical system manage more patients' health (Ahmed et al., 2020). It is likely to have a growing number of machine learning applications in healthcare in the near future as data, analysis and innovation could work side by side to aid more patients. Thus, the efficacy of finding new treatment options and the early prediction of certain diseases based on ML applications could be quite common in different healthcare systems in multiple countries.

- ***Breast Cancer Diagnosis***

Breast Cancer is the most common invasive cancer in women and the second leading cause of cancer death in women after lung cancer (Sharma et al., 2018). To reduce breast cancer deaths, one of the most effective ways is to have an early diagnosis. This requires a precise and feasible diagnostic procedure that can allow physicians to differentiate benign breast tumors from malignant ones without surgical biopsy.

One of the machine learning techniques is presented in (Sadhukhan et al., 2020). The authors obtained some feature values based on the analysis of a FNA image and proposed a model to predict if the tumor-infected cell is cancerous or not. The method included a part in which the authors proposed a methodology for computing the features based on a FNA image (including various image processing techniques) and the second part in which it is described the techniques of classification used for prediction (K-Nearest Neighbor and Support Vector Machine models with the best accuracy for the KNN classifier with 97.4893%).

Another screening method for detecting breast cancer is represented by mammography. It is considered to be the most effective imaging tool for detecting breast cancer in its earliest and most treatable stage, recommended for women aged 40-74 years old (Qin et al., 2018). Since mammography is quite difficult to interpret, more and more scientists have developed deep learning applications in mammography since 1996. The method presented in (Carneiro et al., 2015) in 2015, developed a significant improvement for mass and microcalcification based on deep learning networks pre-trained on ImageNet, a collection of 14 million annotated real-life images. Later, in 2017, it (Kooi et al., 2017) was published a deep learning-based approach with a bigger training dataset of 45,000 images focused on the detection of small malignant lesions. A study further showed that this algorithm had similar patch-level performance as three experienced readers.

A lot of deep learning models have developed recently based on mammograms and are designed to develop an automated system designed to assist radiologists in future mammographic screening.

- ***Pneumonia Diagnosis***

The lung is one of the most vital organs in the human body and its illness in it can have a lot of repercussions towards the health conditions. One of the diseases that lead to life-threatening complications, especially for children or for elderly individuals if it is not diagnosed early, is

pneumonia. It is normally detected with a variety of imaging methods, such as X-Ray, CT and MRI. Chest X-Ray are the most effective tool for diagnosing pneumonia, but actually diagnosing it correctly based on this imaging method is quite difficult and necessitate highly skilled radiologists as these images often overlap with other abnormal conditions of the lungs. Even though the detection of pneumonia is a time-consuming process, it can also lead to differences in diagnosis if the X-Ray images are vague. That is why, more and more Computer-Aided-Diagnosis applications are trying to implement machine learning and deep learning for automated detection of pneumonia. The method proposed in (Bhandary et al., 2020) is suggested for spotting pneumonia in X-Ray radiographs using AlexNet which led to a classification accuracy of 87% for a set of test images of 1000 normal and 1000 pneumonia X-Rays. But, with a Modified AlexNet deep learning technique and with a Support Vector Machine (SVM) classifier, it is obtained an accuracy of 96.8% which is very good for a precise detection of pneumonia on an X-Ray image.

- ***Personalized Medicine***

In the recent years, more and more researchers have been attracted to personalized medicine and the influence of deep learning in this field. Personalized medicine refers to providing a suitable medical treatment to each patient based on common features such as genetics, inheritance and their lifestyle.

As an important field of personalized medicine, drug development is focused on predicting the effectiveness of drugs. Considering the fact that patients have different profiles, their reactions to various drugs vary as well and it is very important to administer the proper medical treatment. Current advancements in the field of drug sensitivity focus more on genetic variations in patients with cancer. The researchers are working on multiple datasets that include details like molecular features, tissue origin, mutation information and responsiveness (Zhang et al., 2018) which are useful to evaluate the performance of machine learning algorithms to generate personalized medical treatment.

Also, disease recurrence is an important topic of discussion as many patients with cancer suffer from repeated onsets. Traditionally, this recurrence has been predicted based on physician's clinical experience and patient's risk factors. But, as the development of machine learning continue to grow, more algorithms can assist this process by identifying key risk factors and make relevant predictions. In (Tseng et al., 2014) the method was based on SVM, decision tree C5.0 and extreme learning machine to select risk factors and predict recurrence for patients with cervical cancer with an accuracy of 68%, 96% and 94% respectively.

Remote Health Monitoring System for Elderly Care

Motivation

As the worldwide aged population is constantly growing and there is always an immense increase in the demand for healthcare services, remote monitoring of physiological parameters provides an efficient method to overcome different emergencies.

Most of the elderly people, unable to take care of themselves, choose to go to a hospital or call for a family member, a nurse or the ambulance. Taking care of elderly people in hospitals, nursing homes or hiring professional nurses to take care of them at home is very expensive and not everyone can afford the specific costs.

An innovative solution that reduces most of these costs is to take care of patients in their personal homes with the help of telemedicine and IoT systems. Telemedicine represents a tool that provides the remote delivery of healthcare services. It involves the use of electronic communications and software to provide clinical services to patients without an in-person visit (Vranas et al., 2018). Therefore, in the recent years, telemedicine and IoT have helped in creating remote connections between the patient and the medical staff.

As people become older, most of them have some common old-age-related problems such as arrhythmias, high blood pressure, high cholesterol and many more. That is why it is necessary to implement real-time monitoring system that could ensure the quality of life, safety and well-being of elder patients. Monitoring the vital signs can be done without the intervention of a doctor, but when a

certain physiological parameter exceeds a threshold, the system can immediately send an alarm to the medical personnel to intervene quickly. This system can reduce the costs of healthcare and improve the quality of life of the elderly.

An example of a remote monitoring system for elderly care

In the context of underdevelopment Ro-SmartAgeing project, an IoT system for remote health monitoring intends to be used for the elderly and it can become an essential tool as engaging technologies such as healthcare sensors and wearable devices with our healthcare system can lead to a safer and convenient environment for everyone to live in.

The proposed system can enable continuous monitoring of elderly people's health to prevent falls or other abnormalities of health parameters and trigger an alarm every time a certain parameter exceeds a threshold.

The system consists of different types of wearable medical devices (sensors or actuators), smartphones, computer networks and software applications which are interconnected to transmit data and the main purpose of the system is to monitor physiological data collected from the patient, send it to a data center and, finally, provide access for authorized care-giver and doctors to see the data anytime and anywhere.

Fig. 1: Main components of RO-SmartAgeing remote health monitoring system.

Figure 1 emphasizes the main components of RO-SmartAgeing remote health monitoring system. It is shown that the data collected from wearable devices and sensors is sent to the Cloud over the internet (through a smartphone or a computer) and, then, it is transmitted and can be visualized, through a monitoring platform, by a clinician.

- ***Wearable Devices***

Wearable health devices provide the acquisition of vital signs and health status monitoring over extended periods and outside clinical environments. These devices can both have fitness and medical purposes targeting the human body monitoring and can measure from electrical to biochemical signs, biosignals that are possible to be extracted and used to better understand the health status and reaction to external factors.

RO-SmartAgeing project intends to use wired and wireless sensors for detecting valuable signs, such as heart rate, blood pressure, respiratory rate, blood oxygen saturation, body temperature, glucose level monitoring, the electrocardiogram, the electromyogram, galvanic skin response or body position in order for a correct diagnosis to be made.

Many more physiological parameters can be detected using wearable sensors and can be used to determine the health status of a patient. This amount of data is then sent to the medical personnel if there are any dysfunctionalities through the help of a smartphone or a computer with access to the internet.

- ***The Cloud***

The Cloud represents the place in which all the data collected from the sensors are sent, stored and processed. Cloud receives the data from the patient's smartphone or computer over the internet to be sorted and to be available for the doctor and/ or caregiver. All data is processed in Cloud and, based on the patient status and diseases, the abnormal changes will be categorized, and the information will be reported to the doctor's platform and/ or the emergency unit depending on the patient health status. A solution used in the project as a Cloud platform is represented by Windows Azure, developed by Microsoft. It is used for building, developing, testing and administrating web applications and services through Microsoft data centers. It is also an efficient tool for IoT projects as it helps users to collect and monitor IoT data from sensors and other devices.

Therefore, Cloud is a bridge that enables collaboration, through its infrastructure, which allows medical professionals to host information, diagnostics about patients, available to be seen by any other clinician as the data can be accessed and updated in real time with faster prescriptions and treatments.

- *Monitoring platforms*

Monitoring patient's records and sensory data has to be done through a platform available to the doctor or hospital. The doctors will be able to visualize the patient's electronic medical records in real time and they can take action if necessary. Developing a monitoring platform for our project consists of a combination of some programming languages, such as Java, C++, Python and NoSQL database. They are used to develop certain user-friendly web applications and to process the data from the IoT devices.

Keeping doctors up to date with the patient health status is essential for an elderly person and it helps a paramedic to take early action in case of an emergency before the situation is getting worse.

4. Applications of machine learning for a remote health monitoring system

The recent developments in technology and innovation in the healthcare domain have become more complex, and artificial intelligence can offer the support of improving clinical processes. The way to use new innovations in therapies as personalized treatments in accordance with the patient's profile or automated detection of a certain disease based on a medical image are some of the applications of machine learning in the healthcare domain.

Moreover, as the aging population is constantly growing and it is difficult for elders to go to the hospital, there is the need for remote communications and connections which creates a remote healthcare interaction between the patient and the doctor. Artificial intelligence could help in addressing this need by developing an intelligent environment in which clinicians could interact, maintain a virtual real-time record of the health status of a patient and alert if there are any imbalances in his/ her health based on the data received.

One application of patient health monitoring using machine learning is presented in (Priyadharsan et al., 2019) and it emphasizes that technological tools such as Internet of Things (IoT), Machine Learning and Artificial Intelligence with Big Data facilitate the job of physicians when putting a diagnostic and predicting the seriousness of a disease using these modern algorithms. The system uses machine learning algorithms to remote monitor the health conditions of patients. In this research, Priyadharsan et al. used the UCI dataset for training and validation of machine learning algorithms and the testing phase was performed on the collected data from heart rate, blood pressure and temperature sensors through the IoT framework and it was designed to estimate the prediction of any abnormalities in the health status of the patient. It was also performed a statistical analysis from data accumulated into the Cloud from the IoT system and it resulted in estimation of the accuracy in prediction percentage. The machine learning algorithm used in this system is K-Nearest Neighbour classifier which is a non-parametric supervised learning technique in which the data is classified to a given category with the help of training set and it obtained an accuracy of 98.02% (for K=1). The conclusion was that for this type of IoT system which continually monitors in real time the human health conditions, machine learning algorithms can play an essential role.

Another study presented in (Lin et al., 2019) proposes a system for electrocardiogram analysis and cardiac disease detection. As arrhythmia is one of the leading causes of heart disorders, it is likely to have a system that could detect this cardiac disease. A front-end IoT-based hardware, a user interface

through an application, a Cloud database and an AI platform are integrated in this system. The hardware part consists of a wearable ECG patch that could detect ECG signals of a patient staying at home. The application displayed on the smart device could show the real-time ECG signals and could also label the abnormalities and detect the disease in real time. Furthermore, the ECG signals are then sent to the Cloud database which is used to store each user's ECG signals and form a big-data database for the AI algorithm that could detect cardiac dysfunctionalities. For the AI algorithm used for classification, Lin et al. proposed a pre-processing method for preparing the signals and a convolutional neural network model with four convolutional layers and three fully connected layers which resulted in an average accuracy of 94.96%.

More and more applications based on the data collected from the sensors continue to be developed and automating the continuous monitoring of health parameters through IoT and Machine Learning techniques could help in estimating an early prediction of abnormalities and could save lives in a much faster way.

Fig 2. Architecture for a machine learning approach using wearable sensor data

As a further application for RO-SmartAgeing project, a general and simplified architecture for a possible machine learning approach using data from the sensors is given in figure 2. The data is collected from the sensors as for both training (in order for the system to learn) and testing (in order for the system to be used by anyone). Both training and testing data are being preprocessed due to the occurrence of noise, motion artifacts and sensor errors. Feature selection part is very important as it aims to discover only the main characteristics of both raw training and testing data. The machine learning algorithms collect the training data and, based on previous knowledge and the data collected up to that point, they provide a specific output. The algorithm is being applied on the testing data after it had been trained and it can detect a certain disease or predict a personalized treatment depending on the tasks applied.

As healthcare system becomes more digitalized and the modern transformations continue to ripple throughout the industry, AI technology will, in turn, grow in importance as an enabler of better elderly care.

In the context of the Ro-SmartAgeing project, we plan to develop a system that could monitor and evaluate an elder patient's health using an appropriate sensor for data acquisition, transmitting the data from patient to clinician, integrating the data with the patient's medical history and sending an alarm if there is an escalation in the care of the patient. As a future perspective, it would be a great opportunity to integrate a Machine Learning algorithm that could predict, based on the collected data from the wearable devices, if there are any abnormalities and eventually alert the medical personnel if there are any significant changes in his vital signs. The algorithm is previously trained for certain problems based on the data received as input. It could be developed to automatically detect arrythmias or other cardiovascular diseases based on the ECG signals, high/ low blood pressure through the pulse sensor, a high temperature based on the body temperature sensor and many more abnormalities also based on the patient's medical history and automatically inform the doctor in such a case without having someone constantly spending time watching the screen.

5. Conclusion

Artificial intelligence is an on-going research area and it has an important role to play in the healthcare domain, especially in the form of machine learning as for precision medicine. Even if the constant

challenges of providing diagnosis and treatment recommendations have not finished, it is expected that AI will master this domain soon. In the context of medical image analysis, machines will most likely be able, at some point, to examine most of the radiology and pathology images, speech and text recognition being already used for communication and capturing medical notes.

Remote health monitoring systems, through wearable health devices, have become a tool worth being integrated in the medical health systems, especially for the elderly patients. The principal value of such a system is to implement and integrate biosensors, intelligent processing and alarms to support medical applications and to predict and detect certain abnormalities and diseases that could help early diagnosis of a patient.

Combining artificial intelligence and Internet of Things can offer a significant contribution in terms of predicting diseases or a treatment based on the data collected from wearable devices through an IoT platform. Unlike humans, AI-based systems never lack motivation or drive and they will never be tired on putting a certain diagnostic, but they require a substantial learning phase which can achieve reliability after a solid amount of time. Therefore, we plan to develop RO-SmartAgeing project with the integration of a Machine Learning algorithm to easily detect certain diseases, predict suitable treatments for the patient and reduce the time-consuming factor thus helping the clinicians to better manage their patients.

Acknowledgement

The authors gratefully acknowledge the contribution of Ministry of Research and Innovation for funding the project RO SmartAgeing - "Non-invasive Monitoring System and Health Assessment of the Elderly in a Smart Environment" for the period 2019-2022

Abstract

The article is devoted to improving mechanisms for the development of export activities of enterprises in industrial regions of Russia. The authors analyzed instruments for coordinating the interaction of regional export development measures between federal and regional authorities. The mechanisms of financial support for the export of industrial products at the federal level were identified and evaluated, a set of measures to support regional exports was proposed and justified, including taking into account its country specificity. The paper presents proposals for the development of regional educational programs aimed at export development, as well as an action plan for promoting brands of industrial regions of Russia.

Keywords: Regional Economy, Regional Foreign Economic Activity, Enterprises Export Activities, Export Activities Marketing, Regional Export Support.

Introduction

The development of export activity is one of the most important tasks of the Russian economy, but this problem is especially urgent for the industrial regions. Most regional industrial enterprises currently have insufficient experience in international cooperation. Despite the intensification of their efforts in recent years to present their products on the global market, the issues of developing regional exports cannot be completely resolved.

The development of instruments to stimulate export activity in the regions, the formation and implementation of measures to support novice exporters are given serious attention by public authorities at various levels. Both at the federal level and at the level of a number of subjects of the Russian Federation, a set of measures operates to stimulate regional exporters. However, at the present time, among theorists and practitioners, a unified approach to this issue is not observed, which determined the relevance of the study undertaken by the authors of the paper.

In the course of studying the problem, official documents of the Ministry of Industry and Trade of Russia, Internet resources, materials of the Federal Statistics Service and the results of monitoring the socio-economic development of the regions of the Russian Federation were analyzed. The “Strategies of socio-economic development for the period until 2035” approved by a number of subjects of the Russian Federation were thoroughly studied and evaluated. The authors' conclusions are also based on a generalization of the practical experience of the Russian regions in the field of providing

exporters with comprehensive support for their foreign economic initiatives. During the study, general scientific methods of synthesis, generalization, system and comparative analyzes were used.

Results and Discussion

A study conducted by the authors showed that presently Russia is widely represented in foreign markets - there are 72 trade missions in 56 countries of the world. Their objective is to represent the country's interests in foreign economic issues, including free assistance to Russian companies and regions that are going to export their products.

At the same time, the creation of export support centers is an important mechanism for export development at the regional level. The main purpose of their activities should be, according to the authors, the provision of financial and non-financial support measures to regional exporters. For this, coordination of efforts with the following Russian organizations is extremely important:

- Russian Export Center, which includes the Russian Agency for Export Credit and Investment Insurance and ROSEXIMBANK, which allows regional exporters to receive comprehensive assistance;
- trade missions of Russia in foreign countries.

At the level of the subject of the Russian Federation, according to the authors, interaction of centers with the following organizations is necessary:

- funds for support and development of small and medium enterprises;
- regional business incubators;
- business microfinance centers;
- multifunctional business development centers, etc.

It should be noted that currently the basis of state support for the export activities of regional enterprises is financial assistance carried out in accordance with the Concept for the development of state financial support for the export of industrial products in the Russian Federation. The financial support mechanisms include:

- compensation for part of the cost of transporting food and agricultural products (up to 50% of the costs incurred);
- tax regulation of foreign economic activity (VAT for exported goods is 0%);
- state guarantees in foreign currency, subject to the compliance of export products with the list approved by the Government;
- concessional lending to foreign buyers and financing of export operations (subject to the compliance of products with the priorities of Vnesheconombank's investment activities);
- export credit insurance (the Russian Agency for Export Credit and Investment Insurance covers up to 95% of losses in case of political and up to 90% of commercial risk);
- financing the export of high-tech goods;

- increasing the effectiveness of Russian expositions at foreign exhibitions, etc.

According to the authors, the main directions of regional export development should be:

- dissemination of information about export opportunities of enterprises through trade missions of the Russian Federation, business councils, investment bureaus, chambers of commerce and industry of foreign countries;
- providing support to exporters through interaction with the Russian Export Center;
- formation of a catalog of region exporters;
- organization of participation in business missions to foreign countries, as well as in meetings with foreign entrepreneurs in the region;
- organization of participation in international exhibition-fair and congress events in the Russian Federation and abroad;
- Search for international partners using the Enterprise Europe Network (creating English language company profiles in the Enterprise Europe Network);
- providing advice on export issues with the assistance of relevant experts;
- translation of information materials into foreign languages;
- creation of websites of exporting enterprises in foreign languages;
- improving goods and services in accordance with export requirements;
- training of representatives of small and medium enterprises, etc.

Given the country specifics of the foreign economic activity of industrial regions of Russia, the authors consider it necessary:

- creation of regional representative offices in countries with the highest growth rates of exports of goods and services from this region;
- creation of inter-regional representative offices in countries with high export values of similar goods;
- sending representatives of regional exporters to work in trade missions of Russia in countries that are key in terms of non-oil exports;
- organizing and conducting internships for regional export specialists in trade missions of Russia in foreign countries to study consumer behavior, products in demand, etc.

According to the authors, the development of the region's export activity will be facilitated by the creation and maintenance of a public register of regional exporters, including: the name and contact details of companies, ranking them by industry, according to the HS codes, and export countries. Updating and clarifying the registry should be done at least once every six months.

To increase non-oil exports, it is necessary to use various debt settlement schemes, including:

- in exchange for obligations of foreign partners for the Russian products procurements;
- to provide preferences to Russian suppliers on market access to the public procurement system;
- to convert debt obligations of partners into equity participation in projects to promote Russian exports, etc.

An important direction in the development of regional exports is the introduction of an online resource dedicated to exports. It should be focused on supporting export-oriented small and medium enterprises, providing advice on conducting foreign trade operations, training on export operations technologies, conducting online conferences for businesses, etc. The resource should contain information on the socio-economic situation of countries and their regions; on the volumes, commodity and geographical structure of exports and imports; foreign trade, tax, investment legislation; organizations promoting the development of foreign economic relations; links to trade and diplomatic missions of foreign trade partners and credit agencies.

A significant direction in developing the export potential of the regions is the introduction of training programs for novice exporters. From the point of view of the authors, there should be the following topics of educational programs:

- role of export in the development of an industrial enterprise strategy;
- effective marketing technologies for exporters;
- basics of business communications in export activities;
- legal support of export activities;
- management of financial resources in export activities;
- documentation support for export activities;
- specifics of customs clearance of export operations;
- logistics technologies in export activities;
- tax support for export activities;
- basics of e-commerce;
- use of the project approach in export activities;
- intellectual property in foreign markets: use, registration, protection.;
- monitoring of export performance.

Training courses must be varied depending on the needs of exporters and built on a modular basis. Access to training courses, including in online format, should be available to any representative of a small or medium enterprises interested in export operations. The implementation of educational programs will allow enterprises to obtain specialists who possess the competencies necessary for exporting and scaling up a business by entering the foreign market.

An important direction in the development of export activities of the regions is the development and promotion of their brands. As the study showed, in many subjects of the Russian Federation, systematic work to promote regional brands is not carried out; efforts are insufficient to create the image of the regions among foreign partners and consumers. An analysis of the image characteristics of the Russian regions allows us to conclude that there are a number of negative stereotypes (unfavorable ecology, economic depression, low solvent demand, limited opportunities for residents to develop themselves, etc.) that hinder the formation of demand in the tourism, food industry, and other export-oriented industries. At the same time, it was revealed that the image of the regions of Russia is formed to the greatest extent due to large-scale sports, cultural and political events.

The described situation reduces the competitiveness of Russian regions on the world market and hinders the development of the export potential of industrial regions of Russia. The action plan for

promoting brands of industrial regions of Russia should include, according to the authors, the following steps:

- study of the image of the region among stakeholders (local population and business, the population of neighboring regions and Russia as a whole, foreign partners);
- analysis of the weaknesses and strengths of the region in the main areas of activity;
- development of a regional brand platform, its positioning strategies;
- development of brand visualization involving a wide range of participants;
- implementation of a brand promotion program in Russian and foreign markets.

The implementation of the proposed export development mechanisms in the industrial regions of Russia will increase their competitiveness in the world market.

Abstract

The article is devoted to the study of ways to improve foreign economic activity as a key area for the implementation of the marketing strategy of the Russian regions. The authors identified the main directions of diversification of regional exports, including natural-production and innovation component. The article explores the export structure of Russia and its industrially developed regions, analyzes industry guidelines for the development of federal and regional exports, and explores the possibilities of expanding the geography of export supplies. As a result of the study, a list of economic sectors promising for export development was formed and justified, the use of which will optimize the marketing strategies of the subjects of the Russian Federation and increase their global competitiveness.

Keywords: Regional Economy, Regional Foreign Economic Activity, Export Operations, Place Marketing, Regional Marketing Strategies.

Introduction

The development of foreign economic activity is an important area of improving the marketing strategy of the Russian regions. To solve this problem, it is necessary to intensify the export efforts of the subjects of the Russian Federation, which, in turn, is impossible without identifying and optimizing their export benchmarks, analyzing the export structure of industrialized regions, as well as promising sectors of the economy in terms of export. The described factors determined the relevance of the study undertaken by the authors of the paper.

In the course of studying the problem, official documents of the Ministry of Industry and Trade of Russia, Internet resources, materials of the Federal Statistics Service and the results of monitoring the socio-economic development of the regions of the Russian Federation were analyzed. The strategies of socio-economic development of the subjects of the Russian Federation for the period until 2035 were studied. The authors' conclusions are also based on an analysis of the practical experience of a number of Russian regions - the Perm, Chelyabinsk, Sverdlovsk, Novosibirsk and Tyumen Regions - in the field of comprehensive support of foreign economic initiatives of exporting enterprises. During

the study, general scientific methods of synthesis, generalization, system and comparative analyzes were used.

Results and Discussion

One of the targets for the development of foreign economic activity of the Russian economy until 2035 is its entry into the top five world exporters and qualitative changes in the structure of exports due to the outstripping growth in exports of high-tech, knowledge-intensive goods and services. An effective tool to achieve this goal at the level of the subjects of the Russian Federation is the formation and subsequent implementation of a strategy for export diversification, which helps to reduce trade, political, commercial and other risks of foreign economic activity.

According to the authors, the key areas of the regional export diversification strategy include:

- natural-production component, including the development of the existing regional competitive advantages: this diversification is the generator of the region's resources and provides it with "quick wins";

- innovative component, which implies the establishment of new competitive industries, focusing on the final stages of the technological cycle and ensuring a high level of innovation.

The authors believe that the strategy of export diversification should be combined with the traditional export specialization of the region, and not act as its alternative, which will solve the following problems:

- increase in the share of non-oil industries' goods and services of small and medium enterprises;

- increase in the share of exporters who regularly carry out export operations;

- increase in the share of companies that expanded their export assortment or entered new country markets.

Let us analyze the industry benchmarks for the development of federal and regional exports. The leading branches of the Russian economy from the perspective of expanding foreign economic activity are presented in table 1.

Table 1: Perspective in terms of foreign trade branches of the Russian economy

#	Branch of the economy	Share of total exports, %	Share of non-oil exports, %
1	Fuel and energy complex	62.5	34.5
2	Metallurgical complex	7.5	12
3	Agro-industrial complex	4.5	8
4	Transport complex	3.5	6.5
5	Production and processing of precious metals and stones	2.5	3.5
6	Military-industrial complex	2.5	4.5
7	Petroleum and gas chemistry	2	4
8	Tourism	2	4
9	Transport engineering	1.5	3
10	Timber industry complex	2	2.5

#	Branch of the economy	Share of total exports, %	Share of non-oil exports, %
11	Nuclear complex	1.5	2
12	Information and communication sphere	1	2
13	Non-nuclear power engineering	0.3	0.6

From the data in table 1 it can be seen that the listed sectors of the economy account for about 94% of the total and over 87% of non-oil exports of Russia.

As part of the study, the authors conducted a comparative analysis of the sectoral structure of the Russian economy and the economy of the Russian industrial region (using the example of the Chelyabinsk region). The state of export in promising sectors of the country's economy is presented in table 2.

Table 2: The state of export of the Chelyabinsk region

#	Perspective in terms of foreign trade branches of the Russian economy	Share in the total export of Russia, %	Share in export of the Chelyabinsk region, %
1	Fuel and energy complex	62.5	0
2	Metallurgical complex	7.5	80.2
3	Agro-industrial complex	4.5	2.84
4	Transport complex	3.5	2.3
5	Production and processing of precious metals and stones	2.5	0.12
6	Military-industrial complex	2.5	2.55
7	Petroleum and gas chemistry	2	0.44
8	Tourism	2	0
9	Transport engineering	1.5	2.3
10	Timber industry complex	2	0.21
11	Nuclear complex	1.5	no data available
12	Information and communication sphere	1	0.33
13	Non-nuclear power engineering	0.3	0.1

Thus, based on the data in Table 2, the sectoral export structure of the Chelyabinsk region is significantly different from the Russian one, and a similar picture is observed in other regions of the Russian Federation, which requires an appropriate emphasis from them.

According to the authors, indicators recommended by the Regional Export Standard approved by the Government of the Russian Federation can be used to assess the effectiveness of mechanisms for implementing the strategy of the regions of the Russian Federation. They are presented in tables 3 and 4.

To assess the possibilities of expanding the geography of export activities of the regions, we will analyze (using the example of the Chelyabinsk region) the main trends in the development of foreign trade. The rating of countries in terms of exports from Russia over 5 years is presented in table 5. These same countries occupy the first lines in the integrated ranking of the importance of export markets for Russia.

Table 3: The main export guidelines of regions of the Russian Federation

#	Indicator	Recommended value
1	Twofold increase in the volume of non-oil non-energy exports of the subject of the Russian Federation in 2020 relative to 2016	100%
2	Share of exporting companies from all companies in the region in 2020	2%

Table 4: Additional export guidelines of regions of the Russian Federation

#	Indicator	Recommended value
1	Number of small and medium Exporters	At least 500 pcs.
2	Annual increase in the number of small and medium exporters	At least 5%
3	Diversification of non-oil exports (maximum share of one industry)	No more than 40%
4	Diversification of supply geography (number of export countries)	At least 25

Table 5: Rating of countries in terms of exports from Russia over 5 years

#	Country	Export volume	Share, %
1	Netherlands	230.2	12.5
2	China	149.8	8.1
3	Germany	133.4	7.3
4	Italy	116.7	6.3
5	Turkey	92.2	5.0
6	Belarus	78.0	4.2
7	Japan	69.3	3.8
8	Republic of Korea	64.2	3.5
9	Ukraine	60.3	3.3
10	Poland	59.9	3.3
11	Kazakhstan	57.7	3.1
12	England	46.6	2.5
13	United States of America	46.6	2.5
14	Finland	43.2	2.3
15	Latvia	38.2	2.1

Table 6 shows a comparative analysis of the structure of exports from Russia and the region over 5 years (2013-2017).

The data presented in the table take into account the current state of exports in the region, including the deviation from the indicators of export activity in the country. At the same time, countries demonstrating positive deviation values should, according to the authors, become an object of promotion on the part of exporters in the region.

Table 6: Comparative analysis of the structure of exports from Russia and the Chelyabinsk region

#	Country	Share of exports from Russia, %	Share of exports from the region, %	Deviation, %
1	Netherlands	12.5	6.5	-6.0
2	China	8.1	0.4	-7.7
3	Germany	7.3	1.0	-6.3

#	Country	Share of exports from Russia, %	Share of exports from the region, %	Deviation, %
4	Italy	6.3	5.1	-1.2
5	Turkey	5.0	7.8	2.8
6	Belarus	4.2	3.8	-0.4
7	Japan	3.8	0.7	-3.1
8	Republic of Korea	3.5	0.5	-3.0
9	Ukraine	3.3	3.2	-0.1
10	Poland	3.3	0.9	-2.4
11	Kazakhstan	3.1	18.7	15.6
12	England	2.5	0.6	-1.9
13	United States of America	2.5	0.8	-1.7
14	Finland	2.3	1.5	-0.8
15	Latvia	2.1	0.0	-2.1

Consider the results of a comparative analysis of the geography of exports of two similar in a number of indicators (geographical location, structure of gross regional product, etc.) of subjects of the Russian Federation - Chelyabinsk and Sverdlovsk regions. Table 7 presents the export volumes of these regions over five years (2013-2017) relative to the rating of the countries of the Sverdlovsk region, since the export volume of the Chelyabinsk region during this period of time is about 60% of the export of the Sverdlovsk region.

Table 7: Export volumes of two regions (2013-2017)

No. in the rating of Sverdlovsk region	Country	Sverdlovsk region, $ billion	Chelyabinsk region, $ billion	Deviation, $ billion
1	United States of America	6.64	0.175	-6.465
2	Netherlands	3.1	1.4	-1.7
3	Kazakhstan	2.62	4.031	1.411
4	Germany	1.74	0.207	-1.533
5	Turkey	1.71	1.676	-0.034
6	Algeria	1.61	0.076	-1.534
7	Azerbaijan	1.32	0.698	-0.622
8	China	1.08	0.083	-0.997
9	Switzerland	0.983		-0.983
10	India	0.938	0.216	-0.722
11	Greece	0.935	0.11	-0.825
12	France	0.855		-0.855
13	Czechia	0.789		-0.789
14	Italy	0.747	1.11	0.363
15	England	0.733	0.129	-0.604
16	Uzbekistan	0.694	0.998	0.304
17	Belarus	0.673	0.83	0.157
18	Ukraine	0.655	0.68	0.025
19	Republic of Korea	0.645	0.12	-0.525
20	Canada	0.518		-0.518

The table shows that the maximum export lag of the Chelyabinsk region corresponds to such countries as the United States of America, the Netherlands, Germany, Algeria, China, Switzerland

and France. Similar data were obtained based on industry and geographical analysis of exports from other regions of the Russian Federation - Perm, Novosibirsk and Tyumen Regions.

According to the authors, in order to optimize the foreign economic activity of the regions of the Russian Federation as part of the implementation of their marketing strategies, it is important to develop a program for the development of exports in the short, medium and long term. It should include the following key objectives:

- identification and reduction of administrative barriers;
- creation of a center for enterprise export support;
- creation of advisory infrastructure for export support;
- maintaining a public register of regional exporters;
- creation and promotion of an information resource dedicated to export;
- promotion of a regional brand in foreign markets, including through official visits of senior officials of the region abroad;
- creation of trade representations of the region abroad;
- training for beginner exporters, etc.

The program, according to the authors, should take into account the targets laid down in the Main directions of export development of the Russian Federation. This will allow to increase the export performance of subjects of the Russian Federation, optimize the marketing strategies of the regions and, ultimately, increase their global competitiveness.

Irina RUDSKAYA

Peter the Great St. Petersburg Polytechnic University, St. Petersburg, Russian Federation, iarudskaya@mail.ru

Abstract

The development of the construction complex in the context of digitalization of economic processes is discussed in a number of research works. It was found that the construction complex is developing cyclically, which is reflected in medium-term Juglar industrial cycles, Kuznets construction cycles, and Kondratiev long waves considering industries in terms of scientific, technical, innovative and digital development. The article discusses the digitalization of the construction complex of the Russian Federation through the BIM-design process, identifies its advantages and disadvantages for the building organizations. One of the main drawbacks of the development of BIM technologies is the lack of a regulatory framework in this field. The article proposes a scheme for the development of the digital potential of the construction complex in the regions of the Russian Federation, with the main focus on the regulatory framework at the federal and regional levels. Based on the proposed scheme, a multi-level structure for the development of the construction complex of the Russian Federation is built in the context of the economy digitalization, indicating the following development levels: 1) the formation of human capital through training and development, and the formation of the scientific and technological base; 2) the base of information and communication technologies; 3) the innovative development base; 4) digital development processes; 5) the controlled structure of digital development. Control indicators are selected for each level, which in the future will provide an assessment of the developmental degree of digital processes in the construction complex of the Russian Federation throughout its subjects.

Keywords: Construction Complex, Digitalization Of The Economy, Economic Cycles, BIM-Design.

Introduction

The construction industry contributes to the development of infrastructure of a particular region at various levels, which provides functioning of its economic systems. The construction industry also provides other sectors of the national economy with the necessary facilities (buildings, roads, bridges and tunnels, etc.), therefore, the digitalization of the construction industry can provide a more intensive development of the whole economy of a region. Let us assume that the construction process that implies activities from dealing with project documentation to the commissioning of an object and involves construction organizations dealing with various aspects of construction should be referred to as a construction complex.

Considering the development of digital processes in the construction complex in the Russian Federation, we should point out an upward trend based on the survey of BIM use in Russia, Report on the study (Website, accessed April 20, 2020). So, the survey conducted in the Russian Federation in 2019 with 174 participants, revealed the following advantages of BIM-design in construction organizations: 1) high quality of the project - 74% of the respondents; 2) better awareness of the project by all participants - 72%; 3) information availability, fast data transfer and information

exchange - 61%; 4) reduction of design time - 46%; 5) 3D and 4D visualization of the construction site - 36%; 6) cost reduction - 33%; 7) increase in profit and profitability of construction production - 32%; 8) efficient use of resources - 25%; 9) reduction of construction time - 24%. At the same time, respondents noted a number of reasons that impede the development of BIM in construction organizations in the Russian Federation: 1) lack of qualified personnel, mentioned by 73% of the respondents; 2) high cost of implementing new technologies - 52%; 3) lack of state standards for the implementation of projects using BIM technologies - 49%; 4) lack of a legal framework for the introduction of BIM-technologies - 49%; 5) lack of investors and customers' requirements - 47%. Hence, the development of the construction complex of the Russian Federation in the context of modern digitalization trends is quite relevant, which is confirmed by the aforementioned survey in terms of the advantages, but the focus should be made on the development of the regulatory framework.

Conducting the analysis of scientific research into the development of digital processes in the construction industry, a fairly large scope of research can be seen: Alaloul et al. (2018), Borremans et al. (2018), Fateeva et al. (2018), Lepekhin et al. (2018), Li (2017), Mesároš et al. (2016), Pertseva et al. (2017), Safronova et al. (2018), Volkov (2018), Zaychenko et al. (2018) and other. For example, Li and Yang (2017) propose a new production scheme for the industrialization of construction, which is based on BIM-design technology. In work Safronova et al. (2018) discuss the digitalization strategy for a construction company to increase its performance in compliance with current trends. Volkov (2018) in his work considers the original systemic engineering scheme for digital modeling of creative activity in the construction industry, and describes seven levels of digital modeling. The study conducted in work Alaloul et al. (2018) reflects the general idea of the industrial revolution 4.0 with the description of important aspects of the construction industry development. In the article Mesároš et al. (2016), the authors consider the development of managerial and digital competencies in the construction industry using BIM-technologies.

Construction complex, like any other economic system, is subject to cyclical processes, and this fact must be taken into account when forming the development tools of the construction complex in the context of the economy digitalization. The relationship between cyclical processes and the development of the construction industry is discussed in a number of works: Allan et al. (2008), Bennett (2005), Gornig et al. (2014), Slueva (2017), Zavadskas et al. (2017) and other, for example, the Zavadskas et al. (2017) of the article reviewed the publications relating to the efforts to harmonize construction processes based on the Web of Science Core Collection database. In some studies the authors consider: 1) the marketing reactions of construction companies to cyclical conditions using the example of the UK, Bennett (2005); 2) the main factors determining the upward and downward cycles in the construction industry of New Zealand, Allan et al. (2008); 3) the stages of the construction complex development in relation to the indicator of the construction volume on the example of Germany, Gornig et al. (2014).

Based on the foregoing, the object of this study is the construction complex of the Russian Federation, and the subject is the development of digital processes of the construction complex at the federal level. The aim of the study is to structure the development of the Russian Federation construction complex in the context of digital economy. In accordance with the purpose of the study, it is necessary to solve the following problems: 1) to analyze the relationship between the development of the construction complex of the Russian Federation and the cyclical nature of the selected socio-economic indicators through diagrams; 2) build a scheme for the digital development of the construction complex in the regions of the Russian Federation; 3) build a multi-level structure for the development of the construction complex of the Russian Federation in the context of digitalization, indicating the levels of development; 4) determine control indicators to assess the identified levels of the Russian Federation construction complex development in the context of the economy digitalization.

Methods of Research

The study is based on the comparison of the theories of economic cycles (J. Kitchin, K. Juglar, S. Kuznets and N.D. Kondratiev) with the development of the construction complex in the Russian Federation through the use of quantitative methods of assessment and analysis. A quantitative research method involves the collection and processing of statistical data with the dynamics of their change over time using the diagrams. Statistical data were selected in the state statistics database for the following indicators: commissioning of residential and non-residential buildings, thousand m^2; GDP per capita, rubles; volume of innovative goods, works, services, million rubles; number of organizations conducting research and development, units.

The qualitative analysis methods are also used in the work and they include the construction of the «Scheme for the development of the digital potential of the construction complex in the regions of the Russian Federation» and the «Multi-level structure of the Russian Federation construction complex development in the context of the economy digitalization». Control indicators are selected in accordance with a multi-level structure.

The relationship of the development of the Russian Federation construction complex with socio-economic indicators

Studying the historical retrospective of the development of digitalization processes on the territory of the Russian Federation, it was found that it is possible to trace the cyclical development of sectors, which is reflected in the innovative and digital development of a specific economic system, Kuzyk (2008) and Loskutova (2009). The regularity of cyclic processes should be considered through the prism of economic cycle theories, Tsvetkov (2013).

When analyzing the cyclic development of industries, the synthetic cycle theories should be highlighted as they represent the main group of economic cycle theories according to Tsvetkov (2013). These theories include studies of the economists on the cyclical nature of economic development conducted since the beginning of the 19th century. The economists describe common stages of economic cycles, but at the same time these cycles are different due to such parameters as amplitude, length, etc. There are different types of economic cycles: 1) short-term 3-4 year cycles (J. Kitchin cycles); 2) medium-term, industrial and business 7-12 year cycles (C. Juglar cycles); 3) construction, reproduction, demographic or long cycles of 16-25 years (S. Kuznets cycles); 4) long waves of 40-60 years (N.D. Kondratiev cycles).

The development of the construction industry is reflected in medium-term industrial cycles of Juglar, construction cycles of Kuznets and in Kondratiev long waves that consider the industry in terms of scientific, technical, innovative and digital development. In this connection, it seems appropriate to analyze the relationship between the dynamics of the indicator characterizing the development of the construction complex of the Russian Federation (commissioning of residential and non-residential buildings, thousand m^2) with such key economic indicators as GDP per capita, rubles, and population, million people. In particular, it is necessary to consider the relationship with the indicators that characterize innovative and scientific-technological activities: the volume of innovative goods, works, services, million rubles; number of organizations conducting research and development, units. It should be noted that the indicator «The volume of innovative goods, works and services» has been collected by the state statistics service since 2004, Federal State Statistics Service (Website, accessed April 10, 2020). The indicator was earlier (1998 to 2003) called «The volume of innovative products by innovation degree» and was collected in two groups: 1) products that underwent significant technological changes or were reintroduced; 2) products that have been updated. In this connection, this indicator in the early period (1998-2003) is considered in this study as the sum of subgroups.

The relationship of the dynamics of the selected indicators of state statistics is shown in Fig. 1-4 for the period from 1998 to 2018, with the reliability indicator of approximation (R^2), which will allow us to attribute indicators to a specific type of economic cycle. It should be noted that the development

of the construction complex in modern Russia is rather difficult to evaluate in terms of Kondratiev long waves because of the lack of data for previous periods (before 1998), therefore, it is difficult to assess the dynamics of innovative processes related to the development of the construction industry over a long period of time (40-60 years). However, the medium-term industrial cycles of Juglar and the construction fluctuations of Kuznets are available for the assessment.

Fig. 1: Relationship between the dynamics of the commissioning of residential and non-residential buildings (thousand m^2) and GDP per capita (rubles, before 1998 - thousand rubles)

Fig. 2: Relationship between the dynamics of the commissioning of residential and non-residential buildings (thousand m^2) and population (million people)

Considering the dynamics of key economic indicators, it can be seen that the development of the Russian Federation construction complex varies in proportion to the change in the level of GDP per capita, hence productivity at construction companies has an upward trend. The indicators of approximation accuracy of R^2 presented in Figure 1 also indicate the interconnection of the indicators dynamics. Based on the indicator of the resident population on the territory of the Russian Federation for the considered period of time (Fig. 2), it can be noted that the relationship between the selected indicators has been observed since 2010. The trend line in terms of the population indicator is not accurate due to a low level of the approximation accuracy $R^2 = 0.0005$, since the time lag of the initial value is small, and the population growth cannot be traced in short-term and medium-term industrial and construction cycles.

Fig. 3: Relationship between the dynamics of the commissioning of residential and non-residential buildings (thousand m^2) and the volume of innovative goods, works, services (million rubles)

Fig. 4: Relationship between the dynamics of the commissioning of residential and non-residential buildings (thousand m^2) and the number of organizations conducting research and development (units)

Analyzing the charts reflecting the relationship between the dynamics of the construction complex of the Russian Federation and the indicators of innovative and scientific and technological development, we conclude that there is a relationship of the indicator dynamics with the amount of innovative goods and services. Thus, the trends reflected in Figure 3 reveal the interconnected growth of indicators, and high R^2 indicators demonstrate their development over time in accordance with medium-term industrial cycles. The indicator of the volume of innovative goods, works and services over time varies in accordance with the selected indicator of the development trend of the construction complex, since the digital and innovative processes as well as BIM-design technologies are widely used in the construction complex. There is also a correlation with the number of scientific organizations, since the innovative and digital processes of the construction complex are being actively studied.

Research Results and Discussion

The development of the construction complex of the Russian Federation in the context of the economy digitalization should be addressed through the formation of interconnected management

structures aimed at the holistic development of the digital potential of the construction complex through the prism of individual subjects of the federation, Kudryavtseva et al. (2019). It seems appropriate to formulate a set of measures that contribute to the development of the construction complex in the regions of the Russian Federation through the implementation of regulatory mechanisms and interconnection of regional authorities, business structures and local population. The activities of the actors should be coordinated and aimed at the development of digital potential within the subject of the federation. The digital development within the regions will be provided by the construction industry through the development of the digital potential of the construction complex of a particular region. To achieve this goal the regional authorities ought to take into account the regulatory and legislative documents of the federal level, namely: 1) the Strategy for socio-economic development of the Russian Federation, About strategic planning (Website, accessed April 20, 2020); 2) the Strategy for the development of the information society of the Russian Federation, Strategy of development N203; 3) the Strategy for scientific - technological development of the Russian Federation, Decree of the President N642; 4) the Development Strategy of the construction industry of the Russian Federation, Ministry of construction of the Russian Federation (Website, accessed April 20, 2020); 5) the list of programs and projects, for example: GOST R 57310-2016, GOST R 57563-2017, SP 331.1325800.2017, SP 333.1325800.2017, SP 404.1325800.2018, Program N1632-R, Order of the Ministry of construction N854/PR, aimed at developing innovative and digital potential of industries and sectors of the Russian Federation, as well as control, including the construction complex. The following documents are also required for development of the digital potential of the construction complex:

1. Strategies for the socio-economic development of the region. This document should reflect the planned development of the subject of the federation with the allocation of priority zones and programs.

2. Strategies for the development of the regional construction complex. The document should be developed in accordance with the characteristics of the territories including the measures necessary for the development of the construction complex. The strategy should be an integral part of the program for socio-economic development of the region, and it should be interconnected with the development strategy of the digital potential of the region's construction complex. A strategic initiative should be taken within the segments «Training, Development and Innovation», «Industry and Entrepreneurship», «Society and the Market», «Finance of the Region», Kozlov et al. (2018) and Kozlov et al. (2019).

3. Development strategies for the digital potential of the region's building sector. The document should be developed in accordance with: 1) the development of human capital, which consists in the collection of the necessary knowledge and skills for the implementation of the projects for the development of the construction complex as well as the scientific and technological base; 2) the base of information and communication technologies that already exist in the region and can provide the digital development of the construction complex; 3) the base for the innovative development of the industry, which will allow for the transition to the implementation of interconnected digital processes within the construction complex of the region. The strategy should be an integral part of the strategy of socio-economic development of the region, and it should be interconnected with the development strategy of the digital potential of the region's construction complex.

In the framework of these regulatory documents of the regional level, it will become possible to form the structure of the regional innovation system (RIS), Rudskaya (2017), with the main factor for its development - the digitalization of the construction complex. The characteristic features of the development of the digital potential of the construction complex in the regions of the Russian Federation are shown in the form of a diagram in Fig. 5.

Fig. 5: Development of the digital potential of the construction complex in the regions of the Russian Federation

The scheme above characterizes the development of a particular region of the Russian Federation in the context of the digital potential of the region's construction complex. In the framework of this approach rapid development can be expected in other sectors of the economy, given the horizontal structure of the construction complex.

Based on the analysis, we can build a multi-level structure for the development of the construction complex of the Russian Federation in the context of the digitalization of the economy (Fig. 6). The structure will reflect the necessary levels for the transition to an interconnected control system for the digital development of the construction complex in the Russian Federation. The multi-level structure includes: 1) the growth of human capital through training and development, and the formation of the scientific and technological base (1st level of development); 2) the base of information and communication technologies (2nd level of development); 3) 3) an innovative development base (3rd level of development); 4) digital development processes (4th level of development); 5) the manageable structure of digital development (5th level of development). This structure of development on the territory of the Russian Federation should be defined as a complex of the generated digital potential of the construction complex in its constituent entities.

Fig. 6: Multi-level structure of the development of the Russian Federation construction complex in the context of the economy digitalization

In accordance with the structure shown in Fig. 6, we can determine the control indicators that will reflect the degree of development of the region at a particular level of the construction complex development in the context of the economy digitalization. At the first basic level, it is necessary to take into account indicators in two groups: 1) education; 2) research and development. The first group includes indicators such as:

- human development index;
- the number of bachelors, specialists and masters, thousand people;
- the number of graduate students, people;
- the number of Doctors of Philosophy, people;
- the number of Doctors of sciences, people.

The second group «Research and Development» should include:

- the number of organizations conducting research and development, units;
- the number of personnel engaged in research and development, people;
- the number of researchers with advanced degrees, people;
- internal costs for research and development in the field of engineering, million rubles.

At the second basic level, you should focus on the following indicators:
- the percentage of organizations using information and communication technologies (personal computers, servers, local area networks, «cloud» services),%;
- the percentage of organizations using the Internet in organizations,%;
- the percentage of organizations using electronic document management,%;
- the percentage of organizations using electronic data exchange between their and external information systems, %;
- the use of personal computers per 100 employees of organizations, units.

Within the framework of the third basic level, the focus should be made on the following industry indicators:

- level of innovative activity of enterprises,%;

- the percentage of innovative goods, works, services in the total volume of goods shipped and work performed,%;
- innovative goods, work, services, newly introduced or updated over the past three years, million rubles;
- the number of advanced manufacturing technologies used, units;
- the number of advanced production technologies, units;
- the number of advanced production technologies new for Russia, units;
- the number of brand new advanced production technologies, units;
- the number of new technologies (technical achievements) and software acquired by organizations, units.

At the 4th development level, the development process of the construction complex should be regulated according to industry indicators, divided into 2 groups: 1) the digitalization level of the construction industry; 2) the level of BIM development. The first group includes the following indicators:

- the percentage of organizations using cloud services in the total number of organizations in the Russian Federation,%;
- the percentage of organizations with the Internet access at a speed of at least 2 Mbps, in the total number of organizations in the Russian Federation,%;
- the percentage of organizations using CRM systems, ERP systems, SCM systems, in the total number of organizations in the Russian Federation,%.

The second group «Level of BIM development» should include:

- the percentage of construction organizations using BIM-technology,%;
- the number of implemented projects using BIM-technologies, units;
- costs of introducing BIM-technologies, mln. rub.;
- the number of personnel involved in the BIM design process, people.

At the 5th level of development, it is necessary to formulate indicators at the federal level, within the regulatory framework concerning the regulation and development of digital processes in the construction complex, in the field of BIM design, in particular. The indicators of this level can include the quantitative data on the programs of the Russian Federation that are being implemented and ready to be launched with regard to the development and regulation of the digital transformation of the construction complex, as well as BIM design.

Conclusion

The observed interconnection of the cyclical development processes of the construction complex (in terms of the indicator «Commissioning of residential and non-residential buildings, thousand m^2») with socio-economic indicators highlighted the trends in the construction complex development in the context of economic cycles, and determined the dependency of the construction complex development on medium-term industrial cycles - Juglar cycles, Kuznets cycles and Kondratiev long waves which consider the industry in terms of scientific, technical, innovative and digital development. Consequently, the development of the construction complex in the context of the economy digitalization is feasible and necessary, as the volume of construction was growing in the period from 1998 to 2018 and demonstrates an upward trend now, which is supported by a high value of the approximation accuracy $R^2 = 0.9478$.

So, the given analysis allows us to conclude that the digital processes of the Russian Federation construction complex must be developed with the focus on the regulatory framework. The proposed scheme for the development of the construction complex digital potential in the regions of the Russian Federation reflects the key positions that should be taken into account when forming the policy of the industry digital development in the regions. In this connection, a multilevel structure for the development of the construction complex of the Russian Federation in the conditions of economy

digitalization determines the development levels. In accordance with each level, control indicators have been selected, the analysis of which in the future will allow for the comprehensive assessment of the development degree of digital processes in the construction complex of the Russian Federation throughout its subjects. Also, it will become possible to assess the subjects of the Russian Federation regarding the formation of RIS with the main development factor - the construction complex.

Abstract

The purpose of this article is to present the author's model, thanks to which it is possible to adapt tasks and functions between various members of teams implementing the concept of Lean Management in enterprises to their personal preferences and psychological conditions. In this model, four perspectives were identified based on which four Perception Styles (perception, specific phenomena and situations) were identified, followed by four Activity Styles. Research under the article was first of all conducted on scientific knowledge and the broad practice of one of the authors in the field of human potential management in organizations. In the next phase, psychologists were invited to research, who focused on developing an analytical and verification tool that could be useful in business practice in the long-term. The tool prepared in this way was then verified as part of the pilot studies carried out.

Keywords: Lean Management concept, Lean Management implementation process, perspektywa poznawcza, style percepcji, style aktywności, model RFCS.

Introduction

High efficiency and, consequently, the successful implementation of the Lean Management concept is determined by many factors, among which the human factor deserves special attention (Baskiewicz 2019, p. 224). A number of studies indicate that employee favor, and thus minimization of resistance, is an important criterion for the success of the process of implementing various management concepts (Morgan, Levitt, Malek 2010, p. 95; Bhasin, Burcher 2006, p. 56) In scientific knowledge, there are a number of ways to limit or even exclude resistance. (Eckes 2011, 34; Koenigsaecker 2000, pp.171-172) According to the authors, appropriate identification and analysis of the psychophysical features of organization members, followed by their targeted involvement at specific stages of work related to the implementation of the Lean Management concept, can significantly increase the efficiency of implementing the concept. Identification of personality traits allows defining the Perception Style and the Activity Style. Perception Style shows what kind of information is most important and useful to a particular member of the organization when they come into contact with a new situation. The Perception Style indicates why priority is given and which areas concentrate thoughts, as well as which mental processes are most efficient. The Perception Style translates directly into the Activity Style, which indicates activities in which each individual member of the organization is the most effective.

Literature Review

Hippocrates has already identified four personality types, followed by abilities, temperaments, interests and needs, and even physiological traits. The above-mentioned features create a set of elements of the psyche and behavior, through which people differ from each other. Sociable sangwinist, imperious choleric, melancholic thinker or observing phlegmatic are personalities identified by Hippocrates. Sangwinists have the gift of being attracted to each other, they are talkative, have a great sense of humor, are energetic, spontaneous, strengthen their contact with listeners through touch, they are simplistic.

Negative features are the lack of consistency and determination in the implementation of plans, very often they do not notice their disadvantages. They are the best employees in terms of contacts with others, they are great as salesmen. Choleric is also an extrovert who is characterized by independence and self-sufficiency. He is a born, dynamic and active leader who has an irresistible need for change, he is not moved, but inspires confidence. Choleric is hard to discourage, he likes to work for the needs of the group and works in unexpected situations. He does not feel the need for a stronger friendship, he is a compulsive workaholic, loves to have control over everything, does not allow others to make decisions and organize actions, because he assumes that only he is right and others are wrong, in addition, he is a master of manipulation. At work, the choleric is a born manager who hates opposition. He is a man quick in action. Among introverts, phlegmatics stands out, which is characterized by restraint, calmness and cool composure. He is patient and balanced, kind and polite, basically does not have bouts of bad humor, does not fall into depression and is easy to have sex. He is a good and caring listener. On the other hand, the phlegmatic looks lazy and postpones his work for later, he assumes that he can avoid it at all, hates coercion and avoids performing daily duties. At work, he is a competent and solid person, calm and consistent. He has administrative capacity, mediates in solving problems and finds easy ways out and avoids conflicts, can be a negotiator, likes routine work that does not require initiative. The last personality type is a melancholic who is also an introvert. Melancholic is a thinker and a pessimist. His temperament is full of extremes, highs are the most important and depression is the deepest. But on the other hand he is analytical and conscientious, serious and determined, distinguished by his artistic abilities, he is sensitive to beauty, philosophizing and poetic. He is a born idealist. At work, the melancholic obeys the regulations, he can easily see the problem and solve it. His place at work looks perfect and professional. Melancholic works best alone, values silence, always finishes the tasks he starts, likes charts, diagrams, numbers.

Based on many years of research and observation, Jung concluded that differences in people's attitudes and preferences are not accidental. He created the well-known division into extroverts and introverts today (Sharp 1987, pp. 25-31). Extroverts are people who generally draw energy from the outside world, i.e. contacts with people, things and events. (Sharp 1987, pp. 37 – 64) The opposite of extroverts are introverts, who draw energy from the inner world and only later transfer it to the outside world, they need space only for themselves. The extroverts are the sanguine and choleric of Hippocrates, while the group of introverts are phlegmatic and melancholic. In addition, Jung distinguished four personality functions, which are two pairs of opposites: perception-intuition and thinking-feeling. (Witzig 1978, pp. 315-331; Richek, Bown 1968, pp.57-65) He also determined that in each of these pairs one of the functions dominates. Jung came to the conclusion that the dominant functions of each person are permanent and independent of external conditions, and their resultant is the type of personality. (Meier 1995, pp.13-27)

In 1938, two American psychiatrists Horace Gray and Joseph Wheelwright, created the first personality test based on Jung's theory, enabling the determination of dominant functions in three dimensions described by him: extraversion-introversion, perception-intuition and thinking-feeling. (Wheelwright., Wheelwright., Buehler 1964; Sato 2017, pp1-7; Wheelwright, Wheelwright, Gray 1964) This test became an inspiration for other researchers. In 1942, also on American soil: Isabel Briggs Myers and Katharine Briggs began to apply their own personality test, extending the classic three-dimensional model of Gray and Wheelwright by a fourth dimension: assessment-observation. (Myers, Briggs 1998) Most later typologies and personality tests referring to Jung's theory also include this fourth dimension. These include American typology published in 1978 by David W. Keirsey (Keirsey 1984, pp. 156-189) and a personality test created in Lithuania in the '70 of the twentieth century by Aušra Augustinavičiūtė. (Augustinavičiūtė 1998) In the next decades, researchers from different parts of the world followed in their footsteps, creating subsequent four-dimensional typologies and personality tests adapted to local conditions and needs.

Research Question

The implementation of process of the Lean management concept is extensive, multifaceted and extended in time. It is worth emphasizing at this point that, in principle, every member of the

organization finds a place in this process so that they can demonstrate their specific abilities, perception and style of activity. Considering the above, the following research questions were posed:

1. What can we distinguish Cognitive Perspectives focused on identifying employee attitudes?
2. What are the characteristics of each perspective?
3. What Activity Styles are there?
4. What are the characteristics of each Activity Style?
5. What activities can be involved in people characterized by individual Perception Style or Activity Style?
6. How do differences in the perception of individual members of an organization affect group communication?

Research Design and Methodology

Based on scientific knowledge in the field of psychology and sociology, four Cognitive Perspectives were identified, which were further characterized in detail. The identified Cognitive Perspectives were developed in detail, taking into account the strengths and weaknesses of each of them, and the relationships between them, especially in the aspect of communication. The developed characteristics of these Cognitive Perspectives were then subjected to empirical verification, which confirmed the accuracy of their identification. The verification was carried out in January 2020 in a group of 24 psychologists who had previously learned the theory regarding each of the perspectives, then in teams of six, identified areas of perception and activities characteristic of each perspective. In the next step, each team presented the features of the perspective being developed - this step was to exclude possible repetition. Then, a survey was developed in which examples of situations were presented, and solutions typical of each of the four perspectives were given in the solution variants. The effect of this work was a tool enabling the identification of individual attitudes in the respondents. The tool prepared and developed in this way was verified by conducting pilot studies among 43 employees of the Częstochowa corporations who were asked to answer the questions posed regarding specific attitudes as well as confrontation and assessment of the veracity and compliance of the analytical description.

Specific Cognitive Perspectives have enabled the development of a model that, through the detailed identification of individual characteristics, enables them to be assigned to specific tasks and operations coinciding with their personal preferences and capabilities, both on the level of cognition and activity.

Results

The RFCS model name is an abbreviation of the first letters of the words Reality-Feeling-Concept-System. They define four Cognitive Perspectives, which in turn are used to describe Perception Styles and Activity Styles. The Perception Styles results from what kind of information, realities, feelings, values or systems, is the most important and useful for a particular person at the moment of encountering a new situation. In addition, the Perception Styles indicates why it is given the highest priority and also which mental processes are performed most efficiently. The Activity Styles, as previously noted, results from the Perception Style and the degree of use of other perspectives and determines the situation in which a person is the most effective. Individual perspectives define in detail the scope of perception of the situation, thus becoming the key to recognizing and characterizing individual types of employees, which directly translates into giving roles and functions in the process of implementing the Lean Management concept.

People in whom REALITY PERSPECTIVE prevails focus on those elements of the situation that appear to be objective and indisputable. In addition, they are characterized by efficient recognition of cause and effect relationships. They can quickly and accurately assess the situation based on facts regarding the effectiveness of implementing a new project, e.g. the Lean Management concept. People with FEELING PERSPECTIVE predominate show the highest tendencies to empathy, these people focus on feelings and interpersonal relationships to the highest degree. Those with a predominance of fellings perspective are guided in their actions by the heart and good of people, often not caring for the good of the organization itself. Their priority is always interpersonal relationships and dependencies in

which they operate. People who, based on research, show most of the features consistent with the CONCEPT PERSPECTIVE are characterized by the ability to perceive the situation globally as a starting point for creating new own ideas. These people are creative and independent, full of ideas, characterized by unconventionality in moving beyond the current state of affairs, which they perceive as one of the possible alternatives. Members with a predominance of concept perspectives freely question current and binding values / norms and discover new, non-obvious relationships. From the SYSTEM PRESPECTIVE a characteristic feature is reaching out to the basics and causes of the situation by analyzing its components. People diagnosed with the predominance of features consistent with the concept of structures penetrate deep into the essence of the problem to get its complete and coherent picture.

As previously emphasized, RFCS defines the Perception Style, revealing the strongest sides of the respondent's mind, sources of perception, and various ways of using information, responding and solving problems. It is worth noting that the RFCS model does not value. Instead of dividing people into better or worse functioning, it emphasizes the uniqueness of each way of thinking. Each style is different and results from the natural predisposition of man and can manifest itself both in the ease of applying procedures and guidelines as well as outstanding abilities. Depending on the dominant perspective, we can divide all members of the organization into players, visionaries, partners and researchers (tab. 1.)

Tab.1: Cognitive perspectives and personality types

Dominant perspective	Dominant way of thinking	Personality type	Personality characteristics
Reality	Logical	Player	Approach to problems: defines one overarching goal, simplifies the problem, finds one simple and practical solution, quickly pursues it. Appreciated for: logic, goal orientation, quick decision making, practicality and concreteness. Criticized for: literality, lack of diplomacy, schematicity, categoricality.
Concept	Lateral	Visionary	Approach to problems: considers the problem globally, finds many completely different alternative solutions, willing to change strategies, also at the stage of operation. We appreciate: flexibility and unconventional thinking ingenuity and original concept of progressiveness. Criticized for: chaoticness, ignoring principles, asymmetrical, generalizing.
Feelings	Intuitive	Partner	Approach to problems, when defining its goal, takes into account with who it is connected, finds several versions of the same solution, intuitively chooses the one that takes into account the most factors. We appreciate for: empathy, showing personal commitment, compromise, awareness of social relations. Criticized for: hypersensitivity, sensitivity to moods, emotionality, changeability of decisions.

System	Analytical	Researcher	Approach to problems begins by collecting a large amount of information, categorizes and analyzes it, strives for an optimal solution taking into account all possible cases. We appreciate: perceptiveness and insight balanced judgment, methodical attention to detail Criticized for: perfectionism, complicated meticulousness, long decision making.

Source: own study based on the example of Research

The Activity Style results from the Perception Style and the degree of use of the other three RFCS perspectives. Indicates situations in which a person is most effective.

The Activity Style results to a large extent from the Perception Style, but the choice of strategy is also influenced by experience, values, habits and operating conditions (including the professional situation) taking into account the combined impact of these factors on the results. The Activity Style shows what perspectives complement the Perception Style in action and determines in which situations and how it can be most effectively used. Experiences and preferences may change over time, which results (unlike in the case of the Perception Style) of a possible change and development of the Activity Style. When defining a person's Activity Style, we divide four RFCS perspectives into visible and invisible in action. The composition of these elements determines both the Perception Style and other preferences. Each Perception Style can adopt one of seven styles of action, depending on the results obtained for the other three RFCS perspectives.

Tab. 2: A way of constructing the Activity Style

A way of constructing the Activity Style		
Concept	**Reality +Feeling +System**	
Perception Style +	Additional preferences =	Activity Style
The style of perception determines the first most natural reaction: 1. Describes how to receive information and how to solve problems. 2. It is a lasting preference from childhood and does not change significantly during life. 3. Describes internal processes, most visible in new situations. 4. Reveals the natural strengths of the mind	Resulting from experience, preferences, habits, conditions, requirements, situations expressed in the perspectives of the RFCS model	This determines how you use the Perception Style: 1. Includes additional preferences, experiences, likes, etc. 2. Develops and may change during life. 3. It can easily be determined by observing a person in action 4. Composes the results of all RFCS components. 5. Reveals the situations in which it is the most effective.

Source: own study based on the example of research

The results show the level of preference for each component of the RFCS model. The clarity of the results depends mainly on the consistency of the answer and the number of "hard to say" answers. The more of them, the less unambiguous the result.

For example, Visionaries who are extroverted tend to be inspirational speakers. Those more introverted - valued advisers. However, working with a Visionary can sometimes be difficult. The visionary tends to share his ideas before he even thinks about them and easily changes the strategy carried away by a new idea, which can reduce his credibility in the eyes of others. When talking to a Visionary, discomfort may be caused by his tendency to change the subject frequently, generalize and expect others to know what he means. The Visionary contributes the most to the team venture at the initial stage of determining the vision of the strategy.

Visionary Communication with other Perception Styles:

Reality - a Visionary's discussion with a Player is a clash of two completely different points of view: "what can be" and "what actually is." A Visionary Player may perceive as unpleasant, criticizing and unimaginative. Player will be annoyed by saying that you have to act, not fantasize. It should be noted that Players actually often achieve their goals and maybe the Player is the person who will know how to implement the Visionary's ideas.

Feelings - a conversation with a Partner can be a pleasure for the Visionary, because he listens kindly about the Visionary's ideas, he is less critical than other Perception Styles. Note that the Partner avoids conflicts, so if he considers the Visionary's plans to be wrong, he often doesn't talk about it or uses a very veiled method. However, there is no better person to cooperate in the team and to persuade others to participate in the Visionary's venture.

Concept - two Visionaries is a recipe for hours of discussion about the problems of the universe. Great agreement, dozens of ideas and inspiration, of which, however, little comes later to the implementation phase. Cooperation with the second Visionary is extremely valuable at the beginning of the venture, when the vision and strategy are clear. At further stages, it is worth involving people with different Perception Styles who will be more motivated to act.

System - Researcher as soon as you hear the ideas will ask a lot of questions about details that are probably not yet thought out. You can be impatient with the fact that he underestimates the novelty of the idea, but breaks it down into prime factors and focuses on insignificant issues. It is worth appreciating, however, that it is the Researcher who is able to change a strict concept into a well-thought-out action plan, project or prototype.

Communication and relationships in other Cognitive Perspectives were similarly described.

Results

Knowledge of their own personality profile allows people to fully use their potential and work on areas that can cause them problems. It is an invaluable help in everyday life in solving problems, building valuable relationships with other people and making decisions regarding education and career.

Personality type determination is not an arbitrary and mechanical process. Everyone, as the recipient and user of their personality, is fully competent to determine which type they belong to. (Chrapek, Kukowska 2015, pp. 11-18) His role in this process is therefore crucial. Such self-identification can be done by analyzing personality types and gradually narrowing down the check box. It is worth emphasizing that honesty towards yourself plays a key role, because the test result depends on the answers given.

Identifying personality types helps you get to know yourself and others, but it should not be treated as an oracle for the future. A personality type can never justify our weaknesses or bad relationships with other people (although it can help to understand their causes).

Discussion

In cognitive psychology, the dominant view is that cognitive styles operate on the basis of established habits, which are clear already in preschool and for the rest of life do not change significantly.

The most important tool of RFCS diagnoses natural predispositions and gives hints in which actions a given person works, how he can approach problem solving most effectively. In addition, it was indicated how it should best communicate with people with the same or different styles of perception. Another determinant of the work of individual employees on themselves is a detailed report focused on the identification of areas that are worth strengthening and on which it is worth working with indications of how to work on them. What's more, thanks to RFCS tools, problems in communication between individual cognitive perspectives are explained.

You can extend the use of this model and the tools that help in its empirical application to the analysis of the entire team. The analysis is then used to develop a map of the team's potential. Each person is assigned a style of perception of activity and attitude, which he most often adopts in the team. The study should consider factors affecting cooperation and communication guidelines. This study may form the basis for identifying the employees' potential, then for assigning individual employees responsibility for the implementation of functions and tasks focused on the effectiveness of the process of implementing the Lean Management concept in the business practice of a specific enterprise.

Abstract

The article explores the possibility of increasing the loyalty of the youth audience - generation Z - to regional brands using the example of the Perm State Academic Opera and Ballet Theater named after P.I. Tchaikovsky. The authors substantiated the use of the SERVQUAL methodology as a key method for studying the influence of the main branding indicators on attracting the attention of young people and increasing their loyalty to the region of residence. Using the SERVQUAL methodology, the authors undertook a study and assessment of the impact of the theater brand on young consumers - representatives of the Z generation.

Keywords: Place Marketing, Region Branding, Brand Quality Attributes, Consumer Preferences.

Introduction

In the current economic and geopolitical situation, cities, as subjects of brand management, regardless of their location, are actively involved in competition for human resources and welfare. This situation is also characteristic of large Russian cities and regions. In this situation, the municipal authorities have the task to characterize their personality as brightly as possible, find a marketing niche, create long-term loyalty of residents and, thereby, take their rightful place in the competition.

In the described situation, increasing the youth's loyalty to the region of their residence is of particular importance. Note that currently all cities are fighting to attract and increase the loyalty of young people born in 2000-2019, and characterized by marketers as generation Z. Entering the stage of active consumption, it is generation Z in the coming years that will become the main workforce, key taxpayers and bearers of city values and, in addition, will determine key consumption trends for at least 20 years.

Based on the foregoing, an important theoretical and practical importance are:

- development of strategies for the territorial development focused on youth audiences;

- formation of the brand management concept in the region;
- creation and promotion of branded economic, sports and cultural objects;
- organization of significant large-scale events and actions, etc., within the framework of campaigns to promote the brand of the region.

Therefore, the authors of the paper attempted to study the basic tools and the degree of influence of the brand on young residents of generation Z of a large city. The study was conducted on the basis of a large regional center - Perm and included a study of the attitude of young people to one of the region's key brands - Perm State Academic Opera and Ballet Theater named after P.I. Tchaikovsky.

Results and Discussion

To study the degree of brand influence on residents of the city belonging to generation Z (not older than 2000 year of birth), the authors consider it appropriate to use the SERVQUAL methodology (V. Zeytaml, L. Berry, A. Parasuraman). It is based on the "expectation minus perception" model and is a questionnaire of 22 pairs of questions with possible answers on the Likert scale - from "completely disagree" to "completely agree". Questions are divided into subgroups depending on the following parameters (each of which, in turn, has 4-5 attributes):

- reliability - the ability to accurately and quickly provide a service;
- responsiveness - the willingness of staff to help consumers;
- assurance - competence of staff;
- empathy - degree of attention to consumers;
- tangibles - physical objects used in the process of providing a service.

The first part of the questionnaire includes questions that reveal the expectations of consumers regarding the brand, and the second part - the level of relevant qualities in the brand. After filling out the questionnaires, the resulting service quality indicator is calculated as the difference between the levels of perception and expectations.

The features of the influence of the city's brand on its young residents were studied by the authors using the example of the Perm State Academic Opera and Ballet Theater named after P.I. Tchaikovsky. The theater is one of the region's brands - it is the center of cultural life, one of the main newsmakers, the venue of the Diaghilev Festival of the world-famous conductor Theodor Currentzis, etc.

As part of a study conducted by the authors in the fall of 2019, representatives of generation Z were interviewed - university students from 17 to 26 years old. The sample was 296 people, including 72% of girls and 28% of boys. The obtained data were processed using the SPSS 22 program. The results of the study are presented in table 1.

In accordance with the method used, negative values indicate that the level of consumer expectations exceeded the level of real perception, and positive values indicate that the level of perception was higher than expectations. Thus, positive and zero values of the indicators are good, satisfactory are negative, but as close to zero as possible indicators, and unsatisfactory are indicators with values well below zero.

Table 1: Average brand service quality indicators

Quality parameter	Perception, points	Waiting, points	Service quality (SQ)
Tangibles (T1-T4)	5.5	5.4	0.1
Reliability (RL5-RL9)	5.7	5.8	-0.1
Responsiveness (RS10-RS13)	5.5	5.9	-0.4
Assurance (A14-A17)	5.6	5.7	-0.1
Empathy (E18-E22)	5.1	5.4	-0.3
Total for the sample:	4.6	4.7	-0.1

From the data in table 1 it follows that representatives of generation Z evaluate the quality of the theater brand quite high, since consumer expectations and real perception showed close values - the differences between them do not exceed 0.3. At the same time, only one parameter showed high results - “tangibles” (SQ = 0.1), to which the modernity of equipment, the attractiveness of interiors and information and advertising materials were classified as part of the study.

Other parameters during the study showed satisfactory values of the service quality indicators. At the same time, respondents positively assessed the “reliability” parameter, which incorporated the efficiency of solving emerging problems, the convenience and clarity of the theater website, and other attributes. When evaluating the “empathy” parameter, respondents, as follows from Table 1, praised the personal participation of employees in solving problematic issues, the availability of specially equipped places for people with disabilities, and the opportunity to visit the theater with children.

Note that the most disturbing results during the survey showed the “responsiveness” and “assurance” parameters, which included the responsiveness to customer requests, the level of information support, courtesy, the friendliness of the staff and other attributes. Obviously, the theater will have to work on their improvement.

The next stage of the analysis was the calculation of the service quality indicator relative to consumer expectations Q1. According to the methodology used, the lower the Q1 value, the more high-quality services the brand represents. Table 2 shows the data for each attribute.

Based on the data in table 2, the highest value of indicator Q1 shows the parameter RS12 “responsiveness”, understood in the framework of the study as constant assistance to the audience. The parameters RL8 and E22 were evaluated as less qualitative - accessibility, unhindered purchase of tickets and the availability of interesting promotions for schoolchildren and youth, respectively.

The theater believes that attractive advertising (T3) is its advantage, however, respondents rated this attribute low (-3.9%). Meanwhile, the personal participation of employees in solving the problems of the audience (E18), the convenience of visiting people with disabilities (E20) and the availability of activities for children (E21) showed high results. In general, it can be argued that the theater provides these services at the level at which a young audience expects them to see.

Table 2: Service quality indicators relative to consumer expectations for each attribute

Quality para-meters	Q_1, %	Quality para-meters	Q_1, %	Quality para-meters	Q_1, %	Quality para-meters	Q_1, %	Quality para-meters	Q_1, %
M1	-0,8	H5	2,2	O10	2,4	У14	3,4	Э18	-0,3
M2	0,0	H6	-0,4	O11	3,4	У15	1,9	Э19	1,4
M3	-3,9	H7	3,8	O12	5,4	У16	1,9	Э20	-1,2
M4	-0,7	H8	0,5	O13	2,6	У17	3,5	Э21	0,3
		H9	2,6					Э22	3,9

Another indicator, Q2, shows the relationship between the perceived quality of the brand and the maximum expectations of the respondents. In this case, it is advisable to take the maximum possible value of expectations equal to seven as the reference value of the indicator. The lower the Q2, the higher the quality of the brand. In other words, brand quality is higher when the respondent's expectations are as close as possible to the standard.

The results of the study showed that the maximum average rating of respondents' expectations about the quality of theater services is 6.2 points (out of 7), which demonstrates its reliable reputation.

So, the study showed that the "reliability" (the brand's ability to provide service accurately and quickly) parameter received the highest ratings of respondents. This indicates a high level of consumer confidence. "Responsiveness" and "assurance" received good marks, indicating that the staff is competent and ready to help the audience. At the same time, these parameters demonstrate a significant discrepancy between expectations and real perception. This can be explained by the fact that employees do not always provide services promptly.

"Tangibles" parameters (advertising materials, employees 'appearance, interior, etc.) received lower but positive ratings, but respondents' expectations in this case were confirmed. The lowest ratings of the respondents received the attributes "sympathy" and "personification of communication with the audience". According to the authors, this is largely due to the lack of conditions for people with disabilities, as well as the lack of options for viewers with children.

Thus, the results of the study showed that the attitude of students as representatives of generation Z to the theater is generally positive. The theater has a good reputation, but attracting young people is one of its targets. In this regard, overcoming the deficiencies identified during the study will help strengthen the theater brand, and, ultimately, the brand of the region.

Abstract

This article discusses the issues associated with the high cost of applying innovative technologies in banking in the Russian Federation, explores the main trends in the development of bank management in the innovative aspect, and assesses the importance of using innovative technologies both in individual commercial banks and in the banking system countries. The most promising innovative products in Russia are currently investigated. Based on the statistics of the Bank of Russia and Markswebb agency, an analysis of the efficiency rating of Internet banks for individuals was carried out. The methodology of applying innovations such as blockchain, cloud storage, API, NFC technologies, the integration of bank accounts with electronic payment systems (EPS) and cryptocurrencies is considered. As a result, the information considered in the article is generalized and conclusions are drawn on the application of innovative technologies not only in the activities of commercial banks, but also their role in improving the efficiency of the country's banking sector in the face of constant progress.

Keywords*:* Banking Innovations, Banking Products, Innovation Management, Internet Banking, Blockchain Technology, Fintech Startups, Cloud Data.

Introduction

In the conditions of continuous development and implementation of the latest technologies in various spheres of life, they are given special importance in the field of banking systems of the world. This interest is due to the desire to improve the efficiency of the banking sector. The main obstacles to the introduction of innovative products are their high cost and the risk of a long payback.

The banking sector of the Russian Federation provides for the accumulation, movement and redistribution of significant cash, taking into account the interests of economic agents. Failures in these processes will entail large-scale problems, such as a threat to the economic security of the state and failures in the functioning of payment systems.

The banking sector of modern Russia is characterized by the following processes:

- toughening competition in the banking services market;
- the impact of the effects of the crisis, resulting in a decrease in the financial stability of enterprises;
- strict supervision of the Bank of Russia over the activities of banks.

In the current conditions, commercial banks need not only to expand the scale of enterprises, but also to progress in the field of business performance. This goal in Russian practice is achieved by bringing the banking services and technological systems being implemented closer to international standards. Absolute competitive advantage in such competition is already established by credit institutions with sufficient resources to invest in new products and services and to introduce new technologies. The creation of conditions allowing customers to feel most comfortable belongs to the same category. The implementation of this direction is achieved through the creation and successful functioning of mobile banks and online services. These forms of interaction with consumers are beneficial to both parties due to the reduction of costs for such elements as service time and maintenance of staff and offices for them. The result of such actions are banking innovations.

Materials and Methods

The first bank in Russia that did not have a retail service office at the time of its establishment was Tinkoffbank. The official creation of the organization dates back to 2006, it was positioned as the first bank that has a remote control at its disposal, referred to as Tinkoff Credit Systems. Over more than a decade of activity, the organization's assets have increased significantly, namely, in 2007 this indicator amounted to 2.4 billion rubles, in 2018 it amounted to 377.7 billion rubles. As of 01/01/2019, the bank ranks 21st in net assets among Russian credit organizations, actively implements its activities and is positioned as the first innovative bank aimed at entrepreneurs in the Russian Federation.

In addition to offering the latest technologies at the time of creation, the bank serves as an example of the development and implementation of a joint business, the basis of which is the provision of services with a minimum of investment with a virtual absence of own assets. Other banks are actively working in this direction, making serious competition.

The main obstacle to the implementation and operation of innovative banking systems in Russia at the present stage is significant costs, the implementation of which is available to a small circle of system-forming enterprises. In the process of their implementation, many medium and small banks are absorbed by larger ones, which inhibits competitiveness.
One of the main goals of introducing innovative developments is to increase the competitiveness of not only individual banks, but also the entire banking sector of the country.

The processes of introducing such technologies are carried out in two directions:

1) development of financial products;
2) the introduction of financial products.
The range of banking products, taking into account constantly evolving technologies, is being actively marketed by large banks in Russia, includes Internet banking, online trading, quick money transfer systems, a system for linking cards to bank accounts, NFC system and other services. However, many banks do not put into practice Internet trading and a quick money transfer system.
Based on the statistics provided by the international analytical agency Markswebb, a list of eleven Internet banks operating most efficiently and conveniently for users in 2019 is presented in Table 1.

Table 1: Performance rating of Russian Internet banks in 2019

№	Internet bank	Performance rating (0-100 points)	Functionality (0-10 points)	Convenience (0-10 points)
1	Tinkoff Bank	78,7	8,4	7,3
2	Bank Left Bank	68	6,9	6,7
3	AK Bars Bank	64	6,4	6,4
4	Uralsib Bank	61,7	6,6	5,7
5-6	Post Bank	60,5	6,1	6
	Raiffeisenbank	60,5	6,1	6
7	Promsvyazbank	60	5,9	6,1
8	Bank opening	59,5	6,7	5,1
9-11	Corn Map	58	5,8	5,8
	Russian standard	58	5,9	5,7
	Internet bank	58	5	6,5

In 2019, Tinkoff Bank became more convenient for users in terms of functional component and interface. Achieving a leading position was possible in connection with the implementation of many functions, namely:

1) automatic determination of the issuing bank and payment system based on the used bank card number has become available;
2) the search form for such debts as fines of the GIBLL and various taxes has been improved;
3) it is possible to implement user limits on the card by type of operation and the ability to block cards has been improved;
4) it became possible to open current accounts and issue cards online without having to visit a bank branch and contact a contact center.

At the development and improvement stage, such common functions as customer support in online chats and platforms for receiving information on the amount of debts on public services and utility payments are currently underway.

According to the data of the National Agency for Financial Research in 2019, more than 81% of all online users in the world prefer the services of online banking rather than mobile banking. In Russia, 69% of the population turn to the help of a mobile bank, of which 52% use its services one or more times a month, 17% - once a month or less.

According to statistics, this service is more in demand among women than men. This ratio is 72% and 66%, respectively. In addition, the largest share of users is a young audience aged 25-34 years, namely 76%. The most popular functions of mobile and Internet banking include crediting funds to pay for mobile communications (76% of users of these services) and monitoring the status and operations of cards and accounts (67% of users). Such types of services as transfers to other individuals, payments for using the Internet and transfers between own accounts carried out via the Internet bank were carried out by 61% of respondents. Payment of online purchases through a mobile bank was carried out by 38%, and through online banking 53% of users of these services. Services on investment transactions are of minimal demand. Similar operations are performed by approximately 2% of users.

The growing popularity of online banking is due to several reasons:

1. Low cost charged for various operations, or its complete absence. Using the services of a mobile bank requires certain costs, such as servicing bank cards, SMS notifications and fees for using the bank itself. These factors encourage users to increasingly turn to Internet banks;
2. Accessibility and ease of use;

3. The quality of service offered by mobile banks is inferior to Internet banks in this category because the latter has a wider range of services. Certain operations are either imperfect in their execution or not available in the mobile application.

Research Results and Discussion

The advantages of mobile and Internet banking are actively exploited in the banking services market. Significant consumer demand stimulates the introduction of the latest technologies in these platforms, otherwise their stagnation, combined with the advent of alternatives in the market, will lead to a massive outflow of customers and, consequently, lower profits. For this reason, most existing banks practice the introduction, development and improvement of these technologies.

Particular attention in Internet platforms is given to transactions - quick money transfer systems. There is a tendency to introduce information technologies for transferring to the "cloud". “Cloud” technologies are a multifunctional environment, consisting not only in the storage and processing of information, but also combining licensed software, hardware, communication channels and operational technical support for users. Their feature and at the same time their advantage is the lack of attachment to certain devices and territories. This means that it is possible for the user from any technical device, regardless of geographical location, having access to the Internet, to be able to manage funds and use banking services.

One of the successful examples of the implementation of "cloud" technologies was Sberbank PJSC, on the account of which the introduction of three products in the field of API (platform of ready-made templates for creating new information tools):

1. Fintech API - a set of methods and tools for corporate clients to integrate affiliate services and products;
2. Internet Acquiring API - providing the ability to quickly integrate Internet acquiring into a bank's product, that is, selling goods and services through the Internet and bank cards through Apple Pay and mobile applications and sites;
3. API DomClick - a tool designed for developers and real estate agents. Its goal is to integrate the accounting system with the DomClick platform. This method allows you to automate the process of applying for loans and checking the current statuses of these applications.

Additionally, it is possible to observe bank statistics.

An important role in the implementation of technologies is played by the use of artificial intelligence, the introduction of which may become mandatory in the activities of commercial banks. The constant change in the market, technology and customer base requires in-depth personalization, the implementation of which is impossible without the latest technology.

A good example of the effective use of artificial intelligence is the project of Sberbank PJSC under the name Iron Lady. Its function is to notify individuals about their loan debt. The introduction of this system allowed Sberbank of Russia to close more than 1.3 thousand branches in the country in 2018. However, it is not planned to reduce the growth rate of their closure. A similar practice applies to employees of a commercial bank. According to the chairman of the board of PJSC Sberbank, by 2025 their number is planned to be reduced by more than half. The obvious advantages of artificial intelligence in comparison with an ordinary employee are the ability of the former to work for 24 hours a day, his lack of tendency to psychological disorders and the possession of an unlimited amount of knowledge that contributes to the solution of many issues. This tool is very successful in managing the costs of the organization.

Currently, the development and implementation of blockchain technologies that contribute to the improvement of transaction services and accreditation are actively underway. Blockchain is a new technology direction, namely a database with specific rules for constructing transaction chains and access to information that excludes data theft and any cyber attacks. The blockchain base can be a

platform for the concentration of any open registries that record transactions. Payment verification will be provided by the resources of the system itself. When using blockchain technology, any operation requires a confirmation request, in parallel with which all data will be encrypted with a code, and the user's personal information will not be publicly available.

Initially, this technology was adopted on the territory of the Russian Federation ambiguously, but after some time it took positive prospects in the country's banking system.

Distribution in the field of innovation development management is currently received by fintech startups acting as developers of alternative solutions to improve the quality of services provided by banks. As competition in banking services is increasing, a greater number of credit institutions are approaching venture investments, where domestic fintech startups are the objects of investment of financial resources. The main objective of the interaction of banks with them is the development of innovative products.

In 2016, with the assistance of the Bank of Russia and the Ministry of Finance, a competition of fintech startups was launched. The main objective of the event was to search for startups offering the most promising technologies in the field of finance. The victory was won by the Oz Photo Expert project, whose specialization is express analysis and identification of fake photographs and documents in electronic form.

An important innovation system used in Russian banking is the merger of bank accounts with cryptocurrencies and electronic payment systems. Payments in the electronic system allow cashless payments, conclusion of contracts and transfer of funds via the Internet. To implement this process, automatic information processing and encoding are used. This system creates convenience for customers of the bank, but at the same time does not exclude the risk of data theft.

The main task of innovation management at present is not only the introduction of the latest technologies, but also in predicting their payback. The average technology implementation period is from 1 year to 5 years, and in some cases exceeds these values. The complexity of the process itself, the price of technology and the services of its implementation, the availability of space for its application can affect this.

Table 2 presents the positive and negative aspects of the application of innovations in the activities of commercial banks.

Table 2 - Advantages and disadvantages of the application of innovations in the banking system

Positive aspects and prospects	Disadvantages and possible negative consequences
1. Improving the usability of banking services by customers of a commercial bank	1. Increase the likelihood of theft of cash
2. Reducing the cost of banking operations	2. The increase in the total cost of introducing technology
3. Expanding the customer base and increasing the competitiveness of the bank	3. Continuous investment in new technologies
4. Reduction of time for banking operations	4. Tighter control of operations

5. Increasing the number of banking services and products, increasing the efficiency of their provision	5. Dependence on technology updates
6. Improving the functional component of banking applications and developing the service	6. The increase in bank costs for the study of consumer needs
7. Reducing the cost of labor and rental premises	7. Increased likelihood of unemployment due to job cuts
8. The implementation of new investment ideas, improving the efficiency of banking	8. The unpredictability of the consequences of the introduction of technologies and forecasting their payback, high investment risks

Based on the data presented in table 2, it can be concluded that innovative technologies have significant advantages for bank customers, namely they help simplify banking operations, increase the ability to use more profitable services, and reduce the cost of their implementation. The main advantage is the ability to access all over the world.

Conclusion

For commercial banks, the introduction of innovation is a time-consuming process that requires significant costs. It includes the involvement of all participants in the banking process, starting from the issuer and ending with manufacturers of electronic devices that ensure the operation of relevant programs. However, in the context of globalization, innovative technologies in the banking sector are an integral requirement for the activities of domestic banks and an important factor in the choice of their customers. The lack of data from the implemented technologies has a negative impact for the bank, which is expressed in a reduction in the number of customers, a decrease in income and profits from the implementation of core activities and, as a result, a decrease in the financial stability and solvency of the organization.

However, it should be borne in mind that not all innovations are effective for commercial banks. So, for example, based on an assessment of the benefits from start-ups sold by Russian banks, the profitability from their implementation is about 2% of the total profitability of bank products. Against the background of such results, fintech startups look most profitable.

The most promising areas in Russia are the areas of blockchain technologies and “cloud” data that can not only increase the efficiency of the banking sector in the country, but also use the experience of the banking sectors of the world.

Rapid development is carried out in the field of implementation and functioning of artificial intelligence, which occupies the position of the basis for the implementation of innovative projects.

In general, the introduction of innovations has a greater positive effect on the country's banking sector. In a short period of time, technologies have qualitatively transformed the bank management system, simplified the process of using the bank for customers and allowed it to reach an international level. Innovation is an integral element of the country's banking sector, and without their use, commercial banks will not be able to fully satisfy the growing rapidly needs of customers, to secure financial stability. At the same time, the use of innovations increases the risks of lowering financial security; for this reason, a number of measures should be taken aimed at strengthening the protection

of customer data. In the case of ensuring financial security and better selection of the most profitable innovative projects, the efficiency of the Russian banking system will be significantly increased.

Abstract

The role of socio-economic indicators as the main indicators of the level of economic development of the regions is determined in the work. On the example of the subjects of the Central Black Earth Region, the analysis of the main socio-economic indicators (GRP, population, unemployment, foreign direct investment, etc.), as well as indicators characterizing the industries of the regional economies, in order to identify priority areas and study the situation in the regions generally. Based on the study, conclusions are drawn about the development of the regions of the Central Black Earth Region.

Keywords*:* Regional Economy, Investment Climate, Foreign Direct Investment, Economic Development.

Introduction

The development strategy of the regional economy is based on ensuring the optimal development of regional economic complexes, improving the specialization of the territory of the subject, efficient use of production capacities, labor resources, as well as maintaining the general well-being of the population. Indicators of regional development are socio-economic indicators that characterize the economic phenomena and processes taking place on the territory of a subject at a given point in time. It is the assessment of basic socio-economic indicators that helps to evaluate:

- the level of development of the national economy;
- the degree of provision of labor resources and the level of their qualifications;
- the unique properties of the region, having value on a national scale and by global standards;

- the degree of provision of the region with natural resources;
- socio-political stability in the region;
- the geopolitical position of the region.

Materials and Methods

Using the example of the regions of the Central Black Earth Region, we will evaluate the main socio-economic indicators in order to identify leaders and outsiders among the subjects under study for overall economic development.

The Central Black Earth Economic Region (Chernozemye) is one of the 12 economic regions of the Russian Federation, which includes the regions of the southern part of Central Russia: Belgorod, Voronezh, Kursk, Lipetsk and Tambov regions. Currently, the largest industrial and economic center of the region is the city of Voronezh. Entered in 2000 As part of the Central Federal District, the Central Black Earth Region specializes mainly in the mining, metallurgical, machine-building, chemical, food industries, as well as in agricultural production and the production of certain types of building materials. The sectors complementing the territorial complex and serving the immediate needs of the population of the region include various sectors of light industry and the service sector.

Research Results and Discussion

The main socio-economic indicators of the Black Earth regions for 2019 are presented in table 1.

As can be seen from the data in table 1, the highest level of GRP in the regions belongs to the Voronezh region - about 30% of the total GRP in the regions of the Black Earth Region. She owns a high population of 2.3 million people, as well as an area of the whole territory (52,216 km²), the average wage in the region (24,001 rubles) and a high unemployment rate (4.5%) among all regions. Despite the high level of GRP, the leader in the highest per capita GRP is Belgorod Oblast, which exceeds the Voronezh Oblast by almost 42%.

Table 1 - Socio-economic indicators of the regions of the Central Black Earth Region for 2019

	Belgorod Region	Voronezh Region	Kursk Region	Lipetsk Region	Tambov Region
GRP, Million Rubles	785647	865223	387577	497981	300554
Per Capita GRP, Rub.	369139	260410	243268	271125	219948
Population, Thousand People	1548	2331	1117	1158	1062
Area, Km²	27134	52216	29997	24047	34462
FDI, Mln.	236,2	261,8	66,2	842,9	13,6
Average Salary, Rubles In Month	23895	24001	23099	23133	20757
Unemployment, %	4	4,5	3,9	3,7	4,3

Belgorod region also has a high level of GRP, occupying 2nd place in the regions of the Chernozem region. She takes the same position in terms of average salary per month: for 2019, she is 23,895 rubles.

The Lipetsk region has average indicators of GRP, population and average wage per month. This region has the highest foreign direct investment among all regions: in the reporting year they amounted to $ 842.9 million, which is almost 62 times higher than the minimum value among other regions of the Black Earth Region. This is due to the implementation of existing large-scale foreign projects in the region, as well as the construction of new large complexes and the development of a special economic zone as a whole. In addition, this entity is one of the three regions of the Central Federal District for foreign direct investment, second only to Moscow and the Moscow region. In addition, the Lipetsk region has the lowest unemployment rate of 3.7%, as well as a high per capita GRP of 271,125.4 rubles.

The lowest socio-economic indicators are in the Kursk and Tambov regions. The Kursk region has indicators slightly better than the neighboring Tambov region: unemployment here is lower by 0.4%; GRP and FDI are 87 million rubles higher. and 52.6 million dollars. respectively; the population, per capita GRP and average wages are also higher than the indicators of the last region, but lower than the average values for the entire Central Chernozem Region. The only criterion by which the Tambov region surpassed the Kursk region is the area area: it is 4465 km² larger than the territory of the Kursk region. In addition, the Tambov region is the only region in which over the past years there has been an abrupt change in the level of GRP: its decrease in 2018 and an increase in 2019.

To assess the general economic situation of the regions of the Central Black Earth Region, it is advisable to analyze the dynamics of indicators of sectors of the economy, namely, indicators characterizing production, construction, agriculture, and also the sphere of trade.

The dynamics of industrial production indices in the regions of the Central Black Earth Region is characterized by a decrease in indicators in almost all areas: the largest drop in indices in 2019 is typical for the Tambov Region - by -43%, although in the previous year it reached its maximum value of 137.2%. In the Kursk region, over the entire studied period, a tendency to a decrease in the indicator is observed: in 2018, it decreased by 9.6%, and in 2019 - by 2.5%. The growth rate in the reporting year was recorded only in the Lipetsk region: after the fall, the index grew by 2.5%. The general tendency to reduce the indicator under consideration may indicate a general decline in production in the regions, which negatively affects the investment climate in the region. Also, a decrease in industrial production indices indicates an increasing dependence on imports and less orientation on own goods.

The volume of work performed by the construction activity in all areas of the Black Earth Region in 2019 exceeded 304.4 billion rubles, which is 4.4% higher than the previous year. Of these, the largest share of work is in the Voronezh region (31%), and the smallest - in the Tambov region (11.4%). In the first, there is a steady decrease in the studied indicator over time over the years. A steady growth in construction work is characteristic of the Kursk and Lipetsk regions: in the reporting year, growth in these regions amounted to 8.4% in each. The growth in construction volumes in the regions is associated with the implementation of large agricultural projects, as well as with an increase in the commissioning of residential buildings.

Agriculture in the Central Black Earth Region is a leading industry in the economy of the region. Having favorable conditions for the development of agriculture, the agro-industrial complex of the regions of the Black Earth Region annually sets records for the gross production of various types of agricultural products. The leading place in agricultural lands is occupied by cereals - 55%, 28% under fodder crops, 12% under industrial crops and 5% under potatoes and vegetable and melon melons. In addition, large livestock complexes are located here, providing products not only to the regions of Russia, but also to other countries.

As for agricultural products, the Belgorod region remains the permanent leader in production over the years: in 2019, the total share of production in this region amounted to almost a third of the total agricultural production. High growth rates are characteristic of the neighboring Kursk region, which increased the volume of agricultural production, first by 15%, then by 12%. The Lipetsk region in the reporting year showed the highest growth among all regions of the Central Black Earth Region, increasing the indicator by almost 18%. In other regions, mainly in 2018, a decline in the studied indicator was observed: in the Voronezh region, the decline was 3%, in the Tambov region - 6.5%.

Non-food and food products, including drinks and tobacco, predominate in the macrostructure of retail trade in the regions of the Central Black Earth Region. The main volume of retail turnover was formed by trading organizations and individual entrepreneurs operating in a stationary trading network (outside the market).

In terms of retail trade in monetary terms, the first place is occupied by the Voronezh region, where according to the results of the last year the total turnover amounted to 552.3 billion rubles. In addition, this region is steadily increasing its performance, first by 6%, then by 7% compared to previous years. The second place belongs to the Belgorod region with a turnover of 336.1 billion rubles. The outsider in this rating is the Lipetsk Region, whose turnover in the reporting year does not exceed 120 billion rubles. It should be noted that in all regions of the Central Black Earth Economic Region, without exception, the dynamics of retail trade turnover is positive. The highest growth rates in the reporting year are characteristic of the Kursk and Lipetsk regions: 8% each, and the lowest - in the Tambov region: over the years, the growth rate does not exceed 3%.

Conclusion

Thus, a comprehensive analysis of the main socio-economic indicators helps to assess the current situation in the region, identify development trends in various sectors of the economy, and also make a macroeconomic forecast for the future.

The regions of the Central Black Earth Region, located in the very center of the European part of Russia, have the entire set of characteristics for successful socio-economic development. However, all of them have significant multidirectional vectors and economic development priorities. Belgorod and Voronezh regions remain the leaders in the main indicators characterizing the socio-economic situation, which indicates the high development of the sectors of the economies of these regions and a favorable environment for attracting investments for the further development of entities. The remaining regions have a less “weighty” set of characteristics in comparison with the leading regions, which indicates the insufficient development of some sectors of the economy and the ineffective implementation of the state strategy for the development and regulation of the socio-economic situation in the regions.

Abstract

Deliberations presented in the article pertain to the issues of project management with special consideration to the organization to project auditing within the Human Capital Operational Programme. The article is intended to indicate the organizational aspects of project auditing in Voivodeship Labor Offices as part of the Human Capital Operational Programme carried out in Poland between 2007 and 2013. The assumed research hypothesis is the auditing procedures condition the project management efficiency by establishing the principles to act and implement any remedial measures. A research method employed in the research was the existing data analysis, so-called desk research.

Keywords: Management, Auditing, EU Projects, Voivodeship Office.

Introduction

Accession to the European Union and adoption of the Act on the principles of development policy of 6 December 2006 allowed Poland to take part in economic development process and economic competitiveness in establishment of appropriate conditions on the labor market and a higher standard of live and social progress (European Union, 2012).

By initiating a number of activities related to socio-economic growth support for the member states, the European Union places particular stress on priorities listed in the EU cohesion policy in terms of supporting the development of the open society. Undertakings related to the process of applying for EU grants and their efficient implementation are becoming more and more important. Correctness of the planned undertakings guarantees rational management of EU funds allocated to entities and minimizes the risk of resources dispersion. Effectiveness of EU funds management depends on the efficiency of the whole management process, namely planning, implementing and auditing of particular projects. Financial management in the European Union may be compared to the process of financial resources management in individual states. An EU budget is established each year, which as a consequence allows to support the member states within 7-year financial perspectives.

The notions presented in the article are focused on characteristics of project management, with special emphasis on the auditing process according to the Operational Programme Human Capital under implementation between 2007 and 2013, which is one of the operational programmes of the European Social Fund (ESF). The essence of the auditing apparatus operation is supervision over the use of the funding from the ESF pursuant to the procedures established in the regulations. The legal foundations for the schemes for management and auditing of the projects co-financed from the ESF is the legislation of both the European Union and Poland.

ESF belongs to five major EU funds through which the European Union support the socio-economic growth in each member state in order to compensate for the differences in their development. The financial resources from the ESF are invested first of all in people, in particular those, who have difficulty finding employment on the labor market (Meredith, 2002, p. 89). One of the operational programmers within ESF is the Human Capital Operational Programme (HCOP) intended to adapt enterprises and their employees to a new and dynamically changing economic and market surroundings by increasing the level of education, improving health and eliminating areas of social exclusion.

Literature Review

In management sciences, auditing poses one of the key management processes within an organization, apart from planning, organizing and managing (Hejduk, 2016, pp. 33-34). Auditing which the function of management consists in checking and correcting the organization's operations in order to ensure that the undertaken tasks will be implemented, and the plans are developed to ensure that they are carried out correctly. In the simplified version of management cycle, auditing is the last stage. Management means auditing to a large extent, namely determining the standards of particular processes and actions as well as continuous supervision over their implementation (Surowiec, 2015, pp. 181-190), as well as intervening when auditing suggest any deviations from the assumed standards (Kirsch , 1996, pp. 1-21, Snell, 1992, pp. 292-327). Meanwhile, project management is a collection of actions performed in order to achieve objectives determined by the project management, both the main and the intermediate ones, in a specific time and using particular resources (Kisielnicki, 2014, p. 227). According to Turner (Bredillet, Engwall, 2003), project management is the art and science of transforming vision into reality. In other words, this is a process based on principles, tools, resources and techniques which allow efficient implementation of the assumed undertaking in conditions of repeated constraints (Miciuła, 2015). Projects and project management pose a key element in implementation of an organizational strategy (Morris, Jamieson, 2005, p. 5). Also within the EU operations, the project groups that form programmes or project portfolios play a key role (European Commission, 2019). They pose a component of larger undertakings, namely the European programmes (Bonikowska et al., 2006, p. 8). The project management practice is moving away from a traditional approach based on predictability and customary planning towards a flexible approach that emphasizes adaptivity, creativity, rapid and customer-oriented actions.

When considering the notion of auditing in project management, it is worth extending this aspect by this type of audit that is performed within the management of EU projects. Legal grounds for management and auditing systems for the EU funds spending can be found both in EU and Polish regulations. One of the key Polish documents that govern the main auditing principles for the EU funds spendings are *"National Guidelines on the Eligibility of Expenditure under the Structural Funds and the Cohesion Fund for the 2007-2013 Programming Period"*. Regulations significant from the perspective of project auditing are presented in the *"Guidelines for the Auditing Process within the Responsibilities of the Managing Authority of the Operational Programme"*. This document points to the auditing procedures carried out by the authorities that manage a particular operational programme (Rydzewska-Włodarczyk, 2011, pp. 296-305).

Research Methodology and Analyses

The Marshal's Office of the Silesian Voivodeship is the Implementing Authority within the framework of the Human Capital Operational Programme 2007-2013 in the area of the Silesian Voivodeship. One of the key actions laying in the scope of responsibility of this institution is to audit the source of project implementation under the programme in question and to explore the achieved deliverables. The Implementing Authority takes care of not only the implementation of various tasks that are directly related to coordination of the implementation of HCOP in the region but also of all issues related to supervision over the use of financial resources by the Intermediate Body (IB).

The function of the Intermediate Body of 2nd degree for selected actions from Priorities 6-9 for the regional component of HCOP is held by the Voivodeship Labor Office in Katowice for the Silesian Voivodeship.

The HCOP in the Silesian Voivodeship was a tool for socio-economic transformations. The positive changes, thanks to the EU funds, were visible in the whole region of the voivodeship (Project Management Institute, 2013). Thousands of people made use of the rich selection of advisory, training and internship programmes, as well as from non-repayable grants to start their own businesses.

The auditing process management in the Voivodeship Labor Office in Katowice requires conscious involvement of intellectual capital, identification of its key resources, strengthening of its value and determining conditions of its resources management. Implementation of priorities adopted by the Voivodeship Labor Office related to both implementation and auditing of the HCOP between 2007 and 2013 required some effective work organization, development of methods and techniques that consider the held resources so the created team of employees, both the management and executive staff, was open to acquisition of knowledge, adaptive and able to transfer the personnel competences to the whole institution (WUP, 2014). Quality of the projects at the selection and afterwards implementation state in the Silesian Voivodeship was borne by the qualified team of officers of the Voivodeship Labor Office in Katowice. The Voivodeship Labor Office employees should be aware that there are numerous resource dimensions that condition the effectiveness and competences in the performance of the official duties. The psychological-consciousness layer helps to identify the direction of changes necessary for self-improvement and self-fulfillment.

Identification of the key intellectual capital consisting of among others knowledge, experience, qualifications, intelligence, reliability, energy, age, etc., allows the managerial staff to correctly delegate the tasks so the natural predisposition of employees helped them in implementation of objectives of the whole institution (Miciuła, 2016).

Diagram 1 presents actions that stimulate development of intellectual capital in the Voivodeship Labor Office, includes training, improvement of qualifications, selection of employees, effective system of recruitment, evaluation of employees, planning of individual development of an employee, team work, advantage of oral communication, strict cooperation with the managerial staff, consultation between units and individual Voivodeship Labor Offices, transfer of knowledge among employees, time for thinking and evaluating one's own work, shaping of effective organizational structure and culture, management of knowledge, education of employees, loyalty, care of reputation, monitoring of needs and expectations of beneficiaries, computer hardware and software.

The Voivodeship Labor Office management factors presented in the below diagram influence the effective management process for an institution and its individual departments. Correct interpretation of the listed determinants is a source of success of the office and its staff.

Source: Own work on the basis of: D. Bubel, Intellectual capital management in non-profit organizations. Case study for public libraries, WZ Publishing House of the Częstochowa University of Technology, Częstochowa 2016, p. 174.

Dedicating tasks to an appropriate group of employees, an individualized process of knowledge acquisition and identification of their competence become crucial in achieving the intended strategic objectives. This concerns in particular the adopted from of recruitment of the project auditing employees, who apart from official contacts inside the office with persons with similar professional competence and clients, also cooperate with entrepreneurs, beneficiaries, often in untamed and uncomfortable places. It must be borne in mind that specificity of auditing creates a natural distance between the auditor and the audited, therefore it is impossible to fulfill the official duties of auditing without specific skills, experience and adaptability.

Ultimately, implementation of actions related to HCOP was related to separation of 118 functions (including Director / Deputy Director of the Office, Chief Accountant and Heads of the following departments: Project Selection and ESF Monitoring, ESF Projects Management and ESF Audit). The units directly involved in the implementation of HCOP are:

- Project Selection and ESF Monitoring Department with 33 full-time employees,
- ESF Projects Management Department with 31 full-time employees,
- ESF Audit Department with 36 full-time employees,
- ESF Projects Financial Support Team with 10 full-time employees.
- The remaining organizational entities conducted only some supporting activities within the implementation system for HCOP 2007-2013.

While analyzing the organizational scheme of the Voivodeship Labor Office in Katowice, the following organizational entities can be distinguished within the scope of ESF along with the area of their activities (developed based on *Opis Systemu Zarządzania i Kontroli dla komponentu regionalnego Programu Operacyjnego Kapitał Ludzki 2007-2013 w województwie śląskim*, August 2014, pp. 6-10):

1) The Promotion and Information Team, which dealt among others with:

   - implementation of the Annual Information and Promotion Plans,
   - conducting information and promotion activities for HCOP,
   - service of the ESF Information Point,
   - implementation of Technical Assistance in the field of promotion and information,
   - coordination of projects implemented in the Office within the framework of Technical Assistance,
   - receiving and registering incoming applications for funding.

2) The Call for Proposals Team, which carried out tasks in the scope of, among others

   - announcing competitions,
   - conducting calls for proposals,
   - formally assessing the applications related to funding of competition projects,
   - organizing the works of the Project Evaluation Committee,
   - drawing up ranking lists of projects,
   - carrying out the appeal procedures, with the exception of those persons who carried out formal or substantive assessment.

3) The Monitoring of Actions and Programming Team, whose main tasks included among others:

   - developing the assumptions for implementation of actions,
   - developing of materials necessary to prepare the Action Plans,
   - preparing and updating of detailed procedures related to HCOP 2007-2013 implementation based on information and data handed over by the remaining organizational units of the Voivodeship Labor Office in Katowice,
   - developing the competition documentation for the implemented actions,
   - preparing the reports on the implementation of actions and quarterly information to the Intermediate Body, in this case the Silesian Marshal's Office,
   - collecting of aggregate data which were related to individual projects, necessary for on-going and ex-post evaluation,
   - responsibility for substantive support for IT systems.

4) Competition Projects Team, taking care of, among others:

   - preparing contracts related to funding of the competition projects,
   - analyzing changes in the projects,
   - annexing the contracts,
   - formal and substantive verification of the beneficiaries' applications for payment,
   - handling the personal data of project participants,
   - on-going cooperation with the beneficiaries.

5) The System Projects Team, which was entrusted with tasks in the following areas, among others:

- preparing assumptions which were related to system projects,
- formally and substantively verifying the applications related to funding of system projects,
- preparing of framework contracts for system projects,
- analyzing of changes occurring in system projects,
- annexing of framework contracts,
- formal and substantive verification of the system beneficiaries' applications for payment,
- handling the personal data of project participants,
- on-going cooperation with the beneficiaries,
- formally and substantively verifying the applications related to funding of system projects of the Intermediate Body, in this case the Silesian Marshal's Office, IB and the Intermediate Body of 2nd degree, namely the Voivodeship Labor Office in Katowice,
- preparing the principles for implementation of system projects of the Silesian Marshal's Office and the Voivodeship Labor Office in Katowice,

6) The ESF Projects Financial Support Team undertook actions related to, among others:
   - making payment to beneficiaries,
   - keeping the accounting records of expenditure in relation to the implemented measures,
   - preparing thee forecasts of expenditure related to the implemented measures,
   - preparing information on any irregularities for the ESF Audit Department,
   - recovering of sums unduly paid as a result of the taken administrative decisions,
   - entering the Beneficiaries in the register of those excluded from the possibility to apply for funding.
   - The Budget and Accounting Team, whose task was to provide financial services for projects implemented in relation to Technical Assistance. The organizational scheme provides for 1 full-time function for implementation of this measure.
   - Legal Counsel, who supervises the process of HCOP implementation in the Voivodeship Labor Office in Katowice in legal terms, *"including formal and legal verification of documentation related to the implementation of ESF Programmes, opinions and initialing of agreements and annexes to agreements on project financing under ESF Programmes, ongoing cooperation and legal consultations with organizational units dealing with the implementation of ESF Programmes"*- 1 full-time function is foreseen.
   - Department of Logistics, IT and Public Procurement, the role of which was to perform tasks in the field of Technical Assistance, concerning the provision of necessary logistic and hardware resources for the personnel of departments dealing with the HCOP implementation. The organizational scheme provides for 1.5 full-time function for implementation of this measure.
   - The IT Team dealing with on-going maintenance of IT systems - 1 full-time function is foreseen.
   - Human Resources and Training Team, the role of which was to ensure HR development, prepare and implement the plan of trainings and implementation of Technical Assistance in terms of HR and training support. The organizational scheme provides for 1 full-time function for implementation of this measure.
   - A stand-alone Internal Audit function, the task of which was to collect and develop information on irregularities and risk assessment. Significantly, *"the staff member holding this function is engaged in an independent and objective evaluation of management control and advisory activities in accordance with the internal audit plan for the year in question"* - 0,5 full-time function provided for in the organizational scheme.
   - The Labor Market Programs Department, the task of which was to prepare and implement projects within the European Union programmes.
   - Directors of the Branch Offices of the Voivodeship Labor Office in Bielsko-Biała and Częstochowa, implementing tasks related to, among others, servicing thee Information Point and exercising official supervision over Control Teams in individual units. Furthermore, *"they are responsible, among others, for day-to-day cooperation with the Promotion and Information Team, in particular for carrying out activities within the scope of promotion and information of the ESF and provide employees, subordinate directly to the*

heads/managers of organizational units, with substantive tasks defined by heads/managers of these units (including the ESF Audit Department)".

The auditing of projects within the Human Capital Operational Programme 2007-2013 carried out by the Intermediate Body of 2nd degree was based on the audit of documentation and on-site audits of project implementation. The Voivodeship Labor Office in Katowice audited the project implementation with reference to the guidelines provided for by the Intermediate Body in a contract as well as based on instructions of the Management Authority and the Intermediate Body. The Voivodeship Labor Office in Katowice audited the system projects and competition projects in parallel. Furthermore, it audited sustainability of operations/deliverables.

Two teams were responsible for auditing documentation in accordance with the procedures: Competition Project Team and System Project Team. In the case of the audit in question, the applications for payment posing a part of the project documentation were audited. The content of those applications included eligible expenditure incurred under the project with consideration of the description of material progress. Three teams were responsible for on-site audits of the projects: Audit Team in Katowice, Audit Team in Bielsko-Biała and Audit Team in Częstochowa. They operated within the ESF Audit Unit. Their activities regarded a particular project and were intended to verify the compliance of project implementation with its initial assumptions as well as the funding contract.

The essence of these audits was the fact that they were carried out in accordance with the Annual Audit Plan of the Voivodeship Labor Office in Katowice, verified and approved by the Marshal's Office of the Silesian Voivodeship. The plan covered the methodology of selecting a sample of projects to be audited and was approved by the Director of the Voivodeship Labor Office and then submitted to a higher instance for approval. Furthermore, the information related to the performed audit were handed to the Intermediate Body not only after each quarter in a given calendar year in a form of a report, but also in annual reports from implementation of Annual Audit Plans of IB2.

Sustainability checks of operations/deliverables are carried out in connection with the obligation to maintain the sustainability of operations/results within the implemented projects. The selection methodology was included in the Annual Audit Plan. Verification was employed in the case of those documents that confirmed fulfillment of obligations related to maintaining durability of operations/deliverables considering the sample of documents chosen based on the sampling procedure included in the Annual Audit Plan. Checklists were used during the audit and at least 10% of documents concerning project participants as well as financial documents were verified. In other areas, at least 5% of documents were subject to auditing.

The Voivodeship Labor Office in Katowice, holding the function of IA/IB2, was also obliged to carry out auditing at the end of the project implementation, namely after the beneficiary had submitted the request for final payment, but before the request was approved. The audit focused on the problems of verifying the completeness of the documentation and its compliance with the rules and procedures, in particular with regard to the expenditure included in the Beneficiary's payment requests, which is a prerequisite for an adequate audit trail. The ESF Audit Department conducted some monitoring visits in the place of direct implementation of a specific form of support. Another form of the audit were the monitoring visits, carried out with the participation of employees of the Voivodeship Labor Office in Katowice, at least once for all projects included in the Annual Audit Plan. Depending on the staff capabilities and legitimacy, the number of visits may have increased. This type of audit was carried out with the participation of two employees of the Audit Department, without informing the beneficiary of the intention to carry it out beforehand.

Summary

The article was intended to indicate the organizational aspects of project auditing in Voivodeship Labor Offices as part of the Human Capital Operational Programme carried out in Poland between

2007 and 2013. The assumed research hypothesis was the auditing procedures condition the project management efficiency by establishing the principles to act and implement any remedial measures.
The EU funds are a tool for searching for innovative solutions to known and identified problems, but they can also serve to identify areas that have been neglected so far. The EU funds pose an opportunity for development not only for individual regions or states, but first of all for the residents, because their key objective is to improve the social cohesion. Both the ESF and the ERDF create a kind of bridge between social groups, between children, adolescents, senior citizens, the unemployed, workers and entrepreneurs.

It is significant that the financial activities of the European Union are directly related to member states' initiatives, including Poland, when it comes to the possibilities of risk arising from both frauds and other illegal actions and operations that have adverse impact on the EU budget. Therefore, in order to counteract any undesirable actions on the part of beneficiaries, numerous regulations concerning project auditing have been introduced, which allow to minimize the level of occurrence of fraud and irregularities. In addition to the European Commission, the European Anti-Fraud Office and the European Court of Auditors are the institutions authorized by the EU to carry out project audits, while in Poland it is the President of the Public Procurement Office and the Supreme Audit Office. The Voivodeship Labor Office in Katowice participated in the audit process of the projects co-funded by the European Union as the Intermediate Body of 2nd degree and at the same time the Implementing Authority. In relation to the Human Capital Operational Programme 2007-2013, personnel of the Voivodeship Labor Office in Katowice performed almost 1900 audits of projects implementation. These were planned, ad hoc audits and monitored visits. Furthermore, there were also verification audits in relation to post-audit recommendations issued by the Voivodeship Labor Office in Katowice within almost 950 audits. They were intended to eliminate irregularities and infringements, which were identified by the auditors during verification of the documents presented by the project beneficiaries. The researched entity performed adequately the planned audits of projects.

The audits are performed in relation to the obligation of sustainability based on the methodology included in the Annual Audit Plan. The considerations undertaken in this article allowed for a positive verification of the hypothesis, thus it can be concluded that development of methodology determines the efficiency of EU project management in relation to auditing as one of the management functions.

Abstract

This article discuss community participation in the local tourism development at an ex-gold mine area . The locals that were enjoying mining-based economy through informal jobs were losing their job. However, they find a new opportunity through a tourism-based economy that is initiated by the local ellites and the gold-mine company. The local community is thriving to participate in the development of the village tourism potentials. However, community participation is unequal among the locals. The local elites use their previous connections with mining sponsors to build a new tourism businesses. The village officials also have the advantage to participate in developing and operating new tourism business by using the district official resources.Local participation in tourism development is low due to the lack of access to information, network, and resources.

Keywords : community-based development, community participation, tourism impact

Introduction

Bantarkaret village is like many other villages in a mining area. The villagers are enjoying prosperity life under a non-formal economy generated from mining activities. Since the beginning of gold extraction by a gold-mine company in 1992, there were hundreds of illegal mining activities by the *gurandil,* the local word to say illegal miner. Even though both the legal and illegal mining activities involve the locals. The gold-mine company hire the locals as labor, security personnel, catering, or other services. However, illegal mining activities give more economic advantages to the villagers. The conventional mining technique that is used by illegal miners requires a lot of labor that usually done by the locals.

However, the mining activity is coming to its end. The concession of the gold-mine company to extract gold in the area only valid until 2021. Meanwhile, illegal mining activity done by the *gurandils* is already prohibited since the end of 2015. This development gives a significant impact on the Bantarkaret village, especially in economic terms. There are a lot of villagers who lost their source of income. This social phenomenon indicates that the local community has a strong dependency to natural resources (John, et al, 2014; Delgado-Serrano, 2017). However, the villagers have a new aspiration to continue their economic life. The early development of tourism potential by various parties in the village has inspired the villagers of Bantarkaret to participate in the tourism businesses.

The transformation of ex-mining area into a tourism destination has become a common practice of sustainable mining (Hidayati and Delianto, 2016). The mining area usually left critical after a long

period of natural resource exploration and exploitation. One of the methods to revitalize a critical land is by altering the land use, which in this case is to turn it into a made-up tourism destination.
The gold-mine company corporation has announced the plan to transform the gold mining site into a tourism destination that is ready to operate in 2021. Specifically, the gold mining site, which is in Bantarkaret village, is in a process of alteration into a gold mining museum. As part of the plan, the gold-mine company already builds two tourism destinations near the area, namely the Kawasan Wisata Cikaret (Cikaret Tourist Area) and the Taman Buah Nusantara (Nusantara Fruit Park). Both tourism destinations are designed as a tourism destination for family and group. The construction of both facilities is finished; however, the commercial opening is yet to be decided by the gold-mine company. The Bogor District officials has launch a tourism development initiative called as the Geopark Pongkor (Pongkor Geopark). The initiative consist a series of tourism destinations around the Pongkor Mountain, including the tourism potentials in the Bantarkaret village.

This working paper is aiming to depict the struggle of the local community in Bantarkaret village to participate in tourism development. For many years the local community of Bantarkaret village depends on their economic life to external parties through the mining activity. To get the benefit of tourism activity in the village, the local community has to participate actively since the early development of tourism potentials (Patanaude and Lewis, 2014).

Literature Review

Several studies have confirmed the effectiveness of transforming an ex-mining area into the tourism area to support the community and the environment sustainability. Research in Bojonegoro regency by Suprayoga in 2008 depicted the process of social change, from a coal mining economy to the tourism economy. The process was running smoothly and in a fairly short time. This happened because the coal mining company was leading the process, and the local community was taking the advantage to participate in a new economic creation in the tourism business (Suprayoga, 2008). Another study in the same regency also confirm how tourism potential could be harness from the natural richness, namely the local forest (Soedarso, Nurif and Windiani 2014).

Several studies also suggest the possibility to revitalize a critical land by transforming it into tourism destination. One of the example comes from Pangkal Pinang, where an ex-copper mine was revitalized by creating a made-up tourism destination (Hidayati and Deliyanto 2016). The ex-copper mining activity leaves a critical land that is no longer productive. To generate a new source of economic, tourism objects were built on that land as a new economic driver. The local people then attracted to participate in their way to support the tourism business as their livelihood. Similar conclusions also come from a study by Carl Cater in 2011. He describes the local community participation to support the tourism business in the Mount Rinjani National Park. The locals provide various services to support the tourist, including lodging, local guides, and transporters of tourist goods or commonly called as porters (Cater, 2011). These studies imply that local community always seeks the way to adopt to the change in the area where they live.

Sustainable development requires the local community participation because negative opinions from the community may hinder the local development. Community participation in tourism development is influenced by their level of awareness toward the development process (Cardenas, Byrd, and Duffy, 2015). One of the ways to upgrade community awareness is by involving them start from the planning sequence to the commercial sequence (Byrd, and Gustake, 2007). Even though it is almost impossible to involve all members of the community in the process, local stakeholders' commitment to the planning process could generate positive opinions regarding tourism development. The involvement also creates supportive perceptions and actions of the community to the development process (Torn, et al, 2008).

The element of tourism village is its whole potential, which can be a space that convertable to be a tourism destination, such as waterfall, hills, agriculture, or simbolic things such as arts and culture (Sugianto, 2016). To develop a tourism business, it is important to form a good tourism management that is to form an organizational structure, creating a conducive organizational climate, capable human

resources in managing organizations, technology that can support business development and most importantly the tourism potential itself (Ghorbani, Amir et all. 2019). Community-based tourism management is not separated from the first four main principles, there are the principle of community participation, natural resource conservation, local economic and the principle of socio-cultural conservation (Wiwin, 2019). These four principles encourage the development and direction of community-based tourism.

Method

This study combines both qualitative and quantitative data collection techniques. The qualitative method is implemented through a series of focus group discussions and interviews with the local officials and community members. The data are used to depict how the community member participates in tourism development.

The quantitative method is used to represent the physical condition of the village, especially the progress of tourism facility development. The data obtained from aerial imagery and field surveys. Spatial data is obtained from aerial imagery downloaded through the Geospatial Information Agency (BIG) portal. Meanwhile, the attribute data which is the tourism object location as the main information in the map is obtained from field survey.

Data processing techniques to produce a map using geographic information systems (GIS), a computer-based system for storing, manipulating geographic information (Syam'ani, 2016). The stages of processing map in the ARC GIS application, starting with the basic map input, there are the village administration and the coordinate point of each attraction. Then, map processing continued by digitizing the location of tourist objects, roads, and supporting facilities in the village. Digitization is the conversion of analog to digital (Savic, 2019). Lastly, is the layout process which purposed to display the scale, the legend, and the map inset.

Finding and Discussion

Bantarkaret village is amid social and economic change. In the past 20 years, the villagers were highly depending on illegal mining activities. The illegal mining was using simple technologies and involved a quite number of unskilled labors. As the gold reserve is depleting, and illegal mining activities are significantly decreasing, the locals can no longer depend on the mining activities. Improving the local engagement with tourism activity could be the main solution to prevent the locals from being excluded from the ongoing process of tourism development in the village.

The development aims to create a better living for the community. A development that is enjoyed by a small number of community members is considered as a partial development. The impact of development should be enjoyed by all. The participation of community members in tourism development, in general, is low. Only local elites who manage to open and run the tourism business. They use their social capital to convince their network to invest in the tourism business under their supervision. These group of local elites are villagers who are previously involved in mining activities.

The gold-mine company can maintain its influence even though its mining business is about to end. Like many other mining companies, the gold-mine company obliges to maintain the sustainability of the environment and community. Thus, they plan to alter the mining site into a tourism destination in the form of a gold mining museum. Their plan is already in motion. The gold-mine company is creating a new family park called with the Taman Buah Nusantara and the Kawasan Wisata Cikaret. These two tourism destinations are located at the access road to the mining site in Bantarkaret village which have made Bantarkaret village become a part of the Pongkor Geopark tourism development initiated by the Bogor Regency government.

There are positive responses from the local community to the ongoing process of tourism potentials development in the Bantarkaret village. However, community participation is considered low because of the lack of access to information and resources. Only a few people that represent the local community and participate in the tourism potentials development, they are local elites.

The local elites that are involved in tourism development can be classified into three groups. First, the local elites who previously involved in illegal mining activity. Second, the local elites who are involved in the village district office. Third, the local elites who are involved in the gold-mine company. gold mining activity. These three groups could involve in the planning and management of the tourism destinations. However, they are still working on the coordination among them, especially in setting their position to the gold-mine company, as the prominent source of tourism development in the Bantarkaret village.

Table 1: The typology of community elites that actively involved in the tourism development

No	Community Grouping	Informant	Testimony in interview sessions
1.	Involved in Illegal Mining	Mr O	Even if I have to prepare the paperwork to legalize my tourism business, I am ready. I have already prepared the land for the parking lot, only about 2 - 2.5 hectares, here near the village. I am building an Off-road area in the mountain. ... that Kawaci [The Taman Wisata Kawaci] was built by the gold-mine company and they had wanted to give the management to Bumdes [the village business entity], so that it becomes money. Because the company doesn't want to receive a ticket at any time. Because he doesn't want to be wrong
2.	The gold-mine company Corp partner	Mr D	Especially if the communication is better with the company people ... This is what the company is willing to give. So yesterday I left the village to approach the company. The result the company is willing to build the Taman Buah Nusantara up here. That's was also my idea. I encourage them to propose the central board to issue its CSR. Now the company is processing the transfer of management to the community...
3.	Village district official	Mr H	We are still organized our business entity ... But hopefully with some people we keep going. Because the village office is very supportive. Hopefully the results have already been seen in 2020. We had wanted to clear it first with the company. With the direction of the village head, we cleared it with the company so that it could be managed by us so it would be nice to clarivy with the people

The first two groups of community elites are represented by individuals. Mr. O and Mr. D are only one of the members of each group. They are very cooperative with the company, and always try to maintain a close relationship with the companys'officials, especially those who are responsible for the Corporate Social Responsibility (CSR) program.

The third groups are more organized because it is also part of the village district office. The village officials build a business entity to manage tourism destinations in the village. This business entity is called with Badan Usaha Milik Desa (Bumdes), and Mr. H is acting as the chairman. Currently, the Bumdes is still organizing themselves to prepare to manage several tourism destinations, including the one that was built by the gold-mine company, especially the Kawaci Park.

The statements from each group representative depict the prominent role of the company in the endeavor to build tourism potentials in the village. This finding is similar to several studies about the

alteration of the ex-mining area to tourism destinations (Hidayati and Deliyanto, 2016), (Suprayoga, 2008), Soedarso, Nurif and Windiani (2014). The gold-mine company corporation also prepares the community to adapt to the new source of the economy by inviting the community representative in the meeting, training, and other occasions (Byrd and Gustake, 2007).

The field survey to observe and tag the location of tourism destinations in the village has managed to track 13 tourism destinations in the village. This finding shows that the community also inspired to actively involved in developing a tourism business, no matter the scale of their business is.

Figure 1: The geotagging result of Tourism Potentials in the Bantarkaret Village

There are 13 tourism destinations which are fully constructed in Bantarkaret village. The detail coordinate locations of those destinations are mapped in figure 1. However, some of the sites are still organized individually by some locals who are respected by the others, or who owns the land where the tourism sites or the road to access the sites are located. Only some of the tourism sites are managed under the Bumdes. Managing tourism business with Bumdes has a huge advantage because it is a business entity that is legally recognized by the state. Therefore, it is possible to seek support and cooperation with the Bogor regency officials.

Conclusion

The potentials of tourism development in Bantarkaret village give the villagers a new hope. They have a new inspiration now, which is participating in the new tourism business although the development in the village is still in its early stages. The finding shows that local community has the intention to participate in the tourism development potentials (Patenaude and Lewis, 2014; Cater, 2011). But the significance of their participations are varies based on their bargaining position in the development process.

This makes community participation in tourism development is relatively low. Only the local elites who have access to information and resources can participate in the creations of tourism destinations. The rest of the villagers are yet to get involved in the tourism business.

Abstract

Shopping activities in the 21st century is taking a social dimension rather than mere commercial activities. This is quite evidence in the importance consumer attached to shopping and their choice of shopping place which has necessitated the increase in the number of megamalls in many cities of the world including Nigeria. This study examined the shopaholic phenomenon, choice of shopping place and the development of megamalls in Ibadan, Nigeria. The study was empirical using both quantitative and qualitative method for data collection. 216 copies of questionnaire were administered to mall customers while In-depth interview was conducted for 6 mall operators cut across malls in Ibadan. Statistical Package for Social Sciences using frequency tables, percentages and histogram chats were used for analysis. The study revealed that most respondents choose megamall as their shopping place and there is a connection between shopaholic phenomenon, choice of shopping place and the development of megamalls. Conducive and serene environment which megamalls portrays have wooed many customers in the urban areas to choose it as their priority as it concerns shopping and that have gone a long way to enhance the development and sustainability of megamalls in Nigeria. For most customers, they patronize malls because of their innate love of shopping, ostentatious life and showy life just to impress friends and well-wishers. The glamour and fascination which megamalls displays cannot be gotten in retail shops or in the open markets. Customers are highly satisfied with their experiences in the megamalls that accounts for their continual patronage of the megamalls over other shopping alternatives.

Keyword: Megamall, Shopaholic, Shopping place, Retail Stores

Introduction

Shopping is a viable business endeavour which is not only limited to consumption but also entails social dimension. It is a social practice which reflects in people's life-style. Megamalls creates a serene environment similar to urban centre with social activities in a different arrangement where shopping activities takes place. The essence of megamall can be found in the variety of choices that individuals make in their daily life. Street life is exciting, but people look for different things in megamalls. Megamall has become the most significant and popular interface where consumers and producers meet. It is a place that attracts huge throngs of people (Rousseau, and Venter, 2014).

Trading activities remain a major key factor for the development of cities and towns as well as of the intensification of their desirability. The right to pursue commerce is very pivotal to this development. Market places seemed to be and are still persistent urban feature (Cohen, 2006). Essentially, people's lives centres around work and leisure. Various individuals by design must of necessity stop and exchange money for products and services which makes possible work and play. Small shop centres connect lives together in a more pleasant way as it has been the usual practice since the olden days till now, this grows into stable or semi-stable dwelling edifices and commercial arenas (Busari, Olonade & Asamu, 2019).

Megamalls are usually a spacious arena with a blend of in and out doors services with great investment in seats, air conditioning, large space and beautiful decors (Njoroge, 1995). Sourcing for markets and patrons are largely by advertisement, special offers and sponsorship with the aim of creating brand-loyalty among customers. Operators of shopping malls generally established arrangement for franchise with multinational organizations which will also be in control of the supply of raw materials used for goods, items, menu and the manner of presentations and arrangement in sections. One of the implications of the continuous development of megamall is that proceeds made from sales by foreign-controlled chains are usually repatriated back to their countries. By implication, the proceeds and large income made are transferred out of the host economy, thereby amounting to labour loss for the country at large (Busari et al, 2019).

Home-made foods with the arrangement of family dinner table is progressively giving way for fast food takeaway consumption which are easily purchased at the megamalls (Wikipedia, online dictionary, 2018). Most importantly, studies have shown that fast food consumption is connected to many diseases which among others include colorectal cancer, obesity, high cholesterol, and depression (Talwar, 2003). Many fast foods tend to be high in saturated fat, sugar, salt and calories (EurekAlert 2018). Critics of the mega malls have long warned about the perils of addiction to processed food, canned items, foreign products, expired materials and consumptions etc. Although the development of megamalls serves as important places for shopping, entertainment and social interaction in Nigeria, the centres are faced with dynamic shoppers' attitude and changeable competitive environment. Since most shoppers are adventurous in nature, they tend to change with the lasts centre in town. In such unstable situation, it is important to understand and be able to predict shopping mall performance. Thus, megamalls are faced with demands to adjust their marketing mix strategies to fit latest market trends. These have originated from the changes in consumption patterns of urban dwellers, citizens' choice of shopping place, which have brought about irregular purchase decisions and extreme competition among the shopping malls and its development in different locations and environment.

Review of Literature

Sharma, Narang, Rajender and Bhatia (2005) assert that shopaholism is a medical term for the uncontrollable craving for shopping activities. It is the same with the term 'onionmania', which is gotten from the Greek words onios (for sale) and mania (insanity). It is described as 'impulse control disorder'. Ridgeway, Braga, Tita and Pierce (2011) submits that approximately 8.9% of the people in America experience this condition. Ostentatiousness is "a pretentious display meant to impress others" or a "boastful showiness" (Perkins, 2008). It is attracting or seeking to attract attention, esteem, or envy often by flamboyance or obviousness. It is excessively elaborate or noticeably characterized by, fond of, or evincing ostentation. People, things, wealth or knowledge portrayed as ostentatious seem to have put themselves on display; they are practically begging to be looked at. Ostentatious applies to items or buildings which are luxurious, mansions and fancy high-rises with marble columns. Some set of people are ostentatious; they have lifestyles which connotes spending extravagancy. Their consumption depicts impressive things they buy. They attract attention not only because of quality but also for an implied luxury. It simply depicts show off. And, in fact, any amount of ostentatious is wrong during the tough economic times like these, it is more wrong than usual (Bhatia, 2005).
Megamall depicts conglomerates and chains of businesses in goods, services, vacation and voluntary acts. It is array of shops and wares lined up for purchase, fun catching, sight-seeing, relationship building and business transacting (Omoniyi, 2018). Megamall can be defined as set of buildings that provide walkways for the public to walk from one unit to another as they go about their business of

exchanging goods and services for money. They are a very large shopping area containing very many shops, cinemas, and restaurants. They are a very large shopping area containing very many shops, cinemas, and restaurants. It is a particular shopping type and pleasure arcade which is commonly in open air and connecting walkways end to end (Munich, 2004).

Common practices in many Nigerian cities such as; Port Harcourt, Lagos, Uyo, Abuja, Umuahia, Jos, Akure etc is the construction of commercial precincts above or under the old road network. The implication of this is that the rich people in the society are disconnected from the paths of urban center areas, and the physical interaction among diverse cultural and social groups as well as their lifestyles and values become more irregular. For the attainment of individuals' sense of consumption in outdoor settings, most mega malls have been planned to ensure adequate security, traffic, attention and fashion-oriented rather than interaction between individuals (Creel, 2006). Megamalls denote a different type of street or arcade in metropolitan commercial areas focused on pedestrians and helped by public transit. It depicts an environment void of traffic situations that turns into a place where people can walk, sit, eat, and observe the various human activities taking place around them (Ferdman, 2018). A number of continuous blocks along a shopping street, which is used by people on foot, have consisted of pedestrian malls. They are formed by closing a street for vehicular traffic and improving the pedestrian street with new paving, street trees, street furnishings, and other amenities such as sculpture and fountains. The full fledge mega mall provides visual continuity, a special character, and help to create an image and sense of place for the consumers or people (Gürçel, 2003).

With most of capital cities with one form of modern megamall or the other, developers have increasingly targeted secondary cities in order to gain first mover advantage in these locations. Bidandi and Williams (2017) opined that developers are now concentrating on building well situated rather than mega-malls as it is suitable with the policy of land economy. It also affords shoppers, patrons and fun seekers a complete and holistic opportunity to shop, play, catch fun, take shots as well as do business with modern and easy-to use technology and all within a time being. Indeed, Megamall development plays a key part in determining the future landscapes of Africa's growing cities.

Before the ideas of megamalls emanated, it is apparently clear that people subscribe to the old conventional means of doing trading activities. The buying and selling takes place within the street through various forms and styles which includes; kiosk/stands, ware display, floor marketing, fast food centre, hawking, stoas, stores, arcades, open or closed bazaars, hans, pedestals, passages, quick service restaurants etc (Chukuezi, 2010). This occurrence has stayed for a very long time and it appears to be growing silently. It is called street vending or selling. Street vending can be defined as an easy, unorganized and frequently non-registered economic activities in the fast growing cities of the developing world. It is an imoprtant part of urban economies across the globe, offering easy access to a wide range of goods and services in public spaces (Egharevba, Eguavon, Azuh, Iruonagbe & Chiarzor, 2016). Street vending micro-economies are crucial for the economic planning and development of many communities. They are involving in many trading activities like fresh vegetables to prepared foods, from building materials to garments and crafts, from consumer electronics to auto repairs to haircuts (Rousseau, and Venter, 2014).

Creel (2006) asserts that street vending businesses are usually owned and operated by individuals or families. Street food enterprises are generally small in size; require relatively simple skills, basic facilities and small amounts of capital. Marketing success of the street food vendors depends exclusively on location and word-of-mouth promotion (Ferdman, 2018). The contribution of street vendors to the economies of developing countries has been vastly underestimated and neglected (Rousseau, and Venter, 2014) and replaced with megamall which provides a total, comprehensive buying and fun experiences for people at a go within the same arena. The significance of the street vending has often been ignored because it is seen only as a prevailing and distinctive component of a broad informal sector. There is increasing recognition that street vending plays an important socio-economic role in terms of employment potential, providing special income particularly for women and provision of food at affordable costs to mainly the lower income groups in the cities (Chukuezi, 2010). Most street vendors offer the main source of revenue for their families, providing food for their households and payment of children school fees. However, in spite of their immense impacts on socio-

economic wellbeing, street vendors are confronted with myriads of difficulties. They are mostly unrecognized as critical stakeholders in the economy and when compared to other enterprises, they are limited instead of been given enabling environment to thrives. Concerns of cleanliness and freshness usually discourage many persons from eating street food or buying items there off (Mukhola, 2007). It is apparently clear that people due reasonable number factors, such as; safety, hygiene, conducive and scintillating environment for play, fun and excitement, holistic buying, business expansions and connections, bulk buying, prefer patronising megamalls than street vending economies.

With the advent of modernization, there is evolution of arcades to malls and department stores into malls also. Small scale retailers and business owners wind up their trade activities as people are opting for megamall to buy cheap and foreign products as well as enjoy quality time with their families and friends. White and Sutton (2001) affirm that characteristics of urban culture includes unfamiliar relations, competitive behaviour and distant bloodlines. This unprecedented migration of people is predicted to continue and in a more intensified level during the next few decades, escalating cities to sizes unimaginable only about hundred years ago. Consequently, the growth of world city population curve has up till recently followed a quadratic-hyperbolic pattern. Urbanisation occurs because people move from rural areas (countryside) to urban areas (towns and cities). This usually occurs when a country is still developing. This applies to the people abandoning small street stores, groceries kiosk to urban areas where megamalls thrive.

Theoretical Framework

Modernization refers to a model of a transition from an orthodox era to a modern society. It came up from the works of sociologist Max Weber (1864–1920) and a shift in paradigm propounded by Harvard sociologist Talcott Parsons (1902–1979). The theory looks at some internal factors and mechanism of a country in a new dimension. It identifies social factors which are capable of contributing to societal growth of societies and seeks to explain the process of societal evolution and development. It can be equated with the processes of urbanization, westernisation and industrialization. Kendall (2007) notes, Modernisation is an overarching process of rationalisation which sees economic conditions are heavily determined by the socio-cultural and political values in such society.

Modernisation theory submits that the wave of buying and selling in an organised, conducive and friendly environment is not negotiable as the world is turning into a more relaxed and social-oriented settings. Due to the nature of people work and non-availability of time, it becomes more convenient to shop, relate and relax in an open arena. The society is presenting an atmosphere which makes people to acclimatized, feel secured and homely as well as purchase goods as at relatively cheap prices. In the same vein, people are capturing this offer and turning the privileges in opportunities for themselves and family. Rather than toe the part of traditional societies, modernisation has made human being see reasons to change their choice of shopping place and move to the trendy place of shopping. There is apparently nothing that cannot be purchased or found in a mega mall or relaxation centres. People pay obeisance to these centres on weekend and privilege holidays to unwind, celebrate, relate, meets people and exchange business or relationship contacts. Unlike the traditional display of goods or local stores which does not make provision for serenity and freedom to relate and relax. Even in core oldies, goods were lined up by the road side with symbols or price tags and buyers pick and drop their pay without interaction and negotiation. Modernisation frowns at this.

More so, critics of this theory submit that modernisation has eroded traditional core values and practices. It has done more harms than goods. It has preached westernization more than the orthodox and conventional means of getting things done devoid of crises, fraud, stealing, fighting and other anti-social behaviours.

Methods

This exploratory study was conducted in Ibadan South West Nigeria. Ibadan was selected for this study because of the preponderance of megamalls in Ibadan metropolis and the increase patronage of people

in megamall over retail shops in Ibadan. The targeted population for this study were selected retail shop owners, megamall costumers and megamall managers in Ibadan metropolis. Both primary and secondary data were gathered. Secondary data were gathered through scholarly articles. Primary data were gathered through quantitative and qualitative techniques. Quantitative data were gathered with 216 copies of questionnaires were administered active megamall users (who must be been using the megamalls in the past 12 months consecutively) while qualitative data were gathered with 6 IDIs (In-depth interviews) from megamall operators who are in the managerial cadre in the selected shopping malls in Ibadan. The study captured the views of both megamalls' customers and operators/managers of megamalls. Purposive and accidental sampling technique was used to select 216 respondents for the quantitative data in various megamalls in Ibadan Metropolis. Quantitative data was analyzed at univariate level using SPSS while the qualitative data was analysed through content analysis and presented as ethnographic summaries. All the ethical issues were strictly adhered to. The principles of voluntary participation, anonymity and confidentiality were observed. The respondents' right for confidentiality and privacy were taken into consideration during the data collection.

Findings and Discussions

Table 1 below presents respondents socio-demographic characteristics of the respondents. The table shows that higher percentage of the respondents 46.8% falls between 25-34years. This shows that 85.2% of shopping mall customers are youths which confirm the fact that the youths are the main megamall users because they want to enjoy the glitz and glamour of the moment. Senior citizens will prefer to patronize small retail shops than going to megamalls, this is because senior citizens may see such outing as a waste of time, energy and resources. They will question the rational of going to a mall which maybe in long distance than purchasing whatever the need in the retail store next door. However, on the contrary, youths see megamall shopping as an adventure, meeting point, sightseeing, dating places etc. On gender, majority (55.6%) of the respondents are male. The above findings are in tandem with the findings of Kuruvilla and Ranjan (2009), when the opined that men visited malls more than women and it refuted the assertions of Dholakai, Pedersen and Hikmet (1995) as they opined that the ratio of shopping centre usage between women and men is 2:1; which implies that shopping malls often to appeal to more to women than male. Most of the people observed in the shopping malls during the study were usually in two (male and female) who are just hanging out and having fun. Most customers of megamall use it as a form of leisure. On level of education, majority of the respondents (80.1%) falls in the category of tertiary level of education and ranked the highest. This finding confirms the fact that megamall is a major part of the modernization process with people who had formal education/western education being oriented towards it. On monthly income, higher percentage of the respondents (32.4%) of the respondents earn #20,000-#40,000, this shows that higher percentage of the megamall users are not really affluent. This could be explained by the fact that some of them could be students and unemployed graduates, apprentices or self-employed youths who are trying to make earns meets. Majority of the megamall customers earned below #80,000 monthly. Ordinarily, such people should make use of the local shops/markets for their daily needs but because of the need to 'feel among' and "show off"; they still spend their meagre income on frivolities at the mall. Most of the youths wants to impress their friends, relatives and fans by going to the megamalls. Some of the megamall users just go there to take pictures and post on the social media, so that they too will be admired and approved. This also reveals by Sohail (2015), Jih and Lee, (2004) and Jewel, (2001). Megamalls depicts a lifestyle that is endearing to everyone as a desirable place to be. Hence, every individual irrespective of their socio-economic status want to be part of it.

Table 1: Socio-demographic characteristics of the respondents

Variables	Frequency	Percentage
Age		
15-24	83	38.4
25-34	101	46.8
35-44	18	8.3
45-54	8	3.7

Table 2 below presents response to time frame of respondents visit to mall, 23.1% of the respondents have only visited the mall in less than a year, 27.3% of the respondents had been visiting the mall for the past 12-24months, 17.1% of the respondents opined that they have been visiting the mall up to 36months now, while 32.4% of the respondents opined that they have been visiting the malls for more than 36months now. This implies that higher percentage of the respondents (32.4%) have been visiting the malls.

Table 2: How long respondents have been visiting malls

Time frame of respondents visit to mall	Frequency	Percentage
Less than one year	50	23.1
12-24months	59	27.3
25-36months	37	17.1
36months and above	70	32.4
Total	**216**	**100**

Source: Authors' Fieldwork, 2018.

Figure 1 below respondents' choice of shopping place, the result shows that 89% of the respondents opined that malls is their choicest place shopping, 7% of the respondents opined that retail shops while 4% of the respondents opined that they prefer to shop in the open market. This implies that majority of the respondents (89%) opined that they prefer shopping in the malls. The above findings are in tandem with the assertion of Omoniyi (2018), megamall depicts conglomerates and chains of businesses in goods, services, vacation and voluntary acts. It is array of shops and wares lined up for purchase, fun catching, sight-seeing, relationship building and business transacting.

Figure 1: Percentage of respondent choice of shopping place

Source: Authors' Fieldwork, 2018.

Table 3 presents respondents' rationale for their above choice. The result shows that higher percentage of the respondent (38.4%) opined that they choose shopping malls because it provides quality and affordable goods at your door step, other rationales includes opportunity to have fun/hangout, opportunity to meet different people from different places, serves as recreational centre, gets almost all you want in a single location amongst others. By implication, respondents are getting value for their time and shopping experience on every visit to the mall. Megamalls provides all these opportunities which retail shops and open markets does not offer. It gives them the opportunities to exhibit their shopaholic and ostentatious lifestyles. The above finding is further collaborated with the qualitative data as some of the respondents interviewed had this to say:

> We stocks consumable goods and non-consumable goods, basically food, beverages, household goods, toiletries and liquor drinks. We offer recreational services like film house, game arcades, bar and launch restaurant services and shopping mall. Other sides' attractions include fast food restaurants, superstores

> and the likes. We sell clothes, shoes and bags while the fifth participants gave a detailed description of what they sell in their mall. So virtually everything you need can be gotten in the mall. (Male/IDI/Mall operators/2018).

Another response by another respondent succinctly captures the distinction of malls and why people patronize malls more than retail shops, this was her direct words:

> Whatever you buy here you can be sure they are genuine and original. It is very rare to find fake things in the mall unlike all these shops in the neighborhood or local markets. Shopping malls have names they want to protect so people have the benefits of getting original stuffs here at affordable prices. Also, there is enough space to accommodate the crowd coming here, malls have sitting arrangement where people can wait and relax. Malls, also have many toys in their children section where children who comes with their parents can stay while the parents go shopping. There is also a large parking lot that can accommodate many of their customers' cars. All these are hardly found in many of these neighborhood shops. Also, the goods and services are reliable, you can't come across fake things and they are all affordable. Malls keep their environment safe and serene for customers to enjoy their shopping. This is a one stop destination where you can get all your goods in a single place at affordable prices. Hence, megamall provides shoppers the opportunity to get all they need in one place than what you can get in retail shops. (Female/IDI/Mall customer/2018).

The above assertion connotes that due to the fact that customers have the opportunity to buy several and diverse items in a single shop goes a long way to influence their choice of malls than retail shop or open markets. Most times costumers' buy items they didn't even plan to buy in the first place because they saw such items and it was appealing to them.

Table 3: Respondents rationale for their choice of shopping

Rationale for choice of shopping	**Frequency**	**Percentage**
Malls provide opportunity to have fun/hangout	53	24.5
Malls provide opportunity to meet different people from different places	31	14.4
Malls serves as a recreational centre	17	7.9
Malls provides quality and affordable good at your door step	83	38.4
In malls you get almost all you want in a single location	32	14.8
Total	**216**	**100**

Source: Authors' Fieldwork, 2018.

Figure two above presents how often respondents visit malls in Ibadan metropolis. The result shows that 24.5% of the respondents' visits malls very often, 22.7% of the respondents opined that they visit the malls somewhat often, 33.4% of the respondents visits the mall often, while 19.4% of the

respondents visit the malls not very often. This is an indication that majority of the respondents visits the mall often.

Figure 2: Percentage of respondents' response on how often respondents visit to mall

Source: Authors' Fieldwork, 2018.

The experiences of the megamall's users were ascertained in the cause of the study. Respondents rated their experiences in the megamall based on their past outings and visits to the megamalls. Table two below presents the respondents opinion on what they experience about the megamalls. The experiences of the respondents in the malls, majority of the respondents (87%) of the respondents opined that they were highly satisfied with their experiences in the malls. This satisfaction could be explained by the fact that apart from shopping most customers visit the shopping malls to have fun and meet people. The above assertion is collaborated with the qualitative finding as the mall operators/managers, one of the respondents interviewed had this to say:

> We maintain good customer service. Customers are our priority here. We make sure that they are satisfied and if the customers make any complain we treat it as urgent and make sure that such thing do not occur again. (IDI/Mall operator/2018)

From the above assertion, the place of good customer service is priority in the mall. This follows the saying that "customers are king" That could explain why malls are experiencing large patronage unlike the small retail shops. Move over, people like to go where they are treated well, places they are appreciated and valued unlike places.
Another respondent interviewed had this to say:

> We make sure we stock quality good here, we keep our environment clean, we have business card for every of our clients and we also sponsor TV shows on celebrities and lifestyles. Also, we make sure that customers and their properties are safe. We cherish our customers and we offer promotional activities periodically especially in our film house. We are also very active on social media to showcase what we have in the mall. (IDI/Mall operator/2018)

From the above assertion, malls endeavours to sell quality goods and that is one of the attractions of the customers. When people trust your products, they will keep coming. This is because people want

value for their "hard earned" money in Nigeria. Also, mall operators ensure that their customers and their properties are safe, that is a good strategy to ensure continual patronage to the mall. People will not continue to go to megamalls if such environment is unsafe and unsecured, invariably, megamall customers keep going there because they consider it safe and secured. In addition, one of the customers interviewed had this to say about her experience in the mall.

> This mall is very helpful to people as it eases them the stress of struggling in the local market. What I mean is that here in this megamall you come in and you get all you need in a place. Unlike the open market where you walk from one end to another on a rough, dusty and bad road, here even if you will walk around, everywhere is clean and tiles, you are inside an air conditional environment, everywhere in the mall is cool and clean. So, I think that is why many people prefer to come here than other places. (IDI/Mall customer/2018)

The above assertion explains why customers patronize malls more. The conducive and serene environment is one of the major factors why people patronize mall. Shopping in the mall exposes customers to less stress than shopping in the open market where one has to move from one location to another before one could complete his/her shopping. The stress of moving from location to another under hot weather condition to shop is prevented and needless when shopping in the malls as the whole shopping malls are air-conditioned and conducive. The above finding could also explain why respondents choose megamall to other shopping alternatives because they are satisfied with the services offered by the megamalls.

Table 3: Response of respondents on their experiences in the malls

Response	**Frequency**	**Percentage**
Highly satisfactory	188	87
Not too satisfactory	26	12
Below satisfaction	2	1
Total	**216**	**100**

Source: Authors' Fieldwork, 2018.

Figure 2 above presents percentage of respondents' perception of how innovative they think the malls are, the result shows that 20.8% of the respondents, higher percentage (46.3%) of the respondents opined that malls are very innovative, 25% of the respondents are somewhat innovative 7% of the respondents opined that malls are not so innovative, while 0.9% of the respondents stated that malls are not innovative at all.

Figure 2: Percentage of respondents' perception of how innovative they think the malls are

Conclusion

Based on the findings of this article, megamalls have developed due to the shopaholic nature of most urban dwellers. Conducive and serene environment, is one the major factors why people chose megamall against retail shops and open markets which has contributed to the development of the megamalls in no small measure. Be that as it may, that does not mean that urban residents have stopped patronizing retail shops and open markets but they have minimized their patronage of retail shops and open markets and increased their patronage of megamalls. patronise mall. Moreover, shopping in the megamall exposes customers to less stress than shopping in the open market where one has to move from one location to another before one could complete his/her shopping. The stress of moving from location to another under hot weather condition to shop is prevented and needless when shopping in the malls as the whole shopping malls are air-conditioned and conducive.

Customers of megamall chose megamall against other shopping alternatives because megamall have the opportunity to buy several and diverse items in a single shop and this goes a long way to influence their choice of malls than retail shop or open markets. Most times costumers' buy items they didn't even plan to buy in the first place because they saw such items and it was appealing to them. Shopping malls also provide quality and affordable goods at your door step, other rationales include opportunity to have fun/hangout, opportunity to meet different people from different places, serves as recreational centre, gets almost all you want in a single location amongst others. By implication, customers of megamalls are getting value for their time and shopping experience as they visit the malls. Megamalls provides all these opportunities which retail shops and open markets does not offer. It gives them the opportunities to exhibit their shopaholic and ostentatious lifestyles. Although megamall is contributing to the socio-economic development of Ibadan metropolis, the importance and contributions of retail shops and open markets should not be downplayed.

The Essence of Environmental Safety in Road Transport

Monika KOZERSKA and Paweł SMOLNIK

Czestochowa University of Technology, Dąbrowskiego 69, 42-200 Czestochowa, Poland,
monika.kozerska@pcz.pl, pawel.smolnik@pcz.pl

Abstract

Environmental safety is a vitally important issue that should be taken into account during human economic activities, including road transport. The objective of the article is to present the threats related to the harmfulness of pollution and noise emissions caused by road transport. An attempt was made to indicate pro-environmental solutions within the transport policy in Poland and the entire European Union.

Keywords: Gas Emissions, Noise, Sustainable Development, Environmental Safety

Introduction

Human need for movement resulted in the invention of car in the 19th century. It is historically accepted that the first in the world car propelled by an internal combustion engine was a vehicle created by Carl Benz in 1885. On a specially designed chassis, a single-cylinder four-stroke engine was horizontally mounted. The fascination with the automotive industry has been the driving force of continuous progress.

The development of cars with combustion and electric engines continued towards the end of the 19th century. The first electric car was built in 1834 by an American, Thomas Devenpont. The vehicle was powered by Volta's galvanic cell. The first electric vehicle in use was a tricycle equipped with 45kg batteries. (https://businessinsider.com.pl/motoryzacja/pierwszy-samochod-elektryczny-na-swiecie-historia-motoryzacji/2jxm5w0) The change occurred in 1859, when Gaston Plantė invented the lead-acid battery. (http://info-car.pl/infocar/artykuly/historia-samochodu-elektrycznego.html)

In the late 19th century, the importance of two-track internal combustion vehicles continued to increase, and the interest in electric ones began to decrease. The discovery of new crude oil deposits largely affected the development of the refinery industry which resulted in a decrease in petrol prices. Consequently, increasingly more petrol stations were built. The growth of oil industry stimulated also the development of the automotive business. More comfortable cars with more efficient engines began to be designed and manufactured. The growth of electric cars was much less dynamic. The works on electric vehicles began to progress soon after 1945. In 1959, Henney Kilowatt introduced an electric car based on transit technology. Kilowatt's maximum speed was 96 km/h and it had a one-hour autonomy on a single charge. (https://businessinsider.com.pl/motoryzacja/pierwszy-samochod-elektryczny-na-swiecie-historia-motoryzacji/2jxm5w0) At the end of the 1990s, the automotive industry suffered from the effects of the fuel crisis. The increase in air pollution with exhaust gases and the growing environmental awareness of potential buyers made the manufacturers reconsider the concept of electric cars. General Motors engineers were the first to present in 1990 the GM Compact model design, and soon the manufacture of EV1 began. The maximum speed of EV1 was 129 km/h. That model could travel about 257 km on one battery charge. At the end of the 20th century, some other electric cars were introduced, including Škoda Favorit ELTRA, Honda EV Plus or Chevrolet S10 EV, but the problem of charging outside cities continued to exist, since the batteries of those models were sufficient to travel a distance of only 100 to 180 kilometres. Electric cars were also a more expensive than the internal combustion ones. All that meant a small number of buyers interested in cars with

that kind of drive. In 2008, the Tesla Roadster was introduced which was the first mass-produced car equipped with lithium-ion batteries, with a maximum speed of 210 km/h and a range of 354 km.

(https://www.politykainsight.pl/_resource/multimedium/20106685). That gave rise to the development of electric cars. (http://info-car.pl/infocar/artykuly/historia-samochodu-elektrycznego.html) In the recent years, electric vehicles have become increasingly practical means of road transport. In 2012, the presentation of the Tesla S model by Tesla Motors was a game-changing development. The maximum speed of the most powerful version is 249 km/h and it is able to cover a distance of 509 km. Moreover, the Tesla S has room for seven passengers. All those features have caused Tesla S to find a large group of buyers despite is high price of USD 70,000 (ca. PLN 276,000) (http://info-car.pl/infocar/artykuly/historia-samochodu-elektrycznego.html). From that moment on, the number of electric-driven passenger cars began to increase.

The figure below shows the evolution of cars over more than 100 years. Not only the looks, but also the manufacturing technologies have changed.

Fig. 1: Evolutionary path the cars have gone through
(https://www.howardsgroup.co.uk/news/group/how-much-have-cars-changed-in-the-last-ten-years)

The dynamic growth of the automotive industry was not only quantitative but, above all, qualitative, i.e. innovative design solutions were constantly developed and implemented, new materials and components were added, and technologies and various operation modes were introduced. New solutions were also introduced to the traffic management.

Safety problems associated with the use of cars have not, for many years, been taken into account which took a toll of the environmental pollution. Therefore, saving the environment from the effects of using motor vehicles started from protection against emissions from cars.

Promoting proper communication attitudes in urban communities is a long-term process. (Świniarska, 2016) This means that it is impossible to immediately depart from internal combustion vehicles in all countries and replace them with the greener ones. An important aspect is also to spread environmental awareness in society, it is hence essential to consistently promote proper education.

Threats Related to Road Transport

The main threats related to environmental safety in road transport relate to air pollution, including exhaust emissions.

As it is well known, the exhaust gases emitted by motor vehicles, especially heavy goods vehicles, release to the atmosphere highly toxic and hazardous substances which have a destructive effect on

the entire ecosystem. The condition and amount of air pollutants from road transport depends, among others, on the type of fuel, type of vehicle and its technical condition. Air quality is affected by so-called primary pollutants, which include nitrogen oxides, carbon dioxide, sulphur dioxide, lead and suspended dust. (Walendzik, Łepkowski, Nowacki, 2016)

The main issues faced by highly developed countries include primarily reducing the overall level of carbon dioxide emissions and the global consumption of non-renewable energy sources such as crude oil, coal and natural gas. The current transformations tend mainly to reduce burning of fossil fuels, as it leads to emission of harmful compounds into the atmosphere. This is particularly important in large cities due to high pollution and traffic intensity, as well as exposure of numerous groups of people living in city centres. The presence of harmful gases and dust in the atmosphere, e.g. carbon dioxide, can have serious health effects, such as cardiovascular or respiratory diseases and contribute to increasing the number deaths, particularly among older people. (Fuć, Lijewski, Siedlecki, Gallas, Szymlet, Sokolnicka, 2017) In addition to carbon dioxide particles, the real threat is posied by the suspended dust PM10 and PM2.5.

Note that the PM2.5 is most dangerous to human health.

Fig. 2: The number of deaths due to air pollution per 100,000 inhabitants and average PM2.5 dust concentration in European countries in 2016. (http://wyborcza.pl/7,75400,21017490,blisko-50-tys-polakow-co-roku-przedwczesnie-umiera-z-powodu.html)

As shown in the graph above, high concentration of the PM2.5 dust (fig. 2) affects the number of deaths. For example, in Poland, 134 people per 100,000 die due to air pollution. The concentration of harmful dust in Poland is also very high. In 2016, eleven Polish cities, Rybnik, Kraków, Nowy Sącz to name a few, ranked among 15 most polluted cities in Europe because of the PM2.5 dust, which is a very negative result (fig.3).(https://wyborcza.pl/7,75400,21017490,blisko-50-tys-polakow-co-roku-przedwczesnie-umiera-z-powodu.html?disableRedirects=true)

Fig. 3: 15 most polluted cities in Europe

(https://wyborcza.pl/7,75400,21017490,blisko-50-tys-polakow-co-roku-przedwczesnie-umiera-z-powodu.html?disableRedirects=true)

In Northern Europe, the concentration of dust is much lower, in particular in Scandinavian countries, e.g. Norway and Finland, while it is increasing in Southern Europe. The number of deaths due to air pollution is the highest in such countries as Greece and Italy.

Current European statistics show that, despite significant reductions in emissions over the past decade, air pollution from all sources is to blame for a large number of premature deaths.

Car exhaust gas is a source of nitrogen oxides, dust (PM10 and PM2,5), sulphur oxides, carbon monoxide and various heavy metals, e.g. cadmium, lead and mercury. Moreover, chemical precursors in exhaust gases may react in the atmosphere, leading to the formation of ground-level ozone. As tires and brake pads wear out, particulate matter and heavy metals are released into the atmosphere which, after falling on the road surface, can thrown into the air again by the passing cars. Exposure to those pollutants can have very specific health effects, while, in general terms, they affect body organs, nervous system and blood circulation, causing or exacerbating such ailments as lung diseases, leading to breathing difficulties, and also heart attacks, asthma, anxiety, dizziness and fatigue.

In 2016, in the European Union, the transport sector accounted for a 25.8% share in the greenhouse gas emissions.

Fig. 4: CO2 emissions in transport in the EU
(https://www.europarl.europa.eu/news/pl/headlines/society/20190313STO31218/emisje-co2-z-samochodow-fakty-i-liczby-infografika)

The road transport generated around 72% of total greenhouse gas emissions from transport (including international air transport). 60.7% of the gases were emitted by passenger cars, and 38.1% by goods vehicles and buses. (Gis, 2017) Although in 2016, compared to the previous year, greenhouse gas emissions from international transport in the EU decreased by 1.1%, by 2050, they have to be reduced by more than 28% in order to achieve the objective of reducing that emission by 40% compared to the 2005 levels. (https://www.eea.europa.eu/data-and-maps/indicators/transport-emissions-of-greenhouse-gases/transport-emissions-of-greenhouse-gases-10)

Exhaust gas generated by vehicles, including airplanes, trucks or passenger cars, are toxic compounds adversely affecting the natural environment and human health. Car exhaust gases are also very harmful due to rapid spread at low altitudes and in high concentrations of toxic particles, which means that people are exposed to them directly. Air pollution brings also detrimental effects on the condition of buildings, crops and forests.

Another significant aspect is the problem of noise emissions, as it may affect the well-being and lead to changes in human behaviour.

The main causes of exposure to excessive noise in the vicinity of roads include:

- heavy traffic of vehicles;
- large percentages of heavy goods vehicles in traffic;
- high vehicle speeds;
- poor technical condition of road surfaces;
- lack of proper categorisation of the road network and too late identification of the problem of accessibility regulation – a large part of national roads pass through towns in the vicinity of densely populated residential areas;
- ineffective urban planning and lack of explicit provisions in the spatial planning legislation to take into account the noise criterion (Gierasimiuk, Motylewicz, 2014).

Individual means of transport emit different levels of sound, e.g. (Leśnikowska-Matusiak, Wnuk, 2014):

- train 79-95 dB;
- airplane 74-108 dB;
- tram 70-95 dB;
- tractor 85-92 dB;
- bus 86-92 dB;
- goods vehicle 83-93 dB;
- passenger car 75-84 dB;
- motorbike 79-87 dB.

Exceeding the 55 dB threshold has adverse effects on health. It causes mainly loss of concentration, fatigue, headaches, irritability, blood circulation problems and insomnia. (Łebkowski, 2016) Prolonged exposure to noise during the day can lead to an increase in blood pressure and cardiovascular diseases. Majority of Europeans live in urban areas near transport infrastructure such as airports or motorways, so most of them are exposed to noise. A significant number of people, including school children, are also affected by noise in addition to road noise caused by flying planes near airports. (https://www.eea.europa.eu/signals/signals-2018/articles/every-breath-we-take).

Road transport generates noise. It is estimated that, in Europe alone, around 30 million people are exposed to excessive noise. (Walendzik, Łepkowski, Nowacki, 2016)

The noise level should not exceed 85 dB, therefore in areas where it exceeds or remains within that limit, the expansion of zones protecting people from harmful noise should be limited. (Czerwiński, Strzelecka, Bucza, Pecyna, 2018).

It is not only people who are exposed to noise. It is worth noting that the existing communication routes form a complex network that extends throughout the country. Therefore, it crosses the areas inhabited by animals. Noise changes the behaviour of birds as well as other animals. Construction of roads near animal habitats puts their lives at risk, e.g. they are at risk of being hit. (Leśnikowska-Matusiak, Wnuk, 2014)

Causes of pollution in road transport

The reasons for the significant percentage of road transport in emissions, i.e. so called linear emissions, include a rapid increase in the number of cars, poor technical condition and age of vehicles, removing diesel particulate filters (DPF, FAP) from new diesel vehicles, ineffective control of exhaust gas emission, and the lack of adequate road infrastructure.

Pollution caused by transport is much more harmful to people than that from industry as it spreads in high concentrations at low altitudes in the immediate vicinity of people. One of the main sources are cars with diesel engines, but it is worth mentioning that only a small percentage of dust generated by cars is the so-called pipe emission, a dozen percent of it comes from abrasion of tires and brake pads, and as much as 80% is the secondary dusting, i.e. picking up dust deposited on the road surface by car traffic.

On a national scale, road transport is accountable for approximately 5-15% of all pollutants, mainly soot, particulate matter, nitrogen oxides and carbon monoxide (in areas with heavy traffic those values are higher, e.g. in Warsaw transport is responsible for over 60% of harmful gas dusts). (https://superflavon.eu/unikanie-zanieczyszczen) There are numerous reasons for the road transport contribution to emissions. Unfortunately, there are increasingly more cars on Polish roads and, moreover, older cars, which unfortunately has a huge impact on the emission of toxic gases.

Strategy of sustainable development of transport in Polish and European policies

In the framework of transport policy, the European Union undertakes actions to counteract the negative effects of the transport sector, which is a sort of a compromise between the environmental, social and economic topics. As part of such activities, detailed methods to reduce negative impacts of transport on the environment by 2050 were presented.

(https://ec.europa.eu/commission/sites/betapolitical/files/biala_ksiega_w_sprawie_przyszlosci_europy_pl.pdf)

The European Union has first of all set the objective of reducing the global climate changes so that the temperature rise does not exceed 2°C compared to the period before the industrial age. To meet that objective, the level of emissions by 2050 has to be cut down by around 90% compared to the 1990 levels. (Motowidlak, 2015)

In order to achieve the necessary emission reductions, policies and actions should be implemented at the EU Member States level in all sectors of the EU economy. While emissions from other sectors are decreasing, road transport is one of the few industries where emissions have rapidly increased. The road transport sector is in the second place among those emitting the most greenhouse gases within the EU, and emissions from this sector, including cars and delivery vehicles, are still growing. Further increase in emissions from road transport can significantly weaken the efforts of other sectors to combat climate change. To counteract that, in a document endorsed in 2011, a strategy was set out to achieve a 60% reduction in greenhouse gas emissions in transport by 2050. Those challenging objectives require appropriate and rapid actions on many levels, including continued decarbonisation of road transport. To accelerate and support those activities, the European Union has developed the recommendations and guidelines planned for 2020 to achieve the target reduction of CO_2 emissions from new passenger cars and new delivery vehicles.

Changing economic models towards more efficient use of natural resources and reducing greenhouse gas emissions has become one of the key challenges of the civilisation. Despite the uncertainty accompanying the long-term forecasting and the increasingly widespread belief of the international community that, without transformation of economic models of the use of resources, including natural resources, the global economy will be increasingly exposed to the consequences of climate change, irreversible loss of some resources and rising prices of energy resources. Despite the controversy regarding human impact on climate change, it is difficult to question the position that reasonable management of natural resources and environmental protection are the prerequisites of sustainable development. (Motowidlak, 2015)

The European Union supports international efforts to solve such problem. As part of those international aspirations, the EU has implemented a policy to facilitate the transition to a low-carbon economy.

In the context of those and other proposed solutions, emissions of air pollutants from transport are expected to continue to decrease which will be beneficial to human health. Nevertheless, 87-90% of city residents in the EU are still exposed to high levels of air pollution which WHO considers harmful. Meanwhile, it is estimated that reducing those levels of pollution in the case of the PM2.5 dust would avoid about 144 thousand premature deaths. In the long run, further integration of measures and political actions in Europe will be essential to reduce air polluting emissions and create conditions for improving citizens' health, as well as to avoid the effects of momentary high concentrations of pollutants similar to those to have occurred in London and Paris.

The world is slowly moving away from internal combustion cars. From 2025 on, it will not be permitted to sell them in Norway and from 2030 in Sweden or Ireland. Currently in Europe, diesel cars are being slowly eliminated. In Hamburg, streets have been marked out with restricted access of diesel vehicles not meeting Euro 5 standards. (Kozłowski, 2019) Euro standards are European

emission standards which are different for petrol and different for diesel engines. They were introduced in 1992. Today, Euro 6 (established in 2013) is the valid standard. Euro standards are primarily intended to reduce emissions of particulate matter PM and other harmful compounds. (Rzędowska, 2018) Reducing emissions from transport would certainly improve air quality, particularly in urban areas.

Even more challenging is the noise situation. Noise in Europe is a widespread harmful factor, and the quality of the European sound environment will continue to be threatened by economic development, industrial production, urbanisation and related transport needs in the future. This will adversely affect the health of Europeans. The greatest threat will continue to be the noise emitted by road traffic, while the noise associated with airport operations will continue to be a nuisance to residents in the immediate vicinity. Improving the reporting on noise is essential to obtain a more holistic insight into the effects of noise on health.

While encouraging countries to further develop noise action plans, the focus should also be on reducing noise at the source, which is a far more effective way of addressing the problem. (Bruyninckx, 2018)

Noise and exhaust gases have harmful consequences for human health and the environment. The EU Member States endeavour to ensure that the new laws being implemented take into account aspects related to environmental protection and sustainable development. However, the continental Europe is a small part of the entire globe so, in order to actually reduce the level of pollution on a global scale, close international cooperation of all countries is essential.

Potential for Limiting Pollution in Road Transport

The society should play an important role in developing transport policies, and the planned transport network should also take into account protected areas, in particular national parks, landscape parks and other natural values. An example of that is building the TEN-T transport infrastructure network where the EU policy emphasises the issues related to biodiversity and protection of the nature. During road construction, tunnels or footbridges are also built to allow animal populations to move across transport routes.

Many cities in Poland and throughout the EU encourage the citizens to change cars to bikes. Care is also taken about the public transport as an alternative to the use of passenger cars. Examples are mobile applications for ticket sales, WiFi on buses or all-day tickets.

There are also websites, e.g. promoting car sharing instead of driving alone, advertising the possibility of partial reimbursement of the cost of transport from those travelling in a similar direction. Unfortunately, people are reluctant to implement changes which often lower their present life comfort. One of the possibilities is also to restrict entry to cities, which may force the public to change their means of transport, namely the passenger cars, to public transport.

The use of older cars, without the appropriate catalysts and exhaust gas filters, could also be prohibited or, following the example of the Chinese authorities, introduce financial penalties for those who heavily pollute the air, which is inextricably linked with a ban on using cars on particular days of the week. However, the constitutions of democratic order states do not allow for restricting human freedom. Citizens should not be deprived of their right for transport. The only solution to this difficult situation is therefore to improve this particular sector of transport.

The first aspect to improve could be a more effective travel planning in a logistics context. The creation of a global system to manage the exchange of goods between different carriers and between different rolling stocks would also be beneficial for the reduction of empty runs, which would directly affect environmental pollution.

The work on expanding the possibilities of greater use during intermodal or multimodal transport, i.e. combining many modes of transport, e.g. road transport with rail transport, where rail transport would be used on long distances of the planned route, and road transport only at the initial and the final sections. In Poland, unfortunately, there are limited possibilities of using multimodal or intermodal transport. One of many reasons is the insufficient number of rail connections between cities, as well as the poor technical condition of the railway infrastructure. In addition to rail transport, transporting containers on barges could also be considered, but there is currently no sufficiently upgraded infrastructure available in the country, e.g. channels that would regulate water levels throughout the year.

Analysing the logistics solutions, an important aspect of road transport organisation is continued optimisation of routes. In their work to optimise truck traffic, logistic staff of large corporations or smaller enterprises should also take into account the environmental aspect but, as it is commonly known, the crucial factor in choosing a route is primarily lower delivery cost, time and end customer satisfaction. However, there are new opportunities for logistics specialists in the field of road traffic optimisation, e.g. the adaptation of urban transport to the needs of society, e.g. closing down rarely used bus lines on an ongoing basis, and increase capacity of those used more frequently, which could reduce empty bus runs at times when the demand for given lines drastically decreases. Due to the need to create an overall bus and tram route schedule, it is impossible to introduce so flexible departure plans without changing the entire public transport management system in Polish cities.

Another category in which enterprises can have their contribution to the reduction of pollution in road transport is upgrading their transport fleets. This is associated with high financial outlays, however, corporations are able to allocate funds for such purposes. An argument that speaks for it is that older vehicles may become more expensive to maintain due to the environmental standards increasingly enforced and implemented by the EU, which can make the cost of transport dependent on the amount of exhaust gas emitted by a given type of vehicle. Although newer cars are more expensive they are equipped with platinum catalysts and have engines of a better design (Dybalski, 2018), while trucks emit various chemical pollutants to the atmosphere, so increasing the number of new vehicles on the streets could bring more satisfying effects.

An interesting fact about the reduction of harmful factors in road transport is the innovative approach to road construction initiated by the Dutch in the city of Krommenie. The road was commissioned in November 2014. Photovoltaic panels were used on the pavement surface.

(https://www.salon24.pl/u/energetyka/953874,w-europie-powstaja-drogi-z-ogniw-fotowoltaicznych-czy-budowanisolarnej-drogi-sie-oplaca) Although it does not directly reduce the CO_2, SO_x and NO_x or PM emissions, the use of solar energy for powering roadside lights and the nearby homes is important in the overall energy balance of the region. The more clean energy is produced using solar radiation, the more the effects of burning fossil fuels and refined petroleum products can be reduced. Moreover, the technology that uses the pressure of passing vehicles on the road to generate energy can be implemented, using piezoelectric materials which produce electric charge carriers under stress. (Stramberky, 2015/2016) Conceptual work is underway and the effects would be similar to those of the PV panels.

Noticeably, there are links between environmental protection, power engineering and road transport thanks to which such activities can contribute to an increase in energy security, reduce the level of atmospheric pollution, and increase public awareness of eco-related topics.

A promising proposal of a solution to the current situation in road transport is also the use of alternative fuels. The automotive industry is currently focusing on combining the benefits of using classic diesel engines in turns with electric motors, but attention should also be drawn to such fuels as hydrogen, which can be used for direct combustion as well as for the direct production of electricity in fuel cells, which can propel electric motors.

Another eco-friendly solution are electric (zero-emission) cars. Electricity can be generated from biomass, fossil fuels or renewable energy sources (e.g. wind). The drawback of electric vehicles, however, is long battery charging time, which requires frequent and long stops, particularly on longer distances. In 2015, electric cars in Poland accounted for an imperceptible 2% of the market, much less than in such countries as Germany, Sweden or Norway. The reasons for such a small percentage include high operating costs of these vehicles and a small number of charging stations, particularly in Poland. Those cars also have a shorter range than the traditional internal combustion ones. (https://www.autotesto.pl/blog/najwazyszne-zalety-i-wady-aut-elektricznych/, 2018) Owners of electric cars in Poland and other European countries have numerous benefits, e.g. in some cities, electric car owners are offered free parking at the city car parks, access to areas restricted for other vehicles or using lanes for public transport, e.g. buses. However, the price of electric cars and a small number of charging stations (although it is expected to increase within a few years) are still among the factors inhibiting the increase of the percentage electric cars in the overall number of vehicles. It is therefore possible to focus more on the use of hydrogen in fuel cells. As a rule, this solution requires installation in the car of a set of cells with a capacity of about 100kWe (equivalent to 130 HP) along with a set of cylinders for compressed hydrogen, which allows for travelling a distance of 500 km. It is a technology that does not release exhaust gases. The only limitation to its widespread use still too high price of cells and uncompleted research stage. If the road transport management system could be combined with hydrogen powered vehicles, a road traffic program could be created in which cars would run on specific routes between hydrogen charging stations and could transport people and cargo at the same time. It is the cleanest and most economically viable solution due to the lack of consumption of fuels which release harmful compounds in the combustion process, and a vehicle traffic optimisation solution. (Pater, 2016)

Pro-environmental activities also include introduction of new car manufacturing technologies, making them more economical, safer and more environmentally-friendly. To this end, hydraulic systems are replaced by more efficient electrical and electronic solutions which eliminate the need for fluids, oils and have no leaks. New cars use increasingly less fuel and are equipped with many comfort solutions (e.g. electronic control of the braking system and ABS drive mechanisms, electronic power steering, EBS electropneumatic brake control, GPS system). In addition to that, works are underway to improve fuel efficiency and minimise exhaust gas emissions, as well as to equip vehicles with comprehensive pollutant removing solutions and a new generation of on-board diagnostic systems reporting e.g. when the vehicle exceeds air pollution standards, analysing the composition of exhaust gases and liquids to indicate the need of an inspection.

One of the ways to reduce the adverse impacts of road transport are also appropriate legal regulations regarding, among others exhaust gas purity standards or fuel consumption checked during the vehicle technical inspection. To register a new vehicle, the OBD II on-board diagnostic system is required and it should also check the quantity and quality of exhaust gases emitted by motor vehicles and control engine operation.

Transport infrastructure is also an important issue. Due to the increasing traffic intensity, there is a need to build and maintain good technical condition of transport facilities (filling stations, service and repair workshops) and roads (mainly bypasses and motorways to take over the heavy goods traffic), which involves both costs and excessive noise. Some countries solve this problem partly by developing cleaner, cheaper and safer rail transport. For example, in Switzerland, in order to promote railways, a mandatory vignette was introduced and fees fordriving to intermodal terminals were withdrawn, driving at night, Sundays and holidays was banned, and part of the receipts from road tolls is used for financing railway infrastructure and protection from noise.

In Austria, however, road carriage of a selected groups of goods is prohibited, and in Tyrol, the speed on motorways at night is limited to 60 km/h. Driving at night and on bank holidays has also been banned (depending on the state), a driving ban for cars with trailers and for trucks put into service before 1992 has been introduced, and a weight limit of 38 tons has been imposed on trucks.

In Germany, the role of rail transport has been strengthened by increasing the capacity on lines important for goods carriage, a special fund has been created to support the construction, extension and restarting of private sidings (financing up to 50% of investment costs), restoration of infrastructure for goods carriage to distances over 50 km is co-financed, subsidies are granted for the construction and development of transhipment facilities, and motorways tolls have been introduced with the intention of extending them to all roads. (UTK, 2017)

The last example of activities reducing harmful factors, e.g. high noise levels, are sound absorbing screens built along motorways and expressways, however, the activities intended to suppress noise are not yet sufficient. There are far less of them than those aimed at eliminating exhaust gases.

Conclusions

Environmental pollution is a global problem nowadays. It has adverse effects on human health and, according to environmentalists, it may also threaten the existence of life on our planet in the future. Transport, including the road transport, is among the factors contributing to air pollution. However, the need for the use of transport is inevitable People nowadays travel on shorter or longer distances using various means of transport. Therefore, actions should be taken to minimise their negative impact on the natural environment and human health. They can include the implementation of modern technologies for reducing emissions (hydrogen-powered cars or hybrid vehicles) and a common and unanimous European policy on sustainable transport.

Introducing modern environmentally-friendly solutions also requires a change in society's thinking and attitudes. The public should be made aware of the need to take care of the environment, which may be reflected by the use of public transport or city bikes. Promoting the public (urban) transport can significantly reduce the environmental impact of cars. However, this requires making the society aware of the benefits of caring for the environment, but also of the need for such activities, as further degradation of the environment will have a negative impact on the future generations. Regulations aimed at protecting the environment, introduced by individual countries or the entire European Union, should not be implemented as the necessary evil, but considered as a manifest of care for our future.

Abstract

Socio-economic trends around the world are determining the need to move towards innovative technologies that can optimize production processes and make significant shifts in the structure of the economy. Unfortunately, Russia's technological development, despite significant progress, leaves much to be desired. To reduce the scientific and technological backwardness it is necessary to increase the intensification of intellectual processes taking place in the economy. The aim of the study is to consider existing opportunities to increase the level of intellectual rent and its impact on the transformation processes in the economy and society. It is assumed that such processes will allow in the future to create a completely new society, in which maximization of knowledge and satisfaction of non-economic needs will become the main dominants. The research is based on the analysis of scientific works on intellectualization, noonomics and quasi-rent. The urgency of forming a sufficient level of intellectual rent is increasing day by day. It is through sustainable growth of its volume that it is possible to build a knowledge economy capable of competing in the world market. Nevertheless, without government intervention and effective economic policy it is impossible to increase the intensity of intellectualization, which will provide a technological breakthrough and, in the future, will create opportunities for a gradual transition to innovation. It can be concluded that the departure from material production is the only rational way of long-term development of human civilization, and the steady increase of intellectual rent will be the first step to the transformation of not only the existing system of management, but also social relations in general.

Keywords: Intellectual Rent, Noonomics, Knowledge-Based Economy, Intellectual Capital, New Industrial Society, Intellectualization, Knowledge Intensity, Nooproduction.

Introduction

Economic relations in the conditions of globalization are unstable, and their dynamics lead to unpredictability of forecasting market environment. This fact indicates the need to maintain the competitiveness of the national economy, which cannot be ensured only by the material and financial factors on which the rational economic theory is based.

Considering the practice of economic development of post-industrial countries, it is necessary to note the fact of obtaining additional income and super incomes by introducing intellectual property objects

into economic turnover. All over the world there is an upward trend in the use of intellectual technologies in economic activity, commercialization of which brings not only increased profitability, but also allows to obtain additional competitive advantages in the market environment (Degtereva et al, 2019; Popkova, Sergi, 2020).

It can be assumed that the trends of not only social and economic but also universal development determine the necessity of transition to innovative technologies, which will make the first step to qualitative structural changes in the economy and society. It is impossible to optimize production and build relationships based on non-material components without activating innovation processes at the national level.

Considering the Russian aspect, it is necessary to note strong scientific and technological backwardness of the domestic economy. It is considered that significant progress is observed in the technological development of Russia, but from the author's point of view, the observed macroeconomic dynamics shows the presence of many problems, without the solution of which there is little opportunity to increase the intensification of intellectual processes occurring in the economy.

The relevance of the study lies in the need to find ways to bridge the gap and dependence on more developed countries. To this end, it is proposed to consider possible ways to increase the level of intellectualization as a way to achieve economic competitiveness and ensure better quality of life. Intellectualization of the economy leads to the formation of intellectual rent, which represents additional profit and super profits through the use of human capital, knowledge, innovation and other achievements of technological progress (Jona-Lasinio et al, 2019; Quarchioni et al, 2020).

However, it is necessary to realize that the reduction of scientific and technological backwardness and innovative development of social and economic relations should not be the ultimate goal. It is necessary to think over further ways of development, which may become a transition to innovation.

The conditions of modern production are undergoing serious transformations and affect the qualitative increase of such elements as "intensity of knowledge" and "capacity of knowledge". With the increasing intensity of knowledge use in the economy, the boundaries between different production operations at the expense of intellectual technologies and human capital are eroding. In turn, the increase in the knowledge capacity of the economy is due to a combination of factors such as the revolution in information and communication technologies and the acceleration of scientific and technological progress (Shpurov, 2016; Bodrunov, 2018).

The authors have suggested that the processes of intellectualization will allow in the future to create a completely new society, in which maximization of knowledge and satisfaction of non-economic needs will become the main dominants, which in the scientific environment is commonly called the new industrial society of the second generation.

Such trends should lead to changes in the structure and content of the needs of individuals, as well as in the way production processes are organized. The displacement of human resources from the sphere of material production should lead to a transformation of economic rationality, which today does not allow for many externalities to be taken into account, such as environmental degradation under technological pressure, the widening gap between the poor and the rich, the inability to meet the growing needs of the population, a demographic disaster (uncontrolled fertility in undeveloped countries and the extinction of the population in advanced intellectual countries) and many others.

On the basis of the listed factors it is necessary to provide a non-economic way of organization of industrial and economic activity, which will be a novelty. In these conditions the production activity will be regulated by people from outside as an external sphere in relation to them. Since human resources should leave the direct production process, then in the future social relations of people will no longer be determined by their participation in production activities (Kondratyev, 2017; Schwab, Werker, 2018; Bodrunov, 2019).

The object of the study is intellectual rent received by the national economy and determines the vector of long-term socio-economic development. The subject of this work is the economic relations arising from the use of intellectual capital at the national level to enhance innovative development.

The aim of the study is to justify the need to increase intellectual rent in order to reduce scientific and technological backwardness and to consider it as a necessary element on the way to a new industrial society of the second generation.

For this purpose, the following tasks are proposed in this paper:

- Consider existing opportunities to improve intellectual rents at the national level;
- to study the impact of intellectual rent on the transformation processes in the economy and society;
- analyze the possibility of transition to a new industrial society of the second generation by obtaining sufficient intellectual rent.

Research Methodology

The research is based on the analysis of scientific works on intellectualization, innovative development, noonomics and quasi-rents. The set of researches will allow to form the material necessary for construction of author's sight at a problem of maintenance of intellectual development and transition to new level of development of social and economic relations.

Many researchers have addressed issues of innovative development, for example, I. Shpurov (2016), J. Albanese (2016), L.V. Nikolova, A.M. Malinin, D.G. Rodionov, M.D. Velikova (2017), I. Rudskaia (2017), D. Mamrayeva, A. Stybaeyeva, L. Tashenova (2018), N. Goncharova, V. Degtereva (2018) and many others. It was found that the formation of an innovation economy is impossible without the use of intellectual capital, which becomes a central resource for digital transformation. The problems of intellectualization were studied by P.P. Vetrenko, E.A. Chernysheva, I.Y. Levitina, O.V. Voronkova, D.G. Mikheeva (2017), E. Zhilenkova, M. Budanova, N. Bulkhov, D. Rodionov (2019), R.V.D. Jordão, J. Novas, V. Gupta (2019) and others. The issues of resource productivity improvement through innovation are presented in V.B. Kondratyev (2017), A. Zaytsev, O. Kichigin, M. Kozlov (2018) and J. Zwiers, M. Jaeger-Erben, F. Hofmann (2020).

Intellectual processes launch processes not only on the economic level, but also on the social level, which leads to the reconstruction of the social and economic formation prevailing in modern society. Most authors consider innovations as a key element of sustainable development of the national economy in the long term. In the future, such relations lead to the formation of a new culture based on non-economic elements, i.e. noonomics.

S.D. Bodrunov (2018; 2019) is engaged in the development of the theory of noonomics and reindustrialization. From his point of view, it is reasonable nouns production that will be the next stage of production development, which will be connected not only with economic aspects of life, but also integrates cultural aspects. Such a relationship can be represented as a sequence (Figure 1).

Fig. 1: Production development in novelty

Nononomics is the result of intellectual change. And if such transformations may not lead to the formation of a new industrial society of the second generation, the transition to such a society without intellectual resources is not considered possible in the scientific environment.

The importance of the processes of intellectualization of modern society requires a more complete study of the role of intellectual capital in the development of industrial relations, since increasing the share of the intellectual component is an integral factor in building an innovation economy, as noted in the works of B.V. Salikhov (2018), G.I. Senchenia (2019), D. Rodionov, A. Zaytsev, N. Dmitriev, O. Kichigin (2019), C. Jona-Lasinio, S. Manzocchi, V. Meliciani (2019), E.G. Popkova, B.S. Sergi (2020).

It may be noted that the development of intellectualization requires a significant injection of investment resources. It is the activation of investment processes and the creation of a sufficient level of investment attractiveness makes it possible to create innovations and systematically improve the quality of human capital. Investment issues were considered in the works of such authors as E.A. Avduevskaia, Y.Y. Kuporov, E.M. Chepikova (2018), S.A. Ciupitu, M. Niță (2018), O. Kichigin, V. Degtereva, A. Zaytsev, N. Dmitriev (2019), G. Onofrei, J. Prester, B. Fynes, P. Humphreys, F. Wiengarten (2019).

Competent investment policy in the field of innovative development and ensuring the increase of intellectual components of economic development gives impetus to the emergence of such a qualitative phenomenon as quasi-rent.

Y.V. Yakovets (2003), A.V. Latkov (2006), T.M. Nazarycheva (2013), L. Fishman, D. Davydov (2015), R. Gaisin (2017), Schwab, E. Werker (2018) and V. Degtereva, N. Dmitriev, A. Zaytsev (2019) studied rent relations, intellectual rent and quasi-rentals. Researchers agree that the urgency of forming a sufficient level of intellectual rent increases every day. It is through its steady growth that it is possible to build a knowledge economy that can compete in the world market.

In particular, in book K. Schwab (2017) describes the technological, economic, and social revolution, as well as the main factors shaping the modern post-industrial economy. It is at this level of development of economic relations that intellectual rents are increasing on a larger scale than at the industrial level. The main elements of the post-industrial economy include the high-tech sector, which was discussed in V.A. Plotnikov (2018).

Activation of innovation processes should start at the level of economic entities. For this purpose, it is necessary to monitor the current trends in the field of scientific and technological progress and introduce relevant innovations into production. For example, block technology or corporate

information systems (Nikolova et al, 2017; Ciupitu, Niță, 2018).

The next level is the qualitative development of the intellectual capital of the territorial association. A competent government policy in this area will ensure the reproduction of intellectual resources in the conditions of building an innovation and digital economy (McAdams, 2016; Zhilenkova et al, 2019). We can conclude that without government intervention and effective economic policy it is impossible to increase the intensity of intellectualization, which will provide a technological breakthrough and in the future will create opportunities for a gradual transition to innovation.

Research Results

In the history of human civilization, globalization processes have been of key importance. In different epochs they distinguished their elements of global civilization dimension. Today such element is intellectual capital, which allows to form intellectual rent, which ensures the development of civilization and domination of one nation over another in the global world scale (Yakovets, 2003; Latkov 2006; Gaisin, 2017).

Civilizational development faces many social and economic problems in the modern world that hinder the advancement of the fourth industrial revolution (Fishman, Davydov, 2015). Such problems include:

- crisis of the existing world order due to the complexity of relations between certain geopolitical forces and the existence of regional conflicts;
- Increasing social inequality and social stratification at regional and national levels;
- huge opportunities for technological development, but lack of opportunities to realize this potential and so on.

The presence of many contradictions prevents the formation of intellectual rent. The products produced under the conditions of transformation of economic relations along the intellectual path contain, in addition to the material basis, the so-called "intangible element" - knowledge that is present in all components of the production process, from materials to human labor. Accordingly, knowledge is, along with the material basis, an integral part of the product of production and makes it possible to obtain intellectual rent (Salikhov, 2018; Bodrunov, 2019).

The increase of intellectual rent is suggested to be considered from the point of view of building a modern economic complex, which is considered in Figure 2.

Fig. 2: Development of modern economic complex

On the basis of the given structure it is possible to draw the following conclusion: development of intellectual processes at macrolevel in the field of development of knowledge intensive production, increase in volume of scientific knowledge and educational processes demands attraction of considerable volume of investments. It is the increasing intensity of these processes that makes it possible to obtain intellectual effect at the micro level and transform educational, cultural and other processes of social and economic character (Schwab, 2017; Bodrunov, 2018).

Thus, intellectual rents at the national level can only be achieved with significant investment. Consideration and projection of intellectual rents can be calculated mathematically.

To date, the use of mathematical analysis and modeling has become one of the main forms of economic research. It is correct to speak not just about the application of mathematical achievements in economic science, but to perceive their synergetic interaction as a necessary component for the rise of economic theory to a higher level (Kichigin et al, 2019; Zwiers et al, 2020).

Economic theory in interrelation with mathematical science allows to make calculations and model intellectual rent flows at all levels of management. If it is possible to calculate intellectual rent, it is practically impossible to determine the boundary of its volume for the shift of the economic paradigm.

In order to consider the possibility of raising the level of intellectual rent at the national level, it is proposed to consider the share of "knowledge-intensive" industries in the structure of gross domestic product, as demonstrated in Table 1 (Plotnikov, 2018; Bodrunov, 2019).

Table 1: Share of "knowledge-intensive" industries in GDP structure (2017), %

Industry	Middle G7	Russia
RESEARCH AND DEVELOPMENT	2,6	1,1
Education	6,0	3,5
Information and communications technology	8,0	2,5
Biotechnology and health care	13,0	4,0
Total	30,0	11,0

Based on the tabular data, it can be seen that Russia lags far behind the leading countries in relative terms. It can be said that only sufficient investment in the most significant industries from the intellectual point of view will allow gaining competitive advantages at the level of the national economy.

Activation of innovative processes demands intervention of the state structures both in investment, and in educational processes. If with investments all is clear, questions concerning maintenance of educational processes are poorly studied. In the early stages of education, individuals should develop entrepreneurial competencies and skills necessary for the quality return on human capital in the future. Educational standards in many developing countries, including Russia, do not meet these requirements, which makes it urgent to find a solution in the near future (Vetrenko et al, 2017; Akhmetshin et al, 2019).

Education, science, post-industrialization and other factors should lead to a revolution in social and economic relations, reflected in an increase in intellectual rent. In turn, the sufficiency of quasi-renta will allow the national economy to generate super profits in the long run. However, sustainable development is only possible if a multitude of innovative contradictions are solved, which should be considered in separate territorial units (Rudskaia, 2017; Goncharova, Degtereva, 2018).

Throughout human history, there has been a shift in production processes from material to non-material. Due to the increase in intellectual rent, the development of humanity along the knowledge-intensive path increases, when the share of "knowledge" in production relations exceeds material components (Bodrunov, 2018; Mamrayeva et al, 2018). This fact leads to an increase in the share of intellectual labour in total costs, which is illustrated in Figure 3, where: 1 - knowledge capacity; 2 - material capacity; 3 - fund capacity; 4 - energy capacity; 5 - resource capacity.

Fig. 3: Changing capacitive parameters in historical process

The structure in Figure 3 is idealized, in practice the boundaries between epochs are very blurred. Unfortunately, the modern humanity is moving towards the rise of more and more needs that do not correspond to human development. Such needs are simulated. Their formation goes along the following chain: 1) satisfaction of needs with reserves; 2) surpluses in satisfaction of needs due to reinsurance and prestigious considerations; 3) consolidation of this surpluses at the expense of market demand bloat; 4) increasing needs that cannot be fully satisfied but require resources (Bodrunov, 2019).

These trends have a strong negative impact on all of humanity. However, management of intellectual processes in the economy will transform social and economic relations in society and will lead to qualitative structural shifts in the economy.

Such shifts are an important element in overcoming many of the crisis factors of civilization's development, for example: uncontrolled growth of simulative needs at the expense of quality needs; increasing man-made threats to the environment; humanity's dependence on technological development; international integration and globalization processes cause serious damage to civilization; the presence of a cultural threat due to a moral shift, and much more.

Control over the movement of social development and the activation of intellectual processes from the author's point of view will allow to move from modern society to the era of nooproduction.

Relationships in modern society are based on the following relationship: Individual → Sphere of production → Individual. Under such conditions, production is a link between individual individuals, which prevents quality development and leads to serious stratification in society.

The era of novelty consists in interconnection of separate individuals among themselves, whereas the sphere of novelty or technosphere is not a link, but a certain control element.

The principal difference between noonomics and the usual system of economic relations is the reduction of people in the process of material production. A possible transition to a new industrial society of the second generation by obtaining sufficient intellectual rent will lead to structural shifts in employment. Such shifts are proposed:

- the development of artificial intelligence technology;
- growing demand for research and development;
- increasing employment in the intellectual sphere;
- the development of robotics;
- reduction in the employment of production workers;
- freeing up work resources.

It may be noted that the release of human resources may not lead to the growth of the intellectual sector of the economy, but may lead to mass unemployment, especially in underdeveloped countries. However, it can be assumed that the qualitative returns from human capital may increase and that intensive production methods may emerge. A shift away from the familiar capitalist way of life and the realization of multiple externalities will lead to increased non-economic needs.

Conclusions and Recommendations

Humanity is in a difficult situation, where solutions to global problems can no longer be postponed for the future and maximum efforts must be made to create mechanisms for their resolution. Progress in science and technology could be an important factor in the transition to a new way of life.

From an author's position is caused by necessity of working out of methods and ways of a direction of intellectualization on a way of qualitative development of innovative processes and a departure from rational economy. Exactly intellectual rent acts as a determinant of appearance of possibilities on transformation of social relations.

Despite the difficulties in defining intellectual capital, it has long been one of the most effective competitive advantages in the information economy. In this regard, the existing methods and approaches to intellectual capital in the future will only be improved in order to obtain the most adequate assessment of intellectualization (Rodionov et al, 2019). One of the perspective methods can be the use of normative-dynamic models in calculations (Zaytsev et al, 2019).

However, existing mechanisms for the development and distribution of rent revenues, which allow for sustainable economic development by maintaining socio-economic and political stability, need to be more fully developed at the moment (Degtereva et al, 2019).

In the author's work the interconnection of intellectual rent and the possibility of transition to noonomics are considered. The necessity of management of innovative processes and their direction in the direction of qualitative civilizational development is determined. Also the main problems faced by humanity and which can lead to significant development problems were listed.

It is possible to draw a conclusion that departure from material production is the only rational way of long-term development of human civilization, and steady increase of intellectual rent will be the first step to transformation not only existing system of management, but also social relations as a whole.

Abstract

Organizations aim to employ green IT solutions to help lessen the negative environmental impact of technology, reduce costs, limit waste and energy consumption. However, implementing these initiatives and adding related devices to networks to monitor energy usage and waste into various IT systems raises security concerns. In this paper, we highlight our initial research highlighting these issues related to green computing initiatives and the need to increase security awareness. This paper also discusses the next steps in our study leading to an in-depth analysis of green IT initiatives and potential security vulnerabilities.

Keywords: Security Awareness, Security Risk, Green IT

Introduction

There is a growing need to consider the environmental impact of the technology we use every day. This includes technology development, usage, disposal, maintenance and production in today's world. Green Computing is seen as the practice of using computer resources wisely, including cost and resource efficiency, along with social responsibility. As we are increasingly becoming dependent on various types of computer technologies, we continue to consume more and produce more e-waste. To help mitigate these negative environmental impacts, multiple techniques and changes in how we interact with, use and build computing technology have been encouraged through various Green IT initiatives.

Even though there is excellent potential in lessening the impacts of our technology usage, there are, however, inherent security concerns in implementing these systems. Organizations aim to employ these new technologies and incorporate them into their networks and IT systems; however, they do not often consider possible security implications. In this paper, we highlight some ongoing research highlighting these issues and discuss the next steps in our research related to green IT initiative and potential security risks.

Green IT Initiatives and Security Risks

There have been many green IT initiatives over the past several years aimed at reducing negative environmental impacts, energy usage and e-waste. As a simple example, consider an organization that decides to digitize their older paper-based records. Not only can these paper records become damaged, lost or destroyed in the process of scanning, one needs to be mindful of who is handling these documents. What data is contained in the documents and who has access? It is highly probable that access to these documents would not be as controlled or monitored the same as in a computerized environment. It is also common to outsource scanning or data entry of these documents which would take potential sensitive data outside of the control of an organization. Green IT often involves virtualization, reorganization of data and the recycling of hardware which raises some security concerns (Gorge, 2008). Specific to the recycling of hardware, some businesses and individuals in their efforts

to recycle or donate equipment fail to erase data properly. These efforts can lead to confidential information becoming compromised. Many organizations have guidelines on how often equipment is upgraded or replaced, leading to many devices becoming a risk every year. As noted by James (n.d.) data on hard drives that have been erased can be potentially recovered even by novice users with the right software.

Another shift relates to the inclusion of automation, sensors and other connected devices through the Internet of Things (IoT). IoT can be understood as devices (things) that exchange data and can communicate with each other or have an Internet connection. Some estimates place the number of IoT devices globally at around 10 billion devices by 2020 and 22 billion by 2025 (Lueth, 2018). Advances in the ability to create and modify sensors have led to the proliferation of devices in a multitude of homes, offices and other environments. Homes and offices equipped with smart energy management can assist with making better decisions on settings based on time of day, outdoor and indoor temperatures and adjust when we are not at home (Anvari-Moghaddam, Monsef, & Rahimi-Kian, 2015). Although having these devices to monitor, automate and collect various data, this connectivity opens doors to security vulnerabilities. Many of these devices are connected to networks unsecured, use and connect to external applications and remain untested for security vulnerabilities. Hossain, Fotouhi and Hasan (2015) present an analysis of IoT attack surfaces, threat models, and challenges.

On a much larger scale, automated systems aimed at making more informed choices and reducing energy consumption via smart cities also pose challenges and risks. Attacks on these systems can cause larger-scale disruptions and loss. As an example, through a study conducted by Ghena, Beyer, Hillaker, Pevarnek and Halderman (2014) has discovered several vulnerabilities in traffic light systems. They point out that it is not the fault of one particular device but however, a combination of lacking security issues. Ghena et al. noted three significant weaknesses in the road agency's traffic infrastructure deployment that was evaluated (2014):

1. The network is accessible to attackers due to the lack of encryption.
2. Devices on the network lack secure authentication due to the use of default usernames and passwords.
3. The traffic controller is vulnerable to known exploits.

Although these weaknesses are specific to traffic systems, these concerns are valid for other systems as well, including connected IoT devices, where there may be known exploits, unchanged default settings and lack of encryption. It has been noted that IoT devices are not always integrated with traffic policing mechanisms of the overall network, designed to be open to new devices, involve automated communications, and often involve cloud or grin computing (Zhang & Green, 2015).

Conclusions and Future Work

Overall, there needs to be an increase in both security awareness and research into the mitigation strategies related to green IT initiatives. Organizations of all kinds can not only benefit from green IT but can benefit from improved security measures. To assess this area of research, we are in the process of examining numerous Green IT initiatives and various related threat models as well as mitigation strategies. The next step in our study is to investigate major green technology solutions of many kinds (e.g. using collaborative tools to reduce travel, life-cycle assessment models for recycling concerning data cleansing, IoT, environmental sensors, energy reduction, etc.) As part of this research, we are identifying what companies are doing to be more "green" and what technologies are being used as part of this practice. How has going green changed business practices, and how have these changes impacted security measures? Have there been cases of security breaches or concerns related to green technologies? We plan to compile this information and make recommendations for various green IT strategies to enhance best practices and encourage ongoing research in this area.

Safe Exploitation of Delivery Vehicles in Transportation Companies

Paulina OWCZAREK

Military University of Technology in Warsaw, Warsaw, Poland
paulina.owczarek@wat.edu.pl

Abstract

The specificity of the exploitation of delivery vehicles in transportation companies is associated with high environmental pressure resulting from the necessity of often express delivery of loads to the customer on time. This may have a negative impact on the safety of the driver, the loads transported and other road users. The research confirms that on Polish roads there are delivery vehicles that exceed their permitted total weight, which according to the vehicle's construction is 3.5 tons. By law, a vehicle's owner does not have to install tachographs in his vehicles, which also affects exceeding by the driver his permitted work time. The aim of the article is to analyze the issues of safe exploitation of delivery vehicles in transportation companies To achieve the objective, a characterisation of the threats and potential risks of dangerous situations endangering the lives of the driver, other road users, the vehicle and the load carried, was necessary. The technical characteristic of the selected delivery vehicle was carried out and the functioning of the systems and installations increasing its safe exploitation was verified. The analysis of the discussed issues allowed to formulate methods and principles of safe exploitation of delivery vehicles in transportation companies.

Keywords: Safe Exploitation, Delivery Vehicles, Exploitation Of Vehicles

Introduction

The dynamic development of the Polish transportation industry and the constantly changing social, economic and legal conditions mean that the results of transportation companies are influenced by many factors. One of the most important areas to be identified and assessed is the safe exploitation of delivery vehicles in transportation companies.

The issue of safe exploitation of vehicles is an extremely important element of transportation systems in companies providing transportation services; unfortunately, it is often overlooked or neglected in many aspects [4].

In 2018, 3,338,166 trucks, including delivery vehicles, transported 1,183,750 thousand tonnes of loads and 377,778 million tonne-kilometres were driven [7]. Every month there are more and more heavy goods vehicles on the Polish roads, which especially on the part of passenger vehicle drivers increases the feeling of danger, unforeseen events or the risk of collisions and accidents.

Referring to the literature on the subject [1], [13], the exploitation of motor vehicles is defined as a set of intentional organisational, technical, social and economic activities of people with a motor vehicle and mutual relations between them from the moment of buying the vehicle to its intended use to its liquidation. These areas of activity are intended to enable the vehicle to fulfil the required functions, together with the need to adapt to constantly changing external conditions. External conditions means, among others, legal, ecological and social requirements for the provision of services and also environmental conditions.

The theory of exploitation pays particular attention to identifying exploitation through two basic elements, which include the vehicle utilization process and the vehicle handling process [3]. Therefore, the security issues to be analyzed will be related to these areas [11].

The research subject of this study are delivery vehicles, whose percentage in Poland in the years 2014-2018 amounted to 81% in relation to all heavy goods vehicle designed to carry loads (Fig. 1) [6].

Fig. 1: The number of delivery vehicles in relation to the number of all heavy goods vehicles between 2014 and 2018 [6]

Recent studies carried out in 2018 also confirm the use of older delivery vehicles. According to the statistics of the Polish Main Statistical Office (GUS), over 65% of all delivery vehicles are over 12 years old.

Analysing the issue of operational safety of delivery vehicles, the results of road inspections carried out by the Inspectorates of Road Transport and the resulting fines for exceeding the permitted load capacity (Fig. 2) [6].

Fig. 2: Results of inspections of delivery vehicles [6]

The Inspectorates of Road Transport legally inspects only heavy goods vehicles with Permitted Total Weight exceeding 3.5 tonnes, while this government office inspects delivery vehicles only if considers there is a clear suspicion that a specific offence occurred. Taking into account the year 2018, out of 10,426 delivery vehicles inspected, overloads were found in 9,251 vehicles. This figure, in relation to the number of all such vehicles, i.e. 2,823,241, represents only 0.33%, but it strongly suggests that there are vehicles on the roads that pose a serious threat to road users.

The aim of this study is to characterize the issues of safe exploitation of delivery vehicles in transportation companies. The analysis has identified the risks associated with the improper exploitation of vehicles, as well as the potential risks of unreasonable exploitation of vehicles. The article presents the detailed technical characteristics of the selected delivery vehicle and the functioning of the systems and installations increasing its safe exploitation was verified. The analysis of the discussed issues allowed to formulate methods and principles of safe exploitation of delivery vehicles in transportation companies.

The ever-growing requirements for transportation companies with delivery vehicles, specialising mainly in express shipments, force transport companies to act often beyond permitted standards, i.e. to overload vehicles, exceed driving and work time of the driver, exceed driving speed, as well as to inadequately fix and secure loads in a load box [3]. These situations pose a potential threat to the life of the driver and other road users, as well as to the proper exploitation of the vehicle.

Technical Characteristics of Delivery Vehicles

Special technical requirements are imposed on motor vehicles, especially on those, whose purpose is to transport loads. The identification of the needs to be met by such vehicles determines certain technical requirements, which in turn are aimed at meeting exploitation requirements

The subject matter of this study indicates interest in delivery vehicles, which, according to the type homologation and the Attachment No 2 to the Road Traffic Law Act, are vehicles designed and constructed for the transportation of goods and having the PTW *(Permitted Total Weight)* not exceeding 3.5 tonnes.

In practice, a delivery vehicle is classified as a light goods vehicle intended for the transportation of small and light loads. Due to the 3.5-tonne total permitted weight, the category B driving licence is sufficient to drive a delivery vehicle in Poland, which means that drivers do not have to undergo special medical and psychological examinations and acquire additional skills to drive a vehicle with a load placed in a load box, and there is no mandatory training to teach safe driving behaviour or the proper and safe arrangement of cargo in load boxes.

As a rule, commercial vehicles are much more mileage intensive than passenger cars and are therefore also more vulnerable to accidents. Only a dozen or so years ago, manufacturers of delivery vehicles used the simplest suspensions, not very efficient brakes, and passive safety equipment was limited to safety belts and soft steering wheel padding. Meanwhile, the fastest delivery vehicles drive on motorways at up to 170 km/h [15]. In the era of rapid technological development, focusing on driving comfort, safety and quality requirements of customers, brakes with ABS and airbags, and even ESP electronic stability programs, have gradually been adapted in delivery vehicles.

Manufacturers of delivery vehicles offer many body and equipment versions which differ very clearly not only in terms of engine power, but also in terms of dimensions, weight, suspension design and type of tyres. Each variant requires completely different software for active and passive safety systems. A perfect example is the ESP system in the Mercedes Sprinter, where each of the several dozen versions of the vehicle must have different software driver. The Electronic Stability Program (ESP) has access to both the brake system and the engine control system [10]. This system continuously in real time analyses measurement data from the steering angle sensor, wheel speed sensors, transverse acceleration sensor and gyro sensor, assisting the driver when the vehicle is in danger of losing stability while

driving. In fractions of a second, ESP reacts precisely by interfering with the engine and brake electronics and supports the driver by actively generating braking forces to stabilise the driving track. The system also contains additional functions that can increase driving safety in certain situations. These systems include the ABS system to prevent wheel lock during braking, the ASR system to prevent drive wheels from slipping and the BAS brake assistant, which can increase the braking pressure if an emergency brake is detected and thus shorten the stopping distance. In this case, the only risk factor in the exploitation of the vehicle is the driver and his actions or failures to act.

Even the best suspension, brakes and safety systems cannot repair mistakes of a driver of vehicle. In the case of delivery vehicles with a total weight not exceeding 3.5 tonnes, these occur relatively frequently. The reason for this is a lack of experience in driving heavy goods vehicles as well as unsystematized legal regulations concerning the utilization of delivery vehicles. Although the cabs of modern commercial vehicles are more and more modern, safe and comfortable, the exploitation of delivery vehicles varies greatly in comparison to exploitation of passenger vehicles. Modern turbo-diesel engines provide excellent performance for delivery vehicles, while the high position at the wheel provides an illusion of full control. However, in violent manoeuvres, a high kerb weight and a high centre of gravity make themselves felt, which poses a serious threat to the safety of the driver, the vehicle and third parties.

The characteristics of a delivery vehicle may be presented by means of technical features referred to in the literature as constructional, structural, physical, geometrical features resulting from the design and construction calculations of the manufacturers. They relate to a set of information specific to a particular class of objects identified by the same construction, e.g. a vehicle model [12].

As with all heavy-duty vehicles, the delivery vehicles have a clearly identified undercarriage in the form of a load-bearing frame. Engines, driving systems and parts used to carry the load are attached to the frame. The location of the engine compartment in different solutions is shown in Fig. 3 [14].

Fig. 3 : Location of the engine compartment: (a) in front of the driver's cab, (b) and (c) inside the driver's cab

The most important element of a van is its bodywork, which is a cargo space that is adapted to carry a specific group of loads and whose detailed technical specifications are created by specific manufacturers.

The example may be the delivery vehicle, Fiat Ducato, designed and manufactured for the transportation of foodstuffs with a refrigerated bodywork is shown in Fig. 4 [5].

Fig. 4: Fiat Ducato with a refrigerated bodywork [5]

A refrigerated vehicle with a container-type bodywork allowing to maintain a controlled temperature in the range from +30°C to -30°C. There is a refrigerator on the front wall, allowing to cool or heat the container. The technical specification of the vehicle shown in Fig. 4 includes a set of individual technical characteristics as shown in Table 1.

Table 1: Technical specifications of Fiat Ducato (own elaboration)

Year of manufacture	2010
Mileage	199,000 km
Engine displacement	2,300 cm^3
Maximum power	140 KM
Maximum torque	350 Nm
dimensions [L x W x H]	5,988 mm x 2,050 mm x 2,764 mm
Type of chassis	Refrigerated vehicle
Transmission	Manual gearbox
Fuel type	Diesel
Exhaust emissions standard	Euro 5
Drive	Front-wheel drive
Payload	950 kg
Permitted Total Weight	3,500 kg
Vehicle Kerb Weight	2,550 kg
Wheelbase	4,035 mm
Permitted axle load	20.00 kN
Maximum speed	162 km/h
Fuel consumption by New European Driving Cycle (NEDC)	7.1 – 7.4 l/100 km
CO2 Emissions by New European Driving Cycle (NEDC)	186 – 195 g/km
Front suspension	Independent MCpherson type wheel suspensions with suspension arms attached to the auxiliary beam, spiral springs and telescopic shock absorbers and stabiliser bar
Rear suspension	Rigid tubular bridge with parabolic leaf springs, telescopic shock absorbers, flexible side bumpers

Safety equipment	ABS - H-1 dual circuit brake system: front and rear disc brakes; EBD - electronic brake force corrector; ASR - traction control; ESP - stabilisation of the driving track; Central lock, Alarm, Immobilizer, Driver airbag
Other equipment	CB radio, On-board computer, Twin rear wheels, Sliding door, Cruise control
Location of the engine	In front of the driver's cab

The technical characteristics, already determined in the needs formulation phase and the production phase, condition and determine the operational capability of a delivery vehicle, the rational exploitation of which is intended to ensure an adequate level of safety.

The Issues of Safe Exploitation of Delivery Vehicles in Transportation Companies. Analysis of Threats and Risk.

The number of delivery vehicles on Polish roads is constantly growing. They are treated by law as passenger cars, so they can travel much faster than heavy goods vehicles, i.e. outside urban areas at speeds of up to 90 km/h, while a heavy goods vehicle can travel at speeds up to 70 km/h, whereas delivery vehicles can travel up to 140 km/h on the motorway unlike heavy goods vehicles, which should not exceed 80 km/h.

Excessive speed of the vehicle carrying the load is a danger not only for the driver and the load being carried, but above all for other road users. The specificity of the exploitation of delivery vehicles indicates frequent exceeding of the permitted standards on the maximum weight of the transported load. This is a breach of basic safety rules. An overloaded delivery vehicle is not only unfair competition, it is above all an irresponsible businessman who is not aware of the dangers of overloading a vehicle that poses a huge risk to other road users when bypassing an obstacle or suddenly braking. An overloaded vehicle also has a much longer stopping distance. The construction of the delivery vehicle is adapted to carry loads up to a maximum of about 1,500 kg, so any exceeding the standard increases the risk of losing control over the vehicle.

The unreasonable exploitation of commercial vehicles poses a number of serious risks, which can result in a number of undesirable situations directly affecting the lives of drivers and other road users. A list of the most important threats and risks associated with them is presented in Table 2.

Table 2. Threats and risks associated with the unreasonable exploitation of delivery vehicles (own elaboration)

Threat	Risk
Overloading	Damage to the frame Tyre breakage Failure of suspension, brake, steering systems; Loss of control over the vehicle; Exposing other traffic participants to danger; Accidents, collisions; Communication damage.
Inadequate securing a load in the cargo space	Damages to the cargo space; Loss of control over the vehicle; Accidents, collisions; Communication damage; Exposing other traffic participants to danger.

Driver's work time exceeded	Low level of concentration Accidents, collisions; Exposing other traffic participants to danger.
No driver experience	Accidents, collisions; Exposing other traffic participants to danger.
No safety systems installed in vehicle	
Excessive speed	
Rapid manoeuvres of a vehicle loaded with a load	Loss of control over the vehicle; Accidents, collisions; Communication damage; Exposing other traffic participants to danger.

Threats arising during the unreasonable exploitation of a delivery vehicle increase the likelihood of undesirable and dangerous situations. The highest level of risk concerns exposure to danger for the driver and other road users. Improper exploitation of a delivery vehicle can expose the owner of the transportation company to breakdowns and damages to the vehicle, which results in unplanned downtime and additional costs associated with restoring the vehicle to its operational condition. A careful assessment of the risk of undesirable situations indicates that the risks presented require control and implementation of preventive measures on the part of the transportation company manager.

Methods and rules of the safe exploitation of delivery vehicles

Vehicle constructors strive to design their delivery vehicles in such a way that they are fully safe when exploited. The specific construction of delivery vehicles, the quality of which is constantly being improved in accordance with users' preferences and legal requirements, increases the safety of transport services provided. Properly adapted cabs with good visibility, effective brakes, driving comfort and driver experience significantly reduce the risk of accidents, breakdowns or damage to the load. Safety systems, i.e. ESP systems that precisely correct drivers' mistakes, allow a higher level of safety [2]. Some cars are also increasingly equipped with systems that warn of obstacles and automatically brake or signal when they leave the lane marked by lines, and have the ability to warn of vehicles that are in the so-called blind spot. Each of these modern technologies takes care of the safety of the driver, the load transported and other road users [9]. Of course, these systems are not able to protect the driver from every event.

The driver using the vehicle is primarily obliged to observe the rules of safe exploitation of delivery vehicles. Such a driver should have basic experience in driving loaded vehicles.

The basic rule of safe exploitation of delivery vehicles is, above all, not to accept loads that would cause exceeding the permitted total weight of a vehicle. The load shall be properly secured, fixed and placed as low and as close to the rear axle as possible. The attachment shall use handles on the walls and floor of the load box. The correctsecuring of the load prevents it from shifting, tipping and related problems and possible damage to the vehicle [15].

Each user of a delivery vehicle is obliged to check the technical condition of the vehicle before setting off on a route. Special attention should be paid to the condition of the tyres and their pressure.

Correct exploitation of vehicles forces users to comply strictly with maintenance intervals and deadlines and to immediately report any noted faults or anomalies in order to prevent further damages. It is also the responsibility of the vehicle user to adapt the vehicle to the specifics of its utilization and designation, including the physical protection of any elements that may be damaged or destroyed, e.g. the floor in the cargo space, engine guards, protecting the vehicle against the permanent action of other adverse factors and taking actions to prevent the deterioration of the vehicle.

The driver's behaviour has a huge impact on the safe exploitation of the vehicle, careful driving with the transported load in mind, concentration and forced rest are the basis for safe driving. Rational

adaptation of speed to the current road situation, observing speed limits and no time pressure is a requirement for the safe exploitation of vehicles adapted to carry loads [8].

All the above rules and recommendations increase the level of safe exploitation of delivery vehicles, the driver, the load transported and other road users. Disregarding the threats arising from the delivery vehicles' exploitation that is improper or is not in line with regulations and the manufacturer's recommendations, increases, in particular, the risk of dangerous situations. This also has implications for the costs incurred in connection with using and servicing commercial vehicles.

Summary

The issue of safe exploitation of delivery vehicles is particularly important due to legal conditions and the specificity of their use. Statistical data confirm that overloaded delivery vehicles drive on Polish roads. Of the 40 vehicles inspected, 36 of them are overloaded. The consequence of unreasonable exploitation of delivery vehicles may be damages to individual parts of the vehicle, breakdowns, the driver may lose control over the vehicle, thus putting himself, other road users and the cargo carried in the cargo space at risk.

Safe exploitation also requires regular maintenance in accordance with the requirements and instructions of the vehicle manufacturer. The Daily handling of the delivery vehicle is also one of the rules that must be met to ensure the safe exploitation of the delivery vehicle in transportation companies.

Abstract

Relevance. Modern trends in the development of the economy of Kazakhstan remembered with complex changes. On the one hand, these changes are one of the conditions of the process of globalization, which has already covered the entire world, and on the other, one of the ways of successful development of the country and a worthy place in the world community. If the twentieth century was the age of technology, the century of the twenty-first century is the age of education and science, as well as innovation. Therefore, the peculiarity of the research is that it fully meets the modern needs of society's development. Thus, the processes of innovative development require constant regulation and support from the state. **Research objective:** conduct a scientific analysis of issues of state regulation of innovative economic development, to prepare theoretical and practical recommendations for improving the competitiveness of the national economy. **Methods:** The research tools used in this research systematic analysis, empirical research, synthesis and comparative analysis of theoretical and practical data. **Results achieved:** theoretical problems of innovation are comprehensively studied, foreign experience and mechanisms of state regulation of innovative development are scientifically analyzed, and the current state of innovation development in Kazakhstan is analyzed. **Practical significance and applicability of the results:** The problems of development and technological modernization of innovation processes in Kazakhstan have been comprehensively studied, adapted for innovation and recommended for use at the stage of transition to applied research.

Keywords: innovations, innovative programs, investments, innovative infrastructure, competitive products.

Introduction

Innovation occupies a large place in the system of economic relations. Because developed countries understand earlier that it is impossible to get competitive products without applying innovative

experience in production. In this regard, can be formulated on the basis of studies in competitive stage of the market economy is reducing the cost of product innovation, increase investment, the formation of image production and transformation of new markets, including external.

Innovation permits the organization to achieve increased productivity (Adams, 2006) and better match the needs of its clients by matching its organization fit to its environment (Schneckenberg, 2009).

Based on the theoretical analysis, two approaches to the interpretation of innovations are identified:

- first, as regards innovation as new ideas and trends, and as a socio-technical and economic process that leads to the creation of the best quality products and technologies with its application (B. Twiss, F. Nixon, B. Santon, etc.).);

- second, it explains innovation as changes in order to introduce and apply new types of consumer goods, new production and transport means, organizational forms in markets and in industry.Innovation is not only a new introduction, it is a new production activity. It is based on the need to change production technology, introduce innovations in organizational, financial, research and other areas (Message to the people, 2015).

1.The availability of a large opportunity to use the results of scientific activity in the market economy has led to the life of the economic category "Innovation". This phenomenon, which arose in public relations, was called the word" innovation" (Yakovets, 2004), meaning"introduction of innovations".

The word "Innovation" originated from the word" innovation", meaning "rebirth and a new"curtain".

The term " Innovation "is closely related to the concepts of" novelty "and"discovery". The concept of "novelty" is explained by new tools, mechanisms, and equipment produced by humans. The concept of "disclosure" is explained by the process of obtaining previously unknown information and the manifestation of previously unknown natural phenomena. In contrast to innovation, the term disclosure is made at the earliest stage and is not intended to generate any revenue.

Materials and Methods

Modern theories of economic relations that reflect the innovative features of modern entrepreneurship have been developed by the following foreign researchers. This Is: Y. Schumpeter (2014), P. Samuel, Campbell, S. Brew, E. Rogers and R. Shoemaker, R. Nelson, L.Vodacek, P. Drucker, K. Freeman,J. Researchers include Dosi, K. Peres and others.

Among our compatriots, the issues of managing innovation activities, innovation strategy, state and industry innovation policy, as well as innovation processes are academicians R. Alshanov, U. Baymuratov, A. Satybaldin, K. Sagadiev, A. Koshanov, O. Sabden, as well as A. Markov, V.Goncharov, F. Dnishev, K. Kazhymuratov, D. Mukanov, S. Abdygapparova, N. Barlybayeva, A. Sattarova, K. E. Kubaev, T. Kupeshova, A. N. Turginbayeva, N.N. Adekenov, N. Kakharman, G. A. Myrzalieva, A. A. Bulasheva, G. K. Zambinova.

Results

The development of the economy on an innovative basis and the introduction of new technologies do not produce the necessary results without state regulation. In other words, what are the main signs of an innovative economy? By stopping. An economy is considered innovative if the society has the following conditions:

- in any place of the state, any individual, ADM group and enterprise can get access to the necessary information about new or known knowledge, innovations (new technologies, materials, machines,

organization and management of production, etc.), innovation activities, innovation process through an automated and telecommunications system;

- access to the above-mentioned information via modern information technology and computer system;

- develop the national information infrastructure that is necessary to maintain the constantly accelerating scientific and technological progress and information development and provides the socio-economic development of society with extensive information, scientific information;

- speed up the process of automation and computerization of all areas of management and production; changes in social structures that carry out innovative activities, etc.

- wide application of innovations for various activities at the necessary time in practice, as well as good use of new ideas, knowledge and technologies;

- development of an innovative infrastructure that can develop innovations based on modern technologies and carry out innovative activities at the right time, and this infrastructure should be able to develop any industry and any production;

- formation of a system of training and retraining of qualified specialists who are able to develop domestic production and effectively implement complex projects in the field of innovation and innovation activities.

The founder of the world's first technology Park is Stanford University in the United States (in the early 50s). In 1997, there were about 160 technoparks in the United States, which made up 30% of the world's technoparks. And in Europe, technoparks appeared only in the 70s of the last century (Freeman, 2015).

Therefore, the formation of an innovative economy requires an effective policy on the part of the state. In this regard, we can highlight several issues that are waiting to be resolved in the country's economy in the context of integration and globalization into the world economy. Solving these issues requires state regulation. It mcleland are among the:

- raw material orientation of the economy;

- weak intersectoral and interregional integration in the country;

- lack of connection between science and production;

- lack of demand from consumers for new goods and services in the domestic market;

- underdeveloped industrial and social infrastructure;

- low level of innovation activity of domestic enterprises and perception of innovations;

- insufficient allocation of funds for research and development;

- lagging enterprises at the technical and technological level;

-the regulatory framework for innovation, science and technology, and other issues are not sufficiently developed.

Among the issues that cause a contradiction between potential and results, the following main ones can be identified: the issue of stability, the problem of the competitive environment, institutional and managerial. As we have noticed, there are a lot of issues that need to be resolved as soon as possible in order to move the country's economy into an innovative direction. The role of the state in solving these problems is special. These issues cannot be resolved without effective government regulation. The

state, in turn, regulates the innovation sphere by providing legal support and various benefits to economic entities engaged in innovative activities (Zhansykbaeva, 2008; Grigorieva, 2017).

Kazakhstan is still considered on the world market only as a producer of oil, gas, ferrous and non-ferrous metals, rare and precious metals, and so on. But in the context of modern globalization, this is not enough to be competitive in constantly changing technologies and commodity markets (Mutanov et al., 2019).

Having started its innovative development path, Kazakhstan allows developing at a faster pace for a young state with a high potential for innovative development and becoming one of the most competitive, politically stable countries in the world community (Turginbayeva, 2012).

Innovative development of the country's economy, its financial support and state regulation require an effective investment climate. According to this process, the country is developing well. Thus, at the end of 2017, the volume of foreign direct investment attracted in the country amounted to $ 14.1 billion. US$, which is 5.9 times more than in 2016. Of this amount, foreign investments attracted for non-resource amounts amounted to $ 1.5 billion. USA. The Netherlands is among the countries actively involved in improving the country's competitiveness and sustainable development ($27.0 billion). of the total, or 22.1% of respondents), the United States ($20.0 billion or 16.3%), the United Kingdom ($10.1 billion or 8.3%), France ($7.0 billion or 5.7%) and Italy ($5.2 billion or 4.2%). In order to increase the number of such foreign investors, a national investment web portal has been launched in 12 languages. The results of such analyses provide a complete basis for deciding that the country has the right investment climate and can believe in the future of our country, that is, to create an innovative economy .

One of the main tasks of the country is the development of domestic production and export of goods. To do this, it is necessary to develop the non-resource sector. The amount of support for the non-resource sector in 2016 amounted to $ 12.3 billion. The United States, and in 2017 this figure amounted to 15.2 billion. In comparison with the previous year, an increase of 23.5%.

Currently, there is a need for innovative dynamics in the diversification of the country's economy and the production of high-quality and scientific products. The globalization of modern markets has begun to impose its own rules and requirements in this area, and in the conditions of instability of global financial markets, the only solution is to choose an innovative direction by the state. The government, the national Bank and the Agency for regulation and supervision of the financial market of the Republic of Kazakhstan in 2016-2017 worked in the following areas::

-stabilization of the financial sector;

-solving problems in the real estate market;

-support for small and medium-sized businesses;

-development of the agricultural complex;

-implementation of innovative, industrial and infrastructure projects.

To Finance this plan, 10 billion us dollars were allocated from the National Fund. USA. Of these, $ 4 billion. sectrda financial stabilization of the United States, 3 billion for the development of the housing complex, 1 billion dollars. for the development of small and medium-sized businesses, $ 1 billion. for the development of the agricultural complex in the amount of $ 1 billion. The United States was used to Finance innovative, industrial, and infrastructure projects. The basis for effective development of the economy of Kazakhstan is the development of innovative activities in the country and the promotion of technological modernization. To date, five branch design bureaus have been created for the technological modernization of the economy of Kazakhstan (Mukhtarova et al., 2017). Specially

allocated funds for the creation of such industrial design bureaus were gradually allocated to JSC "transfer of engineering and technology" and JSC "national innovation Fund".

Financing of innovation activities in the country is also developing independently. Innovative grants have started to be provided in this direction. For the first time in 2016, us $ 7.3 billion was allocated for the provision of innovative grants and innovative technologies and development work.tenge. This year, the total volume in Kazakhstan amounted to 55.4 billion dollars. 679 applications were accepted for the amount of 679 tenge.

In addition, the volume of innovative products in the country in 2017 amounted to 145525.8 million dollars. tenge. The volume of innovative products by region for 2010-2017 is shown in table 1.

Table 1: Volume of innovative products by regions of Kazakhstan. million tenge

Regions	2014 year	2015 year	2016 year	2017 year	2018 year

TheCityOfAstana	2866,8	13,0	13,2	31,1	110,5
Almatycity	7877,5	7836,9	11 085,6	7 711,5	14 056,9
Note: http://www.ifk.kz/index					

From the table above, we noticed that in some regions, compared to 2014, the volume of innovative products decreased in most regions compared to 2018. In General, in Kazakhstan in 2014, the volume of innovative products amounted to 152500.6 million us dollars. tenge, in 2015-111531.1 million dollars. tenge, in 2016-82597.4 million dollars. tenge, in 2017-142166.8 million dollars. in 2018, this figure was $ 145525.8 million. tenge. We see that the volume of innovative products in the country reached its maximum in 2014 and gradually decreased in the following years. The decline in these indicators indicates that the national innovation policy of state regulation of enterprises producing innovative products, support and stimulation of scientific research is still insufficiently developed in the country. (www.stat.kz).

In recent years, the share of innovative products in GDP has been decreasing. These indicators are shown in figure 1.

Figure 1: share of innovative products in gross domestic product %

Note: according to the statistics Agency of the Republic of Kazakhstan for the period from January 1, 2017 to January 1, 2017

As can be seen from the figure, the volume of innovative products in the country is very low and its share in GDP does not reach 2%. The highest indicator of innovative products in 2007 was 1.58% of GDP. This is, of course, a requirement of modern times. Without increasing the volume of innovative products in the country and increasing the activity of enterprises in the perception of innovation, we can not produce competitive products.

Improving the quality of domestic products and ensuring the country's competitiveness, increasing the innovative activity of our country's enterprises. Currently, the number of enterprises that have implemented innovations has reached 399 units. Most of them are located in Almaty (37.8% of the total number of enterprises with innovations). This indicator is 14.0% in Karaganda, 11.8% in East Kazakhstan, 4.8% in Pavlodar, 4.0% in Aktobe, 3.8% in South Kazakhstan and 3.8% in Astana (shown in table 2).

Table 2: Number of innovative active enterprises in the regions of the Republic of Kazakhstan as of 01.01.2018

Regions number of	Respondents number of	Enterprises innovative	Activity of enterprises %
Akmola	589	7	1,2

Karaganda	267	12	4,5
Kostanai	908	56	6,2
Kyzylorda	600	9	1,5
Mangystau	275	4	1,5
SouthKazakhstanRegion	440	6	1,4
Pavlodar	500	19	3,8
NorthKazakhstanRegion	378	10	2,6

EastKazakhstanRegion	687	15	2,2
TheCityOfAstana	705	15	2,1
Almatycity	2 259	151	6,7
Akmola	589	7	1,2
Note: according to the statistical Agency of the Republic of Kazakhstan, 2019.			

In the following years, the number of innovative enterprises gradually decreases. This means that the country's enterprises have a low level of perception of innovation.

One of the main reasons for the activity of the national economy in the perception of innovations is the problems of development of fundamental and General science in Kazakhstan.

According to scientists, fundamental science plays an important role in the modern state and highlights the following tasks::

– the level of science and education in the country is the main indicator of the state. The country's authority abroad is demonstrated by domestic scientists. As an example, the CIS countries currently have a high level of education of the vast majority of the population next to other developing countries. In Kazakhstan, as of January 1, 2018, about 80% of employees engaged in scientific research have higher professional education.

If we compare the innovative activity of enterprises in Kazakhstan with previous years, the best activity is observed in 2014. This year, the number of innovative enterprises has reached 526. These indicators are shown in figure 2.

Figure 2: innovative activity of enterprises in Kazakhstan

Note: separate website of the National innovation Fund. URL: www.nif.kz

In the following years, the number of innovative enterprises gradually decreases. This means that the country's enterprises have a low level of perception of innovation. One of the main reasons for the activity of the national economy in the perception of innovations is the problems of development of fundamental and General science in Kazakhstan.According to scientists, fundamental science plays an

important role in the modern state and highlights the following tasks:

– the level of science and education in the country is the main indicator of the state (Gafurov et al., 2020; Safiullin et al., 2019). The country's authority abroad is demonstrated by domestic scientists. As an example, currently the countries that are part of the group of independent countries have a high level of education of the population, which prevails next to other developing countries. In Kazakhstan, as of January 1, 2018, about 80% of employees engaged in scientific research have higher professional education.

– in countries where basic research is not conducted, there will be no quality education, and only higher education institutions, where most of the teachers are engaged in research, can train qualified specialists with quality education. In 2017, about 30% of the employees engaged in 15,793 scientific research are working in the pedagogical direction (Yankovskaya et al., 2019).

- the prospective economic activity and competitiveness of the state, the development of domestic products with scientific capacity is determined by the availability of highly qualified specialists and the level of scientific research.

Conclusion

Innovation is effected by people and their desire to increase and benefit from change (Walker & Cooper, 2010). A resilient leader of innovation needs to follow a rapid innovation strategy because organizational innovation is critical to the productivity, adaptability, and existence of educational organizations (Bhamra, Dani & Burnard, 2011).

The direction of the economy towards innovation and its development based on new technologies has created serious problems for any state. Especially in the process of integration to the world market and export-oriented products, current market competitive environment, as well as the reduction of time intervals of innovative renewal of production in each industry put before the government issues requiring rapid and complex decision. One of the main problems of each stage, which has characteristic difficulties, is the organization of production of competitive and export-oriented innovative products, through which the renewal of domestic production and the introduction of new technologies, the development of innovative infrastructure and the formation of links between science and production. Addressing these issues requires effective government regulation.

Research results have shown that Kazakhstan is currently developing an innovative industry. Several development institutions and funds have been established in the country to develop the innovation sector. The state, in turn, supports and controls the activities of these institutions (Bexultanov et al., 2018). The development and regulation of innovation infrastructure is carried out by the state through the creation of technology parks, business incubators, technopolises, banks, economic associations and financial groups. Innovation infrastructure institutes provide support for innovative projects of various levels and mass production of products with export potential. Low sensitivity of infrastructure institutions and increased demand for services of development institutions in the event of a crisis affected the development of infrastructure development institutions in the excitement of the production cycle.

Therefore, it is necessary to pay attention to science, science and technology and innovation policy of the state. Only when issues requiring state regulation in this area are resolved will the country achieve high-quality and sustainable development.

The Problems of Project Teams Functioning in Supply Chains – The Results of Empirical Research

Agnieszka JAGODA

Wroclaw University of Economics and Business, Faculty of Management, Department of Strategic Management and Logistics, Jelenia Góra, Poland, agnieszka.jagoda@ue.wroc.pl

Tomasz KOLAKOWSKI

Wroclaw University of Economics and Business, Faculty of Management, Department of Strategic Management and Logistics, Jelenia Góra, Poland, tomasz.kolakowski@ue.wroc.pl

Abstract

The interoperability of various actors in the supply chain is based primarily on a variety of standardized processes, but more and more often also on projects. The research conducted by the authors shows that the tool for merging and joint operations of supply chain entities is setting up and the maintaining the operation of cross-functional and above all cross-organizational project teams therein. The results presented in the article are the result of empirical research carried out in 2019. The subject of the article concerns problems in creating, coordinating and integrating work within the appointed project teams. The considerations made in the article are of literature and empirical character.

Keywords: Project Team, Supply Chain, Supply Chain Integration, Project Management.

Introduction

The success of supply chains is primarily dependent on the ability to integrate and coordinate the activities of the network participants, in particular, the flow processes of products, information and financial resources from the acquisition of raw materials, to the places of consumption, which (as is stressed in the literature of the subject) contributes to the creation of a competitive edge of a supply chain and its customers. The interoperability of various actors in the supply chain is based primarily on a variety of standardized processes, but more and more often also on projects. The research conducted by the authors show that the tool for merging and joint operations of supply chain entities is setting up and the maintaining the operation of project teams therein. However, in the practice in their activity, there are many significant problems that cause disruptions in the creation, coordination and integration of their work. The aim of the article is to present these problems - while the considerations undertaken here are of literature and empirical character.

Project Teams in A Supply Chain - Theoretical Considerations

In the literature on the subject and in business practice it is postulated to create teams at various levels of management and operating within various functions - this is reflected in the creation of, among others, problem teams, local teams responsible for the sphere of production, management teams and project teams focused on the implementation of specific tasks. The analysis of literature and the results of empirical research shows teamwork as a fundamental source of learning and organizational effectiveness (Leonard - Barton 1995; Nonaka and Takeuchi 1995, Senge 1990). Nowadays in turbulent, multinational, and technologically sophisticated environment, the work group has reemerged as a business concept and its unified team performance is now regarded as crucial to project success (Thamhain and Wilemon 1998).

The nature of project teams, regardless of whether they are monofunctional or interdisciplinary, is characterized by temporariness, concentration on a specific goal, a departure from power based on

formal authority in favor of expert power and the lack of strict division of labor within the team (Pinto, Pinto and Prescott 1993, Zmund and McLaughlin 1989). The specificity of the project team is also often characterized by going beyond functional boundaries, and sometimes even organisational ones, as in the case of a supply chain. To successfully achieve the project's goal, project leaders need to build fast, flexible project teams that can dynamically and creatively work to achieve the set goals in a changing environment (Jasswalla and Sashittal 1999). This approach requires effective networking and cooperation between people involved in the project - people from different organizations.

A supply chain is a special type of network organization whose participants - mining, production, commercial, service companies and their clients cooperating in various functional areas – making the streams of product, information and financial means flow (Cooper et al. 1997; Fisher 1997). The cooperation of individual entities of the chain begins at the stage of planning products and the demand for them, and ends with the delivery of orders and service to final customers - thus it relates to various functional areas. The effectiveness of an enterprise operating in a network increasingly depends on the effectiveness of its cooperation with partners. This leads to supply chain management and relations with entities that form its structure. Supply Chain Management is the integration of key business processes from end user through original suppliers that provides products, services, and information that add value for customers and other stakeholders (the definition by The Global Supply Chain Forum) (Lambert et al 1998). This not only reduces costs, but also creates added value for customers by increasing the efficiency of deliveries and the quality of products offered, which results in the fact that more and more often not individual companies but supply chains compete in on market (Hwang and Rau 2007). Therefore, it is increasingly emphasized that effective and synergistic supply chain management can be an underestimated source of competitive advantage (Ketchen and Hult 2007). This approach provides shape and expression to theoretical considerations and empirical research focusing on supply chain management. To a large extent they are devoted to chain integration focusing on two perspectives (Pandey, Bhattacharyya and Kaur 2012):

- the ways to achieve supply chain integration,
- the impact of supply chain integration on its efficiency / effectiveness.

Integration is generally understood as the process of joining parts into a whole. The increase in its level in the supply chain ensures quick access to required information, increases sensitivity to customer needs and shortens the response time compared to competitors (Sezen 2008), which in turn creates value for shareholders by reducing costs and increasing market share (Lee 2000). The literature points to examples of Japanese supply chains as those that achieve the highest degree of integration and lead to building partnerships between individual enterprises. For example, Liker and Choi (2004) describe the Japanese supply chain (Toyota and Honda) as a "partnership model" in which a network of suppliers learns and improves processes in cooperation with producers. Similarly, Iyer, Seshardi and Vasher (2009) describe Toyota's supply chain in terms of close and long-term relationships with a high level of information exchange and cooperation to solve common problems.

Most empirical research on supply chain integration focuses mainly on operational management, the use of information systems and information technologies. However, the cooperation of supply chain entities, leading to the integration of its participants, can also be implemented through selected practices in the field of human resources management (Pandey, Bhattacharyya and Kaur 2012; Menon 2012), including by establishing teams in the network structure. Importantly, it is worth emphasizing at this point that among the criteria indicated for deepening ties between business entities are, among others staff exchange activities (Menon 2012). Moreover, research shows that communication and teamwork were the most important competencies for successful SCI (Prajogo and Sohal 2013). The analysis of this issue, conducted in the earlier papers of the authors, provides the basis for distinguishing two levels of ability to integrate a supply chain by project teams (Jagoda and Kołakowski 2016):

- Level 1 (low) - internal integration variant - project teams are established mainly as a part of a supply chain leader enterprise.

- Level 2 (high) - external integration variant - a supply chain leader enterprise is the initiator in establishing inter-organizational project teams bringing together members from partner organizations.

Within level 1, a project team made up of members of the leader's organization can carry out tasks for the same enterprise as well as for activities implemented in the supply chain. Research carried out by other authors (the Delphi method involving 13 expert practitioners and scientists) shows that the condition for external integration between organizations is internal supply chain integration (Menon 2012). Detailed expert recommendations aimed at its achievement focus on the use of inter-functional teams and building matrix structures. Organizations need to develop a culture that is focused on horizontal workflows, as opposed to traditional functional hierarchies.

In turn, level 2, assuming the establishment of inter-organizational project teams within the supply chain, is a higher stage of integration. Thanks to this solution, in addition to the integration of the individual functional areas within the supply chain, the transfer and the diffusion of knowledge are ensured to the places where there are actually carried out individual tasks of the project. In addition, this option allows a more accurate selection of project team members from the point of view of their knowledge and competences -there is a range of specialists from many, and not a single organization. Importantly, individual organizations (links) of the supply chain will more easily (in comparison with the option from level 1) accept decisions / solutions developed within the project team in which their representative participates (due to the representation of their interests).

These considerations seem indisputable regarding the establishment of project teams as a supply chain integration tool. Importantly, however, attention should be paid to possible problems that are associated with the creation and functioning of these teams.

Research Methodology and General Characteristics of The Studied Enterprises

The results of the empirical research presented in the article were obtained during a three-stage research process. A nomotetic approach was adopted to obtain them in order to present an overall picture of the analyzed problem, which was the identification of human flows in supply chains. The first stage of the research process was the initial stage aimed at identifying the literature gap of the analyzed problem, the second concerned the identification of the research sample. The third, essential stage of the research process was the actual research carried out in autumn 2019. The authors, starting to build the interview questionnaire, analyzed literature from global online databases such as World of Science and Scopus. To determine the research sample, industry reports from Poland were analyzed to distinguish the types of enterprises selected for analysis, which assumed the existence of human flows in supply chains. Therefore, the industries representing this type of enterprise are: home appliances, construction, chemical, wood industry, electrical machinery industry, metal industry, electrotechnical, energy, retail, wholesale trade, medical/pharmaceutical, oil and gas, clothing/textile, food, telecommunications, transport /rail /logistics, armaments and other enterprises. Considering the size of the enterprise, it was decided to examine medium-sized and large enterprises. Over 100 employees was assumed for medium-sized enterprises as the minimum employment size. This choice resulted from the authors' belief that in smaller business entities situations related to the flow of people in supply chains are not frequent. The situations when human flows occur are as follows: quality control, IT systems integration, audit, training, supplying the supplier's workforce in case of insufficient production capacity, replacement, accident, joint tasks/ projects. The spatial scope of research has been limited to Poland. The structured interview questionnaire was used in computer assisted telephone interview (CATI) studies. An attempt to conduct the research was made in 2469 enterprises, of which 1232 agreed to participate in the study. In this group, 500 respondents declared that there were flows in the supply chain, and 732 enterprises denied their occurrence. The interviewees who provided interviews were HR managers in enterprises that are the leaders in supply chains. One type of identified flows was the implementation of joint tasks /projects by the enterprise of the supply chain leader and the enterprise of its suppliers/customers. This situation has been identified in 485 cases. Nearly ¾ of the entities in this group were enterprises employing from 100 to 249 employees. The remaining part (25.6%) are

entities employing 250 people or more. As for the sector of activity, entities from the industry/ construction sector (228 entities - 47%) and services sector 212 responses (43.7%) prevailed. In 45 cases (9.3%) they were enterprises from the agriculture / forestry / fisheries sector - Figure 1.

Fig. 1: The characteristics of surveyed entities - size and sector (in%, n = 485).
Source: own elaboration

As part of the research, an analysis was also made of the branch of the company's activity. Out of 485 entities, over 1/5 of them are retail trade enterprises (103 entities - 21.2%). Food industry entities constituted a fairly large group (61 entities - 12.6%). Out of 18 industries defined, each was represented by at least one entity, with the least numerous being: enterprises from the oil and gas industry (1 entity), armaments and household appliances /electronics (3 entities each) and the mining industry (4 entities). The details in this regard are presented in Table 1.

Table1: Number of entities surveyed by industry (n = 485)

Branch	Number of entities	Branch	Number of entities
Household appliances / electronics manufacturers	3	Retailers:	103
Construction enterprises	28	Wholesale trade enterprises	45
Chemical enterprises	24	Medical / pharmaceutical enterprises	39
Wood industry enterprises	27	Oil and gas enterprises	1
Electrical machinery industry enterprises	20	Clothing / textile / textile enterprises	11
Metal industry enterprises	35	Food businesses	61
Mining industry companies	4	Telecommunications enterprises	11
Electrotechnical enterprises	23	Transport / rail / logistics enterprises	30
Energy enterprises	17	Armaments enterprises	3

Source: own elaboration

Main Problems of Project Teams Creating and Functioning, With Particular Emphasis on The Supply Chain Perspective - Research Results

As indicated earlier, one of the research areas included in the structure of the questionnaire was the problems in the field of creation and functioning of teams /cells /departments within the framework of joint tasks/projects carried out by the enterprise of the supply chain leader and the enterprise of its suppliers/customers.

Respondents answering the question regarding the identification of the main problems in the creation and functioning of such teams had the opportunity to choose a minimum one of the 6 proposed answers, i.e.

- difficulties in reconciling daily duties with tasks of teams/cells /departments (P1),
- difficulties in choosing the right people (P2),
- communication difficulties between team /cell /department participants (P3),
- different views and positions represented by individual participants (P4),
- no material or non-material incentives to participate in teams /cells /departments (P5),
- problems in integrating and coordinating the work of team/cell /department participants (P6).

In addition to the above, respondents had the option to provide their own answer.

Among the surveyed entities, respondents made 670 choices within six proposed answers. Three of them obtained a relatively similar result oscillating around 20%. The most frequently indicated problem is communication difficulties between team /cell /department participants. Almost every fourth entity indicated this answer (155 responses, 23.1%). The next two answers are difficulties in reconciling daily duties with tasks of teams/cells /departments (145 responses, 21.6%) and difficulties in choosing the right people (139 responses, 20.7%). The respondents the least frequently pointed to the issue related to the lack of material and non-material incentives to participate in such teams (30 responses, 4.5%). In no case did the respondents indicate their own answer. Figure 2 presents the exact distribution of answers given in this respect.

Fig. 2: Percentage of responses regarding the type of problem occurring in connection with the creation of project teams (total number of indications = 670)

Source: own elaboration

It follows from the above that the main problems relate to organizational and communication aspects among team members. Definitely, the main problem should not be considered low motivation resulting from the lack of material or non-material incentives. In addition, the fact of indicating as the main problem the difficulties in reconciling daily responsibilities with the tasks of the project team can be explained by the need to carry out part of the project tasks outside the headquarters of the given team member, which is related to the specificity of projects implemented in supply chains.

In addition to the global review of the obtained results, an attempt was also made to provide a more detailed analysis, taking into account such characteristics as the size of the enterprise, sector or industry. Below, Figure 3 presents graphically the percentage of answers given depending on the size of the entity, and Table 1 summarizes the percentage of answers received, having considered such features as the size of the entity and the type of sector.

Fig. 3: Main problems (P1 - P6) in the creation and functioning of project teams – the percentage of answers given in terms of the size of the enterprise.

Source: own elaboration

Analyzing the correlation between the size of the entity and the type of problem, it can be seen that those resulting from reconciling daily duties with the team tasks of in the field of communication and the selection of appropriate people are more often indicated by larger entities, i.e. employing over 250 people. Interestingly, the problem concerning the coordination and integration of work of the project team is more often indicated in smaller entities, as well as the difference of views and represented position, whereas it would seem that these are problems that should rather occur in larger organizations.

Table 2: Main problems in the creation and functioning of project teams – the percentage of answers given due to the size of the enterprise and the sector of business activity

Size of the enterprise (employment in persons)	Difficulties in reconciling daily duties with tasks of teams / cells / departments (P1)	Difficulties in choosing the right people (P2)	Communication difficulties between team / cell / department participants (P3)	Different views and positions represented by individual participants (P4)	No material or non-material incentives to participate in teams / cells / departments (P5)	Problems in integrating and coordinating the work of team / cell / department participants (P6)	Total number of indications in a given group
from 100 to 249, including:	**20,4%**	**20,2%**	**22,6%**	**14,1%**	**5,0%**	**17,6%**	**460**
industry, construction	21,0%	20,5%	21,9%	11,4%	5,2%	20,0%	**210**
agriculture, forestry, fishing	21,9%	28,1%	18,8%	21,9%	3,1%	6,3%	**32**
services	19,7%	18,8%	23,9%	15,6%	5,0%	17,0%	**218**
above 250, including:	**24,3%**	**21,9%**	**24,3%**	**10,5%**	**3,3%**	**15,7%**	**210**
industry, construction	27,2%	20,4%	21,4%	9,7%	3,9%	17,5%	**103**
agriculture, forestry, fishing	23,1%	38,5%	30,8%	0,0%	0,0%	7,7%	**13**
services	21,3%	21,3%	26,6%	12,8%	3,2%	14,9%	**94**

Source: own elaboration

In turn, analyzing the problems through the prism of the sector, it should be noted that relatively high indications regarding the difficulty of selecting the right people are indicated in the agriculture, forestry and fisheries sectors, regardless of the size of the entity. This may be conditioned by a narrow specialization of employees representing this sector and difficulties in their availability on the market. In turn, the industry and construction sector, in particular in the group of entities employing up to 250 people, is characterized by a relatively high percentage of responses regarding the problem of integration and coordination of the work of team participants. It is also important to note that the problem of reconciling daily responsibilities with team tasks is characterized by a relatively even distribution of responses regardless of the sector and the size of the entity.

In addition to analyzing the links between the type of problem and the size of the enterprise and sector of activity, the analysis of the occurrence of problems was made, acknowledging the industry in which the entity operates. The table below summarizes the percentage of responses given by the representatives of individual industries.

Table 3: Main problems in the creation and functioning of project teams - the percentage of answers given in terms of the branch of the enterprise

Branch	Difficulties in reconciling daily duties with tasks of teams / cells / departments (P1)	Difficulties in choosing the right people (P2)	Communication difficulties between team / cell / department participants (P3)	Different views and positions represented by individual participants (P4)	No material or non-material incentives to participate in teams / cells / departments (P5)	Problems in integrating and coordinating the work of team / cell / department participants (P6)
Electrical machinery industry enterprises	25,8%	29,0%	22,6%	12,9%	3,2%	6,5%
Household appliances / electronics manufacturers	50,0%	0,0%	0,0%	0,0%	50,0%	0,0%
Construction Companies	22,6%	17,7%	24,2%	12,9%	1,6%	21,0%
Chemical companies	27,0%	16,2%	29,7%	8,1%	2,7%	16,2%
Electrotechnical enterprises	28,1%	21,9%	12,5%	9,4%	6,3%	21,9%
Energy companies	20,0%	10,0%	35,0%	5,0%	10,0%	20,0%
Retailers:	18,3%	20,2%	23,1%	18,3%	2,9%	17,3%
Wholesale trade enterprises	18,1%	25,0%	30,6%	8,3%	5,6%	12,5%
Medical / pharmaceutical companies	19,3%	19,3%	26,3%	10,5%	3,5%	21,1%
Clothing / textile / textile companies	21,1%	15,8%	15,8%	15,8%	10,5%	21,1%
Wood industry companies	22,9%	22,9%	22,9%	12,5%	2,1%	16,7%
Metal industry enterprises	23,5%	20,6%	17,6%	8,8%	8,8%	20,6%
Mining industry companies	25,0%	0,0%	0,0%	25,0%	0,0%	50,0%
Food businesses	25,4%	28,4%	22,4%	11,9%	0,0%	11,9%
Telecommunications companies	26,9%	11,5%	19,2%	15,4%	3,8%	23,1%
Transport / rail / logistics companies	14,9%	19,1%	19,1%	19,1%	10,6%	17,0%

Armaments enterprises	12,5%	25,0%	12,5%	37,5%	12,5%	0,0%

Source: own elaboration

According to the obtained data, the industry with a relatively flattened distribution of responses is the clothing/textile /textile industry as well as in the field of transport and logistics. This means that in these industries there is no single leading problem in the creation and operation of project teams, and a more complex, diverse structure of problems needs to dealt with there.

In turn, the most flattened distribution of responses from the perspective of individual problems occurs, as it did in the case of the analysis of the size of the entity and the sector, in the event of difficulties in reconciling daily responsibilities with tasks in project teams. This problem is the only one indicated by all the analyzed industries and is quite significant therein.

Conclusions and Summary

The analysis of the research results allows to indicate several important conclusions:

1. main problems related to the functioning of project teams in supply chains concern the issues of communication, the reconciliation of daily duties with team work and the selection of appropriate people, so they are of organizational and personal nature,
2. these problems are indicated more often by large entities, i.e. employing over 250 employees,
3. the lack of material or non-material incentives for a member of the project team is not recognized as the main problem of operation in the described project structures,
4. Interestingly, the problem concerning the coordination and integration of work of a project team, as well as the difference of opinions and represented position, is more often indicated in smaller entities (up to 250 entities),
5. the problem of reconciling daily responsibilities with team tasks is characterized by a relatively even distribution of responses regardless of the sector, branch and the size of the entity.

Based on the above, it can be concluded that the perception of the project team and its problems from the perspective of the implementation of various projects in the supply chain, mainly applies to communication between its members, representing different entities, very often with a different organizational culture, using different terminology, procedures or management tools and the reconciliation of daily duties with work in such a team. This state of affairs may cause that in many entities and projects implemented by them, there may be additional problems regarding delegating tasks to team members by project managers / stem cell managers or assigning them responsibility for performed tasks.

These problems may, as a consequence, lead to conflicts between employees, both at the level of project teams organised within a supply chain and within stem cells. This means that problems from the level of inter-organization projects can be transferred to the internal level of individual enterprises - the links of a supply chain

The obtained research results seem to confirm that building project teams and implementing projects within the supply chain require a different and very thoughtful approach in their management. The rather intense problem of temporary "detachment" of an employee from the stem cell for work in a project team may suggest the need to use different management instruments and the influence on such a team. The main emphasis in the functioning of inter-organization teams should be on proper communication and integration of the work of its participants, often representing links from different levels of a supply chain.

Acknowledgments

The project is financed by the Ministry of Science and Higher Education in Poland under the programme "Regional Initiative of Excellence" 2019 - 2022 project number 015/RID/2018/19 total funding amount 10 721 040,00 PLN.

Abstract

As shown by the international economic and financial crisis from 2008, state aid policy may prove a flexible tool for providing financial help in the affected economic sectors from the Member States, hence reducing the negative spill over effects in the EU. This article outlines the European Commission's response to the crisis, in implementing State aid policy, after the outburst of COVID-19 crisis. Taking into consideration the need for a coordinated response in the EU, a New Temporary Framework for state aid was adopted, allowing Member States to support directly or through the banking system most affected economic sectors has been adopted by the European Commission. Our research aims to analyse the state aid schemes implemented by the Member States, on the legal base brought by the New Temporary Framework, also highlighting some similarities with the special regulatory framework adopted during the international economic crisis from 2008. The methodological approach is based on a series of case studies regarding measures and schemes adopted in the Member States immediately after the outburst of the COVID-19 crisis. In the final part of our paper we will present a comparative approach of state intervention in order to support SMEs during the current COVID-19 crisis, followed by some recommendation concerning the state aid adoption for preventing a serious disturbance of free competition in EU.

Keywords: State Aid, Fiscal Aid, Loans, Subsidised Grants, Competition Policy, Economic Crisis

Introduction

The main objectives of this research are: to explain how state aid can become an essential financing tool in economic crises using a comparative approach between the 2008 crisis and the COVID-19 crisis, while highlighting the different types of state aid used by the Member States since the onset of the COVID-19 crisis.

The research methodology is based on both a comparative approach between the types of aid granted under the Temporary Framework adopted in 2009 in order to cope with the negative effects of the international economic crisis and the types of aid allowed during the COVID-19 crisis (based on State Aid Scoreboard statistics), as well as on the use of case studies based on the evidence provided by DG Competition. Through the case studies presented, we aimed to highlight the diverse and flexible way in which EU state aid policy has been used by Member States to support the economic sectors that have been and are most severely affected by the effects of the COVID-19 pandemic.

The outbreak of the COVID-19 crisis prompted EU authorities to urgently adopt exceptional measures and new regulations in the field of state aid policy, some analysts pointing out that the urgency and seriousness of the situation forced Europe to adopt a true "anti-disaster plan" even in the field of competition policy (Baldwin, Weder di Mauro, 2020). The magnitude of these measures was similar to those applied during the international economic crisis of 2008 (Mateus, 2009).

The new regulations in the field of state aid sought to transform these state interventions (state aid measures and schemes) into a useful tool by which Member States to support their most affected companies, citizens and economic sectors.

Given the magnitude of the economic effects that the COVID-19 crisis will trigger in all Member States and the shock wave produced in the EU economy, the support measures cannot be taken only from the EU budget, but must be granted also from the national budgets of the Member States in the form of state aid. All these aids may be implemented both through sectoral schemes and individual measures targeting the affected companies (see Figure 1).

As regards to direct state aid (targeting certain companies affected by the COVID-19 crisis), such aids may be granted on the basis of the GBER Regulation (General exemption regulation for categories of state aid) immediately, without the involvement of the European Commission.

Figure 1: Types of state aids that may be granted for mitigating the COVID-19 crisis negative economic effects

Source: Authors, based on EU regulations.

Note: The Minimis Regulation on state aid allows support measures limited to a minimum financial ceiling and exempted from the obligation to be notified to the European Commission. The maximum amount is 200,000 euros for each company over a period of 3 years.

Moreover, taking into account the impact of COVID-19 crisis, this situation allows to the Member States to fully use the Article 107 (3) (b) TFEU granting state aids to remedy a serious disturbance of the economy of a Member State.

The New Temporary State Aid Framework – a comparative approach with the measures adopted during the international economic crisis

Some analysis (Lowe, 2009; Drăgoi, 2016) are showing that while state aid policy had a restrictive approach in EU before the international crisis from 2008, the need to support the banking system in order to prevent its general collapse in EU lead to the adoption of special regulation in 2009.

Recently, the European Commission has published the New Guidelines on the measures that Member States can take to mitigate the COVID-19 crisis (European Commission, (a), 2020). Within this document, some principles are set to be used when considering the implementation of such state aid schemes by the Member States. These principles concern: the transport of goods and services, the

supply of goods, health-related measures, measures at external borders and measures at internal borders. As regards to the transport of goods and services, the European Commission document states that any schemes and measures that would lead to a restriction of transport between Member States must be notified in advance to both the Commission and to all EU countries, before be implemented.

For the banking sector, the Commission Guidelines are stating that, given that banks support the necessary flow of liquidity in the economy, and a possible collapse of the banking sector would have catastrophic domino effects in the whole EU, Member States can now grant aid based on the Old Framework Temporary (guarantees, capital injections, aid for rescue and restructuring, while respecting the Single Resolution Mechanism imposed by the Banking Union). Although at present, more than a decade after the international financial and economic crisis, the European banking system is consolidated, the current consequences of the COVID-19 crisis will spread rapidly in the capital markets, and a coordinated action is needed for the Member States in order to effectively support the financial sector.

Being aware of the imminence of this phenomenon, the Community authorities have adopted a New Temporary Framework for State Aid to guide Member States to take appropriate measures to meet their objectives without disturbing free competition in the internal market. Based on the New Temporary Framework, state aid schemes and measures must support SMEs in need of liquidity, provide direct aid to individuals (independent artists, for example) who have suffered major economic losses as a result of cancelled events. The latter type of state aid (as an individual measure and not a scheme) can be granted, based on the regulations in force, without the approval of the European Commission.

Such a Temporary Framework, having an exceptional character in relation to the current regulations in the field of state aid policy, was adopted only in the case of the international economic and financial crisis of 2008, some analyses explaining, however, that that framework was mainly directed towards supporting the banking sector in the EU and only marginally towards the real economy (Drăgoi, a, 2019) .If, in the case of the 2008 crisis, the state aid schemes were directed to the banks and credit institutions affected and suspected of insolvency risk, determining the preponderance of the state aid in the form of guarantees (see table 1).

Table 1: State Aid granted in the EU based on the Old Temporary Framework[1] (EUR billions)

	2008	2009	2010	2011	2012	2013	2014	2015	2016	2017
Recapitalization	269.9	110	184	37.5	150.8	29.6	20.3	18.8	8.5	25.7
Compensation for impaired assets	4.8	338.5	78	6.3	157.5	14.7	3.5	1	0	0
Guaranties	3097.3	87.6	54.8	179.7	275.8	76	38.7	165.4	310.7	328.5
Other liquidities measures	85.5	5.5	66.8	50.2	37.5	9.7	1.7	0	0	14.2

Source: Authors calculation based on State Aid Scoreboard (2018).
*[1] See "**Temporary Union framework for State aid measures to support access to finance in the current financial and economic crisis",** Official Journal C6, 11.1.2011*

Note: The data show state aid (approved and used) to financial institutions in the period 2008-2017 and include both the maximum aid amounts that Member States have been authorized to grant (approved state aid) and the amounts actually paid (used state aid).

While all the capital and liquidity measures being subject to the regulations of the BRRD Directive (Drăgoi, b, 2019), in the current events with destabilizing economic potential, triggered by the COVID-19 crisis, the New Temporary Framework aims to grant direct aids to the real economy. Regarding the measures that should have encouraged investments, the previous Temporary Framework showed that the aid schemes adopted by the Member States are subject to the legislative provisions establishing a limited compatible amount of the aid. This provision was introduced in the old Temporary Framework as an extraordinary measure to provide Member States with an additional instrument during the most

acute period of the financial crisis. Such aid could be granted on the basis of Article 107 (1) TFEU because they exceeded the threshold of EUR 200 000 per company (indicated in Commission Regulation (EC) No 1998/2006 on "De minimis" state aid). In times of severe economic crisis, there is always a risk that competition policy will not come top of the political agenda. In the context of the COVID-19 crisis, governments' immediate focus must be on measures to keep the real economy afloat or maintain employment, and they sometimes believed that these measures could be divorced from competition policy. However, the past month has shown that the EU competition and state aid rules are a crucial component to any recovery plan in any member state.

On March 19, 2020, the New Temporary Framework for State Aid was adopted, through which Member States can offer direct grants of € 500,000 to a company, state guarantees for bank loans and interest rates subsidized to mitigate the effects of COVID-19 (EC, (b), 2020). Member States are obliged to notify the European Commission of such state aid schemes, as in the case of those adopted during the crisis of 2008. Subsequently, after the approval of the European Commission, these schemes can be implemented. There are also exceptions to this general prohibition that allow certain types of aid to be granted under special circumstances without prior notification to the European Commission. Such an exception refers to aid schemes that "help to remedy economic damage caused by natural disasters or exceptional events". This exception allows granting compensation to airlines for losses suffered due to the COVID-19 crisis. Another exception applies to aid schemes aimed at "remedying a serious disturbance in the economy of a Member State" provided that the aid granted is compatible with the internal market. This exception is discretionary and requires to the Member State to notify the Commission of the proposed aid scheme with the obligation to delay the granting of aid until official approval is received. The current Temporary Framework is based on this second discretionary exception to allow Member States the widespread use, but for a limited period, of certain categories of State aid. In fact, this exception has been used extensively by the Member States in the case of the 2008 crisis, and as a result the existence of the previous Temporary Framework has facilitated a faster drafting of the new framework, although the context is different.

The main objective of the New Temporary Framework is to help the real economy and just in the case of necessity, the banking sector. An important clarification is that under the New Temporary Framework the aid granted to banks for maintaining the credit flow to companies will be considered as indirect aid for companies (since they will have the objective of ensuring liquidity and supporting a harmonized fiscal response to EU level). The new Temporary Framework will allow various types of aid for companies that have suffered financial losses after December 31, 2019 (see Figure 2).

Figure 2: Main types of state aid under the New Temporary Framework
Source: Authors, based on EU regulations.

As concerning the state aids for the banking system Member States will be able to help banks and financial companies directly as they are considered to be aids to the real economy. Practically the

Commission will consider any aid directed by the Member States through the banking sector to the real economy as aid delivered directly to help companies rather than as state aid to the banks themselves. However, aid ceilings are introduced to limit undue support or residual financing for the banking sector.

It is very important to notice that the direct aid to banks to compensate for losses directly incurred as a result of the COVID-19 crisis will not be evaluated under the New Temporary Framework, but as a separate exception provided in article 107 (2) (b) . If, because of the COVID-19 crisis, banks would need direct support in the form of liquidity measures, recapitalization or support measures for impaired assets the European Commission will assess whether those measure meets the conditions set out in article 32 (4) (d) of the BRRD Directive. If the eligibility conditions are fulfilled the bank will receive the requested support. Also, to the extent that these state aids address the issues related to the COVID-19 crisis, they are considered eligible under the article 45 of the Banking Communication which sets out an exception to the burden-sharing requirement between shareholders and subordinated creditors.

Exceptionally, some state aids may be temporarily granted as direct loans, repayable advances or tax exemptions based on Article 107 (3) TFEU. Such aids may be granted to businesses and small companies that are suddenly experiencing a lack of liquidity if the member state considers that such measures are appropriate and necessary in the current exceptional circumstances caused by the COVID-19 crisis. Such aids must meet the following simultaneous eligibility criteria: the state aid does not exceed 800,000 euros (before applying tax exemptions or other tax burdens) per company; the aid is granted in the form of a scheme with an estimated budget; the aid can also be granted to enterprises that were not in "difficulty" as of December 31, 2019, but are currently in "difficulty" as a result of the effects of the COVID-19 crisis, the aid is granted until December 31, 2020.

Comparative view of state aid approved in the Member State under the New Temporary Framework

Given that they currently have the legal framework necessary to grant state aid related to the COVID-19 crisis, the Member States have not been late in submitting requests for notification and approval of such schemes. On March 21, 2020, France was the first Member State to notify an aid scheme to support the financial security of companies affected by the COVID-19 crisis. The objective of the scheme is to ensure the continuity of the economic activities and to provide adequate financial support to the companies affected by the economic shock induced by the COVID-19 crisis.

The aid measures under the scheme will be: measure A - a guarantee subsidized by Bpifrance Financement S.A. (public credit company owned by the French state) for investment loans; measure B - a guarantee subsidized by Bpifrance Financement for the confirmed credit lines; measure C - granting of a guarantee subsidized by the French state for eligible credit portfolios containing specific contractual provisions.

For measures A and B the French state estimated a budget of 700 million euros, and for measure C 300 million. Measures A and B apply to all SMEs in France regardless of the sector of activity, and measure C is applicable for a maximum of six years to all French companies in difficulty regardless of size.

Subsequently, a number of Member States (United Kingdom, Denmark Germany, Italy (EC, c 2020), Luxembourg (EC, d, 2020) and Latvia) submitted notifications to the European Commission regarding the granting of state aid schemes to mitigate the negative economic effects produced by the COVID-19 crisis. All of these schemes are intended for financing needs facing the real economy (see table 2).

Table 2: State aid schemes notified by the Member States under the New Temporary Framework

Member State	Beneficiaries	Conditions	Amounts
Germany	Loans for all undertakings that	Based on appropriate justification and self-	The loan amount is less than EUR 1 billion per beneficiary

Member State	Beneficiaries	Conditions	Amounts
	require liquidity for their activities in Germany	certification of the beneficiary of its liquidity needs	and limited to either twice the annual wage bill for 2019, 25% of the annual turnover 2019, or the specific liquidity needs of a beneficiary for the next 12 months (18 months for SMEs). In addition, for loans above EUR 25 million, the loan amount may not exceed 50% of the total debt volume on the beneficiary's balance sheet
Italy	Companies producing medical equipment	Creating new production facilities or extending the existing ones	EUR 50 millions
Latvia	Subsidized loan for investments and lucrative capital	All Latvian companies if they were not in difficulty on 31 December 2019	EUR 50 millions for investments, 200 EUR millions for lucrative capital
Luxemburg	All undertakings (small and medium-sized enterprises, large undertakings) and liberal professionals affected by the economic repercussions of COVID-19 and having temporary financial difficulties. The Luxembourg authorities estimate that there will be over 1000 beneficiaries.	Eligible costs are the staff and rent costs of the beneficiary for the months falling within a period determined by the Luxembourg Government (maximum until 30 September 2020).	The support shall take the form of a repayable advance5 and will be granted in one or more instalments. The maximum aid intensity is 50 % of the eligible costs and the total amount of aid may not exceed the maximum aid amount of EUR 500,000 per single undertaking.
United Kingdom	All SMEs affected by the economic repercussions of COVID-19 and having temporary financial difficulties. The UK authorities estimate that there will be 5.9 million beneficiaries. Subsidized loans up to 80% for SMEs Direct subsidies for IMM	Turnover up to 49 EUR millions	EUR 654 millions
Denmark	Wage compensations for independent artists and liberal profession	If they cannot register revenues due to COVID-19 crisis	26 000 DKK/ per month

Source: Authors based on European Commission's data base on case studies of approved state aid.
See : the Commission Decision SA.56709 regarding « Plan de sécurisation du financement des entreprises » ; the Commission Decision SA.56794 regarding Coronavirus Business Interruption Loan Scheme Grant (CBILS grant);

the Commission Decision SA.56791 regarding Temporary compensation scheme for self-employed financially affected by the COVID 19; the Commission Decision SA.56714 regarding – Germany's COVID-19 measures; the Commission Decisison SA.56722 on Latvian loan guarantee scheme and subsidised loan scheme related to COVID-19.

As a recent OECD study (OECD, 2020) shows, most states have chosen to support SMEs because such companies were most severely affected by the COVID-19 crisis. The measures taken were diverse (either through direct support or by facilitating access to subsidized loans (see table 3).

Most Member states have directly or indirectly support their SMEs, but in order to ensure a return to normal market functioning the value of the subsidy per company is related to the market sector in which the company is active as stated in the New Temporary Framework.

Table 3: Support for SMEs in the Member States

Facilities to reduce working hours and support employees	Fiscal facilities	Banking support	Direct subsidies
Several countries have actively supported SMEs through new regulations on how to reduce working time providing aids for workers and companies and payments for temporary redundancies (Belgium, France, Netherlands, Switzerland). Italy has even implemented further measures on compensatory payments for redundancies.	Various countries offer possibilities for temporary tax exemption or deferment of taxes (Belgium, France) or even tax credits (Italy). Several countries have introduced indirect financial support to SMEs such as: new loans granted by public investment banks (France sectoral support) or loans for tourism industry (Italy). Others have granted public guarantees facilities (Austria) or facilities for SMEs wishing to renegotiate credit conditions (France).	Commercial banks in several countries have introduced support packages that include emergency loans to support their clients who are SMEs. Many banks in the Member States also provide flexibility for existing repayments. In Italy, the Italian banking association has decided to grant one Moratorium on debt repayments. The moratorium applies for the following debts: mortgages and small loans.	Belgium grants direct subsidies to SMEs, especially to those companies that are in difficulty because their supply chains are directly affected. Denmark grants a subsidy package that includes a DKK 125 million credit facility that allows SMEs to defer payment of VAT and taxes.

Source: Authors based on European Commission's data base on case studies of approved state aid.

While we are now in the midst of an even worse economic crisis, compared with the one from 2008, many analysis are underlining that the state support is mandatory for the real economy (Bofinger et al., 2020; Bénassy-Quéré et al., 2020) especially because "beyond its public health dimension, the unfolding coronavirus epidemic also represents a severe economic stress test for Europe that comes from a totally unexpected side".

Conclusions and Recommendations

In order to assist Member States to take urgent and effective measures to preserve economic stability and to provide legal certainty, the Commission adopted the New Temporary Framework for state aids granted in order to reduce the negative economic effects generated by the COVID-19 crisis. Since the adoption of the New Temporary Framework, until now, the Member States have provided a series of support measures, in particular to support SMEs. Due to the fact that Member States have extensively

resorted to state aid, additional support possibilities for other types of support measures would be needed.

According to the current developments in the COVID-19 crisis, new types of state aid would be useful: support for research and development of a vaccine or treatment against coronavirus (research and development state aids), support for the construction and modernization of testing facilities or for products relevant to the outbreak of outbreaks.

Coronavirus such as protective materials and disinfectants, as well as targeted support in the form of deferred tax payments and / or suspensions of employers' social security contributions to helps avoid massive unemployment. The COVID-19 crisis highlighted, as in 2008, the importance of a quick, coordinated and coherent response at Member State level, as well as the fact that state aid is an indispensable tool in situations of major economic difficulty.

However, in our opinion it is absolutely necessary that state support to be clearly defined and limited in scope to what is necessary to address the acute economic crisis generated by the COVID-19 pandemic while excluding unjustified benefits for companies or banks at the taxpayer's expense.

For better mitigate the negative effects of COVID-19 crisis is necessary an appropriate contribution by the private sector by way of an adequate remuneration for the introduction of general support schemes (such as a guarantee scheme) and the coverage by the private sector of at least a significant part of the cost of assistance granted, so as to ensure that there are incentives to return state money).

Also, in order to transform the state aid into an effective tool for supporting the real economy across EU, it is mandatory to impose sufficient behavioral rules for beneficiaries that prevent an abuse of state support, like for example expansion and aggressive market strategies on the back of a state guarantee.

Abstract

The article is devoted to the development of methodology of accounting social responsibility indicators of consumer cooperative organizations. Interest in participation of companies in society development and other social indicators is shown not only by state authorities and public organizations, but also by private investors, which indicates a change in the previously established paradigms of the perception of commercial organization only as a source of profit. The concept of sustainable development has been adopted, based on its concepts of non-financial reporting [1] and integrated reporting [2]. In accordance with these documents and trends in the development of information content of organizations' reports to society, it becomes necessary to develop methods of accounting and reporting, allowing to accumulate and summarize indicators of social responsibility of business to society.

Keywords: Social Responsibility, Integrated Reporting, Integrated Accounting, Social Reporting, Social Indicators, Management Accounting.

Introduction

In recent years, there has been a lively debate in accounting journals about Integrated Reporting (IR) and sustainability reporting. There is no doubt that these two seemingly different concepts overlap. What is common is the desire of developers speaking on behalf of society to be informed about the environmental impact of business in a broad sense. The concept of integrated reporting requires disclosure of various aspects of business impact on the environment: social, environmental

and economic. The idea was put forward in late 1990. Since then, almost three decades have passed. Integrated reporting is produced by a limited number of organizations. John Dumay, Cristiana Bernardi, James Guthrie, Paola Demartini [3], dedicated their research "Integrated reporting: A structured literature review" to the study of publications on integrated reporting. They also studied the application of integrated reporting in the world. It may well be agreed that most scientists are studying the normative rationale, but not the practice of integrated reporting. In addition, there is a logical explanation for this. Integrated reporting goes beyond financial reporting. However, the credibility of the part of reporting that is not based on accounting remains a big problem. Many researchers write about it: Cristiana Bernardi, Andrew W.Stark [4], Vera Palea [5], Warren Maroun [6] and others. Warren Maroun [6] approaches integrated reporting from the perspective of ensuring the correctness of information. This is a serious challenge for an audit. The solution lies in the standardization plane of integrated reporting, which at present is not quite realistic. In South Africa today, integrated reporting is necessary, it is the only place in the world. Kathleen Hertz, Rupley Darrell, Brown Scott Marshall [7] draw attention to the inherent limitations of such reporting due to its voluntary nature. In this regard, they believe that few American companies disclose environmental, social and governance aspects. They do not believe that this information is of interest to investors. We do not share this approach because integrated reporting is necessary for the society, not so much for investors. GAAP and IFRS reports are generated for investors. Vera Palea [5] also wonders to what extent IFRS and sustainable development ideas converge and whether there is a possibility of standardization of reporting for all at the global level. In 2009, it was decided to converge integrated reporting (IR), sustainability reporting (G4) and the Global Reporting Initiative (GRI). The idea of reporting on financial and non-financial information in such a way as to show their impact on each other was further developed.

They reflect the social responsibility of business to society. The section on business social efforts is one part of integrated reporting. The types of social responsibility indicators vary. Some can be obtained from accounting and management accounts, while others can be obtained through public surveys. What are these indicators and which ones sufficiently and fully disclose the social contribution of the organization, whether the indicator is relevant. These questions have not been studied. There is not enough publication on this topic.

Social responsibility of business is inherent in any company, the scale and scope of social programs and projects may vary, but to some extent, they are implemented in any economic entity. Information on the extent to which the social mission is fulfilled is reflected in insufficient volume. Information on the social mission is practically not generated in accounting.

In our opinion, barriers to social accountability in cooperative organizations are:

- the traditional idea of low importance of information on social responsibility of business, established by managers, owners and external users;
- lack of a methodology for recording social indicators and underdeveloped management accounting;
- absence of unified standards for the preparation and presentation of social reporting and the formation of social indicators;
- unsystematic information on the implementation of the social mission, insufficient financial assessments and their subjective nature, incomparability and weak verifiability of the information received, as well as the inability to compare financial and non-financial reporting indicators;
- insufficient qualification of the personnel of economic and accounting services and managers, as well as the lack of culture of public information presentation;
- weak accounting process software;
- quite high cost of developing and implementing an integrated management and financial accounting system and additional non-financial reporting.

The works of Russian economists offer various options for solving the problem of reflecting the aspects of socially responsible behavior in reporting. A significant contribution to the study of the

possibilities of integrated reporting in forming social indicators was made by H. Drager [10], M. King [11], L. Roberts [12] Despite the wide polemics about the classification of social indicators and how they are reflected in companies' reports, no consensus has been reached among scientists.

At this time, problems also remain with the format and legislative framework for social reporting indicators. In this regard, the development of a terminological framework, a unified approach to defining the structure of the social report, a minimum set of indicators and their classification, the relationship between different types of internal (management) reports and social reporting are the most important tasks of accounting and economic services of consumer societies.

All the above problems require detailed research, and the development of appropriate methods to solve them is the purpose of this work. The tasks are to develop theoretical substantiations and form organizational and methodical provisions of management accounting and internal reporting that characterize the social responsibility of consumer cooperative organizations.

Research Methods

The methodological basis for research was the objective principles of scientific knowledge, the basic provisions of accounting theory and economic control. When proving the theoretical provisions and practical results, general scientific and special research methods were used: system approach, analysis, synthesis, abstraction, modeling, economic-statistical, etc. The methodological basis of the research was the objective principles of scientific knowledge. The complex approach will manifest itself in the aggregate of accounting, planning and control in the formation of a model of socially-oriented accounting. Scientific works of domestic and foreign scientists and specialists on the problems of theory and methodology of accounting management and financial accounting, financial and management reporting, management control, analysis, segment accounting and reporting, budgeting, international and Russian accounting standards, materials of periodicals, scientific conferences served as a theoretical basis. The research was based on objective principles of scientific knowledge, basic provisions of the theory of accounting and economic control. At the proof of theoretical positions and generalization of practical results the general scientific and special methods of research were used: analysis, synthesis, abstraction, modeling, economic-statistical and others. The system approach was used to clarify the conceptual apparatus of management and financial accounting, their interaction, development of the concept of forming information on segments in the internal and external reporting of cooperative organizations. The complex approach to a problem has caused carrying out of the researches covering management and such its components, as the account, planning and the control.

Results

There have been studied theoretical bases of management accounting, its parts: budgeting, production accounting, internal reporting; financial accounting and principles of accounting objects disclosure in reporting, including by segments; there have been studied discussion points of conceptual apparatus of management and segment accounting; theoretical aspects of development of management accounting and its concepts, order of its organization and methodical support, formation on its basis of internal and external financial reporting, principles of information disclosure on the center. A large amount of work falls on issues related to the social mission of consumer cooperation, declared as a priority by the Central Union of the Russian Federation, the existing theoretical research in the field of information disclosure about the social responsibility of organizations in integrated reporting, the assessment of the need and possibility of disclosure of such information by organizations of consumer cooperation, the development of methodology for the collection, accounting and control of socially-oriented information to manage the social function of the consumer cooperation. The organizations of medium and small businesses of the consumer cooperation system of the Chuvash Republic and the Republic of Mari El were surveyed. All this made it possible to substantiate the necessity to organize management accounting of socially-oriented information for the purpose of more complete formation of management information both

in internal reports of organizations and for its presentation in financial statements for external interested users, to put forward the thesis that socially-oriented accounting can be considered as a set of segment and management accounting by responsibility centers for a group of companies of district consumer societies, considered in the framework of the program. There was developed a conceptual model of management accounting on the centers of segmentation and responsibility as a result of research of communication links of financial and management accounting and their value for the unified economic information system of consumer cooperative organizations in the context of full and reasonable generalization and disclosure of economic and social components of integrated reporting, which was not previously proposed for use as a holistic methodology. With this formulation of the issue of social responsibility accounting, a system of indicators characterizing social activity in rural areas was developed, with the allocation of accounting and unaccounted for indicators, methods of management accounting of such indicators by segments and centers of responsibility were classified, for the purposes of such accounting a system of budgets, centers of responsibility, their interfacing with segments, a chart of accounts was developed, which details the information required to obtain reporting data on social responsibility, including the real data on social responsibility.

The financial accounting system is designed primarily to summarize monetary accounting indicators, which are formed in the financial statements intended for external users. Reporting by segments includes primarily monetary indicators identical to those in the financial statements, but grouped by segments of the organization, in addition, it may include natural indicators that are formed not in synthetic accounts of financial accounting, but in the management accounting system or analytical accounts of financial accounting.

Underecorded figures can be calculated both in monetary and in-kind terms, contain descriptions of activities or be based on a professional assessment of the situation. The first part of them (cash unaccounted indicators) can be obtained in the system of financial or management accounting, but subject to the introduction of additional analytical positions in the accounts and accounting registers.

Data that contain a description of activities (e.g., communication development, participation in educational activities, charitable activities) or indicators based on the assessment of the situation (e.g., the company's reputation, customer loyalty, customer satisfaction, the degree of social security of employees, the company's image) cannot be generated on a continuous basis in the system accounting. They are determined by accountants-analysts, marketers, other specialists periodically, on the instructions of managers based on a survey of consumers, customers, other stakeholders, personnel, study of the market situation, evaluation of competitors, research Internet portals, etc. The purpose of these indicators, the frequency of their collection, the methods of obtaining information and their approximate nature make it impossible to obtain information in the financial statements. From the point of view of forming social indicators, it is fair to note that part of these indicators in cooperatives is traditionally formed in the system of internal statistical accounting, which is a departmental affiliation. The purpose of such accounting is the compilation of internal statistical reporting, in which social and labor indicators are reflected in significant amounts. These indicators are also partly formed in the financial accounting (primarily monetary).

In line with traditional indicators of the performance of cooperative organizations and their financial situation, it is important to report on the fulfillment of the main purpose of cooperatives - the fulfillment of their social mission.

In terms of content, the social indicators can be grouped as follows: 1) indicators that characterize preservation of natural capital; 2) indicators that characterize the use of labor resources; 3) indicators that characterize the level of social security of employees; 4) indicators aimed at fulfilling the social mission; 5) indicators that characterize the state of the system of labor protection and safety; 6) indicators that characterize the implementation of social programs; 7) indicators aimed at strengthening the reputation of consumer society. Table 1. presents the recommended composition of these indicators.

Tab1: System of social indicators and their disclosure in internal and external reporting of cooperative organizations

Indicator orientation	Indicators Group	Character of indicators	Name and calculation of indicators
Environmental activities	Preservation of natural and productive capital	monetary, thousand rubles	environmental protection costs, payments for pollution of fixed assets
		natural, tons	pollutant emissions, waste volume, waste disposal
		activity overview	participation in environmental restoration, environmental and awareness-raising activities, activities aimed at reducing environmental impact
Social responsibility	Use of labour resources	natural, hour, %	number of employees, working time spent as a whole and per unit of production, labor productivity growth rate
		situation-based	staff demographics, staff education, qualifications
	Level of social security of employees	monetary, thousand rubles	average salary in the consumer society as a whole (software) and by categories of personnel, change (increase, decrease) of average salary, amount of expenses for voluntary medical insurance of employees and life insurance
		natural, %	the relation of the average software salary to the average level in the region
		activity overview	internal communications and corporate culture
	Fulfilling the social mission of consumer cooperation	situation-based	staff loyalty level, software rating among other trade and catering companies in the region, stability of relations with contractors, number of newly built children's and sports grounds
		monetary, thousand rubles	expenditures for charity events (tea tables for the poor, holiday gifts for veterans and pensioners, services at a price below market value, payment of the "cooperative pension" to honored veterans of the PO), expenditures for construction of children's and sports grounds
		natural, pcs, %	number of newly created jobs, share of young specialists, minors and pensioners in the personnel structure, number of charitable events
	Occupational Safety and Health and Injury	natural, pcs, person.	number (absolute and relative) of industrial accidents and occupational diseases, number of accidents, number of employees injured (including fatal accidents), number of lost working days in connection with the said accidents
		monetary, thousand	Occupational health and safety, accident and illness material assistance expenses

		rubles	
	Social programs	monetary, thousand rubles	level of expenditures for staff training, professional upgrading, payment for travel to the place of rest, health-improving vouchers, compensation for meals for employees, loans issued for the purchase of housing and other property, material assistance
Interaction with the external environment	Enhancing Software Reputation	situation-based	level of satisfaction of customers of shops and catering companies with the level of service and the range of products offered
		monetary, thousand rubles	charitable expenses
		activity overview	work on protection of human rights, promotion of consumer cooperative values among the population

In our opinion, the information base for the formation of these indicators can be a management accounting system integrated with financial and internal statistical accounting. As we noted in earlier works, accounting for the purposes of management can be implemented in the framework of accounting, which in this context, we understand the totality of production accounting (accounting system for the formation of internal reporting on cost and production costs) and financial accounting, which is legally regulated and defined as an accounting system for external reporting. Statistical accounting in this integrated accounting system is designated due to the fact that certain social indicators are reflected in statistical reports.

Disclosure of social indicators in the internal and external reporting of consumer societies will lead the management and staff of the organization to rethink their role in society, compliance with the principles of social responsibility of business, understanding the relationship between the process of creating value for themselves and the process of creating socially significant values and products.

Conclusion

There were formulated theoretical provisions for socially-oriented accounting of groups of related consumer cooperative organizations to manage the social mission of consumer cooperative societies in rural areas due to their non-profit legal status. Disclosure of socially oriented indicators in the internal and external reporting of consumer societies will lead the management and staff of the organization to rethink their role in society, compliance with the principles of social responsibility of business, understanding the relationship between the process of creating value for themselves and the process of creating socially significant values and products. Social responsibility indicators should make it possible to assess the cost and usefulness of the organization's activities for society as a whole and for its employees. The proposed methodology for recording and summarizing socially oriented indicators can also be used by agricultural cooperatives.

Annotation

With the growth of the enterprise's economy, a need for use of a risk-oriented approach to many management processes emerges. The control is not an exception. Control based on risk is based in its turn on risk management. Risk management means accounting and analysis of such risks. Risks are advisable to identify for each level of management and process. Processes at all levels are reflected in the accounting. The idea is to extract the necessary information from the accounting data to identify business risks. It is proposed to use the principle of "triple accounting" by Yuji Ijiri. At the same time, it seems useful to expand it to quadro-accounting. The proposed methodology is implemented in the environment of automated information systems (AIS), since the necessary detail can be obtained only with the use of computer technology. The main idea is that the change of capital is analyzed by changing the balance sheet data, and then by revenue and expenditure. The results are presented in formats 1 and 2. The results of factor analysis of capital due to changes in property and liabilities are presented in Format 3. The effect of changes in the components of profit on capital is presented in Format 4. The results of the analysis are used for identification and primary assessment of risks.

Keywords: accounting, analysis, risks, control, management, automated information systems

Basic theses

The proposed methodology for identification and primary risk assessment allows:

1. To use data of accounting systems on a systematic basis to identify business risks;
2. To ensure a continuous approach for identification of risks.
3. Provides a clear picture of the factors that affect capital gains.

Introduction

With the growth of the enterprise's economy, a need for use of a risk-oriented approach to many management processes emerges. The control is not an exception. Control based on risk is based in its turn on risk management. There are risk management models, for example, COSO ERM[1], ferma[2], ISO 31000[3] and others.

They describe the processes of risk management in different ways. But none of them contains methods of using accounting and management accounting data. At the same time, the accounting itself contains the most complete informational base on the economic activities of organizations, which can serve as a basis for any control actions, including risk control.

Work connected with the identification of risks is largely based on economic analysis. It is built on financial and management accounting data. Due to that it seems interesting to explore the possibilities of accounting and economic analysis for identifying and assessing risks. Risk management issues are studied by many scientists. Risks are considered from various positions, e.g. to ensure the security of IT systems built into ISO 31000 [2]. The other examples are: risks and their minimization associated with the activities of managers embellishing the state of the organization in case their revenues depend on profit [19] and business risks, arising in connection with social networks. [3, 20] Many authors consider risks from the quantitative side for various technical nonstandard situations; these issues are also related to management problems. [5, 14, 10]

Some authors explore the nature of risks, its tools and effectiveness. Then they form methods of using risks for business management according to their new experience. [1, 11, 12, 13 18] In the article "Is Risk Analysis Scientific?" [6] Hansson, S.O., Aven, T. raises very topical questions about whether the doctrine of risk analysis is scientific. Does this area of knowledge have inherent attributes of science: subject, method, own field of research, methodology, public needs? The authors make an affirmative conclusion, linking it with socially claimed phenomenon, holistic concepts, methods and applied tools. In general, we can agree with this conclusion. However, it should be noted that risks, especially in economic processes, are highly subjective at the stage of identification and forecasting. That is why the theory about risks should possess reliable methods of their estimation and analysis. In addition, objective methods for identifying, assessing and analyzing risks allow to use them in automated risk management systems and to control them.

Meanwhile, accounting is a quite reliable and objective informational system. It can be used for risk management purposes, for their assessment and analysis. Accounting possesses sufficient objectivity, degree of automation, it can be a basis for constructing objective and sufficiently unambiguous universal methods of working with risks on the basis of IT systems. First of all, these financial and economic risks have internal nature. However, the risks of marketing, currency, etc. can also be identified.

The purpose of the survey is to develop and justify the methodology of using automated accounting systems to identification, evaluation and analysis of business risks. The objectives of the survey are the research of accounting capabilities for identifying risks, the building of a principled model of working with accounting risks and the developing of main ways of risk analysis.

Methods

In modern conditions there are two possible basic principles of accounting, which can be distinguished as a result of scientific and practical activities of accounting specialists:

- uniographic;
- digraphic.

Uniographic principle is the accounting in the form of a usual register entry in a list form. Digraphic principle is the accounting based on a double register entry.

In recent decades, a new paradigm has appeared in accounting theory, the so-called triple-entry, which is influenced by Yuji Ijiri. [7, 8] Ijiri believes that “double bookkeeping is not an absolute system and can be logically expanded” [7, p. 745].

The triple-entry accounting principle means that all accounts are divided into static, dynamic and impulse. Static accounts keep records of assets and liabilities, using the usual accounts, but entries are made on a debit basis. Dynamic accounts take income and expenses into consideration, entries are made on a credit basis. Impulse accounts keep records of the rate of change in income and expenditure in a certain section, on special accounts called 3D. The accounting proposed by Yuji Ijiri is very indicative for managers, since it visually and intelligibly reveals the growth of capital over the period; moreover, it is demonstrated in comparison with the growth of property. Thus, it becomes clear what types of assets are used for incremental capital investment and also how has this capital multiplied. The situation associated with loss is similar.

Like any new theory, the concept of triple-entry has its limitations, among the main and most important one is the lack of universality in the set and the types of factors that affect capital with a positive or negative effect. In fact, the accounting on the 3D accounts (literally in the third dimension, considering the power of impulse) is very conditional, since the result of the analysis of the influence of the factors of growth (or reduction) of capital is taken into account. Many forces cannot be determined from accounting data, since the change in capital is influenced by numerous external and internal factors, for example economic and political situation in the world and in the country, the professionalism of management, the state of the market in which the organization operates etc. Factors that can be arithmetically calculated and recorded on a 3D basis, reflect the consequences of market conditions influence on the growth of capital through changes in the composition of assets and profitability of sales.

On the one hand, a set of indicators that can be disclosed using information from accounts is limited. On the other hand, it is not universal, frequently subjective and will depend on the training of personnel involved in such accounting. Many researchers of accounting pointed to all these and other shortcomings in their surveys [4, 9, 15, 17, 21]

We believe that the technique described by Ijiri cannot be recognized as the accounting one. It can be used to construct analytical calculations because it is more about the form of presentation of accounting data and the analysis that follows from it. It is quite possible to agree with S.A. Samusenko, S. N. Karelskaya and E.I. Zugoy [9, 15] that 3D is convenient to take into account the influence of factors. It will allow to disclose the magnitudes and causes of the change in capital - the most important information for the accounting model based on profit management. In our opinion, this model should be recognized at the same time not so much as accounting, but analytical; model of presentation and disclosure of analytical information according to accounting data. This is why we support the conclusions of S. N. Karelskaya, E.I. Zugi on the availability of additional accounting information capabilities of triple accounting, along with significant limitations, contained in the article “Triple Accounting by Ijiri” [9],

It is necessary to note one more shortcoming. The records that are proposed for 3D reveal the influence of factors on the dynamic index of the organization’s performance. They characterize the change in capital. Factors that change the "static" data on assets and liabilities, that also affect capital, remain aside. A situation where revaluation of assets emerges with the attribution of its value to additional capital can be a good example. The capital increases, but does not form the financial result of the activity. In addition, changes in the composition of the organization's resources can influence subsequent events that directly affect the organization's capital change in the future. Such changes can be judged only by changes in the accounts of assets and liabilities. Using the terms of Ijiri, the change in the structure of resources through the change in the values of certain assets and liabilities is a consequence of reveal of impulses and forces. They can also be measured the same way. It is important for the organization to analyze their size and composition.

In our opinion, the model of the triple accounting of Ijiri gives additional possibilities based on the fact, that it fits well into automated accounting systems. Accounting and management accounting is a subsystem of the organization’s AIS. It implements the possibility to build special form of report, which transmits information to users automatically. In this case it is possible to receive the following results without changing the essence of accounting and standard financial statements: 1) the balance sheet, with an emphasis on the "capital" indicator, 2) the report on the financial results (profit and loss), indicating capital gains, 3) transcription of main factors that influence the capital. This allows management to look in a new way at the familiar data. By forming standard operations to determine the influence of the most objective factors it is possible to provide the necessary unification, which can be detailed in the future.

Such an analytical layout is convenient in many cases as a "starting point". We believe that it is possible to organize accounting in order to obtain information for risk management and risk control. At the same time, we believe that such information is analytical by its nature. This does not contradict the idea of accounting the risks after analysis, because the identification of risks is based on analysis.

Results

On the one hand, factor analysis is an instrument of control, because managers always need to monitor the results of their management on key indicators, among which there will be factors that change profit. On the other hand, control is inextricably linked to risk management, since risk management, as well as analysis, is part of the monitoring toolkit. Therefore, it is possible to obtain objective information for risk assessment by monitoring the components of the financial result from the standpoint of their dynamics and the reasons for changing capital, assets, liabilities, incomes and expenses.

Depending on which model of presentation of data on the financial state of the organization (at historic value or at fair value) is recorded as an accounting one, the change in capital will reflect the increment in the organization's resources based on the actual mass (historical value) or fair value at the submission date - in any case, the change in the capital will be the key indicator characterizing the activity of the organization at a specific moment (at the reporting date). In order to understand the

existing risks of not achieving capital gains in the established amounts (calculated at historical or fair value), it is necessary to analyze the influence of various factors on its magnitude.

In our opinion, based on the idea of the triple-entry of Ijiri, there is an opportunity to improve it in the framework of the AIS. It is more expedient to construct a **quadro-model** that can be successfully applied as an analytical technique in order to manage the risks that are seen from the results of accounting and indicators of financial statements. We regard accounting in this context as accounts and generalization in the system of accounts by the principle of double-entry. Accounting reports are regarded here as reports compiled from the data of accounts in any format, including financial and managerial.

The model of such an analysis can look like this.

The first format characterizes changes in resources. An increase in monetary terms is determined for all accounts of assets. It can be expressed as a positive value or negative if there is a decrease in the asset in the sum expression. Similarly, the amount of change in the debtor indebtedness can be determined. Obligations also participate in calculations, but their changes should be taken into account with the opposite symbol. For example, the increase in liabilities will have a negative value, and their decrease will be taken into account with the symbol "+". Thus, capital gain will be determined for the analyzed (reporting) period as a result of the first calculation.

The second format characterizes the changes in the use of resources. It is built on the basis of information on the accounts of sales, profit and loss. Income and profits will be positive values, costs and losses will be negative ones. The resulting value is the financial result of the period (the reporting (analyzed)). This value will be equal to that obtained in the first calculation, in other words - to the capital gain of the organization for the reporting (analyzed) period.

The third format characterizes the changes that have occurred in the accounts of property and liabilities. Changes in property accounts are affected by two objective factors: quantity and price. The influence of these factors should be specified for each type of property. Thus, risk management will have information about the reasons for the decrease (increase) in assets for use in risk analysis. It is necessary to determine the factors that affect the magnitude of the change in liabilities. Here, turnover in the comparison of the initial and final values for understanding the trend and other factors can be considered as objective factors.

The fourth format reveals the change in capital under the influence of various reasons. Since the change in capital is the financial result of the reporting (analyzed) period, the influence of factors can be realized through the simple formula of balance sheet linkage. However, for the purposes of control and risk management, it is preferable to have calculations related to the assessment of the effect of factors on sales, on cost, on other income and expenses. It is possible to use a multiplicative formula describing the dependence of the main indicator on several factors. In this case, however, it is possible to use the idea of Ijiri: the generalization of sales in terms of price / quantity factors for aggregated groups, specific products (types of work), cost of sales in terms of cost elements, and within them, regarding more specific factors. The main idea is that the change in capital must be fully disclosed in terms of the factors that affected its magnitude.

Such accounting cannot be done manually it makes no sense without the use of accounting automated systems because of the great complexity that will not be justified by the value of the information received. As a result, we will receive automated calculations based on the accounting data and the working balance. This is how the most preferable scheme of the quadro-model will look like (Figure 1).

Source of information			
Accounting balance		**Statement of financial performance**	
Format 1	Format 3	Format 2	Format 4
Increase in assets and liabilities for the period	The impact of factors on asset growth	Total income for the period (by type of business and product type)	The influence of factors on the total income of the period (by type of business, quantity / price factor)
Addition:			
Change in stocks (by types) over the period	Influence of quantity and price factors	Sales revenue	Option 1: Influence of price and quantity factors Option 2: The impact of factors of profitability of sales and profit
Change in debtor indebtedness for the period	Influence of turnover factors	Cost of sales (minus)	Influence of factors depending on the costing items (quantity and price of material costs, the size and productivity of the personnel costs, etc.)
Change in monetary funds for the period	Influence of turnover factors	Commercial expenses (minus)	
Subtraction:		Administrative expenses (minus)	
Change in liability	Influence of turnover factors	Other income	Factors of interest rate, unplanned income
		Other expenses (minus)	Factors of interest rate, unplanned income
		Taxes (minus)	Factors for changing the taxable base
		Changes in capital that are not included in the financial result of the period (+/-)	Factors influencing the emergence of such income/expenses
Capital gains for the period	**Capital gains for the period**	**Capital gains for the period**	**Capital gains for the period**

Discussion

How will the future work with the results of calculations to identify and assess risks look like? We can suppose that the “Report on changes in assets and liabilities” contains information on the growth of finished goods for certain types in a warehouse, while the growth is possible due to a quantitative factor, as can be seen from the "Report on the reasons for changes in assets and liabilities". In order to understand the danger of the current situation, it is necessary to study the data of the "Report on total capital for the period", from which it was clear whether there were sales of this type of finished goods, in what quantity and at what cost. It can be seen in the "Report on the Effect on Total Capital" what is the trend in sales of this product in comparison to the past period. Perhaps the growth in

inventories is due to the growth in sales in general. At the same time, it is necessary to study the production program and the portfolio of orders for these products, as well as the state of the market.

There may be another situation where the "Report on total capital for the period" and the "Report on the impact on total capital" in comparison with the data of the same reports for the previous period show that: 1) the share of sales of a certain product is declining; 2) the selling price of this good decreases; 3) the quantity of a certain product decreases. The external market risk can be seen, and it can be minimized by reducing the production of this product. For a full assessment of the situation on the " Report on changes in assets and liabilities", we can see the scale of stocks of this product in warehouses, as well as the materials necessary for its production. How does the cost of materials and goods behave in relation to the selling price of this product on the market? This information needs to be evaluated in order to understand the quantitative and qualitative characteristics of the risk, as well as to develop management tactics for the identified risk: to take no restrictive actions, to develop measures to reduce the risk to an acceptable level etc.

The resulting documents help to identify the various risks of the organization. "Report on changes in assets and liabilities", "Report on the reasons for changes in assets and liabilities" and "Report on total capital for the period" are more helpful in identifying market risks, while "Report on the impact on total capita" also helps to identify market and financial risks, especially in comparison with such the same report for previous period.

The proposed final documents should be built in electronic form with the ability to print out the necessary fragments due to their comprehensiveness. In addition, signaling documents should be issued in connection with the emergency situations, for example, a decrease in sales with a simultaneous increase in stocks etc. Forming a list of situations that indicate risks is a long and difficult process. Signal documents should be used as primary documents for registering risks. This should be a push for the registration by the Internal Control Department.

It is necessary to understand which accounting reports are appropriate for the purposes of the quadro-model. According to the financial reporting standards, various reserves are formed in the account. The need for this is caused by the uniformity in the displaying of the financial result by periods. It is necessary to use reporting compiled at historical cost for the purposes of accounting of risks. That kind of reporting contains the financial result not distorted by additional leveling procedures.

Reporting that reflects fair value can be investigated separately. The value of the proposed model is that it can be used in both valuation at historical cost and in valuation at fair value. The increase in capital in the second case will not always correlate with the financial result, since not always the fair value is attributed to the financial result. [16] This moment is taken into account in the model: the line "Changes in capital not included in the financial result of the period" was added, and the increment for the period in the value of aggregate capital rather than net profit is also considered.

The format of the quadro-model built on the basis of the "Cash Flow Report" is of particular interest. Such a report provides information on the financial result of the paid sale. In comparison with the reports constructed on shipment, the financial risks caused by the gaps between shipment and payment, as well as the risks of project financing, can be identified.

Further research should be aimed at carefully developing the signal indicators to establish the identified risks for automatic recording.

Conclusion

Risk management and control become the need for systems that operate with significant information flows. Control under such conditions is possible only with the use of automation. Moreover, it is possible to speak about risk management and their accounting and analysis only in the context of information technology.

Automated risk accounting systems require objectively generated algorithms based on specific data collected in the AIS. The source of such data is accounting systems.

The source for risk identification is economic analysis. These risks are further assessed and monitored through analysis. It is necessary to separate the analysis in different processes.

In order to identify risks on the basis of accounting, it is necessary to receive reporting forms containing the result of analytical calculations suitable for identifying risks.

A simple analysis of the indicators that form the capital can be the starting point. Augmentation of capital is the goal of business. The threats to this goal and the associated risks should be determined. The model of presentation of capital from accounting reports is the most reliable. This is the meaning of the quadro-model of risk identification.

Abstract

The problem of regional specialization as the most important factor in the economic development requires close attention, since it largely depends on improving the efficiency of public production. The article deals with the conditions for implementing the possibilities of regional specialization in the agricultural sector. To them the authors refer general market conditions for the functioning of the agricultural economy – a feature of the consumer's assessment of food products, conjunctural macroeconomic fluctuations as well as structural factors – the possibility (or lack thereof) of product differentiation, entry into and exit from the product market. The article describes conditions specific to the agricultural sector that lead producers to take the role of "price takers". To overcome them for the purpose of ensuring successful regional specialization in the agricultural sector it is necessary to implement a number of conditions related to the availability of production resources, the nature of product demand, general conditions for the functioning of agricultural enterprises.

Keywords: Regional Specialization, Product Differentiation, Pricing Policy, Agricultural Production, Agro-Industrial Complex, Production Resources, Dualistic Economy, Agro-Industrial Integration, Agricultural Production Cooperative.

Introduction

Interregional integration into the national economic system is carried out through the effective specialization of regions. This process has objective prerequisites, which are manifested in the presence of certain conditions for the development of a particular industry in the region. Being a phenomenon of the macrolevel of the economy, interregional integration occurs as a result of the interaction of many phenomena of the private level of specialization of specific production units of industry, agriculture, and other sectors of the economy. Therefore, interregional integration can be

called a concentrated expression of the specialization of individual economic units and its consequences. It leads to the natural integration of the region into the national economy.

Materials and Methods

The object of the research is the process of regional specialization in the modern domestic economic system and its most important consequences in the agricultural sector.

The subject of the research is stable, consistently recurring prerequisites, cause-and-effect relationships and consequences of the regional specialization in modern conditions of management of the agricultural sector of the Russian economy.

The theoretical basis of the research has been based on scientific developments, conceptions of the representatives of the classical, neoclassical, and institutional directions of economic thought in the theory of the territorial distribution of production, territorial problems of the economy, and regional specialization. The concept of comparative advantages of D. Ricardo and the factor concept of E. Heckscher – B. Ohlin are recognized as the fundamental provisions in this area. Among the foreign authors of recent decades in this field of knowledge, we can distinguish the works of W. Izard on the territorial problems of the economy; the works of M. Chishholm, describing various areas of the theory of regional economic development; also the works of A. Lesh, H. Bos, S. G. von Tyunen, R. Faini, P. Diken, P. V. Lloyd, P. Krugman, M. Obsfeld and others.

The Soviet scientists P. P. Bondarev, G. I. Granik, S. G. Grodsky, V. I. Gromov, N. N. Nekrasov, A. S. Novoselov, V. E. Rybalkin, V. P. Chernykh, S. I. Sharapov, R. I. Schniper and others made a great contribution to the field of theoretical and practical development of territorial and regional problems of economics and specialization.

The theory of the territorial distribution of production and specialization is currently being developed by Russian scientists V. N. Arkhangelsky, P. S. Zavyalov, A. S. Marshalova, A. S. Novoselov and others.

The methodological basis has been formed by historical and logical, formal and content-related, individual and general approaches, deductive and inductive research methods.

Research Results and Discussion

Transformation of international economic relations in modern society has revealed the difficulty of achieving one of the main goals – increase of the efficiency of public production. This fact is particularly evident in the territorial aspect. Territorial division of labor, coupled with regional specialization and accompanied by a parallel process of industrialization, can affect this dangerous trend and turn it to equalize the conditions for the growth and development of regions and increase the efficiency of public production in general.

At the same time, the study of the process of regional specialization, identification of its prerequisites, regularities, principles can help to solve the practical problem of deriving a maximum profit from the general process of public, private, and individual division of labor, as well as to develop measures of state influence on this process.

In this connection, consideration of the region's ability to specialize in agricultural production should be based on the conditions created in the economic system that is developing towards industrialization. The conditions for working on the market of agricultural production, complicated by a number of general and particular circumstances, require detailed consideration.

The general market conditions for the functioning of the agricultural economy include, first of all, the peculiarity of the consumer's assessment of food products. Unlike most industrial products, food products have a sharp decrease in marginal utility when consumption increases. This feature of the

consumer's assessment of the marginal utility of the product is due to the low elasticity of demand for food, both in terms of price and consumer income.

The aggregate demand responds to agricultural products and macroeconomic fluctuations in a peculiar way. During the recovery phase, the growth of food demand may occur very slightly or may not occur at all. This is also due to the rigid nature of demand for it, as well as the fact that in the conditions of growth, when there is an increase in consumer incomes, the share of population spending on food in their total expenditures inevitably decreases. As a result the demand for food becomes even less elastic in price; in some cases, it does not respond to prices at all. These special demand factors create the conditions for a relatively small increase in supply that cause the market price of food in general, and especially raw food, to fall sharply.

Under such conditions, that is, in the absence of a significant increase in demand, a good harvest in crop production, as well as an increase in livestock and livestock productivity in animal husbandry, can act not in favor of agricultural farms, but to their detriment. In practice, everything depends on the supply: on the change (rate of change) of its volume and the ability of producers (sellers) to influence the volume of the supply and pricing. In some industries, inelastic demand creates excellent market conditions for product sales. These are usually industries where the structural features of the market allow producers (sellers) to manage the volume of supply and set the right prices. This is the case, for example, in the markets of pharmaceutical products (the point refers exclusively to manufacturers).

In terms of the number of sellers, it is characterized by an oligopolistic and often monopolistic structure, which allows it to act very actively in pricing. The product type also gives the manufacturer of this product a good opportunity to influence prices. The product is homogeneous in its class, and often unique and irreplaceable. Freedom to enter and leave the market, or, on the contrary, the difficulty of entering and leaving it plays an important role in the supply and pricing of products in the market with strong demand. It is very difficult to enter the pharmaceutical markets and leave the industry due to the specifics of technologies and a number of other circumstances. This gives additional opportunities for companies operating in the industry. Operating firms can safely, without fear of increased competition due to the emergence of other firms, conduct their pricing policy.

Thus, for successful (we can say, guaranteed successful) activity in an industry where products by their market nature have a strong demand, a set of favorable conditions is needed to create a market form of imperfect competition giving the manufacturer monopoly power. It is equally important that these conditions coincide with the nature of the consumer's product evaluation and the rigidity of demand for it.

In the food market, however, with almost the same rigidity of demand for products as in the pharmaceutical industry, the situation is different with the product supply and its dynamics. An increase in the volume of supply, if it occurs on the scale of the country's market space, even if this growth is relatively small, is nevertheless able to sharply reduce the market purchase prices for agricultural products. The volume of supply of raw food, the main product of agricultural farms, is determined by factors, most of which do not depend on the economic entity. Because of this, the volume of supply of agricultural products is subject to significant fluctuations.

The structural factors of agricultural markets are combined in such a way that they become similar in structure to the model of pure competition. With a comparable rigidity of demand for products, unlike the pharmaceutical industry, the raw food market is characterized by a very large number of producers. According to this indicator, it can not be attributed to any type of imperfect competition, and this feature already deprives the producer of agricultural products of the slightest opportunity to influence prices, fix them on the basis of production costs, and act as a price finder.

It is known that differentiation of products in all possible parameters also gives power over the market and pricing. This differentiation is widely used in many industrial sectors, especially in light industry. In the food industry, there are fewer opportunities to differentiate products than in other

industries. They are limited by the fact that consumption is physiological by nature. However, agricultural producers are particularly deprived in this regard, since they have no possibility of differentiation under normal conditions (if it appears, it is minimal and only under special conditions, for example, when new varieties of plants or new breeds of animals appear). Entry into and exit from the market for raw agricultural products is almost free of obstacles due to the small costs associated with them. The ease of entering and exiting the market dramatically increases competition in the industry, completely depriving manufacturers of any influence on pricing.

In the domestic economy, the factor of misconceptions is often in considerable force in agricultural production, which also contributes to the rapid growth of supply in the agricultural market with constant demand. Since in practice there is no reduction in the overall price level, it is advisable to consider relative prices (price ratios) in the context of an increase in the overall price level. Agricultural farms are quick to notice an increase in purchase prices for grain, vegetables, meat, and milk. However, as a rule, they pay little attention to the increase in prices for most consumer goods and services. It affects the rationality of actions of economic entities in the agricultural sector and leads to its decline. They increase production, considering that payment for labor and manufactured products has increased. This situation takes place at present time and recurs from time to time. Manufacturers with a fair delay reappraise the market situation and take the appropriate economic decision.

Consequently, all the structural features of the market are aimed at making the producer of raw agricultural products a price taker who does not have any opportunity to proceed from his interests in pricing. Having a natural and inevitable in market conditions tendency to increase the supply of agricultural products, combined with a sluggish response of demand to prices, this means a constant threat of a collapse in prices for it.

Agricultural production as a branch of specialization is also characterized by internal factors. These farms are characterized by higher survivability as producers, which is maintained in market conditions and confirmed by practice. Many agricultural farms in the current conditions work, manufacture products for the market when the revenue does not only make any profit, but even does not cover costs. Nevertheless, the agricultural sector continues to function as a producer of commodity output. And this is certainly due to the fact that the inertia of the traditional consciousness of the agricultural producer continues to operate.

Survival in these extreme market conditions occurs at the expense of the labor part of income, that is, the employee's share in it – remuneration of labor. It is lost, not returned by the market in part or in full. And the worker, whoever he is, the owner of a peasant farm, a member of a cooperative organization or an employee of a large agricultural association, does not receive part of the payment for his work. The non-return of part of the labor share in the income of the agricultural economy is a characteristic feature of the dualistic economy, when the economic system of the country consists essentially of two subsystems with different conditions of production and distribution of income.

In theory, the model of the dualistic economy is described and usually associated with the name of V. Levis. It is described in relation to countries with high population density, limited natural resources and poor capital on the basis of the study of the real labor market of such countries as India, Egypt, Pakistan, and others. The industries of these countries develop at a high rate, acquire, use the achievements of scientific and technological progress, create modern infrastructure, integrate into the world economy. Wages in industry and other industrial sectors of the economy are formed according to the marginal product of labor. In this case, the law of marginal productivity applies. At the same time, the agricultural sector of these economies retains many features of the pre-capitalist economy in the forms of production and distribution. The supply of labor is excessive, and the level of wages in agriculture does not respond to the growth of demand for it. The law of marginal productivity in wages does not apply. It is dominated by customs and traditions. Wages and their level are nothing more than an institutionally defined minimum oriented to the average product of labor. In the Russian economy there are all signs of such dualism, especially with regard to agriculture.

The dualistic economy itself is a product of this peculiarity of the agricultural economy as a production unit – to work to the last possible stage of survival. In the case of the dualistic economy, this is essentially due to the refusal of the agricultural sector worker from part of his wage and his consent to work for a much lower wage than in other industries.

The phenomenon of the dualistic economy is characteristic of Russian agriculture and raw food production almost to the same extent as of the economies of the above countries. The survival rate of agricultural farms is also enhanced due to the fact that they can exist, in contrast to the industrial enterprise, in some mode of self-sufficiency. It can, under certain conditions, consume its own products.

The specialization of the farm in the agricultural sector may not be as narrow as in industry. Natural conditions of production make it possible, moreover, profitable its structural diversity. An agricultural farm can produce several types of products at the same time, using the advantage of alternating crops. It can simultaneously engage in crop production and animal husbandry. This provides significant benefits because it allows to use by-products of crop production.

The biological nature of the product in agriculture is due to a special rhythm of production, which can not be changed with relative ease, as in industry. In industry, the company can vary the production cycle at its discretion. In agriculture it is impossible: in crop production the rhythm of production is dictated by the changing seasons and the ripening period, in animal husbandry – by physiological limits of the periods of gestation, growth of young animals, fattening.

Since the agricultural farm operates in conditions of seasonal production, this has a number of consequences in the use of fixed assets. Some types of machinery are operated only a few days in a year, but their physical and, in particular, moral wear and tear occurs even when it stands idle.

In agriculture, rationalization of production combinations and response to market price signals also meet difficulties and obstacles. Compared to industry, the possibilities of rationalizing resource combinations are very narrow and there is no room for maneuvering. The agricultural producer cannot forecast his future costs with the same accuracy as in industry. It's impossible both in crop production and animal husbandry. Much depends on specific weather conditions, natural phenomena, the spread of diseases, always unpredictable, sometimes having the nature of epidemics.

Many of these factors are particularly strong in the agricultural sector of such economic systems as Russia, with its extremely risky for agriculture and difficult for animal husbandry natural and geographical conditions.

Thus, under normal conditions, specialization in the production of agricultural products for many Russian regions, although highly desirable in economic, social, demographic, and ethno-cultural terms, is associated with a number of difficulties and it is necessary to make significant efforts to turn negative factors into positive ones. However, the conditions of production activity in the agricultural sector in modern economy are changing rapidly and in many cases they contribute to the solution of the problem of adaptation.

These changes should be considered in the following areas:

a) conditions for the availability of production resources;

b) the nature of demand for products;

c) general conditions for the functioning of agricultural farms.

The most static indicator is the availability of production resources, in modern domestic economy it has a tendency to change, and not for the better. The indicator of labor supply is deteriorating due to incomplete reproduction of the labor force, and a decrease in the working-age population. The quality

of the labor force is declining, and its degradation is the result of the long lack of demand. At the same time, the quality of the labor force is better in peasant (farm) enterprises, since their labor potential has been formed mainly by specialists of agricultural enterprises, and the least competitive labor force has been concentrated in the households of the population.

Many employees of working age are willing to work in agriculture, if this industry creates tolerable conditions for price ratios and wages. In recent years, the share of officially employed people in agriculture has significantly decreased. This trend is typical not only for the Chuvash Republic, but also for the entire national system as a whole. Previously, those who worked in various sectors of the rural economy were displaced into the households of the population, in so doing they lost all types of social support, most of them are forced to survive by subsistence farming – that is, there is a big social problem here.

The paradox of the rural economy is that with significant unused labor resources in rural areas, agricultural farms often lack labor. The main reason is extremely low wages in this sector of the economy.

As a result of non-use, the quality of another basic production resource – land – also deteriorates. Erosion occurs, soil fertility deteriorates, and agricultural land is overgrown with shrubs, forests.

The problem of successful functioning of the agricultural sector within the strict framework of modern market conditions indicates that the industry is forced to adapt to such conditions, which are becoming more complicated.

For crop production, it can be expected that farms will look for an opportunity to extend the period of production use of land, reduce the duration of vegetation, and increase the shelf life of both raw and processed products.

The extension of production use of land is possible by creating greenhouses. At the same time, the reduction in the relative price of energy carriers creates favorable opportunities for highly profitable activities of greenhouse farms.

The duration of vegetation can be reduced, and this reduction is carried out by planting hybrid varieties, genetically modified plants, etc. But this possibility has a very strict limitation, regulated by nature. This direction towards change and adaptation is inevitably accompanied by a change in product quality, and not just its worsening, but a mutation of the natural parameters of plants and their fruitage.

Extension of the shelf life of the raw product as well as shortening of the ripening period of the product has natural limitations, but not as severe as it has. At least, practice shows that this problem is successfully solved in the regions and countries where the main market flow of fruits and berries comes from.

The increase in the shelf life of processed products is successfully carried out for all food groups. As a rule, increase in the shelf life through canning and adding preservatives is combined with a diverse differentiation of food products. This gives a considerable gain not only in the possibility of more profitable sales. The lengthening of the shelf life, combined with product differentiation, also brings changes in market structures, particularly by product type. The agricultural sector passes from the category of producer of identical products into the category of producer of differentiated products. For him, the market is characterized not by the position of a purely competitive price taker, but by the position of a price finder, i.e. he gets some opportunities to influence the formation of market prices.

Due to the fact that product differentiation actually separates the product into a special unit of competition, the number of producers with whom it is necessary to compete is limited and reduced. This also improves the market position of the food producer.

Product differentiation and longer shelf life also change the conditions for entering and exiting the market. It becomes more difficult due to the fact that deep processing with subtle differentiation increases the costs of entry and exit. This leads to further reduction in the number of competing manufacturers.

Also, the demand for differentiated products with a long shelf life becomes more elastic both in price and in consumer income.

Changes that occur as a result of product differentiation both from the supply side and from the demand side soften the overall market position of the food producer when production volume increases. More elastic demand and more manageable supply prevent a possible collapse of market prices.

When the region specializes in agricultural production, it should be assumed that the livestock sub-sector of agricultural production has its own adaptation features. In modern conditions, livestock farms are increasingly cooperating in agricultural holdings. In animal husbandry it leads to the dominating position of the largest associations and complexes that produce their products on an industrial basis.

In this case, crop production to a great extent becomes an appendage of animal husbandry, working mainly for animal husbandry. The reason for this is the fact that from the point of view of the stability of the market functioning of the enterprise, animal husbandry is a more convenient and promising occupation than crop production. It is easier to overcome those obstacles that are more difficult for or beyond the power of crop production: seasonality, limited differentiation of products, the need to create artificial conditions, the problem of year-round income.

In terms of technology, based on the accumulated experience of industrial countries and according to the rational basis of market integration of animal husbandry, we should expect the process of raising livestock and its fattening to become simpler. On the other hand, the desire to reduce the time is evident. It seems that it is less difficult to do it in animal husbandry than in crop production, at least there is no such strict dependence on the annual natural cycles. There is also a huge experience in this regard, for example, in the production of poultry, eggs.

This evolution of the food market, agricultural production is an objective phenomenon. Although they are carried out by people, in essence, they do not depend either on the will of organized groups of people (collectives) or on the will of an individual. They are dictated by the world order in the sphere of material goods which is established by the market-capitalist system and which they are forced to obey, under the pressure of which economic entities and entire industries are forced to operate, including the agricultural sector we are considering.

The division of the food market into two parts, consisting of products that differ in quality, natural purity and price, has already taken place in many countries. The domestic food market also very intensively implements this differentiation. This fact puts regional food producers before a choice: in the production of which products they will specialize.

The problem of entering the market of a certain type of product forces enterprises to pay attention to the prospects for such adaptation and integration into the national as well as international market. The adaptation of the industry does not mean that this will happen en masse. The most important result of changes in the conditions of the agricultural sector, which has not only economic but also social significance, is the reduction in the number of farms and enterprises due to their enlargement. It is obvious that small and medium-sized enterprises will strive to find an opportunity to stay in the industry, settle down in it in new conditions and work as a full-fledged, competitive market economy. It seems to us that they can get this opportunity when organized in the form of a production cooperative as an association for joint production, processing, and sale of agricultural products.

Here begins the sphere of organizational forms of management of the agro-industrial complex of the region, which is as important for the adaptation of the industry to the changing conditions of functioning and specialization as the sphere of market units and the division of food market into consumer and high quality products sectors.

In the 80s of the XX century, the main organizational forms of agro-industrial integration were agro-industrial enterprises (collective farms, state farms, poultry farms, etc.), agro-industrial complexes (where the role of integrator was performed by enterprises, mainly processing fruits and vegetables) and agro-industrial associations (the role of integrator was performed by agricultural enterprises). In the 1990s, all these state-owned enterprises were reorganized into joint stock companies that transferred the controlling stock to labor collectives of mainly processing enterprises, whereas agricultural producers received insignificant stock. As a result, agricultural enterprises had no power or dividends, since the management of the processing enterprise controlled production.

Of the existing forms of integrated agro-industrial units (agricultural firms, agro-industrial complexes, holdings and cooperatives) participating in the implementation of all of the above opportunities to gain from the specialization of the region and the country as a whole, such type of organization as agricultural production cooperatives can be successfully used. They should be organized taking into account the new realities in the economy, when they do not and cannot have non-working members and absentees, when everyone is interested in the results of the collective's activity and takes the most active part in production and sale. In this case, cooperatives can compete with holdings in efficiency.

In practice, two types of agricultural cooperatives can be observed: vertical producers' cooperatives and horizontal production cooperatives. In cooperatives of the first type, each participant retains his legal, economic and economic independence, can maintain on an equal footing processing enterprises, maintenance departments, etc. Vertical cooperatives make it possible to satisfy to maximum the needs of their farms. Members of cooperatives of the second type unite only for the production of agricultural products and do not have independence.

The main task of agricultural cooperation is to form an organizational and legal system to protect the interests of agricultural producers by creating self-governing forms of management. To date, the main needs of agricultural farms are the sale of raw agricultural products of crop production and animal husbandry at prices that cover costs and provide the necessary rate of return, as well as timely high-quality processing which enables to differentiate these products and to increase demand elasticity by the price. Cooperation provides agricultural producers with timely sales, transportation, and processing of products. The agricultural farm can independently set selling prices, and not accept low prices of intermediaries and processors of agricultural raw materials.

The development of cooperative relations between agricultural producers and processing enterprises will strengthen the influence of the latter on agricultural production in the region – the requirements for the professional level of personnel, for the quality of raw materials, for the rhythm and continuity of supply will increase. This relationship also has the opposite direction – at present, it is becoming profitable for agricultural producers to switch from the gross approach in growing products to point production on orders of processing enterprises, this approach allows producers of agricultural raw materials to solve the acute problem of selling products. The establishment of cooperative and integration relations will help to smooth out seasonality in the use of labor and material resources and turn agricultural work into a variety of industrial, as well as significantly affect production efficiency, as it will enable a more rational use of land resources and technology and integrated use of auxiliary and general services.

The main problem is modernization of the existing production base and reequipment. Its solution requires search for new mechanisms and tools. Under present conditions agricultural enterprises cannot solve this problem on their own – the problem of increasing the level of technical equipment. Financial resources as well as production resources are insufficient. And here, cooperatives get an

incomparable advantage as larger units in lending, and also appears a possibility of more effective capital management within the cooperative itself.

Judging by foreign experience in this field, in countries with market economies, farmers' cooperatives play a very significant, and in some cases decisive role in the system of relations between the agricultural sector and related industries, in the development of the agro-industrial complex as a whole. Almost one hundred percent participation of agricultural producers in cooperatives is traditional for Northern Europe, the Netherlands, Ireland, Japan. In the European Union countries, farmers' cooperatives produce up to 60% of food products, i.e. they play an important role in ensuring food security, and in Japan – about 90%.

The importance, wide distribution and efficiency of such cooperatives is explained by equal partnership of farmers, their economic independence and responsibility for making management decisions. In addition, they allow us to take into account the effect of the scale of production. They are a successful form of interaction between large-scale production and small-scale farming. There is a successful combination of the advantages of small agricultural producers historically established in the regions with their maneuverability in market conditions, economically feasible larger processing enterprises and well-organized supply and marketing system. The specificity of these relations lies in the fact that agriculture is the root cause here, plays a major and even decisive role in the entire system.

Conclusion

Thus, cooperation is currently not only a socially-oriented system that protects the interests of the most economically weak members of society (which is undoubtedly important in rural areas), but also a kind of core that concentrates the agro-industrial complex of the region and makes it possible to achieve maximum effect when specializing in this area.

Abstract

The accuracy of risk assessment inherent in the financial sector is of great importance in modern realities. Gross volumes of operations today are such that even seemingly insignificant increase in the accuracy of calculations, for example, of reserves of funds, the insured share of assets, insurance premiums, etc. can bring a noticeable profit for the owner, seller or buyer of volatility. The algebraic risk theory created in the last two decades offers effective computational methods for assessing the risks of financial instruments and their portfolios, which are characterized by increased accuracy. The computational experiments presented in the work demonstrate the promise of the proposed risk assessment methods against the background of the results obtained using the Monte Carlo method even when the latter utilizes huge computational resources.

Keywords: Algebraic risk theory, Monte Carlo methods, Value at risk.

Introduction

Today, the term “risk” has firmly taken up positions in a huge number of economic, technological, political, etc. constructs. The first scientific approaches to the study of the risk phenomenon date back to the 18th century, to the work of the Swiss mathematician Daniel Bernoulli, who studied the paradox of a game with a coin toss, called the “St. Petersburg paradox” (1738). Since then, the number of publications on the topic of risk has shown explosive growth. At the end of the 20th and the beginning of the 21st centuries, in the works of Ulrich Beck (2000, 2008, 2009), Anthony Giddens (2004) and Niklas Luhmann (1994, 2004) they completely formulated the integral concept

of the "risk society" and, even, "world risk society", Beck (2008). Public awareness of the significance of the risk concept has led, as a result, to standardization processes in the field of risk management, GOST (2012).

However, in spite of such a long history of the formation of the concept of risk, the breadth of the corresponding discourse in society, the use of risk management processes at the industrial level, a universal concept of risk has not yet been formulated, a mathematically rigorous formal idea of risk has not been formulated, as well as ideas about properties of risk as a mathematical object. The situation is no better in the field of risk assessment.

So in the financial sector, risk assessment is often based on the assumption of a certain canonical distribution of one or another key characteristic of the process under study, respectively, the parameters of this distribution are estimated by the sample values of other characteristics, in some way related to the key characteristic. At the same time, the reality is that the distributions discussed can be very different from the canonical ones. This is a typical situation for portfolios containing a small number of financial instruments. The connections between the characteristics of the economic system may have stochastic nature which is difficult to identify. The described situation often leads to low accuracy of risk assessments or, sometimes, to obtaining generally absurd results. The approaches based on the ideas of the Monte Carlo method are often productive in such cases, but require very large computational resources and very careful stability control, especially with extremely large test volumes, Borodin (2014), Urazaeva and Smirnova (2016).

This work proposes a fundamentally new solution to the problem of risk assessment in the financial sector, based on the computational methods of algebraic risk theory, Urazaeva (2017). The proposed approach, on the one hand, easily copes with noncanonical distributions of random variables describing the economic system, and on the other hand, has a number of advantages with respect to the Monte Carlo method.

Elements of the algebraic theory of risk

Assume C as the set of transformations of the state of the economy corresponding to each option of closing a position for each financial instrument, their portfolio or sub-portfolio, which are present in the studied economic system. Further, assume, $\mathbf{I} = [0,1] \subset \mathbf{R}$, where $\mathbf{R}$ is the set of real numbers. Consider the set of multisets defined as follows:

$$\mathsf{A} = \{ \boldsymbol{X} : \operatorname{Supp} \boldsymbol{X} \subset C \times \mathbf{I} \}.$$

Note that for an empty multiset

$$\varnothing = \left\{ k_{\varnothing}(x) * x : \ \forall x \left(x \in C \times \mathbf{I} \right) \left[k_{\varnothing}(x) = 0 \right] \right\},$$

where $k_{\boldsymbol{X}}(x)$ – multiplicity function of element x of the multiset, $\boldsymbol{X}$, $\varnothing \in \mathsf{A}$ is true. Define on the A operation of addition:

$$\boldsymbol{X} + \boldsymbol{Y} = \left\{ k_{\boldsymbol{X}+\boldsymbol{Y}}(x) * x : \ k_{\boldsymbol{X}+\boldsymbol{Y}}(x) = k_{\boldsymbol{X}}(x) + k_{\boldsymbol{Y}}(x), x \in \operatorname{Supp} \boldsymbol{X} \cup \operatorname{Supp} \boldsymbol{Y} \right\}$$

and multiplication:

$$\boldsymbol{XY} = \left\{ \ k_{\boldsymbol{XY}}(x) * x : \ k_{\boldsymbol{XY}}(x) = \right.$$

$$= \sum_{(c_X \circ c_Y,\, p_X p_Y)=x,\, (c_X,\, p_X)\in \mathrm{Supp}\, \boldsymbol{X},\, (c_Y,\, p_Y)\in \mathrm{Supp}\, \boldsymbol{Y}} k_{\boldsymbol{X}}\left((c_{\boldsymbol{X}},\, p_{\boldsymbol{X}})\right) k_{\boldsymbol{Y}}\left((c_{\boldsymbol{Y}},\, p_{\boldsymbol{Y}})\right),$$

$$x \in \left. \bigcup_{(c_X,\, p_X)\in \mathrm{Supp}\, \boldsymbol{X},\, (c_Y,\, p_Y)\in \mathrm{Supp}\, \boldsymbol{Y}} \{(c_{\boldsymbol{X}} \circ c_{\boldsymbol{Y}},\, p_{\boldsymbol{X}} p_{\boldsymbol{Y}})\} \right\}.$$

For the set A and the operations of addition and multiplication defined on it, the following statement is true.

Statement 1. If the binary operation of composing transformations over a set C is commutative:

$$\forall c_1, c_2\ (c_1, c_2 \in C)\left[c_1 \circ c_2 = c_2 \circ c_1\right]$$

then the algebraic system $\langle \mathsf{A}, +, \square \rangle$ is a *commutative semiring with identity element 1*.

To describe the risk in the economic system under conditions of probabilistic uncertainty, we will use multisets of the following form:

$$\boldsymbol{R} \in \mathsf{A},\ \Sigma_{(c,\, p)\in \mathrm{Supp}\, \boldsymbol{R}}\ p k_{\boldsymbol{R}}\left((c,\, p)\right) = 1,\ c \in C,\ p \in \mathbf{I}$$

Each element of this multiset represents a variant of economic development. The element is the essence of the pair: the transformation of the state of the economy corresponding to this option for its development, and the likelihood of this option being implemented. The sum of the probabilities for all options is 1. Consider the set of multisets of the form:

$$\mathsf{R} = \left\{ \boldsymbol{R}:\ \boldsymbol{R} \in \mathsf{A},\ \Sigma_{(c,\, p)\in \mathrm{Supp}\, \boldsymbol{R}}\ p k_{\boldsymbol{R}}\left((c,\, p)\right) = 1 \right\}$$

Obviously, $\mathsf{R} \subset \mathsf{A}$, and, therefore, the same operations of addition and multiplication are defined for R elements. However, note that the R set is absolutely not closed with respect to the addition operation:

$$\forall \boldsymbol{R}_1, \boldsymbol{R}_2\ (\boldsymbol{R}_1, \boldsymbol{R}_2 \in \mathsf{R})\left[\boldsymbol{R}_1 + \boldsymbol{R}_2 \notin \mathsf{R}\right].$$

At the same time, for the R set and the multiplication operation defined on it, the following statement is true.

Statement 2. If the binary operation of composing transformations over C set is commutative, then the algebraic system $\langle \mathsf{R}, \square \rangle$ is a *commutative monoid.*

The obvious interpretation of the operation of multiplication by R is the understanding of the product of risks of two financial instruments as the risk of a portfolio composed of them. Thus, the set of risks, with the operation of multiplication defined on it (calculating the joint risk), form an algebraic system that is a commutative monoid.

For elements of a commutative monoid, as a special case of a semigroup, a natural degree is defined. An interpretation of the *n*-degree of risk of a financial instrument is the risk of a portfolio consisting of *n* of the same such instruments, $n \in \mathbf{N}$, $\mathbf{N}$ - a set of natural numbers. Significant relief in calculating the natural degrees of the elements of the R set (risk of homogeneous portfolios!) can be obtained by using the results of the following theorem.

Theorem 1. Assume the binary operation of composition of transformations over a C set is commutative, and assume, further, the predicates be defined:

$$\pi_1 = \wedge_{i=1}^{m} \left[(c_i,\, p_i) \in \operatorname{Supp} \boldsymbol{X} \right],\ \pi_2 = \left(\Sigma_{i=1}^{m} l_i = n \right),$$

$$\pi_3 = \left[\left(c_1^{l_1} \circ c_2^{l_2} \circ \ldots \circ c_m^{l_m},\, \Pi_{i=1}^{m} p_i^{l_i} \right) = x \right],$$

Then

$$\boldsymbol{X}^n = \left\{ k_{\boldsymbol{X}^n}(x) * x :\ k_{\boldsymbol{X}^n}(x) = \sum\nolimits_{\pi_1, \pi_2, \pi_3} \frac{n!}{\Pi_{i=1}^{m} l_i!} \Pi_{i=1}^{m} \left[k_{\boldsymbol{X}}\left((c_i,\, p_i) \right) \right]^{l_i},\right.$$

$$\left. x \in \bigcup\nolimits_{\pi_1, \pi_2} \left\{ \left(c_1^{l_1} \circ c_2^{l_2} \circ \ldots \circ c_m^{l_m},\, \Pi_{i=1}^{m} p_i^{l_i} \right) \right\},\ m = \left| \operatorname{Supp} \boldsymbol{X} \right| \right\}$$

for any $\boldsymbol{X} \in \mathsf{A}$.

Theorem 1 is valid for elements of A set; however, in the context of this paper, the properties of narrower sets, such as, R set, are important.

Many R multisets are many possible risks in the economies under study or, otherwise, many descriptions of the complete groups of events in these economies at the time of closing any positions. However, quite often it is necessary to consider incomplete groups of events or, even, individual events. Within the framework of the risk paradigm used, incomplete groups of events will be associated with parts of the risk. To describe the parts of risk in the economic system under conditions of probabilistic uncertainty, we will use multisets from the following set:

$$\mathsf{P} = \left\{ \boldsymbol{R} :\ \boldsymbol{R} \in \mathsf{A},\, \Sigma_{(c,\, p) \in \operatorname{Supp} \boldsymbol{R}}\ p k_{\boldsymbol{R}}\left((c,\, p) \right) \le 1 \right\}.$$

It is obvious that $\mathsf{P} \subset \mathsf{A}$ and, therefore, for P elements from the previously introduced operations of addition and multiplication are defined. However, note that the P set is not closed with respect to the addition operation:

$$\exists \boldsymbol{R}_1, \boldsymbol{R}_2\ \left(\boldsymbol{R}_1, \boldsymbol{R}_2 \in \mathsf{P} \right) \left[\boldsymbol{R}_1 + \boldsymbol{R}_2 \notin \mathsf{P} \right].$$

The interpretation of the addition operation on P is the aggregation of risk parts. For the P set and the multiplication operation defined on it, the following statement is true.

Statement 3. If the binary operation of composing transformations over C set is commutative, then the algebraic system $\langle \mathsf{P}, \square \rangle$ is a *commutative monoid.*

We introduce two more classes of sets of multisets that are useful in further constructions:

$$\mathsf{P}_{\alpha} = \left\{ \boldsymbol{R} :\ \boldsymbol{R} \in \mathsf{A},\, \Sigma_{x \in \operatorname{Supp} \boldsymbol{R}}\ k_{\boldsymbol{R}}(x)\, \mathrm{pr}_{\mathbf{I}}\, x = \alpha \right\},$$

$$\mathsf{P}_{\le \alpha} = \left\{ \boldsymbol{R} :\ \boldsymbol{R} \in \mathsf{A},\, \Sigma_{x \in \operatorname{Supp} \boldsymbol{R}}\ k_{\boldsymbol{R}}(x)\, \mathrm{pr}_{\mathbf{I}}\, x \le \alpha \right\},$$

$$0 \le \alpha \le 1 .$$

For the introduced classes, the following statement can be proved.

S t a t e m e n t 4 . The following statements are true:

$$\forall \alpha, \beta \left(0 \le \alpha \le 1, 0 \le \beta \le 1\right) \left[\boldsymbol{R}' \in \mathsf{P}_{\alpha}, \boldsymbol{R}'' \in \mathsf{P}_{\beta} \;\Rightarrow\; \boldsymbol{R}'\boldsymbol{R}'' \in \mathsf{P}_{\alpha \cdot \beta} \right],$$

$$\forall \alpha, \beta \left(0 \le \alpha \le 1, 0 \le \beta \le 1\right) \left[\boldsymbol{R}' \in \mathsf{P}_{\le \alpha}, \boldsymbol{R}'' \in \mathsf{P}_{\le \beta} \;\Rightarrow\; \boldsymbol{R}'\boldsymbol{R}'' \in \mathsf{P}_{\le \alpha \cdot \beta} \right],$$

$$\forall \alpha, \beta \left(0 \le \alpha \le 1, 0 \le \beta \le 1\right) \left[\boldsymbol{R}' \in \mathsf{P}_{\le \alpha}, \boldsymbol{R}'' \in \mathsf{P}_{\beta} \;\Rightarrow\; \boldsymbol{R}'\boldsymbol{R}'' \in \mathsf{P}_{\le \alpha \cdot \beta} \right].$$

Statement 4, in particular, regulates the risk hierarchy in the following sense. Assume there is a decomposition of risk into several parts. Each part of the risk contains one or more outcomes of economic development and corresponds to some logically selected development scenario. If the further analysis of one of these scenarios reveals the presence of previously unaccounted risk in it, then the part of the risk corresponding to this scenario (the element of the P_{α} set, $0 < \alpha < 1$) is simply multiplied in the above sense by the identified risk (the element of the R set) and a new part of the overall risk is obtained (the element is again of P_{α} set).

Now we can formulate an important purely algebraic result: *the set of risks and their parts forms a commutative monoid (with respect to the operation of calculating the joint risk) embedded in a commutative semiring with identity element 1 on which the partial (semiring) operation of addition (risk aggregation) is defined.*

We introduce a number of constructions. We say that the relation r on the groupoid $\langle A, * \rangle$ *is stably (regularly, or uniformly) on the right (on the left)* if $x r y$ $(x, y \in A)$ entails $x * z \, r \, y * z$ $(z * x \, r \, z * y)$ for every $z \in A$. A stable right (left) equivalence relation on A is called a right (left) *congruence on* A. *A congruence on* A is an equivalence relation that is both a left and a right congruence, Clifford (1972).

We introduce a map $\kappa : \mathsf{A} \to \mathsf{A}^1$, where

$$\mathsf{A}^1 = \left\{ \boldsymbol{R} : \boldsymbol{R} \in \mathsf{A}, \forall x \left(x \in \operatorname{Supp} \boldsymbol{R} \right) \left[k_{\boldsymbol{R}}(x) = 1 \right] \right\}.$$

We define it as follows:

$$\kappa(\boldsymbol{R}) \underset{Def}{=} \left\{ 1 * \left[\sum_{\substack{x \in \operatorname{Supp} \boldsymbol{R}, \\ \operatorname{pr}_C x = \theta}} k_{\boldsymbol{R}}(x) \operatorname{pr}_{\mathbf{I}} x \right] \theta \in \bigcup_{x \in \operatorname{Supp} \boldsymbol{R}} \left\{ \operatorname{pr}_C x \right\} \right\}. \tag{1}$$

Using the map (1), we define the relation k on A:

$$\boldsymbol{R}_1 \, k \, \boldsymbol{R}_2 \underset{Def}{\Leftrightarrow} \kappa(\boldsymbol{R}_1) = \kappa(\boldsymbol{R}_2), \; \boldsymbol{R}_1, \boldsymbol{R}_2 \in \mathsf{A} .$$

The following theorem can be proved.

T h e o r e m 2 . A relation k is a congruence on a semicircle $\langle \mathsf{A}, +, \square \rangle$.

In other words, from a probability-theoretical point of view, risks and their parts in a commutative economy are distinguishable up to congruence k .

Let us construct one more congruence that is important for the subject area under consideration. We introduce a map $\tilde{\sigma}:\ \mathsf{A} \to \mathsf{A}_{>0}$ where

$$\mathsf{A}_{>0} = \left\{ \boldsymbol{R} \in \mathsf{A}:\ \forall x \left(x \in \operatorname{Supp} \boldsymbol{R} \right) \left[\operatorname{pr}_{\mathbf{I}} x > 0 \right] \right\}.$$

We define it as follows:

$$\tilde{\sigma}(\boldsymbol{R}) \underset{Def}{=} \left\{ k_{\boldsymbol{R}}(x) * x:\ \operatorname{pr}_{\mathbf{I}} x > 0,\ x \in \operatorname{Supp} \boldsymbol{R} \right\}. \tag{2}$$

Using the map (2), we define the relation σ on A :

$$\boldsymbol{R}_1 \,\sigma\, \boldsymbol{R}_2 \underset{Def}{\Leftrightarrow} \tilde{\sigma}(\boldsymbol{R}_1) = \tilde{\sigma}(\boldsymbol{R}_2).$$

For this relation, the following theorem can be proved.

T h e o r e m 3 . A relation σ is a congruence on a semicircle $\langle \mathsf{A}, +, \square \rangle$.

Thus, from a practical point of view, risks and their parts in a commutative economy are distinguishable up to congruence σ .

Using the notation introduced, we can determine two types of residues: the smallest (simplest) residue:

$$|\boldsymbol{A}|_k \underset{Def}{=} k(\boldsymbol{A}),\ \boldsymbol{A} \hat{\mathrm{I}}\ \mathsf{A},$$

and a significant residue:

$$|\boldsymbol{A}|_\sigma \underset{Def}{=} \tilde{\sigma}(\boldsymbol{A}),\ \boldsymbol{A} \in \mathsf{A}.$$

Accordingly, we can talk about risk arithmetic modulo k and modulo s . Each of these arithmetic allows in its own way to increase the performance of calculations in direct calculation of the risks of discrete systems. The question naturally arises: Is it possible to combine the advantages provided by each of these arithmetic systems?

It can be shown that the answer to this question is positive and this is connected with the result expressed by the following theorem.

T h e o r e m 4 . A relation $\kappa \cdot \sigma$ is a congruence on a semiring $\langle \mathsf{A}, +, \square \rangle$.

The results of Theorem 4 allow us to introduce the concept and natural notation of the *least significant residue* or residue modulo $\kappa \cdot \sigma$:

$$|\boldsymbol{A}|_{\kappa\sigma} \underset{Def}{=} \tilde{\sigma} \circ \tilde{\kappa}(\boldsymbol{A}),\ \boldsymbol{A} \in \mathsf{A}.$$

The properties of all introduced residues are represented by the following theorem.

Theorem 5. On a commutative semiring with identified element 1 $\langle \mathsf{A}, +, \mathrm{g} \rangle$ for any $\boldsymbol{A}, \boldsymbol{B}$ Î A, the following relations are true:

$$\left| \left| \boldsymbol{A} \right|_{\alpha} + \boldsymbol{B} \right|_{\alpha} = \left| \boldsymbol{A} + \left| \boldsymbol{B} \right|_{\alpha} \right|_{\alpha} = \left| \left| \boldsymbol{A} \right|_{\alpha} + \left| \boldsymbol{B} \right|_{\alpha} \right|_{\alpha} = \left| \boldsymbol{A} + \boldsymbol{B} \right|_{\alpha}$$

and

$$\left| \left| \boldsymbol{A} \right|_{\alpha} \square \boldsymbol{B} \right|_{\alpha} = \left| \boldsymbol{A} \square \left| \boldsymbol{B} \right|_{\alpha} \right|_{\alpha} = \left| \left| \boldsymbol{A} \right|_{\alpha} \square \left| \boldsymbol{B} \right|_{\alpha} \right|_{\alpha} = \left| \boldsymbol{A} \square \boldsymbol{B} \right|_{\alpha},$$

where $\alpha \in \{\kappa, \sigma, \kappa\sigma\}$.

In conclusion of the review of the basic concepts of algebraic risk theory, we note that Theorems 1 and 5 allow us to implement effective direct calculations over risks in many interesting applications to the financial sphere.

Currently, the computational algorithms proposed by the algebraic risk theory are implemented as part of the MultiMIR application package, Urazaeva (2016).

Computational Experiment

Consider the task of assessing the risk of a retail loan portfolio. The credit risk management process includes qualitative and quantitative aspects, Lobanov et al (2003). The qualitative aspect is to determine the creditworthiness (reliability) of the borrower or counterparty. The modern approach to quantifying credit risk is based on the concept of "Value at Risk", Holton (2003) and, Jorion (2006), which has become the generally accepted standard for assessing market risks. The application of this approach to risk assessment at the level of the loan portfolio involves the construction of a distribution of a random amount of financial result over the portfolio on any planning horizon and calculation of the corresponding distribution quantile. The calculation of the quantile is a measure of the risk associated with the randomness of the magnitude of the financial result.

The approach to modeling the bank's loan portfolio has traditionally been based on the idea of independent creation of scenario models of individual loan agreements with subsequent joint analysis of an arbitrary set of such models, Borodin (1998).

When analyzing the credit risk of most loan portfolios, it is convenient to use the model of a standard loan agreement, which includes the following four scenarios, Urazaeva (2017):

1) the course of the loan agreement without complications;
2) a single or multiple occurrence of eliminated arrears;
3) the success scenario of the collateral sale procedure in case of unrepaired overdue debt;
4) write-off of bad loans.

Each scenario implements the calculation of the corresponding amount of discounted payment flows under the contract. The discount rules are determined by the objectives of the analysis (market value risk, portfolio book value risk, etc.). Moreover, in the second, third and fourth scenarios, cash flows corresponding to the additional costs incurred are taken into account.

Suppose that at the time of closing a certain position for each of the independent assets, the reduced balance of payments is represented by a random variable X_i, $i = 1, 2, \ldots, n$. These random variables will be considered pairwise independent. The total reduced balance of payments at the time of closing the position in this case will be:

$$S_n = \Sigma_{i=1}^{n} X_i .$$

It is known, Loeve (1962), that if $X_1, X_2, \ldots, X_n$ are random variables with finite mathematical expectations, then the mathematical expectation of their sum exists and is equal to the sum of their mathematical expectations:

$$E\left(\Sigma_{i=1}^{n} X_i\right) = \Sigma_{i=1}^{n} E\left(X_i\right). \quad (3)$$

This immediately implies the linear dependence of mathematical expectation, as one of the measures of risk, on the volume of the portfolio.

It is also known, Loeve (1962), that if $X_1, X_2, \ldots, X_n$ are random variables with finite variances and at the same time they are pairwise independent, then the variance of their sum is equal to the sum of their variances (Bienaimé equality):

$$\mathrm{Var}\left(\Sigma_{i=1}^{n} X_i\right) = \Sigma_{i=1}^{n} \mathrm{Var}\left(X_i\right). \quad (4)$$

Since in our case the independence of credit agreements is assumed, the linear dependence of variance, as a measure of risk, on the volume of the portfolio also immediately follows from Bienaimé equality.

Unfortunately, for the risk measure “Value at Risk”, simple ratios similar to (3) and (4) are not known. One of the traditional approaches to an approximate assessment of this risk measure is based on the use of the Monte Carlo method, Aleskerov et at (2013). For the case when the portfolio is homogeneous, in other words, it consists of (approximately) the same tools, algebraic risk theory offers a method of accurately assessing the risk measure “Value at Risk”. This circumstance, on the one hand, makes it possible to verify new approaches, and on the other hand, objectively investigates the behavior of the Monte Carlo method.

Using the Monte Carlo method to model a loan portfolio in this statement is trivial. Each test involves generating one pseudo-random number uniformly distributed over a segment $[0,1]$ per contract. After that, it is checked that this number falls into one of the intervals of the cumulative probability constancy for the contract model. The financial result is the balance of payments according to the contract scenario corresponding to the right end of the interval (cumulative gap). When summing up financial results for all contracts, the final balance of payments for the entire portfolio is calculated. That is, a financial result is formed from one test of the Monte Carlo method. Given the uniformity of the initial distribution, the tests represent a selective distribution of the financial result for the portfolio, according to which you can evaluate any measure of risk, including “Value at Risk”. The more tests, the closer the sample distribution to the theoretical one.

As an example, we will examine a homogeneous portfolio of loan contracts for urgent needs. The average volume of one loan is 90 thousand rubles. The annual rate is 19%. The system of payments under the contract - annuity in arrears. The probabilities of scenario implementation are 0.63, 0.12, 0.11, and 0.14, respectively. The average costs associated with the elimination of overdue debts under one contract are 5 thousand rubles. When writing off bad loans under an unfulfilled loan agreement, along with losses, additional costs arise associated with the corresponding operating activities. These costs for such an agreement amount to an average of 18 thousand rubles. We will use the listed initial data in all numerical experiments related to the Monte Carlo method.

Consider the dependence of the risk measure “Value at Risk” at a probability level of 0.01 on the number of instruments in this portfolio against the background of the Monte Carlo method tests (see

Fig. 1). The exact values of the "Value at Risk" risk measure were obtained using the MultiMIR application package, Urazaeva (2016). The figure shows that estimating the quantile on the left tail of the distribution is not a trivial task. Indeed, it is enough to note that the substantially (multiple times) predominant part of the volume of the carrier cone, located below the concentration of dots corresponding to the tests, is almost empty. This is a sure sign that a significant amount of testing will be needed with sufficient accuracy to evaluate the Value at Risk measure.

Fig. 1: Dependence of the risk measure "Value at Risk" on the number of instruments in the portfolio (red curve calculated using the MultiMIR software) against the background of Monte Carlo tests (blue dots). Tests are limited by carrier cone. The carrier cone is defined by a brown beam from below and a green from above.

Consider a homogeneous portfolio consisting of 256 loan agreements described above. The choice of number 2^8 is associated with the desire to exacerbate the problems that arise when using the Monte Carlo method with the pseudo-random number generator of the Microsoft Office programming system. Why this choice in the indicated sense is effective will be clear a little later. As a result of the first numerical experiment, the dependence of the assessment of the risk measure "Value at Risk" on the number of tests of the Monte Carlo method in the range from 2^{10} to 2^{16} was obtained, see Fig. 2.

Fig. 2: Dependence of the assessment of the risk measure "Value at Risk" on the number of tests of the Monte Carlo method (blue curve) for the model portfolio. A light brown horizontal line indicates the exact value of the risk measure being evaluated. The inclined red line segment in the second half of the diagram shows the presence of an obvious trend in the assessment.

If the first half of the graph shown in Fig. 2, does not raise any special questions, then something strange happens in the second half of the graph: the assessment of the target risk measure gradually reaches the exact value (calculated using the MultiMIR software), and then it moves away from the exact value at approximately the same rate. This trend is linear, its coefficient of determination $R^2 = 0.88$. What's happening?

To answer the question posed, it was decided to conduct a second numerical experiment in which the right border of the number of tests was pushed back to a value of 2^{18}. This computational experiment required a significantly larger amount of processor time. This and the subsequent resource-intensive tasks described in this article were solved relatively quickly by parallelizing the calculations. The results of the second numerical experiment are shown in Fig. 3.

Fig. 3 sheds some light on the situation. Let's combine the segments $\left[2^{16}, 2^{17}\right]$, $\left[2^{17}, 2^{17}+2^{16}\right]$ and $\left[2^{17}+2^{16}, 2^{18}\right]$ domain of dependence of the assessment of the target risk measure on the number of trials and look at the corresponding parts of the graph of this dependence from areas II, III and IV (Fig. 4). The presence of autocorrelation in the studied dependence is obvious. Based on the data obtained, it is possible to put forward a hypothesis: the period of the sequence of numbers generated by the pseudo-random number generator of the Microsoft Office programming system is $2^8 \times 2^{16} = 2^{24}$. The repetition of the period easily explains the invariance of the assessment of the target risk measure at the end of the I, II, III and IV areas of the graph in Fig. 3 (or, otherwise, the impossibility of further improving the assessment in areas II, III and IV).

Fig. 3: Dependence of the assessment of the risk measure "Value at Risk" on the number of tests of the Monte Carlo method (blue curve) for the model portfolio on the quadruple interval of the number of tests. A light brown horizontal line indicates the exact value of the risk measure being evaluated.

Fig. 4: Combined graphs of the dependence of the risk measure "Value at Risk" on the number of tests from areas II, III and IV of Figure 3. For clarity, the graphs are shifted along the ordinate relative to each other by an amount equal to 4 thousand rubles.

At this stage of the numerical experiments, we were convinced of the limited capabilities of the built-in pseudo-random number generator of the Microsoft Office programming system for solving some problems by the Monte Carlo method. In this regard, the problem arises of selecting a more promising alternative to the full-time pseudo-random number generator. Moreover, as the selection

criteria, one should take into account both the statistical properties of the generator and the possibilities of effective implementation in the corresponding programming system.

In 1997, Japanese mathematicians Makoto Matsumoto and Takuji Nishimura proposed a pseudo-random number generator based on the properties of Mersenne primes and, in this connection, it was called the "Mersenne twister", Matsumoto (1998). One of the variants of this PRNG, called MT19937, has a huge period equal to the Mersenne prime $2^{19937}-1$, provides a uniform distribution of the generated pseudorandom numbers in 623 dimensions (for the best known linear congruent generators, this number of measurements does not exceed four, see table II in papers Matsumoto (1998)) and can be relatively efficiently implemented on 32-bit computers.

Using the MT19937 implementation on VBA (2012), a numerical experiment was conducted to solve our problem of assessing portfolio risk measures. The results of this numerical experiment are shown in Fig. 5.

Fig. 5: Dependence of the assessment of the risk measure "Value at Risk" on the number of tests of the Monte Carlo method with PRNG MT19937 (blue curve) for the model portfolio. A light brown horizontal line indicates the exact value of the risk measure being evaluated.

Discussion

The Monte Carlo process shown in Fig. 5 fully complies with the theoretical concepts of the functioning of this method and, thus, demonstrates the feasibility of using the MT19937 PRNG instead of the PRNG implemented in Microsoft Office VBA in solving problems of at least the class in question.

On the other hand, the result presented is, in fact, a confirmation of the adequacy of the methods of the algebraic risk theory regarding the needs of risk analysis in the financial sphere, at least for some classes of problems.

It is also important that the application of the Monte Carlo method in dimensional problems comparable to our example requires a researcher to carefully monitor the stability of the method and the quality of the PRNG.

Conclusion

Summing up, we note that the results presented in the article are of serious fundamental importance for understanding the nature of risk. They demonstrate the organic connection of the risk phenomenon with well-known and well-studied modern algebra constructs. This kind of knowledge allows you to attract the full power of the apparatus developed by modern abstract algebra to solve the practical problems of risk analysis and assessment.

On the other hand, the work presented reflects the practical side of the theory presented. The article presents the results of evaluating the risk measure “Value at Risk” of a real retail loan portfolio based on the algorithms proposed by the algebraic risk theory, and based on the Monte Carlo method. It is important that both results are consistent with each other, however, the latter method demonstrates the potential presence of "pitfalls", which are important to monitor and ignoring of which can lead to obtaining absurd results.

Abstract

The contribution considers the essential characteristics of financial security in relation to the macro, micro and industry level (for the chemical industry), the main factors that hinder the development of the industry and its entities (technological backwardness of a number of sectors, limited access of Russian products to foreign markets, fierce competition, inconsistency of the level of development of transport infrastructure with export conditions of chemical products, etc.) and have a negative impact on the provision of economic and financial security of organizations. The authors pay particular attention to the characteristics of threats to economic and financial security in relation to organizations of the chemical industry, as well as a system of indicators (including threshold values) to assess their level of financial security.

Keywords: Chemical Industry Organizations, Economic Security, Financial Security, Threats to The External and Internal Environment, Indicators for Assessing the Level of Financial Security.

Introduction

Financial security as a derivative of the economic security category is associated with threats to economic security in the financial sector of the economy and in the financial activities of business entities. We will use this concept in relation to the study of the activities of chemical industry organizations to ensure economic, including financial, security.

The factors of economic and financial security that influence the emergence of threats and risks, the financial stability of business entities, for the most part, are described in the works of foreign experts A. Damodaran (2012), S. Bragg (2007), G. Wang (2019), T Wang (2019), T. Jeitschko (2014), J. Li (2019), S. Linz (2014), S. Myers (2020), C. Nkeki (2018), J. Noguera (2014), A. Otero (2015), H. Tao (2019), L. Haar (2019), S. Chun (2016), P. Atrill (2009) and others.

Materials and methods

The study is based on the fundamental principles of economic science, the works of scientists in the sphere of economic security management. The methodological tools are based on the dialectical method of cognition providing a systematic approach to the problem under study; general scientific methods: induction and deduction, analysis and synthesis, grouping, economic and statistical analysis, etc. The information base is made up of official data of federal and regional state statistics bodies of the Russian Federation, Internet resources, accounting (financial) statements of organizations of the chemical industry of the Republic of Tatarstan, Chuvash Republic and the Republic of Mari El.

Research Results and Discussion

The essence and principles of the organization of financial security at the macro and micro levels

The tiered approach in which the definition of financial security can be given for the state, a subject of the Russian Federation, an economic entity is well substantiated in the scientific literature. It provides the utmost clarity in determining specific areas and tasks of national security in the financial and economic sphere. Identification of threats to financial security involves the determination of criteria and requirements of economic security in terms of:

- ability of the economy to function in the expanded reproduction mode under the influence of a group of threats: decline in production, deformation of the structure of the economy, its raw materials orientation, the upcoming shortage of energy resources, lack of motivation to increase production efficiency, worsening conditions for organizing and conducting business, etc.;

- ensuring a decent standard of living and the possibility of its preservation. Threats: rising unemployment, a crisis in the demographic sphere, deteriorating public health, increasing crime, decreasing the number of able-bodied people, etc.;

- stability of the financial system. Threats: the growth of the shadow economy, insufficient investment, a crisis in the monetary system, a decrease in the efficiency of organizations in the real sector of the economy, an increase in the budget deficit, limited and underdeveloped financial markets, dependence on world oil prices, etc.;

- rationality of the structure of the foreign economic sphere. Threats: disproportions in the foreign trade balance, outflow of capital abroad, discrimination in foreign economic relations on the part of foreign partners, imperfection of the legislative framework and mechanisms for the formation of political and economic development, the spread of corruption and corrupt business schemes, etc.;

- possibility of accelerating the technological and innovative development of the economy.

Threats: technological lag, reduction in the competitiveness of the innovation system, dependence of the economy on imports of machinery and technologies, insecurity of innovative development programs with funding sources, reduced investment attractiveness of priority research and development segments compared to countries with developed intellectual property markets, etc.

The list of threats to financial security can be classified according to different criteria, but more often they use classifications developed in accordance with applicable laws and strategic documents of socio-economic development. All classification groups of threats, no matter by what criteria they are combined, can manifest themselves under appropriate conditions at all levels of government of a state, regions, interfere with economic growth, which of course affects the sustainability of the economic development of the real sector of the economy.

When working out strategic directions of development, all commercial organizations in their financial and economic activities form a system of key indicators, which they are guided by in the short and long term. Most of these indicators are financial: revenue from product sales, production costs, profit, shareholders' equity, liabilities, business value, etc. Sustainable development is ensured upon reaching the established threshold level of the system of financial indicators and determines the organization's security from threats.

The definitions of financial security at the micro level are widely represented in the economic literature from the standpoint of different approaches:

- as a system of quantitative and qualitative parameters of the financial condition with the help of which a comprehensive assessment of the level of financial security of the organization can be obtained;

- main element or part of economic security;

- differentiated level of quantitative and qualitative parameters of the protection of the financial interests of the organization and the basis for measuring and evaluating its financial security.

All of the above characteristics are successfully, in our opinion, summarized by I.A. Blank in the following definition: "The financial security of an enterprise is a quantitatively and qualitatively determined level of its financial condition ensuring stable protection of its priority, balanced financial interests from identified real and potential threats of an external and internal nature, the parameters of which are determined on the basis of its financial philosophy and create necessary prerequisites for financial support for its sustainable growth in the current and future period" [Blank, 2004].

Ensuring financial security in organizations of the chemical industry

In accordance with the strategic documents developed by the Russian Federation, doctrines and the Economic Security Concept, scientists and specialists build their research in the field of economic security mainly around the five methodological provisions formulated by prof. O.A. Mironova [Mironova, 2016]. In one of them areas of economic security are determined based on the presence of external and internal threats - factors affecting the state of economic security of entities whose sources can be established with varying degrees of accuracy. Therefore, any threat and its established source require a quick response from those entities against which they are directed. To classify threats to economic security as well as to classify certain types of economic security (for example, financial), it is necessary to establish safety criteria. They are:

- the ability of the economy to function in the expanded reproduction mode;

- a decent standard of living and the possibility of its preservation;

- stability of the financial system;

- the rational structure of the foreign economic sphere;

- acceleration of technological and innovative development of the economy.

The Forecast of the Long-Term Socio-Economic Development of the Russian Federation until 2030 indicates that the chemical complex in the GDP structure accounts for about 2%, organizations in this industry provide about 5% of the total Russian foreign exchange earnings, and the average annual number of workers in the industry exceeds 600 thousand people. Factors that hinder the development of the industry include technological backwardness of a number of sectors of the chemical industry, limited access of Russian products to foreign markets, fierce competition, inadequate transport infrastructure and its level of development for the export of chemical products, etc. These factors

affect the economic security of organizations, and to overcome this impact it is necessary to eliminate the risks of reducing business performance through ensuring legality and expediency of using labor, financial, industrial and land resources. The concept of "security threat" reflects such changes in the external and internal environment of the organization that lead to negative changes in it.

Threats may include an increase in investment risks and a decrease in the investment attractiveness of ongoing projects, inefficient optimization of the supply chain "raw materials supply - production - sale of products to consumer" considering regional characteristics of the development of counterparty organizations, a decrease in the technological level of the material base and a decline in innovation, inflationary risks due to inefficient diversification of production and (or) unreasonable price improvement policy (Table 1).

Table 1: General description of economic and financial security threats for chemical industry organizations

Threats to economic security	Threats to financial security
Increased investment risks and reduced investment attractiveness of ongoing projects	Reduced investment
Ineffective organization of the supply chain "raw materials supply - production - sale of products to the consumer" considering regional characteristics of counterparty organizations	Disruption of delivery and default
Inflation risks with inefficient diversification of production and (or) unreasonable price improvement policy	Failure to meet production and sales volumes and, as a result, financial situation deterioration and organization default
Decrease in the level of technological development and innovative activity in the organization	The decline in the quality of products and in sales, the inefficiency of innovation and, as a result, the deterioration of the financial situation and default

The main goal of financial security regulation is to develop a system of mandatory financial prerequisites for the sustainable development of the organization in the short and long term. In the short term the main goal of financial security is to improve the financial condition of the organization, in the long term - to ensure financial stability as an adaptive ability to respond quickly to threats to the internal and external environment, including threats to financial security (see Table 1), while ensuring the appropriate liquidity and solvency level on the basis of a balanced risk management policy, and to solve its strategic tasks together with interested parties in order to reach sustainable success and increase the market value of the company.

Ensuring financial security is becoming one of the main tasks of managing organizations of the chemical industry the activities of which involve risks. Risks as carriers of threats to financial security in relation to organizations of the chemical industry can be classified in different ways. For each group and a specific type of risk it is necessary to determine the conditions for their identification and select the tools for their assessment. This will provide an opportunity to effectively manage risks arising at all stages of production. Management risk factors are especially pronounced in such areas as supply, sales, production management, planning and forecasting of sustainable development indicators, management of certain types of activities and structural units.

To determine the financial security level of chemical industry organizations a reasonable choice of systems of indicators from the entire possible data set of all types of reporting is necessary, to which not only financial and comprehensive economic analysis methods can be applied but also methods that expand the range of obtaining the necessary information for making informed decisions in the sphere of countering threats and reducing (neutralizing) risks. In this regard, risk indicators are also indicators based on which reasonable decisions can be made to ensure financial security in the current and strategic perspective.

Having taken an accounting and analytical data system that includes various types of accounting and generated reports as an information base for the formation of indicators for assessing the level of financial security of chemical industry organizations we obtain the indicators shown in Table 2.

Table 2: Scorecard for assessing the financial security level of chemical industry organizations

Indicator	Characteristic	Threshold value
1. Personnel safety indicators		
1.1. Quantitative staffing level	Is defined as the ratio of the organization's full-time employees to the average number in the reporting (planning) period	100 %
1.2. Qualitative staffing level	Is determined by the ratio of employees of the appropriate qualification level to the number of jobs (positions) according to the staffing table	100 %
1.3. Staff turnover rate	Is determined by the ratio of the number of laid-off employees in the reporting period to the average number of employees	10 %
1.4. Average annual wage	Is determined by the ratio of the annual employee payroll to the average number of employees in the reporting year	Not lower than the average industry wage
1.5. Average monthly wage	Is determined by the ratio of the monthly wage fund to the average number of employees in the reporting month	Not lower than the average industry wage
1.6. The proportion of workers in the total number of employees	Is determined by the ratio of the number of workers (in accordance with the number of jobs in the organization) to the average number of employees in the reporting period	50-90 %
1.7. Profit per employee of the organization	Is determined by the ratio of profit in the reporting period to the average number of employees	Not less than 10% of the average monthly wage per employee
2. Investment security indicators		
2.1. The ratio of own and borrowed funds	Is determined by the volume of loans and borrowings to the total volume of own sources (capital, profit, target financing, etc., reflected in Section 3 of the balance sheet)	50/50
2.2. The ratio of the volume of investments to the total volume of own and borrowed sources of funds	Is determined by the volume of investments received to the total amount of own and borrowed sources of funds	50/50
3. Indicators of tax security		
3.1. Tax burden	Is defined as the ratio of the total amount of accrued (paid) taxes to the amount of revenue (income) received for the period	30-40 %
3.2. The growth dynamics of the aggregate tax base in relation to the growth in revenue (income)	Is determined in relation to each tax paid by the ratio of the amount of payments on this tax to the total amount of revenue (income) over several periods. Dynamics is analyzed	positive
4. General indicators of financial security		
4.1. Organization profit	The methodology for calculating indicators is traditional, based on the data of financial statements for the period. Indicators are	Set in organization planning documents
4.2. Shareholders'		

equity volume	considered in dynamics. The dependence of each indicator on a certain group of factors is determined, which can serve as the basis for determining the integral indicator of financial security	
4.3. Working capital volume		
4.4. Production profitability		

All indicators in the process of the financial and economic activity of the organization are subject to the influence of risks, therefore, to ensure financial security it is necessary to develop appropriate requirements in order to prevent possible risks and to adequately respond to their appearance.

Conclusion

The selection of indicators can be carried out:

- to identify key success factors in the strategic development of the organization and increase its competitiveness;

- to determine the level of sustainable financial development of the main activities of the organization in the current and strategic perspective taking into account the prevailing conditions for the development of the sub-sector of the chemical industry to which this organization belongs (mining, inorganic chemistry, organic chemistry, production of chemical reagents, paint and varnish, pharmaceutical, household chemicals, microbiology);

- to strengthen specific areas of management to achieve the overall financial security of the organization.

When establishing the acceptable level of the selected system of indicators, risks that are carriers of threats to financial security can be assessed by traditional methods with their classification in a specific zone: acceptable, critical or catastrophic risk.

Allowable risk is determined by the level of actual indicators below the threshold values; catastrophic can be qualified exactly the opposite, and its actual values will indicate the excess of the established threshold values and the onset of the threat of bankruptcy of the organization. When the system of planning and control is effectively organized risk assessment is of significant informative value allowing making informed management decisions in order to successfully implement contractual relations between producers and consumers of chemical products.

Abstract

The article discusses current issues of the state and development of the social infrastructure of the rural areas. The necessity of state support of rural social development is substantiated. The main directions of the state program of the Chuvash Republic "Integrated development of rural territories of the Chuvash Republic" are considered.The current social situation and the lack of socially acceptable living conditions in rural areas are a brake on the formation of socio-economic factors for the sustainable development of rural territories.These provisions determined the following tasks of scientific research:
- to assess the social consequences of ongoing agricultural reforms and the current level of development of rural social infrastructure in general in the Russian Federation and in the Chuvash Republic;
- to identify the trends with the construction and commissioning in rural areas of the social infrastructure of the agricultural sector;
- to analyze the directions and volumes of financing the objects of the social infrastructure of the agro-industrial complex in the Chuvash Republic in accordance with the target programs;
- to substantiate possible ways to improve the social development of the village on the basis of the study of theoretical principles and scientific concepts, generalization of domestic and foreign experience, Russian agricultural history;
- to develop new approaches and priority areas for the development of rural settlements, taking into account the integrated solution of economic and social problems to increase the competitiveness of the region.

Keywords: Social Infrastructure, Program-Targeted Method, Sources Of Financing.

Introduction

At present, the role of social infrastructure in the economic and social development of society as a sphere of production of services and spiritual goods is growing, this role is also expressed in the fact that social infrastructure forms the quality of life of the rural population and helps to stimulate investment activity in the agro-industrial complex by creating favorable infrastructure conditions in the countryside.

The current social situation and the lack of acceptable living conditions in rural areas hinder the formation of socio-economic factors for sustainable rural development.

The relevance and need for the development and implementation of a long-term federal target program for rural social development is determined by the socio-political urgency of the problem and its federal significance, determined by the wide range of functions performed by the village - demographic, labor-resource, cultural, recreational, and environmental.

For the emergence of competitive markets in the sectors of the national economic complex, a carefully prepared social infrastructure is required, the role of the state in this is growing.

The need to create equal social conditions for residents of the village compared with the townspeople of the Chuvash Republic and other Russian regions together makes the chosen topic of scientific research extremely relevant and determines the objective need for a comprehensive study of the consequences of agrarian reforms, employment and social protection of the rural population in unity with socio-economic development of rural areas.

Materials and Research Methods

The research was attended by teachers and staff of the Chuvash State Agricultural Academy and the Cheboksary Cooperative Institute (branch). The scientific problem was studied using data from the Federal State Statistics Service (Rosstat) and the Territorial Authority of the Federal State Statistics Service for the Chuvash Republic, the Ministry of Agriculture of the Chuvash Republic, and data provided in scientific publications.

In the course of the work, widely tested reliable research methods were used - general scientific methods of dialectics, analysis, synthesis, induction, deduction, analogy.

Research Results and Discussion

One of the effective ways of state regulation is program-targeted planning. Since 2003, the main target tool for the development of rural areas has been the federal target program "Social development of the countryside." In 2018, the federal target program was transformed into the subprogram “Sustainable Development of Rural Areas” of the general State Program for the Development of Agriculture and Market Regulation, and then into the departmental target program, which reduced the level of attention to this topic.

The need to develop programs at the level of the constituent entities of the federation (Fig. 1) is explained by the fact that regional programs allow taking into account the structural and production features of the agro-industrial complex and, based on this, reasonably coordinate its development.

The priorities of state policy in the field of agriculture are defined in the Federal Law "On the Development of Agriculture", decrees of the President of the Russian Federation dated January 30, 2010 N 120 "On approval of the Doctrine of Food Security of the Russian Federation", dated May 7, 2018 N 204 "On national goals and strategic objectives of the development of the Russian Federation for the period until 2024, "Decree of the Government of the Russian Federation of July 14, 2012 N 717" On the State Program for the Development of Agriculture and Market Regulation s agricultural

products, raw materials and food, "the decision of the Cabinet of Ministers of the Chuvash Republic from June 28, 2018 N 254" On approval of the Strategy of socio-economic development of Chuvash Republic till 2035 ".

Fig. 1: The relationship of regional and federal target programs.

The use of the program-target method in relation to the development of the social infrastructure of the agro-industrial complex proceeds from the need to give the highest possible level of specificity, quantitative certainty of setting program goals. At the same time, it allows setting goals in a qualitative formulation that do not have a clear numerical expression, but are clear enough to represent targets that can be used to establish the required orientation of program actions.

The application of the program-target approach allows you to implement a comprehensive approach to the development of the object, linking of social goals and objectives with the resources of all types necessary for their implementation becomes real.

Next, we will try to derive a model of the relationship of the main social factors with the competitiveness of the agricultural enterprise. Our studies have allowed us to make assumptions about the existence of significant relationships between the variables in terms of the presence of social infrastructure in a given territory, personnel management (especially young personnel), organization of production and the final results of the enterprise, which we tried to show on a graphical model in the form of an increasing crisis pyramid (Fig. . 2).

Fig. 2: The growing crisis pyramid of the agricultural enterprise

Acceleration of the crisis began from an insignificant factor - the absence of a kindergarten and school. The need to take children to these educational institutions and bring them back distracts parents from work, creates nervousness and dissatisfaction of workers with social conditions. Gradually, the social crisis develops into a personnel crisis - their departure from the enterprise or even from the village. If the management of the enterprise does not notice the emerging trends and does not take measures, a crisis of underproduction is inevitable, and in the future a financial crisis. The deepening financial crisis will lead to insolvency of the enterprise.

The current state and development of social infrastructure is characterized by the following main factors and trends (Table 1, Table 2, Figure 3):

- the widespread network of state and municipal institutions of the social sphere with low capital-labor ratio and outdated equipment;
- inconsistency of the existing network of institutions of socio-cultural sphere and the volume of services rendered by them to the needs of the population;
- a reduction in the number of these institutions, both as a result of structural changes in sectors and the limited financial resources for their maintenance and maintenance of the material and technical base;
- a decrease in the volume of capital investments in the social sphere, a slowdown in the rate of commissioning of facilities, and an increase in construction in progress.

Table 1: Provision of facilities and services of social infrastructure to the rural population of the Chuvash Republic

Indicators	per 1000 rural population							
	2011	2012	2013	2014	2015	2016	2017	2018
The Number of hospitals	0,097	0,099	3,802	3,804	0,080	0,030	0,040	0,040
The Number of beds in hospitals	7,290	7,254	0,095	0,087	6,416	5,094	7,316	6,328

hot water	4,52	5,56	6,07	6,31	6,79	6,96	8,62	7,70
floor electric stoves	15,69	15,09	11,32	7,25	4,29	5,80	5,56	4,23

The existing conditions for the functioning and development of social institutions require a government policy aimed at the rational use of limited investment resources. The negative impact on the rural population is compounded as a result of a further decline in the quality of social services and infrastructure, the development of which in the Russian Federation as a whole is significantly behind the city.

There was a sharp reduction in the volume of investments in the social and engineering infrastructure of the village, the only exception being the laying of networks for the supply of natural gas.

Despite the positive dynamics of changes in the indicators of the provision of communal amenities to the rural housing stock, it is obvious how far the village is behind the city by this criterion. Only the gasification of the housing stock of the village corresponds to the city. This is due to the fact that the main work on gasification of settlements of the Chuvash Republic has been completed. There is water supply in 22 percent of rural houses, central heating in 82.3 percent, sewage in 15.7, hot water in 7.1 percent of houses.

Fig. 3: Commissioning of social facilities and public utilities in rural areas in the Chuvash Republic

It is also obvious how controversial the situation is in rural areas with the security of the population living there with social infrastructure facilities. The provision of rural residents with hospital and outpatient clinics has significantly decreased, while the number of beds and the number of visits per shift of outpatient clinics has increased, which means an increase in the remoteness of these objects of social infrastructure from people's places of residence and their concentration in larger settlements, most often in district centers. The number of educational institutions decreased. Most indicators have a negative trend.

Such trends are of great concern, as they indicate that the gap between the city and the village in relation to the development of social and engineering infrastructure is not narrowing, but widening. The current situation in rural Russia, in addition to implementing a coherent program of agrarian reforms, requires urgent measures.

As a result of insufficient investments, the volume of construction of social facilities and engineering infrastructure in rural areas decreased, the excess wear and tear of their fixed assets increased, accompanied by an intensive reduction in existing social facilities and life support systems.

When determining the need for objects of social infrastructure in rural areas, it should be borne in mind that the most important factor in the accessibility of social institutions to the population is the degree to which these objects are far from the places of population living. The determination of the need for social infrastructure facilities for the rural population should also be carried out taking into account specific conditions affecting the organization of social services for the population in certain areas, cities, regions, territories, republics (population density, road conditions, transport, climatic conditions).

In the Chuvash Republic, program planning methods are priority and are used to justify the development of economic and social sectors in the medium and long term.

The system of goals that ensure a stable increase in the quality of life of the population is presented in Fig. 4.

Fig. 4: The system of strategic goals to achieve European standards of living

Economic and social indicators of these goals are presented in table 4.

Table 4: The system of indicators for the implementation of the state program "Integrated development of rural territories of the Chuvash Republic"

Indicators	2019	2020	2021	2022	2023	2024	2025
Creating conditions to provide affordable and comfortable housing for the rural population							
The volume of input (purchase) of housing for citizens living in rural areas, sq. meters	6300,0	2300,0	846,0	2170,0	2200,0	2300,0	2300,0

The number of implemented socially significant projects for the	x	6	x	x	14	15	15

improvement of rural territories, units							
Number of implemented public infrastructure development projects based on local initiatives, units	620	620	620	620	620	620	620
The number of completed projects to equip engineering infrastructure and landscaping sites located in rural areas for compact housing, units	x	0,0	1,0	0,0	3,0	3,0	3,0

The catalyst in the social development of the village of the Chuvash Republic is the republican budget (Table 5).

Table 5: Directions and sources of financing the activities of the state program "Integrated development of rural territories of the Chuvash Republic", thousand rubles

Financing Areas	Total	Including by sources of financing			
		Federal budget	republican Budget	Local budgets	Extra-budgetary sources
Creating conditions to provide affordable and comfortable housing for the rural population	595822,1	224605	13733,3	238338,3	103211,5
Improving the living conditions of citizens in rural areas	343064,9	224605,0	13733,3	1515,1	15248,4
Creation and development of infrastructure in rural areas	3945474,4	1461619,7	1994726,6	246008	243120,1
Complex arrangement of settlements located in rural areas with objects of social and engineering infrastructure, as well as construction and reconstruction of roads	3814045,2	1370739,4	1993618,6	226287,5	223399,7
Implementation of measures for the improvement of rural areas	131429,2	90880,3	1108	19720,5	20828,5
Development of the labor market (human resources) in rural areas	2810,4	834,7	8,3	0	1967,4
Assistance to agricultural producers in providing qualified specialists	2810,4	834,7	8,3	0	1967,4
Total	4291349,7	1687059,4	2008468,2	247523,1	348299,0

The predominant funding from the republican budget as compared to the federal budget illustrates the uneven distribution of the burden on the corresponding budgets for financing the social sphere in rural areas: 1.19 rubles (2008468.2 / 1687059.4) from the republican budget were allocated for 1 ruble from the federal budget.

Since the republic has a reputation as a good borrower, Chuvashia is given a fairly high rating, combined borrowing schemes, issuing republican securities, and guaranteeing social projects to international organizations are actively used.

The establishment of clear and transparent rules in intergovernmental relations with municipalities, and the implementation of municipal finance reform programs also served to develop the social sphere in the countryside.

Extrabudgetary sources are attracted to the financing of investment program activities on the principle of social partnership, on a contractual basis by adopting legislative and other acts at the republican and local levels that ensure the attractiveness of investments by business entities in the development of the social sphere and engineering infrastructure of rural municipalities.

Personal funds of citizens are directed to individual housing construction, water supply, gasification and telephone installation of houses (apartments).

Conclusion

Having considered the implementation of targeted programs for rural social development at three levels of government - federal, republican and local, the following conclusions are suggested.

Because of lobbying in government bodies to support and protect the interests of some groups, regions, industries, enterprises when dividing one pie - the state budget, state (public property), the public law of some groups is infringed in favor of others. This is especially evident in the examples of the agro-industrial complex and the social sphere of the village.

The level of state support for agriculture in general and rural social development is very low. Budget expenditures for social development in rural areas during the years of reform are the subject of constant disagreement between the Government and deputies of the State Duma of the Russian Federation. In the Duma, the interests of the social sphere are not consolidated, which is why it is not possible to significantly increase the appropriations allocated for the development of the socio-cultural and engineering infrastructure of the village. The initial allocations proposed by the Government of the Russian Federation in the draft budget do not increase. Arguments in favor of a significant increase in allocations for social development of the village, as a rule, are not accepted.

In addition, in the process of disbursement of funds, something like sequestration occurs, aimed at a systematic reduction of costs. Thus, the total amount of federal budget expenditures on the social sphere is determined to a large extent during the political process, and not economic justification. A serious drawback of the budget process in the social sphere is the isolation of the annual budgeting process from the medium-term concepts of the strategic development of the agro-industrial complex. Although the leadership of the Chuvash Republic, in contrast to the Russian Federation, seeks to support the agro-industrial complex from the republican budget, however, due to the small size of the budget itself and the need to finance other areas of the region's activities, village financing as a whole remains insignificant.

The main reasons that hinder the implementation of program tasks include:
1. The allocation of funds from the federal budget to the full extent provided for by the program does not allow the commissioning of capacities and the incentive to attract funds from the constituent entities of the Russian Federation and extrabudgetary sources.

2. Untimely and incomplete fulfillment by the constituent entities of the Russian Federation of obligations to co-finance program activities for the social development of rural territories. There is sequestration by executive authorities of the constituent entities of the Russian Federation of the expenditures of regional budgets for the financial support of events.

3. The schemes of interaction between the constituent entities of the Russian Federation with respect to the choice of a state customer for the implementation of program activities and insufficient coordination of the agro-industrial complex management bodies in the constituent entities of the Russian Federation with the regional public health, education, culture, building complex, physical

education and sports, consumer cooperatives are not fully developed. That does not allow you to make operational decisions on the current management of the implementation of program tasks.

The Importance of Psychological Support In Companies In Poland Based On The Results of The Survey "New Trends In Human Resources Management In Large Companies"

Ewelina CHRAPEK

Czestochowa University of Technology, Czestochowa, Poland

ewelinachrapek@wp.pl

Abstract

The article presents selected results of the research as part of the project: "*New trends in human resources management in large companies*". The project assumed the identification of social and psychological factors supporting the development of personnel in organizations, identification of intangible assets of the organization and social capital and trust management processes in organizations.

Purpose: The study aimed to illustrate the need for monitoring the mental health of employees from the standpoint of the company representatives and to present the extent to which different forms of psychological support are available in companies.

Methods: *Sample***:** The survey involved 179 representatives of companies randomly selected from 500 largest companies in Poland. *Measures*: Quantitative methods of measurement were used: CAWI *Computer Assisted Web Interview*) and the CATI telephone survey (*Computer Assisted Telephone Interview*). *Procedure***:** The CATI or CAWI surveys were addressed to the representatives of companies with substantive knowledge in the field discussed in the study.
Findings: Of the respondents, 63.7% stated that psychological problems of employees should be monitored in relation to their effect on the functioning of the company, while 6.2% think that there is such a need for such monitoring, but it is the employee who should take responsibility for their problem. When asked about forms of psychological support used in their companies, 60.1% of answers indicated the lack of such support. Among the forms of support available in companies, the most (14.8%) of the choices concerned training oriented at specific skills or problems, while 12.8% concerned support for individual employees.
Practical implications: The results of the study show a clear discrepancy between the need to monitor psychological problems in employees and the actual psychological support in companies. Therefore, it is necessary not only to increase the entrepreneurs' awareness of the benefits of taking care of the mental health of employees for the company's interest, but also to encourage the implementation of such forms of support in practice. This should be achieved by systemic solutions aimed at increasing the availability of mental health programmes for employees.

Keywords: Companies, Mental Health, Psychological Support, Work, Workers

Introduction

According to a report of the World Health Organization (WHO), mental disorders will have been the second in the ranking of diseases that affect the world population by 2020 (WHO, 2001). This problem seems similarly serious in Poland. In a study conducted in accordance with WHO standards in the Polish population of people aged between 18 and 64 years ("Epidemiology of Psychiatric Disorders and Availability of Psychiatric Health Care - EZOP Poland"), as many as 23.4% of the respondents suffered from at least one mental disorder during their lives (out of the 18 categories of disorders according to the diagnostic criteria of the ICD-10 International Statistical Classification of Diseases

and Related Health Problems and DSM-IV Classification of Mental Disorders of the American Psychiatric Association) (Kiejna et al, 2015; Kalbarczyk, Murawiec, Kalbarczyk, 2016). Furthermore, according to the report from the Global Burden of Disease 2015 Study, which analyzed the causes of years lived with disability (YLDs) in the case of the Polish population, depression was in third place among the ten most important causes, whereas anxiety disorders were in eighth place (GBD 2015 Disease and Injury Incidence and Prevalence Collaborators, 2016). Given their prevalence, mental health problems in the working environment become particularly important and topical. For people who are employable, work is an important way of improving their well-being, but also that of families and societies (Waddell, Burton, 2006). Furthermore, for workers with mental health problems, maintaining or returning to employment can be an important part of the recovery process that influences self-esteem, confidence and social inclusion (Perkins, Farmer, Litchfield, 2009. These arguments emphasize the need to guarantee the necessary protection of workers' mental health not only outside the workplace but also in the working environment.

Research Background

Based on a survey conducted by the American Psychological Association (APA) among PhDs in the field of psychology, it can be concluded that more than 6% of psychologists are employed in private companies and government institutions (Zimbardo, Gerrig, 2016). Furthermore, according to the forecasts of the American Bureau of Labour Statistics, the employment of industrial-organizational psychologists will have increased by about 53% by 2022 (Richards, Terkanian, 2013). It is worth considering what this trend is related to. The current changes in the labor market, expressed in terms of increased competitiveness of companies or the increasing requirements of international corporations, very often impose a rigorous pace of work, excessive work standards or expectations of above-average employee commitment. Growing competition and demands in the workplace correlate with the demands and problems of private life. At the same time, in recent years, the long-term absence of employees (particularly stress-related) is increasing. (Henderson, Glozier, Elliott, 2005). An important problem is the economic consequences. In 2010, the estimated global cost of mental disorders was $2.5 trillion, of which $1.7 trillion (68%) were indirect costs (lost productivity from absenteeism and presenteeism) (Trautmann, Rehm, Wittchen, 2016). It is estimated that the annual cost of depression will have increased to $6.1 trillion by 2030. In 2012, the total costs of depression in Poland incurred by the Social Insurance Institution (ZUS) amounted to ca. PLN 320 million, of which the costs of sickness absenteeism caused by this problem amounted to ca. PLN 255 million, while the costs of disability benefits were PLN 37 million (Kalbarczyk, Murawiec, Kalbarczyk, 2016). These are probably some of the causes that generate the need to employ psychologists in the business sector, not only as trainers or recruiters but also as experts focused on the mental health of employees (Hauk, 2010). Increasingly, the work of a psychologist translates into the therapeutic work aimed at maintaining the well-being of the employee, minimizing and counteracting employment problems (e.g. workaholism, occupational stress, mobbing, burnout, etc.), and interventions in case of personal difficulties of the employee. Although the measurable benefits of providing psychological support to employees are unquestionable, it still seems to be a practice underestimated by entrepreneurs.

The article presents selected results of the research as part of the project: "*New trends in human resource management in large companies*" illustrating the needs for the monitoring of mental health of workers from the standpoint of representatives of large companies and the range of different forms of psychological support actually offered to workers.

Methods

The research was conducted as part of the research project "*New trends in human resources management in large companies*". The project aimed to identify social and psychological factors supporting the development of personnel in organizations, intangible assets of the organization and social capital and trust management processes in organizations.

Sample

The sampling frame was a database of the 500 largest companies in Poland classified based on the ranking of the *Rzeczpospolita* daily by revenue category for 2018. Random sampling was used. In the case of refusal of an company to participate in the project, another entity was sampled. The sampling yielded a representative group of 179 companies with the general population size of 500 entities and a confidence interval of 95%.

Measures

The research within the project was carried out with the use of quantitative research methods using mixed techniques: CAWI (*Computer Assisted Web Interview*) and the CATI telephone survey (*Computer Assisted Telephone Interview*). The combination of the two quantitative methods was used to increase the response rate.

Procedure

The survey with the representatives of companies was started by using the CATI method. Those who refused to participate in the survey, interrupted the survey, or declared another deadline, were given the option to complete the survey via a dedicated web platform (CAWI). The survey was addressed to employees with knowledge in the field discussed in the study. The survey was conducted in the first half of 2019.

Results

This research was based on selected results of the survey concerning the scale of monitoring of psychological problems of employees and the forms of psychological support used in companies. The results are presented in Tables 1 and 2, respectively.

Table 1. Monitoring of psychological problems of employees

Do you see a need to monitor the psychological problems of the employee (e.g. occupational burnout, emotional control disorders, other stress-related disorders)?	**n=179**	**%**
Yes, this is an important factor that affects productivity and the working atmosphere	114	**63.7**
No, it is outside the company's area of interest	31	**17.3**
Yes, but it is a personal employee's problem that he or she should take care of in his free time	11	**6.2**
I have no opinion	21	**11.7**
No answer	2	**1.1**

Of the 179 representatives of companies participating in the survey, the most (63.7%) claimed that the psychological problems of employees should be monitored in relation to their effect on the functioning of the company. A significant minority (6.2%) believes that it is necessary but it is the employee who should take responsibility for his or her problem. Furthermore, 17.3% of respondents believed that it is not necessary as this was not the company’s problem.

Table 2. Forms of psychological support offered to employees in companies

Which forms of psychological support does the company offer to employees? (choose all matching answers)	**number of choices**	**% of all choices**
Individual employee support	26	**12.8**
Support groups for employees	3	**1.5**
Training on communication, motivation, conflict solving, coping with stress, professional burnout, dealing with organizational pathologies (e.g. mobbing, discrimination, sexual harassment)	30	**14.8**
Workshops on developing diverse competences, coping with stress, professional burnout, dealing with organizational pathologies (e.g. anti-mobbing workshops)	14	**6.9**
Other	1	**0.5**
We do not offer such support to employees	122	**60.1**
I have no opinion	7	**3.4**

When asked about the forms of psychological support in a given company, the respondents most often (60.1%) answered that psychological support for employees is not offered in their company. On the other hand, the largest number of indications of the representatives of companies (14.8%) with regard to the forms of support offered concerned training focused on specific skills or problems. The second form of psychological support in the order of occurrence was individual support for an employee (12.8%), while respondents indicated support groups for employees relatively rarely (1.5%).

Discussion

The article presents selected results of research as part of the project *"New trends in human resources management in large companies"* concerning monitoring of psychological problems of employees and forms of psychological support used in companies. The results show a clear gap between the need to monitor employees' mental health and how effective the practice of supporting employees in companies is. More than 63% of company representatives admit that the psychological problems of employees need to be controlled in the workplace because of their relation to work efficiency, but when asked about the forms of support offered, as many as 60.1% of the choices concerned the option *"We do not offer such support to employees"*. A similar relationship was presented in an UK study presented by Weinberg et al. (2019), where awareness and implementation of *National Institute for Clinical Excellence* (NICE) guidance on workplace psychological health was analyzed. Of the 163 companies surveyed (public, private and non-profit sectors), 37% were familiar with the guidelines, while only 12% implemented them in practice. Furthermore, according to a survey carried out by the Confederation of British Industries (CBI) with over 800 companies, as much as 98% of respondents said they thought the mental health of employees should be a company concern and should be part of company policy. However, less than one in ten of the companies sampled had an official policy (Sinclair, O'Regan, 2007).

So why is there such a discrepancy? There seem to be at least a few explanatory factors. This research shows that in the perception of the representatives of companies, there is an awareness of the relationship between an employee's mental state and his or her functioning at work and thus the importance of this relationship for the overall functioning of the company. Similar studies by Kaszyński and Cechnicki (2011) found that employers notice difficulties resulting from mental problems. According to 56.4% of the employers surveyed, mental illness limits an employee's ability to perform paid work. However, the conviction about the strength of this effect may vary. Perhaps the representatives of companies assess this effect not as an essential determinant of the company's success, but more as a factor which may slightly increase or decrease an employee's efficiency at work. Meanwhile, many empirical data indicate that mental health problems significantly worsen the functioning of employees at work. As indicated by Gilmour and Patten (2007), as many as 79% of the

employees with symptoms of depression admitted that the depression affected their ability to work, with ca. 19% considering this effect to be significant. In another study, 30% of employees with anxiety disorders confirmed a decrease in productivity over the previous 4 weeks compared to 0.5% observed in employees without such disorders (Harder, Wagner, Rash, 2014). It is worth noting that emotional disorders and overall mental health are strongly associated with so-called presenteeism, which significantly reduces productivity at work (Burton et al., 2008; Collins et al., 2005). Furthermore, the problem may be particularly pronounced when mental health disorders are of a prolonged nature. In a study of a group of employees by Lerner et al. (2000), 22-49% of employees with chronic health problems showed difficulties in meeting physical requirements at work, and 27-58% failed to meet psychosocial requirements. Another explanation may be related to the perception of the costs of psychological support at the workplace. It is likely that investment in various forms of psychological support seems not as profitable for entrepreneurs as an investment in other assets essential for the company's direct profit. Investment in broadly understood psychological support for employees may not be profitable for the company at first, but in the long run, it may prove very profitable. The authors of the British report published by the Department of Health in London presented estimates indicating possible savings for the company resulting from the implementation of various forms of mental health support for the employee (McDaid et al., 2011). In the case of an company with 500 employees, where the support for mental well-being is provided to all employees, it is estimated that an initial investment of £40,000 will result in a net return of £347,722 in savings mainly due to a reduction in presenteeism and sickness absence. In explaining the discrepancy obtained in the present study, reference can also be made to the general reluctance to finance mental health initiatives. Interesting research in the German population was conducted by Schomerusa et al. (2006). The respondents stated that if they were to choose the health care sector whose budget should be reduced, they would choose the care for the mentally ill. Polish health care reports highlight the underfunding of psychiatric services (Łozy, Gryglewicz, 2015; Moskalewicz, Kiejna, Wojtyniak, 2012). Other countries around the world have also struggled with the problem of insufficient investment in psychiatric care (Ormel et al., 2008). Perhaps this general social trend, in which human resources related to mental health are not given as much attention as other resources (e.g. physical health), also translates to some extent into entrepreneurial attitudes.

The results of the survey show that in some companies, however, some forms of psychological support are emerging, i.e. training and workshops aimed at different types of employee skills, and individual support and support groups for employees. To the author's knowledge, no studies have presented statistical data on the prevalence of various forms of mental health support in companies. However, it is possible to compare the results obtained in this study to other test results with slightly different methodological properties. The result obtained in terms of individual employee support (12.8%) can be compared to the results of the implementation of employee assistance programs (EAP) among American worksites (Hartwell et al., 1996). The aim of the EAPs is to identify 'troubled employees' (e.g. those at risk of alcohol problems), motivating them to resolve their troubles, and providing access to counseling or treatment for those employees who need these services. The results of this survey indicated that 33% of the more than 32,000 private, non-agricultural worksites in the USA with more than 50 employees offered EAP services to their employees. Importantly, the use of the EAPs was linked to the size of the workite. Among the companies employing more than 1,000 employees, this ratio was approximately 76%. This means that psychological support systems for employees may be more common in larger companies. An interesting point of reference for the problem of mental health promotion at the workplace may be the opinion of workers themselves. The National Employee Mental Wellbeing Survey conducted in the UK provided this perspective. This report is based on the key findings from a YouGov panel survey of more than 4,000 full and part-time employees (Mental Health at Work 2019 Report, 2019). When asked "*Are any of the following available where you work or through your employer*?" among the various categories of support, the category of counseling or psychotherapy services covered 13% of employee indications, while workload or time management training and training on common mental health conditions yielded 8% and 6% indications, respectively. Furthermore, 7% of the answers concerned the categories: peer or colleague led support group or network. In this study, the highest number (25%) of employee indications concerned the category of employee Assistance Programme in the form of a confidential helpline.

In this study, most of the choices made by entrepreneurs (14.8%) concerned the organization of training as a form of psychological support for an employee, while slightly fewer choices (6.9%) concerned the workshop form. Although the differences between these forms of psychological support in terms of the objectives or areas of the problems to be addressed seem insignificant, some problems may be generated by the lack of a clear definition of the terms discussed here. It is, therefore, necessary to take into account a certain likelihood of not fully adequate distinctions within the two categories. It is assumed that training is a process aimed at acquiring and developing knowledge and skills related to the performance of specific tasks at work, carried out through formal, structural and guided measures (Rakowska, Sitek-Lutko 2000). Training can also be understood as a series of lectures on a given subject organized to extend someone's knowledge of a given field (Doroszewski, 1958-1969). Furthermore, the workshops, which can be a part of the training, mean a form of group activities, where participants actively, e.g. through problem-solving in a group or designing proposals for solutions, acquire practical skills (Kowolik, 2006). It is worth noting that the approach to the role of training in the company has changed over the years (Łaguna, 2010). It is increasingly seen as a potential for long-term business benefits. However, in some companies, training can still be viewed as a necessary expense and fit into a wider corporate policy, conducted according to mandatory official arrangements (e.g. anti-mobbing training). They are implemented as a consequence of formal regulations, regardless of the individual assessment of their suitability form the standpoint of the representative of a given company. It is also possible that the form of training (or workshop) is the most preferred form of support in companies, as it can simultaneously cover a larger group of employees, and its subject matter is most often very clearly and directly related to the effective functioning as an employee (e.g. coping with professional stress, conflicts in the workplace, preventing occupational burnout, etc.). These features may argue for approaching training as the most optimal and cost-effective form. This is in contrast to the individual support, as it concerns selected employees and can take into account a very wide range of individual problems and not just the focus on those directly related to work. Therefore, these can be problems such as coping with the stress of crisis events, depression, or employee addiction. Similar forms of group support are those that can play a therapeutic role for employees with similar difficulties, or for workers who found themselves in a similar situation (e.g. they witnessed a fatal accident of a colleague). Support groups received the least number of choices in the group of the entrepreneurs surveyed. Perhaps this results from the above-mentioned causes (individual problems of only a certain group of employees, lack of a clear link between the nature of the problems and the perspective of the professional role, costs incurred by the company, resistance to dealing with mental health problems), which make up the assessment of this form of support as not being in a clear, strong, direct relationship with the interests and responsibilities of the companies.

Several limitations of this study should also be mentioned. The survey was of a questionnaire character and was therefore based on subjective assessments of the representatives of individual companies. This involves the likelihood that those who completed the questionnaire had incomplete knowledge of the situation in the company or misinterpreted the questions. The representatives of companies were not always top-level managers, whose knowledge, especially when asked about the need to monitor employees' mental health problems, can be presumed to be the most substantial. The research was conducted only in the group of the largest companies in Poland, and therefore its results should not be generalized to the population of all companies. Further research on the prevalence of psychological support systems for employees should also take into account the perspective of small and medium-sized enterprises. Other variables should also be considered, such as the company's business profile, the nature of the work performed by the employees or the number of employees.

Conclusion

The scale of the prevalence of mental health problems in Poland and worldwide is reaching worrying proportions. Consequently, the problem is becoming increasingly clear in all areas of human functioning. An area of particular importance is the working environment and professional activity, which can play a health-promoting role or become additional burdens on mental health. As a result, there is a growing demand for psychologists working in the business not only as HR staff, but also as mental health professionals.

The article presents selected results of a survey conducted as part of the project "New trends in human resources management in large companies". The demand for monitoring of mental health problems of employees and the level of support offered in the group of representatives of 179 largest companies in Poland were analyzed. The results revealed that more than 60% of the respondents saw the need to monitor the mental health status of employees due to its possible effect on productivity and atmosphere in the company. However, in relation to the question about the forms of support offered in the company, most (60.1%) of the respondents' choices concerned the category "We do not offer such support to employees". This discrepancy may be due to various factors. It is likely that in some companies, the effect of mental health problems on the employee's work efficiency and further on the productivity in the entire company is underestimated. This may also be associated with a general social reluctance to deal with mental health problems. Furthermore, the implementation of psychological support systems requires financial resources which are not necessarily considered as a profitable investment from the perspective of the company. Nevertheless, some of the companies surveyed offer their employees psychological support in various forms. Of the above-mentioned forms of support, the largest number of choices (14.8%) concerned the category of support in the form of training. This form most often covers issues directly supporting the functioning of an employee in his or her professional roles, e.g. training in coping with professional stress, which may constitute its significant advantage over other forms of support. Training can also cover a large group of employees at a time. A similar approach may be applied to workshops (choice rate of 6.9%), which may also be part of the training, and a fair distinction between the two categories in the study could cause some difficulties. The individual support of the employee was characterized by slightly fewer indications (12.8%). It is likely that as a form that typically concerns individual problems, individual support is not perceived as lucrative for the company as is the case with training. It is also likely that the nature of these problems does not oblige the company to take particular responsibility for them, leaving them to the employee. The fewest indications concerned support groups for employees (1.5%), which may be related to the aforementioned arguments, where the nature of the problems solved with this form of support seems to be the most important.

The results of the study form an important basis for practical implications. It is important to raise awareness of the importance of mental health systems at the workplace among entrepreneurship. This concerns the importance, which is not only related to the interests of the employees but also the interests of the company. Entrepreneurs should be convinced that an investment in the mental well-being of employees is a profitable investment in the long term and that the relationship of employee well-being with productivity and the company's atmosphere is strong. Furthermore, it is important that this conviction should also be followed up by concrete actions related to the support implemented. Systemic support offered by specific standardized psychological support programs for employees and through increasing the availability of such programs (e.g. advertising, legal regulations, funding assistance) may be irreplaceable. There is still a lack of such solutions in Poland, and it seems that they could effectively encourage companies to take on responsibility for the psychological well-being of employees.

State Defense Readiness as The Support for The National Security System

PhD Sylwia WOJNAROWSKA-SZPUCHA

Faculty of Security, Logistics and Management - Military University of Technology in Warsaw, Poland.
sylwia.wojnarowska-szpucha@wat.edu.pl

Abstract

The states of defense readiness of the state are an extremely important issue related to maintaining security in the state. Individual entities, in order to be properly prepared to respond to various types of threats to national security, are obliged under the state's permanent defense readiness to perform specific tasks. This is to properly prepare them for efficient functioning in changed crisis and war conditions. The appropriate level and implementation of the tasks of permanent defense readiness of the state is very important and will have an impact on achieving higher states of defense readiness of the states, i.e. during a crisis and a war.
Due to the variety of contemporary threats related to their unpredictability, volatility and surprise in the state's defense readiness, it is extremely important to maintain the ability to quickly make decisions and respond to growing threats, which is why it is so important to properly prepare the individual entities responsible for state security.

Keywords: State Defense Readiness, Constant State Defense Readiness, Defense Readiness During The Crisis, Defense Readiness During The War, State Security

Introduction

The state's defense readiness depends on many different external and internal factors. The external ones include the threat to national security resulting from the development of the geopolitical situation in the region and in the world. Keeping the defense potential of the state in constant readiness is extremely expensive, therefore in Poland a defense readiness system has been organized, which will be launched at the time of changes taking place in the event of a threat to national security.

Analysing the state's defense readiness as a research problem, it should be expressed in the form of the following question. *How and through what actions does the state prepare its resources to counteract threats to its security?* The author presents an attempt to solve this problem in the following study, by specifying the tasks and undertakings regarding individual states of defense readiness of the state.

In the literature on the subject of research, the state's defense readiness is defined (Pawłowski, 2009) "as a state of stability of the elements of the state defense system to maintain national security and to act effectively in emergencies and the ability to oppose any crisis and war threats". The appropriate level and implementation of the tasks of permanent defense readiness of the state is very important and will have an impact on achieving higher states of defense readiness of the state (time of crisis and time of war). The ability to quickly make decisions, act within the framework of various threats to national security, which today are characterized by volatility, unpredictability and surprise, is crucial in ensuring national security.

The purpose of the state's defense readiness is to maintain security in the state, its trouble-free functioning, and in the event of a crisis, to respond appropriately to this situation to prevent its escalation and large-scale conflict.

This goal is achieved by performing:

- crisis management projects and procedures (Journal of Laws of 2020, item 148, 284, 374);
- undertakings included in the Defense Response Plan (DRP), which is the basic document of political and strategic defense planning, prepared in order to counteract potential threats to national security of a political and military nature;
- implementation of tasks under Host Nation Support (HNS) contracts, aimed at securing the admission, stay and movement of allied forces through the territory of our country;
- tasks related to maintaining and creating strategic reserves (Journal of Laws of 2020, item 374);
- tasks related to the mobilization of the economy and armed forces;
- political and diplomatic activities aimed at peaceful resolution of conflicts and preventing crises.

The state's defense readiness concerns all entities forming the state's defense system (public administration, business entities, services, guards, inspections), it has a nationwide scope and significance for the existence of the entire nation and its security, its task is to counteract threats and, in the event of their occurrence, to appropriately react to them.

Professor Jan Wojnarowski (2010) emphasizes in his book that "the state's defense readiness is a kind of a system that consists of individual elements, which include:

- readiness of the military subsystem, i.e. combat readiness and mobilization of the armed forces;
- readiness of the state defense management subsystem – defense and security management positions;
- readiness of the non-military subsystem".

State Defense Readiness

Currently, pursuant to the Regulation of the Council of Ministers of September 21, 2004 on state defense readiness (Journal of Laws of 2004, no. 219, item 2218), the following three states of state defense readiness apply in Poland:

- state of constant state defense readiness;
- state of defense readiness of the country during the crisis;
- state of defense readiness during the war.

Increasing the state's defense readiness in situations of external security threat is accomplished by introducing higher states of defense readiness of the aforementioned Regulation of the Council of Ministers.

Constant defense readiness of the state is a state in which there are no significant threats to the external security of the state, but at the same time forces and means are ready to perform defense tasks. The essence of this state is to keep the defense system ready for an efficient transition to a higher state of defense readiness in the event of a threat. The tasks that state bodies and institutions perform as part of permanent state defense readiness are related to planning, organizing, training and controlling. As part of constant defense readiness, conditions for the implementation of defense tasks are created, force and rescue measures are kept to eliminate the effects of accidents, catastrophes and natural and ecological disasters, to clean the area of hazardous and potentially explosive objects, constant monitoring of potential threats is carried out.

The main undertakings of constant defense readiness of the state include tasks related to:

- monitoring and assessing potential threats;
- operational planning and programming of the state's defense and protection tasks;
- organization of defense preparations and their provision with material and financial human resources;

- maintaining the armed forces in constant combat and mobilization readiness to enlarge them during the war;
- maintaining the readiness of the remaining forces and resources forming the defense system of the state in readiness to develop in the event of a crisis or war;
- conducting trainings, schoolings and inspections;
- introducing permanent duty hours in public administration bodies (Journal of Laws of 2004, no. 219, item 2217 and 2218) in order to ensure adequate, efficient and rapid response of the state to threats to its security and alert levels (Journals of Laws of 2016, item 1101), introduced as part of permanent defense readiness of the state.

Constant defense readiness of the state aims to ensure the safe development of the state, the possibility of rapid and smooth change of state, depending on the occurrence, scale and nature of the threat.

Defense readiness of the state during the crisis will be introduced (Journal of Laws of 2004, no. 219, item 2217 and 2218) in the event of an external threat to the security of the state requiring the activation of selected elements of the defense system or implementation of tasks set for this state.

The implementation of the tasks of defense readiness during the crisis is associated with the preparation of forces and means to counteract external threats to national security and remove the effects of their occurrence.

These tasks are carried out by developing selected elements of the state defense system and consists of:

- implementation of tasks resulting from the introduction of a state of emergency;
- securing the mobilization and operational development of the armed forces;
- preparation to develop management positions;
- review and update operational plans;
- intensification of civil-military cooperation;
- preparation for the mobilization of state defense resources;
- mobilizing strategic reserves (Journal of Laws of 2020, item 374);
- preparation of organizational units for militarization (Journal of Laws of 2009, no. 210 item 1612), (Wojnarowska-Szpucha, 2019);
- adopting and securing the regrouping of allied reinforcement forces;
- protection of critical infrastructure, facilities of particular importance to security and defense, of the population.

The state of defense readiness of the state during the war is introduced in order to repel a direct military attack on the territory of the Republic of Poland or when international agreements show a commitment to joint defense against aggression.

As part of introducing the state of defense readiness of the state during the war, universal mobilization is carried out and martial law is introduced (Wiśniewski and Szyłkowska 2017), (Journal of Laws of 2017, item 1932), and the state's defense system is fully developed to repel military aggression directed to the territory of the Republic of Poland or to another allied state.

In the state of defense readiness during the war, the state defense system is fully developed, the following tasks are carried out:

- resulting from the introduction of martial law;
- securing the needs of the armed and allied reinforcement forces;
- launching the main and spare positions for managing national defense;
- launching operational plans at all levels of administration and entrepreneurs;
- launching tasks included in the Mobilization of Economy Program (PMG – a planning document setting out tasks related to the preparation of the national economy for increased defense services during a period of threat to national security and during war) (Polish Armed Forces, 2020);

- using strategic reserves for the defense of the state;
- militarization of organizational units of public administration and selected enterprises of the national economy;
- minimizing losses and damage;
- protection, evacuation of people;
- fighting against crime.

Summary

The state's defense readiness depends on the development of the political and military situation of the state, the emergence and escalation of the crisis, and on the allied obligations of the state. In each state, they are defined by the ordinance of the Council of Ministers of September 21, 2004 on the state's defense readiness to carry out tasks, depending on the emerging crisis conditions. Planning and implementation of defense tasks related to increasing the state's defense readiness are coordinated by (Journal of Laws of 2004, no. 16, item 152) ministers with respect to tasks performed in government administration departments, as well as by heads of subordinate and supervised organizational units and voivodes in relation to tasks performed in the voivodeship by the managers of subordinate and supervised organizational units, entrepreneurs, for which they are founding bodies, local government bodies, entrepreneurs who are not organizational units subordinate to or supervised by ministers, social organization authorities.

Maintaining the state's defense readiness depends on the state defense system prepared for launch, the possibilities and conditions for the mobilization of armed forces that constitute the basic link in the state's defense potential, and on the Economy Mobilization Program prepared for launching, as well as on a number of other tasks included in the defense system of the state (concerns the militarization of organizational units, protection of particularly important facilities, medical and transport security, and complaints from citizens of military service during the war). However, in order to effectively counteract carious types of non-military threats, the Polish Armed Forces must cooperate with other entities of the national security system.

Higher states of defense readiness of the state are introduced in order to launch appropriate undertakings, depending on the scale and nature of threats, aimed at preventing the emergence of crisis situations and, consequently, their development. States of defense readiness are implemented sequentially or selectively, depending on the development of the political and military situation.

In the case of introducing higher states of defense readiness (state of defense readiness during the crisis and state of defense readiness during the war), tasks included in the "Defense Response Plan of the Republic of Poland" will be implemented, which is developed on the basis of the Regulation of the Council of Ministers of June 15, 2004 on conditions and the mode of planning and financing tasks performed as part of the state's defense preparations by government administration and local government bodies, this is the basic document of political and strategic defense planning in the Republic of Poland.

The above study presents tasks that are/will be implemented by all entities (Świerszcz, 2016), whose duty is to care for broadly understood national security. The sentences implemented in the state of constant defense readiness of the state are extremely important, because by properly preparing for various threat scenarios in their free time, the state's ability to effectively counteract them or minimize their effects is increased.

Sociology of Security as an Opportunity for Social Security

Adam KOLODZIEJCZYK and Jerzy ZALEWSKI

Military University of Technology in Warsaw, Warsaw, Poland
adam.kolodziejczyk@wat.edu.pl
jerzy.zalewski@wat.edu.pl

Abstract

The article refers to that idea of the fathers of sociology, postulating the need to develop a sociological reflection on human security. This new security research paradigm known as "sociology of security" has appeared recently and needs to be developed for many theoretical and practical reasons. The authors of this article refer to previous publications and present new thoughts on two problems: 1) the presence of sociology of security in scientific discourse; 2) and an opportunity for developing of social security. According to the authors opinion sociology of social security is very important direction of the research but, as a science, still needs theoretical justifications.

Keywords: security, human security, threats, sociology of social security

Introduction

Sociology, in the intention of its creators (August Comte, Herbert Spencer, Emil Durkheim) was to be a panacea for the chaos or disorder observed in social life. The establishment of sociology as a science was to serve the purpose of creating social order. During the period of about two centuries, the area of research interest in sociology increased immeasurably. The author of this article has long referred to that idea of the fathers of sociology and postulated to separate, from the extensive and dispersed in various specific fields of sociology and other social sciences, a sociological reflection on **human** security or more precisely on the security of humans as social beings. In the opinion of the author of this article, shared by many experts on security issues, such a new subdiscipline of sociology may be a subdiscipline called ***sociology* of security** (K. Clements, 1990, Z. Zagórski, 1999, A. Kołodziejczyk, 2001, 2007, 2017, L. Stampnitzky, 2013).

Presence *Sociology of Security* in Scientific Discourse

Analysis of the literature on the subject has made it possible to formulate the thesis that three approaches undoubtedly dominate in research on security: philosophical approach, political science approach and recently, an approach presented especially in security sciences: the interdisciplinary and transdisciplinary approach. This analysis also makes us aware of the fact that there is no clearly defined sociological cognitive perspective. Some elements of the sociological theoretical reflection on security are already present in Polish scientific literature, however, they are quite few and limited to some selected, generally subjective or objective aspect of security. A much broader reflection on security, with regard to sociological perspective, is practiced by Anglo-Saxon authors in the field called "security studies".

A review of literature and the author's many years of personal participation in international security research allows the following initial theses to be formulated. First, in security research should more attention should be paid to the sociological approach, because in its nature security is a social phenomenon, and more specifically a socio-cultural phenomenon (A. Kołodziejczyk, 2007). Secondly, the current practice of research on broadly understood security should be expanded and ordered to include various sociological dimensions (levels/ entities/ areas/ contexts) of collective life security. Already in the 1990's, such targeted research appeared, which may include sociology of dispositional

groups (J. Maciejewski, 2012] and since recently the anthropology of security (S. Jarmoszko, 2015) related to sociology.

And finally, and thirdly, and in connection with the above, a new paradigm should be developed for practicing the sociological theoretical and methodological reflection on security within the new sociological discipline called "sociology of security" (A. Baranowska, 2016). It is not only about a certain ordering and classification effort in the area of the current reflection on collective security, but also development of coherent, multi-year inter-national research programs empirically oriented but based on the foundation of sociological theory modeled on the inter-national German-Polish-Czech research "Security, Nation and Partnership" (Report SOWI, 1998).

It should be noted that the introduction of a new sociological subdiscipline does not automatically mean discovery of a new field of phenomena, entities or regularities, nor the implementation of a new science methodology or previously unknown research methods into research of security phenomenon. It is, above all, a rational application based on sociological imagination of the existing theoretical and methodological output of social sciences, in particular of sociology for study of security and its absence.

It is worth noting that although the issues of security and threats has accompanied human kind since the dawn of its history, it is present in scientific theoretical reflection since recently (J. Świniarski, 1998). Only after the fall of communism can one speak about a separate philosophical reflection on security and about the introduction of a "security philosophy" into the language of science (R. Rosa, 1995, J. Świniarski, 1997). While strictly sociological studies and research on collective security have an even shorter history. The name "sociology of security" so far has been used incidentally and without a broader justification (K. Clements, 1990). In Poland, this name was used for the first time by Zdzisław Zagórski in 1998 (Z. Zagórski, 1998) and repeated in 1999 as the title of a paper delivered at a conference on sociological problems of national security (Z. Zagórski, 1999). During the 11th National Sociological Congress in Rzeszów - Tyczyn, in September 2000, the concept of "sociology of security" appeared in the title of the paper: “Od socjologii wojska do socjologii bezpieczeństwa narodowego? (From sociology of the army to sociology of national security?)” as a postulate to practice sociology of the army within the framework of sociology of national security (A. Kołodziejczyk, 2001).

Then, in the late 90's of the 20th century, called a decade of the dividend on peace, an analysis of security issues led me to the conclusion that the current demand for sociology of war and of the army gives way to the need for general and non-military reflection on security, including sociology of national security and a more general sociology of security of collective life. From the discussions held during the sessions devoted to sociological issues of security, one could get the impression that this idea and its justification met with a favorable reception among sociologists dealing with these issues. This was also reflected in the papers submitted to me as the organizer of the session, devoted to theoretical problems of national security and the problems of studying it using empirical methods. A clearly articulated postulate to establish a new field of sociology can be found in the papers of Janusz Świniarski (2001) and Marian Cieślarczyk (2001) submitted for publication.

Many years have passed since then and security, although it is already the subject of research in numerous scientific disciplines such as "security science" (M. Lutostański, 2015; E. Nowak, M. Nowak, 2015) or securitology (L.F. Korzeniowski, 2012). Despite these and many other valuable publications deepening security issues, it is still being discussed in the periphery of sociology. This is despite the widespread awareness that security is one of the most important needs of social entities: individuals, groups, nations and wider (international) communities, organizations, structures and systems. What's more, interest in this subject is increasing from other disciplines of science and its importance in the practice of social life is growing. When it comes to interest in this problem on the side of sociology-related sciences, traditionally the most attention to security is paid by representatives of political science, philosophy, psychology, law, ecology and history. Interdisciplinary security studies/research ("security studies") are already so far developed and complicated that in this case the problem of their systematization remains open, also in terms of the strictly sociological aspects of their content.

The postulate to separate sociology of security from the conglomerate of security studies is a manifestation of a more general trend in modern science called specialization. In order to say something more about the emancipation of sociology of security, undoubtedly, the previously suggested review of the existing scientific reflection on this subject should be made. It is not about a mere re-evaluation or questioning of the existing research directions, but about extracting, from the multitude of interpretations, those that capture security in a sociological or socio-cultural perspective.

A separate issue, undoubtedly, are the various specific cognitive inspirations derived from security-oriented research conducted in Poland since the early 1990's of the twentieth century at the National Defense University, especially interdisciplinary research, and study work on the issue of education for security and security research methodology (R. Stępień, ed, 1994; P. Sienkiewicz, H. Świeboda, 2012a, 2012b, 2013). Despite these achievements described and not described here, in my opinion these works have not resulted in works synthesizing the research achievements in this field yet, and the multitude of research teams, various competences of research participants and various research approaches have generated a phenomenon of secondary disorder, which is common in modern science.

In our opinion, from the point of view of contribution to scientific achievements, the highest methodological and theoretical level have works in the field of "security philosophy", especially those aimed at determining of the nature of security and personal and structural security, as well as works from the borderline of psychology and sociology focused on psychosocial risks of national security and concerning a certain category of groups working for social security called dispositional groups ("dispositional groups") or, in a narrower sense, "uniform groups" ("uniform groups"). While, a more pragmatic and strictly military point of view is revealed in a number of valuable studies on the "security system" (S. Koziej, 2006) and its elements in which the security system is understood in a classical way.

From the mid-90s of the twentieth century, there has been a dynamic development of sociological studies on security focused on the so-called dispositional groups at the University of Wroclaw. A significant advantage of the scientific and research activity of the Wrocław environment are systematically organized (since 1997) conferences devoted to broadly understood security issues and special issues of the scientific journal "Forum Socjologiczne: (*"Sociological Forum")* titled *Specjalne Zeszyty (Special Notebooks).* An important source of inspiration in determining the status of sociology of security for me were the reflections of Zdzisław Zagórski on the paradigm of contemporary sociology and studies of Jan Maciejewski on dispositional groups. They made it possible to put forward and verify many theses regarding the relationship "security - sociology", which resulted in my conviction that the most promising paradigm of modern sociology is "sociology of security". (A. Kolodziejczyk, 2001, 2007, 2017).

The reflection on security mentioned above and the advancement of the institutionalization of sociology of security are not sufficient, according to the author of this article. In particular, further constant improvement of the methodological systematization of research areas, development of conceptual apparatus, theories, methods and techniques of studies and, above all, systematic, programmatic study of this attribute of human existence is necessary due to its social significance, dynamics of civilization, social and cultural changes. The implementation of the sociological perspective for security studies seems to be very interesting and promising also for practical reasons. Namely, such studies can contribute to a better diagnosis of many problems, better penetration into their nature, more accurate determination of the *metaphors* of security indicating to us alone the answer to the question "what do we live by" (G. Lakof, M. Johnson, 1980) and, thus, to constructing of concepts, educational programs, scenarios and strategies as well as organizational structures and activities for the benefit of social order and improvement of the quality of collective and individual life that are more adequate to the threats, opportunities, risks and challenges.

Everything that I have presented above increases the significance and even the need for permanent study of human security and its "nurturing", like health, adequately to the changing social, historical, cultural and civilization-and-technical circumstances. It can also be said without a risk of exaggeration that security, like health, must be thought of in advance and taken care of in advance, guided by the

sociological imagination suggested *explicitly* by another outstanding thinker Charles W. Mills (P. Sztompka, M. Kucia, 2006) Because what ends the lack of reflectiveness and imagination on the part of the international community is shown by the events related to the war in the Middle East, Afghanistan, Iraq and Syria, as well as the situation in North Africa and in the East of Ukraine. Recently, the consequences of ill-considered actions concerning refugees and economic immigrants from Syria, Iraq, Eritrea and other countries in crisis or fall (like Yemen) show the importance of an accurate and reliable recognition, monitoring and response to the emerging and developing threats to the security of states and nations.

The Subject of The Sociology of Security

Attempts to define the concept of security, and therefore the content corresponding to this concept, are taken from various positions. Therefore, we can talk about the large number and variety of approaches in defining it (J. Stańczyk, 2017) To prevent chaos from creeping in here, some general, logical criteria should be adopted for (re)constructing of the content of the definition of security. The proposal of K. Ajdukiewicz postulating the use of pragmatic logic principles seems to be useful in this regard. From this point of view, there are three options for organizing the content of any concepts (K. Ajdukiewicz, 1975, pp. 50-51) that can be related to the content of the concept of *security*.

First of all, one can reconstruct the content of the concept according to a fixed, finite set of its designations, i.e. by listing the set of all features associated with the name "security". The content understood in this way is deemed to be the cited *full and comprehensive content* of this concept of *security*. In the case of this phenomenon, this approach is unreliable, because the content describing the term of security is sometimes very extensive and beyond the scope of presentation in a scientific article or even a book. Therefore, when reconstructing the content of this concept, some simplifications are made, omitting many less important features and emphasizing only the set of features that is considered significant - *characteristic* for its designations (S. Koziej, 2006, p. 6). As a result, *the characteristic content* for the term of security determines the scope of its name.

However, even here, a reservation should be made that the set of characteristic features for the name of security often turns out to be extensive and unnecessary from the point of view of the problem being analyzed, especially when a particular type of security is discussed, such as political, economic, community, social, cultural or military security. Therefore, from the available set of characteristic features only those that are necessary and sufficient for the determination of the scope of the defined concept are selected. In addition, based on Ajdukiewicz's suggestion, one can define the concept of security by grasping such a set of features that are necessary and sufficient for the determination of the scope of the name of security, and thus constitutes its *constitutive content,* that is, a certain minimum definition necessary to determine it.

The approaches mentioned above can be very useful because they make you aware of different ways of constructing the concept of security, especially when taken from different theoretical, methodological and practical positions. Such logic in constructing of the content of the definition of security is also useful in the secondary analysis or reconstruction of the content of various theoretical concepts (and doctrines) of this socio-cultural phenomenon. Thanks to this approach, it is possible to distinguish, within each terminological proposal of a definition of security, its comprehensive, characteristic and constitutive content. Awareness of these matters can be important for the organization and rationalization of the debates on the scope of a conceptual category of *security* (J. Stańczyk. 2018, pp. 17-84).

The problems mentioned in the beginning, related to the definition and understanding of the meaning of the concept of security prompt to review the definitions of security contained in the literature, to reconstruct their content, to take into account a new, socio-cultural look into its essence and sense, and therefore to adopt the approach appropriate for sociology and to adopt such a view of security, in which it is treated as a peculiar socio-cultural phenomenon. As part of the suggested review of definitions of the term security, one can use the following logic: the review should begin with definitions of generalized security found in colloquial language and included in dictionary studies, belles-lettres and

social philosophy since the 1990's of the twentieth century within the frameworks of philosophy of security, securitology and other social sciences, especially political science (J. Stańczyk, 2018, pp. 90-180, J. Zalewski, 2015a).

Etymologically speaking, the term security comes from the Latin "sine cura" or "securitas", which meant "no custody" (Słownik wyrazów obcych, 1980, p. 673). Such archaic meaning of the term security is very general and focused on its objective and practical dimension. This approach to the term security, however, has some current value, because it draws attention to its colloquial and collective sense, in which, according to John L. Austin, "a common set of words embodies all distinctions that people found worth carrying out, and relationships that during lifetimes of many generations people recognized as worthy of meaning" (J.L. Austin, 1993, p. 243). Starting from the review of the colloquial (dictionary, literature) understanding of security issues, one can determine the first components of the general problem field of security, treated here as a socio-cultural phenomenon associated with various forms of human thinking and activity.

Today, even in general dictionary terms security is already presented as a social phenomenon, i.e. a characteristic specific to social relations, in which one of the parties "does not threaten anything" and others "does not feel threatened". Security is also gradable. It is said that someone is "safe", "safer" or "not endangered." (Słownik poprawnej polszczyzny, 1980, p. 40). Yet another general property of security as such is provided by D. Lerner in Dictionary of the Social Science, according to which "In the most literal sense, security is actually identical to the term <safety> and means no physical threat <danger> or protection against it" (A Dictionary of the Social Sciences, 1964, p. 629). In this case, the sense of the general term of security has dual nature, because on one hand it is the antithesis of physical threat, and on the other hand it is practical, because it postulates the need or the necessity to protect against this type of threat.

Colloquial knowledge and fiction can provide interesting examples of the general understanding of the term security. It can also be provided by philosophical literature, or more precisely social philosophy. An example of such a general, philosophical definition of security is the definition by Janusz Świniarski, according to whom "Security is a form of existence of a given state of affairs achieved by eliminating, avoiding and counteracting threats in order to prolong this existence" (J. Świniarski, 1997, p. 173). The author here identifies the general concept of security with each form of existence ("life") and extends it to other, non-human, forms of existence. In addition, he emphasizes different types of ways to counteract threats in order to protect (prolong) his existence.

Among the general scientific definitions, the definition of security proposed by J. Kukułka is frequently referred to in the literature on the subject, especially in political science literature. According to this author, "security is not so much a specific state of affairs as a continuous social process." In connection with this, "social entities are trying to improve mechanisms that provide them with a sense of security." The lack of satisfaction of the need for security, according to Kukułka, "causes damage to an individual or a human group, because it destabilizes his identity and functioning. Therefore, they tend to act to change the existing state of affairs, e.g. to resist unfavorable changes in their external-objective sphere and to use protective measures that can restore their sense of security" (J. Kukułka, 1995, pp. 198-199, J. Zalewski, 2015b).

An analysis of the content of the above mentioned definition implies that the concept of security has de facto nature of a sociological category, because it is one of the basic needs of social entities, besides it is also a specific state and social process (J. Kukułka, 1994, pp. 40-41). In addition to the dominant descriptive approach here, Kukułka clearly emphasizes the valuative approach to term of security. Security as a need is treated by him as value, which is something that is worth the efforts and sacrifices. As a value, it can have the status of real value or at least of desired value. In this approach, security is perceived as a need that is an important goal and stimulator of activity of organized social entities focused on its preservation or restoration. Security, according to the same author, is a state of the "spirit" of certain social entities, the subjective or conscious feeling of one's own existence, i.e. of "being" (J. Kukułka, 1994, pp. 40-41).

According to another expert on this issue at the level of international relations - Ryszard Zięba, security is first and foremost the need of a broadly understood subject. The subject can be not only a man and a social group, but also the state structure and the international system. Zięba extends the notion of a social entity to include *social structure* and *social system* (also international). Similarly to Kukułka, he notes that the lack of ensuring the need for security has some negative consequences for the (individual or congregational) subject, which may be "anxiety, fears, concern and uncertainty" of people, and their "tendency to influence their environment and the internal sphere, in order to dismiss the threat or at least reduce the negative feelings." Security in this interpretation therefore has twofold social character: *objective* and *subjective*. It is an inalienable need of various social entities and structures, and - more importantly - it is also a conscious need of these social entities. R. Zięba specifies the basic determinants of the most general meaning of the term contained in scientific and journalistic literature. The author mentions eight such general, constitutive designations of the term security given in general definitions of this word. These include: "existence, survival, wholeness, identity (sameness), independence, peace, possession and certainty of development" (R. Zięba, 1997, p. 3).

It is noteworthy not only the rather narrow range of designations of security, but their sequence. Undoubtedly, the first designation of the concept of security "existence" is the most important, and less important, though not insignificant, are the last designations. However, are such security properties and their ordering appropriate for all cultures? This cannot be prejudged without reference to empirical research, especially intercultural research. Because of the relationship to the social entity to which *security* is assigned, many authors consider the distinction - at a general level - between "internal and external security" justified. "Internal security - writes R. Zięba - means stability and harmony of a given organism or system (collective entity), while external security means no threat from other entities. Together, both aspects, according to the quoted author, constitute the general security of a given entity" (R. Zięba, 1997, p. 4]. For this reason, the sense of the concept of the security of such collective entity e.g. a nation or a state, may be considered from an internal and external point of view, or taking into account both these points of view in common communication.

Becoming aware of which meanings of the term *security* the authors apply is extremely important for a sensible debate on security and, which seems to be the most important, for rational practical solutions and implemented policies. It is also an important supplementation to the review of the considerations contained in this article on security so far, as a socio-cultural phenomenon by two new aspects: *internal aspect* and *external* aspect (J. Zalewski, 2017). The latter is the result of external influences and relations, existing circumstances and influence of the environment, in particular interactions with other subjects of international life.

The examples of definition of the term *security* presented above are not formulated by sociologists. However, it can be assumed that at least the last two proposals formulated on the basis of political science and international relations are characterized by a general and at the same time close to sociological approach to this phenomenon. Each of the authors treats *security* like a sociologist as a social phenomenon, focuses on its social essence, social features and dimensions. Based on the definition proposals cited above, a general sociological model of studying security can be derived, which is presented in the table 1.

Table 1: General concept of security, its subjects and defining features.

Definition feature of security / **The subject of security**	**State** (Existence)	**Process** (trend, development, progress)	**Need** (value)	**Identity** (integration, consistency)	**Relation** (interaction)
Individual	+	+	+	+	+
Small social group	+	+	+	+	+

Large social group, organisation	+	+	+	+	+
Social structure	+	+	+	+	+
Social system	+	+	+	+	+

Source: author

As it follows from the above, even generally understood *security* belongs to the class of social phenomena with quite diversified connotations. The methods of defining (understanding) security are distinguished with regard to the possibility of creating various configurations of entities and related potential definition features marked with a plus (+). According to the author of this article, this model can be a starting point for developing the classification of various types of definitions of security and presenting various levels and dimensions of security (e.g. subject-object-spatial) (A. Kołodziejczyk, 2007, pp. 244-245) as a part of sociology of security.

Based on the data collected as a result of the review and reconstruction of approaches in defining security and its absence, a cognitive attitude, which emphasizes multidimensional thinking about security and its absence, can be adopted as valid. Definitions of security presented above emphasize various aspects of this social phenomenon and varying degrees of generality. In general, in such approaches the subject of security is clearly defined. However, its definition features include very different features that reflect the preferences of its author or authors. This creates a sense of chaos in defining the concept of security. Therefore, it seems necessary to derive a general model or a comprehensive approach to security that would introduce a certain order by establishing key subjective aspects of security and its absence, basic defining features and relationships. An attempt at such a general and comprehensive approach to security of a social entity and its absence is presented in the table 2 below.

Table 2: Model of a general, comprehensive approach to human security and its absence

Basic defining features / **Entity**- its aspect	**Security as**:			**Absence of security** (uncertainty, threat)
	No danger	Opportunity	The challenge	
Objective (objective state)				
Subjective (state of consciousness / psyche)				
Practical (purpose of the action)				

Source: author

In this sense, at the general level, security, in the broad sense of the word, consists not only of its basic components, but also of absence of security. Each of these basic definition features of security can be considered in an objective, subjective and practical (organizational) aspect. In addition, there may be relationships (couplings) between the specified security components (definition features) and aspects

that may give security a new quality, whether in the form of its strengthening (synergy) or in the form of its weakening.

The above-mentioned concepts constituting the definiens of the general concept of security are partial and secondary in relation to the subjective criterion. However, they reflect the various aspects and possibilities of classification of security that exist in social sciences, and some in international relations. Because security, in the broadest sense of the term, belongs to the group of subjective needs, the division according to the subjective criterion is a priority here. On the basis of sociology, security of an individual is also an important cognitive issue, but in relation to social issues. Other, non-subject, approaches to security significantly enrich the description of this dominant approach in social sciences, and therefore they must not be underestimated. Therefore, the typology of defining security as a social phenomenon must necessarily be based on different classification criteria

Conclusion

The above, quite general reflection on human security indicates the usefulness of sociological reflection and its conceptual grid in the study of this socio-cultural phenomenon. Next, sociology can demonstrate its huge role in the study of human security issues, showing at least the usefulness of sociological theory for establishing the foundations for the study of such security; determining of cultural imponderables of security; analyzing varieties and dimensions of security as a socio-cultural phenomenon, performing sociological analysis of institutions - structures and systems - security; determining the impact of social change, including the globalization process, on human security, etc.

An analysis of the literature on the subject shows that a sociological approach to the study of human security issues can be heuristically promising. Also, confronting the sociological approach with the achievements of other social sciences may reveal new cognitive possibilities. Such an example can be the issue of a subjective approach to security issues at the macro (state, nation) level and in relation to other entities of the same kind. Because analyses of definitions of security have shown that it is a convenient starting point for the study of communities of various scales: smaller than the state and nation, and larger ones. The whole range of security subjects from a sociological perspective can be an appropriate basis for developing policies more relevant to the challenges of the modern world that take into account real and potential problems in the field of human security.

Developing and institutionalizing of the paradigm *sociology of security*, according to the author of this article, will depend on the ways and directions of education in this field of social knowledge. One of the conditions for obtaining the scientific status of sociology of security will certainly be the fact whether the proposed security research concept will be developed as a socio-cultural phenomenon. For now, the prognosis seems to be very optimistic.

Determinants of Military Mobility in The Aspect of Military Security of The State

Slawomir BYLEN

Military University of Technology, Warsaw, Poland
slawomir.bylen@wat.edu.pl

Abstract

The article presents the results of research on the impact of transport infrastructure on the military mobility of Polish troops, especially allied forces, equipped with military equipment increased in size and weight, which requires engineering structures of increased load-bearing capacity (road and railways) as one of the basic determinants ensuring Poland's military security. The article presents a verification and assessment of the impact of transport infrastructure on military mobility. Factors determining the development of military mobility were presented, including the increased presence of allied forces on NATO's eastern flank. The article describes and verifies infrastructure, legal and legislative barriers as well as transport infrastructure requirements.

Keywords: Military Security, Transport Infrastructure System, Military Mobility, Host Nation Support.

Introduction

The subject of research described in this article is transport infrastructure in Poland and its impact on the mobility of the transport system of the Polish Armed Forces as one of the basic elements of ensuring military security in Poland. The reason for writing this article was an attempt to assess the functioning of the military transportation system in the conditions of limited possibilities of the transport infrastructure in Poland. The purpose of the article is to check, verify and assess the impact of transport infrastructure on military mobility in the aspect of the capacity of non-military sector to create conditions enabling free movement of troops on the territory of Poland. Detailed research problems were formulated as follows: What factors and to what extent determine the development of military mobility? What is the role of the increased presence of allied forces on NATO's eastern flank in the development of military mobility? What are the barriers which hamper military mobility, taking into account various modes of transport?

When preparing the article, the following research methods were used: diagnostic survey conducted using the uncategorised interview technique, statistical data analysis method, critical analysis of the research literature and documents concerning the subject of article. The article describes and verifies infrastructure, legal and legislative barriers, transport infrastructure requirements as well as the state of transport infrastructure and insufficient means of transport in individual modes of transport. On this basis, determinants of military mobility in defence logistics have been verified. The structure of military transport in the assessed period is presented in Table 1, after the occurrence of military threats related to the security of NATO's eastern flank.

Table 1: Structure of military transport in the multi-branch system in the years 2014-2018

Type of transport	2014	2015	2016	2017	2018	Remarks
Maritime transport	7	5	1	2	0	
Air transport	239	170	224	281	231	Flights carried out including NATO programs (SALIS and SAC)
Rail transport	122	187	198	411	314	Operational and supply transports
Road transport	8618	9440	10225	11835	12852	Based on the number of permits issued for road transport

Source: in-house elaboration compiled on the basis of [5].

The implementation of tasks arising from the obligations of the host country requires the preparation of elements of Polish defence system for the purpose of using as national defence resources. This is a new challenge for our country as a host country. The total number of allied forces stationed in Poland in the form of rotational stays, military training and transits is presented in Figure 1.

Fig. 1: The number of allied soldiers staying in Poland

Source: in-house elaboration compiled on the basis of [1-2; 7–10].

The conducted research shows an eightfold increase in the number of soldiers stationed in Poland in various forms in 2017, in comparison to the period before the Ukrainian crisis. It is also the highest number of troops stationed in our country since the end of the Cold War in 1989. A significant increase in the number of allied troops is also planned in 2020, when the "Defender-20" military exercise related to the movement of the American military forces to Poland will take place [9-10; 12]. A formal requirement for the arrival of allied troops to the territory of the Republic of Poland is to obtain a residence permit or a transfer permit [5, 15].

Table 2: Tasks of the road transport subsystem implemented by the Chief of the Movement and Transportation Division-National Movement Co-Ordination Centre Polish NMCC (STiRW-CKRW) in the years 2014-2018

Name of the project	2014	2015	2016	2017	2018
"Permission for road transport" of military columns, non-standard vehicles and of hazardous goods by the Polish Armed Forces	8618	9440	10225	11835	12852

Permission for the Polish Armed Forces vehicle to leave the country	757	1269	1141	1793	2459
Permission for the transfer of foreign troops on the territory of the Republic of Poland	477	854	930	1225	1494
Securing the piloting of non-standard vehicles and military columns by traffic regulation companies	624	692	982	806	1511

Source: in-house elaboration compiled on the basis of [5, 6, 10].

In case of non-standard vehicles, the existing limitations of road infrastructure always require consultations with relevant infrastructure managers, i.e. establishing contact with about 2,900 civil infrastructure managers of the public road network in Poland. In addition, there are customs procedures as well as tax forms regarding exemptions on imported equipment and military materials [10]. In the next stage of the RSOM process, i.e. further transfer of troops, further physical obstacles can be encountered, related to the transport network capacity (road, railway, port terminals or airports) to support heavy military equipment of non-standard sizes, as well as limited means of transport.

Selected examples of the implementation of transport tasks as part of the support of the host country - results of the research

In NATO during international military exercises tasks of support are carried by the host country, concerning transport and movement of troops for the benefit of military units of allied and partner countries based on the "HNS STANDARD" program [9], which envisages access to transport infrastructure, including sea and air ports and road and rail border crossings as well as access to air, sea and railway military reloading points, free of seaport and airport charges, which are not directly related to the services requested and received. The number of military exercises that have been organised in Poland in recent years is shown in Figure 2.

Fig. 2: The number of multinational military exercises in Poland with the participation of allied forces

Source: the in-house elaboration.

The research, presented in the figure in the form of a summary, shows the increased effort of the transport authorities of the Armed Forces of the Republic of Poland, associated with the dynamic increase in the number of military exercises in Poland that took place after 2014. The increase in the number of military exercises is NATO's response to the increase in the military threat on NATO's eastern flank, resulting from Russia's armed aggression against Ukraine. A similar trend occurs in case of the increased number of permits issued in Poland for the transport of allied troops through the

territory of our country, which is shown in Figure 3 and the number of soldiers of allied troops transported through the territory of our country (Figure 4).

Fig. 3: The number of permits issued for the transport of allied troops through Poland
Source: the in-house elaboration.

Another indicator of the burden on the military transport system resulting from additional tasks as part of support of allied forces is the number of permits issued for the transfer of allied forces through the territory of our country. The conducted research shows that during the analysed period there was more than a twenty-fold increase in the number of permits issued (2058%), which was associated with a huge effort of the military transport authorities issuing permits (Military transport and movement coordination centres).

Similar conclusions can be drawn on the basis of the increase in the number of NATO soldiers who are deployed through our territory (Figure 4).

Fig. 4: The number of soldiers of allied troops transported through the territory of Poland
Source: the in-house elaboration.

The highest increase in comparison to 2013 was recorded in 2016, which results from the record number of military exercises performed in Poland.

"ANAKONDA-16" Exercise

"Anaconda-16" was the third edition of the multinational military exercise which involved representatives of the armed forces from 24 allies and partner countries. The complexity of the exercise consisted in providing logistics support of many complicated operational activities, conducted in seven different locations. The above-mentioned determinants influenced the scope of

tasks of the army transport and movement system. The main functional areas of HNS in the transport subsystem included providing access to airports and seaports of unloading as well as assistance in crossing the border, in moving and deploying allied troops in exercise areas. In this respect, the Military Transport and Movement subsystem provided transport for a total of about 31,000 soldiers, including as part of HNS for 18,192 allies and 454 partner nations soldiers [1-2].

Poland as the host country was responsible, among others, for: welcoming NATO troops on the state border, supervising the movement of troops in Poland, coordinating deployment to exercise areas and monitoring the movement of troops, using about seven thousand pieces of military equipment [3, 13]. The equipment for military exercises was transported to Poland by air, sea, rail and road (Figure 5). First of all, heavy military equipment was transported by sea, including, among others, from the USA (1,400 pieces), from Spain (400) and from Great Britain (200). Lightweight military equipment and pallets with military equipment as well as soldiers with equipment reached the exercise area by air [11-12].

Fig. 5: The number of military equipment delivered to Poland for the "Anakaonda-16" exercise
Source: in-house elaboration compiled on the basis of [1,2].

First of all, military equipment from Germany arrived in exercise area by rail and road. As far as transport is concerned, Poland under RSOM was responsible for transport of approximately 3,000 pieces of allied military equipment to the exercise areas, including: Abrams tanks, Leopards 2A4 and 2A5, Patriot missile batteries, aircraft, including: F-16 aircraft, C-17 Globemaster, C-130 Hercules and C-295M, and Apache and Blackhawk helicopters as well as 21 naval ships. In terms of operations, the "Anaconda-16" exercise was a test of the ability to conduct joint operations for the Polish Armed Forces. However, for the Military Transport and Movement subsystem it was primarily a test of the state's ability to secure the reception, displacement and deployment of allied troops in the host country.

"SABER STRIKE -18" Exercise

"Saber Strike" is a series of exercises organised within the territory of the Baltic States and in Poland by American troops stationed in Europe. The main purpose is to increase interoperability and mobility as well as to project military power. Over 18,000 soldiers from 19 countries took part in the "Saber Strike-18" exercise. Exercise took place mainly in Poland and Estonia, and some operations were also carried out in Lithuania and Latvia. The most numerous forces delegated to participate in the exercise were the American forces, while Poland was the second nation in terms of the number of soldiers involved. Multinational battalion battle group that have been stationed from 2017 on NATO's eastern flank played an important role during "Saber Strike-18".

A great undertaking for Poland as the host country was the reception at the borders of a large number of equipment and soldiers and their displacement to the exercise area. The biggest challenge was to organise the acceptance and displacement of a large number of military equipment that was delivered to the exercise area by various means of transport. The number of transports is shown in Figure 6.

Fig. 6: The number and type of operational transports delivered to the exercise area of "Saber Strike-18"

Source: in-house elaboration compiled on the basis of [5, 6, 10].

The research shows that the majority of equipment was transported to the exercise area by road. However, it should be considered that - unlike other modes of transport - one transport by sea is a one-time delivery of up to several hundred pieces of heavy equipment. Road and rail transport, by which mainly heavy equipment was transported, played a significant role in the effective transfer of equipment. On the other hand, air transport was used primarily to displace soldiers along with their equipment.

The largest number of military equipment used during the exercise was recorded on 6.06.2018, when almost 2,000 foreign army equipment pieces and almost 1,150 pieces of Polish military equipment were located in the training grounds. This required a significant involvement of the transport subsystem and movement of the troops both during the transfer to the operational area of destination (to participate in military exercise) and during the return to the places of permanent dislocation in the home countries. The largest number of soldiers participating in the exercise was recorded on 6 June 2018, there were over 7,200 soldiers of allied countries and almost 4,500 Polish soldiers took part in exercises at training grounds. This required a lot of organisational effort from the transport subsystem to ensure efficient movement for such a large number of people.

"TESTEX-17" Exercise

Before the trial road transport of heavy tracked equipment, a network of defence-important routes was designated for the army. The routes selected in this way were tested as part of relocation of allied forces. Practically as part of"TESTEX-17" exercise a relocation of a heavy equipment with a weight of approx. 120 tons and loads of approx. 115 kN/axle was planned, including the British CHALAGER 2 tanks with a weight of approx. 80 tons. A total of fifty soldiers and fifteen vehicles participated in the trial transport, including 5 sets of low loader equipment of the HET 1070F type [10]. The following military equipment was designated for the transport:

- Challenger 2 MBT,
- AS-90 self-propelled howitzer, caliber 155 mm,
- vehicle for technical support.

Figure 7 shows the planned route for moving a column of British vehicles transporting oversized cargo from the border crossing in Świecko, on the German-Polish border, to the border crossing in Budziska on the Polish-Lithuanian border.

Fig. 7: Transportation route of heavy military equipment via Poland

*Source: in-house elaboration compiled on the basis of [**Error! Reference source not found.**1].*

On the route, five parking and resting places have been prepared (respectively in the following towns: Międzyrzecz, Toruń, Sochaczew, Białystok, Suwałki). During the determination of the route, it turned out that due to the fact that two engineering facilities on the A2 motorway did not meet the technical requirements, the column was forced to drive off the A-2 highway towards Bydgoszcz to the A-1 highway. However, the biggest obstacle to the efficient transport of the column was the insufficient load-bearing capacity of bridges along the route, as compared to the total weight of the equipment. The fact that bridges were not adapted to the transport of heavy equipment resulted in the need for additional unloading and loading of equipment five times in order to enable the tanks to drive through bridges individually. On these sections, the convoy had to move separately and after crossing the engineering facility, the equipment was reloaded onto a low loader semi-trailer.

The UK Armed Forces jointly presumed that it would take three days to relocate soldiers from a base located in Germany to a base in Estonia. In fact, the movement of troops through the territory of Poland took four days. As a result of the rules on drivers' working time, the convoy was forced to stop for a total of three days. The research shows that tractor units play a very important role in ensuring military mobility, especially that in Poland, as part of fulfilling its obligations of the host country, an increased number of NATO forces has been deployed since 2017.

Infrastructure Barriers - Research Results

Road Infrastructure

During the design and construction of road infrastructure, taking into account the national defence requirements, many restrictions and barriers may be encountered. At present, in the era of modern construction methods, when planning a wide range of earthworks, it is possible to design and build roads without taking into account unfavourable terrain conditions. Modern routes have minimal gradients, facilitating the journey and allowing higher speeds than before.

The removal of barriers in the road transport infrastructure is associated with the improvement of technical parameters of roads and all facilities located on them, including bridges, viaducts, tunnels and even roads at water dams. From the point of view of improving military mobility, the following parameters should be taken into account [11]: width of the horizontal clearance; height of vertical clearance in tunnels and under railway viaducts; load-bearing capacity of engineering objects (calculated in tonnes) and load-bearing capacity of the road adapted to the vehicle load (expressed in tonnes per axle).Military requirements in terms of improving the technical parameters of the road infrastructure are presented in Table 3.

Table 3: Improvement of technical parameters of the road network

Parameter	Value	Examples of technical parameters of bridge structures
Load-bearing capacity of a bridge	150 t	7 t
MLC load-bearing capacity of a bridge	MLC 120 tracked vehicles MLC 150 wheeled vehicles	
Turning radius for heavy equipment	25 m	20 m
Maximum vehicle height	4.5 m	2.4 m
Maximum vehicle width	5.0 m	4.0 m
Vertical clearance	4.5 m	

*Source: in-house elaboration compiled on the basis of [**Error! Reference source not found.**1].*

Railway Infrastructure

The conducted research shows that one of the most important limitations in the use of railway infrastructure for defence is the slowdown of traffic caused by insufficient network capacity, because heavy traffic on selected railway lines and railway stations, in an emergency situation, may lead to delays in military operational transport.

Another barrier is disproportionate density of the railway transport network in the country, which is not particularly conducive to the functioning of the transport network during a crisis or war, because not all loading/unloading stations are properly adapted for reloading works, according to the intended use for army. The location of front and side ramps on railway lines is also extremely important.

The research also shows that additional reloading equipment such as cranes, forklifts or container lifts is more and more often used during railway reloading. Their access to the reloading location is limited by the low parameters of the access road to the reloading station. Moreover, during railway transport of heavy tracked equipment or oversized equipment, significant shortcomings in the railway infrastructure were found, where the large vertical and horizontal clearance on railway tracks is particularly important.

Airport Technical Infrastructure

The basic barrier limiting the use of airports for defence purposes is ensuring convenient communication with other modes of transport. From the point of view of ensuring military mobility, the following issues should be taken into account: Is there convenient access by public roads with the required capacity? Are there any alternative access roads? Are there any access roads for freight traffic designated for vehicles with heavy mass and large sizes? Is there any railway connection capable of handling passenger and freight transport?

When assessing air transport infrastructure in Poland, the research shows that the technical parameters of runways and aprons determine the size and number of aircraft using an airport.

Strength and size of aprons is also an important issue, which must be taken into account during the design phase. Prosperous international airports are constantly expanding their ground infrastructure by adding new parking spaces. The main and the only goal is to increase capacity, which in case of the army means increasing military mobility. Military requirements for improving airport infrastructure are presented in Table 4.

Table 4: Improvement of technical parameters of airports

Parameter	Value
Runway	3000 x 60 m
Apron	66.500 m^2
Horizontal clearance (tunnel)	6.5 m
Platform axle pressure	40 t / axle

*Source: in-house elaboration compiled on the basis of [**Error! Reference source not found.**1].*

It is equally important to have an appropriate number of reloading equipment, because in recent years the use of air transport for movement of military equipment (vehicles, power generators) that needs to be unloaded from the aircraft has increased. Equipment transported on pallets also frequently needs storage. It is often necessary to secure and store hazardous materials, most often it concerns ammunition or explosives. They require separated zone, located at a safe distance from the runways, with enhanced protection.

Technical infrastructure and equipment of seaports

The infrastructural barrier in the use of seaports is, among others, communication of ports, often hindered by the direct proximity of city centres, for example Szczecin or Gdańsk. Communication of the port with the road network may be limited by narrow and built-up streets or frequent junctions causing delay in reaching the port. As in the case of airports, reloading devices and equipment adapted to the highest number of types of transported cargo play a key role here. From a military perspective, sea containers as well as military wheeled and tracked equipment are most often transported. Technical parameters which should be applied to seaport infrastructure are presented in Table 5.

Table 5: Improvement of technical parameters of seaports

Parameter	Value
Wharf length	310 m
Maximum draught of a vessel	12 m
Number of wharves	3 / port
Load-bearing capacity of wharves	MLC 100

*Source: in-house elaboration compiled on the basis of [**Error! Reference source not found.**1].*

The most effective solution for unloading vehicles is the use of "ro-ro" ramps, enabling the equipment to be individually transported from the vessel to the wharf. Moreover, the load-bearing capacity of the "ro-ro" ramp and wharf should be taken into account so as to enable transport of even the heaviest equipment. The possibility of reloading and the availability of warehouse infrastructure for storage and warehousing of hazardous materials is also crucial for military transport.

Challenges to Minimise Infrastructural Restrictions and Improve Military Mobility

Overcoming Infrastructure Barriers

The challenge that the Ministry of National Defence faces is to identify critical infrastructure elements that are already affecting the duration of transfer. The awareness that during the war they will pose a real threat to the timely transfer and relocation of forces imposes the necessity to take actions to eliminate them. In order to improve mobility, the focus is mainly on the implementation of rail and road infrastructure projects. It includes the renovation and modernisation of existing road infrastructure, including engineering structures in road routes, railway lines, loading and unloading stations on railway lines used for the purpose of military transport. It should be beneficial, allowing for smooth and timely land transport of troops.

The first way to improve military mobility is to invest in the development of transport infrastructure using European funds under the CEF Connecting Europe Program, which is intended solely for dual-use transport infrastructure. Another condition that must be met in order to apply for funding is the need that roads or rail lines correspond to the infrastructure of the trans-European TEN-T transport network. As part of efforts undertaken by Poland to obtain co-financing of transport infrastructure, sections of rail and road routes have been designated that meet the above conditions. Decisions on the granting of financial assistance have not yet been taken. The release of funds for the implementation of investments under the "Connecting Europe" Program is planned for 2021-2023 [14].

Due to the increasing needs of military transportation or resuming railway traffic in the directions not used for a long time, there is a need to modernise or restore the use of sections of railway lines or loading/unloading stations. For example, railway line No. 239 between Lębork and Maszewo Lęborskie, its revitalisation was financed from the PRPO Program funds.

Additional challenge is constantly growing number of allied troops stationed in Poland. This involves the expansion of military bases and thus the need to improve the condition and parameters of access roads. This can be exemplified by the expansion of the air force base in Powidz and providing access road to the base for wheeled vehicles. Local Government Road Fund established at the end of 2018 is another financing possibility, which provides funds for investments in poviat and commune roads. Table 6 presents the required technical parameters of reloading facilities and equipment in terms of shortening military equipment reloading time.

Table 6: Reducing the time of reloading military equipment and materials at airports, seaports and railways

Parameter	Value
Reloading area for Armed Forces	240 m^2 /parking space 100 m^2
Number of wharves	2 / port
Reloading capacity	50 TEU / day
Fixed or movable front rail ramp	100 t
Reloading capacity	300 TEU / day
"Ro-Ro" ramp	2 x MLC 100
"Lo-lo" crane	2 x 100 t

*Source: in-house elaboration compiled on the basis of [**Error! Reference source not found.**1].*

Loading and unloading time of military equipment and personnel can be shorter due to modernisation of reloading ports, providing space and manoeuvring areas for heavy reloading equipment or mechanisation of works. At sea ports, the technical infrastructure is currently equipped with the best specialised reloading equipment. Parking spaces and manoeuvring spaces necessary for creating marching columns constitute an obstacle in the fulfilment of the army's needs. Table 7 presents military requirements for the improvement of transport and storage capacity in air and sea bases.

Table 7: Improvement of transport and storage capacity of air and sea bases

Parameter	Requirement	Parameter	Requirement
Increasing transport capacity		Increasing storage capacity	
Direct access to roads	Motorways and national roads	Storage area	100 m^2
Direct access to the railway line	2 x railway ramp	Permanent Warehouse	2 x 1000 m^2
Direct access to the railway line	1 x railway ramp	Permanent Warehouse	100 m^2

*Source: in-house elaboration compiled on the basis of [**Error! Reference source not found.**1].*

An equally important problem in ensuring military mobility by the infrastructure of sea and air force bases is the provision of parking spaces and rest areas for convoys, which in addition to parking spaces should also provide manoeuvring areas suitable for low-loader units.

Elimination of Legislative Barriers

In terms of eliminating legislative and regulatory barriers related to crossing the borders, the deadline for issuing permits for transfer on designated roads has been reduced so far for vehicles of foreign armed forces to 5 working days and to 3 days for High Readiness Forces.24-hour (24/7) dispatcher services were established to supervise the movement of troops [10].Works were undertaken aiming at:

- reducing the deadline for submitting applications for permission to enter Polish territorial waters (from 30 days to 5 days) for NATO and EU vessels;
- adapting the provisions regarding the entry of EU military aircraft which should be treated equally to NATO aircraft.

Other elements of mobility are transport networks, whose technical parameters do not always meet high military requirements. So far, as part of activities related to the elimination of physical barriers to the road network, roads dedicated to military movements have been selected as well as technical parameters were analysed in relation to the minimum technical and defence requirements developed by the EU Military Staff in correlation with NATO requirements.

Conclusions

The results of research presented herein show that the defence system in Poland only to a limited extent satisfies the transport needs of its own and allied troops, enabling the movement of troops and maintaining continuity of supply during missions conducted on Polish territory. The following conclusions can be drawn on the basis of the research:

1. Despite undertaking many actions improving the functioning of the transport infrastructure in Poland, there are still numerous critical points limiting the free movement of troops on roads, especially in case of non-standard vehicles.
2. The current capabilities of the road transport infrastructure do not fully take into account the needs of Polish troops, and especially allies, in ensuring the freedom of movement on roads within our territory. Among other things, the main shortcomings include the lack of an adequate number of bridge structures which comply with the technical parameters required by the army. Among others, there is insufficient load-bearing capacity of some engineering structures, which

requires designation of long detours. The army's requirements in ensuring transport of military equipment weighing up to 120 tons are not met as well.

3. An important limitation of military mobility results in the need for special procedures concerning the transport of heavy vehicles over bridge structures that causes delay in troops movement. For example, the duration of movement of column of British military vehicles in autumn 2017 lasted three times longer than expected.

4. In view of the existing barriers in Polish transport infrastructure, especially the road infrastructure, it is difficult to comply with the assumed time regime for the movement of troops from A to B.

Recommendations

The aim should be to enable the use of designed devices and civil structures (objects of the state transport infrastructure) for defence purposes, even if it would go beyond the needs of the civil (commercial) market. At the same time, when designing weapon systems and military equipment civil needs and standards should be taken into account, where possible. In order to ensure military mobility, the requirements and needs of the Ministry of National Defence should be taken into account when preparing transport infrastructure to meet the defence needs of the state. It is required to build new roads as well as to expand and rebuild the existing road network, enabling the determination of convenient road routes for heavy military vehicles. Moreover, the transport capacity of Abrams, Challenger and Leopard tanks should be improved by adapting to the technical and operational parameters of the road network designated for high readiness VJTF forces and by increasing the number of railway rolling stocks.

Safety of The System of International Relations in The Context of The Coronavirus Pandemic COVID-19

Jacek BIL

Military University of Technology in Warsaw, Poland
e-mail: jacek.bil@wat.edu.pl

Abstract

Contemporary international relations are built on the relationships between geopolitical entities belonging to specific alliances of political, economic and military nature. International safety and security is defined by joint projects and activities that define the achievement of the objectives. In the situation of the crisis caused by the coronovirus COVID -19 pandemic, there are strong voices of disapproval for the actions taken by the community of European countries. This is particularly important because of the risk of undermining the system of cooperation between democratic states which have been established for years and which have relied on the principles of consolidated democracy in favour of a particular system of nation states. The purpose of this article is to present the risks that may arise in the area of erosion of the European Union caused by autocratic decisions of individual European decision-makers. This threat is all the more worrying because the destabilisation of the system of international relations between the countries of the European Union and the United States of America is a clear realisation of Russia's foreign policy objectives.

Keywords: International Relations, Security, Safety, Nation States, Pandemic

Introduction

The experience of social unrest and of individual realization of political assumptions of representatives of autocratic countries causes the conclusion that it is necessary to build international relations based on a liberal background, rejecting at the same time particular trends of realism. Following Joseph Nye's position, for example, it should be stressed that international institutions play a particularly important and positive role in international relations, since they are a tool to facilitate cooperation and indirectly guarantee stability, safety and security. In international relations they are a corrective element in relations between states. The high degree of institutionalisation of international relations ensures a constant flow of information, the possibility of exchanging views and allows the creation of norms and standards that reduce the risk attributed to an anarchised international environment. The economic and political interdependence of countries leads to a high probability to maintain world peace. This position is justified by the view of Richard Rosecrance, who argued that the source of prosperity of highly developed countries was not wars, but trade contacts conducted at a high economic level (Ostaszewski, 2008, 2010, p. 25-26). The opposite view of the indicated functioning of the international community are the references to a realistic vision of the international order, as well as the views of Russian representatives of the “Russian order”. It should be noted that in the era of information struggle as a tool of soft power to influence individual geopolitical objects, as well as the decisions of their representatives, there is an extremely high risk of achieving the Kremlin's political goals.

Leszek Sykulski in his book *“Russian Geopolitics versus the Information War”* points out that from the point of view of the realization of the Russian conservative paradigm, opposite to the values of the Western world, it is important to strengthen radical circles that are capable of destroying the existing political and economic order in Europe. At present, the radical right wing using conservative slogans is an ally of execution of the Russian world order assumptions. The message, the sources of which are anchored in the Kremlin, raises anti-Western values criticising liberalism, and at the same time pointing to the United States of America as its greatest enemy. The author, referring to the Manifesto of the Global Revolutionary Alliance - GRA (a network organization set up to realize the goal to fight for the

awareness of radical Western societies), points to a particularly dangerous aspect of the realization of this ideology, because it refers to the usage of any means depending on the needs, which can pose a very high threat to European safety and security. This narrative is not only present in the identity of circles declaring a connection with neo-imperial ideas, but is also promoted by part of the liberal circles. The GRA warns against a so-called world government based on a world oligarchy, in which monopolists become the core of this entity. The above-mentioned Manifesto underlines that the method of fighting against the global dominance of the USA and against the global West is to support revolutionary forces that do not agree with the values of the capitalist Western world. To this end, every military conflict in the world should be used to fight the United States and its allies (Sykulski, 2019, pp. 119-127.).

The current situation of the global crisis caused by the epidemic gives the supporters of the Global Revolutionary Alliance a convenient situation to achieve the goal, i.e. to weaken the potential of liberal Western countries. Although the COVID-19 virus is not a military conflict, it certainly destabilises the political situation and, as indicated above, all means should be used to achieve the objective, depending on the needs. Of course, it can be accused that the position of the Global Revolutionary Alliance - GRA is not an official postulate of Russia's foreign policy, but it should be noted that they follow the ideology presented by Alexander Dugin, whose activity is identified with people associated with the decision-making environment of the Russian state.

Nationalism and Nation States

The analysis of the assumptions accompanying Russia's vision of the world order allows us to conclude that the subjects of Russia's direct interest are radical right-wing circles practising populist policy. As Benjamin De Cleen notes in his article "Populism and nationalism", nationalist populism manifests itself, among other things, in rejection of ethnic and cultural diversity. The radical right-wing parties, i.e. the French party, the French Front National, the Austrian Freiheitliche Partei Österreichs and the Belgian party Vlaams Belang, are the groups that are particularly concerned about the rejection of ethnic and cultural differences, but it should be noted that these values are also rejected by other right-wing parties. Right-wing parties point out that they care about the interests of all social groups, raising the fact that ordinary people are the main victims of multicultural society and suffer from immigrants. In this respect, they point out that immigrants deprive them of work, contribute to the reduction of pension benefits and commit criminal offences. The members of these parties accuse the political elite of strengthening the rights of foreigners and immigrants to the detriment of their own interests, and thus do not sufficiently represent the entire nation, but selected social groups, leaving aside those most in need. Nationalists, by using populism, also fight for national autonomy, accusing liberals of cutting themselves off from authentic national identity. This kind of articulation can be found in German nationalism, as well as in Eastern and Central European nationalist movements fighting for national identity in the past, and which is nowadays transferred to the extreme right. Nationalist populism also touches on antagonistic issues concerning both national and foreign elites. Populist political movements articulate national interests, which contradict the vision of transnational organisations. In the populist rhetoric of the right, the antagonism manifested itself mainly around the defence of national identity against the multicultural and globalist policies imposed by community organisations. According to nationalists, these threats threaten the identity, culture and economic interests of the nation. In Europe, the European institutions in particular are accused of undermining cultural identity and national interests through lenient migration policies and of promoting integration and globalisation. Right-wing groups also accuse decision-makers of allowing the movement of workers from other countries and of losing the possibility to take national economic and social decisions to the benefit of Community actors (Benjamin De Cleen, 2017, pp. 10-17).

Rogers Brubaker in the study *"National Minorities, Nationalizing States, and External National Homelands in the New Europe Notes toward a Relational Analysis"* points out that nationalism remains central point of the policy of nation states and the relations between them. Europe faces a potentially explosive dynamic of international relations, as many nation states promote heterogeneous values (Brubaker, 1993. p. 4-15).

A different understanding of nationalism is proposed by Aleksanr Dugin and Alain de Benoist (the main theorist of the French New Right movement), who, while advocating a rejection of populism, assume a different understanding of right-wing values. Observers of the European political scene already at the beginning of the nineties of the last century, finding in the nationalistic concepts of Dugin and de Benoist a threat to safety and security of Europe, led to a sharp criticism of the ideologies of these thinkers, creating a media campaign against this threat. Noting, of course, the discrepancies between Dudin's and de Benoist's thoughts, for example, in their different approaches to traditionalism, there are common patterns of the classical right-wing advocating glorification of nationalism. Both thinkers have criticised nationalist views in their countries, raising errors in distinguishing this phenomenon by both the left and the right. However, Dugin and de Benoista, urging the revitalisation of nationalist thought, assumed that political conquest first requires the capture of cultural power. Dugin, by drawing on the assumptions of the French and Belgian right-wing thought, and using Jean François Thirart's view, among other things, expressed his opinion about the need for a national-community movement, whose common value would be to strive for a limited democracy at the service of the national community. Such a democracy, by promoting political unanimity, encourages a return to a natural social hierarchy in which there would be no place for people from outside the designated social group. The racial arguments of nationalistic assumptions (of people outside the social hierarchy) also remain important in the views of Western political thought. Coming back to Dugin, it should be emphasized that his texts abound in references to the classical consequences of racial ideology and the idea of superiority of whites, i.e. the concept of Eurasia of Indo-European Slavs. Dugin, proposing a postmodern understanding of the nation, calls for the restoration of all ideas, both religious and ethnic, that were lost by the modernists. The ethnic issue is used against globalised liberalism, which causes destructive differences between nations. The ideology of Eurasia has a strong influence on the ideology of the great Russian power seen through the eyes of Putin's establishment, as well as on traditionalism and other religious doctrines addressed to both Russian and foreign intellectual circles (Laruelle, 2006, pp. 9-19). When analysing the collected research material it should be unequivocally assumed that the vision of the nation state is not only promoted by Russia, it is present in the opinions of many political circles in France, Belgium, Germany or Poland.

Information appearing in the media space in connection with the fight against coronavirus COVID-19.

In a press release on 1 April 2020, the Director General of the Word Health Organization, informing the world's views on global action against the coronovirus, stresses that 74 countries have joined the process of finding effective solutions to combat the pandemic, including attempts to develop a vaccine against the disease. In addition, it stresses the need for intergovernmental cooperation to increase the production of personal protective equipment for medical personnel and the public. The communication of 1 April was complemented by a media statement by the WHO Director General on 3 April, informing that 1 million confirmed COVIDs-19 and 50,000 deaths were reported to WHO. At the same time, it stresses that the situation is somehow bigger than a health crisis because it causes huge social and economic changes. It also stresses the need to reduce debt in pandemic countries in order to avoid an economic collapse. Close cooperation between the World Health Organisation, the World Bank and the International Monetary Fund is being established in this area. The WHO calls on all countries to provide full funding for basic public health actions. This Communication points out that if all countries were to rush to lift restrictions too quickly, the virus could revive and cause even greater disruption to many countries' economies (WHO, 2020).

The fight against the pandemic also gives rise to worrying examples of the use of the crisis situation by many circles which, under the guise of the fight against the coronavirus, are striving to implement their political undertakings. In this context, there are credible assumptions that opponents of a Community policy built on the line of European-Atlantic consensus will use social unrest to undermine the foundations of the EU and international organisations, undermining their incompetence and effectiveness. Declarations of Russian policy on the reform (liquidation) of the UN, destabilisation of the EU, or Russia's imperialist aspirations, are real security threats that increase in proportion to the amount of negative information. Bearing in mind that nowadays information is the basic tool of the

information struggle conducted in order to destabilize the system of international political-military relations, it is necessary to accurately identify and neutralize the message resulting from manipulation or disinformation. Other forms of information struggle used by Russia are not insignificant, such as influencing by means of influence agency or using reflexive management. In this context, one can critically assess the behaviour of individual political decision-makers who, by pursuing their own goals, deform the democratic system of EU countries and thus fulfil (consciously or not) the Kremlin's assumptions.

The Hungarian Parliament, taking up the fight against the coronavirus, approved a law that gives Viktor Orban, according to the opposition, unnecessary and unlimited power. The solution adopted allows the state of emergency and the associated powers of government to be extended indefinitely by decree without parliamentary approval. The new regulations also provide for a prison sentence of up to five years for disseminating false information about the pandemic or against government actions taken to fight the virus. According to commentators of political life in Hungary, the regulations implemented on the grounds of the fight against the pandemic significantly limit the freedom of the Hungarian media and the right to reliable information. Orban's rhetoric towards these accusations, addressed to the "European screamers", is credible in the need to fight against the virus. In a similar vein, Hungarian justice minister Judit Varga said that the criticism of the adopted solutions is based on conjecture and does not correspond to reality (Malinowski, 2020). Commenting on the events in Hungary, Professor Kim Lane Scheppele from Princeton University claims that Orban is moving away from governance with even a seemingly constitutional democracy and a tri-partite power, because any regulation of the law will be able to be changed by the Prime Minister according to his vision. In Hungary, in the context of the pandemic, immigrants and independent media informing about the event became the target of attacks. In March 2020, the V-dem institute, in a report examining the quality of democracy, for the first time in the history of the study, classified a European Union country - Hungary as undemocratic, indicating that it has an electoral autocracy system. The Chairman of the European Parliament's Civil Liberties Committee, Juan Fernando López Aguilar, informed Hungarian parliamentarians that all actions taken by EU members in the fight against the pandemic must comply with the principles of democracy, the rule of law and human rights. Thus, he announced that he would propose to the European Commission to challenge the Hungarian law to the EU Court of Justice for violation of Article 2 of the EU Treaty (Wójcik, 2020).

Rhetoric about the actions taken by the European Union also takes place in Poland. Publicist Grzegorz Jankowski used Twitter to ask questions about the EU's involvement in the fight against the virus, declaring that the entire burden of counteracting the pandemic fell on national governments. It should be noted that this entry has received four thousand liked ones and nearly a thousand further applications (these data are important because the information published in modern media is of particular value to the informational fight - author's note). In a similar tone, Marcin Palade wrote on Twitter, asking about European actions, pointed out the special role of nation states, not bureaucratic Eurofederalism in the fight against pandemic. A politician from the United Right, Janusz Kowalski, criticized the actions of the European Union. He accused the EU of being ineffective in fighting any crisis, raising the role of the Polish government in the fight against the coronavirus. In addition, he stressed the need to reconstruct the EU in order to strengthen nation states and to move away from centralisation. At this point, it should be noted that Russian propaganda is not inactive in this regard, as the mass media, such as Russia Today (RT), report on the European Union's lack of capacity to fight the coronavirus and the news of the imminent end of European unity. The authors of the articles published by means of RT communicate to the recipients of the content about the burnout of all European Union funds in the fight against the coronavirus and using the slogan "First Brexit, ...then CorExit?" suggest that the misguided EU reaction to the pandemic may be the last nail in the coffin of European unity. Russia's use of soft power against the European Union has also been identified by the EU's East StratCom Task Force, which, by analysing Russian disinformation and manipulation, reports on individual examples, which include the presentation of coronovirus as a tool of Western imperialism and American biological weapons used against China. A separate theory of Kremlin propaganda refers to the designation of NATO as an organisation deliberately spreading the virus within the European Union (Jabłonowski, 2020). The Polish media coverage also includes statements by Prime Minister Mateusz Morawiecki, who stated at a press conference on 18 March 2020, "It is known that here the EU does not act as fast

as the nation states, not as fast as Poland. We have built a significant shield today". This type of narration is also visible in the pro-government media (Pankowska, 2020). A wave of criticism of the European Union was denounced by a letter sent on 12th March to the largest editorial offices in Europe by the deputy director of the Italian newspaper "La Repubblica", in which he accused Brussels of having a minimalist approach to the fight against the coronavirus. This narrative was also taken up by Polish Television, which reports that no effective methods of fighting the pandemic have been developed (Pankowska, 2020, 13.03).

The mistakes made by the EU administration are also spotted by Western commentators. Charlotte McDonald-Gibson in the Times notes that when the coronavirus epicentre moved from China to Europe in the first half of March the pillars of the European Union collapsed because the free movement of people and goods was stopped, border controls were put in place, and governments of individual countries were gathering medical supplies without paying attention to their neighbours. At the same time, he argues that during the EU's efforts to find aid mechanisms to combat the epidemic, populist and nationalist forces, just as in the eurozone and refugee crises, are also trying to use coronovirus in this situation. Mateo Salvini, leader of the Italian political party Northern League, suggested that immigrant boats brought coronavirus and Orban accused illegal immigrants of spreading infections (McDonald-Gibson, 2020). Katya Adler in her editorial *"Coronavirus: Can EU get a grip on crisis?"* points out that Italian Twitter has been flooded with posts from politicians who have expressed negative opinions about the role of the EU in preventing coronavirus. He also points out that French President Emmanuel Macron told the leaders of the Member States that a political response after the crisis could mean the end of the European Union. It should be mentioned that despite the negative narration adopted in the initial version of the article, the author summarizes the wide range of solutions taken by the European Union to fight the coronavirus (Adler, 2020).

The Russian narrative of events related to the fight against the coronavirus is in the sphere of accusing the European Union of failing to take appropriate and effective solutions. Nadim Zouauaui, in his editorial "*В Европарламенте оценили меры ЕС по борьбе с коронавирусом"* published in the RIA Novosti, referring to an interview with Virginie Jordan, a Member of the European Parliament, states that the European Union could not cope with the crisis and provide the necessary assistance for the spread of the pandemic on the territory of the Member States. In addition, indicating the words of his interlocutor, he states that the situation around the Coronavirus has shown an uncivilized globalization that undermines nation states. In the publication the author also refers to the failures of the Union related to talks with Erdogan on the migration crisis. In the interview there was also room for a critical assessment of the virus prevention by the American administration (Зуауи, 2020). Aleksandr Nosovich in his editorial *"Коронавирус поставил под вопрос существование Евросоюза"* states that Europe has become the world's leading distributor of coronavirus, while China has coped with the outbreak of new infections and Russia and other pro-Soviet countries are successfully fighting against the spread of the virus. Europeans, according to the author, are increasingly seen as the spreaders of the disease, and the European Union as an institution that does not deal with the problem must reflect on its existence (Носович, 2020).

Yuri Sheikhko, in the editorial *"Какие фейки о коронавирусе распространяют из России в ЕС"*, brings the reader closer to the examples of "fake" information about coronovirus, which are to come from Russia. The Sheikh, citing the words of EU spokesperson Petr Stano, argues that Russia is not the only source of misinformation about Coronovirus. In addition, based on the words of Johannes Barke (associated with Stano), he adds that most of the pipes are generated and distributed by the users themselves. On the other hand, President Dmitry Pieskov's spokesperson called the disinformation report prepared by the EEAS (European External Action Service), a Russophobic obsession and accused her of spreading unjustified accusations (Шейко, 2020).

Summary

Problems in relations between Member States became apparent long before the COVID-19 coronovirus pandemic. The differences of opinion between European countries should not be a cause for concern, since the overriding objective of international policy is to achieve the intended objectives. However, care should be taken with the relationships that are not built on the basis of accepted diplomatic solutions, but which refer to historical past, religious superiority, political emotions or claims not supported by normative sources. Any failure is an excellent excuse to accuse the European Union authorities of being incapable of conducting political dialogue. The arguments of the opponents of European integration are perfectly well placed in the field of Member States' misunderstandings. The current pandemic situation is an unimaginable challenge both for each country and for the community administration and other international organisations. In the opinion of political commentators, the pandemic is compared with military actions that have not taken place in the European arena since the end of World War II. In the era of extraordinary struggle, differences of opinions and interests of countries are born, which is also a recurring and predictable phenomenon. However, the disruption of the structure of political relations arises when an attempt is made to annihilate the political order based on accepted legal regulations and customary norms. The deformation of inter-state relations triggered by the pandemic crisis is an excellent opportunity for external interference aimed at breaking the existing division of the international political system. Recognizing the current information struggle, one cannot help but notice the hostile undertakings aimed at the current weaknesses of EU solutions. An additional challenge for the European Union is the promotion by Russian propaganda centres of activities aimed at deforming and disrupting the system of EU states by fuelling the values of nation states as advocates of cultural and religious values, opposite to spoiled liberal democratic values. The lack of understanding of contemporary security principles based on political and military alliances may cause serious problems with stabilizing Community solutions for nationalist movements, which in the end will fulfil the assumptions of Kremlin's international policy.

Abstract

Foreign direct investment stimulates the modernisation of economic activity, exports, local employment, and economic growth. Decisions to invest abroad are determined by a complex set of factors. The objective of this article is, in a first stage, to establish structural relations among several determinants of foreign direct investment recognized in the literature through exploratory factor analysis, in two different sub-samples, composed, on the one hand, by countries with high foreign direct investment net inflows and another with low, in a total of 128 countries. With the results obtained a cluster analysis was performed for each subsample. The results of the exploratory factor analysis suggest the predominance of one factor integrating indicators of good governance, information and communication technologies development and market size. It was possible to find three significant distinct clusters in each sub-sample, and in the group of high foreign direct investment, clusters with a higher share of foreign direct investment in GDP have higher institutional quality, information and communication technologies, market size and higher economic growth. Governments must have the ability to formulate and implement sound policies to foster FDI.

Keywords: Foreign Direct Investment, Governance, Information and Communication Technologies.

Introduction

Foreign direct investment (FDI) is a fundamental constituent of a system of globalisation and a stimulus to economic and sustainable development, providing social and environmental benefits. For the Secretary-General of the United Nations, António Guterres, "Inclusive sustainable development depends on a global policy environment that is conducive to cross-border investment" (UNCTAD, 2019: iii). The global FDI inflows reached 1.3 trillion of dollars, mainly directed towards developing economies (54.4%), followed by developed economies (42.9%) in 2018 (UNCTAD, 2019). Despite the magnitude of FDI, it fell by 13% compared to 2017, which represents the biggest drop since the global economic crises. Increasing foreign investment inflows is crucial, since they drive technological spillovers, enhances human capital through training and on-the-job learning, foment the international trade integration and set up a more competitive business environment, contributing to economic growth (OECD, 2002). The interest of countries in capturing FDI is recognized in the economic literature, however, the decision to invest abroad usually submits to a set of factors, which may influence it, such as institutional quality, diffusion of Information and Communication Technologies (ICT), market size, economic growth, human capital, and fiscal policy, among others.

Based on indicators traditionally recognized as influencing decisions on the location of foreign investments and on the division between countries with high and low FDI net inflows, the objective of

this article is to establish a structural relationship between these indicators for each subset and, based on the results obtained, to determine homogeneous groups of countries.

Literature Review

Foreign direct investment is very important for international development. The main determinants of FDI in literature can be classified into locational or pull factors and push factors. Among the pull factors, the traditional group of economic variables are the size of the market and the growth rate of Gross Domestic Product (GDP), economic stability, degree of openness of an economy, infrastructures, as well as several institutional variables. The push factors are related to the conditions in the source country.

Among the more traditional economic variables explaining FDI inward flows, mainly market-driven, is usually highlighted the size of the market of the host country in both absolute (GDP) and relative terms (economic growth). Host countries with higher per capita income and higher economic growth provide advantages not only for market-seeking FDI projects but also for those that are export-oriented due to the economies of scale that can be achieved and spillover effects. Empirical evidence suggests a positive effect of economic growth on FDI inflows (Gani, 2007; Saidi et al., 2018; World Bank, 2002). Empirical evidence also reveals that the market size of the host country has a positive relationship with FDI (Chakrabarti, 2001; Mohamed and Sidiropoulos, 2010; Salike, 2016), but in others the results are inconclusive (Vijayakumar et al., 2010)

Economic literature, either theoretical and empirical, emphasizes the relationship between international trade and FDI. Higher trade openness allows for greater specialization of economies, economies of scale, greater efficiency (Yazdana and Sadr, 2013), and through imports of intermediate inputs and equipment potentially enhances technology transfer. FDI is fostered when there is greater freedom of international trade since multinational companies have a higher propensity to export (Beven and Estrin, 2004). Open trade regimes mean that more markets are available for exporters and resource allocation is more efficient, providing economic welfare gains (Castro and Nunes, 2013), but it also allows to contribute to integrating the host economy in the worldwide economy (OECD, 2002). However, the relationship between FDI and openness to trade is complex as some mechanisms and policies influence that relationship, such as free trade preference agreements, tariff reductions and other incentives for FDI (Castro and Nunes, 2013; Ponce, 2006). Several authors found a significant positive relationship between FDI inflows and the degree of openness (Agiomirgianakis et al., 2006; Gani, 2007; Habib and Zurawicki, 2002; Iamsiraroj, 2016; Mathur and Singh, 2013). Liargovas and Skandalis (2012) analysed the importance of trade openness for attracting FDI inflows in a sample of developing countries. Using several indicators for the degree of trade openness, the results suggest a positive relationship in the long run.

According to UNCTAD (2000), governments are increasingly seeking to attract FDI, notably through tax incentives, to influence location decisions by foreign investors. Given the competition between countries to attract FDI, the tax burden could play an important role in this process (Bieltvedt Skeie, 2017; De Mooij and Ederveen, 2003; Desai et al., 2004; Janský and Palanský, 2019).

ICT can "improve the performance of businesses and the efficiency of markets, empower citizens and communities, increase their access to knowledge, and help to strengthen and redefine governance at all institutional levels" (United Nations, 2006, in Economou, 2008:2). Access to different ICT is crucial for businesses to benefit from the digital economy and enable enterprises to become more efficient and better connected, allowing them to perform complex online tasks (UNCTAD, 2017). According to UNCTAD (2007), the globalization of production occurs simultaneously with the growth of ICT. For Economou (2008) countries that are perceived as more attractive for foreign investors score relatively high in ICT.

ICT can be seen as a determinant of the FDI either directly as a locational factor, or indirectly through the effect on other determinants. ICT directly affect FDI because it increases efficiency, productivity,

reduces search time and its costs, allows enterprises to perform more complex online tasks, and can be considered a "pull factor" (Clarke et al., 2015; Economou, 2008; Gani and Sharma, 2003; UNCTAD, 2015). Choi (2003) using data from 14 source countries and 53 host countries found that the internet induces more FDI since it improves productivity. But ICTs can also have positive impacts on other influencing factors of FDI, such as innovation and transparency. Besides, they can facilitate exports by providing logistical support and attract foreign export-oriented investors (Overby and Min, 2001; Rhee, 2005). Nevertheless, Kotnik and Hagsten (2018) in a study for 11 EU countries didn't found a relationship between ICT use and export propensity for all of the countries included in the analysis, denoting different roles of ICT in exports dynamics. ICTs also reduces the distance effects, enabling new organizational models of international production (Economou, 2008).

The new institutional economics emphasises the role of institutions for the proper functioning of market economies (Rutherford, 2001), which currently figure, in most of their dimensions, in good governance. The World Bank (2002: 59) considers that a climate favourable to FDI flows requires, among others, fair and efficient public sector administration, low corruption and effective law enforcement, sound regulation, and measures to ensure the health and education of the workforce. The nature and quality of institutions in the host countries influence FDI since they provide opportunities or constraints for developing economic activities (Nielson et al., 2017). Institutions with low quality bring additional costs of doing business resulting from high levels of bureaucracy, corruption, political instability, and inefficient legal systems. Several studies highlight the role of institutions on FDI inflows (Ali et al., 2010; Jude and Levieuge, 2017; Rodriguez-Pose and Cols, 2017; Ross, 2019). Several studies found a negative impact of corruption on FDI, not only in level (Lambsdorff, 2003) but also in its quality (Habib and Zurawicki, 2002, 2010). Habib and Zurawicki (2010) also show evidence that differences between the level of corruption in the host and home countries impact FDI inflows.

Access to a skilled workforce is essential for multinational investors. Previous work reflects the role of the quality of human capital in the host country to attract foreign investment since it enhances the workforce productivity and boosts the return of the business, facilitates innovative activities, and the adoption of new technologies in the production process (Rizvanolli, 2012). Noorbakhsh et al. (2001) consider that, in developing countries, human capital is not only an important determinant of FDI but has also increased over time. Other studies found a positive relationship between the level of human capital and FDI inflows either in developed and developing countries (Bellak et al., 2009; Habib and Zurawicki, 2002; Shatz, 2003) while in others the relationship is not robust (Rodríguez and Pallas, 2008; Castro and Nunes, 2013).

Methodology

The empirical investigation is carried out on a sample of 128 countries for which all the necessary information was available. The list of the countries included is reported in the Appendix. Data were collected from 2014 to 2018 and the average values in this period were used to avoid specific or temporary shocks in a particular year that could influence the FDI net inflows. For the FDI inflows, it was used the FDI net inflows as a percentage of GDP. Foreign direct investment is the net inflows (new investment inflows less disinvestment) of investment to acquire a lasting management interest (10 percent or more of voting stock) in an enterprise operating in an economy other than that of the investor (World Bank, 2020).

The choice of the determinants of FDI was guided by previous empirical studies on the determinants of FDI, discussed in the literature review, and includes the market size, economic growth, indicators of good governance, ITC and human capital. The market size was proxied by GDP per capita in constant 2010 US$, economic growth was measure by the annual growth of real GDP per capita, and trade openness by the ratio of total exports plus imports to GDP. The source of data was the World Development Indicators of the World Bank. Human capital was proxied by Secondary school enrolment ratio, collected from Unesco – Institute for Statistics.

For measuring ICT, following Latif et al. (2018), it was constructed an ICT composite index using five indicators: the number of internet users, secure internet servers, fixed telephone subscriptions, fixed broadband subscriptions, and mobile cellular subscriptions, all per 100 people. Data were collected from the International Telecommunications Union, ITU.

Institutional quality is measured by the Worldwide Governance Indicators, developed by Kaufmann, Kraay and Zoido-Lobaton (1999) to the World Bank: Voice and Accountability, that capture the perceptions of the extent to which a country's citizens are able to participate in selecting their government, as well as freedom of expression, freedom of association, and a free media; Political Stability, that measures the perceptions of the likelihood of political instability and/or politically-motivated violence, including terrorism; Government Effectiveness, that captures the perceptions of the quality of public services, the quality of the civil service and the degree of its independence from political pressures, the quality of policy formulation and implementation, and the credibility of the government's commitment to such policies; Regulatory Quality, that captures the perceptions of the ability of the government to formulate and implement sound policies and regulations that permit and promote private sector development; and Rule of law, that captures the perceptions of the extent to which agents have confidence in and abide by the rules of society, and in particular the quality of contract enforcement, property rights, the police, and the courts, as well as the likelihood of crime and violence. These indicators range approximately from -2.5 to 2.5, with higher scores denoting better government performance.

From the variable FDI in percentage of GDP, a binary variable was defined – FDIbin – based on the mean value. Countries with low mean values of FDI are categorized as Low FDI economies while countries with high mean value are categorized as High FDI economies:

$$\text{FDIbin}_i = \begin{cases} \text{High FDI economies} & \text{if } \dfrac{\text{FDI}_i}{\text{GDP}_i} \geq 4.085\% \\ \text{Low FDI economies} & \text{if } \dfrac{\text{FDI}_i}{\text{GDP}_i} < 4.085\% \end{cases} \quad \forall i \qquad [1]$$

As a result, the sample was divided into two sub-samples according to whether the average value of FDI as a percentage of GDP is above (high FDI) or below (low FDI) the average.

The analysis will be performed in two steps: first, it was made an Exploratory Factor analysis to look at the structural relationship between the variable in each sub-sample; second, with the factors extracted, a cluster analysis was carried out to identify homogeneous subgroups of countries within the two subsamples. ANOVA was applied to examine how well the used variables discriminate among clusters.

Results and Analysis

Sub-samples characteristics

The sub-sample of countries with high FDI consists of 33 countries, of which 6 are European, 11 are African, 8 are Asian and 8 are from Latin American and the Caribbean. According to the classification of economies by per capita GNI in June 2018 by the United Nations, 30.3% of those countries belong to the *High-Income* group, 21.2% to the *Upper Middle Income*, 24.2% to the *Lower Middle Income* and 24.2% to the *Low Income*. The other sub-sample includes 95 countries, from which 24 are European, 2 American, 31 African, 24 Asian, 12 from Latin American and the Caribbean, and 2 from Oceania. 38.9% of those countries belong to the *High-Income* group, 21.2% to the *Upper Middle Income*, 23.2% to the *Lower Middle Income,* and 16.8% to the *Low Income*.

Figure 1 and Figure 2 reports the level of FDI net inflows and the values for the FDI in percentage of GDP (mean values in the period 2014-2018) in the two sub-samples.

Fig. 1: FDI net inflows (average values in the period 2014-2018) in countries with high net inflows in percentage of GDP

Fig. 2: FDI net inflows (average values in the period 2014-2018) in countries with low net inflows in percentage of GDP

Factor Analysis

To assess the validity of the EFA it was used the Keiser-Meyer-Olkin criterion, having an observed value of 0.781 and 0.891 for the sub-samples of high and low FDI, respectively, denoting sampling adequacy, and Bartlett's test of sphericity (χ^2=467.22 for the high FDI sample and χ^2 =1215.08 for the other), significant at (p<0.0001) in both sub-samples, concluding that the variables are significantly correlated, so the AEF has proceeded. The relational structure of several FDI determinants recognized in the literature was evaluated by the Exploratory Factor Analysis of the correlation matrix, with the extraction of factors by the method of principal components with varimax rotation. For the subsample of low FDI economies, human capital was removed since the communality value was below 0.5. Common factors retained were those who had eigenvalues greater than one and according to the screen plot. Loadings are high, all over 0.70. As reported in Table 1, the factor analysis for the countries with high FDI led to four factors that explain 88.22% of the variance. Factor 1 (F1), which explains 59.39%

of the variance, includes all the dimensions of good governance, the level of digitalization, openness, and GDP per capita. Factor 2 (F2) is related to corporate taxes and explains 10.42% of the variance, Factor 3 (F3) to economic growth (explains 9.23% of variance), and factor 4 (F4) to human capital (9.18%).

Percent of variance explained (%)	59.390	10.421	9.227	9.182	
Cumulative percentage (%)	59.390	69.811	79.038	88.22	

For countries with low FDI inflows in percentage of GDP, three factors were retained that explains 83.42% of the total variance (Table 2). F1 includes all the dimensions of good governance, the level of digitalization and market size, and explains 58.52% of the variance. F2 includes taxes and openness (14.48% of variance) and F3 is composed of economic growth.

Table 2: Factor analysis for countries with low FDI net inflows (in % of GDP)

	Component Factor Loadings			Communalities
	F1	F2	F3	
Rule of Law	**0.969**	0.149	0.067	0.966
Government effectiveness	**0.952**	0.178	0.08	0.944
Control of corruption	**0.949**	0.114	0.043	0.915
Regulatory Quality	**0.938**	0.172	0.105	0.920
Market size	**0.858**	0.093	-0.304	0.837
Voice and Accountability	**0.820**	-0.036	0.277	0.749

Political Stability	**0.802**	0.234	-0.004	0.699
ProfitTax	-0.027	**-0.865**	0.012	0.749
Openess	0.300	**0.733**	0.067	0.631
Economic growth	0.064	0.045	**0.974**	0.955
Percent of variance explained (%)	58.516	14.477	10.429	
Cumulative percentage (%)	58.516	72.993	83.422	

Comparing the factors obtained for the two sub-samples, it should be noted that F1 (which explains a higher percentage of the total variance), includes the indicators of governance, market size and ITC (and degree of openness in the case of countries with high FDI). However, the contribution of each variable to the factor, as measured by the absolute value of the loadings, is different in the two sub-samples. While in countries with low FDI the Rule of law, Government effectiveness and Control of corruption are the variables that most contribute to the factor, in countries with high FDI are Regulatory Quality, Rule of Law, and Control of corruption.

Cluster Analysis

Based on the factors obtained on EFA and the values of FDI as a percentage of GDP it was made a cluster analysis to group countries in each sub-sample with similar patterns. A hierarchical cluster analysis was applied, with the nearest neighbor method using the squared Euclidean distance as a measure of dissimilarity among countries. After the analysis of the dendrogram, a three clusters solution was decided according to the R^2 criterion. Subsequently, the analysis was refined from the K-means technique and the three-cluster resolution provided the most interpretable result for both sub-samples. Table 3 reports, for the three clusters retained, the average values for the variables in the subsample of countries with high FDI net inflows. The analysis of the F-value of a one-way ANOVA allows concluding that the clustering variables' means differ significantly for the FDI (Sig.<0.001), Factor 1 (Sig.<0.05) and Factor 3 (Sig.<0.10), and the variables that allow greater discrimination among the clusters are FDI and Factor 1. Cluster 2 (C2) has the highest average values for FDI, flowed by Cluster 1 (C1) and Cluster 3 (C3).

Table 3: Cluster centers and ANOVA for countries with high FDI

Variable	Final Cluster Centers			ANOVA				
	Cluster 1 (C1)	Cluster 2 (C2)	Cluster 3 (C3)	Sum of Squares	df	Mean Square	F	Sig.
	n=5	n=2	n=26					
FDI (% GDP)	20.584	38.024	6.443	2451.640	2	1225.819	173.393	0.000
Factor 1	1.111	1.513	-0.330	13.585	2	6.792	11.065	0.000
Factor 2	0.068	0.197	-0.028	0.122	2	0.061	0.057	0.944
Factor 3	0.265	1.489	-0.166	5.496	2	2.748	3.111	0.059
Factor 4	0.017	0.190	-0.018	0.082	2	0.041	0.039	0.962

The economies with the highest net inflows of FDI as a percentage of GDP (C2) perform best in F1, i.e. in good governance, ICT, GDP per capita, and openness. This pattern is also visible for C2, with an average FDI of 20.58% of GDP, the second-highest, compared to C3, where that ratio is only 6.4%. Except for Mozambique (C1), the clusters with the highest share of FDI in GDP are high-income countries. Of the countries in C3 where FDI varies between a minimum of 4.2% and a maximum of 11.7% of GDP, 30.8% belong to the Lower middle-income group, 26.9% of upper middle income, 26.9% of low income and 15.4% of high income (Figure 3). Almost all (92.3%) are developing economies and 38. 7% are African, 30.7% are from Latin America and the Caribbean, and 23.1% from Asia.

Legend: The line in bold represents the median, framed between the 1st quartile (lower end of the box) and the 3rd quartile (upper end of the box). The lower and upper bars represent, respectively, the minimum and maximum distributions.

Fig. 3: Boxplot of FDI net inflows (% GDP) by cluster and level income in countries with high FDI

For countries with FDI ratios in GDP below the sample average, 3 clusters were obtained, and FDI values, F1 and F3 differentiate more the groups of countries. The largest cluster (C2), with 68 countries, has the highest average FDI value of 2.38% of GDP and Standard Deviation (SD) of 0.936, ranging from 0.30% to 4.05% (Table 4). On the contrary, in C3, the FDI net inflows are negative. Contrary to the sub-sample of countries with high FDI, the same pattern is not found for F1. However, for F3, which is among the three factors that most discriminate the clusters, it is found that the subgroup (C2) with higher FDI also perform better in economic growth.

Table 4: Cluster centers and ANOVA for countries with low FDI

Variable	Final Cluster Centers			ANOVA				
	Cluster 1 (C1)	Cluster 2 (C2)	Cluster 3 (C3)	Sum of Squares	df	Mean Square	F	Sig.
	n=5	n=68	n=22					
FDI (% GDP)	-2.148	2.375	1.169	108.860	2	54.430	59.911	0.000
Factor 1	1.318	0.147	-0.754	22.674	2	11.337	14.623	0.000
Factor 2	0.224	-0.097	0.250	2.263	2	1.132	1.135	0.326
Factor 3	-0.225	0.394	-1.168	40.854	2	20.427	35.360	0.000

In C2 most countries are developing (63.2%), and investment flows are mainly to Europe (29.4%), Africa (22.1%), and Latin America and the Caribbean (14.7%). In this group, 38.2% are high-income and 25% low-middle-income economies. C3 only includes developing economies, of which 27.3% are high-income and 27.3% low-income and concentrated in Africa (54.5%) and Asia (36.4%) (Figure 4).

Legend: The line in bold represents the median, framed between the 1st quartile (lower end of the box) and the 3rd quartile (upper end of the box). The lower and upper bars represent, respectively, the minimum and maximum distributions.

Conclusions

In today's globalised world it is difficult for some countries to maintain their competitiveness without FDI. Foreign investment inflows not only promote and transfer production technology and know-how as well as contribute to competitiveness and allow access to international trade networks.

In a sample of 128 countries divided between economies with FDI as a percentage of GDP above and below the average, this article investigated the structural relationship between several determinants of foreign direct investment in each sub-sample, namely, the six key dimensions of governance present in the Worldwide Governance Indicators (regulatory quality, rule of law, control of corruption, government effectiveness, voice and accountability, political stability and absence of violence), ICT, market size, economic growth, openness to international trade and human capital. The findings show that the institutional environment is crucial as it creates favorable or discouraging conditions for foreign investment. To invest abroad is fundamental to find an enabling environment in the host country that is “investor-friendly” (OECD, 2002). Good governance with a solid rule of law, efforts in controlling corruption, with political stability and policies and regulatory frameworks to foster a well-functioning business sector is crucial to attracting foreign investors. Access to different ICT also allows businesses to benefit from the digital economy favoring FDI.

Attract foreign investment to endorse economic diversification and structural transformation in developing countries is a growing need, but FDI must be a sustainable investment to promote social and environmental developments as well.

Abstract

Information and Communication Technologies (ICT) developments, in many different strands, are growing continuously with high rates, and are seen as an engine of growth for the world economy. The objective of this article is to analyse the non-linear impacts of ICT on economic growth in large panel data covering 126 countries over the period 2002-2017, by employing data on ICT diffusion, particularly internet, mobile and fixed phone subscriptions, and two indexes purpose-built. The results suggest that ICT diffusion has a positive effect on economic growth, but the marginal positive effect lessen as ICT diffusion enlarges and Internet penetration has greater effects than the mobile phone. The quality of governance is also a crucial determinant of economic growth. Some countries need to develop strategies to promote and increase the effects of ICT diffusion on economic growth.

Keywords: Information and Communication Technologies, governance, economic growth, human capital.

Introduction

Information and Communications Technology (ICT) is "one of the most potent forces in shaping the twenty-first century … [and] is fast becoming a vital engine of growth for the world economy" (G8 Information Centre, 2000: 1). The traditional version of the neoclassical theory of economic growth is that differences in economic growth rates are the result of exogenous technological differences (Cass, 1965; Solow, 1956; Swan, 1956) and sustained exogenous growth in the input supply (such as population growth). Romer's (1986) article on endogenous growth gave a great boost to economic growth theory and subsequent empirical work on the determinants of economic growth. The theoretical literature emphasises the positive effects of ICT on economic growth (Acemoglu and Robinson, 2012; Hanclova et al., 2015), although negative effects are also presented in the literature (Kenny, 2003). Vu et al. (2020), in a literature survey of the papers that analyse the link between ICT and economic growth, summarises the main effects in: 1) learning, technology diffusion, and innovation; 2) quality of decision making; cost reduction and increased choice that has positive effects on demand and supply. ICT diffusion can be an enabler of productivity growth by enhancing the efficiency in the uses of production factors and facilitating the adoption of other technologies (Cirera et al., 2016). However, empirical research suggests inconsistent results. While some revealed positive effects (Inklaar et al., 2005; Latif et al., 2018; Myovella et al., 2019; Pradhan et al., 2018; Vu, 2011), others found negative or mixed, (Bojnec and Fertő, 2012; Maurseth, 2018; Wamboye et al., 2015). This may result from the non-linearity of the ICT effects on economic growth.

The extent of the contribution of ICT towards economic growth is an ongoing debate. This study aims to contribute to the existing empirical literature on the impact of ICT on economic growth, analysing the non-linear effects of ICT diffusion on a large panel data of countries to determine if positive effects

of ICT only can be achieved after a certain threshold or if its impact only occurs up to a certain critical level beyond which it ceases to have positive effects. The effects of internet, fixed and mobile phone usage on economic growth will be estimated and also through two indexes constructed from those indicators. It will be also analysed the importance of governance quality to economic growth.

The remainder of this paper is designed as follows: in the next section, a comprehensive review of literature is performed on the theoretical effects of ICT diffusion and governance on economic growth and of previous empirical research. The proposed methodology, the model to be estimated and the data will be presented afterward, followed by the presentation and discussion of the results. The paper closes with conclusions and discusses future work.

Literature Review

This section aims to review the existing literature on the determinants of economic growth, focusing on ICT and governance, and whether there is consensus among researchers on their effects on economic growth. Since our study is based on panel data, the review of the empirical literature will emphasize papers using panel data. The reviewed papers are from academic journals, mainly indexed on Web of Science or Scopus, selected by their impact (number of citations) and if possible published recently, and other influential publications. There was also the concern to integrate papers with different perspectives and findings.

In the neoclassical growth model, economic growth, in the long run, is explained by exogenous changes such as in population growth or technological progress (Solow, 1956). With the developments in economic growth theory, in particular endogenous growth theory (Lucas, 1988; Romer, 1986), and subsequent works (Aghion and Howitt, 1992; Grossman and Helpman, 1991) technological change has been endogenized. Several studies have emerged investigating the endogenous factors that determine economic growth. Technological changes, including ITC, can boost economic growth (Acemoglu and Robinson, 2012; Gwilliam et al., 2008). Theoretical studies suggest that ICT change the way how transactions are made, facilitates access to the global market, reduces the costs of doing business, allows enterprises to produce better and helps in decision-making, creates important spillovers and externalities, enhances market transparency and reduces information asymmetry (Bojnec and Fertő, 2012; Cheng et al., 2020; Röller and Waverman, 2001; Vu, 2011, Vu et al., 2020). Hofman et al. (2016) claim that ICT contributes to economic growth since it satisfies the demand for digital products and increases the productivity and investments in sectors that use ICT. Furthermore, ICT supports human capital development through training, education, and better health care (Dahlman et al., 2016; Myovella et al., 2019). Besides the benefits on economic growth, it also improves life expectancy, level of democracy, health outcomes and reduces literacy and poverty (Gwilliam et al., 2008; Myovella et al., 2019). There are also theoretical arguments of negative effects on economic growth. Kenny (2003) pointed out that although the use of the internet may provide better functioning of markets and firms may also bring lower returns for the less developed counties due to the negative externalities associated with e-commerce.

The existing empirical studies vary in the proxies of ICT, other independent variables, sample, and estimation methods, thus making it difficult to compare the results. However, empirical research leads to inconsistent results. Myovella et al. (2019) found a positive contribution of ICT (mobile phone subscriptions, internet users, fixed broadband subscriptions) to economic growth in the two groups studied, 41 Sub Sahararian Africa and 33 OECD countries. Niebel (2018) analyse the impact of ICT (information technology equipment, communication technology equipment and software) on economic growth in developed, emerging and developing countries and confirm the positive link, and that there aren't significant differences among the three group of countries. On the contrary, Bojnec and Fertő (2012), in 34 OCDE countries over the period 1998-2009, found a negative and significant effect of total broadband per 100 inhabitants on growth, while growth is significantly positively associated with access channels per 100 inhabitants, and insignificant associated with standard access lines per 100 inhabitants. Also, Maurseth (2018) found that Internet has negative and significant effects on economic growth on data for 207 countries from 1991 to 2015, while Choi and Yi (2009) with the same data but

for the period 1991-2000 had found a positive role on economic growth. Previous research has also investigated the presence of non-linear effects of ITC on economic growth (Bahrini and Quaffas, 2019; Roller and Waverman, 2001; Sassi and Goaied, 2013; Wamboye et al., 2015; Vu, 2011). These non-linear effects can reflect the network effects if ICT levels need to reach a certain threshold to boosts economic growth. In this case, economic growth results from the direct network effects derived from the sharing of data, and indirect effects that emerge from the use of complementary services (Wamboye et al., 2015). Sassi and Goiaed (2013) also found significant non-linear effects of internet users, mobile users, telephone lines, and ICT imports on economic growth. However, telephone lines and ICT imports need to achieve a certain threshold to impact positively economic growth. In contrast, also in the presence of non-linear effects, the marginal positive change on economic growth can be at an ever slower pace as the diffusion of ICT increases (Vu, 2011). In a panel data of 102 countries for the period 1996-2005, Vu (2011) found that ICT penetration boosts economic growth, and the marginal effect of the penetration of internet users is larger than mobile phones and personal computers. Wamboye et al. (2015), in Sub-Saharian African countries, found a linear negative impact of ICT (mobile phones, internet, and fixed telephone lines) but a robust non-linear effect of fixed-line telephones and mobile cellular on labor productivity growth. Other studies analyse the non-linear effects (Albiman and Sulong, 2017; Bahrini and Quaffas, 2019; Röller and Waverman, 2001), but the contribution of ICT towards economic growth is still under debate.

Governance is the "manner in which power is exercised in the management of a county's economic and social resources for development" (World Bank, 1992: 1). Good governance matters for economic growth since if there is accountable and efficient management by the public sector it provides a framework for market development and economic growth. Several econometric studies tested the relationship between governance performance and economic growth and found a positive relationship (Bota-Avram et al., 2018; Islam and McGillivray, 2020; Kim et al., 2018; Law and Azman-Saini, 2012; Olson et al., 2000).

Model, Methodology and Data

This section presents the theoretical framework based on an extended version of the standard economic growth model, the reduced form to be estimated, and data to determine the effects of ICT and governance on economic growth. The empirical investigation on the impact of ICT on economic growth is examined for a panel of 126 countries, for which all the necessary information was available, in a period of 16 years (2002–2017). The model specification will include a quadratic term for the ICT variables to capture potential non-linear effects of ICT on economic growth, and a set of control variables. Several indicators of ICT will be included, and we will set up two indexes of ICT, one of them employing Principal Component Analysis. It will be presented some descriptive statistics of the main variables used to analyse the performance of the countries. The empirical analysis will be conducted employing alternative econometric techniques, such as pooled OLS, fixed effects (which allows the intercept to vary for each cross-section), and random effects (where intercepts are treated as random variables) models. It will be performed diagnostic tests to decide between pooled or panel data, and the Hausman test will be used to determine the appropriate model to use (fixed or random effects model).

To capture the impact of ICT on economic growth, we consider a Cobb-Douglas production function (Mankiw et al., 1992):

$$Y_{i,t} = A_{i,t} K_{i,t}^{\alpha} H_{i,t}^{\beta} L_{i,t}^{1-\alpha-\beta} \quad [1]$$

Where Y is Gross Domestic Product, *K* represents the physical capital, *H* the human capital, *L* the labor force, *i* each country in the panel and *t* the time. Taking the logarithms of eq. [1]:

$$lnY_{i,t} = lnA_{i,t} + \alpha lnK_{i,t} + \beta lnH_{i,t} + (1-\alpha-\beta) lnL_{i,t} \quad [2]$$

Considering that technology varies over time, according to the following expression, where $\theta_{i,t}$ represents a country technological growth:

$$A_{i,t} = A_0 e^{\theta i,t} \quad [3]$$

After log transformation is given by:

$$lnA_{i,t} = \ln A_0 + \theta_{i,t} \quad [4]$$

Supposing that ICT can boost technological progress, a relationship between these two variables can be expressed through (Majeed and Ayub, 2018):

$$\theta_{i,t} = \delta_1 + \delta_2 ICT_{i,t} \quad [5]$$

Replacing eq. [5] in [4] and considering $\beta_0 = log\ A_0 + \delta_1$, we obtain:

$$lnY_{i,t} = \beta_o + \beta_1 ICT + \beta_2 lnK_{i,t} + \beta_3 lnH_{i,t} + \beta_4 lnL_{i,t} \quad [6]$$

The model will be estimated including some determinants that are traditionally recognized in the literature to influence economic growth, and takes de following form:

$$\ln Y_{i,t} = \beta_1 ICT_{i,t} + \beta_2 ICT_{i,t}^2 + \beta_3 GOV_{i,t} + \beta_4 INV_{i,t} + \beta_5 HC_{i,t} + \beta_6 LF_{i,t} + +\beta_7 ITRA_{i,t} + u_i + \varepsilon_{i,t} \quad [7]$$

Y represents GDP per capita in constant 2010 USD and data were collected from the World Development Indicators from the World Bank. The variables for ICT are: number of internet users, fixed telephone subscriptions, and mobile cellular subscriptions, all per 100 inhabitants. Data were collected from the International Telecommunication Union. To measure ICT diffusion it was also established two indexes: one obtained through an unweighted average of the three indicators (ITC Index) (Majeed and Ayub, 2018), and other using the Principal Component Analysis (ICT Index (PCA)) (following Latif et al., 2018; Rath and Hermawan, 2019). In this case, the eigenvalue rule higher than one was used as a criterion to choose the components, and according to the screen plot. One component was retained that explains 75.70% of the total variance. All the variables are used to analyse the robustness of the results. We explore the non-linear effects by including polynomial terms in ICT variables into the regression model. Considering the non-linear effects of ICT on growth, the extreme point will be calculated through:

$$\frac{\partial lnY_{i,t}}{\partial ICT_{i,t}} = \beta_1 + 2\beta_2 ICT_{i,t} = 0 \ \wedge \ \frac{\partial^2 ICT_{i,t}}{\partial ICT_{i,t}^2} = 2\beta_2 \quad [8]$$

If $\beta_1 < 0$ and $\beta_2 > 0$ there will be a threshold that a country must achieve to have growth effects from ICT, and the hypothesis of network effects occurs. On the contrary, if $\beta_1 > 0$ and $\beta_2 < 0$, the second-order condition will be negative, and marginal positive effects of ITC on economic growth will lessen as the ICT penetration increases. At the margin, the total effect of the variation of ICT diffusion on the logarithm of GDP per capita can be calculated by the partial derivates:

$$\frac{\partial lnY_{i,t}}{\partial ICT_{i,t}} = \beta_1 + 2\beta_2 ICT_{i,t} \quad [9]$$

and the percentage change on GDP per capita would be given by $\left(e^{\beta_1 + \beta_2 ICT} - 1\right) \times 100$.

Good governance was measure by the six governance indicators developed by the World Bank: Rule of Law, Regulatory Quality, Government Effectiveness, Control of Corruption, Political Stability and Absence of Violence, and Voice and Accountability. These dimensions identify how "governments are

selected, monitored and replaced; the capability of the government to effectively formulate and implement sound policies; and the respect of citizens and the state for the institutions that govern economic and social interactions among them" (World Bank, 2020). They range approximately from -2.5 to 2.5, with higher scores denoting better government performance. Since these indicators are highly correlated, and for reasons of multicollinearity they cannot be considered simultaneously, it was made an unweighted average of these six indicators (GOV), as Bota-Avram et al. (2018) and Law and Azman-Saini (2012).

The model includes other variables that traditionally are recognized to influence economic growth. The differences in the accumulation of human capital are also fundamental for explaining the growth differences between countries (Barro, 1991; Rath and Hermawan, 2019; Wamboye et al., 2015). Human capital (HC) accumulation, proxied by secondary school enrolment, can enhance labor productivity and provide efficiency gains, which can have positive effects on economic growth. Labor was measured by the growth rate of the labor force (LF). Investment in physical capital is recognized in the literature as a determinant of economic growth (Barro, 1991; Levine and Renelt, 1992; Maurseth, 2018; Pradhan et al., 2018), and it was proxied by gross fixed capital formation per capita (INV). According to the Export-Led Growth hypothesis, exports foster economic growth (Balassa, 1978) through greater efficiency in the allocation of resources, higher investment and international revenues. The model has included measures of country-level trade intensities (ITRA) such as exports divided by GDP (EXP) and imports divided by GDP (IMP). Data were collected from the World Development Indicators from the World Bank.

Results and Discussion

The sample is formed by 126 countries for which all the necessary information was available and 29.4% are developed economies, 62.7% developing and 7.9% in transition, according to the classification of UNCTAD. 15.1% belongs to the low-income group, 23.8% lower middle, 24.6% upper-middle and 36.5% high income (according to the World Bank analytical classification), which is very similar to the percentages observed in the world (15.5%, 21.6%, 25.7%, and 37.2%, respectively). The results of the descriptive statistics (Table 1) show that the average for GDP per capita is USD 14,900, ranging from a minimum of USD 214 (Burundi, 2017) to a maximum of USD 112,000 (Luxemburg, 2007). For the variables of ICT, the highest observed average value is for mobile cellular subscriptions per hundred of persons, of 82.7 (Standard Deviation (SD)= 47.50), with a minimum of 0.00 (Buthan, 2002) and a maximum of 328.79 (Macau, 2017). The share of internet users is very different among countries. The average value was 36.2 per 100 inhabitants (SD=29.7). Tajikistan reported the minimum value in 2002 (0.055) while in Iceland has the highest number of users per 100 people in 2017. There are statistical differences in the use of the internet, fixed telephone and mobile phone subscriptions among countries by levels of income (Through one-way ANOVA F test equals to 1031.962, 1483.760 and 322.089, respectively, with a p-value<0.0001). The mean values for the internet, fixed telephone and mobile cellular penetration are, respectively, 5.3, 1.1, and 37.4 in low-income countries, 16.4, 6.8, and 63.4 in lower-middle-income, 31.9, 17.5 and 85.9 in upper-middle-income, and 64.5, 40.1 and 112.9 in high-income. Tukey's multiple comparison tests reveal significant differences (p-value<0.0001) among all income groups for the ICT variables. Figure 1 plots the regression between ln GDP per capita and the ICT Index by the level of income, in 2017.

Table 1: Descriptive statistics

Variable	Mean	Median	SD	Minimum	Maximum
GDP per capita (constant 2010 USD)	14900	5690	19800	214	112000
Gross Fixed Capital Formation per capita (constant 2010 USD)	3460	1445.8	4449.2	18.23	24856
Labor force growth (%)	1.43	1.39	1.78	-6.77	10.40
School enrollment secondary (%)	82.70	89.70	29.30	6.55	164.00
Exports (in % of GDP)	43.80	35.80	31.90	4.69	229.00
Imports (in % of GDP)	46.80	39.80	27.90	10.80	221.00
Governance	0.09	-0.15	0.92	-1.72	1.97
ICT Index	46.827	48.760	28.143	0.22549	144.71
ICT Index (PCA)	1.889e-015	-0.056	1.507	-2.332	4.173
Individuals using the Internet (% of population)	36.20	30.00	29.70	0.06	98.30
Fixed telephone subscriptions (per 100 people)	20.80	15.90	18.90	0.00	74.60
Mobile cellular subscriptions (per 100 people)	82.70	88.90	47.50	0.00	328.79

SD – Standard Deviation

Fig. 1: Regression between ICT Index and GDP per capita (ln) by the country's level of income, 2017

Regarding governance indicators, in 2017, high-income economies have positive median values for all six dimensions, although there are countries with negative estimates in Control of corruption, Political stability and Voice and accountability (Figure 2).

Legend: The line in bold represents the median, framed between the 1st quartile (lower end of the box) and the 3rd quartile (upper end of the box). The lower and upper bars represent, respectively, the minimum and maximum distributions.

Fig. 2: Governance indicators by country's level of income, 2017

In the upper-middle-income group, only Botswana, Costa Rica, and Mauritius score positively in all dimensions of governance and more eight countries in, at least, three dimensions. In lower middle-income countries Buthan has positive estimates for all dimensions, except Regulatory quality, and 79% of the countries have poor governance performance in all the dimensions.

The panel data regression was run for pooled ordinary least squares (OLS), fixed effects (FE), and random effects (RE). Tests diagnosis showed that OLS would produce inconsistent estimates (χ^2 =657.279, with p<0.0001), indicating that panel data is more appropriate. Using the Hausman test to guide the choice between fixed and random effects, the null hypothesis was rejected, implying that the individual effects are correlated with the explanatory variables (χ^2 =601.585, with p<0.0001). So, we concluded that the RE estimator is inconsistent and that the FE estimator is more appropriate. Therefore, we resorted to the fixed-effects estimator, allowing us to control for unobserved heterogeneity. The discussion of the results is based on the findings of the FE model, which are reported in Table 2.

The variables used for control and that are significant in the model at the level of 0.05 have the expected sign. The estimated coefficients for Gross Fixed Capital Formation per capita in all regressions are, according to the theoretical predictions, positive and statistically significant. An increase of 1 USD in per capita investment increases GDP per capita by 0.002% to 0.004% ($(e^{\beta_k} - 1) \times 100$). The importance of external trade for economic growth comes through the benefits resulting from economies of scale, comparative advantages, and increased exposure to knowledge diffusion and competition (OECD, 2000). The estimated coefficients denote the positive and statistically significant impact of exports in models (1), (2), (3) and (5), while the expected impact of the import rate is negative, although not statistically significant in all models. The labor force was not statistically significant as in Pradhan

et al. (2018). According to the results, governance performance is a very important determinant of economic growth. An increase of 0.01 points in this indicator could allow an increase in per capita GDP of 0.22% to 0.24%. The results also show evidence of the relevance of human capital to economic growth and is significantly positive in all regressions.

The estimated coefficients of ICT diffusion (β_1), when ICT is evaluated by the indicators considered, are positive and statistically significant, except for fixed telephone subscriptions that are not statistically significant although with positive signs.

The coefficients of the quadratic terms of ICT variables and indexes (β_2), are negative and statistically significant, except for fixed telephone subscriptions. These findings suggest on one hand that the effects of ICT are positive up to a certain limit or critical value, and on the other hand that the marginal effects of ICT on economic growth are positive but are decreasing as the ICT diffusion increases. These results are in line with Vu (2011). For the ICT index, this critical value is 167.26 (given by eq. 8), which is higher than the maximum observable until 2017, of 144.71, which takes place for Macau. As Figure 1 shows, for 2017 figures, all countries in the sample are below the threshold. These findings imply that although each unit increase in ICT index, GDP per capita grows lessen, countries can benefit from ICT diffusion. For ICT Index (PCA) the critical value is 9.94, which is higher than all the values obtained for each country. Regarding the number of internet users, the critical value is 78.41 per 100 inhabitants, and beyond that, the increase in the number of users ceases to have a positive impact on the growth of GDP per capita. This result shows that there are countries that can benefit from the increase in the number of Internet users. Specifically, and taking the 2017 figures as a reference, in all low-income and lower-middle-income countries, 94% of upper-middle-income countries and 17% of high-income countries, would benefit from the increase in the number of internet users. For mobile cellular subscriptions, the threshold is 360.7 per 100 inhabitants which exceeds the maximum value that is verified for Macau in 2017.

From the results of Table 1, it is also possible to calculate the marginal effects of ICT, given by eq. [9]. These marginal effects depend on the value of the variable. Considering the average values in 2017 of 31.25 for ICT index, 17.24 for internet users, and 75.65 for mobile users the marginal effects on GDP per capita growth would be 0.682%, 0.737%, and 0.285% respectively. It is worthwhile to notice that the marginal effects of ICT diffusion are larger for internet penetration than for mobile phones, as in Vu (2011) and Majeed and Ayub (2018).

Finally, since $\beta_1 > 0$ and $\beta_2 < 0$ and the marginal effect depends on the level of ICT diffusion, it is possible to conclude that the lower the level of ICT diffusion the larger are the marginal effects. Therefore, countries with lower levels of ICT could benefit more from ICT development.

Conclusions

Structural changes in socio-economic development processes, which have an impact on economic growth, occur in a society with advances in ICT, and which change the way citizens, organizations and institutions work. New technologies and greater access to information enable decision-making, support human capital development, creates important spillover and economic growth.

The main objective of this paper was to analyse the non-linear impacts of ICT diffusion on economic growth, when controlling with other variables, namely governance performance. The main findings from this empirical analysis in panel data with 126 countries over the period 2002-2017 can be highlighted in the following points. Based on the estimations, good governance is crucial to promote economic growth. The quality of governance determines the level of efficiency in providing public goods and the definition of sound policies that create a favourable climate for stable economic growth. Human capital, physical investment, and exports are also sources of economic growth.

Regarding ICT diffusion, firstly, it should be highlighted the positive influence on growth in GDP per capita. In particular, it is observed that, except for fixed telephones subscriptions that were statistically insignificant, other ITC such as internet and mobile phone usage have significant effects on growth. Secondly, and due to the non-linear effects that resulted in a concave function, a threshold was found for each indicator of ICT, beyond which there would be a marginal negative contribution to GDP per capita. However, these thresholds are far from being attained, except for the internet in some countries. Thirdly, the marginal effect of ICT on economic growth is higher through internet usage than mobile phones. Finally, the marginal effect depends on the level of ICT diffusion and the results suggest that the countries with low levels of ICT diffusion could benefit more.

The findings suggest the countries with lower levels of ICT need not only to define strategies to promote their diffusion but also to increase the effects of ICT on economic growth. Although governance resulted in a source of economic growth it would be important to understand its effects on economic growth, namely through e-government developments.

If ICT has been regarded as an engine of productivity and economic growth, in the present context of the Covid-19 pandemic it has revealed decisive. In the situation of social distancing measures that have been widely adopted, the functioning of the economies is essentially due to the use of digital technologies. It has ensured business continuity since it is helping people to communicate. The outbreak has strengthened the importance of an interconnected world, thus the need to reinforce ICT infrastructure to drive economic growth. In future research, it would be interesting to estimate the impact of ITC usage in economic performance during the pandemic.

In the severity of the situation the world is living in, good governance is central to an effective response to the crisis. But if governments need to take critical actions, some coercive in the name of the common good, they must be taken ensuring democratic principles such as transparency and accountability. This crisis highlights the need to reflect on the effectiveness of governance systems and the strengths and weaknesses of the different models of governance.

Abstract

The destinations, worldwide, have seen a progressive increase in international arrivals, consolidating their position in the international context, on the one hand, but also diversifying the source markets. The United Nations World Tourism Organization predicts 69 million Halal tourists for 2020, representing an average annual growth rate of 6.7% between 1995 and 2020.
Halal tourism has seen a growth in total number of tourists, in receipts volume, and a growth of niches, such as women and some generations, promoting a special interest in DMO's. Considering these aspects, it is a constant challenge for tourist destinations to adapt to the Halal market, thus reinforcing their competitiveness and developing the branding and image of the destination. Destinations should prepare their offer, considering the specificities of each of those niches, ensuring good performance in terms of satisfaction, and behavioural intentions, to recommend and return to destination.
This article intends to present a diagnosis regarding Halal tourism in a global perspective, considering several emerging niches, and presenting opportunities concerning tourism destination management.

Keywords: Tourism – Halal – Muslim – Women

Introduction

Exploring recent trends in the tourism sector, rapid growth in tourism in areas such as Asia, Africa and the Middle East has been visible in recent years. In these areas consumption is growing at an accelerated rate, and for this reason they are considered long-term emerging economies dominated by young populations and the middle class. A large percentage of the population in these areas is of Islamic origin and has mostly a strong purchasing power. The Islamic economy currently grows twice as fast as the world economy's pace, as more than a fifth of the world's population is of Islamic origin. According to this conjuncture, this is a factor that is considered a strong catalyst for the global economy because it is considered a market recognized for its strong purchasing and consumption power, especially in the sectors of catering, finance, tourism, fashion, media, and also in the pharmaceutical and cosmetic industry. Consequently, the Islamic market, as it is constantly growing and developing, is a strong promoter of the growth of global tourism demand, giving rise to a link with the Halal tourism segment.

As for the tourism sector, Halal tourism represents a solid growth over the last few years and is recognized as one of the sectors with the greatest impact on the global tourism balance, being recognized as an increasingly large travel market (Oktadiana, Pearce, Chon, 2016), becoming, for this reason, a very recent research area, especially in non-Islamic context (Jia & Chaozhi, 2020), from both the perspectives of practitioners and researchers (Battour & Ismail, 2016). Concerning these considerations, any strategy to develop or market Halal tourism products services must be guided by Islamic law (Shariah) (Battour & Ismail, 2016). According to the previous authors, the two concepts, 'Halal Tourism' and 'Islamic Tourism', used as being the same, in several research, are vague, presenting definitional ambiguities in terms of the Islamic law, the target customers (i.e. Muslims or non-Muslims), the location of activity (i.e. destination attributes), the product and service offered (i.e. food, facilities), and the purpose of travel (Battour & Ismail, 2016). To Jia & Chaozhi (2020), travel motivation of Islamic tourism is religious in nature, while Halal tourism is not limited to the religious motivation.

The Halal tourism market encompasses countries such as Bahrain, Jordan, Kuwait, Oman, Qatar, Saudi Arabia, United Arab Emirates, Malaysia, Indonesia, Brunei and residents in Europe, South Asia, the United States of America and the United Kingdom. Global tourism spending in 2015 reached $145 billion, expected to rise to $300 billion by 2026. Projections for 2020 predict a value of $233 billion concerning tourism expenditure by Halal tourism. Although the trend of Halal tourism is directed mainly to the countries of Asia and the Middle East, Europe and the United States of America are notably the ones that benefit the most in terms of revenue from Islamic tourists (Global Muslim Travel Index 2019). The World Tourism Organization forecasts 69 million Halal tourists, only for tourism in the Middle East by 2020, representing an annual growth average of 6.7% between 1995-2020, placing above the global average (Battour & Ismail, 2016). In 2018, there were 140 million international Muslim visitors, being projected to reach 230 million by 2026. Halal tourism is considered a very specific market with characteristic needs due to religious and cultural conditions. One of the main motivations of Halal tourism is of a religious nature associated with the Islamic faith, but other motivations are also evident such as visiting family and friends, leisure, business and cultural tourism. There are factors of preference on the part of Halal tourists that will be addressed throughout this section, which proves that Halal tourism is constantly developing, and industries and tourist destinations feel the need to adapt to the characteristics of this trend. In view of these aspects, it is a constant challenge for tourist destinations to adapt to the Halal market, thus strengthening their competitiveness and developing the branding and image of the destination. Some of the most relevant terms are presented in table

Table 1: Halal Travel Glossary

Concept	Definition
Muslim travel	Muslims travelling for any purpose.
Muslim tourism	Muslims travelling for tourism.
Halal travel	Muslim travellers, who do not wish to compromise their faith-based needs while travelling for a purpose, which is permissible or it can also be defined as Halal conscious travellers, travelling for any purpose, which is Halal (permissible).
Islamic travel	Muslims travelling mainly for religious reasons and/or to visit Islamic religious sites.
Muslim-friendly destination	Destinations catering to the needs of the Muslim travellers.
Muslim friendly facility/service	The service or the facility has considered some faith-based needs of Muslim travellers. Although Halal-friendly facility/service may also convey the same meaning, the term Muslim friendly service/facility is more appropriate.
Shariah-compliant services/facility	The service or the facility not only caters to all the key needs of the Muslim travellers, but also strictly adheres to many other Islamic requirements. This includes adhering to company governance and operations, which consider several Islamic requirements such as Halal non-interest based financing, among other aspects.

Source: Crescent Rating (https://www.crescentrating.com/online-halal-travel-glossary.html), Adapted

The current situation regarding travel by tourists from countries of the OIC (Organization of Islamic Cooperation) is constantly growing. In 2014 there were 116 million arrivals of Halal tourists valued at $121 billion, and in 2020 180 million arrivals are estimated, representing $212 billion in receipts.

Table 2: Arrivals of Islamic tourists (2010-2020)

(Millions)	Year 2010	Year 2014	Year 2020	Growth Forecast (2015-2020)
Total Muslim Visitor Arrivals	98	116	180	54.50
Total Muslim Visitor Arrivals to OIC	53	64	98	51.87
Total Muslim Visitor Arrivals	45	52	82	57.75

Source: CrescentRating, 2015, Adapted

By 2020, a growth in tourist arrivals in OIC member countries is expected, estimated at 98 million tourists, representing a growth rate of 51.87%. The growth rate, comparing to the arrival of Islamic tourists in countries that are not members of the OIC is about 57.75%, being the effort of countries that are not members of the OIC to attract Halal tourists, recognized. Traditionally countries like Singapore, the United Kingdom, Germany and France attract Halal tourists, however new trends such as Japan, Korea and Australia are current players in the competitive sector. The growth of Islamic tourists will represent 76.3% between visits in OIC member countries and non-OIC countries.

As CrescentRating (2019) refers, while Muslim travellers in general will appreciate destinations and facilities which cater to their faith-based service needs, a combination of culture, demographic, budget requirements and purpose of travel will result in unique Muslim travel segments with different preferences, being these aspects an opportunity to personalize service offerings according to their unique profiles, presented in table 3, as follows:

Table 3: Muslim key traveller profile

Key Traveller Profile	Preferences
Purpose	Leisure; Ramadan; Business
Demographic	Millennials; Females; Families; Senior Citizens
Budget	Luxury; Average Budget; Low Budget
Culture	GCC; South East Asia; Western Europe

Source: Global Muslim Travel Index 2019

The countries leading the outbound tourism of Islamic visitors are Malaysia, Indonesia and Turkey. Halal tourism worldwide accounts for more than 10% of spending. The United States of America and Europe represent the markets with the highest demand for Halal tourism, accounting for 44% of the global market corresponding to $64 billion of receiving tourism spending. Asian and Middle Eastern countries are a strong trend and account for more than a third (37%) of world spending. For OIC countries, this market represents 60% of the global market, resulting in $60 billion of issuing tourism spending. Muslim tourists contribute to the world economy not only through tourist revenues and expenditures, but also through the resulting tax impact during their travels. Halal tourism contributes to the payment of fees and taxes on their trips abroad, as most countries charge tourists a fee when buying goods and services. Halal tourism contributes to the payment of fees and taxes on their trips abroad, as most countries charge tourists a fee when buying goods and services. These industries benefit from tax rates in the sense that they earn revenue on their expenses as well as property taxes, licenses, among others. These taxes paid by tourists also contribute to the payment of wages to workers in the tourist industry. Analysing from an overview and through the data presented above, the destinations that distinguish themselves as leaders in the market of halal tourism demand, are Malaysia, Turkey and the United Arab Emirates as well as Indonesia, Saudi Arabia and Qatar. Recently, one of the emerging destinations is Japan which stands out equally for the demand for Halal tourism. Malaysia is currently and since 1974 the most popular destination on the part of the demand for Halal tourism, especially due to the

attention of the Malaysian government with the foundation of the "Research Centre for the Islamic Affairs Division", a department specialized in Halal needs. Tourists from the Middle East represent a lucrative niche market in Malaysia's tourism industry as they have strong purchasing power. For the same reason, the Malaysian government has joined initiatives such as "Feel-at-Home" and "Ain Arabia", these are advertising campaigns that promote Middle Eastern culture and advertise services such as restaurants and tourist information presented in Arabic language. Tourist establishments adhere to the growth of Halal tourism by adapting their multilingual menus and hiring employees fluent in Arabic both in catering and in accommodation and commerce (Shafaei & Mohamed, 2015). The emergence of the Halal tourist market in Japan is due to the combination of several factors, that is, the efforts made to adapt services to the Halal tourist market. Examples of this adaptation are visible at airports with prayer rooms with adequate space, as well as hotel units and the restaurant sector. Other influencing factors that attract Halal tourists is the devaluation of the Japanese currency and the ease of obtaining visas, a measure adopted in 2013 comprising 66 countries, some of them members of the ICO. Another attractive factor for Halal tourists is the provision of applications for smartphones that indicate which Halal restaurants are closest, as technology plays an important role in this tourist segment. The interest on the part of Halal tourism for this tourist destination is sustained not only by presenting itself as a recent trend in the "Halal friendly" market, but also due to the historical connection that remote to the period between the fifteenth and eighteenth centuries where this region was ruled by the Ottoman civilization. Croatia is one of the European destinations that has been adhering to the Halal certificate and is considered a "Halal friendly" destination. More and more tourist industry service, including hotel units, restaurants, and travel agencies, are interested in obtaining a Halal friendly certificate granted by the Center for Halal Quality Certification of the Islamic Community.

Literature Review. Defining Halal Tourism and its niches

Halal has become an area of interest for tourism academics and industry professionals in recent years mainly due to the increasing global Muslim population. According to Kim, Im & King (2015), Al-Ansi, Olya, & Han, (2018) and Al-Ansi & Han, (2019), the halal-friendly environment and availability of Muslim friendly attributes are very important aspects to attract Muslim tourists. To Duman (2011) "Islamic tourism" can be defined as “the activities of Muslims traveling to and staying in places outside their usual environment for not more than one consecutive year for participation of those activities that originate from Islamic motivations which are not related to the exercise of an activity remunerated from within the place visited”. Sureerat (2015) defines Halal tourism as the offer of packs and destinations that are particularly designed to meet Muslim needs. Osman (2015) defines Muslim tourism being based on Islamic education that encourages individuals, especially women and children, to travel with their muhrim, that is, someone who has a blood relationship with them to provide them with protection. The Islamic Tourism Centre (ITC) defined Islamic tourism as "an activity, event and experience absorbed in a state of travel that is in line with Islam. Not making the distinction between these two types of tourism may not be well accepted in Muslim culture perspective. The term halal is defined as "That which is permitted, with respect to which no exists, and the doing of which the law-giver, Allah, is allowed" (Al-Qaradawi, 2010), i.e. the term is understood as permitted/authorized according to Islamic teachings (Sharia law). Halal is also one of 5 actions that categorizes the morality of human action in Islam, the other being Fard (mandatory), Mustahabb (recommended), Makruh (poorly seen) and Haram (forbidden) (Al-Faruqi, 1992). From the Islamic perspective, Halal, as already defined, refers to any practice or activity in tourism that is allowed according to Islamic teachings. On the other hand, the term "Islamic" is precisely applied only to what relates directly to faith and its doctrines (such as Shariah law, Islamic values, principles and beliefs), (Douglass & Shaikh, 2004). These points of view suggest that Muslim men, women and countries are not necessarily Islamic, and Islamic man and Muslim man have different definitions. Halal tourism is considered a very specific market with characteristic needs due to religious and cultural conditions. One of the main motivations of Halal tourism is of a religious nature associated with the Islamic faith, but other motivations are also evident such as visiting family and friends, leisure, business, and cultural tourism.

Halal tourism is a subcategory of tourism targeted at Muslim families who obey Islamic rules. Hotels in such destinations do not serve alcohol and have segregated pools and spas. Malaysia, Turkey, and more countries are trying to attract Muslim tourists from all over the world by offering amenities according to their religious beliefs. Currently, there are no international standards for Halal tourism. The Halal tourism industry also provides flights where there is no alcohol service or pork products, hours of prayer are announced, and religious programmes are broadcast as part of the on-board entertainment pack. Many international hotels serve halal dining options, prepared according to the teachings of Islamic Sharia and free from any substance prohibited by Islam, such as pork and alcohol. Some hotels have employees from Muslim culture for the purpose of service translations and other types of assistance that Muslim tourists may need.

Recent research, presented in table 4, demonstrates the recent and growing interest in halal tourism, degree of satisfaction regarding the offer of tourist product, values, attributes of halal-friendly hotels, tourists' behavioural intentions, motivational factors for travel, identification of trends and opportunities, quality attributes regarding the services provided, and analysis of the opinion of tourists on social networks.

Table 4: Recent Research in Halal Tourism

Author	Goal	Research project	Notes and results
Abror Abror, Yunia Wardi, Okki Trinanda & Dina Patrisia (2019)	To find the relationship between Halal tourism, religiosity, customer engagement, and tourist's satisfaction.	The population of the study were Muslim tourists who visited West Sumatra, Indonesia. The data were 393 respondents.	Halal tourism and customer engagement have significant impacts on the tourist's satisfaction. Religiosity is a significant moderating variable on this relationship.
Padmali Rodrigo, Sarah Turnbull (2019)	Understand the perceived values considered by Muslims when undertaking a halal holiday.	Application of 21 semistructured interviews conducted among Sri Lankan Muslims.	Islamic values captured by Iman play a significant role in customer expectations regarding perceived consumption values. Thus, tourism and hospitality organizations need to develop products and services that are Sharia-compliant. Such initiatives would enable tourism and hospitality firms to demonstrate their responsiveness to specific cultural needs.
Yoksamon Jeaheng, Amr Al-Ansi & Heesup Han (2019)	To identify the attributes of a halal-friendly hotel and evaluate the role of these attributes in motivating the behavioural intentions of Muslim customers	Qualitative and quantitative approaches identified 30 validation and reliability items involving five distinctive dimensions, which included halal-friendly service, facilities, foods and beverages, privacy, and customer-service equality.	The findings showed the variance in intentions; three attributes were positively related to cognitive evaluation, four attributes had significant influence on affective evaluation. Cognitive and affective evaluation worked as mediators.
Amr Al-Ansi, Heesup Han (2019)	To observe the intricate procedures involved in Muslim tourists' behaviour toward a non-OIC ('Organization of Islamic Cooperation') destination. Analyse the relationships among halal-friendly destination performances, perceived value, destination satisfaction, destination trust, destination loyalty.	A psychometric analytical process was employed to achieve this goal.	The findings of the structural analysis revealed that halal-friendly destination performances highly and positively associated with the responsiveness developed constructs, which significantly contribute to predict Muslim tourists' attitudes and future desire toward a destination. In addition, the moderator effect of an overall halal-friendly destination image was evaluated on the conceptual model.
Naeem Akhtar, Jin Sun, Wasim Ahmad, Muhammad Nadeem Akhtar (2019)	Developed a research model of Halal restaurants' non-verbal messages to tourists that lead to their offensiveness and their interaction adaptation, which determine their behaviors.	Examines how non-verbal messages—defined as those that are not delivered face-to-face—trigger consumers' interaction adaptation; how experience and credence attributes moderate the relationship between interaction adaptation and consumers' offensiveness; and the relational outcomes. This model is applied to Chinese settings, where data were collected from 622 Muslims tourists who visited Halal restaurants in three of China's cities (Beijing, Shanghai, and Xian).	A positive effect of visual and audio messages on Muslim tourists' interaction adaptation and the likelihood of their offensiveness. Also found that tourists responded to their offensiveness in the form of negative electronic word-of-mouth (e-WOM) and lowered continuance purchase intentions. The experience and credence attributes positively moderate the relationship between interaction adaptation and consumer offensiveness.
Heesup Han, Amr Al-Ansi, Mehmet Ali Koseoglu, Pearl M. C. Lin, Jinah Park, Jongsik Yu & Wansoo Kim (2019)	To identify halal-friendly travel motivation factors and unearth their role in Muslim customer retention process in Korea.	Qualitative and quantitative procedures were used to achieve research objectives. A comprehensive structural model was developed to distinguish the role of all proposed indicators.	Halal-friendly travel motivations are significantly associated with customer return on investment and satisfaction, and such relationships contribute to improve customer retention. The effectiveness of higher-order structure of halal-friendly travel motivations was demonstrated. The formation of Muslim customers' post-purchase decisions was significantly moderated by the sense of belonging to a tourist destination.
Tareq Rasul (2019)	To clarify the ambiguity surrounding the concept of halal tourism. To standardise some	A systematic literature review.	The theoretical contribution of this study includes characterising the conception, definition and principle of halal tourism, and the practical

Author	Goal	Research project	Notes and results
	dimensions of halal tourism, such as conceptions and definitions, principles, scope and impacts, trends, and opportunities and challenges.		contribution includes economic, socio-cultural and environmental impacts.
Junaidi Junaidi (2020)	To depict the halal tourism concept, its business process, and investigate dilemmas faced by tourism industry and proposes strategies to resolve the constraints based on the best practice from the tourism business operators. In addition, this study tries to investigate the influence of various factors on halal tourism.	Triangulation method used by combining personal in-depth interview, documentation/literature review and field observation to generate the discussion and conclusion. Interview process was conducted by selecting four tourism operators in Indonesia who won the best halal category award by The World Halal Travel Award in Dubai. Additionally, for the empirical analysis, a questionnaire was also developed, and data collected from a total sample of 313 Muslim tourists in the region of Indonesia.	A significant and positive influence of quality and certification of halal food, male serving in the restaurants, halal activities and separate recreational facilities on halal tourism industry.
Yoksamon Jeaheng, Amr Al-Ansi & Heesup Han (2020)	To examine the critical associations among service quality attributes, perceived price, satisfaction, trust, and revisit intention.	A robust structural model was developed to achieve this objective, and a two-step analytical approach was used to test the construct measurement and the proposed structural models.	A significant relationship between the study variables directly and indirectly either as predictors or mediators. The study also evaluated the role of the moderating effect of involvement. The results supported the significant relationship on satisfaction and revisit intention only when the hotel's Muslim guest has a high level of involvement.
Sulaiman Ainin, Ali Feizollah, Nor Badrul Anuar, Nor Aniza Abdullah (2020)	Examines halal tourism trends by analysing posts (known as 'tweets') on the social networking service Twitter.	A total of 85,259 tweets were examined. Nineteen keywords (English and Bahasa Malaysia) were used in the extraction process. Using the extracted tweets, the study examined the origins of tweets among the global population related to halal tourism, identified the major populations around the world that are engaged in halal tourism tweets, analysed the sentiment valence in relation to halal tourism, and identified the popular destinations in tweets.	The findings showed that Japan is the most-tweeted-about halal tourist destination, followed by Malaysia and Indonesia. The findings can be used by the various halal tourism stakeholders to plan their future strategies in relation to halal tourism.
Erhan Boğan, Bekir Bora Dedeoğlu, Orhan Batman, Recep Yıldırgan (2020)	Investigates work- and halal-related predictors of job pursuit intention in Muslim-friendly hotels in Turkey.	Data were collected through a questionnaire of 474 hospitality students. The proposed model was tested via partial least squares structural equation modelling.	Job attractiveness and person–organization fit were both significant predictors of organizational attractiveness and job pursuit intention. Negative perceptions of Muslim-friendly tourism negatively affected organizational attractiveness. Organizational attractiveness was the most significant predictor of job pursuit intention. Organizational attractiveness complementarily mediated the effects of job attractiveness and person–organization fit on job pursuit intention.
Xiong Jia & Zhang Chaozhi (2020)	To explore Muslim tourists' needs and tourism practitioners' responses in China.	A qualitative approach, specifically in-depth interview, was adopted. This research conducted 32 in-depth interviews during July 2018, including 15 tourism practitioners and 17 Muslim tourists.	Muslim tourists' needs include six aspects, namely food, hotel, transportation, entertainment and shopping, toilet, and service staff. Regarding religious-related needs, they only demand for halal food, water-friendly toilets and prayer facilities. This research suggests halal tourism attributes developed in Islamic countries cannot be applied to non-Islamic countries.

Source: Authors

Also, Jia & Chaozhi (2020), found in their research, that Muslim tourists' needs include six aspects, namely food, hotel, transportation, entertainment, and shopping, toilet and service staff, demanding, regarding religious-related needs, halal food, water-friendly toilets and prayer facilities, being considered several changes in Muslim travel market, as shown in table 5, namely the connectivity with destinations, through smart technologies such as Artificial Intelligence and skilled human resources in the hospitality industry, reporting to this special growing market.

Table 5: Primary Halal Travel 1.0 level and a new Halal Travel 2.0 phase

	HALAL TRAVEL 1.0	HALAL TRAVEL 2.0
Objective	Sell products and services to Muslim Travellers	Engage with travellers to co-create better solutions
Enabling forces	Globalization, Technology	New technologies, Social Activism, Millennial Demographics
View of Muslim Travel Market	Travellers looking for solutions for their faith-based needs	Dynamic travellers who are active citizens in the travel space
Key concept	Adaptation	Activation
Company guidelines	Sell product and service features to Muslim travellers	Converse and engage with Muslim travellers
Value proposition	Functional and Spiritual	Connectivity and experiences
Interaction with Muslim Travellers	Transactional	Managing relationships

Source: Global Muslim Travel Index, 2019

Also, according to Crescentrating (2019), in 2018, there were 140 million international Muslim travellers - a number projected to nearly double by 2026, being almost half of these Muslim travellers (63 million – 33% less than 20 years; 34% between 20-40 years), women who spent an estimated $80 billion on their journeys. Muslim women plan their trips between 1-6 months in advance, 65% prefer free and independent travel, only 5% opt for customized guided tour; the average trip length is 4-6 days, and the majority travel about 2-3 times a year; 80% look for family-friendly attractions, 71% look for kitchen facilities and 49% look for children-friendly amenities. Considering data obtained from the previously mentioned document, two-thirds of this population were 40 years of age or younger, indicating the growing power Muslim women – particularly young Muslim women – have in the global travel market. Muslim women travellers generally seek the same things that all female travellers worldwide want, which are: - safety and security, healthy food options and good retail experiences, to incorporate their faith into their travels – whether through halal dining, accessible religious facilities, single-gender spas or beauty salons that enable them to practice modesty, practicing also eco-friendly tourism as a priority. During the pre-trip phase, during the planning phase, there are some important topics searched, such as: child-friendly options, halal food options, payment methods, shopping places, modes of transportation, special events, family-friendly attractions, accommodation, learning opportunities, adventure activities, cultural activities, and spa & wellness. Concerning Muslim women traveller faith-based service needs regarding Halal travel 2.0, it is important to analyse which aspects are included in several considered categories, as presented in table 6.

Table 6: Muslim traveller faith-based service needs 2.0

Need to have	**Halal food service**	**Salaath (prayer) facilities**	**Water friendly washrooms**	**No Islamophobia**
	Healthier halal options; Halal children meals	Prior to performing a prayer, Muslims are required to take wudhu (ablution) using water; Women areas	Muslims require water to clean themselves after using the toilet or to take wudhu; Cleanliness of wudu facilities for women	Safety has become a primary concern for Muslim travellers; Safe Travel Climate for Muslim Women Travelers
Good to have	**Social Causes**	**Ramadan (Fasting) services & facilities**	**Local Muslim Experiences**	
	Social causes (eco-friendly practices); Volunteer Groups; Social causes for women-only beneficiaries; Women-only volunteer groups.	Suhoor and iftar arrangements at restaurants; Suhoor and iftar room service; Suhoor and iftar served by female staff	Islamic heritage Tours; Interacting with local Muslim communities; Interacting with local female Muslim communities; Islamic heritage tours for females	
Nice to have	**No Non-Halal Activities**	**Recreational spaces with privacy**		
	Facilities with no non-halal services: drinking of alcohol, gambling and discotheques	Women-only spas/beauty/hair salons Women-only pools/hours Women-only gym/gym hours Women-only beaches Women-only floors in hotels

Conclusion

Through several platforms that provide information on Halal tourism in other countries, demand and supply are not always synchronized. The countries where this trend has been felt most recently are Malaysia, Japan, and Croatia. Answering the question "Is it a growing trend?", we proved that in fact this typology of tourism is growing worldwide. In the future, since this market is one of the potential holders of one third of the world's tourists, it makes perfect sense to increase the knowledge concerning this tourism niche market. As Salam Standard (2016) states, DMO's must identify stakeholders representing the government, local authorities, infrastructure managers (e.g. airport and train station operators) as well as businesses including tour operators, hotels, airlines, eateries, shopping centres, tourist attractions and event organisers, visioning the value proposition of the Muslim travel market. The deeper knowledge of this niche challenges the creation of diversified tourist products but meeting the specificities and needs of halal tourists:

- Develop awareness strategies to ensure healthy growth of Halal tourism.
- Nurture values of diversity, integration, and tolerance in different cultures.
- Create connections at the level of religion to find and value similarities rather than differences, thus contributing to greater reception and promotion of Islamic tourism.
- Innovate in new technologies with Muslim friendly applications creation, as well as the use of social networks and marketing programs according to geographic location.
- Plan specific tours for Halal tourists, offering Halal catering services, an itinerary designed to respect prayer hours, visits to mosques and other places of historical interest that identify themselves of Islamic origin and tour guides fluent in Arabic.
- Staff training to raise awareness and understand the needs of this market segment and the best way to receive Halal tourists.

Abstract
The development of the online shopping in Malaysia is expanding each year as a type of e-commerce, turning to a main concern by the government. Students have been recognized as an important role in building and maintaining this type of shopping. Thus, the purpose of this study was to identify the factors affecting university students' attitude towards online shopping. The second objective was to determine the relationship between factors such as quality, prices, saving time, wider selection & trust and the attitude toward online shopping. One variable from the Theory of Planned Behavior (TPB) was adapted in this study. This study followed the quantitative method which used the questionnaires for data collection purposes. The respondents of this study were the university students. The data then was analyzed using the Statistical Package for Social Science (SPSS). The findings of this study showed that wider selection of products, saving time, cheaper prices and trust were the most influential factors that affect the students' attitude towards online shopping. The findings also showed that all the independent variables are corelated with the dependent variable.

Keywords: Online Shopping, Attitude.

INTRODUCTION

JARING is the first Malaysian network access supplier (ISP) in 1990 and later TM Net in 1995 (Ramlan & Omar, 2011). From that time onwards, the usage of internet is expressing a huge expanding each year. The internet usage for the commercial purposes has started in 1993 with the development of the World Wide Web (Vladimir Z., 1996). The rise of the Internet and World Wide Web (WWW) as a vehicle for business exchanges, web-based business has started to become common turning into the main concern of the global communities (Harn et al., 2006). This important shift changed the way the sellers and the clients interact and conduct electronic transactions; the process has become easier, simpler, and cheaper compared to the traditional trading (Margherio L., 1998).

The internet has recently become more than a social media; it is the means of doing business as a new trend of shopping in the global market (Choudhury D., & Dey A., 2014). Online shopping is a type of

electronic trading that gives customers the chance to get their goods or services from the seller over the internet (Jusoh and Ling, 2012). With the advanced development in the internet, the physical shops have become online, and online shopping is no longer rare (Manwaluddin, I. I. et al., 2018). According to a survey that was done in France, Germany, UK and U.S. by Periscope by Mckinsey (2018), most of the consumers around the world are reaching and purchasing packaged goods through the internet.

Today, online shopping is the trend of shopping in all the countries, both developed and developing. The number of internet users in Malaysia has grown to 87% at the national level (Malaysian Communications and Multimedia Commission, 2018); and Malaysia has the highest penetration of online shoppers in Asian countries, 67% of Malaysians online (The Sundaily, 2017).

Attitude is the most important variable that influence the students' intention, which in return translated into the actual action, the online shopping. Students' attitude is affected in many ways. For example, students will have good impression when they find that online shopping is cheaper than the physical stores. This is what will give them good attitude toward the online shopping. Moreover, since the e-commerce market is growing, there is a need to identify the factors that play an important role in this development and determine the relationship between the factors and the attitude toward online shopping for the online sellers and the government to be under their concern.

This type of shopping is gaining popularity among the university students. Both undergraduate and postgraduate students are impacted by many factors like quality, prices, saving time, wider selection, and trust when ordering online. Online purchasing is cheaper than the traditional shopping since the online venders do not need the expenses of the normal operations done by the offline vendors. Furthermore, online shopping minimizes the transaction costs which is an advantage for the buyer and seller (Chandra and Sinha, 2013). Some product quality during the online purchasing is different from the real quality needed by the students. This lowers the level of trust in the online stores. The majority of the students are affected by the late delivery of the products. It happens that sometimes a student orders a product and discover that the product has been delivered to the wrong place or branch. This certainly result in the student losing his time waiting and contacting with the online vendor.

Moreover, online shopping provides students with a wider selection of products. This makes students confused for selecting the suitable product they are looking for. A recent study conducted in 2017 by Citizens Advice on some 2,000 online shoppers shows that although customers are satisfied with the online shopping, about 66% of the customers have had at least one issue with a product delivery in the previous 12 months (Consumer Rights for Parcels Delivery, 2017). Based on the problems mentioned above, there is a need to investigate whether or not these issues influence attitudes of university students toward online shopping. This paper will fill the gap found in literature review. It focuses on the five factors because the studies on factors that influence the attitude to purchase online among the university student consumers are still lacking.

Moreover, despite having a considerable number of Internet users, students are using online purchase only for small number of categories the most like booking hotels and flights. Thus, it is important to understand the factors that influence the Online shopping which is still lacking. Delafrooz et al., (2010) stated that the research on the attitudes toward online shopping is still lacking since the e-shopping is still the early stages. “The influence of the attitude was by far the most influential variable and the focus of future studies should be on the underlying factors of the attitude”, (Norshazliza, 2018). More importantly, Malaysia is one of the pioneers countries in Asia that has stablished a ministry that is related to the electronic trade development, and the popularity of shopping online is rapidly increasing. Despite this, the number of the companies which adopt e-commerce is still low. Thus, this paper aims to determine the factors affecting the university students’ attitude toward online shopping.

Review of Literature

Online Buying has been one of the subject matters for researchers in both Marketing Sciences and IT as the e-business is expanding. Rastogi (2011) discovered that online shopping nowadays is an important part of our life because of the technological advances in internet and our hectic life. This has resulted in customers going for easier, cheaper, and secure shopping. Online shopping has provided many advantages as it saves their valuable time and give them the chance to select from a range of products with the best price. Out of the many research in the related area, some of the literature related to this study is discussed here.

Kaur & Kochar (2018) attempted to analyze the factors influencing the behavior of customers toward online shopping. It was found that customers have more satisfaction with e-shopping because they are able to shop in any place and anytime with safety and ease of payment options. They are also able to compare the available products by saving their time and money. The provided information of online product facilitates the process of comparison of the products content and quality of website and the security measures taken by the retailors all affect the attitude of customers to purchase online. Jadhav V. & Khanna M. (2016) have conducted a qualitative analysis on the factors affecting college students' purchasing behaviors in Mumbai, India. The most affecting variables for online purchasing were determined as variety of products, low price, promotions, comparison, convenience, ease of use, attitude, time saving, trust and availability. The results matched the outcomes of Usha Vaidehi (2014) as they both found that cheap products and saving time are the most influential variables. Budiharseno R., (2017) conducted a study on the college student in South Korea trying to explore the factors influencing the internet buying among the respondents. The respondents agreed that internet shopping is cheaper than traditional shopping. Moreover, all the respondent satisfaction with the time efficiency of internet shopping since the students are having many classes to attend.

The study of (Delafrooz et al., 2010), has identified the items that affect the attitudes of the students when shopping online in Malaysia by conducting a survey and based on literature. It was revealed that customers' attitudes toward online shopping are affected by many factors like convenience, wider selection and price. According to the same study, the graduate students' attention to internet shopping is relatively high and the attitude of the respondents is also positive. (Kim, 2010), in his study found out that privacy, security and trust, time saving, ease of use, convenience, enjoyment provided by shopping, company reputation and tactility are the most significant factors that influenced the customers who buy online.

Other researchers have also concentrated on other factors which affect the behaviors of online shopping customers. The paper of Gupta & Khincha (2015) aimed at studying the factors that affect the customer behavior. This paper has concluded that time saving and delivery facility are what influence the customers and make them happy. Choudhury D., & Dey A., (2014) studied the factors affecting online shopping attitude among the university students. The researcher has studied factors of gender, internet literacy, and the price. The results showed that there is no significant impact of these factors on the attitude of students. Another factor was studied is the quality. This factor prevents the customers from online shopping as they cannot touch the products. The study recommended that the online sellers should provide cheaper prices to promote the online shopping.

Methodology

This study is quantitative in nature because it aimed at studying the factors affecting the university students' attitude towards online shopping. The random sampling was utilized, and the unit of analysis is individuals (the university students), both the undergraduate and postgraduate. Data was collected from September 2019 until October 2019. Based on Morgan (1970) model, the sample size of this research was determined as 375. This research depends on two main methods to get the data. The first

and main method was the hard copy questionnaires that were distributed at the university (286 questionnaires), out of which 280 questionnaires were returned. The second method was the online soft copy questionnaires. Sum of 90 questionnaires were collected from the second method. Only 6 questionnaires were not accepted as it seems that the respondents did not have the interest to fill them out completely. In total, 369 sets of questionnaires were returned and represented about 98.7%. "IBM Statistical Packages for Social Science (SPSS) Statistics" version 22.0. was used to analyze the data. The types of analysis methods used in conducting this study includes pilot test, normality and validity analysis, descriptive analysis, frequency analysis, correlation analysis, and regression analysis. Table 1 represents the return survey rate.

Table 1: Survey Return Rate

Population	Sample Size	Questionnaire hard copy returned	**Questionnaire online returned**	Total Questionnaire returned	Return rate (%)
14593	375	280	90	370	98.7

ANALYSIS AND DISCUSSIONS

Reliability for Actual Study

Reliability analysis for actual study was conducted after the data has been completely gathered by the researcher. Table 2 shows the reliability analysis for the actual study.

Table 2: Reliability for Actual Study

No. Of Respondent	*No. Of Questions*	*Croncbach's Alpha*
370	28	0.721

The overall Cronbach's Alpha value of the real study is 0.721. Thus, referring to Sekaran (2003) it can be inferred that the overall Cronbach's Alpha for real study was having a good reliability level.

Respondent's Demographic Characteristic Analysis

The frequency analysis of all demographic analysis is represented clearly in the following tables.

Table 3: Respondents' Gender

Categories	*Frequency*		*Percentage*
Male	191	51.6	
Female	179	48.4	
Total	370		100.0

Table 4: Respondents' Age

Categories	*Frequency*	*Percentage*
18-22	217	58.6
23-27	123	33.2
28-32	25	6.8
Above 32	5	1.4
Total	370	100.0

Table 5: Respondents' Education Level

Categories	*Frequency*	*Percentage*
Bachelor	304	82.2
Master	60	16.2
PhD	6	1.6
Total	370	100.0

Table 6: Respondents' Race

Categories	*Frequency*	*Percentage*
Malay	239	64.6
Chinese	57	15.4
Arab	40	10.8
Indian	27	7.3
Pakistani	1	0.3
Somali	6	1.6
Total	370	100.0

Table 7: Respondents' Percentage of Shopping Online

Categories	*Frequency*	*Percentage*
Weekly	38	10.3
Monthly	126	34.1
Once in Three Months	94	25.4
Once in Six Months	56	15.1
Yearly	35	9.5
Never	21	5.7
Total	370	100.0

Demographic data is summarized in the previous tables. There were 191 (51.6%) male respondents who took part in the questionnaire, while 48.4% (48.4) participants were female. Second is the analysis of the respondents' age. Huge number of the participants aged between 18 - 22 years old; their number was 217 (58.6.4%). The participants aged between 23 - 27 years were 123 (33.2%). However, those who are between 28- 32 years were only 25 respondents (6.8%). Finally, a small number of the respondents were above 32 years old who recorded only 1.4% (5 respondents). Third is the education level. 304 respondents (58.6%) were Bachelor students. About 60 respondents (16.2%) were master students. However, participants who are in their PhD level were only 5 respondents, and they accounted for (1.4%). Fourth was the race of the respondents. Most of the participants were Malay (239 respondents, at 64.6%). This was followed by the Chinese respondents as they were 57 respondents (15.4%). Next was the Arab respondents. They were 40 respondents and they account for about 10.8% of the total number. Indian respondents also participated in the questionnaire and their percentage was 7.3% as they were only 27 respondents. The smallest numbers were from the Somali and Pakistani respondents. Fifth is the respondents' frequency use of online shopping. A huge number of respondents (126 respondents at 34.1%) mentioned that they use online shopping monthly. This was followed by those who stated that they use online shopping every three months whose number was 94 and their percentage 25.4. Others also mentioned that they use online shopping once in six months (56 accounting for 15.1%), weekly (38 accounting 10.3%) and yearly (35 accounting for 9.5%), and never (21, amounting 5.7%).

Findings of Objective 1

The main first objective in this study was to identify the main factors affecting university students' attitude toward online shopping. This has been first achieved through the literature review. However, this section will stress more on the of significance of this factors. The factors that were determined in this study were (Quality, Cheap prices, Saving Time, Wider selection of products, and trust). In fact, the mean analysis was used to find the central tendency. The results of the mean analysis are shown in table 8. The five factors were considered in the high central tendency, except for the quality of the products the central tendency of which is moderate.

Table 8: Descriptive statistics

	Factors	*Average Mean*	*Std. Deviation*	*Total Average mean*	*Mean score interpretation*
Attitude	Q7	4.12	.696	3.74	High
	Q8	4.07	.747		
	Q9	3.04	.933		
Quality	Q10	3.32	.992	3.64	Moderate
	Q11	3.46	.892		
	Q12	4.10	2.214		
	Q13	3.70	.855		
Cheap Prices	Q14	3.96	.834	3.84	High
	Q15	3.26	1.095		
	Q16	4.31	2.191		
Saving Time	Q17	4.27	.760	4.00	High
	Q18	4.40	3.019		
	Q19	3.63	2.292		
	Q20	3.72	.833		
Wider Selection	Q21	3.86	.791	4.22	High
	Q22	4.21	2.186		
	Q23	4.06	.711		
Trust	Q24	3.54	.865	3.76	High
	Q25	3.48	.827		
	Q26	4.22	.711		
	Q27	3.81	.758		
	Q28	3.75	.756		

The mean and standard deviation values were analyzed by using SPSS Version 22.0. Each variable for this study was stated in Table 8. The variables were measured using a five-point Likert scale from 1 (strongly disagree) to 5 (strongly agree). Thus, if the mean score was between 2 and 4, it was rated as average. Meanwhile, a mean score was greater than 4, it was considered as high. Table 8 shows the mean, standard deviation and Cronbach‟s Alpha values of variables as below. The dispersion of the variables from their standard deviation is measured by the standard deviation. A good example can be Q7 with the value of 0.671 is one standard deviation below the mean in the above example in which

the variable, has a mean of 4.47. This mean indicates that most of the respondent have agreed on the statement.

The mean scores for the variables ranged from 3.64 to 4.22, with standard deviation value ranged from .030 to 0.708. The highest mean value was Wider Selection of Products with 4.22 (Std. Dev: 1.22), followed by Time Saving with 4.00 (Std. Dev: 1.22), Trust with 3.76 (Std. Dev: 0.791), Attitudes with 3.74 (Std. Dev: 0.792), and lastly Quality with 3.64 (Std. Dev: 1.23). we can conclude that most of the respondents chose rank 4 (agree) based on Likert scale questions in the questionnaires provided to them.

Thus, objective one was achieved with the careful analysis. The findings show that all factors affect the attitude of the student with a little change in the degree of the affect. Wider selection of products was the most significant factor with an average mean of (4.22). This was followed by the saving time factor with an average mean of (4.00). the third factor was the cheaper prices, and the fourth factor was trust, with average means of (3.84 and 3.76respectively). Finally, the last significant factor was the quality of the products with a moderate average mean of (3.64).

Findings of Objective 2

The second objective of this research was to find the relationship between the dependent variable (attitude toward online shopping) and the five factors that affect the attitude of university students towards online shopping. Normality test was conducted to know whether the data was distributed normally or not and to determine which test was effective to test the relationship between the variables.

Normality Test

Since the sample of this study was more than 200 questionnaires, to test the normality, Kolmogorov-Smirnov was used. The result indicated that the data was not distributed normally because the significant values are less than 0.05.

Table 9: Normality Test

Variables	*Kolmogorove-Smironv Significant*	*Shapiro-Wilk Significant*
Attitude	.000	.000
Quality	.000	.000
Cheap Prices	.000	.000
Time Saving	.000	.000
Wider Selection	.000	.000
Trust	.000	.000

Correlation Analysis

Table 10 shows the results for the correlation analysis of the study. It is clear that the strongest relationship is between the wider selection and the attitude (r = .440, P-value = 0.000), while saving time has the weakest relationship with the attitude toward online shopping (r =.2.33, P-value = 0.000).

H1a: There is a significant relationship between quality and attitude toward online shopping.
The study hypothesized that the relationship between quality and attitude toward online shopping is positive. According to Table 10, the p value of Spearman correlation between quality and attitude toward online shopping is 0.000 which is lower than the 0.01 level. The r value is .292. This indicates that there is a positive relation between the dependent variable and quality of products.

H2: There is a relationship between price and attitude toward e-shopping.
The hypothesis posits that there is a relationship between cheap prices and attitude towards e-shopping. According to Table 10, the p value of Spearman correlation is .000 which is smaller than the 0.01 level, while the r value is .296. This indicate that there is relationship between the cheap prices and the attitude toward e-shopping among university students.

H3: There is a relationship between saving time and attitude toward e-shopping.
The research hypothesis posits that there is relationship between saving time and attitude towards e-shopping. According to Table 10, the p value of Spearman correlation is .000 which is smaller than the 0.01 level, while the r value is .233. This indicates that there is a relationship between the saving time prices the attitude toward online shopping among university students.

H4: There is a relationship between wider selection and attitude toward online shopping.
It is hypothesized that there is a relationship between availability of variety of products and the attitude towards online shopping. Based on Table 10, the p value of Spearman correlation is .000 which is lower than the 0.01 level, while the r value is .440. This indicate that there is a positive relationship between the availability of variety of products and the attitude towards e-shopping among university students.

H5: There is a relationship between trust and attitude towards e-shopping.
The hypothesis states that there is a significant positive relationship between trust and attitude toward online shopping. According to Table 10, the p value of Spearman correlation is .000 which is lower than the 0.01 level, while the r value is .311. This indicate that there is a positive relationship between the trust and the attitude toward e-shopping among university students.

Table 10: Correlation Analysis

Attitude		*Quality*	*Cheap Prices*	*Saving Time*	*Wider Selection*	*Trust*
	Correlation	.292**	.269**	.233**	.440**	.311**
	Sig. (2-tailed)	.000	.000	.000	.000	.000
	N	370	370	370	370	370

Multiple Regression Analysis

To test the effect of Independent variables "Quality, Price, saving time, wider Selection, and Trust" on the dependent variable "Attitude Toward Online Shopping" this study used the multiple regression analysis. The results of the multiple regression analysis are shown in Table 11. If the significant value is less than .05, it means that there is a significant relation or impact. However, when the sig. value is more than .05, it means there is no impact on the dependent variable.

Based on table 11, the standardized coefficients for quality .162, Price -.009, saving time .045, wider selection of product .227, and trust .212. Besides, the results showed that not all the independent variables significantly related to the dependent variable. Quality, wider selection of products, and trust are the only variables that are significantly related to the university students' attitude towards e-shopping because their value is less than .05.

Thus, according to the T test, there are two factors that are not relevant to the equation. The hypothesis of cheap price and saving time were not supported. This was strengthened by the R Square (.175) which is very low. The R Square result shows that all the factors can express only 17.5 % of the changes in the attitude. This is an accepted figure in the social research.

Attitude= a + B1 Quality + B2 Price + B3 Time saving + B4 Wider Selection + B5 Trust

The given regression analysis model summary in table 12 illustrates that the R value is (0.419). This mean that there is a positive correlation between the attitude toward online shopping and the independent variables, namely quality of products, cheap prices, saving time, wider selection of product and trust.

The results of ANOVA of the regression analysis in Table 13 shows that the overall model is significant because p sig. value (0.000) is less than 0.05. And thus, the model has accomplished a satisfactory level of goodness of fit in predicting the variance of attitude toward online shopping in relation to the fifth factors. According to the F-test, the equation regression analysis is correct.

Table 11: Coefficients for Relationship between Dependent Variable and Independent Variables

Coefficients						
Model		Unstandardized Coefficients		Standardized Coefficients	T	Sig.
		B	Std. Error	Beta		
1	(Constant)	5.014	.783		6.405	.000
	Quality	.103	.031	.162	3.318	.001
	Price	-.006	.032	-.009	-.174	.862
	Time	.020	.021	.045	.947	.344
	Wider	.147	.032	.227	4.553	.000
	Trust	.142	.035	.212	4.058	.000
a. Dependent Variable: DV

b. Predictors: (Constant), Trust, Time, Quality, prices, Selection						

FINDINGS

Based on the data collected from the 370 respondent and was analyzed, wider selection of products is the main factor that made them purchase online as this variable scored the highest mean (4.22). From

the findings, the respondents have highlighted that they are motivated to buy online as they are able to find different products and brands that satisfy their needs and desires. In addition, the respondents have also showed that online shopping is a popular method of shopping among them as it enables them to get the products that may not be available in the nearby market. The results support the studies of Delafrooz, et al, (2010) and Harn et al. (2006).

The second significant factor was saving time. The average mean for this factor was 4.00 which is considered high. Most of the respondents agreed that online shopping saves the time and save them from the traditional market crowded chaos of traffic. Interestingly, most of the respondents also agreed that the delivery of the products takes long time. This is a negative effect.

Cheap prices came in the third place as a factor that affect the Students' attitude toward online shopping. This factor scored a mean of 3.84 which is considered high. This factor has three questions in the questionnaire. The mean of this factor illustrates that the respondents believe that online shopping is cheaper than traditional shopping. The results also show that online shopping enables the respondents to control their expenses by the function which link the online website to the students' bank accounts. This function has made it easy for them to track how much they have spent on a particular product and compare prices easily. The finding is consistent with previous studies done by Jadhav & Khanna (2016), and Ferri et al., (2010).

The fourth factor was the trust. This factor scored an average mean of 3.76. This mean is also considered high. The results of this factor show that most of the respondents agree on the safety of the online transaction. The result of this study is consistent with previous studies which claimed that trust is a very influential factor (Veena & Rajkumar, 2017; Usha Vaidehi, 2014; Chandra and Sinha, 2013)

The fifth significant factor was the quality of the products. This factor scored average mean of 3.64. This mean is considered as moderate, with less influential effect to motivate students to buy through online than the other factors. This is probably because the students are disappointed by the quality of products they have bought from online websites. It can also be related to the respondents' background since most of them are in their twenties and from a business background, so they are more aware of this issue.

Regarding objective two, the correlation analysis Results showed that all factors have relation with dependent variable. The p value of Spearman correlation between all the factors and attitude toward online shopping was 0.000 which is lower than the 0.01 level. This result can be strengthened by the fact that all the majority of the respondents are coming from the business and technology management background. More than that they are all educated and are aware of the benefits they gain from using online shopping. The results are similar to the finding of Delafrooz, et al (2010) who has studied the online shopping orientation and the perceived benefits from this type of the e-commerce. In his study, it was stressed that there is a strong relationship between the attitude towards online shopping and the perceived benefits gained from online shopping such as wider selection and cheap price.

In addition, the strongest relationship was between the wider selection and the attitude towards online shopping (r =.440, P-value = 0.000). This was followed by the relationship between the trust and the attitude towards online shopping while saving time has the weakest relationship with the attitude toward online shopping (r =.311, P-value = 0.000). However, the relation between saving time and attitude towards online shopping was the weakest relation (r =.233, P-value = 0.000).

On the other hand, regression analysis was used to determine the effect of the independent variable on the dependent variable. The regression analysis showed different results. Only three variables were determined as having strong effect on the attitude toward online shopping which are the quality of the product, wider selection of products and the trust with a Sig. value of .001, .000, .000 respectively. However, cheaper prices and saving time were found to have no effect on the dependent variable as their Sig. value scored .862 and .344 respectively.

Conclusion

This study was on the factors affecting the university students' attitude toward online shopping. The results of this study have shown that wider selection of products has the highest value among the factors that affect the participants' attitude toward e-shopping. The study also has shown that quality, cheap prices, saving time, wider selection of products and trust are positively corelated with the dependent variable. It is recommended that should apply this study in other states in Malaysia throughout many states, using interview technique to obtain in depth data.

ACKNOWLEDGMENT

We would like to express our greatest gratitude to the Research Management Centre Fund E15501 of Universiti Tun Hussein Onn Malaysia, Batu Pahat Malaysia for funding the publication.

Abstract

The increasing of environmental awareness and the requirement of sustainable economic development has led to implementation of green business practices (GBP) to minimize the destructive impact of business on local and global environment, society, community and economy. Nevertheless, the concept of GBP itself is ambiguous and underexplored especially tin the context of multinational companies. The objective of the study is to review green business practices articles specifically tackling on the issues of contradictory definitions, significances, issues and challenges faced by the multinational companies. Recent articles have been reviewed using a systematic literature review method. This paper contributes to the thorough understanding of the concept and how it bring significances and pose challenges to companies. Certain managerial implications have been highlighted to the multinational companies to bring GBP effectively on board on their strategic planning process.

Keywords: Green Practices, Green Business, environment, multinational companies.

INTRODUCTION

In recent years, the rapidity of economic growth to fulfil increasing customer consumption worldwide has caused negative impact to the environment. Chuwuka (2018) mention that developing the economics of worlds was having a greater percentage on environmental problem and it attributes to activities of profit driven entrepreneurs. Over consumption of resources for earning the profit is causing environmental issue such as haze, global warming, pollution, climate change, ozone layer depletion and so on. Rahbar (2011) states that global warming, air pollution, ozone depletion and overpopulation are the major problems which increase the importance of saving the environment. The impact of environmental makes the consumers feels that is important to concern about environmental and consciousness towards the cause of perish natural resources (Pino, Peluso, and Guido, 2012: Prakash

and Pathak, 2017). Mukthar (2016) states that increasing of environmental awareness and the requirement of sustainable economic development has led to implementation of green business practices to minimize the destructive impact of business on local and global environment, society, community and economy.

Brown and Ratledge (2011) states that green business refers to an establishment that produces green output. Slovik (2013) defines green business with a broader view which is a green business refers to an organization uses renewable resources and persist in responsible to human resource aspect of their activities. Nowadays, the environment has been polluted by multiple factories and buildings that have sprouted a lot over the years. Big corporate companies have started to invest in building new offices, exploring new areas for gaining resources as well as expanding their manufacturing factories thus causing them to resort to deforestation in developing countries. This can cause numerous disadvantages especially to the inhabitants in the forest as well as human beings alike. Factory emissions releases carbon dioxide into the atmosphere causing an increase in air pollution. Unregulated factories have also managed to pollute the rivers and seas by dumping hazardous chemical waste. Manufacturing companies and factories has enabled this to happen and it has created multiple threats to all life forms. Human beings and animals have started to contract all kinds of diseases such as flu and asthma caused by harmful gases as well as pollutions such as air pollution, water pollution etc. Therefore, existing businesses as well as future businesses will have to take certain actions in preserving and improve the current environment by practicing green business (Peterson, 2018).

According to Slovik (2013), a green business defines as an organization that uses renewable resources which is environmentally stable and is also able to hold itself for the human resource aspect of their activities which is to say that they are also socially responsible towards the environment whereas Čekanavičius et al (2014) states that a green business is an organization that is committed to the principles of environmental sustainability in terms of its daily operations and strives to utilize renewable resources as well as minimizing the negative environmental impacts of its operations. For instance, Nestle in Indonesia implemented green marketing and are able to regulate their factories in utilizing raw materials, water and energy efficiently as well as apply environmentally friendly principles to benefit the society (Riduan, 2016). Hence, the objective of the study is to review green business practices specifically tackling on the issues of contradictory definitions, significances, issues and challenges by the multinational companies.

Contradictory View of Green Business Definitions

By today, the substance concept of the green business is still ambiguous because it was defined by different definitions that could be found in different sources, the green business practices may differ among industries and organizational, it depends on what kind of good and service they produce. So, it is impossible to have one process is the same that used by different organization. In addition, green business practices are still far from universally accepted and applied by the business environment around the world. This is due to several reasons, first, the 'green business practises' is still perceived as an extra burden in terms of increasing of cost or losing in revenue. Second, it is related with cultural, political, and economic difference (Čekanavičius et al, 2014).

According to Mukthar (2016) green business fundamentally involves the implementation of sustainability concepts to business operation. Green times (2013) define green business as "being concerned with and supporting environmentalism" and "prone to maintain environmental quality". Green business refers to "Organization that preparing a plan and implementing an action to reduce environmental impact on current concern area" (Sustainable Green, 2013). Calling Green (2011) define green business as "Business activities that do not have negative impact on environment." Lina, Rugile and Agne (2014) were summaries that green business refers to an organization that obligate to environmental sustainability concept on operation, attempt to use renewable resources and endeavour

to minimize business activities that cause negative impact to environment. Besides that, green business also relate with green business practice which is the action taken by company in business activities to reduce the negative impact of environment.

Green business practice defines as all related projects has an explicit purpose to help company in saving money and also reducing the environmental impact of their business operation (Chukwuka, 2018). Muhktar (2016) believe that green business practice includes the environmentally friendly activities that commence by organization to become more sustainable. In other words, organization that apply environmentally friendly concept on business activities such as operation, marketing, production and so on consider as a green business practice. The example of green business practice are includes green packaging, eco label, carbon management, green logistics and so on.

Furthermore, green business practices involve five environmentally friendly models which are Reduce, Reuse, Recycle, Repair and Rethink (Chukwuka, 2018). Reduce model means that reduction in using natural resources and waste accumulation. Reduce model refer to create a mechanism that fulfil the current demand and future demand. Recycle model define as process to transform waste to a reusable material. Repair models are referring to maintenance a damage product and transfer it into reusable material while the rethink model refers to the process thinking again to acquire an innovative and creative alterative to solve the environmental problems. According to Mukthar (2016), an environmentally awareness organization should involve in any 4R which is Reduction, Reuse, Recycle and Recovery. 4R can be achieved via some of practices such as reducing power waste, energy saving, using renewable and natural ingredient and products, green packing, green building, eco-cleaning, eco labelling, reduce printing for less using paper, green packaging, using public transport, waste sorting and spreading consciousness about green business.

Nevertheless, we can conclude that green business is a business practice aim to minimize the negative consequence towards the environment and ensure the sustainability. This will lead us to understand the characteristic of green business. In general, a business can be classified as a green business if they have these criteria (Green Business Network, n.d.). First, the business is responsible for social and environmentally. The main principle of green business is to protect the people (social) and planet (environment). Therefore, the green business will ensure they involve all the goals such as justice of social and economic, health and development of community as well as environmental sustainability into their operation activity.

Significances of Green Business Practices

Green business practices can be implemented in all areas of the organization such as at production site, in the office, towards suppliers, in the marketing and sales as well as to the organization's product design. These green practices can be used to reduce pollutions that comes with the daily activities conducted in the organization. For instance, the basic switching off the lights if the room is unused is an effective way of saving energy. These small steps can eventually save the environment in the smaller scale, but it will undoubtedly impact the environment greatly. One of the biggest wastages in an office is the unlimited usage of papers. Trees are known to be cut down and used to create papers for office daily usage. Most organizations use excessive amounts of papers to print minute meetings, memos, and reports.

According to Esty and Simmons (2011), organizations find it difficult to switch from paper-based systems to electronics systems as the electronics systems are costly compared to paper – based ones and it is also difficult for the employees to adapt to new changes. However, change is inevitable when it comes to going green. Organizations should aggressively adapt green practices in their working place in order to reduce wastage. By adopting electronic systems such as Adobe Live Cycle and Adobe Acrobat, these applications can generate, authenticate and disseminate documents electronically. Etsy

and Simmons (2011) also stated that not all company documents needed to be printed plus unnecessary paper equals to unneeded expense.

This is an important step which an organization has to overcome by regulating the amount of papers used in the organizations as these simple interventions can be of great significance towards the environment and also increase efficiency. The organization can benefit greatly from this as switching to electronic system can reduce costs of purchasing heaps amount of papers. On the other hand, if the electronic systems such as printers, fax machines and scanners are old, it considered inefficient as it uses large amounts of ink and consumes more electric energy. Hence, by prompting the organization to invest in new and smart devices as well as encouraging the staff to practice double sided printing, it can eventually boost efficiency and reduce wastage. At the same time, there are other green practices that an organization can adopt such as going digital whenever possible, encourage usage of public transportations, practicing recycling in the workplace and many more.

The positive effects of these green business practice are that it can directly save cost and increases revenue of an organization. According to Čekanavičius et al (2018), a business can obtain two kinds of benefits by going green which are revenue rising and cost saving. Revenue rising refers to product differentiation and brand image, customer communication, additional value as well as higher productivity. As an organization that goes green, they can appeal towards the customers and other businesses that prefers green products. This shows that customers are willing to purchase more green items alongside the added value to the product. In terms of saving cost, an organization that practices green approach can save energy related cost, boost workforce morale and innovations as well as have a societal impact (Lagas, 2015). Electric energy and water costs are the main concerns for a manufacturing company. This is because machines and products require resources to continuously produce non-stop. Hence, by switching to energy-efficient lighting and flexibility adjustments following the production schedule it can ultimately reduce an organization's long-term electrical cost.

Issues and Challenges faced by Multinational Companies in adopting Green Business

Multinational companies play an important part in implementation of green business practices in the workplace. Multinational companies are considered international as they have grown out of their domestic corporate framework and expand their boundaries in host countries by purchasing branches through mergers and acquisitions (Ishak et al, 2017). Multinational companies in host countries have manage to exercise their green practices by upholding certain criteria's and benchmarks in par with environmental standards in their host countries. For instance, Unilever has cut off several of its palm oils suppliers for failing to meet its rainforest protection standards. This shows that these companies are aware of their responsibilities towards the current environment hence it is vital for multinational companies' business strategy in facing the challenge of environmental pollution and natural resources management.

Most of multinational companies have principles on Corporate Social Responsibility (CSR) whereby they have to help the communities in the development process. According to Abels and Martelli (2012), the definition of corporate social responsibility is a voluntary way for a company to improve its public image and reputation by incorporating responsible activities that satisfies a need of society beyond its legal requirements. Corporate social responsibilities are beginning to play an important part in the current business world. Multinational companies should care about their stakeholders' interests but at the same time, they have to emphasize on other areas such as adopting green business practices apart from solely making profits.

For example, IKEA cares about its responsibilities towards maintaining sustainability hence the IKEA range of products shall comply with the strictest laws and safety standards in all their markets and has detailed requirements on the use of chemicals and other substances in the manufacturing process. If

one country tightens its rules, IKEA introduces new regulations in all IKEA markets where and when possible. This shows that multinational companies have the ability to be flexible in wherever they are conducting businesses.

Patagonia is one of the companies that well known for its environmentally friendly way of doing business. Patagonia is an outdoor apparel and gear company has been champion of environmental stewardship and social responsibility (Matthews, 2013). They publish advertisement by encouraging people not to buy things that are unnecessary for them, even though for their own products. Wetsuits are made of natural rubber and plastic bottlers are turned into parkas. In reducing the unnecessary consumption, Patagonia always make sure their product does not end up in landfills. They always responsible well in buying their materials.

Seventh Generation is a decent green company and the most popular green companies in the consumer market. Seventh Generation provide environmentally friendly household product that help consumer to reduce their impact for the planet (Seventh Generation n.p., 2018). They were the first companies that self- declared "socially responsible" as they come out with many of the eco-friendly products. Their packaging mostly made with recycled material, almost all of their packaging can be easily recycled (Jennifer, 2010). Even now the brand like Clorox have created greener version for their product, so that can easily meet the demand from environmentally conscious consumer.

International Business Machine (IBM) was another early adopted of sustainability and eco-friendly business. Approach for IBM is twofold: to make their existing products and processes more efficient and develop new innovation that can help the world. IBM ensure their company is alert in protecting the environment across all of the operations they applied and utilized. Today, IBM's efforts include smart building that reduce resource demand, green procurement, and water resource management (Viles, 2016).

In conclusion, with climate change a growing problem, there are important for the individuals, corporation and business concern for the environment. With innovative technology, not only can increase accountability, improvement of operation whilst can take care of the planet as well. Together, we can improve the sustainability of business and our planet.

According to Eccles et al (2012), stakeholders in multinational companies are not only concerned about profits as their interest also includes corporate social responsibility aspects of a company such as environment, ethic, governance, and human rights. These factors affect the fate of the company in a long term. It is proven that there is a competitive advantage for corporations that have a higher reputation and are more socially responsible and they also result a higher return on investment. Consumers prefer a company that is aware of its surroundings and cares for the environment and with added value of green practices in producing their products, it can boost the company's sales and increases profit. If a company fails to comply and resort to irrational and backwards way, it can damage the reputation hence will end up being criticized by the public.

Other than that, within a multinational company, the functional management has also an important role to play in practicing green business practice. Because without these departments, the company will face dangerous risk. The role of each functional department in terms of production, logistics and procurement as well as marketing and sales to its building facilities all play a part in ensuring that the company uses green practices. This can showcase to the stakeholders that the company is capable in making the environment eco-friendly and convinces them that the company really takes its corporate social responsibility seriously.

The role of multinational company is important in introducing to the developing countries of how professional they can be at producing their product at the same time keeping the environment clean and healthy. Educating small and medium enterprises by looking towards how multinational companies conducts its business can also inspire them to go green no matter the type of businesses.

Big companies have begun their awareness towards new regulations and policies that they need to obey in order to protect the environment from harmful pollutions. Organizations cannot afford to ignore the rules or environment challenges that already is at their doorstep. Failure to comply with the rules has definitely resulted in the companies paying a loads of money for fines. Environmental issues that pose as a risk to the organizations needs to be managed cautiously. According to Esty and Simmons (2011), the risk come in forms of:

a) Accidents or fuel spillage either chemicals or any hazardous materials
b) Liability for products linked to environmental harm
c) Shifts availability of natural capital such as water and land
d) Tougher regulation
e) Political disfavour and new laws
f) Public backlash
g) Withdrawal of the social license to operate

These risks can be dangerous towards the organization's reputation and performance. Multinational companies such as Apple were not aware that some of their products are made up of environmentally unacceptable materials thus receiving backlash from NGO's. Eco-related risks have caused organizations to limit their materials as they need to acquire them from different alternatives. For instance, plastic bottle companies have been banned from using chemical BPA as this chemical material was the one of the components in producing plastic bottles (Bauer, 2016). BPA is known to be found in polycarbonate plastics and epoxy resins. Now they resort in finding a substitute chemical to replace BPA.

The environmental factors have caused other organizations certain risks and cost whereas for others it creates opportunities. In addition, those who wish to survive must learn how to deal with the challenges of adopting green business practices. It is considered very complex in understanding the pros and cons of incorporating green business practices in an organization. However, in spite of changing and shifting towards a greener perspective, the industry would definitely thrive in the long run. According to the Kolk et al (2016), enhancing a corporate reputation for environmental responsibility has become an important aspect for multiple multinational corporations today. Companies that are able to adopt green practices are more resilient in the market and has more competitive edges compared to the companies with ordinary practices (Ishak et al, 2017).

While company increase their importance for the further greening of business and the enhancement of a sustainable future, it often met with many kinds of challenges.

The challenges that company faces is lack of internal capital. Company that lack of internal capital like financial and human resources will be barriers for the company to develop or implement green business. Implement green business require large amount of investment, where the payback period is long as well, thus customers or shareholders refuse to invest in the company that are high degree of uncertainty. Indirectly it will affect the company for expand their business.

Furthermore, the challenges that company met is lack of well-aligned team. Financial team and sustainability team are often do not effectively engage together. Employees that come from different background and education are the common causes lead to team members were not aligned on a common path in order to achieve the company's goals. Everyone have their own department's strategy, objectives and goals, so when they are sitting in a chair for discussion, will occur intensive argument among themselves. They normally lack of communicate to each other as they are come from different cross-functional department. Therefore, when they need to participate in a new program like green business, it will cause a dispute among them. For an example, when sustainability team complete the project planning too late and this will cause problem for the financial team to make decision making within the time given. All this was result from lack of communication between them.

Resistance to change is one of the challenges that will stop the company to enhance their performance. The reason people resistance to change because they are unwillingness for a change and sharing of information and material, fear of the unknown and misunderstanding about the need for change. Some of them are used to with old method or processes, thus when company want to change to latest technology, they are resistance to change as some of them are fear of the unknown. They fear they do not understand about how to use the technology, so when they feel something are threaten their job, they immediately reject for the case of switching existing materials for greener option in their company. Some of the employees are traditional mind-set to business. They always maintain the repetitive routine without expect of doing something changes.

Although green business practice had been proven can reduce the negative impact towards the environment at the same time ensure the sustainability of the business, however, how to implement it effectively to reach the win-win situation for both environment and business isn't an easy process. This section will discuss a few challenges during implement the green business practice.

The first challenge to implement green business practice is engaging top management and employees to carry out green business practices. According to a survey done by a firm that provide sustainability consulting service – 2 Degrees Sustainability Consultants (2DSC) (University of Colorado Boulder, 2018), they found that 65% from 700 business agree that the greatest challenging to implement green business practice is to persuade the leader and top management to accept it. The survey also shows that if an organization's leaders or top management are successfully persuaded, then they will be committed to the mission of creating green business practice environment in organization. There is a reason why convincing leader or top management is important for green business practices because the mission and objective of a company are determined by top management.

After the top management has been persuaded, another challenge will be going to engage employees involve in green business practice. Based on the survey, 47% of respondents agreed encourage the involvement of employees is the greatest challenge. This is because from the view of human being, most of the people prefer to stay at their comfort zone rather than change to or adapt with new approach. That is why encourage the employee will be the greatest challenge. However, company can use some ways such as incentives, communication with employees, employee education or even through the company disciplinary committees to encourage involvement of employees.

Other than engaging top management and employees to carry out green business practices, the next challenge is how to set indicators to evaluate the plan. Setting the indicators is very difficult because as mentioned before the concept of green business is still ambiguous. So, they don't have a standard to help in developing the indicators, all of the indicators must determine by organization itself based on what kind of objectives they want to achieve. For instant, if a company is planning to use energy efficiency, monitor the monthly costs is the useful ways. The indicators must be easily understood by employees, otherwise, the goal is not going to implement successfully. In addition, before setting the indicators, don't just consider the profitability, but also need to consider the impact towards environment and community surroundings.

Last but not least, the business objectives also become a challenge in implement green business practice. Normally, when talk about green practices, it will surround with increased of operation costs. This is definitely opposite with the main objectives of organization which is maximizing the profit. However, this kind of rhetoric is totally wrong. Green business practice will increased the efficiency in usage of operation resources and energy usage. These will result in operation costs decreasing at the same time protect the environment. The misunderstanding and ambiguous towards green business practice towards business objectives cause the green practice not accepted by most organization.

In a nutshell, in order to develop green business practices, businessman must find effectively ways to overcome all these barriers. So that, they can adapt to the strategies and techniques in order to improve

the environmental in processes.

CONCLUSION

It can be concluded that green business practices bring significances and pose challenges to companies. The companies must first start to take the first initiative to implement these practices internally thus affecting their reputations in the eye of the world. Even though the simple step such as switching off the lights when space is unused, it can conserve energy and save the environment. On the other hand, the issues of implementing green business practices have its own pros and cons and it can affect the company one way or another. It's the companies' willingness to commit and face the actual reality as the consequences can be highly devastating if not being done promptly. Furthermore, the role of multinational companies in bringing in their green practices of standards according to their host countries influences how they deal with local suppliers as well their stakeholders. This enables the host country suppliers to be educated and comply with the rules and regulations in order to ease their business dealings with the multinational companies. Multinational companies that are aware of its corporate social responsibilities can eventually influence other companies to follow their step in doing green business practices. This topic is very interesting to read on about and it is definitely useful for the current and potential future businesses who wish to adopt green business practices.

In conclusion, green business practices should not be a barrier towards an organization. It is proven to be beneficial in the long term and along the way each green step taken can definitely save the environment. Green business practice should be adopted step by step as our climate is changing every day and new issues will arise hence new policies will be implemented for the businesses to follow. As fellow human beings, it is important that we are allowed to consume natural resources only as fast as it can be renewed. Businesses no matter big or small enterprises play an important part as they are the pillars that fuels our everyday needs. Companies should take initiative to reassess their strategies in order to use green practices as well as refining their plans for future use. With the increase in all types of pollutions and diminishing of natural resources, it has caused most companies to take a critical step in adopting green practices in order to reduce cost while at the same time increasing their profit margin.

The Impact of Lifelong Learning on The Process of Contemporary Digitization

Michal GOLINSKI

Warsaw School of Economics, Warsaw, Poland

mgol@sgh.waw.pl

Abstract

We are witnessing another civilization revolution, most often characterized by the term *digital*. The resulting changes will affect the society, economy, culture and politics - practically all areas of the surrounding reality. The world that is being created will be subject to constant change. Digital destruction will affect each of us. Employers' expectations towards employees and, more generally, the expectations of the environment towards our skills, habits and ways of doing things will change quickly and profoundly. This will require constant adaptation to the changing world. The previously acquired skills and knowledge will quickly become obsolete. The importance of lifelong learning (LLL) will increase considerably. The aim of the article is to analyze the relationship between digitalization processes and LLL in EU countries, with particular emphasis on Central and Eastern Europe (CEE). This analysis shows a low level of LLL in the countries of this region. Already today, it is a barrier to the digitalization of CEE countries and in the future it may prevent them from fully participating in the civilization transformations and escaping the middle-income trap.

Keywords: Information Economy, Lifelong Learning, Adult Participation In Learning, Digital Multiverse, E-Metrics.

Introduction

For historical and cultural reasons, the level of development of the CEE region has been notably different from the rest of Europe. The last decades have been marked by a continuous effort to reduce this gap. The effects of these efforts deserve recognition. The achievements are remarkable but there is still much to be done, also in the area of digitization. Technological, financial and organisational barriers have been relatively easy to overcome. The CEE countries have access to the same, state-of-the-art solutions. In some areas, their infrastructure is even more modern than in other European countries. The CEE countries have taken advantage of the necessity of making a rapid transition to newest technology, leapfrogging certain stages of development and implementing the latest solutions immediately. Often greater difficulties are associated with social and cultural limitations. One of such limitations is the low level of acquiring and updating knowledge after leaving formal education. The article attempts to describe the relationship between the level of digitization and the level of LLL in CEE countries.

Digital Multiverse and the Methods of Measuring It

The ascertainment that we are entering a new stage of civilisational development is widespread. The transformations taking place are revolutionary in nature and their scale and intensity correspond to the great civilisational transitions known from history. The main factor of the transformations taking place is, undoubtedly, the exponential development of information and communication technologies (ICT).

The discourse is abundant in terminology that describes the impact of ICT on our contemporary times. Recently, the most frequently used terms are *digital society* or *digital economy*. However, they do not fully reflect the extent to which ICT alters our whole reality. To reflect the complexity and

multidimensionality of the research area, the author suggests using the term *digital multiverse*. For the purpose of this article the author's definition of the term will be used.

Digital multiverse (DM) is a network of people, organizations, communities, devices, systems, applications and data and their relationships of a global nature, whose main driving force is the exponential scientific and technological progress. The constitutive elements of DM are: intensive use of ICT, integration of physical and digital systems, hyperconnectivity forcing interdependence and cooperation, automation of information exchange and data analytics, unpredictability of development, disappearance of barriers and the resulting new development opportunities and, in the economic sphere, new business models. The driving forces determining the nature of DM are the processes of digital destruction and digital transformation. The described phenomena determine the characteristics of DM, such as: flexibility of structures and processes, high level of innovativeness, increasing efficiency, globalisation, speed of reaction to signals generated by the environment, creation of new consumer needs, intensification of business interactions, creation of intelligent products and services, progressing servitisation of the economy and rise of new occurrences and phenomena. The emergence of DM generates new opportunities, but also new threats in practically all areas of human existence.

Modern technological progress is exponential, digital, and combinatorial (Brynjolfsson and McAfee 2014). These generate the phenomenon of *digital disruption*, which is responsible for the collapse of the organisations, industries or phenomena unable to adapt to the changes taking place. Today, however, it affects not only the economy but the whole reality in which we exist. This means a constant change of the existing rules and an unremitting necessity to adapt. The most important issue in these deliberations is the need to constantly update the skills, knowledge and experience gained to date. It is unavoidable. This means the collapse of the current idea of education and the necessity of lifelong learning.

The Issues Regarding Measuring Digital Multiverse

Quantitative DM studies are derived from traditional telecommunications statistics. They concentrated on the development of infrastructure, skipping social aspects. Disadvantages of such approach became increasingly apparent. An analysis limited to the technical infrastructure was becoming insufficient in explaining the DM phenomenon. The use of ICT is inextricably linked to capabilities, skills and motivations of people using these technologies. The role of information in a society is an economic, social, technological, political and cultural phenomenon. If the research topic is DM, the sphere of social and human factors cannot be ignored. This growing interdependence of ICT and the social sphere increasingly requires the incorporation of new tools, allowing assessment not only of the access to ICT and its use, but also its impact as well as barriers to its adoption.

Majority of existing empirical studies have focused on three fields: infrastructure, its use and indispensable skills. Skills and education can be characterized by the prevalence and level of: general education as a result of participation in formal educational structures, skills needed to use information products and services, dedicated skills to develop and create ICT solutions and lifelong learning. These areas are represented in quantitative DM studies to varying degrees. Lifelong learning is underrepresented. According to the author, the continuous improvement of skills throughout one's professional activity is essential for DM. LLL is crucial already today and its role will increase in the future. The analysis of these issues may allow to identify the areas in the society or economy that are jeopardized by civilization and social exclusion.

Lifelong learning

Constant change, digital destruction and exponential development of ICT are constitutive features of DM. They result in annihilation of many patterns of behaviour. This also applies to the education model and acquiring skills and knowledge. The former model assuming education up to about 25 years of age (for higher education), and then applying the acquired knowledge for four or five decades is irretrievably lost.

Markets, economic sectors and employers' expectations are changing dynamically. An increasing wave of automation will affect many of the largest professional groups. The effects of automatization of work will be far-reaching; according to MGI estimates (2019): "Nearly 40 percent of current US jobs belong to professional categories that could shrink between now and 2030. Other estimates maintain that in 60 per cent of jobs at least 30 per cent of activities could be automated (MGI 2017). Even if we assume that emerging occupations will replace those that will disappear so as to mitigate the rise in unemployment, we still face fundamental changes that may reach further than previous technological revolutions. The scenarios developed by MGI suggest that by 2030, 400 million people will have their jobs automated. The remaining 75-375 million workers (3 to 14 % of the global workforce) will have to change professional categories (MGI 2017).

All employees will face the change of the nature of their work. This will often require a higher level of education or new skills, such as teamwork, creativity or emotional intelligence and other soft skills (MGI 2018). This means major changes for millions of employees.

The technologies used to automate work will bring a considerable increase in productivity. They will irreversibly alter the nature of many jobs and this process will only intensify. Some professions will disappear and be replaced by new ones, unknown today. Many professions will become niche and others will emerge. The nature of tasks and work will transform fundamentally. It is becoming a huge challenge to equip people with the knowledge and skills that will help them move into new roles and adapt to new challenges. As Brynjolfsson and McAfee (2014) state: "(...) it's becoming harder and harder to have confidence that any given task will be indefinitely resistant to automation. That means people will need to be more adaptable and flexible in their career aspirations, ready to move on from areas that become subject to automation, and seize new opportunities where machines complement and augment human capabilities."

At the first stages of education, formal educational establishments are responsible for preparing people for the upcoming changes. However, their effectiveness is naturally limited. Young people - up to 25 years old, at the most - are within their "reach". Those who have completed their education and work or are unemployed are not covered by these establishments. In the "good, old" economy this was not a major problem. A well-educated engineer, manager or doctor could use their knowledge effectively for years. The forecasts presented earlier show that this is no longer the case. There arises the need for continuous learning.

The concept of lifelong learning is not new. However, at the end of 20th century it was becoming increasingly important, which led to its recognition by the Ministers of Education of the OECD countries as a policy framework (OECD 1996) in 1996. Eurostat defines LLL as follows: "Lifelong learning encompasses all learning activities undertaken throughout life with the aim of improving knowledge, skills and competences, within personal, civic, social or employment-related perspectives. The intention or aim to learn is the critical point that distinguishes these activities from non-learning activities, such as cultural or sporting activities. (Eurostat 2020a). Eurostat also distinguishes adult education, which it defines as follows: "Adult learning refers to the participation of adults in lifelong learning. Adult learning usually refers to learning activities after the end of initial education. The policy indicator on adult participation in learning refers to the age group 25-64". And it is this group that will be the subject of further analysis.

The attention that the EU pays to LLL is emphasized by establishing the Strategic Framework - Education & Training 2020 as a forum for Member States to exchange best practice and learn from each other. It defines specific benchmarks for Europe to meet by 2020. Some of them concern the scope and quality of youth education and will not be discussed here. The postulate that at least 15 % of adults should participate in learning by 2020 (ET 2020) is key to the subject of this paper.

The relationship between LLL and DM is bi-directional. The changes caused by ICT evoke the need

of continuous education. At the same time, only ICT is able to provide implementation of the concept of LLL for a significant number of people. The number of those who will require training will likely significantly exceed the capabilities of traditional educational structures. The only possible solution from a technical and organizational point of view is the use of e-learning techniques.

Digital Multiverse and Lifelong Learning

Methodology

DESI - Digital Economy and Society Index (EU2020a) will be applied as a measure of DM development level. The DESI is a composite measure created by Directorate-General for Communications Networks, Content and Technology (DG Connect) to assess the degree of the implementation of the Digital Single Market strategy (DSM 2020).

Eurostat data concerning the field of "Education and training" (Eurostat 2020b) will be used as a measure of adult education activity. A measure of lifelong learning is the participation rate in education and training of all kinds. Adult education activity is described by the "adult participation in learning" (APL) indicator, which refers to persons aged 25 to 64 who stated that they received education or training in the four weeks preceding the interview.

In the study – for all characteristics – the values from 2018 are used.

Selected APL characteristics related to DM development are presented in Table 1. Next figures show the relationship between these APL characteristics and DM. The following indicators were selected as relevant for further considerations:

- As a measure of DM, the DESI indicator (values and rankings) was chosen: Table 1 - rows 1-2.
- Four groups of indicators were chosen as measures characterizing the participation in APL:
- Overall adult participation in learning (APL) - rows 3-4,
- APL by educational attainment level - rows 5-10,
- APL by labour status - rows 11-14,
- APL by degree of urbanization - rows 15-20.

The following figures provide a graphic representation of the relationship between DM and APL. DM (Y-axis) is captured by DESI. APL issues (X-axis) are captured in the following figures by the characteristics listed in table 1. Each figure shows two characteristics divided according to UE average values. This allowed the division of the countries into four groups:

- DM development above the average value and the characteristics corresponding to APL above the average value - the right, upper part of the figure – "digital learners",
- DM below the average and APL above the average - the right, lower part – "analog learners,
- DM below the average and APL below the average - the left, lower part – "analog non-learners",
- DM above the average and APL below the average - the left, upper part – "digital non-learners".

Data source: DESI (2018a) and Eurostat (2020a)

Results

In the category of digitization, Sweden is the leader (which, in a somewhat irritating way, is the leader in all, both digital and educational characteristics). Among the CEE countries, only Estonia exceeds the EU average. Slightly below the EU average are Lithuania and Slovenia, ahead of France or Italy. Bulgaria, Romania and Greece bring up the rear (see table 1 - rows 1-4 and figure 1).

Fig. 1: DM and APL

Data source: DESI (2018a) and Eurostat (2020a)

In the adult learning category, Sweden is the first and Romania is the last. However, the values diverse enormously - only 0.9% of all adults in Romania improve their qualifications, compared to 31.4% in Sweden. The EU average is slightly exceeded by Slovenia and Estonia. The lower left part of the chart is occupied by the remaining CEE countries and southern European countries.

The low EU average of 11.1% should also be emphasized. The Strategic Framework - Education & Training 2020 includes the requirement that in 2020 at least 15% of adults participate in the learning process. The data presented here concern the year 2018. However, it does not seem likely that this parameter will increase so significantly within two years that the target will be reached.

The left bottom part of the chart - "analogue non-learners" - is the majority of CEE countries and part of southern European countries. The "digital non-learners" group consists of Germany and Belgium. The group of "analogue learners" - Slovenia and France. The elite group of 11 "digital learners" consists

of highly developed Western European countries and Estonia, with clear leadership of the Scandinavian countries.

Figures 2 and 3 show the relationships between DM and APL analyzed in terms of education (tables 1 - rows 5-10). In all three groups Sweden is the leader. In the group of the least educated, Croatia is the last one, and among the CEE countries only Estonia exceeds the EU average. In the middle group, Romania takes the last place. Estonia is the only CEE country that exceeds the EU average. In the group with the highest level of education, Romania is the last one. The EU average is exceeded by Slovenia and Estonia.

Fig. 2: DM and APL by education – levels 0-2

Data source: DESI (2018a) and Eurostat (2020a)

Fig. 3: DM and APL by education – levels 5-8

Data source: DESI (2018a) and Eurostat (2020a)

An increase in APL along with an increase in education is an important phenomenon. In the EU, 4.3% of people with the lowest level of education, 8.8% of people from the middle group and 19% of people with the highest level of education continue their education. Thus, the number of people continuing their education approximately doubles in every next group. Interestingly, in the highly developed countries of Western Europe this trend is, roughly speaking, maintained. The values for different groups do not vary noticeably. In the CEE and Southern European countries the opposite is true. In Greece, participation in further learning of people from the middle group is almost six times higher than that of the least educated. In Poland, the number of the best-educated is 4.5 times higher than the number belonging to the middle group. These are specific records in the surveyed group of countries. This gives rise to the danger of further widening of the educational gap in poorer EU countries.

Figures 4 and 5 show the relations between DM and APL analyzed in terms of labour market activity (table 1 - rows 11-14). On average, in the EU, 11.8% of the employed and 10.7% of the unemployed continue their education. Sweden is the leader in both categories, an impressive 47.3% of unemployed adults participate in some forms of education. This result is by almost 20 p.p. better than the value for

Luxembourg, in the second place. For the unemployed Croatia takes the last place, and for the employed - Romania. Among the CEE countries, only Estonia and Slovenia are above the EU average.

Fig. 4: DM and APL of employed

Data source: DESI (2018a) and Eurostat (2020a)

Fig. 5: DM and APL of unemployed
Data source: DESI (2018a) and Eurostat (2020a)

Both for the EU as a whole and for most of the countries surveyed, the share of adults continuing their education is similar among the employed and unemployed. The most observable preponderance of the unemployed in education over the employed is noted for Belgium, Luxembourg and Sweden. This indicates a conscious use of APL to fight unemployment. Lithuania, Hungary, Malta, the Czech Republic and Italy show the opposite proportion. There are considerably more working people continuing learning than in the case of the unemployed. This seems to be a negative trend. It further increases the skills of those who already have a job, worsening the chances of those who are out of work,

Figures 6 and 7 show the relationships between DM and APL analyzed in terms of the place of residence (tables 1 - rows 15-20).). On average, in the EU 13.5% of the inhabitants of cities, 9.8% of the inhabitants of towns and suburbs, and 8.8% of the inhabitants of rural areas continue learning. In all three categories Sweden is the leader and Romania is the last. Among city dwellers, only Estonia and Slovenia are above the EU average, also in the category towns and suburbs and rural areas.

Fig. 6: DM and APL by degree of urbanisation – cities

Data source: DESI (2018a) and Eurostat (2020a)

Fig. 7: DM and APL by degree of urbanisation – rural areas

Data source: DESI (2018a) and Eurostat (2020a)

The level of APL is clearly linked to the place of residence. On the EU scale, adult participation in learning in cities is one and a half times higher than in rural areas. However, there is a group of countries where the advantage of urban over rural areas is significant. The highest disproportions are reported by Bulgaria (more than 4 times), Poland (more than 3 times) and Greece (3 times). This seems to be a dangerous tendency, which is conducive to progressing civilisation marginalization of rural areas.

These figures show a disquieting picture of APL in CEE countries. Practically, in all tested characteristics values for CEE are significantly lower than the EU average. This means that CEE countries did not use the challenge and opportunity of APL. Estonia is a proud exception. The positions it occupies in particular characteristics predispose it to "abandon" the CEE group and join the Scandinavian leaders.

Conclusion and Further Research

The importance of the APL issues for DM development justifies, in the author's opinion, the inclusion of this subject in the quantitative analysis of DM. It is supported by significant interdependence between DM level and all APL characteristics (correlation coefficients between 0.78 and 0.87). These

characteristics have been selected arbitrarily by the author. The choice of appropriate indicators and specific solutions may, of course, be the subject of further discussion.

Many empirical studies of DM support the idea that success is determined by infrastructure and education. Less recognized (albeit essential and interesting) are social and cultural aspects. It seems to be a reasonable argument that, at a certain level of DM development, such issues can become crucial. The social and cultural context of DM is quite a broad and complex area. The research object may encompass a broad spectrum of problems. One of the most relevant topics is the issue of APL. In addition to education in the formal educational structures, continuing education plays a crucial role. An example of the CEE countries has shown that this issue requires improvement and activation.

In many CEE countries there are large differences in adult participation in educational processes in the areas analyzed earlier. Those less educated, unemployed and dwelling in rural areas are less active in APL, which is a very dangerous trend.

A large proportion of these groups may be prevented from active participation in DM. This, obviously, does not concern the use of ICT. Easily accessible, increasingly intuitive devices, providing attractive user experience, will provide these people with the digital content they need. The problem will lie in the lack of the ability to consciously and actively participate in the changes taking place, which can often mean a lack of opportunities to find a job and participate more broadly in the society.

A growing percentage of ineffective and unproductive people will constitute a huge social problem and an excellent breeding ground for populist political movements, which we already witness today. As a consequence, the social cohesion of many countries and the European Union as a whole may be threatened.

The considerations presented in this paper are of groundwork character. However, the discussed topics seem to be interesting and worth of further study. Such studies will help determine which characteristics should be analyzed and which indicators should be used in order to better analyze the relationship between DM and APL. The complexity of digital multiverse will increase exponentially. The answer to the question what tools to use to measure such a complex reality will become a great challenge for the researchers involved. The limitations of the analysis presented in the paper should be clearly indicated. First of all, it is subjective and the views expressed in it are those of the author. It is an invitation to discussion, rather than a final assessment.

Low level of APL in the CEE countries is the result of interplay of many cultural, social and historical factors. Their detailed analysis would go far beyond the scope of this paper. Improving the situation in the APL will reduce the gap across Europe and allow the CEE countries the realization of the vision of the digital multiverse. This is one of the conditions for these countries to avoid the middle-income trap and continue their civilization development.

Abstract

A revenue from activities in the hotel market significantly depends on a few external factors. One of the most important is the number of tourists arriving at the destination. The authorities make effort to prevent coronavirus spreading in Russia that led to the closure of the country's borders and the cessation of transport links for tourism. The authors study a spreading of coronavirus in the regions of the Russian Federation and its impact on the hotel market in St. Petersburg. The analysis of seasonal rates in St. Petersburg hotels allows us to conclude about the possible catastrophic consequences of a decrease in the number of tourists for the hotel services market in the eve of the high season of White nights. Based on the analysis of the recommendations of experts in the sphere of hospitality and examples from the practice of world hotels, hotels are needed in strategies for actions in COVID-19 environment.

Keywords: Coronavirus, Hotels, Hospitality, Hospitality Market, Hotel Strategies, St. Petersburg

Introduction

The analysis of foreign and local experience shows that the development of tourism as a service industry sector is influenced by a significant number of factors in the external and internal environment. However, tourism does not belong to the basic needs of the population, therefore industry has a significant decrease in the number of tourists with adverse changes in the environment. The development of tourism at the global level brings not only global opportunities, but also global problems. One of the significant global problems is the spreading of coronavirus, that affects national economies. The tourism as one of the sectors of the economy has experienced a significant decrease of income because of the restrictive measures of the governments of different countries. The hospitality industry, being one of the most important elements of tourism, also has felt a strong influence of the coronavirus spreading.

This article will present the results of a research about coronavirus impact on the activities of hotels in St. Petersburg.

Materials and Methods

The research materials were scientific articles, opinions of experts in the field of hospitality, and statistical information. The main methods were analysis and synthesis.

Literature Review

In the Russian Federation, tourism development has significant regional differences (Degtereva, V.A., Zaborovskaia, O.V., Sharafanova, E.E., 2018, Tanina, A., Zaborovskaia, O., Shabunina, T., Yakishin, Y., 2018)). These specifics must be considered how to plan an income from the activities of organizations of the tourism industry and tourism infrastructure (Khadra, J.B.; Goncharova, N.L.; Radwan, Y., 2019, KUZNETSOV Sergey V., SELENTYEVA Tamara N. and MIKHEL Ekaterina A., 2019). The pronounced seasonality of touristic attractiveness in most regions of Russia due to geographical location (Korchagina, E., Shignanova, R., 2018, Tanina, A.; Mudrova, E.; Sigov, V.).

The hospitality industry among other elements of tourism has a number of features (VEREVKA Tatiana V., 2019, Skhvediani, A.E., Kudryavtseva, T.J., Kravchenko, V.V., 2017, Rodionov, D.G., Rudskaya, I.A., 2017), including the need for significant expenses when any hotel tries to enter in the market (buying or renting real estate, repairing, buying furniture and equipment, etc.), and during ongoing activities (remuneration, taxes, purchases for food, cleaning and other hotel services). Therefore, the receipt of a fixed income from activities is the main condition for the existence of the hotel business. According to crisis conditions, the main task of hotel management is to find the optimal balance between reducing costs and maintaining the required level of service (Verevka, T.V., 2019, Saenko, N.R., Prokhorova, V.V., Ilyina, O.V., Ivanova, E.V., 2017).

Results

The end of 2019 was remembered by the world community because of the news about the emergence of a new type of coronavirus in China. Soon enough, from a local outbreak the disease has spread almost in all over the world. The absence of visible symptoms among patients did not allow to prevent the spreading of infection, therefore virus spread primarily in the countries that have a common border. Due to international flights Covid-19 has got to other continents.

In Russia for quite a long time (compared with European countries) there were no cases of infection with coronavirus of a new type. The first two cases in the country belonged to Chinese citizens and in fact they were in relatively sparsely populated regions in the east of the Russian Federation.

Nevertheless, from February 1st flights with China were limited, and all remaining flights (only flights to Beijing, Shanghai, Guangzhou and Hong Kong) were transferred to one terminal of Sheremetyevo Airport in Moscow. Russian Railways canceled direct Moscow-Beijing trains. The evacuation of Russian citizens began from Hubei province, Hainan island and Wuhan city. The regions of the Russian Federation with a common border with China (Amur Oblast, Khabarovsk Krai and the Jewish Autonomous Oblast) have closed border crossing points (The first cases of a new coronavirus have been identified in Russia, 2020).

From March 18 to May 1, entry into the Russian Federation is restricted for all foreign citizens and stateless persons without exception (like the external borders of the EU). On March 19, due to the threat of the spread of coronavirus, the mode of high alert was introduced by the authorities for all 85 regions of Russia. Mass events were canceled in all subjects, universities and schools switched to distance learning.

On March 20 Rostourism recommended for Russian citizens temporarily to refrain from traveling outside the country until the epidemiological situation gets normalized. Beginning from March 30, traffic through all border checkpoints, including road and rail, was restricted (Komarova A., 2020).

On April 9, 2020, the number of infected people was 10,131 people, 76 people who died, 698 people who recovered (About confirmed cases of a new coronavirus infection COVID-2019 in Russia, 2020). The sick is in 50 regions, most of them are in 10 regions (table 1).

Table 1 : Regions of the Russian Federation with the maximum number of patients with COVID-19 (as of April 9, 2020)

Region	Number of cases		The population of the region as of 01.01.2019	% of cases from the population of the region
	Absolute, pers.	Relative,% of the total number of cases		
Moscow	6698	66,11	12615279	0,0531
Moskovskaya oblast'	748	7,38	7599647	0,0098

Republic Komi	150	1,48	830235	0,0181
Leningradskaya oblast'	112	1,11	1847867	0,0061
Krasnodarskiy kray	105	1,04	5648235	0,0019
Bryanskaya oblast'	97	0,96	1200187	0,0081
Nizhegorodskaya oblast'	87	0,86	3214623	0,0027
Tul'skaya oblast'	66	0,59	1478818	0,0045
Ivanovskaya oblast'	60	0,59	1004180	0,0060

Source: compiled by the author according to (Grouping of subjects of the Russian Federation by population as of January 1, 2019, Confirmed infections by region of Russia, 2020)

From the data of table 1 the vast majority (83.8%) of cases are in only 10 regions out of 85 in the whole country. Moreover, most cases in the capital are logical, because of the significant passenger traffic in Moscow, including transit traffic. The capital also leads in the proportion of cases in the population, although this rate (0.0531%) cannot be named threatening. Nevertheless, the city leads in the growth rate of infected people and make the rules more tough for a population being in the megalopolis

In St. Petersburg, which is often called as the second capital of Russia, the situation with the coronavirus spreading is more favorable. Due to the smaller number of people entering from abroad (Pulkovo airport rather quickly limited, and soon stopped sending and receiving air traffic) and as well as more stern and restrictive measures by the city leadership that were taken at the initial stage of the pandemic. Thanks to this, the number of cases is almost 18 times less than in Moscow, although it continues to grow.

Let us consider how the spreading of coronavirus affected tourism in St. Petersburg and the activities of hotels. For this it is necessary to consider the features of the development of the hotel services market in St. Petersburg.

Unlike Moscow, where the seasonality of tourist flows is not so pronounced, in St. Petersburg there is a pronounced peak of the season that appears only during “white nights season”. In the narrow sense, white nights mean the period from June 11 to July 2, in a broad sense - from May 25 to July 17. During the white nights, the loading of hotels in St. Petersburg is the highest, and the tariffs are maximum and can significantly exceed prices in the low season. Table 2 shows the prices for double occupancy in a standard room for the weekend (Friday - Sunday, 2 nights) in St. Petersburg hotels of various categories. Breakfast is included in the booking. There are hotels that have been chosen for comparison and located in the historic center of the city, which is popular among tourists for a walking.

Table 2 : Prices in high and low season in hotels of St. Petersburg

Hotel	Category	Rating on booking.com	Price, rub.		Price difference, %
			19-21.06. 2020	16-18.10. 2020	
Belmond Grand Hotel Europe	5*	9.3	65040	31200	208
The State Hermitage Museum Official Hotel	5*	9.3	37800	31600	19
Corinthia Hotel St Petersburg	5*	8.9	45600	25800	77
Pushka INN hotel	4*	9.5	54000	25000	216
Crowne Plaza St. Petersburg-Ligovsky	4*	9.2	40320	25920	56
Rossi Boutique Hotel	4*	9.3	30400	23800	28
Metropolis Hotel	3*	9.5	24798	16398	51
Kaleidoscope on Moika	3*	9.4	30470	9000	339
Grand Apart near Nevsky	3*	10.0	11897	9981	19

Source: compiled by the author according to booking.com

Table 2 shows that in hotels of different categories (despite the difference in tariffs), similar trends in pricing are observed. Some hotels set tariffs for accommodation during the white nights a few times higher than in the low season (from 2.08 times for Belmond Grand Hotel Europe 5 * to 3.39 times for Kaleidoscope on Moika 3 *). The pricing of other hotels is insignificant (from 19% at The State Hermitage Museum Official Hotel 5 * and Grand Apart near Nevsky 3 * to 28% at Rossi Boutique Hotel 4 *) differs in seasons. In general, hotels in St. Petersburg tend to increase prices in the high season within 50-100%.

The holding of international events has a strong influence on the pricing of St. Petersburg hotels. The city is a major center of international tourism, including congress type and every year it holds political, economic, sports, cultural and other events of global and national level.

June 2018 did not meet the expectations of St. Petersburg hotels for a large increase in revenue. Overpriced (even compared to the usual high prices of the "white nights season") prices did not allow to attract traditional tourists, and the guests of the mundial provided a loading of only 71%. At the same time, the June load in 2016 was 82%, and in 2017 - 78%. It should be noted that the traditional growth of the June loading is provided not only by tourists who came to enjoy white nights, but also by guests of the St. Petersburg International Economic Forum, which was held in May 2018. As a result, prices in luxury rooms in June were much lower than in May and amounted to 38 thousand rubles in the most expensive hotels of the Northern capital. The loading of high-level hotels amounted to only 65%, and prices were two times lower than in Moscow (JLL: all segments in two capitals increased prices, while Petersburg scared off some tourists, 2020)

Despite the fact that from loading point of view the high season of 2018 did not meet to the expectations of St. Petersburg hotels, the holding of the World Cup had a strong influence on the promotion of the city and the improvement of its tourist image on a world level. The increase of the loading occurred in accommodation facilities of all categories. Mid-level hotels, mainly large hotels with many rooms, oriented towards group tours, became the leaders in the growth of loading. These hotels have the highest RevPAR growth (20%), while the tariff and loading are growing equally. Other segments of the hotel services market showed an average loading growth of 3%, RevPAR growth was 6-17%. At

the same time, almost all market entities show a more active growth in ADR, but not loading (which is the opposite for Moscow hotels).

The following main trends contributed to the growth of tourist flow to St. Petersburg in 2019:

- a recognition for several years as the best urban tourism destination in Europe.
- the successful holding of notable events on the international level (the World Cup, the Assembly of the World Tourism Organization, the St. Petersburg International Economic Forum, etc.).
- free electronic visa introduction to visit St. Petersburg and Leningrad Region from October 1, 2019.
- an active promotion of the territory, including the official city tourism portal of St. Petersburg "Visit Petersburg".

According to the results of 2019, the tourist flow exceeded the number of tourists per year during the Championship by 10% and amounted to 9.1 million (Petersburg in 2019 for the first time in history received more than 9 million tourists, 2020).

Favorable trends in 2019 allowed us to hope for a further increase of the tourist flow, especially since 1.10.2019 after the start of the operation with electronic visas, the city was visited by over 60 thousand people from 52 countries.

In 2020 the World Congress of Chefs, SCO and BRICS Summits, 4 matches of the European Football Championship and other global events were planned in St. Petersburg. The "open skies" mode in Pulkovo would increase the flow of foreign tourists.

But the spreading of coronavirus has become a source of great losses for tourism and the hospitality industry in general.

The first loss was the closure of borders for Chinese tourists, whose number in the total tourist flow in St. Petersburg has grown steadily in recent years. The total number of hotels in St. Petersburg is estimated at about 30 thousand rooms. In 2019, 750 thousand Chinese tourists visited St. Petersburg, therefore the average monthly flow in St. Petersburg amounted to 62.5 thousand guests. It is easy to see that the lack of tourists from China greatly influenced the loading of rooms.

Mid-range hotels (3 *) were the most suffered, in which group tourists came from China. The share of Chinese tourists in such hotels could be 70-90% therefore, to attract customers such hotels significantly reduced prices. In January-February the most hotels kept the standard loading for this season on the average at 40-55%, but hotels could not raise tariffs (at least by inflation rate) due to a decrease in tourist flow and the cancellation of reservations of the guests from Europe (Coronavirus: how are things really in hotels in St. Petersburg?, 2020).

The beginning of March brought cancellation due to COVID-19 of Russia's largest business event - the St. Petersburg International Economic Forum (SPIEF). The lost income because of cancellation is estimated at between several hundred million and 3 billion rubles. The forum has been held since 1997 and received the unofficial name "Russian Davos". In 2019, SPIEF was visited by over 19 thousand people from 145 countries. Due to the large number of delegates and accompanying people, hotel rooms, halls in restaurants and venues for organizing events were booked six months before the start of the forum. Some service providers receive up to 20% of annual income for 4 days of the event.

Undoubtedly, the cancellation of SPIEF will significantly affect the operational indicators of St. Petersburg hotels. Even though the forum itself lasts only four days, it affects the hotel industry of the city for 2-3 weeks - technical experts and support services are placed in hotels in advance. The cost of standard rooms for the days of SPIEF is usually at least 3-4 times higher than the tariffs for other days.

Hotels of the highest price category suffered the most, because their loading is provided by delegates, representatives and participants of the forum. The number of five-star hotels rooms, which traditionally

host SPIEF participants, is almost 2500. In the period of such a huge demand, hotels can sell rooms at premium prices when they are fully loaded with a significant depth of sales. The best hotels during the SPIEF could offer the presidential suite for 2.5 million rubles per day. Moreover, for this period a number was not being sold by the day, but as a package for all days of the forum. The luxury hotels received additional income from the maximum use of hotel services such as restaurants, car rentals and conference rooms. According to experts of the hotel industry, the loose from the cancellation of SPIEF for the most popular hotels of this category will be as minimum 60-65 million rubles in a day. The cancellation of the forum has reduced the income not only luxury hotels. 4 * hotels also suffered from losses. Their main guests are journalists and other categories of visitors not related to the participants (Melnikova K., Zhitkova V., Gaysina I., 2020).

In early March 2020, even after the cancellation of SPIEF, hotel representatives hoped that the summer loading will be remained, primarily due to the European Football Championship. The possibility of holding matches without spectators was considered, but on March 17 UEFA announced the postponement of Euro 2020 matches to 2021 (UEFA postpones EURO 2020 by 12 months, 2020).

A closure of the transport connection and restricting of the entry for foreign citizens into the Russian Federation by May 1, 2020 (with the possible extension of restrictions) does not allow to predict favorable results for the high season of hotel enterprises in St. Petersburg.

The situation is complicated by the fact that by the beginning of the season (May-June) about 2,000 rooms in service apartments will have to enter the market. The owners of the apartments are mainly private owners who invest in the construction of apartment hotels to generate income. To ensure the owners' income, management companies can significantly reduce prices, which will result in dumping among three- and four-star hotels (Coronavirus: how are things really in hotels in St. Petersburg?, 2020).

In such conditions, hotel organizations need to develop a plan of actions. But actions during the period of the coronavirus spreading should differ from measures that level the influence of only economic factors.

A lot of hotel industry experts (Pierre Verbeke, Alisa Voitika, Catala Thibault, Erulin Aymeric) agree that big discounts will not be able to attract customers during a pandemic if tourists do not travel due to border closures or concerns about their own safety. A significant discount can change the target audience of the hotel, but such guests cannot bring the expected income due to the inability or unwillingness to pay for additional services other than the accommodation itself.

The examples during the financial crisis of 2008 clearly showed that when the discount is being used, demand gradually recovered after 6-8 months, but ADR took more than 3 years to return to the pre-crisis level (Pierre Verbeke, 2020).

Another recommendation is to maintain a budget for marketing activities. To attract customers, the best thing is not to reduce prices for all without exception, but to develop package offers and promotions to save current guests and attract potential customers. The standard options are Stay 3 Pay 2, free breakfast, room upgrades, free spa services, etc. During a crisis, it is important to maintain the loyalty of the target audience.

For a few hotels, new marketing approaches have been shown to be effective, for example, segmenting customers for other reasons and developing personal offers with additional value for guests. A significant impact on the behavior of guests can have a unique offer that competitors do not have.

Hotels that spend more on marketing during a downturn can get RevPAR in 18.5% higher than hotels that cut their marketing costs (Alisa Voitika, 2020). Although all hotels in crisis may expect less loading, the data shows that there is a strong positive correlation between marketing costs and efficiency in times of crisis. Investing a digital marketing budget in revenue sources, such as meta-

searches and retargeting, can help the hotel to achieve returns not only in difficult times, but also in the long running .

Despite the decline in revenue in a pandemic, it is unacceptable to lower hotel standards. Oppositely, guests must receive additional value through information on ensuring the safety of accommodation and upon receipt of services. The cost saving is acceptable in those areas of the hotel that minimize the quality of service and the image of the hotel. If you need to cancel any services or reduce their quality, the hotel must warn the guests in advance.

A special importance in crisis conditions are the conditions of the reservation, especially the cancellation. Now it is impossible to predict whether the trip will take place not only in the long, but also in the short term due to the rapid change in the situation with the incidence in different territories. Clients are waiting for a flexible approach to canceling or reserving, regardless of the recognition at the national level in each country of the consequences of coronavirus force majeure.

The most acceptable for customers is cancellation of the reservation without penalty regardless of the initial conditions of the tariff. For a hotel, cancellation of the reservation (especially with a refund of the deposit) is not the best option, as it implies a loss of income not only in the present, but also in the future. Therefore, hotel companies should focus their efforts not on cancellation, but on transferring the reservation to another time, encouraging guests with additional bonuses, services for their consent. Instead of refunding money for failed trips, a few European airlines give vouchers for a ticket price valid for 1 year. Perhaps for hotels, such practice (considering seasonality) will also save customers.

Non-refundable options should be excluded from the tariff options of the reservation. The best way is the “book now, cancel later” option without prepayment or cancellation penalty (Petrova M., 2020). A modern digital service allows you to implement deferred payment by credit card. Due to the impossibility of long-term planning in the current conditions, many clients, having a vacation in the summer months, look at suitable options, but do not make a reservation. The hotel may offer deferred payment by credit card as a payment method. When the reservation makes, the guest does not need to make an advance payment immediately, but in the confirmation letter with the reservation he will receive a link to pay by credit card. The hotel itself determines how long this link will be active. If during this time the guest does not make an advance payment, the reservation will be automatically canceled.

A support is needed not only for customers, but also for a staff. To maintain the proper level of service and loyalty in the organization, it is necessary to pay attention to the moral and awareness of the staff in difficult conditions. The safety must be provided not only for guests, but for the staff. It is necessary to foresee a plan of actions for all people in identifying a case of illness of a guest or employee and to observe it strictly. If staff reductions are needed, support must be considered for employees (Sundareva E., 2020).

If it is not possible to provide enough loading to pay for current expenses, hotels are forced to choose one or more strategies:

- temporary preservation of the hotel.
- closing part of the hotel for guests.
- bankruptcy of the hotel.
- accommodation in the room fund of doctors working with patients with coronavirus.
- the provision of single rooms to keep with the isolation.

It should be noted that the period of crisis associated with the lack of customers can bring benefits to the hotel, not economic, but social. A creative approach, for example, the formation and maintenance of relationships with other local hotels in difficult times to create partnerships or the foundation of a community for participants in excellent events at the hotel can demonstrate leadership positions for all market participants (Nicki Graham, 2020).

The support of the territorial community when placing in rooms for medics or persons, who are needed in the isolation, significantly improves the image of the hotel enterprise among not only customers, but also society, including government agencies.

For example, hotel companies, including members of ITP Caesars Entertainment and the NH Hotel Group, distribute food packages to local food banks and charities. Hotel Wyndham offers facilities for workers who cannot go to work and need professional space outside the home (Madhu Rajesh, 2020).

However, the choice of such strategies requires large financial resources, which is possible in the following cases:

- compensation of expenses by owners at their own expense.
- availability of reserves within the international hotel chain.
- payment of expenses by local or state authorities.

What strategies do the hotels of St. Petersburg choose? The vast majority significantly reduced costs by eliminating the use of outsourcing staff, reducing working hours and bonuses. But the lack of a significant part of the hotel's financial reserves and a catastrophic drop in loading can lead to bankruptcy of enterprises.

The closure of the air traffic and the borders of the Russian Federation made inbound tourism impossible; the further closure of museums, theaters and other objects of touristic interest also stopped domestic tourism. As a result, the average loading in March amounted to 15-20%, and in April it is planning at the level of 8% (against the planned 65%). The lack of income led to the closure of hotels. On March 19, the Finnish company Sokos Hotels closed one of three hotels in St. Petersburg - Original Sokos Hotel Olympia Garden. The RA hotel chain stopped four of the six hotels - on Nevsky, 102, Ligovsky, 87, Rybinsk, 7 and Tambov, 11.

Other hotels have accepted the way of optimization, conserving part of their number of rooms. So, the Oktyabrskaya Hotel now has only two floors and half of the rooms are serviced. The loading does not exceed 20%, and room prices have fallen because of the absence of demand by half. At Rossi Hotel & Spa 35–40% of rooms are available. Helvetia decided to stay just one floor, decommissioning about 90% of the number of rooms.

Preservation means that linen and bedding are being cleaned, pillows and blankets are being packed, minibars are being taken apart, and the rooms themselves are no longer being serviced. This allows you to reduce operating costs and survive these difficult times.

According to market participants, business travelers who continue to come to St. Petersburg save them from complete collapse. Some hotels are doing well targeting such clients. For example, The Kempf Hotel, which opened on Kamennoostrovsky Prospekt 12 in January 2020, is now almost 100% full. The main customers of the company are PJSC Gazprom, which continues to send employees on business trips from Moscow as well as Rossiya Airlines, which removes numbers for its crew members: although international flights have ceased, the carrier continues to serve domestic flights (Boyarkova G., 2020).

Among the guests there are delayed European guests who did not have time to leave before the cancellation of flights and the closure of borders. Another group of tourists is coronavirus dissidents who specially come to the deserted city, mainly from Moscow. Residents of the Northern capital rent rooms for a night or two if they want to diversify their lives in self-isolation.

To survive, hoteliers are trying to beat the coronavirus trends. For example, Helvetia launched a self-isolation service for a pandemic. The hotel offers to rent a room for a month at the price of renting a business-class apartment.

To prevent collapse, hotels are also trying to get discounts on rent. One part of the landlords gives a 50% discount, another part provides an instalment plan, as it understands that even for a year hotel cannot compensate lost profits.

Unofficially, market participants admit that they are still forced to work at a loss and can only survive with the support of the owners. Those, who do not have such a financial pillow, have a risk of receiving a lot of legal actions from clients soon, because they must return the money they have already spent. A significant seasonality of demand leads to the fact that in winter hotels exist by prepayments of the summer season. Booking.com's decision to refund unilaterally for canceled, even non-refundable reservations increase customer loyalty, but not all hotels can afford to think about loyalty in the absence of funds for current activities.

The gradual normalization of the situation with coronavirus in China gives hope for the restoration of pent-up demand and the return of Chinese tourists to the city (some hotels have increased the number of bookings by the Chinese for the summer season). But no one can guarantee the growth of the tourist flow soon.

Discussion

The situation in the hotel services market remains tense. A professional message in the field of hospitality in the Russian Federation is only being formed and does not have a significant impact. Nevertheless, the existing professional associations of hoteliers jointly developed an appeal to the Government of the country with proposals to support the industry and prevent the closure of hotels and the dismissal of staff.

The market players are asking to introduce a moratorium on taxes before the end of the year, to subsidize utility bills, to exempt hotels from payments to social funds, to help ensuring credit breaks for existing hotel loans, to compensate employees for wages, to allocate funds for promotion and advertising of St. Petersburg for abroad (The current situation with the hotel business in St. Petersburg: figures and facts, 2020).

The Government of the Russian Federation has not yet voiced real measures to support the hotel industry, even though hotel associations and federations have proposed taking effective measures to avoid mass layoffs and ruining of market players.

The Influence of Direct Payments on The Production Value of Agricultural Branch in Romania

Ana URSU
PhD Scientific researcher II, Research Institute for Agricultural Economics and Rural Development (I.C.E.A.D.R), Bucharest, Romania, ursu.ana@iceadr.ro

Ionut Laurentiu PETRE
Scientific researcher, Research Institute for Agricultural Economics and Rural Development (I.C.E.A.D.R), Bucharest, Romania, petre.ionut@iceadr.ro

Abstract

In this paper it is desired to investigate whether the direct payments, granted through the EAGF, in Romania, can have implications on the economic situation of agriculture, respectively on the value of production in different sectors of agriculture or even the value of the production of the whole branch. The research hypothesis is that, in Romania, given the structure of the agricultural sector, direct payments positively and with an average intensity affect the value of agricultural production. With the help of statistical data on the values of agricultural production and direct payments and by correlating them and determining a simple linear regression, it was found that, indeed, direct payments positively and with a medium to strong intensity, influence the value of the production of the whole agricultural branch in Romania.

Keywords: the vegetal sector, the animal sector, the value of agricultural production, direct payments, Romania.

Introduction

In this paper it is desired to establish whether the direct aids granted by the European Union, taking over the EAFRD fund have any influence on the economic state of agriculture, respectively on the value of the production, either in sectors or of the whole agricultural branch.

From the literature, one can see a broad approach regarding the impact of direct payments on a large and diverse number of variables, thus, Kropp and Katchova (2011), stated that the direct payments could improve the liquidity position of the farmer or the repayment capacity which to allow farmers to obtain more favourable credit conditions. Under more favourable credit conditions, a farm could remain in business or expand production. Given how direct payments are calculated and managed, direct payments are likely to affect beginner and more experienced farmers differently. A significant positive relationship was found between the level of direct payments (in dollars) and the debt coverage ratio for experienced farmers, which suggests that direct payments improve the repayment capacity.

El Beni et al, 2012 conducted a research with the purpose of examining the effects of agricultural policy reform, in particular the transition from market to direct payment support - on the variability of Swiss farm incomes. They found that the shift from market-based support to direct payments decreased the variability of farm incomes and household incomes.

Constantin, 2019, emphasized through his research the role of public support in agricultural development and how direct payments have influenced agricultural production and especially farm incomes. The author considers that the development of agriculture depends strongly on the intervention of the public power by granting direct payments, along with the market measures that aim to ensure the stability of the farmers by supporting agricultural incomes and increasing productivity. Among the conclusions of the study is the assertion that granting direct payments to

Romania after 2008 has led to the improvement of the economic situation of the agricultural sector. Thus, the agricultural income increased by more than 70% during the analysed period, on the one hand, as a result of rising prices for production and agriculture and, on the other hand, because of direct payments.

AgriFood economics centre created a report by Bray et al, 2017, on the impact of direct payments. In Chapter 4 of the report, certain scenarios were developed using the CAPRI model, to investigate how direct payments affect agricultural land use, income, production and other factors. To determine this impact, a comparative analysis was performed between the baseline scenario (ie the one in which the current policies are continued) and an alternative scenario without direct payments. Among the results, the authors point out that direct payments contribute to maintaining the use of agricultural land. If they were missing, land use in the EU would fall by 6.5%. Another result would be that direct payments increase agricultural incomes by 21% in the EU as a whole.

Some authors believe that direct payments can have less positive effects. Such research is presented by Cionga et al, 2008, which evaluates who is likely to benefit, in the short term, from the implementation of the CAP in Romania, focusing on the distributional impacts of agricultural subsidies within the CAP. Preliminary results reveal an extremely uneven distribution of farm subsidies. As a result, the difference between Romanian low-income and high-income farms will become larger, the most vulnerable hardly benefit from the introduction of direct payments.

Another more pessimistic approach is also found in the study of Latruffe et al, 2008, which investigated the relationship between CAP direct payments and managerial efficiency for French vegetable and beef farms. The authors are adamant that there is a substantial component of inefficiency that is due to adverse conditions. Moreover, there is a significant negative relationship between managerial efficiency and CAP direct payments for vegetable farms and a positive relationship for livestock farms. Area payments and less favoured areas reduce the efficiency of vegetable crops, but head / animal and agri-environment payments increase the efficiency of farms for raising beef.

Kozar et al, 2005, conducted a study as soon as the country joined the EU, regarding the effect of direct payments on incomes. Its findings also include the fact that the estimated benefits are greatest in the case of the standard direct payment scheme, followed by the lump-sum payment option (fully decoupled). The results of the model also show that the reform of the policy will have redistributive effects in favour of agricultural households engaged in extensive agricultural production.

The importance of small farms is given by ensuring food security, ensuring viability in predominantly rural areas and ensuring employment, so supporting this sector is a strict necessity. In this regard, Volkov et al, 2019, presented a research on a system of indicators on quantifying the effects of direct payments on the economic and social sustainability of small farms. This research had Lithuania as a case study, the results showing that in this country the direct payments system did not contribute to improving the sustainability of small farms from a social and economic point of view.

Taking into account the characteristic of the agricultural sector in Romania which is divided into two categories, in terms of agricultural production, namely semi subsistence farms and large farms, and taking into account their share, and the fact that large farms represent less than 10% of the number of farms realizes half of the agricultural production, the hypothesis from which this paper starts, which wants to answer the research question formulated in the first paragraph, is that according to which the direct payments positively influence the value of the production of the agricultural sector in Romania.

Material and Method

The study aims to demonstrate the dependence of agricultural production on direct payments in the agricultural context in Romania. For this purpose, the hypothesis was defined that there is a statistically significant dependence between the quantity of agricultural production and the volume of

direct payments. Secondary data published by the National Institute of Statistics (INS) and EUROSTAT data were used to achieve the objective. The available data presented are for the time horizon 2008-2018. In the analysis is used the simple linear regression model that describes the linear relationship between direct payments and the value of agricultural production. The intensity of the dependence was measured by the correlation coefficient. For the calculation, the Pearson correlation coefficient was used, which determines the direction and rate of the statistical dependence force of the two mentioned numerical variables. The Pearson correlation coefficient has values between -1 and 1 and was determined based on the following calculation formula:

$$r_{x,y} = \frac{\sum_i (x_i - \bar{x}) * (y_i - \bar{y})}{\sqrt{\sum_i (x_i - \overline{x})^2 * \sum_i (y_i - \overline{y})^2}}, \text{ where}$$

x, y ... xn, yn are the measured values of the independent random selection of size n of the two random variables X, Y from the two-dimensional normal distribution; sample mean.

The correlation coefficient (r) was interpreted as follows (Colton's Rules, 1974)

- 0.25 <r <0.25. A correlation coefficient from -0.25 to 0.25 means a very weak or no correlation.
- -0.5 <r <-0.25 or 0.25 <r <0.5. A correlation coefficient from 0.25 to 0.50 (or from -0.25 to -0.50) means a weak correlation (acceptable degree of association)
- -0.75 <r <-0.5 or 0.5 <r <0.75. A correlation coefficient from 0.50 to 0.75 (or from -0.50 to -0.75) means a moderate to good correlation
- r <-0.75 or r> 0.75. A correlation coefficient greater than 0.75 (or less than -0.75) means a strong correlation (very good degree of association).

The Pearson correlation coefficient also indicates the direction of a linear relationship as follows.:

- r> 1 there is a direct linear relationship between the variables;
- r <1 there is an indirect linear relationship between the variables;
- r = 0 variables are not linearly dependent.

The analysis continued with the elaboration of a statistical model based on simple linear regression, with which the connection between the two variables will be determined, in order to determine the influence between them. To test the variation of y explained by the regression equation, the analysis of the variant (ANOVA) was used. Also by analysing the variant, the ratio between the variant explained by regression and the variant of residuals (F) is calculated.

Results and Discussions

The agricultural production in Romania is a primary one, respectively made up of raw products, which cannot have a high added value, considering that the processing component is not so common. This aspect can be verified by analysing the value of agricultural production by sectors, as divided into national statistical databases.

Thus, in order to determine the level and evolution of the value of the production of the agricultural branch, all the components of this branch will be analysed, according to the nomenclature of the National Institute of Statistics of Romania.

Figure 1: Evolution of the value of plant and animal production

Source: own processing based on NIS data

Figure 1 shows the production values for the two main sectors of the Romanian agriculture, respectively the plant and animal sector. The data provided by the NIS were converted from the national currency of Romania, using the average annual exchange rate, in euros. Thus, with regard to the value of the agricultural crop production, it can be observed that it has recorded fluctuations from year to year, considering that this sector is greatly influenced by the climatic conditions, so the obtained production has varied during the analysed period. On average, each year the value of plant production was 10.9 billion euros, with a standard deviation from this average of 1.6 billion euros, which resulted in a coefficient of variation of 14.7%. During the period analysed (2008-2018), the evolution of the value of the vegetal production registered a slight growth, having an average growth rate of 1.06% per year.

Regarding the value of the animal production, its evolution was more constant, registering an annual average value of 3.96 billion euros, registering an average deviation from this value, of 214 million euros, which causes a variation of 5.4%. As for the evolution of the value of animal production, this is almost constant, registering a slightly negative annual average rate of -0.04%.

By summing the two values of the production (the plant and the animal), the value of the agricultural production of goods results according to NIS. This is shown in Figure 2.

Figure 2: Evolution of the value of agricultural production of goods

Source: own processing based on NIS data

The evolution of the value of the production of agricultural goods, is given, in large part by the evolution of the value of the vegetable production, considering that, on the one hand, the evolution of the value of the animal production is a constant one, and on the other hand the share of the vegetable sector in the agricultural production. of goods, as shown in figure 2, occupies values between 66.6% and 73.1%. On average between the two sectors the weight is thus distributed, 73.1% representing the value of the plant production, and 26.9% representing the value of the animal production. On average, the value of agricultural goods production in Romania was during the analyzed period, of 14.9 billion euros, annually, with a deviation of 1.63 billion euros, which determines a coefficient of variation of 11%.

Figure 3: Evolution of the production value of the agricultural branch

Source: own processing based on NIS data

If the value of agricultural services and the value of processing products are added to the value of agricultural goods, the value of the production of the whole agricultural branch can be determined. The evolution of the value of the production of the whole agricultural branch is represented in figure

3. As can be seen, it recorded values for the period 2008-2018, ranging from 14.16 billion euros to 19.34 billion euros. On the one hand, these values are largely influenced by the level of production obtained in the respective sector, and on the other hand the prices of agricultural products or services can have a significant influence on this value. The average annual value of agricultural production in Romania was, during the reference period, of 16.42 billion euros, with an average deviation from this value of 1.68 billion euros, which resulted in a coefficient of variation of 10.2%. On average, over the period the evolution of the value of agricultural production was slightly increasing, registering an average growth rate of 0.77% per year.

Considering that the purpose of this study is to determine the influence that the subsidies can have on the economic indicators analysed previously, it is considered necessary to analyse the evolution of the subsidies granted in agriculture. In this respect, with the help of the annual reports of the European Commission on accessing the European Agricultural Guarantee Fund, the evolution of the support granted to Romania regarding direct payments could be realized.

Figure 4: The evolution of direct payments in Romania

Source: own processing based on the annual reports of the European Commission

Regarding the evolution of the direct payments made in the Romanian agricultural sector, in figure 4, we can observe a significant and continuous increase of them from one year to the next. If in 2008, through the EAGF fund, grants of 422.3 million euros were granted, they increased from year to year, reaching in 2018, direct payments worth 1.775 billion euros, being 4.2 times larger, as in the first year.

On average, each year, direct payments amounting to about 1.09 billion euros were granted; from this value, there was a rather large average deviation of 479 million euros, which resulted in a coefficient of variation of 44.1%, which indicates that the data string is not homogeneous. The reason for this situation is recorded, the quite large increase from one year to the next of the allocated amounts, on average the annual growth rate was 15.4%, and if we refer to the absolute difference, from the equation of the line of trend can be seen that, on average, the value of direct payments increased by 144 million euros from year to year.

Considering the hypothesis of this research, namely that direct payments influence the value of agricultural production, in conjunction with the objective of the paper to determine this influence, it is considered necessary to determine the dependent variable, respectively the one that the total value of direct payments most influences. In this sense, further, with the help of the additional data analysis program, more correlations will be made between the independent variable (direct payments) and a number of possible variables.

Table 1: Determination of the dependent variable using Pearson correlation

	Agricultural production of goods	*Agricultural production*	*Production of the agricultural branch*	*Direct Aids*
Agricultural production of goods	1			
Agricultural production	0,9998	1		
Production of the agricultural branch	0,9966	0,9975	1	
Direct Aids	0,6445	0,6543	0,6883	1

Source: own calculations

Table 1 determines the Pearson correlation coefficients, between direct payments and the value of agricultural production. These calculations were made on the basis of the national currency, so that the exchange rate does not affect the statistical model. Thus, between the direct payments and the value of the agricultural goods a positive coefficient of 0.6445 is registered, which denotes a close and directly proportional connection between these variables. A similar link is registered between direct payments and the value of agricultural production (0.6543), but the highest correlation coefficient is recorded between the direct support and the value of the production of the whole agricultural branch, this being of 0.683, which causes a connection close and directly proportional between these two variables. Thus, the value of the output of the whole agricultural branch will be used as a dependent variable.

Table 2 Determination of the link between variables through the simple linear regression model

Regression Statistics	
Multiple R	0,6883
R Square	0,4737
Adjusted R Square	0,4152
Standard Error	6610,9820
Observations	11

ANOVA						
	df	*SS*	*MS*	*F*	*Significance F*	
Regression	1	354021495,2	354021495,2	8,100	0,019	
Residual	9	393345746,7	43705083,0			
Total	10	747367241,8				
	Coefficients	*Standard Error*	*t Stat*	*P-value*	*Lower 95%*	*Upper 95%*
Intercept	59346,509	4870,262	12,185	0,000	48329,211	70363,807
Direct payments million lei	2,610	0,917	2,846	0,019	0,535	4,684

Source: own calculations

Table 2 presents the statistical linear regression model in which the value of the production of the agricultural branch is correlated with the value of the direct payments. Thus, as mentioned above, the correlation coefficient (multiple R) between these two variables is 0.668 which denotes a close link between the variables and positive, respectively when one grows, grows and the other. The coefficient of determination (R Square) is 0.473, so it can be considered that the dependent variables are explained by the independent variables in proportion of 47.3%.

Moving on, to determine if the model is statistically significant, it can be said that yes, because the sig. (signifiance F) is 0.019 lower than the maximum allowed threshold of 0.05, so it can be considered that the model is statistically valid.

As far as the coefficients of the function are concerned, they are also statistically valid considering that sig. (P-value) is also below 0.05, and the confidence intervals do not contain the null value. Thus, by determining the coefficients of the function it can be written in the following form:
Y = a*x+b: Agricultural branch production value = 2,61 * Direct payments + 59346,5

Therefore it can be said that direct payments significantly influence the value of the agricultural branch, and quantifying this aspect, when the value of direct payments increases by one unit, the value of the whole agricultural branch will increase by 2.61 units.

Conclusions

Taking into account the necessary caution in interpreting the results, we can draw some general conclusions on the paper that aimed to determine the influence of direct payments on the value efficiency of the agricultural branch in Romania. Following the analysis of the results, it was found that the agricultural sectors with a higher share of direct payments on the value of production presented a variable value efficiency, this variability being given by the weights occupied by the vegetable (73.1%) and animal production sectors (26.9%) in the value structure of agricultural production. The value of the vegetal sector, in the period 2008-2018, registered an annual growth rate of 1.06%, and for the animal sector the average annual rate is negative, of about 0.04%. The average annual growth rate for direct payments was 14.5%, which suggests that the Romanian agricultural sector is dependent on direct payments, payments that have contributed to ensuring the efficiency of the agricultural sector.

The evolution of the value of production of the entire agricultural branch means that as the amount of direct payments increased from one year to another, the value of production was directly proportional to the increase in subsidies (r = 0.6888) at a moderate pace, due to price volatility of the demand and supply of agricultural products. Also, direct payments provided as support for farmers' incomes contribute to maintaining agricultural holdings to remain in agriculture in the idea that they can improve their technical efficiency and productivity, but those farms produce goods for self-consumption and do not contribute to the value chain.

Through the developed statistical model, which includes a simple linear regression, its function was determined and implicitly the influence that the independent variable (direct payments) has on the dependent variable (the value of the production of the agricultural branch). Thus, the linear function recorded a regression coefficient of 2.61, which indicates that when direct payments increase by one million, the value of production of the entire agricultural sector increases by 2.61 million.

Acknowledgment

The work is part of phase no. 2 of the ADER project 23.1.1./2019, entitled: „*Technical and economic substantiation of production costs and estimates on the capitalization prices of the main plant and animal products, obtained in the conventional system and in organic farming*", project funded by the Ministry of Agriculture and Rural Development.

Diversification of Farm Liquidity in the EU

Janina JĘDRZEJCZAK-GAS

Faculty of Economics and Management University of Zielona Góra
Zielona Góra, Poland, j.jedrzejczak-gas@wez.uz.zgora.pl

Abstract

The aim of this study is to analyse and evaluate the diversity of liquidity of agricultural holdings in the EU. The financial liquidity of agricultural holdings was examined by time, by EU countries, as well as by economic size of holdings (ESU) and farm type (T8). The studies used statistical data from the EU Farm Accountancy Data Network (FADN).
The average level of current farm liquidity in the EU countries ranged from 4.4 to 6.6, while the average level of fast liquidity from 2.9 to 4.9. Thus, in the light of the normative values, it is a high level of financial liquidity.
The optimum levels of liquidity presented in the literature are not applicable to agricultural holdings. There are very large differences in the level of liquidity of farms between the EU countries. Liquidity is dependent on the economic size of farms - both the current and quick liquidity is lower the higher the economic size of the farm. There is a significant variation in the financial liquidity of agricultural holdings by type of farming.

Keywords: Financial Liquidity, Agricultural Holdings, EU.

Introduction

The topic addressed in this article is financial liquidity of agricultural holdings. Liquidity is one of the most important factors that determines the existence of an enterprise on the market, and its loss is the main cause of financial problems and bankruptcy of many enterprises (i.a. Masdupi, Tasman and Davista, 2018; Khan and Guruli, 2015; Jędrzejczak-Gas, 2013; Mokhova and Zinecker, 2013). On the other hand, the overliquidity may limit the development possibilities of an enterprise by reducing its ability to generate profit, which should be the main source of development financing. Therefore, the issue of financial liquidity is widely analysed in the literature on the subject, but most often in relation to non-agricultural economic activities (i.a. Kontuš and Mihanović, 2019; Almeida, Campello, Cunha and Weisbach, 2014; Liua, Niu and Zhang, 2019; Jędrzejczak-Gas and Kużdowicz 2016). However, it is addressed to a definitely limited extent in relation to the agricultural sector. Yet, agricultural enterprises must function as any other economic entity (Kułyk, 2013; Kułyk 2019) and it is necessary to manage financial liquidity in such a way as to enable timely payment.

The research shows that there is an exceptional situation in the case of the liquidity of agricultural holding entities. They maintain liquidity at a higher level than in other sectors (i.a. Bieniasz and Gołaś, 2008). Therefore, there is a need to undertake further research on the liquidity of agricultural holding entities. As a result, surveys have been carried out which attempt to answer the question: How does the financial liquidity of agricultural holdings in the EU (in the time profile, in particular EU countries, in the system of economic size of holdings (ESU), by farm type (T8)?

The aim of this study is to analyse and evaluate the diversity of liquidity of agricultural holdings in the EU. The article consists of two parts. The first part, based on the literature, present the most important issues concerning the concept and measurement of financial liquidity. The second part presents the results of the study on the variability of financial liquidity in EU agriculture. The financial liquidity of agricultural holdings was examined by time, by EU countries, as well as by economic size of holdings (ESU) and farm type (T8). The studies used statistical data from the EU Farm Accountancy Data Network (FADN).

Concept and Measurement of Financial Liquidity - Literature Analysis

A company is liquid if it has sufficient financial resources to meet its financial obligations in a timely manner at minimum cost (Maness and Zietlow, 2005, p. 31).

In the literature on the subject one can find various definitions of financial liquidity, which indicate its various aspects. Most often, financial liquidity is defined in terms of asset,asset and capital and cash flow (Kosińska and Cicirko, 2010).

In terms of assets, liquidity means the ability to convert individual assets into cash in the shortest possible time and without any impairment of their value (Wędzki, 2003, p. 32; Gajdka and Walińska, 1998, p. 465; Grzywacz, 2014, pp. 11-12). Assets that can be quickly converted to cash without a significant decrease in their value are defined as liquid assets (Helfert, 1997; Brighman and Houston, 2004, p. 77).

In terms of asset and capital, liquidity is the ability of an enterprise to meet its short-term liabilities on time. This aspect therefore concerns the mutual relationship between the assets that secure the timely repayment of liabilities and the liabilities that finance the asset (Wędzki, 2003, p. 33). Therefore, financial liquidity is closely related to the size and structure of current assets. The company's current assets are most easily converted into cash, which makes them the main source of cash to cover maturing liabilities (Shapiro, 1990, p. 734).

In terms of cash flow, financial liquidity is the ability to cover expenses resulting from current liabilities and necessary future expenses with expected current cash inflows (Kusak, 2004, p. 10; Wojciechowska, 2001, p. 14; Dudycz and Wrzosek 2000).

Liquidity in terms of assets andasset and capital is static. It is calculated on the basis of assets and liabilities that the entity has at a given time. In turn, financial liquidity in terms of cash flows is dynamic - it shows financial processes streamlined in the form of cash receipts and expenses.

To sum up, financial liquidity is a function of current assets and current liabilities and their structure. The level of a company's liquidity depends on the amount of cash and other assets that can be quickly converted into cash, the amount of liabilities that will need to be repaid in the near future, and the company's ability to raise cash by issuing securities or borrowing money (Chambers and Lacey, 2011 , p. 489).

Liquidity assessment is carried out primarily on the basis of financial reporting and should take into account indicators of a static nature (asset and asset-equity aspect) and indicators of a dynamic nature (cash flow aspect). In practice, this measurement is most often carried out on the basis of static indicators.

There are many different static liquidity ratios in the literature (Brigham and Houston, 2012, pp. 99-101; Dyson, 2010, pp. 222-225; Correia, Flynn, Uliana and Wormald, 2001, pp. 5-13). These indicators most often include: current liquidity ratio, quick liquidity ratio and instant liquidity ratio (see Abraham, Glynn, Murphy and Wilkinson, 2008; Atkinson, Young and Kaplan, 2004).

Current ratio - indicates how many times current assets cover current liabilities. It informs about the ability of the company to settle its current liabilities with the global volume of current assets as quickly as possible. In the literature there are discrepancies as to the optimal level of this ratio. For example, the optimal range of the value of this index according to E. Nowak is 1.5-2.0 (2008, p. 205), 1.3-2.0 according to B. Olzacka, R. Pałczyńska-Gościniak (2007, p. 56), 1.6-1.9 according to P. Kralicek (1995), 1,2-3,4 according to A. Niemiec (2014). The optimum level of financial liquidity does not apply to all industries. In agriculture, the current liquidity ratio is generally higher, which is a result of a long production cycle and the need to accumulate stocks of means of production (Ziętara, Kosiorek, Tchorzewska, Kondraszuk 1994, p. 98). The research indicates that in agricultural holdings

the value of current liquidity indexes is higher than the optimum one from literature (Wasilewski, Zabolotnyy, 2016; Mańko, Sobczyński and Sass, 2008, p. 10-20).

Quick ratio - indicates how many times assets with a high degree of liquidity exceed current liabilities. It is most often assumed that the optimal level of the ratio is between 0.8 and 1.2. However, it should be noted that similarly to the current liquidity ratio, there are discrepancies in the literature on the subject as to the optimal level of this ratio (Kreczmańska-Gigol, 2015, pp. 37-38).

Cash ratio - indicates how much of the current liabilities can be repaid immediately if they become suddenly due. It is most often assumed that this ratio should take values from 0.2 to 0.3, but similarly as in the case of the two previous ratios, there are discrepancies in the literature on the optimal level of this ratio (Kreczmańska-Gigol, 2015, p. 39).

Liquidity in EU Agriculture

The results of the study on the diversification of liquidity in EU agriculture are presented below. Statistical data of the EU Farm Accountancy Data Network (FADN) from the years 2004-2017 was used. The financial liquidity of agricultural holdings was examined by time,by European Union (EU) countries, as well as by economic size of holdings (ESU) and by farm type (T8).

The literature presents many different indicators on the basis of which the financial liquidity of enterprises can be assessed. However, due to the lack of data in the FADN accounting database, two indicators, i.e. the current liquidity index and the quick liquidity index were the subject of research.

The current liquidity ratio is presented in Table 1, while thequick liquidity ratio for EU-25 for 2004-2006, EU-27 for 2007-2012 and EU-28 for 2013-2017 is presented in Table 2.

Table 1: Indicators of current financial liquidity in EU agricultural holdings in the years 2004-2017

	2004	2005	2006	2007	2008	2009	2010	2011	2012	2013	2014	2015	2016	2017

Source: Own study based on FADN (https://ec.europa.eu/agriculture/rica/database/database_en.cfm).

The data presented in Tables 1 and 2 show that in the years 2004-2017, the average level of current farm liquidity in the EU countries ranged from 4.4 to 6.6 and the average level of fast liquidity from 2.9 to 4.9. Therefore, in the light of the normative values, it is a high level of liquidity. In the analysed period there was an increase in the liquidity of EU agricultural holdings. In the years 2004-2005, the current liquidity index amounted to about 4.5, in the years 2006-2010 - increased to about 5.5, while in 2011 it reached its highest value in the whole analysed period - 6.6. In the following years, its value decreased slightly, but was not lower than 5.5, and in the last analysed years it amounted to about 6.0 (Table 1.). A similar increase is observed in the case of the quick liquidity index - its value increased from 2.9 in 2004 to 4.9 in the years 2010-2011, while in subsequent years it slightly decreased, but did not go below 4, and in the last years under study it amounted to about 4.6 (Table 2.).

Source: Own study based on FADN (https://ec.europa.eu/agriculture/rica/database/database_en.cfm).

The research shows that there are very large differences in the level of liquidity between EU countries. In the whole analysed period, the highest levels of liquidity ratios occurred in such countries as: Italy, Spain, Cyprus, Slovenia, Belgium, Greece, Austria, where often liquidity ratios were even over 100, and in some years even over 1000 (e.g. in 2012-201 in Italy, in 2017 in Greece). The lowest value of the ratios was reached in countries such as: Germany, Great Britain, France, Estonia, Czech Republic, Bulgaria, Hungary, Latvia, Denmark, Sweden and the Netherlands. In addition, it should be noted that in many countries liquidity has changed significantly over the period considered. A very large increase in liquidity took place in countries such as Greece (from about 12 to about 200 or even over 600), Austria (about 7 to about 100) or Ireland (from about 4 to about 25-30), while a decrease was observed in countries such as: Belgium (from about 40-30 to about 9-7), Luxembourg (from about 5 to about 2-3) or Slovakia (from about 8-5 to about 1).

The very high diversity of liquidity of agricultural holdings in the EU is also confirmed by basic descriptive statistics (Table 3). In all the years of the analysed period, the variability indicators calculated for the financial liquidity indicators were very high, in some years their value exceeded even 300%.

Table 3: Descriptive statistics on the current and rapid liquidity of EU farms in 2004-2017

Analysing the data for the sector of agricultural holdings by economic size, it can be seen that with an increase in the economic size of an agricultural holding, liquidity decreases. For example, in 2017, for micro farms, the current liquidity amounted to 43.4 and quick was 34. For very large farms, the former amounted to 3.0 and the latter to 1.8. The differences in the level of financial liquidity between micro and large farms are very clear because their liquidity ratios differ even 20 times.

The survey showed that in all groups of farms distinguished by economic size (ESU), except for micro farms, there was a decrease in financial liquidity during the surveyed period. The greatest decrease took place in very small, small and medium-sized farms - their ratios decreased about 2 times.

Table 4: Indicators of current and fast liquidity by economic size of agricultural holdings (ESU) in the EU in the years 2004-2017

	2004	2005	2006	2007	2008	2009	2010	2011	2012	2013	2014	2015	2016	2017

Source: Own study based on FADN (https://ec.europa.eu/agriculture/rica/database/database_en.cfm).

The analysis of financial liquidity by type of farming indicates that there is also considerable variation in this arrangement. Four groups of farms can be distinguished, which differ in their financial liquidity.

The first group is made up of one type - other permanent crops - in which there is high liquidity in the whole analysed period (the current liquidity ratio was between 18.3 and 28.7, the quick liquidity ratio - between 16.6 and 25.7). Moreover, the difference between the level of current and quick liquidity in this type was between 0.9 and 2.0. Taking into account that the liquidity ratios in this type were very high, it can be concluded that the difference is not big.

The second group consists of two types: wine and other grazing livestock. Their current liquidity was about 5-9 and fast 2-6. This group showed the biggest difference between the current and quick liquidity (2.5-3.3). This means that farms belonging to these types have a liquidity determined to a relatively large extent by stocks. In the analysed period, both the indicators of current and fast liquidity decreased, while whether the biggest drops were recorded by fast indicators and in 2017 they were at a level similar to the other types (except for the Other permanent crops type).

The third group consists of three types, i.e. fieldcrops, horticulture, milk, with anmild level of liquidity, compared to the other types. Their current liquidity was about 3-6.4 and quick liquidity was 2.7-5.3. In the period under study, both the current and quick liquidity ratios decreased to a similar extent. In the case of this group, the difference between the level of current and quick liquidity was at the lowest level. This means that in the case of these farms, inventories are at a relatively low level and are not significant in shaping the financial liquidity.

The fourth group consists of two types with the lowest liquidity, i.e. granivores and mixed. Their current liquidity was at the level of about 3.4-5.2 and quick liquidity was1.7-3.3. Farms belonging to

these types are characterised by a relatively high level of stocks (this group takes second place in this respect), which means that their financial liquidity is to a large extent determined by stocks.

Moreover, it should be noted that in the last years of the analysed period (2016-2017) there was a decrease in financial liquidity in all the examined types of agricultural holdings, with the greatest decrease taking place in 2 types: horticulture and wine. In these farms, the current liquidity index decreased by about 43% and 33% respectively, and the quick liquidity index by about 51% and 60% respectively. These changes resulted in the fact that in the last years of the analysed period the differences in the level of financial liquidity between particular types of agricultural holdings have decreased.

Table 5: Indicators of current and quick financial liquidity by type of agricultural holdings (T8) in the EU in the years 2004-2017

Discussion

The topic of financial liquidity is the subject of many studies and publications, but most often in relation to non-agricultural business activities. However,this issue is less addressed in relation to the agricultural sector. The published studies on the financial liquidity of agricultural holdings most often concern studies conducted in individual countries (i.a. Odalo and Achoki, 2016; Tóth, 2013), but there are few studies on the financial liquidity of agricultural holdings in the EU. The topic of diversification of financial liquidity of agricultural holdings in the EU was the subject of research by Bieniasz and Gołaś (2008) and Ryś-Jurek (2013, 2018). This article complements and continues the analyses presented by the above authors to some extent.

The conducted research also confirmed (cf. Bieniasz and Gołaś, 2008; Ryś-Jurek, 2013, 2018) that there are huge differences in the level of liquidity of agricultural holdings in individual EU countries.

Compared to previous years, there has been an increase in the average level of liquidity in EU farms. In the years 1997-2004 the liquidity indices did not exceed 3-4 (Bieniasz and Gołaś, 2008, p. 47),

whereas the presented studies show that in the years 2004-2017 the current liquidity index amounted to 4.4-6.6 and the quick liquidity index to about 2.9-4.9.

The study confirmed that high fluidity occurs in countries such as: Belgium, Spain, Slovenia (cf. Bieniasz and Gołaś, 2008; Ryś-Jurek, 2013, 2018) and Austria, Cyprus, Italy (Ryś-Jurek, 2013, 2018). Low liquidity occurs in countries such as: Czech Republic, Estonia, France, Germany, Hungary, Latvia, the Netherlands, as well as Bulgaria, Denmark, Sweden (cf. Bieniasz and Gołaś, 2008; Ryś-Jurek, 2013, 2018). Moreover, the research shows that the group of countries characterized by high liquidity in recent years has also been joined by Greece, while Croatia should not be rather included in this group (very high liquidity ratios reached only in 2013).

The research also confirmed (cf. Bieniasz and Gołaś, 2008; Ryś-Jurek, 2013, 2018) that financial liquidity decreases with the increase of the economic size of the farm.

Taking into account the type of farming, four groups of farms were distinguished in the presented studies, which differ in their financial liquidity - unlike Bieniasz and Gołaś (2008) and Ryś-Jurek (2013, 2018).

Conclusions

The presented analysis of the diversity of financial liquidity of agricultural holdings in the EU in the years 2004-2017 allows to conclude the following:

- The average level of current farm liquidity in the EU countries ranged from 4.4 to 6.6, while the average level of fast liquidity from 2.9 to 4.9. Thus, in the light of the normative values, it is a high level of financial liquidity.
- The optimum levels of liquidity presented in the literature are not applicable to agricultural holdings. In EU agriculture, liquidity ratios are higher, which is a result of, among other things, long production cycles and the need to accumulate stocks of means of production.
- The average level of financial liquidity of EU agricultural holdings increased in the period under consideration. The current liquidity increased from about 5 to about 6, while the quick liquidity increased from about 3 to over 4.
- There are very large differences in the level of liquidity of farms between the EU countries. The highest value (more than 100, and in some years even more than 1000) of liquidity ratios were reached in such countries as: Italy, Spain, Cyprus, Slovenia, Belgium, Greece, Austria. The lowest value (about 1-3) of these indicators was reached in such countries as: Germany, Great Britain, France, Estonia, the Czech Republic, Bulgaria, Latvia, the Netherlands, Hungary, Denmark and Sweden.
- In many countries, liquidity has changed significantly over the period considered. A very large increase in liquidity took place in countries such as Greece, Austria or Ireland. A decrease was observed in countries such as Belgium, Luxembourg or Slovakia.
- Liquidity is dependent on the economic size of farms - both the current andquick liquidity is lower the higher the economic size of the farm.
- In all groups of farms distinguished by their economic size (except for micro farms), there was a decrease in financial liquidity in the examined period. The greatest decrease took place in very small, small and medium-sized farms - their indices decreased about 2 fold.
- There is a significant variation in the financial liquidity of agricultural holdings by type of farming. Four groups of farms can be distinguished which differ in their financial liquidity (1.other permanent crops, 2. wine and other grazing livestock, 3. fieldcrops, horticulture, milk, 4. granivores and mixed).
- In the last years of the analysed period (2016-2017), there was a decrease in financial liquidity in all the examined types of agricultural holdings, with the greatest decrease taking place in 2 types: horticulture and wine.

Abstract

For any business, the correct flow of information is extremely important. The condition for the smooth functioning of today's enterprises is use of the potential of modern technologies, aimed at supporting efficient and efficient work in every department. Currently, one of the most important aspects of doing business becomes elements of logistics customer service. The success of the company on the market is mainly dependent on quality and handling. Efficient and satisfactory service significantly increases the company's prospects and can be a guarantee of future success. The aim of the article is to present modern information technologies and analyze the possibilities resulting from their use during customer service logistics processes on the example of the company.

Keywords: logistical customer service, information flow, enterprise, logistics process.

Introduction

All logistics activities that play a very important role in meeting needs and thus representing customer satisfaction when purchasing a product (good or service) are closely intertwined. Thus, the completeness of the customer service logistics process can be determined at its last stage, starting with placing the order, and ultimately ending with the delivery of the product to the customer or the execution of the commissioned service (Grzybowska 2009). In other words, logistical customer service includes all the elements of contact between the supplier of goods and their buyer (Crochet 2012). Logistical customer service can also be understood as meeting customer expectations by adapting the service to its requirements. Logistics activities are primarily skills based on the development and satisfaction of the needs that are taken to maintain a high level of service, result in priority customer satisfaction (Grabowska 2013).

Activities in The Logistics System of Customer Service

Multidimensionality in the concept of customer service affects the interpretation of this issue in a broad sense. It consists of various elements, both in the fields of logistics and marketing, finance and many others. This service primarily consists in meeting a variety of needs as well as customer expectations. Customer service in logistics is based on meeting certain aspects that are a positive course of sales. The most important of these is to provide the customer with a properly selected product, in accordance with his expectations, at the right time and in the right place. If any of these aspects are disturbed and the product is not available to the customer at any given time, as well as the place, then it will not be right or worth (Christopher 1998).

Despite the emergence of many logistical customer service formulations and their diverse description by many authors, we can all classify into one of the three methods of defining this field. The first of

the three possibilities is based primarily on activities closely related to the execution of the order process, where it can be distinguished (Long 2006):

- preparing the company for service,
- acceptance and confirmation of orders,
- maintaining a relationship with the customer,
- internal contract development,
- inventory management,
- completeand release of the ordered product,
- dispatch and carriage of goods,
- transfer of the product to the recipient,
- invoicing and handling payments,
- installation of certain products,
- warranty and post-warranty service,
- accepting possible complaints or returns,
- packaging.

Nevertheless, the number of activities performed related to the transfer of the product to the target customer does not constitute the completeness of all the characteristics of logistics customer service (Skowron-Grabowska 2010). Another method of showing customer service concerns the supplier's guarantee of a certain quality of service by maintaining high standards or the level of implementation of its essential components, i.e. the fixed delivery time and its timely compliance, completeness of the order, as well as the availability of the offered products (Kempny 2009). The last method of perception of logistical customer service is based on meaning as a target point of the company. In order to be able to do so, all activities taken by the company should focus on the needs of customers and the methods by which these needs can be met. Thanks to such an organized level of customer service and its orders, the company can achieve and most importantly- maintain a high position in the market (Listwan 2009).

The main objective of existing and emerging enterprises is to achieve the highest possible level of customer service, together with the lowest possible total expenditure, which is the sum of the costs, which consists of any activities taken related to the implementation of the requirements, regarding the quality of service. Obtaining economic benefits when trying to meet such assumptions requires a very good organization of the entire customer service process, as well as satisfactory actions taken for the good of the company and the consumer itself. All elements of such a operating system should form a coherent whole by defining the purpose and its benefits, ways and means to meet it. The entire customer service is formed (Kauf, Tłuczak 2018):

- a strategic part linked to decisions taken by the management staff, which presents the characteristics typical of the undertaking in order to distinguish it from the competition. The main elements that determine the individuality of a given company are the mission, philosophy of operation, logo and marketing activities. At this stage, key purchasing factors are developed and evaluated, aswell as the definition of employee satisfaction with their work,
- the organisational part responsible for bringing together the activities of employees around the most important elements, i.e. the mission, targets and procedures to meet the highest standards of service and customer satisfaction. In order for all these activities to form a coherent whole, it is very important to communicate employees and decision-makers in the company efficiently, as well as organizational culture based on openness, commitment, decision-making skills and cooperation.
- the operational part is an extremely important stage of customer service, based primarily on the knowledge and motivation of trained staff responsible for direct contact with the client, where their high qualifications allow to create long-term relationships. In order for the service of a potential customer to be successful, sellers should be positive about work, confident, their skills, as well as well-educated in the company's activities and the products or services offered. (Szymszal, Gajdzik, Piątkowski 2011).

The essence of a very prosperous customer service process is to orient the company to the needs of the consumer, to adapt the product to its expectations, and to ensure its availability. Meeting these criteria, the customer will be satisfied and, consequently, will be loyal to the brand, so that the risk of making a purchase from the competition will be relatively low(Kauf, Tłuczak 2018). There is therefore no doubt that customer service is one of the most important aspects of the company's operation and, like other processes, should be continuously improved and audited.

Activities in The Logistics System of Customer Service

In order to establish a well-functioning information and decision-making system in an enterprise, the focus should be on analysing meaningful information from multiple sources. Organizing such a system in terms of communication between the marketing department and the logistics department, allows a more conscious and more advantageous adaptation of the product to the customer's needs(Nowakowska-Grunt, Chłąd 2015). This also entails the company's distinction from competition and an increase in market position, meeting certain production conditions. Each company must create such a system for the flow of marketing information to decision-makers in this department in order to meet their needs and bring mutual benefits (SIM) (Unold 2001). As regards the definition, this system consists of people, equipment and techniques for collecting, organizing, analysing and evaluating, and then providing timely necessary and accurate information to marketing decision makers. (Nowicka-Skowron 2000).

The company's logistics systems are complex and require many activities, both inside and around the organisation (Grabara 2004). Coordination of such activities requires cooperation between all departments of the company, which makes it possible to achieve a specific strategic objective. The system approach, which allows you to choose the right solutions for your business, significantly increases its market prospects. It is essential for today's existing traders (Harrison, van Hoek 2018).

The research group consisted of 100 randomly selected consumers, which included men and women between the ages of 20 and 60. The aim was to indicate whether there are relationships between age and perception of the company's activities and to help with possible actions that tailor marketing campaigns to the appropriate group of people. The age structure of respondents is shown in Figure 1.

Figure 1: Age structure of respondents

(studyon the basis of studies carried out)

According to the age structure of those surveyed, the largest group of respondents was the one connecting customers between the ages of 30 and 40, representing 65% of the group of respondents. The second group in terms of numbers were those surveyed aged 20-30 (20%), while the third group concerned respondents aged 40-50 (10%). The last smallest group turned out to be customers in the age range 50-60 years (5%). People over the age of 60 did not participate in the survey. A larger group were women with a combined share of the study of 85%. Men made up 15% of those surveyed. This disproportion is due to the fact that randomly selected customers of the companywere asked to take part in thestudy.

Another aspect of the audited aspects was the issue of obtaining information about the company. These messages allow you to detect unused areas that can be used from enterprise advertising processes. The sources of obtaining information about the company are presented in the next chart.

Figure 2: Source of information acquisition
(Study on the basis of studies carried out)

When asked "From what sources did you find out about our store", about 75% replied that "from friends" 20% "from the Internet", while 5% of respondents replied that "from television". In the survey, the press and others were not taken into account. It is also important for the company to attach the customer to its brand. Figure 3 shows how often you use your business services.

Figure 3: How often you use your business services
(Study on the basis of studies carried out)

Another question in the questionnaire of the survey concerned the frequency of use of the company's services. Respondents most often pointed to the "quarterly" option, compared to 86% of respondents, the answer "once a month" was 10%, while "less than once a year" only 5% of respondents said. In companies where customer contact is a daily occurrence, it is often repeated that when the wrong product is delivered, 20% of customers will cease to use the services provided to them. However, in case of dissatisfaction with the service, as many as 80% of buyers will not return to the point. For the company, therefore, a very important aspect is the feedback of customers regarding their satisfaction with the service. Figure 4 shows a subjective assessment of customer service in your company.

Figure 4: Subjective assessment of customer service in the enterprise
(Own study on the basis of studies carried out))

Two people (5%) marked the option "I have no opinion". Nearly 15% of respondents responded "well". The biggest score, hovering around 80% was the answer "very well", which will certainly have a positive impact on the final result of the survey. Another aspect assessed by customers was the overall quality of the product and the punctuality of execution of orders. The observations resulting from this assessment are shown in Diagram 5 and 6.

Figure 5: Product quality assessment
(Own study on the basis of studies carried out)

The quality of the company's products was appreciated. 68% of respondents rated them as very good, 30% indicated that somehow services are good. The average rating was given by 2% of respondents surveyed. This type of customer opinion is satisfactorily influenced by the research and for the owners of the company.

Figure 6: The timeliness of execution of orders
(Own study on the basis of studies carried out)

Another question in the questionnaire of the survey was about the timeliness of the execution of orders by the company. Respondents largely rated the answer "very well" on 82%, 8% were the "good" answer, while as many as 10% of respondents indicated the option "I have no opinion", which certainly does not positively affect the reputation of the company, as it is a production company that tries to fulfill orders using the "Just in Time" method. When consumer assessment of the company, it is important how the company implements its after-sales policy. It is very important for the buyer how the possible complaint process proceeds, as it may result in loss or increased confidence in the selected brand. In Figure 7, the company's customer feedback on the implementation of possible complaints.

Figure 7: Method and time of execution of the complaint
(Study on the basis of studies carried out)

When asked about how and when the complaint was completed, the most, that is, about 78% indicated the answer "well", about 18% "very good", 4% "I have no opinion". This question is very important, for this type of activity, especially for this company, this will be described in detail in the following sections. Nowadays, online shopping plays an important role. The company, based on these trends, strives to develop electronic sales as best as possible. Chart 8,which isabout visiting an online store,can help you assess the popularity of this method ofshopping.

Figure 8: Using online store services
(Study on the basis of studies carried out)

In a question aimed at determining whether customers also use the company's online store, a larger number of people representing 65% of respondents answered in the negative, while 35% of respondents indicated the option "yes" as they use the services of the company's online store. In addition to the issue of the electronic store is Chart 9,which more accurately indicates the issue ofthe assessment of satisfaction with online purchases.

Figure 9: About theprice of quality and time of online orders
(Study on the basis of studies carried out)

Another question in the questionnaire of the survey concerned the quality and time of online procurement. This question was answered only by respondents who, in the preceding question,

indicated the answer 'yes' that they used the services of an online store they made up 35% of the respondents. Of these people, 20% responded "very well", 12% "well" and 3% "average". The time and quality of order fulfillment depends on courier companies with whom the company cooperates. As mentioned earlier, it is very important for the company to attach the consumer to a particular brand. A satisfied customer who wants to reuse the services of the company is today an indicator of success. Figure 10 indicates feedback on how to reuse the company's services.

Figure 10: Willingness to reuse the services of the company
(Study on the basis of studies carried out)

Given the data in the chart, it can be concluded that, for the most part, respondents would be happy to benefit once again from the services of the store, because as many as 80% of those surveyed, while 20% replied 'rather yes', which is also a very good result, the answers 'rather not' and 'definitely not' were taken into account. The last issue raised was the declaration of the service offered by the company to other customers. Figure 11 provides feedback on how to communicate brand products to a wider audience.

Figure 11: Willingness to recommend the company to other customers
(Study on the basis of studies carried out)

The final question in the survey was "would you recommend the*company to other customers?"* As in the previous question, the overwhelming number of people 75% answered 'definitely yes' and 25% 'rather yes'. The 'rather no' and 'definitely not' responses were also not taken into account by respondents.

Conclusions of the Studies Carried Out

According to a survey conducted among the company's clients, the gender advantage that answered the questions were women. The survey focused on the satisfaction of retail customer service at the manufacturer of children's shoes of the brand. From the above studies, it can definitely be concluded that customers of this brand rate it at a very good level. When asked about the frequency of product purchases, most people responded "quarterly", which is very important for the company, as this means that customers buy at least two pairs of shoes per season.

The question of the level of customer service has largely been assessed satisfactorily. Customers rated the level overwhelmingly as "very good". This is probably the result of hard work, both from the store's

employees and their involvement, as well as the owners of the company themselves, who place great emphasis on very good training of employees, both from service and from product knowledge. Product quality is also becoming a very important aspect. For customers of this brand, this is very important and answering the question are definitely satisfied with its quality. The company focuses on the high quality of the product, and therefore the price, which is quite high for children's shoes, but consumers often explain this so that "the quality and method of workmanship is adequate to the price of the product"

Another quite important aspect is the way and time of implementation of the complaint by the company. Here, the sentences were divided between "very good" and "good". The vast majority responded "well", for this company the subject of complaints is quite "delicate", as as a rule, complaints are unfounded, as they have mechanical damage not subject to repair/replacement or reimbursement, which customers often ask customers to avoid unpleasant situations, recognizes complaints "politely" by repairing the customer's shoes. However, not every customer appreciates this and often considers it to be mistreatment of the company by reading in the complaint form "the complaint has been dealt with politely". The company strives to make every customer satisfied and gives them a discount for subsequent purchases. Through this type of marketing, such a customer will always return to the product of this brand.

The survey questionnaire also asked whether customers also use their online store. The vast majority do not use the online platform, but there were those surveyed who answered the question in the affirmative and rated quality and time as "very good". This type of service depends largely on courier companies with which companies sign contracts. If these companies comply with their contract and deliver packages on time, the customer of the company is satisfied. Unfortunately, however, it happens that couriers do not deliver shipments to a given place and make it difficult to pick up, so that for equally courier companies and their contractors lose trusted customers. On the basis of the analysis of the study carried out and the conclusions, it is certainly possible to see the correctness of the findings:

- Good knowledge of the product, leads to customer satisfaction with the service – if you, the employee knows theproduct well, it can also sell it well. What was shown in the above studies. Customers rated the level of service satisfactorily.
- The price of the product always goes hand in hand with its quality - customers, often ask a question about the price of the product, which is quite high. In this case, on the other hand, the price is adequate to the quality, as also confirmed by the respondents.
- The method of handling the complaint does not always have to be received negatively by customers - enterprise for several years has been conducting a policy of dealing with complaints so-called. "courtesy", which has caused herself to gain fans of this brand and who often return for the product. The marketing they applied by granting a discount to customers certainly encourages them to reuse the company's services.

The company, thanks to the use of information technology and modern methods of communication with the customer, established its position as the most popular supplier of children's footwear on the regional market. The survey was aimed at identifying customers' opinions additionally and identifying further potential opportunities for brand development.

Value Relevance of Comprehensive Income and Net Income

Michal HENDRYK

The Faculty of Economics, Finance and Management of the University of Szczecin,
Szczecin, Poland, michal.hendryk@usz.edu.pl

Abstract

The issue of reporting comprehensive income generally derives from the long-standing debate about reporting income via the "current operating performance" or the "all-inclusive" concept (Brief, Peasnell, 1996; Khan et al., 2018). It itself triggers discussions on the usefulness of accounting information about earnings. The key actors in this dispute are net income and comprehensive income. The paper contains a broad review of studies on value relevance of comprehensive income and net income. It also contains a proposal for a classification framework of value relevance studies on comprehensive income, which is based on methodologies developed by various authors. The paper discusses the results of 31 value-relevance studies on the issue of usefulness of comprehensive income as well. The multidimensional analysis is aimed at answering the question, whether the comprehensive income is a more useful (more value relevant) measure of the company's performance for investors. The conclusions of the analysis indicate that it is not clear which measure is more useful (more value relevant). One of the factors influencing research results may be the fact that it still remains unclear what items could be presented in other comprehensive income and what their economic nature is. Unfortunately, the new Conceptual Framework for Financial Reporting (2018) has not resolved the issue.

Keywords: Value Relevance, Financial Reporting, Net Income, Comprehensive Income

Introduction

The issue of reporting comprehensive income generally derives from the long-standing debate about reporting income via the "current operating performance" or the "all-inclusive" concept (Brief, Peasnell, 1996; Khan et al., 2018). Officially, the theoretical concept of comprehensive income issue emerged with the publication of the Statement of Financial Accounting Concepts (SFAC) No. 3: Elements of Financial Statements of Business Enterprises by FASB in 1980 (FASB, 1980). The definition developed in this document was similar to the one presented today in IAS/IFRS. Under IAS 1, comprehensive income reflects "the change in equity during a period resulting from transactions and other events, other than those changes resulting from transactions with owners in their capacity as owners" and basically is a sum of net income (profit or loss) and other comprehensive income (IAS 1 §7), which includes revenues, expenses, gains and losses that have not yet been realized (for example changes in revaluation surplus and gains and losses arising from translating the financial statements of a foreign operation). As stated by Frendzel and Szychta (2013), by assumption the comprehensive income should be a more comprehensive measure than the net income, as it also includes capital gains and losses. The concept has been implemented into accounting standards in 1992 (Great Britain), 1994 (New Zealand), 1997 (the U.S.), 2005 (Canada) and in 2007 for companies under IFRS (Szychta, de la Rosa, 2012).

The debate on the usefulness of accounting information about earnings is still ongoing and the main actors are net income and comprehensive income. Value relevance (usefulness) studies on comprehensive income are one of the key research areas on this issue. The importance of this kind of studies is crucial. First of all, they may provide insights into questions of interest to standard setters and other constituents. Value relevance studies can be used to examine the relation between equity values and various accounting figures. They are also tailor-made for assessing whether accounting amounts reflect information used by investors in process of valuing enterprises' equity. What is more,

value relevance studies employ well-established methods for mitigating the effects of various econometric issues. These features clearly demonstrate the usefulness of such research in principle for almost all stakeholders (Barth, 2001). Therefore, the purpose of this paper is to examine which measure – net income or comprehensive income – is more useful (more value-relevant) on basis of the existing value relevance studies.

The paper is structured as follows. Section 1 is a broad review of studies on value relevance of comprehensive income. In this part literature review method was used. Section 2 contains a proposal for a classification framework of value relevance studies on comprehensive income and it is based on methodologies developed by various authors. Section 3 is based on the results of 31 value-relevance studies on the issue of usefulness of comprehensive income and it answers the key research question presented in the previous paragraph.

Literature Review

There is a wide scope of research related to the value relevance of comprehensive income. Definitely more studies on value relevance of comprehensive income were performed in American context, which is probably due to the fact that comprehensive income concept has been brought to those standards almost 10 years earlier than in IAS/IFRS. This section of the paper outlines the key conclusions derived from the selected studies.

There are several studies which have found the net income to be more useful (more value relevant) than the comprehensive income. For example, by using a 1972-1989 sample of US companies, Cheng et al. (1993) came to the conclusion that net income is much more useful than comprehensive income in terms of the explanatory power of earnings for returns. Similar to Cheng et al. (1993) the study conducted by Dhaliwal et al. (1999) does not support the hypothesis that comprehensive income is a more useful measure of the company's performance than the net income. Brimble and Hodgson (2005) also came to strong conclusions by conducting a study on 920 observations from the Australian market from 1988-1997. The results showed that the value relevance of net income is higher than value relevance of comprehensive income which, “at best is irrelevant or, at worse, confusing”. A study carried out by Wang et al. (2006) indicates that both the net income and comprehensive income are measures associated with rates of return, but the value relevance of net income is higher. Kubota et al. (2007) also failed to prove that comprehensive income is more value relevant than net income on the basis of 4,994 observations concerning companies listed on the Tokyo Stock Exchange in 2000-2005. However it should be noted that they succeeded in proving that the some other comprehensive income components – changes in cumulative foreign currency translation adjustments and changes in the balance of unrealized gains and losses on securities available-for-sale – have significant incremental information content. In an attempt to answer the question whether the comprehensive income is a more useful measure of the company's performance for investors than the net income, Goncharov and Hodgson (2008) carried out an analysis of 56,695 observations from 1991-2005, which was the most extensive study found in terms of the research sample. As the authors have pointed out, the finding that net income as a core valuation metric dominates comprehensive income in terms of value relevance were not surprising. Taking a research on 647 observations from the Iranian market, Dastgir and Velashani (2008) concluded that the value relevance of comprehensive income is lower than the value relevance of net income, both when considering the research sample as a whole and when dividing the research sample by industry sectors. Azzali et al. (2010), also failed to prove that, in general, comprehensive income is a more useful measure than net income. An interesting analysis was conducted by Kabir and Laswad (2011) too. Authors examined four key factors of net income and comprehensive income – persistence, variability, predictive ability, and value relevance. In terms of value relevance, net income was the dominant measure. The conclusion that the comprehensive income is less relevant than net income was also drawn by Tsuji (2013) and by Jahmani et al. (2017).

There are also several studies which have found that the comprehensive income may be considered as a measure more value relevant than net income. One example is an article conducted by Cahan et al.

(2000), in which authors pointed out that the comprehensive income is a more useful measure than net income at aggregate level. However, they also emphasized that particular components of other comprehensive income are not value relevant. The study carried out by Kanagaretnam et al. (2005) on a sample of 25,073 observations also shows, that aggregated comprehensive income is more strongly associated with both stock price and returns compared to net income. Similar conclusions were also reached by Lin (2006), who examined 3,836 observations from 1993 to 1998. Lin et al. (2007) concluded that on an aggregate level, the comprehensive income is a more value relevant measure than the net income. This means that disclosing aggregate information about other comprehensive income positively influences the usefulness of the financial statements. Kanagaretnam et al. (2009) on basis of 203 observations from 1998-2003 from the Canadian market also came to the conclusion of previously cited studies, that the aggregated comprehensive income is information perceived by investors as more useful than net income. A study conducted by Takahashi and Wong (2012) on the basis of a sample of 24,949 observations from Japanese market from 1998 to 2010 emphasized that the net income plus aggregated other comprehensive income is a more value relevant than the net income alone. The conclusion of Pereira (2015) study is that, on an aggregate level, the comprehensive income is a more useful (more value relevant) measure, while on a disaggregated level, other comprehensive income items do not show any added information value, which may be due to a lack of understanding of this category by investors. The evidence that comprehensive income is more value relevant than net income were also presented by Acar and Karecaer (2017) and Khan et al. (2018).

For some studies, due to various circumstances, it was difficult to clearly assess which measure – net income or comprehensive income - was more value relevant. This refers in particular to studies conducted by Dehning and Ratliff (2004), Biddle and Choi (2006), Choi et al. (2007), Devalle and Magarini (2012), Xu and Qi (2017), Park (2018) and Sajnóg (2018). The following section presents a detailed research process and outlines a classification framework for value relevance studies.

Research Design

The analysis was based on four key stages. Under stage one, using worldwide scientific databases, including in particular: Google Scholar, ScienceDirect, Scopus, ResearchGate, ProQuest and Web of Science, the literature review on empirical research on comprehensive income was conducted. The keywords used to generate a wide database of research papers were the following phrases and their Polish equivalents (together with a wide range of variations, the use of which slightly increased the number of results):

1. comprehensive income;
2. other comprehensive income;
3. net income vs. comprehensive income;

Next, after an initial review of the articles found by using the above keywords, the scope of the search was extended. The following phrases were added as part of this process:

1. value-relevance;
2. informational content;
3. predictive ability / predictive power;
4. usefulness;
5. volatility;
6. reporting;

Within this research strategy, a total of 151 scientific papers were identified. These papers were subjected to critical analysis in the next step, which resulted in the rejection of 17 papers going significantly beyond the topic of relation between net income and comprehensive income. Thus, 134 scientific papers were included in the next stage of the research.

As a part of the second stage of the literature study, the articles were re-analyzed, which was aimed at separating strictly theoretical papers (not containing the empirical element) from the papers in which the empirical study was carried out. As a result, 96 empirical articles were included in the next stage of analysis.

In the third stage a multidimensional review of the papers was carried out. It was aimed at identifying key research concerning comprehensive income issue. These included (see also Fig 1):

1. value-relevance research (research on the relationship between changes in variable values and share price or rates of return) – 52 papers (54%);
2. studies on the impact on the value of net income based indicators (whether there are significant discrepancies between net result based indicators (EPS, ROE) and the same indicators based on comprehensive income and which measure better reflects the financial standing of the enterprise) – 7 papers (7%);
3. studies on the form of presentation of the statement of comprehensive income (whether companies present the statement of comprehensive income as a single bottom-line statement of comprehensive income or in two statements containing (a) bottom-line net income and (b) bottom-line comprehensive income, and how this affects the perception of the market) – 17 papers (18%);
4. other studies not falling into any of the above categories (for example a content analysis of letters sent by constituents in standard-setting process) – 20 papers (21%);

Fig 1: Classification of studies on comprehensive income issue

Source: own elaboration.

The value relevance studies were by far the most popular direction to examine the issue of the comprehensive income, so this paper is aimed at a detailed analysis of this issue. As part of the fourth stage of the study, value-relevance studies on comprehensive income were classified according to the seven criteria indicated below:

1. data used in research (van Cauwenberge and de Beelde, 2010);
2. type of value relevance test (Biddle et al., 1995);
3. approach in running relevance test (van Cauwenberge and de Beelde, 2010);
4. econometric model used in the analysis;
5. number of models applied in the analysis;
6. number of variables used in applied models;
7. size of sample;

According to the "data used in research" criterion, value-relevance studies on comprehensive income may be classified as:

1. studies using data from the period before implementation of comprehensive income reporting (as-if data).

2. studies data after the implementation of comprehensive income reporting (as-reported data).
3. studies using as-if and as-reported data.

In studies using as-if data, financial measures concerning years before implementation of comprehensive income into standards are arbitrarily adjusted to the reality after the implementation. In other words, financial data prior to the introduction of the standards is brought to a state of comparability with financial data presented after the introduction of these regulations. Studies using as-reported data take into account only "reported" data, i.e. including the provisions of the standards in the period to which they relate. Studies with as-if and as reported data applied are aimed at capturing the conclusions from both as-if and as-reported studies and comparing the value relevance before and after implementation of the comprehensive income concept into standards.

Value relevance studies on comprehensive income may be classified by “type of value relevance test” criterion too. Value-relevance tests may be either relative or incremental. According to van Cauwenberge and de Beelde (2010), relative association studies examine the association between stock market prices (or returns) and alternative bottom-line measures. In case of examining the usefulness of comprehensive income, the comparison is performed mainly between net income and comprehensive income. Incremental value-relevance studies may be considered as these comparing whether one accounting measure (for example comprehensive income) provides information content beyond that provided by another (see also Biddle et al., 1995).

Fig. 2: Relative vs. incremental information content

Source: own elaboration based on Biddle et al. (1995).

Value-relevance studies on comprehensive income under the “approach in running relevance test” criterion may be categorized into measurement perspective studies and informational perspective studies (see also Barth, 2000; Barth et al., 2001). Measurement perspective studies provide a link to a valuation model (mostly Ohlson, 1995) that expresses firm value as a mix of accounting

measures such as book value, income etc. Conversely, the informational perspective studies are focused only at accounting figures and consider whether accounting data is useful to investors (see also Lev, 1989).

Another criterion for the classification of value relevance studies may be the econometric model used in the analysis. Within this criterion three types of studies were distinguished: studies in which linear econometric models were applied, studies in which logarithmic econometric models were applied, and studies in which other econometric models were applied. These studies could be also classified in terms of number of models applied in the analysis, number of variables used in applied models as well as in terms of sample size used.

After the rejection of papers going beyond the subject of value relevance of comprehensive income, as well as excluding papers for which the full texts were not available, 31 empirical papers were scrutinized and classified according to the criteria indicated above. Five of them contained a value-relevance analysis of other comprehensive income only, so they were excluded from the conclusions due to the fact that the analysis was aimed at answering the question whether the comprehensive income is a more useful measure than net income.

Research Design

At the beginning of the in-depth analysis, the studies were reviewed from the perspective of the period they covered. The result of the analysis is a summary presented in Table 1. The key conclusions were as follows:

1. the average period analyzed in studies was about 6 reporting years, which may be assumed as the lower limit of the time span to be adopted in value-relevance studies.
2. the average span between the last analyzed period and publication of the study was 3 years, which may be considered as the lower limit of 'freshness' of data on which the analysis should be based.
3. the longest period covered by the study was 15 reporting years (Louis, 2003; Goncharov, Hodgson, 2008), while the shortest period covered by the study was 1 reporting year (Kabir, Laswad, 2011; Jahmani et al., 2017), which, using also the coefficient of variation at the level of 58%, indicates a significant variation in the periods analyzed in the selected studies;

As presented in Table 2, the selected value-relevance studies on the comprehensive income have covered nearly 28 markets. However, it should be noted that a significant number of markets appear in the list as a result of their inclusion in by far the widest research conducted by Goncharov, Hodgson (2008). It covered the largest sample (56,695 observations) and sixteen countries of the European market (Austria, Belgium, Denmark, Finland, France, Germany, Greece, Ireland, Italy, Netherlands, Norway, Portugal, Spain, Sweden, Switzerland and the United Kingdom). This means that the characteristics taken from Austria, Belgium, Denmark, Finland, Germany, Greece, Ireland, Italy, Norway and Switzerland appear in the analysis only on the basis of a study that aggregated many different markets and may overlook certain country characteristics. The remaining studies mostly included a smaller research sample (usually one, maximum two markets).

By analyzing the articles according to “data used in research” criterion, it can be considered that there is a certain research niche concerning the application of both as-if and as-reported data. This means that, in principle, there are a very few analysis of the usefulness of comprehensive income before and after the introduction of standards that implemented this measure into accounting reality. The analysis of the superior usefulness of comprehensive income or net income did not provide a clear results. On the one hand, the as-if studies presented the net income as a more useful category than comprehensive income to a slightly greater extent, however, due to the nature of these studies (in studies using as-if data financial measures in years before implementation of comprehensive income into standards are arbitrarily adjusted to the reality after the implementation.), it is not appropriate to conclude on their basis (see also Fig 3).

Fig. 3: Value-relevance studies on comprehensive income classified by "data used in research" criterion

Source: own elaboration.

The analysis by "type of value relevance test" criterion demonstrates that it is hard to distinguish one leading direction of this kind of value-relevance studies. It can therefore be concluded that researchers are interested in both the question of which measure – net income or comprehensive income – is more useful for investors and which of these measures has a higher information value (and therefore offers an information "surplus" over a competitive measure). However, it seems very interesting to analyze the results of the studies itself. Analyzing only the results of relative information content studies, i.e. studies based mainly on aggregated values, the net result is the dominant measure for reasons of usefulness. The opposite relation occurs in the case of incremental information content studies, which were performed to a greater extent on disaggregated (more analytical) measures. None of the studies classified in this category confirmed a higher usefulness of the net result than comprehensive income, which indicates that, in principle, components of other comprehensive income have a positive impact on the usefulness of company performance information. In the case of studies that take both of these types of value relevance into account, the significant differences in determining the usefulness of the financial measures are generally blurred, so it is not possible to determine from them which measure is more useful to investors (see also Fig 4).

Fig. 4: Value-relevance studies on comprehensive income classified by "type of value relevance test" criterion

Source: own elaboration.

Considering the "approach in running relevance test" criterion, the advantage of informational approach studies is clearly established. They account for nearly 55% of studies identified in value-relevance studies on comprehensive income. Therefore, it can be concluded that there is a certain research gap in the measurement approach to testing the overall result of usefulness of comprehensive income. The analysis of value-relevance studies according to the criterion of the

"approach in running relevance test" also does not allow to draw any unambiguous conclusions about the higher usefulness of comprehensive income or net income (see also Fig 5).

Fig. 5: Value-relevance studies on comprehensive income classified by "approach in running relevance test" criterion

Source: own elaboration.

Value relevance studies are generally covering many different economic relationships, as evidenced by the fact that 6 and more econometric models have been applied in the vast majority of studies on comprehensive income (most of them - about 94% - were linear models). This indicates that in most cases researchers try to test as many economic relationships as possible. Taking into consideration "number of models applied in the analysis" criterion, it is difficult to distinguish which measure – comprehensive income or net income - is more useful (see also Fig 6).

Fig. 6: Value-relevance studies on comprehensive income classified by "number of models applied in the analysis" criterion

Source: own elaboration.

Similar situation applies to the classification of value-relevance studies on the comprehensive income by number of variables criterion. It is difficult to determine which measure is the more useful (see also Fig 7).

Fig. 7: Value-relevance studies on comprehensive income classified by "number of models applied in the analysis" criterion

Source: own elaboration.

Taking into account the size of research sample adopted for the studies, the conclusions are extremely interesting. In the case of studies based on a relatively small research sample (from 0 to 999 observations), the net income is the rather dominant category in terms of usefulness. A set of studies with medium size samples used (from 1,000 to 9,999 observations) indicates significantly ambiguous results. Finally, studies based on large research samples (more than 10,000 observations; the largest research sample was 56,695 observations) mostly indicate comprehensive income as a more useful category than net income. Despite the fact that the conclusions are placed on a limited sample of selected studies, differences between research sample sizes may indicate that the more "comprehensive" research, the more useful category for investors is the comprehensive income (see also Fig 8).

Fig. 8: Value-relevance studies on comprehensive income classified by "size of sample" criterion

Source: own elaboration.

Surprisingly, value relevance studies in general do not indicate which measure – comprehensive income or net income - is more useful. It seems extremely interesting that, given the values presented in Fig 9 below, the authors of the research are nearly equally divided as to the superiority of the comprehensive income over the net income as a more useful (value relevant) category (see also Table 3).

Concluding Remarks

The results of the study indicate that, in general, it is not possible to state clearly which measure – net income or comprehensive income – is more useful. It is worth noting that studies based on a large research sample more often indicated that the comprehensive income is a more relevant measure than net income. However, these results are not convincing enough, as it was not possible to draw firm conclusion on this issue.

As it is not possible to indicate which measure is more useful, at least two key questions should be raised:

1. Is there a potential for improving the methodology of value relevance comprehensive income research?
2. Was it premature to introduce comprehensive income into the IAS/IFRS and other standards?

To answer the first question, there are several areas that have not been addressed by most researchers. Firstly, studies usually include only annual financial data and do not analyze shorter periods of time (e.g. quarters). However, this may be due to a problem with data availability. Secondly, studies involving larger research samples, which are based on observations from markets with different circumstances, are mostly based on the assumption that investors around the world react similarly to disclosure in financial statements. In other words, it is also rare for research to take account of regional specificities. Thirdly, only some researchers see the importance of including sectoral

specificities in their research, but this is a rather rare practice. Undoubtedly, the usefulness of the information on comprehensive income may vary depending on the analyzed industry sectors.

The answer to the second question is very difficult. In order to form an opinion on this issue, the process of introducing the concept of the comprehensive income into IAS 1 was carefully followed. Respondents to Exposure Draft ED/2010/5 "Presentation of Items of Other Comprehensive Income" indicated a whole range of problems related to the introduction of other comprehensive income and comprehensive income issue. More than 67% of respondents highlighted the problem of the lack of any conceptual basis for other comprehensive income. The problem is still present, because the new Conceptual Framework for Financial Reporting (2018) has not resolved the issue. It remains unclear what items could be presented in other comprehensive income and what their economic nature is (Mućko et al., 2019). Moreover, the respondents to Exposure Draft ED/2010/5 notice a whole range of issues related to the other comprehensive income, for example (Hass, 2010):

1. other comprehensive income items are mainly not transitory value adjustments and not financial performance items, so they may be a source of major confusion for the financial markets;
2. other comprehensive income components have no predictive value in terms of predicting future cash flows;
3. other comprehensive income items are rather part of future but not current performance;
4. from the stewardship point of view, management's performance is neither internally nor externally assessed based on comprehensive income;

It should also be stressed that the studies reviewed in this paper have identified only a few value relevant other comprehensive income items (mainly foreign currency translation gains or losses, gains or losses on investments available for sale, and gains or losses on derivatives held as cash flow hedges). The rest of other comprehensive income items are, according to the researchers, not value relevant.

The results of the study and the arguments indicated above are the evidence that the studies on usefulness of comprehensive income and its components should be continued. This applies to both regional and global academic research as well as to standard setters analyses. The next step in the author's research path is to analyze value relevance of comprehensive income on the Polish market.

Abstract

Maritime logistics is an integral part of global logistics, due to the opportunities for creating benefit and innovation in terms of optimization approaches adapted to specific strategic contexts. Therefore, it would be wise to deal with maritime logistics phenomena from the point of view of Supply Chain Management, which therefore constitutes an opportunity to project the concepts of logistics management in the maritime context and to draw applicable results. In the sense of bringing benefits through the innovation of a number of managerial practices. In this approach, the question of the management of shipping lines, which constitute a major capacity in the field of maritime logistics, is registered. The results show that the cooperation strategy of shipping companies is highly dependent on the supply and demand of ships. The port, which collaborates with the shipping companies, will have a significant reduction in port charges, which creates the advantage of gaining more demand for stopovers, but this will have a limited effect on the load of the other port. Cooperation can result in loss to the port, so reallocation of profits is necessary to maintain the coalition. Consolidation as a strategy involves considerable risk that if the targeted benefits are not achieved, it depends on how effectively the management of the consolidation task is carried out.
According to analyzes it represents both an opportunity and a threat insofar as volumes will increase considerably in certain transshipment ports to the extent that operations will be centralized while other transshipment ports will lose their profits because they are not selected for Hub-key network planning.

Keywords: Maritime logistics, Innovative System, Supply Chain.

Introduction

With the development of the world economy, international trade has become an important factor for the economic advancement of nations. As a key element in the international trade chain, since the two important elements in the maritime industry are; shipping lines and ports so that their performance creates a significant impact on both regional economic development and industry competition. However, after the economic crisis in 2008, the international shipping industry collapsed into a trough. Ports and shipping lines face the challenges posed by the imbalance between supply and demand for shipping, which therefore makes competition in the shipping industry stronger. Following the financial crisis, the shipping industry experienced overcapacity issues. This is due to the wave of orders from container ships before the slowdown observed in the market.

As such, rates on the main route between Asia and northern Europe have risen to unprofitable levels. In order to regain profitability, the consolidation of shipping lines on certain shipping lines and the globalization of shipping companies have become standard practices. The three shipping leaders, the "P3" alliance between *Maersk*, MSC and CMA CGM, have taken steps to engage their fleet in a joint operation that will operate the ships from a center located in London in 2014. In addition, in order to reduce costs, P3 networks have concluded an agreement to consolidate three trade routes: Asia-Europe, Trans-Pacific and Transatlantic. As a result, shipping lines, which previously operated the

majority of their partially loaded fleet, will operate larger vessels that are more fuel efficient and fully loaded (REUTERS, 2014).

In order to maintain a competitive advantage, ports must improve their port facilities and their level of management. Meanwhile, cooperation has become another important means to promote port competitiveness. This manifests itself in cooperation between port operators and cooperation between shipping companies and ports. The competition to become a port hub is so intense that the main ports often find it difficult to form a partnership in a given region, so the predominant form of cooperation between ports is between large ports and small feeder ports. However, cooperation between shipping companies and ports has gradually become a general topic in recent years. The relationship between shipping companies and ports is so special. Managerial decisions made by a shipping line or transshipment port can often change the stage of a region's shipping industry and, by sharing a large share of total revenues in a single supply chain, ports and shipping companies can become mutually beneficial partners. With the implementation of a managerial strategy and a sharing of the profits generated on a chain that is both vertical and horizontal, offering the entire maritime industry a new option for achieving change.

For pure import/export volumes, the volumes will not change. But if the port has several different terminals Consolidation will favor the larger terminals which have the capacity to process the total consolidated volume. So how can we position the question of consolidation between the strategic choice and its business model?

The objective of this research aims to show the impact of consolidation in the liner shipping industry on the port industry; does this consolidation represent a threat or an opportunity for the various port stakeholders?

To this end and in order to better understand the impact of the current organization of the sector, we will be particularly interested in identifying the impact of the evolution of trends in maritime transport on ports.

Literature Review

Vertical And Horizontal Integration

The maritime industry is no longer characterized by competition between individual companies, but by a consolidation trend, that is to say the integration of services, vertically and horizontally (Fremont, 2007). Vertical integration guides cooperation between stages of the supply chain (van de Voorde, 2009), such as handling services within terminals, hinterland and port transport services, warehousing, distribution, etc.

Maersk is the most distinguished example of vertical integration. A typical supply chain will likely look like the image below, including towing activities, the yard as well as land activities within the port, all related to the transportation and handling of cargo. The consolidation of services along the supply chain has led to the creation of "*Third-Party Logistics*" (3PL) or even 5PL or LLP. 3PLs refer to integrated intra-company logistics services, ranging from transport, warehousing and distribution delivered to the wishes of consumers (Selviaridis, 2008). The 3PL offers a certain competitive advantage, namely the value-added aspect of the supply chain, which in the eyes of customers is of paramount importance.

After presenting the vertical integration scenario so far, the attention of this document will be focused on horizontal integration. Horizontal integration refers to cooperation between two or more competing companies in the same sector or market (Hill, 2008).

Besides vertical consolidation, the maritime industry is dominated by horizontal integration, either by mergers, acquisitions, or by strategic alliances.

The bulk shipping industry is not much affected by the presence of an alliance, this document will examine the case of container shipping on regular lines. There are many alliances in this part of the maritime sector, mainly because the maritime industry is a capital-intensive industry (Cariou, 2000).

Strategic Alliances

Due to standardization and containerization, global trade and investment have become possible to a large extent, increasing the coverage of consumer markets. And In order to continue to participate in the maritime industry as a global player, maritime transport companies have decided to conclude strategic transport alliances in order to reduce operating costs, in particular through the asset sharing (Van de Voorde, 2009). In this sense and before starting, what are the alliances? Strategic alliances imply a cooperation agreement, hence a deliberate relationship between two or more companies for current use and the integration of certain assets of the company in order to achieve the mutual objectives defined above (Hung, 1992) . In this sense, alliances include joint ventures.
Research on this subject has divided these strategic commitments into three categories (Harrigan, 1987), as shown in the table below. In strategic relationships, mergers and acquisitions are also included, but the difference between these two and alliances will be highlighted later in this section. According to *Harrigan*, strategic relationships can be broken down as follows: full ownership (for example, mergers and acquisitions), partial ownership (for example, joint ventures) and no ownership agreements (for example, research and development agreements) (Harrigan, 1987).

The way of cooperation as a vector for developing the competitiveness of the maritime chain

The competitiveness of ports from the perspective of shippers

In order to study the competition of shippers, *Nir et al.* (2003) take three regions of Taiwan as cases to investigate the behavior of the choice of ports by shippers. The theory of revealed preferences is applied to build a model of competitive port choice. The results indicate that the negative effects on shippers are compatible with the container travel time. Shippers are ready to choose the nearest port to save travel time. However, frequencies and routes do not have a significant influence on the choice of port choices by shippers. In addition, the value of time for the choice of port will be higher if calculated by the experimental model, compared to this experimental model and the global competitive model, despite the competition between ports. This means that the decision to choose the future port will be affected by the choice of the experienced port. Other factors such as port facilities, port services, routes and frequencies have no significant effect on the choice of port behavior. (Ibid)

Unlike other researchers, *J. L. Tongzon* (2009) divides shippers into three types: the first group shippers are those who have already established long-term relationships with shipping companies. Thus, they do not have to choose a port, but leave this decision to the shipping lines. The second type is the one who cooperates with the *Freight Forwarders*, and the third is the one who is independent. In which *Tongzon* believes that the latter two types of shippers should make such a decision to choose a port and independent shippers often choose a port from the perspective of intermodal or operator selection. Based on this understanding, *Tongzon* surveys *Freight Forwarders* in Southeast Asia, finding that the frequency of ships in port, port efficiency, port location, competitive port charges and rapid response to the needs of *Harbor* users are the most important factors for a Harbor so that the *Freight Forwarders* can compete.

By asking the respondents, *Tongzon* noted that port efficiency was ranked first by the *Freight Forwarders* sampled, followed by the shipping frequency, the appropriate infrastructure and the location.

The Perspective of the ports from the vision of the Maritime lines

However, the factors influencing the choice of ports are different from the perspective of shipping companies. *Tongzon* and *Sawant* (2007) use the survey and preference assessment method to analyze

the main factors in choosing a port from the perspective of shipping companies. Through the survey method, he finds that the efficiency of port operations is the most important factor, and the following factors are the price of the port, the connectivity of the port, the geographic location of the port, the service coverage and the size of the freight. However, he finds the various results that the port price and the efficiency of port operations are the critical factors by the preference assessment method.

Anderson et al. (2008) suggests that shipping companies are primarily concerned with freight volume, port handling costs, dockside conditions, transshipment freight volume and feeder port connectivity. It also indicates that these main lines are more sensitive to the port price than the feeder lines. For practice, the port should treat the main lines and the feeder lines in a different approach. Since value-added services and the price of the port are the main concern of the main lines, the port must provide a more complete range of value-added services to the main lines and lower tariffs as much as possible. At the same time, the port must improve its market scale and optimize the operating environment to attract line vessels from feeders. *Lirn et al.* (2004) applies the Analytical Hierarchical Process (AHP) method to analyze the preference of international shipping lines over the transhipment port. The conclusions are the main concern of shipping companies, the price of the port and the shippers value the position of the port. He notes that the main concern of international shipping companies is the quality of port service. *Yuen et al.* (2012) analysis the preference choice of port, from the perspective of shippers and *Freight Forwarders* by applying the Analytical Hierarchical Process (AHP) method. The conclusions are the main concern of shipping companies, the price of the port and the shippers value the position of the port.

Cooperation in The Shipping Industry

The removal of trade barriers and the liberalization of the market significantly facilitate world trade. Creating an efficiency sector has already become a main driving force in the market where ports and shipping companies operate. In order to meet the substantial challenge raised by the process of globalization and containerization, ports and shipping companies are devoting themselves to the search for an effective strategic compromise. Horizontal and vertical cooperation, as forms of industrial integration, is becoming an important approach to improve the efficiency of the maritime industry.

In this section, an introduction to the horizontal and vertical cooperation that occurs in this market is provided.

The two types of horizontal cooperation are discussed: cooperation in shipping lines, port cooperation and a type of vertical cooperation, Cooperation between ports and shipping companies.

Regular Lines

Shipping lines play a leading role in facilitating world trade. They allow not only the cross-border transport of cargoes, but also the Marketing plan for international trade. Therefore, maintaining the competitiveness of shipping lines to provide an efficient service becomes of crucial importance to the market. However, the existence of high fixed costs, indivisibilities and other aspects of the transmission line, makes it difficult for a single transport line to respond effectively and efficiently to the challenge of the market. Different forms of cooperation, to varying degrees, allow shipping lines to broaden their reach, rationalize their service and reduce their costs (Bergantino and Veenstra, 2002).

The most important example in history is the pricing agreements between shipping companies (Shashi Kumar, 1999) and there is also a plot and fleet sharing agreement (Lu, Cheng and Lee, 2006). Today, a more global and flexible form of cooperation has emerged, which is a global strategic alliance (Bergantino and Veenstra, 2002).

a. The motivation for cooperation in shipping lines

Given the dynamic environment of the shipping market, increasing attention has been paid to economy of scale, cost control, frequency of services and risk control. Horizontal cooperation between shipping companies offers an effective approach to achieve an economy of scale, share risks and investments in order to provide a better service to users with a low cost (Bergantino and Veenstra, 2002).

b. Types of online transport cooperation

The shipping lines alliance can be divided into three types: a strategic or global alliance, a vessel-sharing agreement and a niche charter (Ferrari et al, 2008; Panayides et Wiedmer, 2011).

c. The strategic alliance

The global strategic alliance, which is defined as "*an agreement of two or more companies that attempt to collectively increase their competitive advantages over competitors in a global market*" (Bergantino and Veenstra, 2002) is the type of most important cooperation between shipping companies (Midoro and Pitto, 2000a).
By sharing limited sources and risks, and improving customer service, product quality and market accessibility, partners in a global alliance gain a variety of competitive advantages over others and therefore an improvement in profitability (Bergantino and Veenstra, 2002). However, Alliances do not cover joint sales, price fixing, joint ownership of assets, sharing of management functions or the share of results (Panayides and Wiedmer, 2011). There are three major global strategic alliances in the world, which are CKYH Alliance, Grand Alliance and New World Alliance.

d. Sharing the ship and slots

The vessel sharing agreement, as explained by (T. Heaver, Meersman and Van DeVoorde, 2001), is the cooperation that partner transportation companies work together to fulfill a particular trade route by sharing vessels and performing joint optimization on their departure Deadlines and ordering of shipping orders to ships . An important basis for sharing vessels is the sharing of demand information. In the slot sharing relationship, the partner shipping companies improve the ships deployed on the same route with different timetables. By exchanging a fixed percentage of the vessel's capacity, carriers can reduce operating costs (Panayides and Wiedmer, 2011). However, different types of cooperation exist in the shipping market, there are still a number of shipping lines acting as soloists, such as *Maersk* Line and MSC. The shipping line which is not in a cooperative relationship generally has a large fleet and a large service network itself.
For these large shipping companies, they do not necessarily need collaboration with competitors. Economies of scale can usually be achieved by themselves.

Cooperation between shipping companies and ports

For there to be cooperation between the shipping line and the port, there are natural conditions that must exist to form a coalition. Since the shipping line and the port are two different elements of maritime logistics and there is no direct competition between them, it makes the coalition easier and more profitable. Meanwhile, the vertical integration of the shipping line and the port can effectively satisfy the maritime logistics and improve the level of service. In addition, as shipping lines choose where to drop their vessels, it is increasingly critical for a port to cooperate with one or more shipping companies to ensure long-term prosperity. The shipping lines have taken steps to get more efficiency and reduce costs and In order to achieve improvement, the adoption of large vessels and global strategic alliances were born (Asteris and Collins, 2010).

Because of this, the small shipping companies are struggling to survive, and the shipping companies are getting bigger and fewer. Therefore, being in a cooperative relationship with a major transport line can guarantee the interest of a port for a considerable period of time.

The benefits of shipping lines

Vertical cooperation in the shipping supply chain allows transport companies to expand their activity up and down. By these means, they can reduce the internal cost of the supply chain and provide better service to customers.
Cooperation can help shipping companies reduce costs and get higher profit. In case of port congestion, shipping companies can receive priority for access to the terminal by investing in a port. After the investment, a number of locations and the operating efficiency will be guaranteed at the shipping line so that the transport program of the line is not delayed by the congestion of the port and that the risk will be reduced.

Port investment is a means of diversifying the revenues and risks of the shipping company. By obtaining income from the capital invested in port operations; shipping lines can achieve a stable profit in the shipping industry, which disperses the risk of a shipping line.

Results

Modelization

A model can be defined as a tool with which a problem can be solved can be solved. Models are created to solve problems and are therefore closely linked to the problem they were created to solve (Hägg and Wiedersheim-Paul, 1994). Models exist to represent a certain reality and provide a simplification of this reality. In creating such simplifications, it is essential to identify the basis of the key concepts being modeled. As such, negligible and not indispensable factors of reality can be ignored. It should be borne in mind, however, that there can be no fixed, unchanging and real representation of reality and that it is therefore open to interpretation. As such varied interpretations may exist; models of the same reality may exist in many different forms, without being "correct" or "incorrect". This connection is illustrated in the figure 1.

Figure 1: The methodological framework, Source: (Hägg and Wiedersheim-Paul, 1994, p. 12)

In this study, the model is used to describe the influence of factors and the profit of ports and shipping companies. By analyzing the results of this study, a conclusion will be reached. In order to ensure the stability of the results, the sensitivity analysis will also be carried out.

Case study

Another notable aspect of consolidation is to calculate the **Herfindahl-Hirschmann Index (HHI)** for the industry. The HHI is a measure of market concentration and, as a benchmark, the US competition and justice authorities consider that an industry with an HHI greater than 2500 is very concentrated and an industry with an HHI between 1500-2500 as moderately concentrated.
A source of advantage of scale comes from the size of the ship, as we have already seen earlier. What an alliance allows is the creation of advantages of scale as well as flexibility within a network. As a very simple example, consider 4 shipping lines each providing weekly service between Asia and Europe. They cover all cargo from 10 ports in Asia to 10 ports in Europe. A total of 100 pairs of ports to maintain.

Each shipping company may have chosen to make only 5 stopovers only in order to have a competitive transit time. As a result, each transmission line covers 25 pairs of ports directly, and must use local feeders and associated transshipment operations to cover the remaining 75 pairs of ports. If the four shipping companies conclude an alliance, they can collectively design a network composed of 4 weekly services, with the option of providing direct port-to-port service for one of the 100 port-port pairs.

Example: The niche market

First of all, it should be noted that the "niche" carrier must be understood in a relatively broad sense.
With the evolution of the market, a niche carrier in this context is essentially a carrier that is not part of the small grouping of global shipping lines.

The reason that all of the remaining shipping lines can be called niche carriers is that they will face competition in an environment where it will be impossible to match the main lines on the main marketed products they offer. But that does not mean that there is not a margin of competition between them, on the contrary. For each of the main benefits of the major shipping companies, i.e. the scale, standardization and digitalization, let us examine how these can be used as assets for well adapted niche carriers.

On the aspect of the scale, we have already seen how this applies both to the size of the ships and to the range of the network. At first glance, it seems difficult for niche carriers to compete with, but the reality turns out to be different.
First of all, however, it should be borne in mind that niche lines have a high potential for profit compared to using larger vessels. In fact, their relative increase is much more significant than for the large shipping companies.

Discussion

Nowadays, the maritime transport industry knows a perpetual growth that it is because of the technical gigantism by the way of introducing giant ships more and more efficient, of an increasingly high productivity of the ports and terminals or the scale of production sites and emerging markets. However, in order to meet the increasingly increased requirements of this industry, it is essential to deal with the phenomenon of the consolidation of shipping lines so that ultimately the maritime supply chain will have the capacity to manage this important economic flow. This capacity, dynamic of course, presents relevant solutions for the challenge of optimizing logistics costs and increasing the added value generated, however the choice of the business model and the appropriate forms of consolidation will subsequently constitute a real operational problem than strategic.

Better cooperation and closer work between the terminals of a port is a proposed approach, with the idea of creating a single virtual terminal. For example, the ships could be distributed centrally at the first "*berth window*" available at any terminal in the port and the Yard equipment could be shared, depending on how the terminals are contiguous and if they have the same types of equipment (A common mode of operation). However, this presents many challenges, if a number of different

terminal operators have varied goals and interests and knowing that the terminal establishes the *Berth window* which corresponds to each planning of stopover networks with a predefined time interval, which thwarts the option of having the ships start again at the first available *berth window*.

Increased cooperation between terminal operators in a port and efforts to facilitate inter-terminal transfers will help, but to some extent this avoids the real problem. Consolidation is the only real long-term solution that has two aspects:

- Physically strengthen the capacity of the terminals through capital investments and civil engineering works
- Consolidation of the ownership of terminals where there are many players in the same port.

Perhaps the most practical approach, the ability to physically move and combine the capacity of terminals in a port, is this which encourages mergers between terminal operators and thus aligns interests and operational control. In this managerial approach, we identify several key learning points for any shipping company considering consolidation with another player:

- Consolidation between two shipping companies should lead to savings, thanks to synergies and longer-term strategic advantages.
- Consolidation offers a greater advantage if the geographic locations of the two companies are complementary rather than generating additional volumes in the same businesses.
- The main cost savings come from economies of scale and smarter operation opportunities with consolidated volumes, eg. Improving network usage and reducing container costs and imbalances.
- Although additional volumes can support the use of larger vessels, in many cases the benefits of scale in ship systems are already being achieved through membership in the Alliance.
- A key objective during any consolidation must be to retain the customers of the two lines, the loss of volumes or market share can cancel the cost advantages obtained.
- Communication with all parties involved, including staff, customers, suppliers and partners, is essential throughout the process.

Taking into account the increase in containerized freight flows by ports

This increase will have to be taken into account by ports, terminals and ships. The introduction of very large container ships (VLCS Very Large Container Ship) and the planned deployment of ultra-large container ships (ULCS Ultra Large Container Ship) are changing shipping models and require port extensions and upgrades. The mutual relationships between trade, shipping, large vessels and ports should be addressed to assess whether the projected larger trade flows created by fluctuating trends in world trade can be efficiently shipped and supported by ports. US trade is shipped via European ports.

Automation and digitalization

When automation is discussed in the context of line navigation, it is often from the perspective of technological possibilities. It includes subjects such as autonomous vessels, fully automated container terminals. This section will look at automation, but not from the point of view of a specific technology, and therefore not from the point of view of how the technology will work in detail, or who will develop it. Instead, he will look at automation from the point of view of how it will change the dynamics and business models in the industry.

Automation is quite simply the transformation where human work is replaced by computers or robots. When the job is replaced only with software, we would call it scanning. This is possible for all aspects of the workflow related to capturing processing and transferring information. When physical work is replaced by robots, this is called automation.

Conclusion

Container ports and terminals will experience significant changes, in part due to changes in the shipping industry, and in part due to demographic changes, the main development we are likely to see is a significant struggle for market share in the coming years driven by all of the changes mentioned above. This battle will have been largely settled, with a series of larger local ports, the expansion of certain large transshipment centers and a significant drop in the volumes of other transshipment centers. The coming years will therefore be crucial for the future of many ports and terminals.

Faced with this situation, the question of innovation of new Organizational forms at the service of the consolidation of shipping lines and activities related to the shipping industry, turns out to be of strategic necessity in order to respond effectively to the challenges of gigantism and of globalization.

Adrianna GUZOWSKA

UTP University of Science and Technology, Bydgoszcz, Poland

email: adrianna.guzowska@utp.edu.pl

Summary

The article presents the results of the study of the students' opinions on applying MS Excel in management accounting education. The first part of the article provides a review of literature on MS Excel in education. Then the justifiability of providing classes in management accounting in a form of computer laboratory is given. A substantial part of the article presents the opinions of the students of the Faculty of Management of the UTP University of Science and Technology on the justifiability of MS Excel application in management accounting education. The empirical study used a survey questionnaire. The study results show that the students support delivering those classes in a form of computer laboratory using the spreadsheet. In their opinion the tools learnt in those classes are adequate to the job market requirements. It is proposed to extend the study by a greater number of respondents from other higher education providers which offer management accounting classes. Besides the authors intend to interview the representatives of enterprises employing the graduates to get to know the employers' spreadsheet skills expectations.

Keywords: Management Accounting, Students, MS Excel, Education

Introduction

As for teaching the economics courses, the classes using the MS Excel spreadsheet are very important. The spreadsheet provides a high functionality and it is user-friendly. It allows the user for extensive applications in accounting-related fields (e.g. management accounting, financial accounting, controlling, etc.) if the user knows most of the functionalities offered by the program.

The aim of the publication has been to present the justifiability of providing management accounting classes using the spreadsheet based on a literature review and a survey. The empirical study has been to get to know the opinions of the students on the MS Excel application for the management accounting course in a form of computer laboratory and to verify what MS Excel tools are most frequently used by the students.

The first part of the publication has been a review of literature on the IT skills desired by employers, especially MS Excel, and the professions they are especially important for. Further the article points to the purposefulness of delivering those classes in a form of computer lab. Then there has been discussed the methodology of the preliminary study carried out among the students and graduates of the Faculty of Management of the UTP and the results are presented. Finally, a recapitulation has been made and the directions for future studies have been proposed.

Literature Review

The literature review first makes the analysis of the MS Excel tools skills based on the historical studies. Then the skills desired by the employers and the professions the skills are especially essential for are listed.

To verify how the students and graduates evaluate their knowledge of MS Excel, the Talent Development Foundation (fundacjarozwojutalentow.pl 2018/2019) has performed an applicable study of the students in the academic year 2016/2017, which involved 803 persons. A five degree-scale was proposed, where 0 meant “I do not know”, and 5 “I know very well”. 53% of the respondents have declared that they can manage tables, charts and functions very well, and determined their level as 4. Another 9% of the respondents value their skills even higher and claim that their spreadsheet skills are excellent. The lowest number of the respondents marked their skills as representing 2 and 1 (5% and 1%, respectively). None of the respondents claimed not to know MS Excel at all. In the academic year 2018/2019 the Foundation carried out such study again among the students and higher education graduates. A total of 511 persons were interviewed, where 42% evaluated their MS Excel skills as 3; 19% declared that they know it well. As compared with the study performed in the academic year 2016/2017, one can conclude that the students’ and graduates’ knowledge of MS Excel dropped.

The Provincial Job Centre in Szczecin (wup.pl 2007) conducted a survey e.g. to get to know the factors affecting the selection of the personnel by employers. The respondents, using a seven-degree scale (where 1 stood for "of little importance”, while 7 “very important”) were asked to determine the level of importance of the knowledge of computer programs for lower management positions. 39% of the respondents claimed that it is very important, 13% of the respondents marked it as 6. The lowest number of the respondents selected levels 2 and 3 (2% and 4%, respectively). As for the required knowledge of computer programs, the MS Office package (Excel, Word) and a number of financial programs were pointed to. Most often the employers indicated the MS Excel package (18%). The knowledge of other financial programs scored as follows: accounting (7%), “Płatnik” (4%), financial (3%).

Initially, to young persons the Excel spreadsheet seems complicated and difficult, which is a considerable barrier to learning it. It can discourage due to a considerable number of tools, functions and possibilities offered to the user (Próchnicki 2012). However, once you start working with the spreadsheet, you change your mind. Próchnicki has stressed that currently it is not used only by accountants, finance or controlling experts but everyone uses it in everyday work. It also shows that the knowledge is already an obligation and not an advantage.

The standard requirements from the accounting job applicants include: professional experience, a fluency in accounting problems and fiscal regulations, the accounting law; the knowledge of financial and accounting programs, a very good knowledge of office packages, including the Excel spreadsheet (Chomuszko 2017).

According to another study performed among the employers in the category of “hard’ knowledge, the work organization and an effective time management (self-management) skills, analytical skills and IT tool skills are essential (Budnikowski et al. 2012). It is necessary to keep improving the IT tool skills (namely Excel and other basic programs at advanced level).

Sithole (2015) has investigated the accounting knowledge and skills desired by the employers and the level of satisfaction with the skills demonstrated by the accounting graduates at basic level. The results of the survey questionnaire made among 35 employers (accountants) show that they require the candidates to know e.g. computer techniques and reporting skills. They consider the accounting graduates to be the persons with high skills of measurement, reporting and research skills. The employers have shown that they expect a greater knowledge of accounting packages and spreadsheet competencies from primary school graduates (Sithole 2015).

The study which covered the accounting graduates and employers from Ghana on the required graduates’ accounting knowledge and skills has demonstrated that, as for the IT skills, the use of spreadsheet packages was considered by both groups as most important. The only differences between the two groups were the IT skills for word processing and Windows (Awayiga et al. 2010).

The results of research provide useful information for the scientists and academic teachers responsible for introducing changes in their curricula. Besides, it turns out that a fast and efficient skill of using the Microsoft Office package, especially Excel, is considered indispensable in many professions. Not every enterprise can afford expensive business intelligence solutions and that package is used not only by many enterprises but also by many individuals. MS Excel can automate and speed up the execution of reports, breakdowns and similar tasks, providing the employee with more time for drawing conclusions, analyzing the situation and taking decisions on any potential corrective actions.

MS Excel is an extensive program with a number of extensive possibilities. On the market there are many enterprises offering applicable training addressed, especially, to professionally active people who do or intend to do the office work. It is one of the most frequently used office work programs. It enjoys a great popularity globally, both in small and large enterprises. With a literature review there has been developed a list of some professions in which the spreadsheet knowledge is applicable (projektgamma….; porady.pracuj.pl……; praca.pl 2019;):

- Human resources department: it facilitates an efficient management in the enterprise, it is a link between the management and respective employees. The human resources specialists use the spreadsheet for employee recruitment and for such human resources works as e.g. employee vacation calculation, contract development;
- Secretariat: the secretary's responsibilities often include a development of text documents, developing breakdowns and data collecting and ordering. To do it well, one must know the most important Word and Excel functions;
- Accounting department: the use of the spreadsheet functions speeds up the work considerably, which, in turn, makes analyzing respective data much easier;
- Logistics department: document formatting, data entering and ordering as well as developing reports are just sample responsibilities of the logistics expert. A lack of MS Office competencies, in fact, makes it impossible to work in this profession;
- Production planner; the spreadsheet is an excellent tool for developing the production plan and schedule. It is possible to develop many formulas, interdependent cells and sheets, and the program will perform tens of thousands of calculations within a short time. Production planners with IT personnel can adjust the spreadsheets to the specific nature of the enterprise very well;
- Customer service specialist: collecting and processing the claims and updating databases are impossible without the knowledge of the word editor and spreadsheet;
- Receptionist: he or she takes care of the image of the enterprise, provides information and develops documents, organizes business trips and events held by the enterprise. The knowledge of the MS Office package allows for doing it efficiently and accurately;

Web portal pracuj.pl, where job ads are posted, on 19 March presented 47 job offers in Bydgoszcz where the employers require the knowledge of the MS Office package (there were 197 all intellectual job offers). Most professions which require the knowledge of the MS Excel package are production planners, logistics specialists, process engineers, supplies experts, and calculation specialists (pracuj.pl 2020).

Management accounting course provided as computer lab

There is a gap between what the students learn in terms of accounting at schools and what skills are expected by the employers from the graduates (Weaver and Kulesza 2014; David et al. 2011). The gap is especially a problem for the students looking for accounting and managerial jobs (Cable et al. 2009). The accounting employers often require the candidates to know a specific accounting software. It turned out that few people demonstrate such skills. An employment advantage is found then in the graduates with experience (David et al. 2011). A low level of the students' knowledge of the MS Excel functions is also confirmed by the study conducted at the Wrocław University of Economics (Kes and Kotłowska 2013).

The syllabi at schools of higher education cannot meet the job market needs adequately. They syllabi have been severely criticized as not being adequate to the useful skills required by the corporate employers (Bennis and O'Toole 2005; Seggie and Griffith 2009). Over the recent dozen or so years many leading business schools have followed a wrong model. Instead of measuring the competencies of their graduates or how well their faculty understands the important factors affecting the business results, they measure almost exclusively the requirements of their scientific research. Most practical-profile higher education providers execute a double mission: to educate the practitioners and to create knowledge through research. From a historical point of view the emphasis is made on the first one at the expense of the other.

The application of computer technology for management accounting classes improves the students' results in the final exam both as compared with the results in the mid-term exam and the results in the introductory accounting course (Bawaneh 2011).

As reported by Halabi, who has compared the effectiveness of computer-aided learning with that of a face-to-face lecture, the advantages and disadvantages of applying computer-aided technologies in accounting courses have been noted (Halabi, et al., 2010). A computer-aided study material is, in general, user-friendly as it divides information and skills into small packages, facilitating the student learning at achievable stages. The disadvantages are costs and time limits required to develop and to implement computer learning modules.

Students consider the application of computer-aided learning methods as effective for a better understanding of accounting problems. Considering the differences in the students' characteristics, technology can offer a better learning possibility and help to develop the key competencies (Pittmann and Edmond 2016).

A study performed among the managers and young professionals has demonstrated that the top five skills include the MS Excel skills from intermediate to advanced (Weaver and Kulesza 2013)

Accounting-related jobs most often use the MS Excel tools which include: pivot tables, entering data and cell formatting, plotting diagrams and logic functions (Lee et al. 2015). The least frequently used tool was the Solver. The new employees also mentioned the above tools as most essential. The author has indicated that the most often required program at recruitment was MS Excel.

The technology and IT systems education are of key importance for the future of the students (Ainsworth 2001). As suggested in the literature review, it is expected that the accounting students will enter the job market with a set of basic accounting technology and knowledge-related competences. The fact that Excel is a useful tool also comes from the number of trainings and the number of enterprises offering such training. Having analyzed the available MS Excel management accounting courses, it was found that their prices range from PLN 2100 to 2600. It was also noted that the topic coverage is very similar to the syllabus of the management accounting class provided at the Faculty of Management of the UTP University of science and Technology in Bydgoszcz. The courses include the problems provided in Table 1. Having analyzed the topic coverage, it is about 80% compliant with the class syllabus, which justifies providing classes in a form of computer lab.

Table 1: Topic coverage and the use of MS Excel tool in management accounting class labs

Class topic coverage	**MS Excel tool used**
Price calculation and defining models	Lookup Result
Profit sensitivity planning and analysis models	Scenario manager, Lookup Result
Graphic profitability threshold analysis	Lookup Table
Optimizing management accounting problem	Solver
Multi-dimensional revenue and cost analyses	Pivot tables

Development of multi-stage contribution margin calculations and determining the ranking of product and client profitability	Excel formulas

Source: own study based on: http://wz.utp.edu.pl/wp-content/uploads/2020/02/5_sylabusy_SS_FIR.pdf, as on 31.03.2020.

Since 2017 in Poland there has been operating the social idea "ExcelDay". Together with globally recognized brands, it helps students and graduates to acquire and to develop their professional competencies required to enter the job market. The project is a voluntary organization of competencies. The job-market-experienced volunteers demonstrate a practical use of the spreadsheet to young people thus filling in the diagnosed competence gap (Fundacja Rozwoju Talentów 2019).

The universal nature of MS Excel allows to use it to solve most management accounting problems. For that reason, the educational institutions should stress spreadsheet training for accounting students, if they have not done it yet.

Result of student survey on MS Excel in Management Accounting Courses

Trying to contribute to the existing literature determining the skills expected by the employers when hiring new employees, especially for accounting or managerial jobs, a survey was made among the students of the Faculty of Management, the UTP. The research objective has been to learn the opinions of the students on the spreadsheet application in accounting classes provided in a form of computer lab and to verify what MS Excel tools are most often used by students.

The study included closed-ended questions and one open-ended question. To develop the survey questionnaire, the Google Form tool was used. With it, the results could be saved in MS Excel, which facilitated an efficient analysis of the survey results.

The study involved 52 regular students majoring in finance and accounting who, in the summer semester 2018/2019 (17.31% of the respondents) and 2019/2020 (82.69% of the respondents) participated in the management accounting labs at the Faculty of Management of the UTP University of Science and Technology in Bydgoszcz.

Table 1 presents a breakdown of the topic coverage for the classes together with the respective MS Excel tools used in management accounting course computer labs at the Faculty of Management, the UTP. Next to those tools provided in the second column, the students also used the chart inserting option, entered the data unassisted, formatted the spreadsheet, and used simple formulas, e.g. the sum, product, Vlookup, index, etc.

The aim of the management accounting classes provided in the lab is to get the students to know the key MS Excel functions in terms of data and methods of presentation, facilitating the right decision-making. The students are shown how to use the program for various analysis presentation methods and for automating reporting and graphic presentation of the most beneficial solutions in the enterprise.

During classes the students acquire the practical spreadsheet skills to organize their work and to reduce time considerably to automate the processes of reporting and drawing conclusions.

The present study has shown that as many as about 42% of the respondents were studying and working at the same time. The others (about 58%) were studying only. Most of the respondents were working in the following sectors: accounting (27.27%), commerce (22.73%), food industry (13.64%), and the fewest respondents – education, customer service and administration (4.55% each). The most frequently used MS Excel tools (Fig. 1) indicated by those working were: simple functions, namely the sum, min.k, max.k etc. (about 41%), pivot tables (about 23%) and Solver (14%).

Fig. 1. Tools used at work by working students.

Source: own study.

To answer the multiple-choice question where the students most often use the MS Excel tools, the students indicated the university (88%) and for developing their diploma thesis (80.77%). The students also use the spreadsheet at home and at work (30.77% and 28.85%, respectively).

To answer the question which of the MS Excel tools was most often used by the respondents, they could only indicate a maximum of 3 answers. Most often the answer was: formulas (96.15%) Lookup Result (28.85%) and pivot tables (25%). Scenario manager and Lookup Table were least frequently used (5.77% and 7.69%, respectively).

To verify the students; opinions on the level of MS Excel applicability, a five-degree scale was used, where 1 stood for "not applicable", and 5 "applicable". Almost 67% of the students considered it very applicable and 27.47% - applicable.

98% of the respondents claimed that their level of the knowledge of the tools and spreadsheet increased after the completion of the management accounting classes.

All the students agreed that the management accounting classes should be taught in a form of computer lab. Besides, in the opinion of more than 72% students, delivering the management accounting classes in a form of computer lab complies with the job market requirements.

The last question was open-ended. The respondents could indicate other IT tools which, in their opinion, should be used in management accounting classes. The answers included the SAP and financial ratio analysis software.

Recapitulation

Adjusting the syllabi to the market needs is possible thanks to the cooperation of academic teachers with the practitioners. Adjusting the syllabi to provide the skills desired by the employers will satisfy the demand of the enterprises for qualified employees. The students who will graduate with a specific set of skills will enjoy a competitive advantage over those who do not have it.

The results of the study point to the importance of introducing considerable modifications into student management accounting syllabi. It is evident from the literature review, job ads and from the positive opinions of the students of the Faculty of Management on the spreadsheet application for the classes of the course. As it turns out, the students use the spreadsheet not only at the university but also at work. Everyone has considered the lab as a form of classes which is adequate, and 98 % claimed that

the level of MS Excel knowledge after completing those classes increased. Both the aim of the study and the aim of the article have been executed.

From the point of view of the requirements for the candidates, especially for accounting jobs, one must point to the need to develop a new accounting teaching method to include of the legal, organizational and technological conditions. The article presents the arguments which should encourage a launch of such educational path. Numerous spreadsheet accounting teaching advantages have been provided. Nevertheless, the study covered the students of a single higher education provider and so the results cannot be representative; hence a further such study proposal. The first study worth performing is to verify the opinions of the students and graduates of other higher education providers who have participated in management accounting classes in a form of auditorium and laboratory using MS Excel. It would be then possible to compare the analytical, cognitive and professional skills in the students of two groups: taught with the use of the traditional auditorium form and the lab form. Other study which would verify the purposefulness of implementing the spreadsheet as an accounting teaching tool would be a study among the representatives of the enterprises employing the higher education providers' graduates to find the skills they expect from such persons. The study could help defining the teaching skills most desired by the employers which would supplement traditional education. Besides, it would supplement the results of research provided in this article.

The topic is vast, however, it seems worth considering and implementing. The use of the spreadsheet in management accounting education is adequate to the today's reality and it allows for a better preparation of accounting students for their future jobs.

On top of that, well-educated students with professional skills help the schools of higher education execute their objective; the top job placement of talented students to allow their further development. Thanks to it, they can become a new generation of leaders.

Abstract

Exponentially decreasing data examples can be found all over in the world. While most of these decrease to zero, there are some examples that decrease with a vertical shift. Data in this form can be difficult to fit to a mathematical model. Iterative algorithms, such as Levenberg-Marquardt for nonlinear least squares curve-fitting, exist to fit the data to a curve, but have some constrains that need to be considered, some hyperparameters that need to be tuned and convergence can be slow.

A new method will be presented in this paper that is not using the above mentioned iterative algorithms, while maintaining the accuracy; has no hyperparameters and the only constraint it has is that the data needs to roughly (data can be noisy) follow the exponential decay curve: $Ae^{-\alpha x} + B$ with A, α and $B \geq 0$. This method was tested on both simulated and real data and performed equally well in both cases much like the curve_fit method from the Python library SciPy but having no hyperparameters and converging faster.

Keywords: exponential decay, curve fitting, Least Squares, regression calculation, forecast, interpolation, data mining

Introduction

Exponential decay is common in the natural sciences. It occurs when a quantity decreases at a rate proportional to its current value. Some examples of this are the decay in time of a pendulum swinging in the air (Huang & Huang, 2000) and the growth in time of an initially small bacterial colony (Zwietering, et al., 1990). Data that decays exponentially in the form $y(t) = Ae^{-\alpha t}$ is very simple to fit a model to by simply taking the natural log of each data point and using simple linear regression to fit the transformed data to a line. When the data does not decay to zero, however, it is not as simple. Data in the form

$$y(t) = Ae^{-\alpha t} + B \tag{1}$$

also occurs naturally. Data in this form is not as simple to fit a model to, especially if only a small number of data points are available.

One set of data in this form is hCG measurements in women with Gestational Trophoblastic Disease (GTD). It has been shown in the research study of (You, et al., 2010) and (You, et al., 2013) that hCG levels in these women decrease exponentially according to model (1). Figure 1 shows a sample of hCG measurement. We can observe that the hCG measurement follows an exponential decay, it can be noisy and that there are time samples where there is no hCG measurement (which significantly increases the difficulty of using certain algorithms). If a forecast is desired from the first few measurements, then we must also deal with a slight vertical shift.

The aim of this study is to use the method of least squares to fit the data to the model (1). The method of least squares is a model fitting method in which the best possible parameters to fit a model to data are calculated. This method might prove useful in making predictions about future hCG measurements for women with GTD.

Figure 1: A sample of hCG measurement.

Of the several methods used to fit a model to data, the least squares method is the most commonly used (Forsythe, et al., 1977). There are packages that are used by many mathematical software, however, these methods are not always reliable when fitting a model in the form of (1) to data.

The problem of mathematically modeling hCG in Women with Gestational Trophoblastic Disease was done in a research study by (Costigan, et al., 2016) using logarithmic transformations. The idea presented there was that we can take $n - k$ data point from the beginning of a sample and use them to compute a logarithmic curve in the form of $Ae^{-\alpha}$, then use the remaining k points to compute B. This method works fast, and it gives good results if k is chosen correctly. Later in the paper we will refer to this as the "PseLogLin" algorithm.

Another solution to fit a sample of hCG measurement to a curve would be the "The Levenberg-Marquardt method for nonlinear least squares curve fitting problems" by (Gavin, 2011) in which the errors between the function and the measured data points is iteratively reduced through a sequence of updates to the parameter values by combining two optimization methods, the gradient descent and the Gauss-Newton method. In the case of the Gestational Trophoblastic Disease we can consider the nonlinear function to be the one from (1) with the parameters A, B and α.

An implementation of this algorithm is available in the SciPy python library and it proved to be very accurate. Later in the paper we will refer to this as the "Iterative" method.

The rest of this paper is structured as follows:

1. Section 2 presents how the new solution was built up from mathematical concepts
2. presents what was used to implement the concepts from section 2
3. presents results, comparison of three algorithms in different scenarios and the improvement possibilities
4. presents results, comparison of three algorithms in different scenarios and the improvement possibilities
5. concludes the paper.

Theoretical Concepts

Least Squares Method

When fitting data with n data points to a model with m parameters, the least squares method can be used when $n > m$. In the case when $n < m$ the problem is underdetermined, and the best fit parameters are not unique. Interpolation is a special case of this method and arises when $n = m$ (Forsythe, et al., 1977).

Definition 1. *Given the points* $(x_i, y_i)_{i=0}^{n-1}$ *and the model* $f(x)$ *that has been fit to the data points. The residuals (errors) are the values*

$$r_i = y_i - f(x_i) \tag{2}$$

for each value of $i \in \{1, \ldots, n\}$.

The method of least squares minimizes the sum of the squares of the residuals in order to find the best parameters to fit the model to the data.

When using the least squares method to fit a model, say $f(a_1, a_2, \ldots, a_k, x)$, where $a_1, a_2, \ldots, a_k$ are the parameters to be estimated, to a set of data $\{x_i, y_i\}_{i=0}^{n-1}$, the aim is to minimize the sum of the squares of the residuals

$$\phi(a_1, a_2, \ldots, a_k) = \sum_{i=0}^{n-1} (f(a_1, a_2, \ldots, a_k, x_i) - y_i)^2 . \tag{3}$$

Usually, when using this method ϕ is minimized by solving the system of equations

$$\begin{aligned} \frac{\partial \phi}{\partial a_1}(a_1, \ldots, a_k) &= 0 \\ \frac{\partial \phi}{\partial a_2}(a_1, \ldots, a_k) &= 0 \\ &\vdots \\ \frac{\partial \phi}{\partial a_k}(a_1, \ldots, a_k) &= 0 \end{aligned} \tag{4}$$

for $a_1, a_2, \ldots, a_k$.

Finding α, A and B

In this case of model (1), the function ϕ is defined to be

$$\phi(A, B, \alpha) = \sum_{i=0}^{n-1} (Ae^{-\alpha x_i} + B - y_i)^2 \tag{5}$$

Then

$$
\begin{aligned}
\frac{\partial \phi}{\partial A}(A,B,\alpha) &= \sum_{i=0}^{n-1} 2(Ae^{-\alpha x_i} + B - y_i)e^{-\alpha x_i} \\
&= 2A\sum_{i=0}^{n-1} e^{-2\alpha x_i} + 2B\sum_{i=0}^{n-1} e^{-\alpha x_i} - 2\sum_{i=0}^{n-1} y_i\, e^{-\alpha x_i} \\
\frac{\partial \phi}{\partial B}(A,B,\alpha) &= \sum_{i=0}^{n-1} 2(Ae^{-\alpha x_i} + B - y_i) \\
&= 2A\sum_{i=0}^{n-1} e^{-\alpha x_i} + 2B\sum_{i=0}^{n-1} 1 - 2\sum_{i=0}^{n-1} y_i \\
\frac{\partial \phi}{\partial \alpha}(A,B,\alpha) &= \sum_{i=0}^{n-1} -2(Ae^{-\alpha x_i} + B - y_i)Ax_i e^{-\alpha x_i} \\
&= -2A^2\sum_{i=0}^{n-1} x_i\, e^{-2\alpha x_i} - 2AB\sum_{i=0}^{n-1} x_i\, e^{-\alpha x_i} + 2A\sum_{i=0}^{n-1} x_i\, y_i e^{-\alpha x_i}
\end{aligned} \tag{6}
$$

We define the functions f, g, h and l so we can have a simpler form of the above equations

$$
\begin{aligned}
f_k(\alpha) &= \sum_{i=0}^{n-1} e^{-k\alpha x_i} \\
g_k(\alpha) &= \sum_{i=0}^{n-1} y_i\, e^{-k\alpha x_i} \\
h_k(\alpha) &= \sum_{i=0}^{n-1} x_i\, e^{-k\alpha x_i} \\
l_k(\alpha) &= \sum_{i=0}^{n-1} x_i\, y_i e^{-k\alpha x_i}
\end{aligned} \tag{7}
$$

and rewrite the equations

$$
\begin{aligned}
\frac{\partial \phi}{\partial A}(A,B,\alpha) &= 2Af_2(\alpha) + 2Bf_1(\alpha) - 2g_1(\alpha) \\
\frac{\partial \phi}{\partial B}(A,B,\alpha) &= 2Af_1(\alpha) + 2Bf_0(\alpha) - 2g_0(\alpha) \\
\frac{\partial \phi}{\partial \alpha}(A,B,\alpha) &= -2A^2h_2(\alpha) - 2ABh_1(\alpha) + 2Al_1(\alpha).
\end{aligned} \tag{8}
$$

In order to minimize $\phi(A,B,\alpha)$, we need to solve

$$
\begin{aligned}
\frac{\partial \phi}{\partial A}(A,B,\alpha) &= 0 \\
\frac{\partial \phi}{\partial B}(A,B,\alpha) &= 0 \\
\frac{\partial \phi}{\partial \alpha}(A,B,\alpha) &= 0.
\end{aligned} \tag{9}
$$

and we can say that

$$
\begin{aligned}
2Af_2(\alpha) + 2Bf_1(\alpha) &= 2g_1(\alpha) \\
2Af_1(\alpha) + 2Bf_0(\alpha) &= 2g_0(\alpha) \\
2A^2h_2(\alpha) + 2ABh_1(\alpha) &= 2Al_1(\alpha).
\end{aligned} \tag{10}
$$

Using Cramer's Rule on the first two equations

$$\begin{aligned}\Delta &= \begin{vmatrix} f_2(\alpha) & f_1(\alpha) \\ f_1(\alpha) & f_0(\alpha) \end{vmatrix} = f_0(\alpha)f_2(\alpha) - f_1^2(\alpha), \\ \Delta_1 &= \begin{vmatrix} g_1(\alpha) & f_1(\alpha) \\ g_0(\alpha) & f_0(\alpha) \end{vmatrix} = g_1(\alpha)f_0(\alpha) - g_0(\alpha)f_1(\alpha), \\ \Delta_2 &= \begin{vmatrix} f_2(\alpha) & g_1(\alpha) \\ f_1(\alpha) & g_0(\alpha) \end{vmatrix} = g_0(\alpha)f_2(\alpha) - g_1(\alpha)f_1(\alpha),\end{aligned} \tag{11}$$

we get

$$\begin{aligned} A &= \frac{\Delta_1}{\Delta} = \frac{g_1(\alpha)f_0(\alpha) - g_0(\alpha)f_1(\alpha)}{f_0(\alpha)f_2(\alpha) - f_1^2(\alpha)}, \\ B &= \frac{\Delta_2}{\Delta} = \frac{g_0(\alpha)f_2(\alpha) - g_1(\alpha)f_1(\alpha)}{f_0(\alpha)f_2(\alpha) - f_1^2(\alpha)}. \end{aligned} \tag{12}$$

The value for α can be found by finding one of the roots of the third equation

$$Ah_2(\alpha) + Bh_1(\alpha) = l_1(\alpha) \tag{13}$$

after replacing A and B this becomes

$$\frac{g_1(\alpha)f_0(\alpha) - g_0(\alpha)f_1(\alpha)}{f_0(\alpha)f_2(\alpha) - f_1^2(\alpha)} h_2(\alpha) + \frac{g_0(\alpha)f_2(\alpha) - g_1(\alpha)f_1(\alpha)}{f_0(\alpha)f_2(\alpha) - f_1^2(\alpha)} h_1(\alpha) = l_1(\alpha). \tag{14}$$

Preposition 1. *Given a set of data* $\{x_i, y_i\}_{i=0}^{n-1}$ *and a model*

$$y(t) = Ae^{-\alpha t} + B, \tag{15}$$

the best value for α *can be found by finding a root to the equation*

$$\frac{g_1(\alpha)f_0(\alpha) - g_0(\alpha)f_1(\alpha)}{f_0(\alpha)f_2(\alpha) - f_1^2(\alpha)} h_2(\alpha) + \frac{g_0(\alpha)f_2(\alpha) - g_1(\alpha)f_1(\alpha)}{f_0(\alpha)f_2(\alpha) - f_1^2(\alpha)} h_1(\alpha) = l_1(\alpha). \tag{16}$$

and then using this value of α*, the best values of* A *and* B *are found using the equations*

$$A = \frac{g_1(\alpha)f_0(\alpha) - g_0(\alpha)f_1(\alpha)}{f_0(\alpha)f_2(\alpha) - f_1^2(\alpha)}, \tag{17}$$

$$B = \frac{g_0(\alpha)f_2(\alpha) - g_1(\alpha)f_1(\alpha)}{f_0(\alpha)f_2(\alpha) - f_1^2(\alpha)}. \tag{18}$$

The algorithm to find the best parameters for (1) is straight forward:

Algorithm 1 Finding A, B and α using the nonlinear least squares method

input: $(x_i, y_i)_{i=0}^{n-1}$

α = findAlpha ($(x_i, y_i)_{i=0}^{n-1}$) {find alpha using equation (16)}

A = findA (α, $(x_i, y_i)_{i=0}^{n-1}$) {find A using equation (17)}

B = findB (α, $(x_i, y_i)_{i=0}^{n-1}$) {find B using equation (18)}

output: A, B, α

While *findA* and *findB* are easy to compute, *findAlpha* requires more attention. α can be found by finding one of the roots of equation (16). This means we must solve the following equation:

$$\frac{g_1(\alpha)f_0(\alpha) - g_0(\alpha)f_1(\alpha)}{f_0(\alpha)f_2(\alpha) - f_1^2(\alpha)} h_2(\alpha) + \frac{g_0(\alpha)f_2(\alpha) - g_1(\alpha)f_1(\alpha)}{f_0(\alpha)f_2(\alpha) - f_1^2(\alpha)} h_1(\alpha) - l_1(\alpha) = 0, \tag{19}$$

which depends on the input data $(x_i, y_i)_{i=0}^{n-1}$. This equation does not have a single solution and with mathematical calculus it's not easy to find any of its roots. A more practical approach is to approximate one of its roots using a root-finding method.

Bisection Method

One such root-finding method is the Bisection method which is an iterative root finding method that searches for a root in an interval known to contain a root of a particular function. Starting with an interval (a, b) and a function $f(x)$ the value $f(a) \times f(b)$ is found. If $f(a) \times f(b) < 0$ then, by the intermediate value theorem, the interval contains a root. Assuming the interval (a, b) does contain a root, the next step is to find the midpoint of the interval, say c. Then it is necessary to check which of $f(a) \times f(c)$ and $f(c) \times f(b)$ is negative in order to find which subinterval the root is contained in, then the interval being searched may by redefined to be the subinterval that contains the root. This process continues until the interval being searched is smaller than the required accuracy.

Using the Bisection method to find a root of equation (19) is challenging, because we need to find an interval in which the function is continuous, it contains a root in the given interval and the sign of the function is positive at one end while negative at the other end of the interval. After all this, it's not guaranteed that the found α value is the best that can model equation (1), thus multiple attempts at finding the best value of α could be necessary.

Improvement on finding α for hCG

Equation (19) can be rewritten as a polynomial by making the following substitution

$$e^{-\alpha} = t. \tag{20}$$

This substitution reduces the functions from (7) to a simpler form

$$\begin{aligned} f_k(t) &= \sum_{i=0}^{n-1} t^{kx_i} \\ g_k(t) &= \sum_{i=0}^{n-1} y_i\, t^{kx_i} \\ h_k(t) &= \sum_{i=0}^{n-1} x_i\, t^{kx_i} \\ l_k(t) &= \sum_{i=0}^{n-1} x_i\, y_i t^{kx_i}. \end{aligned} \tag{21}$$

and results in equation (19) taking the following form

$$\frac{g_1(t)f_0(t) - g_0(t)f_1(t)}{f_0(t)f_2(t) - f_1^2(t)} h_2(t) + \frac{g_0(t)f_2(t) - g_1(t)f_1(t)}{f_0(t)f_2(t) - f_1^2(t)} h_1(t) - l_1(t) = 0. \tag{22}$$

One of the useful properties of this equation is that it has a root in the interval (0,1), which makes finding t guaranteed and independent of the data points, with the Bisection method. Finding t helps in finding alpha using the inverse transformation:

$$\alpha = -ln(t) \tag{23}$$

In summary, finding α using equation (19) and the Bisection method is difficult, because we lack the interval in which to search for it, but using (22) we can find t in the interval (0,1), independent of the data points and independent of what should be the value of α, and finally using (23) we can find the best value of α from the value of t.

Implementation Details

The method presented in Preposition 1 together with Algorithm 1 and the improvement from the above section were implemented in Python version 3. The choice for using Python was:

- the capability to run code in a Read-eval-print loop (REPL) which gave a significant boost to developing the final solution and running tests on it
- the vast offer of libraries that can be used for data science

The following libraries were used for developing the final solution:

- NumPy - for storing arrays in memory and for fast computations on them
- Matplotlib - for plotting the results in 2D
- Pandas - for importing the hCG measurements from a CSV file to an in-memory table
- SciPy - for using existing algorithms like the Bisection Method or curve fitting with Levenberg-Marquardt Method

A great deal of effort was put into transforming the mathematical formulas to code in a manner in which we can use NumPy's vectorization, for three reasons:

- to be able to compute in batch mode (feeding a time series at once)
- to better reflect the formulas from the Theoretical Concepts section
- to benefit from the true speed of NumPy

The final solution contains three algorithms to compute the best fit parameters:

- the method from Preposition 1
- the improved version of the method from Preposition 1, described in the above section
- a logarithmic approach presented in (Costigan, et al., 2016)

Real world data was used to validate the usefulness of the method presented in this paper, and although the data cannot be shared in public space, the final solution contains means to generate synthetic data, for the purpose of play-testing.

Source code is available on GitHub at: https://github.com/akerestely/nonlinearBestFit

Results

Simulated Data

In order to test the method for estimating A, B and α some data (see Figure 2) of the form $\{x_i, y_i\}_{i=0}^{n-1}$ was generated using Algorithm 2. Note that $x_i \leq 0$ in this algorithm, but it's just for visualization purpose, to mimic the original data more closely.

Algorithm 2 Generating Random Data

```
import numpy as np
def gen_rand_points(n:int, A:float, B:float,
        alpha:float, noise:float) -> (np.ndarray, np.ndarray):

x = np.random.random(n) * n
```

```
y = A * np.exp(-alpha * x) + B
ynoise = np.random.random(n) * noise - noise / 2
y += ynoise
return x, y
```

Figure 2 : Synthetic data sample, generated with A, B, α and noise having the values 1000, 3, 1 and 0 respectively

The model was then fit to the data to see if the method for estimating the parameters could find the original parameters. To validate the accuracy of the found model numerically also, not only visually, the *root mean square error (RMSE)* method was used.

Figure 3 : The curve generated by the found parameters matches the data perfectly.

In Figure 3 we can see: the parameters found by the curve fit method presented in this paper, that they perfectly match the ones used to generate the data and that the $rmse$ is 0.

Next, we tested the robustness of the method. Noise was added to the generated data and different a combination of parameters was tested. Figure 4 shows the data generated by the original parameters salted with noise and the curve defined by the found parameters. Rmse tells how close the match is. From left to right, the noise increases, while from top to bottom the parameters used to generate the data change.

Figure 4 : Curve fitting in different scenarios. The parameters change in each row and the noise in each column.

While the results were already satisfying, we were curious about how well our algorithm would fare against other existing algorithms. In Figure 5, three different datasets were generated and on each, the following three algorithms were run:

- curve_fit from the SciPy python library which internally uses Levenberg-Marquardt, an iterative curve fitting method; labeled 'Iterative'
- the algorithm presented in this paper; labeled 'BestFit'
- the pseudo logarithmic curve fitting approach presented in (Costigan, et al., 2016), labeled 'PseLogLin'

For all algorithms the found parameters and the rmse is shown. The found parameters are shown informatively while the rmse is shown to be able to quantify which algorithm found the best solution. We can observe that 'BestFit' does equally well (overlaps) with 'Iterative', while 'PseLogLin' has the most error in each case.

Figure 5: Comparison of three different curve fitting algorithms.

There are some cases where the 'Iterative' algorithm does not find a match while the 'BestFit' and 'PseLogLin' do, as it can be seen in Figure 6. This is because the iterative method uses some initial guesses for each parameter of the searched function, which defaults to 1 in the case of SciPy's curve_fit method if not stated otherwise. These guesses can be thought as the hyperparameters of the iterative method and although the defaults are good enough in most cases, they should be adjusted for each dataset. These initial guesses also determine the number of iterations the algorithm will try until either a solution is found, or the maximum number of iterations has been reached, which by default is 800 in the case of SciPy's curve_fit.

Figure 6 'BestFit' and 'PseLogLin' find a solution while the 'Iterative' method does not.

'BestFit' method compared to the 'Iterative' method does not need any hyperparameters to work properly, if the data is on an exponential decay curve. A second advantage of the 'BestFit' method is that it also converges faster than the 'Iterative' method, almost constantly in all cases; the variation in the convergence time is given only from the bisection method, which iteratively searches for the root of equation (22).

Real Data

Real data comes from hCG measurements in women with Gestational Trophoblastic Disease (GTD). These measurements are normally done periodically. In the beginning, weekly and after a period monthly. In practice there are weeks and months where the patient does not show up for the tests or the doctor decides that a test can be skipped as the progress of the patient is clearly in the good direction.

From the point of view of a data scientist missing measurements pose a serious problem. They need to be set to a constant value, say 0, or the mean of the neighbors, or any other value that helps avoiding them while not potentially modifying the output; or could be left out by careful engineering. In this case the missing measurements were left out leaving the datasets with only valid entries.

The next problem involving the real data was the insufficient measurements in the case of some patients. More precisely, to define a function of m parameters one needs n equations, where $n \geq m$. In this case the parameters are A, B and $alpha$, which make m, the number of parameters, equal to 3, meaning that n, the number of equations, measurements in this case, needs to be greater than 3. Taking this into consideration, any sample which does not have at least 3 data points, is discarded from the dataset.

Figure 7 shows the result of running the three different algorithms mentioned before on three samples of the real dataset. It's worth mentioning that all data points from a sample were used to find the solution.

The algorithm presented in this paper can also work as an extrapolation method. If we feed at least 3 data points to the algorithm, it can learn a model, which we can use to generate future data points i.e. to forecast the normal devolution of the disease. To test the effectiveness of the algorithm on the extrapolation, we used a dataset with all its points to find the model and calculate the rmse. Next, we

used the same dataset but used only the first few points to find the model and again we used all the points to calculate the rmse. Looking at the rmse values we can see how close the extrapolation is from the actual values and we can also see how the quality of the prediction is affected by adding new points to the model fitting. Results can be seen in Figure 8.

Figure 7 : Results of three algorithms on three samples of the real dataset.

Figure 8 : Fitting the curve on the same dataset with different number of training data points (blue dots).

The model generated by the algorithm can be used to validate new measurements. Having a forecast, a doctor can easily tell if a new measurement is in acceptable thresholds and decide if actions should be taken. The model can also be updated with new data points, making it generate a new forecast. If at any time the algorithm fails to converge to a result, that means that the measurements are too noisy, or that the disease is not devolving. In both cases it should be a warning to the doctor. Figure 9 clearly shows this case. When using the first 3 data points, the algorithm finds that the measurements increase exponentially. The doctor probably notices the same thing and takes action. When using the first 5 data points, the algorithm cannot determine an exponential curve, as there is big uncertainty. After the 10th

Figure 9 : Three behaviors of the curve fitting algorithm, depending on the moment the prediction was run.

data point the algorithm starts to guess that the measurements decrease exponentially, converging slowly to the form of the final curve.

Conclusion

This paper presented a new method to fit a model to some data points that follow an exponential decay curve in the form $Ae^{-\alpha x} + B$ with A, α and $B \geq 0$. Data of this type appear in women with Gestational Trophoblastic Disease (GTD). This new method uses mathematical calculus to determine what model best matches the data points. It outperforms other existing methods either in accuracy, convergence time or ease of usage, by not having hyperparameters.

Ideas were also presented in this paper as to how the curve fitting could be used in real life scenarios. Extrapolation, forecasting, interpolation or validation of data points are some of these use cases.

The paper comes with an open source code that can be used to reproduce or modify the results presented, using synthetically generated data.

Abstract

In a period of uncertainty as a result of expected economic recession, great competitive rivalry and increasing demand from consumers, companies are currently facing countless difficulties, namely in understanding which is the most adjusted mode of action in the market. Consumers are also more attentive and participative, demanding higher attention, timely and objective responses from organizations to their needs. In this tricky context, where companies need to strengthen their marketing policies more than ever, market orientation should be reinvigorated and addressed differently focusing consumers. Though this is always the proper approach, nowadays it is even more important, since industrial companies are facing additional surviving and competitive challenges. In this study, a qualitative methodology is proposed using semi-structured interviews as a data collection tool. These interviews were used to understand the relationship between industrial companies and marketing policy implementation. 10 interviews were conducted and analyzed at industrial companies in Barcelos, in the northern region of Portugal. Results tend to indicate a general lack of knowledge by industrial entrepreneurs regarding the concept of marketing as a market orientation. Marketing is seen as a tool more than as a management philosophy. There is also a notorious disinvestment of the companies in question in this area, in line with the lack of recognition of their potential as a source of competitive advantage. Future research should explore deeper the relationship between the demographic profile of individuals and this adoption of the concept of marketing in industrial activities.

Keywords: Market Orientation, Marketing Concept, Competitive Advantage, Industrial Companies.

Introduction

The need for organizations existence arouses from people, whether they are employees or consumers, so their satisfaction should be the main objective. Many Portuguese entrepreneurs, pressed by the need to recover the investment capitalised, despise strategic marketing procedures, which for Silva (2009) is a total mistake. This entrepreneurs despising, causes them to invest on inappropriate products and wrong segments, which leads to a waste of time and money. For this reason, entrepreneurs must "make sure they actually know what their business is, the purpose of their products and the needs they already meet" (Silva 2009: 1).

This study focuses on some of the fundamental aspects of marketing, aiming to perceive its concept and their surroundings and understanding entrepreneurs and companies' profile in industrial contexts. We also identify and understand factors which contribute for entrepreneurs' disbelief in marketing reinforcing the idea that customer and market orientation brings real benefits to the business.

The focus on issues related to the importance of marketing within organizations, has its importance because it makes companies to invest more in marketing in order to see it as something fundamental and not something accessory to its evolution, but also helps to understand the reasons that keep companies away from these kind of strategies.

This research intends to understand the need of adjusting the way marketing is perceived in industrial organizations, and to what extent it will be justified to create a new way of acting and to modify the approach of these companies to the market, looking at consumers as the main focus. The crucial question is understanding whether the process of implementing the marketing concept as a market orientation will lead to better organizational performance. To better perceive this reality, an empirical study will be developed, supported by some research instruments.

In conclusion, the purpose of this work is to perform an analysis / reflection on the importance of marketing within organizations. By the end of this paper, a balance of its real importance and its perceived misperception by industrial entrepreneurs will be presented. It will be possible to conclude why no serious commitment on marketing is made based on the real benefits that its implementation brings as a competitive advantage over the rivalry.

An Approach To Marketing Concept Over Time

Searching for A Marketing Definition

Marketing definition emerges in the early of the XX century and begins to take a greater importance in american universities, where the first courses of sales and distribution were created (Silva et al., 2019). The word itself emerged from the words market and action, which means action for the market or moving market (Ferreira et al., 2015). Some authors, such as Murphy et al., (2008) consider it as a philosophy that aims to achieve companies' goals, thus determining the needs and desires of the market, being able to satisfy those needs and desires effectively and efficiently. It is further "(…) defined as the group of activities aimed at analysis, planning, implementation and control of programs designed to obtain and serve the demand of products and services, which will meet the needs and desires of consumers and / or users, with quality and profit for the company "(Ferreira et al., 2011:19). Therefore, it provides a well-designed market, focused on consumer needs and coordination of all marketing functions in contact with customers. As it turns out, it takes an outside-in, market-to-business perspective. Gama (2011) reinforces to survive in the market, companies should focus their attention on consumers and their surroundings, as well as knowing the competitiveness where the market is inserted.

This concept can also be defined, based on Lindon et al. (2009: 30) in four dimensions: a personal attitude and a company culture supported by the knowledge of the target audience; a strategy based on the marketing strategy itself: objectives, competitors, segments, positioning and marketing mix; a series of techniques and resources reflecting marketing techniques / tools more valuable; and a practice made of anticipation and reactivity, which predicts what may go wrong, realizing the reaction triggered by the competition and what adjustments will need to be developed. In marketing you have to think, evaluate strategies and predict opportunities.

To summarize, most researchers and marketers understand this concept as a policy that aims to find out what the real needs and interests of their target audience are and then how to meet them, meaning, their starting point is to interpret what are the needs felt in the target market and create the conditions for them to be met, as a set of procedures developed to meet the needs of consumers and at the same time create value for the company they represent. In a very simplified way, marketing aims to find out what are the needs and interests of the target audience to fulfill them. That is a group of procedures aimed meet the needs of consumers while creating value for the companies represented.

Market orientation and segmentation should be related with the target audience (Oliveira and Sousa 2020). One must take into account a specific product directed to the needs of the desired segment,

looking at the market uniformly, as it represents a group of people with individualities and individual needs (Sousa et al., 2019).
The target audience, according to Lovelock and Wirtz, (2011) is a segment selected by the company across the market. These are a set of potential buyers with similar needs and particularities that the organization decides to assist (Kotler and Scheff, 1997). It is also based on assessing the potential of segments and choosing those same segments for the organization to serve (Kotler and Armstrong, 2014).

The Implementation Of The Marketing Concept

Marketing, as a core part of any business, needs to be taken into account from the very beginning and should follow the all business planning, it is a crucial tool in this organizational world, bringing to any organization a value aid in achieving their goals since "(…) it helps companies stablishing their competitive leverage against the rivals, in a way that it demands action and gathering of all efforts from all functions" (Ferreira et al., 2009:25). Morgan (1996:20) thinks that "(…) implementing marketing (…) demands keeping a particular direction, (orientation) Kohli and Jaworski (1990) reinforce the concept of marketing shall be understood as a philosophy where the term orientation for the market translates its implementation.

With a market segmentation well established these days, with rivalry growing, products life cycle are shorter, as technological changes and even more demanding costumers demand companies to have an even more competitive strategy (Day, 1990). For this, elaborating a marketing plan can give companies better marketing practices as such: effectively satisfying their costumer; being better than the rivalry; better understanding market development; maximizing income; effectively utilizing resources in order to get the leverage; reducing treats; identifying and understanding the strengths and weaknesses (Simkin, 1996)

Marketing plan, according to Simkin (1996) and Dibb (2002), is a document guiding companies in the implementation and control of marketing activities, so it is the outcome from planning the process, where specific marketing actions should be linked to the planning stage of the company (Cobra 1991). This important document helps to understand the situation of any company, determine companies' objectives, define strategies of marketing and the mechanisms needed to reach pretended goals, stablish deadlines for the execution of defined programs and to define targets e programs such as, predictions and budgets properly quantified (Campomar 1983). On the marketing plan, different aspects should be defined such as: define target audience; company`s strategic mission in the market; the company`s position in that market; the opportunities and the treats; strengths and weaknesses; type of leverage acquired; market strategy adopted; and finally translate the strategic objectives defined for each element of the marketing mix (Lambin 2000).

Reaching this aspect above described in harmony with Campomar (1983) can bring companies different benefits, such as: exact analysis of their conditions; more clarity of the objectives defined; greater environment between departments giving the possibility for teamwork, allowing the creation of new relationships; more emphasis over key factors of success; greater focus on costumers needs.

Market Orientation As A Key Factor On Industrial Performance

Background

Market orientation is defined by three behavioral elements: customer orientation, rivalry orientation and interfunctional coordination (Narver and Slater (2006). Customer orientation and rivalry orientation is based on gathering information about customers and rivalry companies, and also sharing information between the different departments in the company. Rivalry orientation also aims to know the rivalry, manly their strengths, their weaknesses and their strategies. Having the capacity to be the first against rivalry can be the way to get a sustainable and competitive leverage. Interfuntional coordination is the coordinated management of company's resources in order to create superior value

for the costumers, so it wants to follow the orientations previously mentioned, coordinating efforts from different departments, in specific the marketing department, focalizing on the information gathered to create value to target audience (Narver e Slater 2006).

The same authors also perceive this as a concept like an organizational culture more effective and efficient able to create essential behaviors for the creation of superior value to customers, granting this way, a better performance (Narver e Slater 2006).

This behaviors, creators of value to the customers, are characterized based on an organizational culture focused on the customer (Grinstein 2008). Investigations were conducted in order to understand what are the customer's needs. This type of behavior gives companies a better knowledge of their customers, and so it allows adjustments to their necessities, creating superior value for them and contributing for more customer satisfaction.

From the work developed by Heiens in 2000, it is possible to conclude that this concept must be based in two key aspects: customers and rivalry. Companies must understand in details these two agents in an external environment, focusing all the efforts on their behalf. He also believes, though customers are the key element on market orientation, companies neve to adopt a wider perspective.

Adapted of Narver & Slater (2006)

Narver and Slater (2006) understand this concept as a more effective and efficient organizational culture, which provides the essential resources for creating superior value for consumables, application, mode, superior performance for an activity. These procedures that provide value creation for consumers, are characterized by an organizational culture directed towards the customer (Grinstein 2008), or are, they are investigated in order to understand what the customer really needs, that is, how their needs. . This type of behavior administered to the company with a greater knowledge of its customers, which, in turn, allows it to adjust its offer to the requirements, thus creating a superior value for them, contributing to their greater satisfaction.

Market orientation "(…) refers to production, dissemination and action accordingly, knowledge of the market for the entire organization" Kohli and Jaworski, (1990: 3). It is therefore "(…) a production, for the entire company, the knowledge of the market that respects the current and future requirements of customers, the dissemination of knowledge across all departments and the performance in accordance,

throughout the company ”(Kohli and Jaworski, 1990: 6). must reinforce the importance of market orientation, encouraging its employees to keep up with market changes, deciphering their needs (Murphy, et al., 2008).

All the theories previously exposed, arising from investigations, are particularly indispensable for understanding the concept of guidance and its real importance in the general perspective of marketing. Even so, in spite of all these scientific tributes, there is no absolute concept. However, the various studies indicate in general that there is a connection between market orientation and the concept of marketing, that is, market orientation, generally results from the implementation of the concept of marketing, although it is also consensual to perspective that market orientation is not the exclusive responsibility of marketing, but of all functions linked to the company. Another homogeneity in theories is the fact that this type of guidance by companies provides, in the long run, greater profitability, an increase in the level of perceived quality, more satisfaction and loyalty on the part of consumers, as well as greater satisfaction of all internal staff, this being the main objective of companies that develop a policy of orientation towards the market.

Finally, to obtain consistently superior market performance, an organization must create a sustainable competitive advantage (Aaker, 1984; Porter, 1985). The organization needs to create added value in a sustainable way for its public, that is, more than satisfying their needs, it is necessary to exceed their expectations. In this way, a market-oriented company is closer to creating that superior value for its customers in a sustainable way, privileging here the possibility of creating a loyalty relationship with them.

Towards a Customer and Marketing Orientation

Customer orientation is “the heart for market orientation” (Narver and Slater, 1994:20). Activities for customer orientation, according to Narver and Slater (2006) they are not based on customer knowledge, but on is chain value comprehension, understanding this way, which are the potential customers, understanding not only their current needs but also their future ones. These authors highlight the success of new products is related with the orientation level that companies present in the market.

Authors Saxe and Weitz (1982) speak about the importance of companies to put customers satisfaction first rather their own interests since is this kind of profile which identifies companies really well orientated for their customers. They try also to show that it can be advantageous to leave short term deals in order to get an increment in future deals, contributing to the loyalty of their public. Trust relationship between buyer and company is stronger when there is a customer orientation, since customer is more receptive when this kind of approach is present.

Customers loyalty, objectively defined, is to make customers to buy regularly company´s products and/or services. Loyal customers, bring money to the companies and increase their sells, notoriety and value. They also bring advantages to customers themselves, like a personalized customer service, rewards, trust in the products, among others (Quintino, 2017).

In order for the products and services offered by companies to be part of customers preferences, it is essential to build a strong brand and put it in the market in an effective way (Colbert, 2003; Vivek et al., 2010). The process begins with the search of things related to the brand, measuring the strength of the connection between the brand and customer auto concept (Alvarez and Fournier, 2016). A strong connection with the brand can facilitate the acknowledgment of it, a loyalty increment and notoriety (Sousa e Silva, 2015).

Marketing orientation has a predominant role in order to get competitive leverage. Authors Kohli and Jaworski (1990:6) emphasize marketing orientation is “creating knowledge about the market referring customers current and future needs, disseminating that knowledge over the different departments and the response given by the organization to that knowledge”. The authors also believe this orientation is based in three behaviors: collection, dissemination and response, in which all departments in a company should focus and not just the marketing department.

The competitive leverage is the leverage of understanding in a proactive way, first their rivalry, market trends and the ability to align the offer based on tis anticipation (Ansoff 1965). From the 70s, with the growth in competition between industries, there was a need to develop strategies focused in competitivity. Competitive leverage, by then, started to occupy an important place in companies' strategies, where planning and leadership became indispensable for any company. A strategy holds two central elements: decide which product to offer and in which market it should be placed and development of a sustainable and competitive leverage (Aaker 1984). This concept, according to Porter (1985), can result from factors related to product innovation, production methods or company´s marketing capacity, recommending three categories for these factors: firstly, he highlights the benefits of the size, respecting to scale economies, being large scale production a possible leverage; secondly, he refers the advantages of privilege access to resources since the access to specific differentiated raw materials, such as, access to new markets, among others, can certainly be a benefit compared to rivalry; lastly he mention the viability for strategical flexibility since the agility over the strategy can also be a leverage factor. The author clearly highlights the competitive leverage is inevitably connected to the strategy adopted, meaning it is connected to the execution of strategical activities more significant to the chain value, being either applicable in a less expensive way or in a way superior to the rivalry (Porter, 1985). In the year 2000, Vasconcelos and Cyrino (20), define competitive leverage, as being an "occurrence of levels of economic performance above market average related to the strategies adopted by the companies", showing, to fill the concept, four theorical chains of investigation: strategic positioning theories, resources theory, theories based on market processes and theories on dynamin competencies.

Based on these comphrension of what is marketing orientation, an empirical research was developed in order to get further the understanding about the perception of north Portuguese industrial companies towards the comprehension and application of marketing concept in their firms. Nedxt chapters will detail metgodology and main results.

Methodology

Investigation methodology, as defended by Pardal and Lopes (2011:10), can be defined as the "guiding body of the research, obeying to a system of norms, where is possible to select and articulate techniques, in order to develop a process of empiric observation".

In this investigation, both primary and secondary resources were used. Primary resources include information obtained by the author about interviews planning and development. Secondary sources come from documental research since the author guides himself through a group of information collected from different authors (Sousa and Baptista, 2014).

This paper uses qualitative methodology, which according to Wahyuni (2012) best fits in the realism paradigm. With this type of methodology, the objective is to give a better understanding, gaining this way, a qualitative knowledge about the reasons and motivations implicit in a specific phenomenon (Malhotra and Birks, 2006). This investigation resorts to a bibliographic and exploratory research, with a qualitive approach, as mentioned before, conducting semi-structured interviews to selected companies' managers, collecting data and then analyzing and interpreting the results. Miles and Huberman (2014:18) mention that "the qualitative researcher starts by focusing on questions from the study, the participants to be observed, data collected and how all that data should be managed and analyzed".

The objective of present research is to unravel whether, in fact, a marketing orientation is a factor that enhances competitive advantages for companies. companies that will be part of this study. It also aims to understand the behavior, profile and functioning of companies and their managers, trying to understand their degree of market orientation in industrial contexts, focusing on a specific geographical area: Pousa, council of Barcelos, district of Braga.

The main purpose is to understand what are your main reasons and / or limitations for implementing the marketing concept. Therefore, with the development of this project, it will be possible to answer some questions, particularly:

• Is there a marketing orientation by companies in the industrial sector?
• What are the main motivations for companies to implement the marketing concept?
• What are the main limitations / barriers to the implementation of the marketing concept?
• Does the implementation of the marketing concept determine competitive advantage?

In the end, it will be determined the impact that the orientation towards the market and the customer has as a determinant in the competitive advantage, and the importance that the implementation of a marketing policy has in this orientation and that advantage, as well as in the relationship management. and customer loyalty in industrial organizations.

Qualitative research, which the main objective was to collect qualitative knowledge over specific phenomenon, specifically its reasons and motivations. Usually, in this type of research, collected data is not structured and its treatment is not statistically orientated. Related to the dimension of the sample, there were used a reduced number of non-representative cases (Malhotra and Birks, 2006), so the instrument used was the semi-structured interview. Wahyuni, (2012), mention that this type of interview provides a sharing of perspectives, histories and experiences related to the peopled being interviewed and also related to the subjected studied by the interviewer. This type of instrument gives the freedom to the interviewee over his speech during the all process of the interview, enabling this way to freely talk about whatever he or she desires. This allows a collection of a more complete and detailed data (Wahyuni, 2012).

As mentioned befor, 10 interviews were conducted and analyzed. industrial companies in Barcelos, in the northern region of Portugal.

The elements of the non-probabilistic sample were chosen taking into account important aspects of the study, such as the choice of companies linked to the industrial sector. The study was developed with 10 interviews with 10 people from 10 companies, all connected to the industrial sector as previously mentioned. We tried to select different sectors of activity, in order to obtain information in different contexts, making the research richer, covering possible influences of the context in question. Thus, for the interviews, sectors were selected, such as: plastic, granites and marbles, laser cutting and engraving equipment, food sector, sector related to imports and finally the textile sector. Top and intermediate level managers were interviewed. The interviews were recorded on audio with the authorization of the participants and, later, fully transcribed.

Results and Discussion

The creation of value for the client goes beyond just focusing on them, as the orientation towards competition is also essential, namely in their identification, in the technology they use, in their target audience, in their strengths and weaknesses and in your way of acting.

The implementation of the marketing concept in an organization is certainly, as was exposed throughout this work, based on several reference authors, an essential tool for organizations to understand what the market needs, thus adjusting their offer. It is fundamental for any business because it is a necessary and adjusted mechanism for any decision to be taken. It is a tool that can make a difference, being able to anticipate the change in the markets and adapt to these changes in order to provide the customer with greater satisfaction and the company a greater profitability. The long-term survival of a company depends on its ability to anticipate in a timely manner the evolution of the markets in which it operates and to adapt its structure to its requirements.

The concept of market orientation highlights the importance of marketing, as it is always supported by marketing, representing a set of activities that reflect the implementation of the concept. It is an

essential determinant in the performance of organizations, regardless of market turmoil or the environment in which it operates, it must be seen as something important to achieve greater business performance.

In this study, a qualitative analysis methodology was proposed using semi-structured interviews as a data collection tool. An analysis of the degree of market orientation by 10 companies linked to the industrial sector was intended, verifying the relationship between this orientation by them and their performance, that is, if the implementation of the marketing concept determines competitive advantage . The objective, in addition to perceiving the behavior, profile and functioning of the companies and their managers, was to understand how these companies belonging to the industrial aspect face the marketing policy regarding their implementation, if they understand that this implementation contributes to the existence of advantages competitive for them and understand what are their main reasons and / or limitations for implementing the concept. In this way, the industrial organizations that participated in the study showed, some of them, that they adopt procedures that imply marketing practices, although in some cases they interpret it as just a means to communicate. Although most companies express a policy of no marketing orientation, many of them develop their relationships according to marketing practices. Marketing planning is in most cases quite simple, or practically nonexistent, and not all officially define your target audience.

Almost all research organizations have demonstrated to realize the importance of orientation towards the market and to the client, however, they made believe that in industrial contexts this orientation may not be significant and does not bring, in the understanding of these, competitive advantages. There is also the importance of perceiving customer loyalty in relation to its customers, as well as the concern to communicate in a coherent and effective way using communication to publicize their products and services.

Table 1 summarizes some of the main results

Table 1: Results

Marketing approach	Results	Illustrative quotes
Market orientation	Great concern with information about competition but few deep tools to get that information	"*As for competition, there is not as intensive monitoring, (…) it will be more of a monitoring in terms of the market, of seeing in the areas that [affect] them (…) in terms of technologies, what progress is there, what changes (…), what's new"…*
Marketing orientation	Devalued the implementation of the marketing policy in industrial companies.	*"(…) Marketing is necessary in a secondary way, and in this case, in a company like ours that does not have its own product for sale, marketing has an extremely secondary role because we work a lot with products that customers want. The customers are the ones who have the marketing, the customers are the ones who make the sale and do all the advertising and we just*

		have to present a price and a proposal for that product"…
Focus on Target market	Have a well-defined target	*"We have a well-defined target market (and they almost clearly identify who that market is"*
Customer orientation	Almost all understand the relationship with the customer as fundamental to the success of their business	*"The main aspect, notice, we have to make a profit, to have a return, we have to provide products as specified by the customers, having specifications, products that correspond to the needs of the customers, products that are in accordance with what the customers have defined, such as the important characteristics of the products…"*
Loyalty	Know the concept of loyalty and recognize its importance in the business world	*"Loyalty is when you can win the trust of a consumer, a customer"*
Communication channels	Although they differ in the way and in the means in which they communicate, they all find communication important to the market and have the perception that they communicate effectively, managing to transmit what they want.	*"We communicate through digital platforms, physical presence at fairs, (…) stores, among others". The means used for this communication focus on "(…) social networks, messages via cell phone, letters ..."*
Marketing policies implementation	Although practically none of the companies bet on the implementation of the marketing concept, almost all assume this policy as very important for the creation of competitive advantage in relation to the others	*"Yes, I think that a market and customer orientation can, in some way, help to understand what the customer and the market need"* *"(...) in practice it doesn't work, (...) in our sector it doesn't work, it's even irreversible, because when a lot of marketing and a lot of information appears, the customer starts to think that we are making a lot of money"*

Final Considerations And Future Research

Implementing the concept of marketing as a guidance to the market, leads, in fact, to a better organizational performance, however it can be concluded that there is a necessity to tune the way market is understood by industrial organizations in question, proceeding afterwards into a new way of acting and modifying the approach from companies of this market sector, looking at customers as the main focus as previously stated during this paper.

It is important to mention there is a tendency from industrial companies in not to invest in marketing, despite not really knowing, in most of the cases, its real concept and importance, meaning, it was noticed companies face difficulties in obtaining cost from something they can not actually see, or touch, making it difficult to believe in its results, betting in such politics, and also in an essential investment through its implementation

Before finishing, it is important to state that as a matter of fact the basic marketing principals are being adopted by the organizations, however, there is still plenty of potential for marketing in an industrial context to develop and for the sector to adopt marketing principals more broadly, still all this conclusion is vague since it mirrors a small research.

It would be pertinent, after this first exploratory, qualitative and comprehensive study, which tried to understand the reasons and motivations of businessmen relatively to the implementation of marketing, to develop a survey not only to the companies of that region but even to the companies in the region, extended to the national context.

Abstract

Within the development of the specialized literature on the culture of corporate entrepreneurship, it is particularly important to understand the relationship between human resources management and corporate entrepreneurship. The general theme of entrepreneurial literature is to understand why some companies are able to generate higher levels of corporate entrepreneurship than others. Human capital (represented by the knowledge, skills and abilities of the employees) is one of the main factors on which a business can be based in its effort to differentiate its products or services and to build a competitive advantage. This article presents the link between human resource management practices and corporate entrepreneurship. In response, we propose a review of the literature that will be based on a conceptual reading of corporate entrepreneurship, human resource management practices and the relationship between them.

Keywords: corporate entrepreneurship, human resource management, Strategic management, SME

Introduction

Corporate entrepreneurship, which has become an important area of management science, has been described as "the presence of innovation, plus the objective of rejuvenating or redefining organizations, markets or industries accordingly, to create or sustain superiority." (Covin, et al., 2000). Corporate entrepreneurship, which is also defined as "the activities an organization undertakes to improve product innovation, risk taking and proactive response to environmental forces" (Miller, 1983) and as "the sum of efforts to innovation, adventure and renewal of a company" (Zahra, 1996) is a facilitator for human resources management practices (Covin et al., 1999). Researchers and practitioners have found that human resource management practices play a vital role in promoting corporate entrepreneurship (Hornsby et al., 2009). Moreover, human resource management is an area of managerial decision making that affects corporate entrepreneurship (Kuratko, 2013). Therefore, human resources practices could have a considerable effect on strengthening corporate entrepreneurship. Chandler et al. (2000) propose that human resource management affects creativity and innovation by creating a supportive culture. A large number of policies related to human resources management can affect corporate entrepreneurship (Burgelman, 1983). In this article, we focus on the relationship between human resource management practices (HRM) and the promotion of corporate entrepreneurship (EC). This article aims to analyze the relationship between human resources management and corporate entrepreneurship by exhaustively studying the specialized literature and the most visible works in the field.

Literature Review

Corporate Entrepreneurship

Even if the concept of corporate entrepreneurship is already several decades old, defining the phenomenon of corporate entrepreneurship is far from giving the authors unanimity. Burgelman (1983) identifies that corporate entrepreneurship refers to the process by which firms engage in diversification

through internal development. Such diversification requires new combinations of resources in order to be able to expand the activities of the company and in other areas that are not related or are marginally linked, to its current field of competence but also to the corresponding set of opportunities. For Vesper (1984), corporate entrepreneurship involves the initiative of employees from the bottom of the organization to do something new. An innovation created by subordinates, without being asked, waiting, or maybe even allowing senior management permission to do so. Three major definitions of corporate entrepreneurship are developed by Vesper, which can be identified as a new strategic direction; a bottom-up initiative and the creation of autonomous businesses.

Jennings et al. (1989) defined corporate entrepreneurship as the extent to which new products and / or new markets are developed. An organization is entrepreneurial if it develops more than the average number of new products and / or new markets. This definition is similar to the definition provided by Spann et al. (1988), who define corporate entrepreneurship as setting up a separate corporate organization to introduce a new product, serve or create a new market or use a new technology. Another definition developed by Zahra, in which corporate entrepreneurship: "refers to formal and informal activities aimed at creating new businesses in setting up companies through product innovations and processes and market developments (Zahra, 1996). These activities can take place at the corporate level, division (business), functional or project, with the unifying objective of improving the competitive position and financial performance of a company. Corporate entrepreneurship also implies the strategic renewal of an existing business". In a global sense, corporate entrepreneurship refers to the development of new business ideas and opportunities within large and established corporations (Birkenshaw, 2003). In this respect, Guth et al. (1990) emphasize that corporate entrepreneurship encompasses two types of phenomena and the processes that surround them: the emergence of new businesses within existing organizations, and the transformation of organizations by renewing the key ideas they are built on, namely strategic renewal.

Schendel (1990) adds that corporate entrepreneurship involves the notion of creating new enterprises within permanent enterprises and the transformation of stagnant, ongoing enterprises that need resurrection or transformation. Ireland et al. (2003) presented corporate entrepreneurship as a process whereby people in a start-up are pursuing entrepreneurial opportunities to innovate regardless of the level and nature of current resources available. It describes the total process by which start-ups are acting in an innovative, risk-taking and proactive way (Zahra, 1996; Dess et al., 1999). From this definition, we can conclude that many terms are used to describe entrepreneurial efforts within the existing organization, including corporate entrepreneurship (Zahra, 1996), corporate entrepreneurship (Biggadike, 1979), entrepreneur (Pinchot, 1985), internal corporate entrepreneurship (Jones et al., 1992), internal entrepreneurship (Vesper, 1984), renewal strategic (Guth et al., 1990), adventure (Hornsby et al., 2009). For Zahra (1996), the outcome of the corporate entrepreneurship process can be innovation, adventure and strategic renewal. Furthermore, Brizek et al. (2007) report that corporate entrepreneurship covers the creation of new business within an existing organization and the strategic renewal that includes innovation and creativity. They described corporate entrepreneurship as "organizational innovation, risk taking, diversification and organizational empowerment" and labeled it in many ways, such as corporate adventure; corporate internal entrepreneurship; and strategic renewal. From these perspectives, Ling et al. (2008) they approached corporate entrepreneurship as the sum of a company's innovation, renewal and adventure efforts.

Hence, it is clear that innovation, strategic renewal and corporate venturing are all important and legitimate parts of the concept of corporate entrepreneurship. Therefore, innovation refers to the creation and introduction of products, production processes and organizational systems. Renewal means revitalizing the company's operations by changing its sphere of activity, its competitive approaches, or both. It also means building or acquiring new capabilities and then creative support to add added value for shareholders (Zahra, 1996), and Adventure and hazard refer to firm behaviors, such as introducing new businesses by creating or acquiring new business organizations (Cheesbrough, 2002).

The importance of corporate entrepreneurship

"Entrepreneurial thinking and action change the way business is carried out at all levels. Companies cannot be static - they have to adapt and redefine continuously "(Morris et al., 2010, p. 3). Indeed, entrepreneurship and innovation - from new start-ups and established corporations - remain the driving

forces for economies (Marcus et al., 2015). Especially in the 21st century, corporate entrepreneurship has become essential for established companies to tackle the problems of rapidly growing new competitors, inefficient traditional approaches to management, leaving top employees for more innovative roles, and productivity and efficiency issues (Kuratko, 2013). Corporate entrepreneurs have been recognized as important factors in organizational-organizational performance by recognizing opportunities, developing a team, gathering resources and creating something valuable. Corporate entrepreneurship has been identified as a critical factor for high levels of organizational performance (Hornsby et al., 2009; Zahra, 1996). Established organizations can use an entrepreneurial strategy to maintain a competitive advantage over rival firms (Covin et al., 2000; Ireland et al., 2003) by rejuvenating, renewing and redefining organizations, markets and markets. of industries (Covin et al., 2000). By diversifying the inputs and outputs generated by internal development, firms focus on new resource combinations to expand their competencies and pursue new opportunities (Burgelman, 1983). This commitment to create new business opportunities through product innovation, process innovation, market evolution and strategic renewal enhances the competitive position and financial performance of firms (Zahra, 1996).

Previous literature has provided a multitude of frameworks for the background and results of corporate entrepreneurship. In the most complete summary so far, Ireland et al. (2003) synthesized three decades of previous research, including nine theoretical models, into conceptualizing the company's entrepreneurship strategy. This model incorporates the precedents, elements and results of the corporate entrepreneurship strategy. Background includes external environmental conditions and individual entrepreneurial knowledge (Ceptureanu SI et al, 2018a). The elements consist of a strategic entrepreneurial vision, a pro-entrepreneurial organizational architecture, processes and entrepreneurial behavior. Important results include competitive ability and strategic re-positioning. This article provides an excellent point of approach for future corporate entrepreneurship research efforts. Hitt et al.(2011) have provided a similar model of entry-process-exit specific to strategic entrepreneurship, making up the input of resources, process orchestration and multi-level results that are central components of strategic entrepreneurial construction. The authors assert that strategic entrepreneurship helps firms "create and sustain a competitive advantage, identifying and exploiting new opportunities simultaneously" (Hitt et al., 2011, p. 57). The input elements of the model include environmental factors, organizational resources and individual resources.

Orchestration processes consist of structuring, packing, leveraging and creating and acquiring values. Important results include creating value for customers, competitive advantage, accumulating resources and benefits for individuals, organization and society. A final remarkable review of the background and results of corporate entrepreneurship was provided by Zahra (1996), in which they discussed the evolution and contributions of previous literature. Important antecedents of corporate entrepreneurship include national cultures (Hayton et al., 2005), industry conditions (Zahra, 1996), organizational structure (Covin et al., 2000), organizational culture, managerial systems and firm ownership (Zahra, 1996). Other internal organizational factors that influence corporate entrepreneurship include managerial support, rewards and consolidation, time availability and organizational-organizational boundaries (Hornsby et al., 2009). On the other hand, critical outcomes of corporate entrepreneurship include competitive advantage, organizational performance, profitability and growth (Zahra, 1996), organizational learning (Yang et al., 2009), knowledge creation (Dushnitsky et al., 2009) and capacity development (Sapienza et al., 2006; Yiu et al., 2007).

Strategic Management of Human Resources

We can hardly find a satisfactory definition of the term "human resources management". Continuing these review manuals, we note that some of them ignore such a definition (Gosselin, 1997), they deal with the management of human resources without highlighting the significance they attach to the concept. Others - most - give the term a very broad meaning: it refers to "man and the social" (Ok, 2011), "structures and people "(Susomrith et al., 2013) or refers to" regulation of work in organizations "(Ok, 2011)" management of work and employment "(Batt et al., 2012)," management of people in organizations "(Hunt, 1992) or in "all the practical planning, direction, organization and control of human resources within the organization" (Susomrith et al., 2013). According to Legall (1996), human resources management is "one of the specialties of the great field of management". It is also, for him, "a

corporate function that aims to achieve efficiency and support over time between employees and jobs in terms of number and qualifications. It aims to further optimize skills for the business strategy". Susomrith et al. (2013) argued that HRM represents the set of measures (political, procedural, etc.) but also activities or practices (training, recruitment, etc.) that involve human resources and target the efficiency and optimal performance of individuals and the organization. From these definitions it is very clear that the importance of human potential is necessary for the proper functioning of a company and that special attention must be paid to human resources, because they value all other forms of company resources.

In the contemporary business environment, human resources (HR) represent an indispensable contribution to organizational effectiveness. Therefore, efficient human resource management plays an important role in the performance and success of the organization (Chung et al., 2008; Ceptureanu SI et al, 2018b). Rapid market change and increased global competition force many companies to re-examine their activities and reprioritize their operations (Ok, 2011). Many organizations strive to find better ways to become competitive in the dynamic environment (Susomrith et al., 2013), planning flexible restructuring and development.

According to Boxall (1998) human resources management represents those activities associated with the management of work and people in companies. Human resources are the only source with which we work together, communicate and transmit information about other sources of an enterprise. Also, other authors have emphasized the importance of human resources in the context of communication in specific fields, such as the medical one (Dutu et al., 2015, Popescu et al., 2019). Human resources are strategic for both basic viability and advantage (Boxall, 1998).

HRM helps to direct the attention and behavior of the employees towards the sustainability objectives of the company through the general approach and through the individual policies and practices that embody this approach (Egri et al., 2002; Ramus et al., 2000; Ceptureanu SI et al., 2018c). Modern human resource processes are grouped into areas of human resource management, as they offer added value to internal and external customers. The main areas of human resources processing are: recruitment and personnel, compensation and benefits, training and development, career development, talent management, leadership development, human resource control (Robbins et al., 2017).

Human resources studies should link the classic HR functions (recruitment, selection, training, performance management and compensation) and the business strategy that covers the role of industry in these functions and explain how these functions work (Batt et al., 2012). Human resources management activities are an increasingly expensive component of the operations of all enterprises (Susomrith et al., 2013). HRM is both a means and a goal of achieving the strategic objectives of a company (Huselid et al., 2011). As a means, HRM policies and practices help to direct the psychological settings of the employees and to the actions necessary to reach the objectives of supporting the firm's capacity (Egri et al., 2002).

Human resources managers have traditionally been responsible for selecting, recruiting, training and managing workforce compensation; they are now expected to be more flexible, responsive and efficient in these activities, as well as to contribute to the strategic decisions of their organizations (Mihajlović, 2016). The different human resources practices within a given organization should complement each other, in order to improve employee performance and improve the competitive advantage of the organization (Stanton et al., 2011). HRM is also one of the key functions in the development and implementation of the strategic process (Sondhi et al., 2013).

Strategic management is intended to ensure that the business needs of the organization and the individual and collective needs of its employees can be met through the practical human resources policy (Armstrong, 2002). According to Koubek (2007), the strategic management of an organization is linked to a personal strategy. The objectives incorporated in the human resources strategy are achieved through a real activity, real efforts - strategic management of human resources. The human resources policy follows the human resources strategy. It focuses on the implementation of the human resources strategy and procedures that define the stages of the different processes in the field of human resources management. Although strategic human resource management (SHRM), as a discipline, has evolved rapidly and has shown relevance in recent decades, inconsistent results on how human resources

contribute to achieving strategic goals are still common (Guest, 2011; Woodrow et al., 2014). Specifically, Huselid et al. (2011) criticize most studies for focusing on human resource content.

Strategic management of human resources represents a link between human resources management and the strategic management processes of a company. Strategically it means that human resources activities should deliberately design and connect to an analysis of the business and its context (Schuler et al., 2001). Strategic management of human resources, therefore, through interventions in the field of human resources, such as employee involvement, suggestion schemes and knowledge exchange is considered as a function of value-added human resources (Cooke et al., 2010). The HRM strategy concept concludes that individual human resources functions, if viewed in isolation, tend to lack congruence in most organizations (McEvoy et al., 2013).

A human resource management strategy is usually defined as the strategic orientation adopted explicitly or implicitly by organizations to manage their human resources. If consistently designed, the HRM strategy provides guiding principles for other HRM initiatives and ensures management consistency (Garcia-Carbonell et al., 2016). On the other hand, an HRM system reflects the coordination of a specific set of practices conceived to implement the HRM strategy (Martín-Alcázar et al., 2005). Success in implementing a human resource management strategy requires that the implemented system be distinctive, consensual and consistent. For this to happen, the human resources management system should not only be designed based on vertical (external matching) and horizontal (internal matching) conditions, but should also be adequately communicated. (Garcia-Carbonell et al., 2016).

Empirical research on HRM in SMEs shows that there is a great diversity of human resources management practices in small enterprises, and the size of firms re-presents a major determinant of their adoption and formalization (Cassell et al., 2002). A research in the Spanish context also offers evidence regarding the variations of HRM practices according to the size of the firm (Urbano et al., 2008). The literature reveals that the majority of studies examine the relationship between HRM and organizational performance (Ericksen et al., 2005; Wright et al., 2005).

Huang (2000) examined the links between human resource strategy and practices, human resources practices and firm performance. The results showed that the overall strategy affects the human resources practices, those having a direct effect on the organizational performance, and the business strategy moderates the relationship between the human resources practices and the organizational performance. He found that firms with a higher level of performance were more likely to adopt certain SHRM practices, such as planning, staffing, evaluation, compensation and training and development. Richard et al. (2001) found that SHRM efficiency significantly reduces turnover, Harris et al. (2001) tested the relationship between SHRM and performance.

Human Resource Management Practices in SMEs

Implementation of certain practices within companies such as human resources planning, the recruitment process (recruitment, selection and reception), compensation, career planning and evaluation, training, information dissemination are in line within human resources management (HRM). Although there are several approaches to define and identify different human resource practices, we will analyze some of the so-called traditional practices presented below. To analyze these human resource management practices, Garand et al. (1992) propose a framework of analysis, both practical and very simple. According to these authors, human resources practices affect different aspects, namely: the acquisition of human resources, the conservation of human resources and the development of human resources.

Acquisition of human resources within SMEs- This goes through the analysis of the recruitment process and the job analysis.

Job analysis- According to Anderson (1999), job analysis consists of collecting, classifying, and examining data on what makes the assignment of specific functions. This serves not only in describing the position for recruitment, but also in determining the qualification of the workforce, that is, in determining the "value" of each position.

Recruitment- This is a very important step in the search for efficiency and performance in any organization, because the consequences of poor recruitment are huge and may be fatal to the company.

Martory et al. (1984) state that "the recruitment process is an essential part of the company's human resources policy; in fact, it can influence directions completely contrary to the state of human potential".

Conservation of human resources- The conservation of human resources goes through the motivation of the employees, good compensation practices, career management and performance evaluation.

Motivation- According to Nadler et al. (1977), motivation is a mathematical combination of effort, performance and results. In this way, the employee will be motivated when he thinks that he is able to make the efforts to work at the required level of performance, that, finally, his behavior will lead to certain results and that the results are really attractive. Consequently, this theory reinforces the forms of performance-related remuneration, forgetting that human behavior is not always rational and that man does not always work just for money.

Human resources development- It refers to the formation of human resources and to the dissemination of information within the company. Human resource development (HRD) is extremely important, as SMEs know that any employee improvement and development is essential to the organization's advancement, and employees are eager for opportunities to develop their skills to ensure the advancement of their organizations. This competitive business world is more focused on the human factor, because the skills of the employees have been distinguished as the most important device for the growth and long-term advancement of an enterprise.

Training / Formation- Training is a vital part of the gear, and human resource management is an essential catalyst for the human development of the company. It aims to develop human resources by anticipating and satisfying the training needs. It enhances its individual capabilities and promotes their development. In addition, training helps maintain the competence and efficiency of human resources through the appropriate position / position.

Information and communication- Communication within the company is all the more important, as information is recognized as a raw material in decision making. The practice of communication within a company consists primarily of the development of information circulation practices. Inform him, get to know him, help him understand; find a balance between lack and excess. There is a gap in both the entrepreneurship and human resources literature, and this gap should be addressed by examining the role of HRM in entrepreneurial firms (Keating et al., 2007).

The link between corporate Entrepreneurship and Human Resource Management practices within SMEs

The practice and theory of human resources management can contribute to the understanding of the problems that the entrepreneurial company faces (Altinay et al., 2008). The entrepreneur operates in contexts used to carry out the project. Its action led to the stimulation of an organization with which it is in a symbiotic relationship, and the organization, which can develop, is composed of resources that crystallize to serve its vision. Moreover, the company is seen as a portfolio of resources and skills (Barney, 1999). From this perspective, the entrepreneur is the first human resource of the national organization. Indeed, the development of the entrepreneurial initiative expressed as in the creation phase than in the existing organizations raises questions regarding the conditions of control and development of human resources.

Human resources management within SMEs and the importance of its practices

The requirement of creating human resources management seems to be more than obvious. The entrepreneur is soon faced with the problem of recruitment, compensation, especially when the project is part of an entrepreneurial team. Entrepreneurship is not just for entrepreneurship alone. Existing organizations, regardless of their size, can favor an entrepreneurial orientation. Developing and maintaining this guideline is an organizational practice in the field of HRM that enables autonomy assessment and risk taking (Stevenson et al., 1990). For each human resources practice there are design options which are, in fact, options for promoting and consolidating the different characteristics and behaviors of the employees (Schuler, 2001). Moreover, he points out that HRM practices can reflect the culture of an organization. Specifically, many authors (Peters, 1990) have suggested that corporate

entrepreneurship requires a culture built around emotional commitment, autonomy, empowerment, earned respect and a strong work ethic.

On the other hand, "companies founded by entrepreneurs who are unable or unwilling to deal effectively with human resources problems find it difficult to attract and retain top employees, they are not able to motivate those who they remain and generally fail to maximize the value of their human resources - often with serious consequences for their survival "(Baron, 2003). Moreover, the ability to identify and pursue new opportunities that can be described as entrepreneurial capacity implies having human resources to understand and exploit such opportunities. In this regard, recruitment, remuneration and promotion policies influence the entrepreneurial potential. Human resources management policies: recruitment, selection, training, performance appraisal and compensation are intended to guarantee employees the characteristics required for effective organizational performance and provide an appropriate behavior index and reinforcement to guide and motivate desired behaviors (Morris et al., 2010). Various human resource management practices need to be in line with each other, while differences in human resource practices are likely to be associated with changes in the level of entrepreneurship observed in organizations, as is consistent with contingency theories of organizations (Dabic et al., 2011).

Fig. 1: The relationship between entrepreneurship and human resources management (Cardon et al., 2004, p. 298)

Previous studies on the recruitment practices of entrepreneurial firms have revealed that informal recruitment or, more precisely, recruitment through networks are more frequently adapted and considered more effective than formal practices (Aldrich et al., 1997)

Behaviors and characteristics specific to employers

The founder's abilities, culture, motivation, behavior, learning and experiences are all topics for which the researcher may be interested in human resources. "As new-found organizations grow and mature, their human resource requirements and needs change rapidly, creating a number of challenges for entrepreneurs and organizational leaders at all levels" (Longenecker et al., 2008, p. 23). In this way, an organization must really maintain its entrepreneurial dynamism if it wants to stay alive, to grow, to improve its performance and to renew itself (Randerson, 2013). In this way, there are many factors, related to the practices of human resources management that contribute to the motivation of the employees and to the creation of the entrepreneurial spirit.

Based on its literature review, Schuler recommended that the following employee characteristics be associated with successful entrepreneurial endeavors: creative and innovative behavior, risk taking, long-term orientation, focus on results, flexibility in change, cooperation, independent behavior, tolerance of ambiguity and preference for assuming responsibility (Schuler, 2001; Ceptureanu EG et al.,

2018a). Hayton points out that the two main problems remain those of the role of risk taking and the autonomy of actions ("discretionary behavior") of individuals (Hayton, 2005). The first factor can be encouraged by certain HRM practices, such as recruiting people with tolerance for ambiguity and implementing a compensation system that even recognizes risk taking. When it is the second factor, it can be stimulated by incentives and by supporting middle management.

Table 1: Organizational incentives needed for entrepreneurship

Factors	Objectives
Ideas requested	Employees are encouraged to propose and develop ideas.
Autonomy	Generates the spirit of managing a project, consolidating the initiative in decision making and solving problems
Performance based on a reward system	Employees are encouraged to take the risk of their projects.
Assessing the risks assumed	Employees are encouraged by the company to commit even if there is a risk of failure
Schooling	The opportunity offered to companies to strengthen the desired entrepreneurial culture and mentality
Rotating the workplace	The perception of new business opportunities is stimulated

Conclusions

In today's competitive environment, human capital is becoming a major success factor. People represent the greatest wealth of an organization on the basis of which it creates its basic competitive advantage. The labor market has changed a lot in recent years and is constantly changing and developing. The changes are linked to a number of new trends. Connecting human resource management processes with marketing, public relations, corporate strategy and vision is widely discussed. The human resources strategy is an essential part of the corporate strategy.

Its specific objectives are based on the objectives of the company. The human resources strategy thus contributes to the development of the systematically managed organization, together with the objectives of other departments. The human resources strategy clearly sets out what and how to change human resource processes so that organizations can best achieve their goals.

Many small businesses have fewer than five employees, and therefore the role of human resources in these businesses is one of their minor. In fact, human resources are very important in small businesses because of the significant impact one or a few employees may have on the business (Sheehan et al., 2011; Ceptureanu EG et al, 2018b). Although we could expect the human resources management to be done systematically in SMEs, it seems that even today, only 42% of the Romanian companies are managed using a human resources strategy. Other companies either do not have a human resources strategy or do not pursue it. The managers evaluate the HRM process between 6-7, which is the tip on the 9-point scale. The human resources management process operates at 71% in SMEs, it ranks 5th among other processes. Production is first, followed by quality management and sales.

In particular, small businesses do not have a separate staffing department, so the man-ager manages to work with people, so the operation of this process is no bigger. The human resources strategy is present and followed in particular by such enterprises for which it is important to hire and retain high quality employees and to take care of their development (Pech et al., 2018). Human resource problems are steadily increasing in all types of organizations, young workers want more freedom and a faster career (Westerman et al., 2011). Small and medium-sized enterprises have their own specificities in all areas of existence and, of course, also in the management of human resources. Perhaps the most striking feature is that small businesses rarely have a human resources department or a human resources specialist. The human resources strategy of small businesses is one of the least researched (Mankelow, 2008). Also, small businesses need human resources managers. The strategic performance and efficient management of human resources allows the entrepreneurs to improve the quality of their production.

The carrier and implementer of the human resources strategy and works is usually the owner (manager) of the enterprise. As such a person is especially an expert in other fields, he concentrates his forces mainly on production, sales, technology and neglects the importance of the human factor in the organization. In addition, a small business is more vulnerable to changes in the external environment; it has no long-term resources and reserves. The error of each worker is more visible and may threaten the reputation and competitiveness of the organization in relation to customers and business partners.

The common argument of managers for underestimating the human resources department is that the organization must be very flexible and no strategy is required, including HR. However, it is a priority for the owners of these organizations to focus their attention on human resources, to acquire the necessary knowledge and skills of strategic management and to create a human resources concept that will increase the organization's long-term competitiveness and also , to increase employee satisfaction. A well-defined HR strategy is essential for any organization, because without a strategy HR processes are not efficient and human resources development is impossible.

As the human factor becomes more and more important in business, the importance of the long-term human resources strategy will increase exponentially. Its quality will also depend on the ability of an enterprise to compete in a competitive fight for good quality human resources. Each business should establish its own human resources strategy and have its own human resources policy. Only the right relationship of the human resources strategy with the entire strategy of the organization can lead to long-term success (Yiu et al., 2007). In order to effectively create the human resources strategy, this should be a recurring process. Its location and importance will depend first and foremost on the importance of organizing human resources for achieving long-term business objectives and creating the overall market value of an organization. The increased importance of human capital is also due to easier access to financial capital and material resources.

Abstract

This study explores how farmers' acceptance of radio programmes related to agriculture and broadcast in native dialects have influenced the marketing of agricultural products in Nigeria. The study specifically seeks to ascertain farmers' interest in the radio programmes related to agriculture broadcast in native dialects; determine farmers' acceptance of the radio programmes related to agriculture broadcast in native dialects and establish if the agricultural programmes have influenced the marketing of their farm produce. Using the survey research design, the study was anchored on development media and agenda-setting theories. The questionnaire was administered on 663 randomly selected farmers in Plateau, Nasarawa and Benue states. Findings show that 72.7% of respondents' have an interest in the radio programmes in native dialects and these programmes address the needs of farmers such as marketing and providing links with potential buyers of agricultural products. Findings further show that the programmes *U yivin ikyese I kwaghyan* (Filling the Food Basket); *Mukoma gona* (Let us go back to farming) and *Muryan Manoma* (Voice of Farmers) all broadcast on Harvest FM Makurdi, Nasarawa Broadcasting Service (NBS), and Plateau Radio and Television Corporation (PRTVC) have played an important role in helping farmers to market their products. The study concludes that the critical role these programmes play in the greater efficiency for farmers and other stakeholders in the production chain is sacrosanct. The study, among other things, recommends that agricultural radio programmes in native dialects should continue to be encouraged and sustained. This will help keep farmers abreast of trends in the agricultural sector.

Keywords: Agriculture, Farmers, Native dialects, Marketing, Programmes, Radio

Introduction

Radio programmes related to agriculture broadcast in native dialects play an integral role in the marketing of farm products. This is evident in the language of engagement as it informs farmers on how to improve their agricultural yield and also ensure that their products are adequately marketed and priced accordingly. Over the years, these programmes have provided a kind of engagement between farmers and extension workers as well as farmers and consumers of their products (Adeyeye *et al*., 2020; Hampson, Leclair, Gebru, Nakabugo, & Huggins, 2017).

Marocchino (2009) notes that agricultural marketing is a series of interlinked activities: preparation, production, planting, harvesting, grading, packaging, transportation, storage, farming and food processing, distribution and sale. This operation cannot occur without information exchange between producers and purchasers. Marketing of agricultural products is relevant in the production process as it ensures that harvested agricultural products are transmitted to consumers to give farmers value for the

time, energy, and resources spent in producing these crops. Radio programmes in native dialects have been used successfully in agricultural extension in many countries (Nwammuo & Salawu, 2019; Idiegbeyan-Ose *et al*., 2019; Adeyeye *et al*., 2019). Evidence from previous studies shows that farmers attitude and perceptions are influenced by the media and programmes they are exposed to (Bharti, & Bharti, 2019; Kumar, Ansari, & Singh, 2017).

The peculiarity of these programmes in reaching farmers in a language they understand underpins the need to thoroughly utilize this medium to interact with them on the need to market their products further. This is evident because these programmes which include, *Let us go back to farming* in Nasarawa State, *Voice of Farmers* in Plateau State and *Filling the Food Basket* in Benue State help disseminate relevant agricultural information to different farmers at a minimal cost. Thus, farmers can have access to the required information, especially in hinter communities, where extension workers cannot be easily accessible.

Access to timely information is also essential for farmers' involvement in markets as it lets them learn about market prices and demand for particular products and markets. Information on market conditions and market rates may also help farmers negotiate better on their products' rates. Farmers may also bypass local traders and contacts with traders and therefore directly sell their goods to markets or traders. This knowledge is useful because it is local, timely and reliable, diverse and widely accessible and understood by the rural community as a whole (Magesa, Michael & Ko, 2014).

This study thus examines how farmers' acceptance of radio programmes related to agriculture broadcast in native dialects have influenced the marketing of agricultural products in Nigeria. The study underscores how farmers perceive the information gotten from these radio programmes. The programmes include *U yivin ikyese I kwaghyan* (Filling the Food Basket); *Mukoma gona* (Let us go back to farming); *Muryan Manoma* (Voice of Farmers). These programmes are broadcast on: Harvest FM Makurdi, Nasarawa Broadcasting Service (NBS), and Plateau Radio and Television Corporation (PRTVC) respectively.

Objectives of the Study

The following objectives guide the study:

- To ascertain farmers interest in radio programmes related to agriculture in native dialects understudy
- To determine farmers acceptance of the radio programmes related to agriculture in native dialects
- To establish if the agricultural programmes under study have influenced the marketing of their farm produce

Literature Review/Theoretical Framework

Radio through its programmes is one of the several ways of transmitting knowledge to Nigeria and the rest of the world. The fact that it is cheap to buy, and that it can be worked with or without electricity, cannot distinguish the explanation for its broad and appropriate existence. This explains why its target is not only literate and mainly urban areas but also citizens in the farthest part of the globe, i.e. the citizens of rural areas. As part of the benefit of radio over other media, the target audience may opt to use a language that is peculiar to them. Thus, it's easy for a Hausa man to know via radio that the next things happen in Lagos affect him.

Oyeyinka, Bello and Ayinde, (2014) examined the radio use in Oyo State, Nigeria for the marketing of agricultural products. One hundred and fifty (150) farmers for the analysis were chosen by using a random sampling technique. The findings indicate that the majority (66.7%) were women between the ages of 41 and 50 years. The rest of the respondents were females. A majority of respondents have been married (67.3%) and employed (72.0%), and their use of marketing knowledge has a positive influence. The main occupation (81.3%) of respondents is agricultural work. Many of them (68.0%) are cultivated over 6-15 years. The findings further indicate that the majority of farmers (84.0%) used the agricultural radio program as their source of knowledge on the agricultural market. Inferential statistics indicate substantial connections between farmer usage and education ($X2 = 16.35$; $< .05$) of the farm-radio

service and primary occupation (X2 = 61.25; < 0.05) of selling agricultural commodities. However age (X2 = 5.54; > 0.05) and marital status (X2 = 10.46; > 0.05) had no relevant connection to the usage of agricultural commodity marketing radio programmes related to agriculture. Also, farmers 'awareness results (r = 0,632, p < 0.05) and farm radio use were positive, while the restrictions (R = -0.0256, P < 0.05) had negative relation with farmers' use of farm radio to sell farm commodities. The results also had a positive relationship with farmers. In addition to radio, extension agents and direct communication with fellow farmers are the primary sources of market knowledge for farmers. The crux of Oyeyinka, Bello and Ayinde's study was to examine radio use for the marketing of agricultural products. This study goes a step further to underpin radio programmes aired in indigenous languages as it influences the marketing of agricultural products.

Magesa, Michael and Ko (2014) note that for participating in agricultural markets, access to agricultural and exchange information is essential. The farm marketing chain gains most from a professional and well-equipped member. As rural farmers have limited access to agricultural markets, other actors (traders, customers, and intermediaries) have relied too long on subsistence farming as a benefit for more. They argued that these rural farmers had limited access to markets because of poor road infrastructure, lack of transport means and generally because of the lack of knowledge on the agricultural market. Because of the lack of information on the market, such as market prices, the quality and quantity of products available in the markets, farmers in rural areas are negotiating prices of their produce from information supplied by traders. Due to the absence of market knowledge, including market costs, quality and quantity of goods, farmers negotiate prices of their products based on information received by traders. These factors are substantially rising rural farmers 'bargaining power, thereby fostering the uncompetitive market growth. Rural farmers are required to switch from subsistence farming to the primary economic activity of agriculture if they are given a reasonable share of their goods. Remote rural farmers have not gained much from reliance on radio programmes related to agriculture and mobile calls for information on the demand in agriculture.

This study is guided by the development of media theory and agenda-setting theory.

Development media theory suggests that the mass media would promote developed countries' growth goals. Folarin (2002) outlined the main concepts of the theory that Dennis McQuail originally suggested. The media need to recognize and carry out constructive development activities in compliance with national policies and the right of the press to open up to economic goals according to national policies. He also pointed out that the media should make national culture and languages the focus of their content.

The development media theory is chosen as a relevant frame because these programmes aid agricultural development which eventually brings about constructive development activities in compliance with national policies and the right of the press to open up to economic goals according to national policies. When farmers' adequately market their products and improve economic activities, it brings about the advancement of national culture and languages.

The agenda-setting theory also explains the power of the media to decide which topics will form the basis of public discourse or reflection. The principle of "agenda-setting" does not grant the press the power to determine audience views, according to Folarin (2002, p. 75). Still, it does allow them the capacity to decide what to be aware of. In order for a topic to become important, it should be recorded consistently and given attention to a level of controversy and accumulated media-specific consequences (Folarin, 2002).

Agenda setting theory is relevant to this study because the media through agricultural radio programmes in native dialects provide an array of innovations in agriculture that require farmers to adopt if they desire an improvement in their overall output and also market their products. By emphasizing technological innovations in agriculture, farmers' see it as essential to improve their agricultural yields. On the other hand, media silence on these issues will also make the farmers regard them as unimportant no matter how important they are. Thus, emphasis on these issues will bring about the availability of improved, tested and trusted methods of farming and food security is fully guaranteed. Additionally, they are kept abreast of trends in marketing their farm products.

Materials and Methods

The study adopts the survey research method. This type of research method aims at collecting data on a particular problem from a sample of a given population. Wimmer and Dominick (2000, p.101) argue that it can be used to investigate issues in realistic settings adding that the method is also more economical. The questionnaire was designed to elicit general information about the study objectives from farmers in the selected states. The choice of using the questionnaire was based on the effectiveness of the instrument to obtain diverse opinions and feelings from the sampled respondents. Plateau, Nasarawa and Benue State are selected as the area for this study; the states are located in the Northcentral geopolitical zone of Nigeria. It has an approximate population of 1,150,000 farmers as indicated by the All Farmers Association. The geopolitical zone under focus is acknowledged as the highest contributor to Nigeria's foreign exchange earnings in agricultural crop export (Maroya, Balogun & Asiedu, 2014; Bamiro, Afolabi & Daramola, 2012; Consultative Committee on Agricultural Export Commodity Statistics, 2005). Examples of crops produced by this zone include maize, yam, cassava, soya beans, melon, rice, and tomatoes. The three top states in the geopolitical region known for successful crop farming (Benue, Nasarawa and Plateau States) are examined. Additionally, the States emphasize radio programmes related to agriculture broadcast in native dialects as against other States in the geopolitical zone (Iwuchukwu, Ineji & Inyang, 2018).

A sample of 221 from each of the selected states were chosen randomly, giving a total of 663 farmers. The sample size was ascertained using the Krejcie and Morgan (1970) sample size determination table. Data gathered were analyzed using tables of frequency and simple percentages to show the distribution of results and understanding of analysis.

Results

Six hundred and sixty-three (663) copies of the questionnaire were administered among the farmers across the three selected states who provided the data analyzed in this section.

Fig. 1: Age distribution of Respondents

Age distribution of respondents across the three (3) selected states in Nigeria is as presented in Figure 1 revealed that out of 60 respondents that are within the age group of below 18 years in all the three selected states, 25(41.7%) were from Benue, 17(28.3%) were from Nasarawa while 18(30.0%) were from Plateau. Similarly, the total number of respondents from all the three states that are within the age group of 18-35 years was 305 out of which 108(35.4%) were from Benue, 117(38.4%) were from Nasarawa while 80(26.2%) were from Plateau. The findings also revealed that 206 respondents were within the age group of 35-50 years. Out of 206 respondents from the three selected states, 66(32.0%) were from Benue, 63(30.6%) were from Nasarawa, while 77(37.4%) were from Plateau. Also, the total number of respondents that are within the age group of 50 years and above was 92. Out of these 92 respondents, 22(23.9%) were from Benue, 24(26.1%) were from Nasarawa while 46(50,0%) were from Plateau. Sequel to the data presented above, it shows that most of the respondents across the three selected states were within the economically active population of 18-50 years.

Fig. 2: Gender Distribution of Respondents

The gender distribution of respondents from all the three selected states, Benue, Nasarawa and Plateau as presented in Table 4.2 and Figure 4.2 show that out of the 362 total number of male respondents from all the selected states, 130(35.9%) were from Benue, 130(35.9%) were from Nasarawa while 102(28.2%) were from Plateau. Similarly, out of 301 female respondents, 91(30.2%) were from Benue, 91(30.2%) were from Nasarawa, while 119(39.5%) were from Plateau. The data presented, however, revealed that most of the respondents from Benue and Nasarawa were male while in Plateau, most of the respondents were female. This suggests that women on Plateau are more engaged in farming than their male counterparts.

Table 1: Agricultural Radio Programmes in native dialects vis-à-vis Marketing of Agricultural Products

	SA 5	A 4	U 3	D 2	SD 1	Mean	SD
I have interest in the radio programmes related to agriculture broadcast in native dialects on radio	113 (17.0)	369 (55.7)	92 (13.9)	61 (9.2)	28 (4.2)	3.7210	.99042

The radio programmes related to agriculture broadcast in native dialects on radio address needs of farmers on marketing	107 (16.3)	336 (50.7)	117 (17.6)	61 (9.2)	41 (6.2)	3.6772	1.92335
Experts used in the radio programmes related to agriculture broadcast in native dialects on the radio to explain issues understand modern techniques of farming (marketing inclusive)	95 (14.3)	351 (52.9)	119 (17.9)	74 (11.2)	24 (3.6)	3.6320	.98032
The amount of time the radio programmes related to agriculture broadcast in native dialects is sufficient	83 (12.6)	199 (30.0)	187 (28.2)	154 (23.2)	40 (6.0)	3.2247	1.35057
The time the radio programmes related to agriculture broadcast in native dialects is appropriate	81 (12.2)	250 (37.7)	184 (27.8)	122 (18.4)	26 (3.9)	3.3590	1.03894
I love radio programmes related to agriculture broadcast in native dialects on radio	101 (15.2)	350 (52.8)	109 (16.4)	74 (11.2)	29 (4.4)	3.6335	1.01197
I don't miss the radio programmes related to agriculture broadcast in native dialects for any reason	47 (7.1)	246 (37.1)	177 (26.7)	133 (20.1)	60 (9.0)	3.1312	1.09626
I believe in the practices recommended by the radio programmes related to agriculture broadcast in native dialects	65 (9.8)	351 (52.9)	132 (19.9)	69 (10.4)	46 (6.9)	3.4827	1.03529
I participate in the radio programmes related to agriculture broadcast in native dialects through calls and SMS	62 (9.4)	222 (33.5)	193 (29.1)	120 (18.1)	66 (10.0)	3.1418	1.12690
It is not a waste of time to listen to the radio programmes related to agriculture broadcast in native dialects	132 (19.9)	338 (51.0)	88 (13.3)	80 (12.1)	25 (3.8)	3.7119	1.03560

The acceptance rate of agricultural radio programming in indigenous languages by the respondents in the selected states was measured with nine (9) items on the research instrument using five (5) Likert's scale ranging from strongly agree (5), Agree (4), undecided (3), disagree (2) and strongly disagree (1). The scale addressed the extent at which respondents perceived the items on the research instrument.

To determine the extent the respondents agreed to the items on the research instrument was established by the mean score and standard deviation. The assumptions and threshold of the mean score and standard deviation depict that if mean is between 0.1 and 1.30 it is an indication that it is fragile; 1.31 - 2.40 means score shows that it is very fair, 2.41- 3.45 is regarded as moderate; 3.46 - 4.50 is strong while 4.51 - 5.00 is an indication that the means score is powerful.

Table 1 shows respondents' opinion on acceptance of the agricultural radio programming in indigenous languages. To know if the respondents have interest in the radio programmes related to agriculture broadcast in native dialects, 113(17.0%) of the respondents strongly agreed that they have interest in the radio programmes related to agriculture broadcast in native dialects, 369(55.7%) of the respondents agreed that they have interest in the radio programmes related to agriculture broadcast in native dialects, 92(13.9%) of the respondents were indifferent about the statement, 61(9.2%) disagreed with the statement. In comparison, 28(4.2%) strongly disagreed with (Mean score = 3.7210, Standard Deviation = .9904). Therefore, most of the respondents agreed that they have an interest in radio programmes related to agriculture broadcast in native dialects.

It must also be noted that 107 (16.3%) of the respondents strongly agreed that radio programmes related to agriculture broadcast in native dialects on local radio station address needs of farmers, 336(50.7%) of the respondents agreed that radio programmes related to agriculture broadcast in native dialects on local radio station address needs of farmers, 117(17.6%) of the respondents were indifferent about the statement, 61(9.2%) disagreed with the statement. In comparison, 41(6.2%) strongly disagreed with (Mean score = 3.6772 Standard Deviation = 1.9234). Therefore, most of the respondents agreed that radio programmes related to agriculture broadcast in native dialects on local radio station addresses the needs of farmers. However, 95(14.3%) of the respondents strongly agreed that experts used in the radio programmes related to agriculture broadcast in native dialects on the radio to explain issues understand modern techniques of farming, 351(52.9%) of the respondents agreed that experts used in the radio programmes related to agriculture broadcast in native dialects on the radio to explain issues understand modern techniques of farming, 119(17.9%) of the respondents were indifferent about the statement, 74(11.2%) disagreed with the statement. In comparison, 24(3.6%) strongly disagreed with (Mean score = 3.6320, Standard Deviation = .9803). Therefore, most of the respondents agreed that experts used in radio programmes related to agriculture broadcast in native dialects on the radio to explain issues understand modern techniques of farming.

Similarly, 83(12.6%) of the respondents strongly agreed that amount of time the radio programmes related to agriculture broadcast in native dialects airs is sufficient 199(30.0%) of the respondents agreed that the amount of time the radio programmes related to agriculture broadcast in native dialects airs is sufficient, 187(28.2%) of the respondents were indifferent about the statement, 154(123.2%) disagreed that the amount of time the radio programmes related to agriculture broadcast in native dialects airs is sufficient. In comparison, 40(6.0%) strongly disagreed with (Mean score = 3.2247, Standard Deviation = 1.3506). Therefore, most of the respondents agreed that the amount of time the radio programmes related to agriculture broadcast in native dialects airs is sufficient. Likewise, 81(12.2%) of the respondents strongly agreed that the time the radio programmes related to agriculture broadcast in native dialects airs is appropriate, 250(37.7%) of the respondents agreed that the time the radio programmes related to agriculture broadcast in native dialects airs is appropriate, 184(27.8%) of the respondents were indifferent about the statement, 122(18.4%) disagreed that the time the radio programmes related to agriculture broadcast in native dialects airs is appropriate. In comparison, 26(3.9%) strongly disagreed with (Mean score = 3.3590, Standard Deviation = 1.0389). Therefore, most of the respondents agreed that the time the radio programmes related to agriculture broadcast in native dialects airs is appropriate.

Equally, 101(15.2%) of the respondents strongly agreed that they love the radio programmes related to agriculture broadcast in native dialects, 350(52.8%) of the respondents agreed that they love the radio programmes related to agriculture broadcast in native dialects, 109(16.4%) of the respondents were indifferent about the statement, 74(11.2%) disagreed that they love the radio programmes related to agriculture broadcast in native dialects. In comparison, 29(4.4%) strongly disagreed with (Mean score = 3.6335, Standard Deviation = 1.0119). Therefore, most of the respondents agreed that they love radio programmes related to agriculture broadcast in native dialects. It is equally important to report that, 47(7.1%) of the respondents strongly agreed that they don't miss the radio programmes related to agriculture broadcast in native dialects for any reason, 246(37.1%) of the respondents agreed that they don't miss the radio programmes related to agriculture broadcast in native dialects for any reason, 177(26.7%) of the respondents were indifferent about the statement, 133(20.1%) disagreed. In comparison, 60(9.0%) strongly disagreed with (Mean score = 3.1312, Standard Deviation = 1.0963).

Therefore, most of the respondents agreed that they don't miss the radio programmes related to agriculture broadcast in native dialects for any reason.

It must be noted that 65(9.8%) of the respondents strongly agreed that they believe in the practices recommended by the radio programmes related to agriculture broadcast in native dialects, 351(52.9%) of the respondents agreed that they believe in the practices recommended by the radio programmes related to agriculture broadcast in native dialects, 132(19.9%) of the respondents were indifferent about the statement, 69(10.4%) disagreed. In comparison, 46(6.9%) strongly disagreed with (Mean score = 3.4827, Standard Deviation = 1.0353). Therefore, most of the respondents agreed that they believe in the practices recommended by the radio programmes related to agriculture broadcast in native dialects. Also, 62(9.4%) of the respondents strongly agreed that they participate in the radio programmes related to agriculture broadcast in native dialects through calls and SMS, 222(33.5%) of the respondents agreed that they participate in the radio programmes related to agriculture broadcast in native dialects through calls and SMS, 193(29.1%) of the respondents were indifferent about the statement, 120(18.1%) disagreed. In comparison, 66(10.0%) strongly disagreed with (Mean score = 3.1418, Standard Deviation = 1.1269). Therefore, most of the respondents agreed that they participate in radio programmes related to agriculture broadcast in native dialects through calls and SMS.

Meanwhile, 132(19.9%) of the respondents strongly agreed that it is not waste of time to listen to the radio programmes related to agriculture broadcast in native dialects, 338(51.0%) of the respondents agreed that it is not waste of time to listen to the radio programmes related to agriculture broadcast in native dialects, 88(13.3%) of the respondents were indifferent about the statement, 80(12.1%) disagreed. In comparison, 25(3.8%) strongly disagreed with (Mean score = 3.7119, Standard Deviation = 1.0356). Therefore, most of the respondents agreed that it is not a waste of time to listen to the radio programmes related to agriculture broadcast in native dialects.

Discussion of Findings

The mean score and standard deviation determined the acceptance rate of radio programmes related to agriculture broadcast in native dialects by the respondents in the selected states. Results show that 72.7% of respondents' have an interest in radio programmes related to agriculture broadcast in native dialects. It should also be noted that 67% of respondents agree that radio programmes related to agriculture broadcast in native dialects on local radio station address the needs of farmers. Additionally, most of the respondents agree that experts used in the radio programmes related to agriculture broadcast in native dialects on their local radio station to explain issues understand modern techniques of farming.

Similarly, most of the respondents agree that the amount of time the radio programmes related to agriculture broadcast in native dialects airs is sufficient. Likewise, the time the radio programmes related to agriculture broadcast in native dialects broadcast is appropriate. Furthermore, 68% of respondents agree that they love radio programmes related to agriculture broadcast in native dialects and they don't miss the radio programmes related to agriculture broadcast in native dialects for any reason. Therefore, most of the respondents agree that they believe in the practices recommended by the radio programmes related to agriculture broadcast in native dialects. Additionally, they participate in radio programmes related to agriculture broadcast in native dialects through calls and SMS. It is not a waste of time to listen to the radio programmes related to agriculture broadcast in native dialects.

A study conducted in Northern California by Jenkins and his contemporaries lay credence to this and has shown that mass communication has supplied a lot of helpful agricultural information, and the experience has been quite significant (Donye, 2018). Radio has proven to be an essential instrument for improving agricultural production in rural areas. Radio programmes related to agriculture are a powerful and effective medium for the dissemination of agricultural information and expertise in developing nations (Nakabugu, 2001; FAO, 2005).

According to Sharma (2008), the benefit of radio programmes related to agriculture as a means of communication is that its transmission, presentation and portability are cost-effective. Radio can be an essential tool for teaching farmers if it attracts them to new programmes utilizing modern farming techniques. However, to correctly understand and execute such programmes, indigenous language use

is crucial in ensuring that farmers are educated on new practices in agricultural development (Nazari & Hasbullah, 2010). As rural farmers participate in radio programmes related to agriculture, because of the sensation of ownership, they become more exciting and efficient. This readily gets through the message and information. Nakabugu (2010) confirms that data on enhanced agriculture, seed improvement, planting, agricultural forestry, improved harvesting methods, soil preservation, marketing, processing and diversification after harvest. He added that rural radio offers farmers the chance to interact, through live talk shows, telephone programmes and regional broadcasts, and with each other and with other competent authorities such as the extension staff, plant and animal experts.

Research by the FAO (2005) discovered that acceptance of farm radio programmes related to agriculture have contributed to strengthening social unity, improving communicative capacity, providing historical understanding, maintaining the environment, and solving community issues. The study suggested extensive use of farm radio programmes related to agriculture as an instrument for rural development. The educational role of the radio is first and foremost to assist farmers in embracing current agricultural technology to achieve higher returns and change the age-old low yield ideas. Farmers' willingness to increase their farm income by implementing advanced enhanced farming methods to be considered a most notable change in their behaviour. These programmes broadcast in indigenous languages are instrumental for disseminating credible agriculture-related information to bring about change in farming techniques and thus bring about economic transformation in the nation (Shree, 2011).

Findings from this study also show that farmers have improved their production based on the information gotten from radio programmes related to agriculture broadcast in native dialects. Findings also show that 66.9% of respondents embrace innovations which have improved their capacity as a result of radio programmes related to agriculture broadcast in native dialects. Farmers also affirmed that they employ technology in farming based on radio programmes related to agriculture broadcast in native dialects. They are also exposed to new markets for their produce because of radio programmes related to agriculture broadcast in native dialects.

The statistics presented also revealed that 66.4% of the respondents agree that radio programmes related to agriculture broadcast in native dialects on local radio station have appreciably improved farmers' knowledge and productivity. Furthermore, most of the respondents agreed that farmers are exposed to agricultural funding through radio programmes related to agriculture broadcast in native dialects. Sheila and Hezron (2017) corroborated the findings in this study. They found that access to information from media outlets have managed to improve farmers yield over time. Their argument supports this study in the area of geopolitical zonal radio application for keeping farmers abreast of innovations radio which has improved their productivity. Njoku (2016) focused on the efficacy of the RAF programme in technology transfer to rural farmers and discovered that the RAF programme was efficient in technology transfer to rural farmers. The study supports this present research because it recognizes that radio is useful in transmitting technological expertise in the state understudy to rural farmers. Ango, Illo, Abdullahi, Maikasuwa and Amina (2013) also confirm the role played by agricultural radio programmes related to agriculture in raising awareness among farmers. Their research discovered that the information disseminated via radio was adopted by farmers, which was found to be extremely applicable to the agricultural operations of farmers. Farmers have acquired an understanding of farm management methods, prevention of post-harvest losses and adequate fertilizer implementation, and this has been discovered to be very crucial and efficient for most farmers ' economic operations. This research is an open-minded one about the role of agricultural radio programmes related to agriculture in raising awareness among farmers

Conclusion/Recommendations

The findings in this study portray the potentials of agricultural radio programmes in native dialects in improving the marketing of farm products through effective agricultural communication via the programmes studied. The study underscores the critical role of these programmes can play in greater efficiency for farmers and other stakeholders in the production chain. It shows that the programmes *U*

yivin ikyese I kwaghyan (Filling the Food Basket); *Mukoma gona* (Let us go back to farming) and *Muryan Manoma* (Voice of Farmers) all broadcast on Harvest FM Makurdi, Nasarawa Broadcasting Service (NBS), and Plateau Radio and Television Corporation (PRTVC) have played an essential role in helping farmers to market their products. This is evident from the results of this study in the way these programmes educate farmers by consciously telling them to produce beyond consumption and to sell to the right people at the correct prices.

The study showed that farmers have an interest in radio programmes related to agriculture broadcast in native dialects and confirmed that the programmes address the needs of farmers. Experts used in the radio programmes related to agriculture broadcast in native dialects on the radio to explain issues understand modern techniques of farming (marketing inclusive)

The following recommendations are, therefore made:

a. Agricultural radio programmes in native dialects should continue to be encouraged and sustained. This will help keep farmers abreast of trends in the farming sector.

b. Successful farmers with large scale farmlands should be engaged in these programmes to serve as a reference point to others who are coming up.

c. With the diversification in native dialects in hinter communities, agricultural radio programmes in local dialects should further be decentralized to meet the needs of such areas.

Abstract

Due to the fact that one of the most important resources held by contemporary economic organisations are people, the employees' satisfaction is of a great importance for the functioning of the whole organisation irrespectively of the size thereof. It influences both, the organisation's results, as well as the development and the competitive position. This article describes issues regarding job satisfaction of small and medium-sized enterprises' (SMEs') employees by indicating factors shaping satisfaction and specifying its influence on the competitive position of enterprises. The main aim of this paper is to attempt indicating determinants influencing the professional satisfaction of employees of small and medium-sized enterprises in Poland in the context of developing the advantage of those enterprises. The research has been conducted among employees of the Polish SME sector. The empirical research had a quantitative character. The diagnostic survey, where a research tool was an independently developed survey questionnaire, was adopted as the research method. The main research question was the following: What are the main factors influencing the satisfaction of SME employees in Poland? Therefore, it has been attempted to indicate factors influencing employees' satisfaction with various aspects of their work. The assessment covered, among others: systems of motivating and remunerating employees, communication, relations in the company and the sense of permanence and stability of employment. The research hypothesis had the following wording: Satisfaction of SMEs' employees influences the competitive positions of those companies. The conclusions reflect not only the main ideas discussed herein, but also the aim of the article. The research results confirmed that satisfaction of the SMEs' employees influences the competitive position of those companies, whereas, the higher the level of job satisfaction, the better the competitive position of the company.

Keywords: job satisfaction, competitiveness, human capital, SME.

Introduction

Nowadays, maintaining a competitive position is not an easy task. Entrepreneurs have to deal with more and more difficult and complex conditions of development. In the knowledge-based economy, the main source of development constitutes intangible assets (knowledge assets) (Ejrami et al., 2016). Employees, their knowledge, skills and qualifications become more important than material resources, the driving force of development of economic entities (OECD, 1997). As underlined by Prahalad (1983), market leaders are distinguished with human capital and not physical or financial capital.

Employees, their competences and attitudes, as well as engagement constitute a foundation of functioning, development and results achieved by the enterprises (Feeman et al., 2006), through the agency of which a positive image of an enterprise can be created (Leoński, 2015). However, the level of engagement in the organisation is significant, since engaged employees are the key factor of success of each organisation. High engagement of an employee, loyalty, long-term employment and low absence strongly correspond with the high level of job satisfaction. Swarnalatha & Prasanna (2013) underline that employees with a higher level of engagement work harder, are more loyal and more often "take a step further" than non-engaged employees. They generate results by 20% better than non-engaged employees and are by 87% less prone to leave the organisation. Whereas, Rucci et al. (1998)

indicated that per each 5% of an increase in the employees' engagement the customers' satisfaction increased by 1.3%, and a company noted an increase in revenues by 0.5%. Therefore, entrepreneurs face a challenge of creating a working environment favouring effective work and increasing the level of employees' satisfaction. As underlined by Ulric (1991), strategic human capital management is of bigger and bigger significance.

Issues related to human capital management have been present in the literature for many years. The research conducted by scientists oscillate around various problems, often resulting from the dynamically changing situation in economies. Deliberations of many authors focus on the significance of human capital in developing competitive advantage of enterprises (Matejun et al., 2010; Piecuch, 2010; Durany, 2016; Rybak, 2003; Rosińska, 2007; Lawler, 2008; Nahapiet, 1998), underlining, among others, that the human capital constitutes a significant factor of reinforcing the market position and developing the competitive advantage of enterprises. However, the literature review indicates a certain shortage in the scope of the research concentrating on the competitive position of enterprises and the level of satisfaction of those organisations' employees. Therefore, the authors attempted to study the correlation between the satisfaction of employees employed at small and medium-sized entities and the competitive position of this scale of companies. The research covered employees of small and medium-sized entities, since this is the most numerous group of entities making the contemporary economy. While building the competitive position on the market, they have to use features which are characteristic for them and give advantage over other entities.

Literature Review

Employees are one of the most important resources of companies in the fight for maintaining the market position (Dubra, 2010). The combination of knowledge, skills, innovativeness and individual possibilities of employees makes the human capital (Edvinsson & Malone, 1997), which has a particular significance for small and medium-sized entities (Matejun et al., 2010), influencing their effectiveness and wining the competitive battle (Piecuch, 2010). Employee empowerment enables companies to design a culture that helps to build and sustain unique competitive advantages (Durany, 2016; Gorzeń-Mitka, 2018). The human capital is indicated as the source of enterprises' competitiveness (Rybak, 2003; Jagódka, 2011). Employees generate uniqueness thus, they can constitute the factor of the competitive advantage (Rosińska, 2007; Lawler, 2008).

Human capital is owned by the organisation's employees and they decide how much should be invested in the organisation, at which they are employed. As underlined by Abun et al. (2019), persons engaged in work feel a part of the team to a larger extent and are ready to make greater efforts to achieve the aims of this team. The research conducted by Singh (2017) indicated that there is a causal link between job satisfaction and employees' engagement. For many satisfaction from performed work is the priority and factor increasing engagement, which, in turn, translates into generated profits and organisation's market position (Baradaran et al., 2008).

The concept of job satisfaction has been discussed in the subject literature for many years (selected definitions have been presented in table no. 1). According to Hellriegel et al. (1995), it is a product of what an employee receives at work and what they believe they should receive. Satisfaction is a positive affective (emotional) state resulting from the assessment of work (Judge & Bono, 2001), attitude to the work environment and performed professional duties (Staples & Higgins, 1998). This is an element of broadly understood motivation or a person's wellbeing, which results from satisfaction of needs and aspirations. It may be a positive or negative feeling, yet, it is subjectively conditioned.

Table 1: Defined job satisfaction

Author/s	Definitions
Vroom (1964)	positive attitude towards work;
Locke (1976)	result of perceiving own work as allowing achievement of important values from work, provided that these values are compliant with the person's needs or help in achievement thereof;
Wexley & Yukl (1984)	set of the employees' feelings and attitudes towards work;
Agho et al. (1993)	combination of factors related to the performed work, environmental factors and personality factors (positive affect);
Stamps (1997)	the extent to which employees like their jobs;
Saari & Judge (2004)	product of many factors resulting from, among others, employee attitudes, a positive or negative approach to the performed work and the manner of measuring satisfaction;
Schultz & Schultz (2006)	subjective assessment of positive and negative feelings and attitudes that refer to the professional duties performed by employees;
Czarnota–Bojarska (2010)	emotional attitude toward the employing organisation, tasks performed at work and other aspects important for the professional and social functioning;

Source: own study.

As underlined by Abdullah & Ramay (2012), professional satisfaction influences not only the organisation's profitability, but also its competitiveness. Competition is defined as an activity of individuals who seek to achieve the benefits that others want to gain at the same time and in the same conditions (Grzebyk & Krynski, 2011). Business competitiveness describes the ability of a business to regularly and successfully yield products or services that meet the requirements of an open market and enable the business to stay operational by gaining market share (Sipa et al., 2015), the ability to remain in the competitive, fair market for a long period of time (Fathi & Ahmadian, 2016).

According to Saari&Judge (2004), the product of factors determining the employees' satisfaction makes up the result of the enterprise's activities. Higher satisfaction of the employed contributes to their higher engagement and productivity. According to Mrówka (2010), job satisfaction is a motivator, which used as a management tool gives competitive advantage to managers and their organisations. In the case of small and medium-sized enterprises, due to their high heterogeneousness, there are many models of measuring their level of competitiveness. Among sets of factors taken into consideration in measuring the level of competitiveness, human resources are also enumerated (Stoner, 1987; Bambergera, 1989; Slevin & Covin, 1995; Chaston & Mangles, 1997; Chawla et al., 1997).

Judge & Kammeyer-Mueller (2012) and also Iaffaldano & Muchinsky (1985) indicated that higher job satisfaction contributes to lowering: the level of absence and rotation of employees, the number of reported complaints of job dissatisfaction. A satisfied employee performs their duties more diligently and with higher engagement (Reijseger et al., 2017), increasing organisational effectiveness (Hanaysha, 2016).

In the case of SME, the work environment is especially important (Sousa-Poza & Sousa-Poza, 2000; Gazioglu &Tanselb, 2006; Skalli et al., 2008). Without the work environment supporting engagement of employees, rotation thereof will increase and the productivity will decrease, which will lead to the worsening of the relations with customers and decreasing value for stakeholders (Swarnalatha & Prasanna, 2013). The organisation's management should maintain the achieved level of satisfaction or strive for a higher level and not to allow lowering this level. Higher satisfaction level of SMEs' employees decreases the risk of them leaving the company (Basma et al., 2017). High level of job satisfaction is achieved with flexible working hours, lower workload, proper approach to teamwork and management's support. Employees can become more engaged in their activities, more motivated to work hard, which can generate benefits for the enterprise in the long term. Thus, job satisfaction at

SMEs has a direct and positive impact on the internal entrepreneurship (Sehunoe et al., 2015). Job satisfaction is shaped by many factors, among which, the following are enumerated: systems of motivating and remunerating employees, communication, relations in the company, as well as the sense of permanence and stability of employment (Vlosky & Aguilar, 2009; Lewicka, 2010; Gros, 2012). Jun et al., (2006; Wyrwa, 2019) notice that in small and medium-sized enterprises employee trainings are significant for job satisfaction. However, one of the most important elements of the sense of job satisfaction is the remuneration (DeVaney & Chen, 2003; SHRM, 2017).

Methods and Materials

The aim of this study is to attempt indicating determinants influencing the professional satisfaction of employees of small and medium-sized enterprises in Poland. The research results presented herein are the fragment of the project witch concerned the issue of development of small and medium-sized enterprises in CEE countries. This project implemented in the period from February to July 2019. The conducted empirical research was of a quantitative character. Using the survey questionnaire as the research tool allowed a percentage combination of collected answers constituting subjective opinions of respondents covered with the survey. The survey questionnaire included questions on job satisfaction factors grouped into five areas. While assessing the factors affecting job satisfaction, relationships in the company, communication, systems of remuneration and motivating employees as well as a feeling of constancy and employment stability were analyzed.

All surveys were correctly completed and used during the research. The survey was completed by 209 employees from various companies. Due to the small sample size, the following results should be treated as a pilot study. For the purposes of this study, enterprises conducting business activity in Poland have been separated. Detailed characteristics describing the research sample have been presented in table no 2.

Table 2: Characteristics of the research sample

research sample = 209 (100%)		
Characteristics describing respondents participating in the survey:		
sex of respondents	Women	27.8%
	Men	72.2%
age of respondents	up to 25 years old	11.5%
	26-35 years old	16.7%
	36-45 years old	29.7%
	46-55 years old	34.0%
	over 55 years old	8.1%
education of respondents	Higher	37.3%
	Secondary	42.6%
	Vocational	20.1%
seniority	up to 5 years	11.5%
	5-10 years	14.8%
	11-20 years	46.4%
	21-30 years	19.1%
	over 30 years	8.1%
Characteristics describing enterprises covered by the survey:		
company size by number of employees	micro-enterprise (0-9)	48.3%
	small enterprise (10-49)	43.5%
	medium enterprise (50-249)	8.1%
Year of establishing the company	…-1989	21.1%
	1990-2000	23.4%
	2001-2010	41.1%

	2011-…	14.4%
The range of the company's activity (prevailing market)	national	16.3%
	local	39.2%
	regional	34.9%
	international	9.6%
Localisation of the company's registered office	urban municipality	54.1%
	urban-rural municipality	32.5%
	rural municipality	13.4%
Competitive position	very good	1.9%
	good	33.5%
	average	4.3%
	low	29.2%
	very low	31.1%

Source: own study

The following research question was asked: What are the main factors influencing the satisfaction of SMEs' employees in Poland? The research hypothesis has been formulated in the following manner: Satisfaction of SMEs' employees influences competitive positions of those companies.

Discussion and Results

At the beginning of the research respondents were asked if they feel satisfaction from performed work. As many as 72.7% of respondents answered "yes" and "rather yes", which has been presented in figure 1.

Furthermore, respondents were asked if they feel satisfaction from various aspects of their work. The assessment covered, among others, systems of motivating and remunerating employees, communication, relations in the company and the sense of permanence and stability of employment.

Fig 1. Satisfaction with the work performed

Source: own study

The basic issue studied in the research was the employees' satisfaction with motivation systems binding in a company (fig. 2). A lack of job satisfaction of studied employees from binding motivation systems is clearly visible. There were as many as 87.6% of negative responses and only 5.7% positive responses.

The employees' motivation system covers many various factors, which are to guarantee a properly high level of employees' motivation. It provides grounds for proper use of the human capital for the organisation's development irrespectively of the size thereof. Proper motivation may also contribute to the increase in innovative behaviours of employees and can translate into achieving better results and better competitive position of companies.

Fig. 2: Satisfaction with incentive systems in force in the company
Source: own study.

Motivation systems in companies were assessed with regard to selected elements that shape them (table 3). As can be seen in the studied SMEs, motivation systems are not only clearly defined, but also understandable. Whereas, the issue of direct motivation of employees by their superiors has positive implications. Every employee, irrespectively of a held position, expects the effects of their work to be noticed. Noticing small achievements, expressing recognition and respect constitutes a very important (though, not always appreciated) manner of cost-free reinforcement of motivation of employees. Work should also give an employee a possibility of development, that is, satisfy the need for self-development. It is an extremely difficult task for managers, since individual employees understand self-realisation differently. However, what is important is for work to give the employees the opportunity to use their potential and take the initiative (Sidor-Rządkowska 2004).

Table 3: Factors influencing the assessment of the satisfaction with the motivation system

Specification	Yes	Rather yes	Rather no	No	No opinion
The rules of the motivation system are clearly defined and understandable	0.5%	14.4%	47.8%	32.5%	4.8%
My superior motivates me to work better	7.2%	22.5%	47.4%	23.0%	0.0%
What I do is noticed at the company	3.8%	42.1%	31.1%	23.0%	0.0%
I am praised for good work	2.4%	43.5%	42.1%	12.0%	0.0%
The periodical assessment is used for planning my professional development	1.0%	1.0%	23.0%	67.5%	7.7%

Source: own study.

Satisfaction of studied employees with binding remuneration systems achieves a slightly higher level than in the case of satisfaction with motivation systems (fig. 3). In this case, there were only 19.6% of positive answers, which indicates a significant dissatisfaction with systems of remunerating SMEs' employees.

Currently, with generally low salaries in the SME sector, the majority of employees treat money as the main motivation measure. However, small and medium-sized enterprises often deal with financial problems and they cannot afford to motivate with higher monetary incentives, therefore, they resign from positive motivation to the benefit of negative motivation, that is, threatening what the employee has already achieved. It is often manifested with used threats.

Fig 3. Satisfaction with the remuneration systems in force in the company
Source: own study.

The tactics of "threat-based motivation" is currently very popular. Implying that employees should be happy with the fact that they even have a job is a short-term solution, which works only in the case of employees with low level of education and low self-esteem. It results in the sense of the employee's frustration and performing duties at the lowest cost possible. In this situation, shortages in the scope of non-material motivation are especially visible (Smolarek, 2017).

Another issue studied during the research was the issue of feeling satisfaction with the amount of received remuneration (fig. 4). Over half of the respondents are not satisfied (61.2%) with the amount of received remuneration.

Fig 4. Employee satisfaction with remuneration received
Source: own study.

In the case of the remuneration, the respondents were asked to assess it in comparison with other economy sectors (fig. 5). Slightly over a half of respondents – 51.7% indicated that it is at a lower level. Only 17.2% of the respondents stated that it is at a higher level.

Fig 5. Salary assessment compared to other economy sectors

Source: own study.

Remunerations in companies were assessed with regard to selected elements that shape them (table 4). The basic problem of the majority of human resources managers and management specialists, especially in SMEs, consists in using obsolete human resources management tools e.g. in the scope of remuneration and connecting them incompetently with work results. These factors are often related to the dissatisfaction of employees, which disturbs the atmosphere and relations at work and influences lower work results, which is also proven by other research results (Dzieńdziora, Smolarek, 2016).

Table 4: Factors influencing the assessment of the satisfaction with the remuneration system

Specification	Yes	Rather yes	Rather no	No	No opinion
My remuneration is adequate to the effort made in performing duties	0.5%	13.9%	37.8%	47.8%	0.0%
Results generated by me influence the amount of my remuneration	0.5%	18.2%	52.2%	29.2%	0.0%
Improved skills are reflected in the amount of received remuneration	0.5%	5.7%	13.9%	79.9%	0.0%

Source: own study.

Each organisation should be characterised with an effective communication system and its internal atmosphere, since satisfied employees are able to deeply engage in the organisation's matters and, as a result, lead to full satisfaction of customers. Therefore, another studied issue influencing job satisfaction was the contentment with the communication at the company (fig. 6).

Communication in a company was assessed with regard to selected elements that shape it (table 5). Superiors' skills of communicating with subordinates have a significant impact on the in-house communication processes and effective implementation of changes thereto. As noticed by the respondents, the communication rules do not hinder the everyday work and employees do not have bigger problems with obtaining necessary information. Unfortunately, the company's mission and strategy are known to employees to a small extent. Also the issue of expressing their own opinions is problematic. Furthermore, employees do not have an impact on what is going on in a company.

Fig. 6: Satisfaction with communication in the company

Source: own study.

Table 5: Factors influencing the assessment of the satisfaction with the communication in a company

Specification	Yes	Rather yes	Rather no	No	No opinion
I know the mission of the company for which I work	0.5%	15.8%	47.8%	35.9%	0.0%
I know the basic strategy assumptions of the company for which I work	0.5%	16.7%	51.2%	28.2%	0.0%
I am informed of the economic and financial situation, development perspectives and chosen directions of changes at the company	6.2%	15.8%	13.4%	64.6%	0.0%
Rules and procedures binding at the company do not hinder everyday work	11.0%	53.1%	31.1%	4.8%	0.0%
I control the course of my work independently	9.1%	41.6%	26.3%	23.0%	0.0%
I admit making mistakes without fear	1.9%	15.3%	45.0%	37.8%	0.0%
I have access to the information necessary to perform my duties	1.0%	42.1%	6.7%	50.2%	0.0%
I know, where I can find information necessary to perform my duties	1.4%	43.1%	26.3%	29.2%	0.0%
All information reaches me on time	1.0%	42.6%	8.6%	43.1%	4.8%
I can freely express my opinion on what is going on at the company	0.5%	12.0%	31.6%	50.7%	5.3%
I am convinced that I have influence on what is going on at the company	0.5%	5.3%	21.5%	66.5%	6.2%

Source: own study.

The relations in a company have been similarly, positively assessed by employees (fig. 7). As many as 68.9% of the respondents assessed these relations that way.

Fig. 7: Satisfaction with relations prevailing in the company

Source: own study.

Relations in a company were assessed with regard to selected elements that shape them (table 6).

Table 6: Factors influencing the assessment of the satisfaction with the relations in a company

Specification	Yes	Rather yes	Rather no	No	No opinion
I like the management style of my superior	5.3%	57.9%	33.0%	3.8%	0.0%
I trust my superior	6.7%	47.8%	18.2%	27.3%	0.0%
I receive support from my superior in the scope of performed tasks	5.7%	42.6%	21.5%	30.1%	0.0%
My superior is open to new suggestions and ideas	8.1%	52.2%	20.6%	19.1%	0.0%
It is possible at the company to openly express own ideas and opinions	10.0%	46.9%	19.6%	23.4%	0.0%
I can always talk to my superior about my professional problems	9.6%	38.8%	26.8%	24.9%	0.0%
I am not afraid to talk to my superior about difficult matters	8.6%	36.8%	33.0%	21.5%	0.0%
The superior gives criticism without participation of third parties	16.3%	68.9%	9.1%	5.7%	0.0%

Source: own study.

Job satisfaction is influenced by the employees' feelings regarding the permanence and stability of employment. This feeling among respondents is very high, since as many as 90.9% indicated occurrence of this factor in their professional work (fig. 8).

Fig. 8: Workers' feeling of constancy and job stability

Source: own study.

Verification of the research hypothesis. In the further part of the analysis, employees' job satisfaction has been analysed in the context of the enterprise's competitive position according to the opinions of respondents. To this end, the sample has been divided into two groups: first group includes respondents, who assessed that the competitive position of their companies are good or very good, and the second group includes respondents assessing the competitive position as average, weak or very weak (fig. 9). The first group included 74 respondents, whereas, the second group - 135.

Fig. 9: Job satisfaction vs competitive position of the enterprise in the employees' opinion

Source: own study

The following assumptions have been made:

- H_0: structure of the level of job satisfaction in the sample and in both groups is the same (non-significantly different),
- H_1: structure of the level of job satisfaction in the sample and in both groups is not the same (is significantly different).

As a result of the conducted calculations t_e=3,82. Having verified that $t_\alpha < t_e$, at the level of significance of α = 0,05, the assumption H_0 (structure of the level of job satisfaction non-significantly different) is rejected, that is, structure of the level of job satisfaction is significantly different. Therefore, the structure of the level of job satisfaction has an impact on the group with the good competitive position and weak competitive position, and is significantly different. Studying the similarity of structures is difficult in the case of fragmentation of the feature and requires in such a case applying the structures' similarity indicator, which, in this case, amounted to 0.53, which proves the lack of similarity of studied structures. Moreover, the results of selected tests concerning the verification of the assumed research hypothesis on the grounds of methods based on testing parametric hypotheses, in particular, testing equality (difference) of means, have been presented in table 7. Thereon, it can be stated that the level of job satisfaction influences the competitive position of small and medium-sized enterprises.

Table 7: Test values (F_e, t_e) and critical values (F_α, t_α from tables) in tests of equality of means and tests of equality of variances

Specification	Value
Value F_e	1,146
Value F_α	1,642
Value t_e	4,498
Value t_α	1,972

Source: own study

Values of correlation coefficients have been presented in table no 8. These results prove the clear correlation between the competitive position and job satisfaction of the company's employees.

Table 8: Values of correlation coefficients

Specification	Value

Source: own study

While summing up the received results, it can be stated that the higher the level of job satisfaction, the better the company's competitive position.

Conclusion

Employees' satisfaction has an immense significance for the functioning of the whole organisation irrespectively of the size thereof. It translates both, into the results and development of the company, therefore, the issue of job satisfaction becomes the aim and, at the same time, the measure of organisational effectiveness. Satisfied employees are especially valuable due to the initiative taken by them, loyalty to the employer, favourable atmosphere at work created by them and significantly lower level of absence. The increase in the work effectiveness is one of the most desirable results of the

professional work, as it leads to increasing effectiveness of the whole organisation and thus, influences the achieved competitive position.

Employees of the studied SMEs feel satisfaction from performed work, but they assess factors influencing this satisfaction differently. One may notice positive assessment of the communication system, relations in companies and the sense of stability and permanence; whereas, it should also be noticed that, while the communication rules do not hinder everyday work and employees do not have bigger issues with obtaining necessary information, the company's mission and strategy is, unfortunately, known by employees only to a small extent. Also the issue of expressing their own opinions is problematic. Furthermore, employees do not have an impact on what is going on in a company. Also, relations in companies and the sense of stability and permanence of employment were positively assessed by employees. Simultaneously, the analysis of research results indicated negative assessments in the scope of binding motivation systems and remuneration systems of SMEs' employees.

The research results also allowed indicating a relation between employees' satisfaction and the competitive position of those companies; whereas, the higher the level of job satisfaction, the better the competitive position of the company. Professional satisfaction does, in fact, translate into engagement in work, employees' loyalty, trust in the organisation, customers' satisfaction of the organisation, as well as creativity and innovativeness, which, in turn, leads to better results of the whole organisation (Sipa, 2018; Sipa 2019).

To sum up, it is worth ensuring maintenance thereof at a high level, since high work results are identified with employee's satisfaction. The significance of satisfaction is also manifested in the fact that it influences attitudes towards work, profession and organisation, being an important component of employees' competence potential. Therefore, taking care of maintenance of the professional satisfaction of SMEs' employees at a high level may, in consequence, lead to strengthening the employer's role on the market and increasing the company's competitiveness.

Limitations

The basic limitations of the research include: dependence of conducting the research on the voluntary cooperation of respondents and limitation of the research to selected factors of job satisfaction. At the same time, searching for factors conditioning job satisfaction is hindered by, among others, personalised attitude of employees to entrusted duties and individual job satisfaction.

Perspectives

While considering in details the factors conditioning achievement of satisfaction, studies could focus on, among others: particular workplaces, characteristics of work, type and character of activity conducted by the employer, as well as respondents' age, gender, life situation etc. Therefore, further research could focus on better recognition of the process of shaping the employee's satisfaction and thus, on the attempts to specify the influence of the level of employee's satisfaction on their behaviours. The scope of such research could be interesting, yet, vast.

Abstract

This paper examines two discretionary activities utilized by managers to influence share prices. These discretionary activities are referred to as environmental disclosure and earnings management. In a sharp contrast to earlier studies, the study's goal is to ascertain the influence of environmental disclosure and earnings management on firm share prices. The study adopts agency and signalling theory in providing a theoretical background to explain the relationship. The ex-post facto design was employed, which involved 70 non-financial firms for a 7-year period from 2011-2017. The study utilised a panel regression analysis to analyse the data and found environmental disclosure was positively related to firm share prices while earnings management appeared to have an inverse relationship. The results have implication for the signalling theory as well various stakeholders who wish to understand the dynamics surrounding the firm's share price. The findings also suggest that investors in developing economies are well-informed about earnings management activities. The study recommends mandatory reporting of environmental information as well as improved standards to minimise earnings management and enhance earnings efficiency.

Keywords: Accounting; Disclosure; Environmental disclosure; Earnings management; Panel regression; share prices; Nigeria.

Introduction

Accounting research on the capital market has developed over time with the utilization of accounting fundamentals that can affect share price behaviour. It is well established that the share price reacts to information released especially earnings announcements, which result in a huge impact on the price of a company's stock. In this light, researchers, investors, the academia and other stakeholders have in recent times given increased attention to information relating to earnings and corporate disclosures. This appears logical considering non-financial disclosure is beginning to also generate stock market reactions. In addition, market participants have become increasingly sensitive to investors sentiments, financial, non-financial information and indeed any other type of information that can cause reactions in the market.

Corporate annual reports still remain a veritable tool for obtaining information on firm performance. Therefore, the corporation's reported earnings are retained to satisfy management's interest and ensure it attracts investment (Nuryaman, 2013). Managers are thus encouraged to exploit accounting rules to provide the investors with a good image of the business (Butt, Rehman, Khan, & Safwan, 2010). Managers, also influence the behaviour of their company's share prices by the use of earnings management tools. Earnings management (EM) is said to occur when management employ their discretion in preparing the annual report such that they are able to conceal the true economic situation of the firm in an attempt to profit from the purported numbers (Healy & Wahlen, 1999; Uwuigbe, Uwuigbe & Okorie, 2015). A well diverse board is recommended for better quality in financial reporting and timeliness. (Uwuigbe, Damilola, Uwuigbe, Teddy and Irene, 2018). The board attributes also have a role to play in reducing the activities of EM (Obignemi, Omolehinwa, Mukoro, Ben-Caleb & Olusanmi, 2016).

Environmental disclosure refers to information regarding environmental activities made available at the discretion of managers. In developing countries, there are usually little or no regulatory requirements. According to Caroll (1999), environmental disclosure refers to commitment to making contribution towards the environment. Organizations disclose environmental activities in other to improve their reputation. They promote their environmental friendly actions to attract the interest of stakeholders (Lyon & Maxwell, 2011).

Environmental disclosure (ED) and earnings management (EM) have been described as opportunistic behaviours or variables utilized by managers to influence performance (Chih *et al,* 2008; Orlitzky, 2013; Muttakin, Khan & Azim, 2015).

Several publications in the last few decades have attempted without success to arrive at a consensus on the stock market reactions and activities. These studies have utilized macroeconomic determinants, technical analysis, fundamental analysis or models (Ita & Joe, 2013; Muhammed & Luqman, 2013; Onakoya, 2013; Orlitzky, 2013; Cyprian, 2017; Osaze & Nosakhare, 2017). The decision by a significant number of investors (usually termed irrational investors) on which stocks to acquire is influenced by bias or perception (Ambrose & Vincent, 2015; Orlitzky, 2013). Hence, the traditional finance theories have failed to sufficiently explain the pattern of share price movement for these irrational investors. This suggests a limitation of earlier studies and the gap in explaining share price movement.

A plethora of earlier studies have examined environmental disclosure and share performance (Aggarwal, 2013; Bowerman &Sharma, 2016; Odetayo, Adeyemi, Sajuigbe, 2014; Uadiale & Fagbemi, 2012; Uwalomwa & Egbide, 2012). Some other studies have examined Earnings management and share price behaviour (Chan, Jegadeesh & Lakonishok, 2006; Cahan, Emmanuel & Sun, 2009). A noteworthy deficiency in the literature is that the collective influence of environmental disclosure and earnings management on share price activity is yet to be sufficiently evaluated by prior studies.

Furthermore, this study aims at discovering the implied effects of environmental disclosure and earnings management on share prices. The significance of this study stems from its ability to enable managers understand the impact of the opportunistic behaviours (environmental disclosure and earnings management) on share prices considering the opportunity cost between the concerned variables. The study extends the frontiers of knowledge on market efficiency by combining these variables to ascertain their role in influencing share price behaviours. The remaining part of the paper is organised in this manner. The review of literature and hypothesis development is discussed in Section 2. Section 3 presents a breakdown of the methodology adopted. Section 4 reports and analyses the findings emanating from the analysis. Finally, section 5 concludes and provides recommendations.

Literature Review and Hypotheses Development

Environmental Disclosure

Environmental disclosure is an umbrella term that described diverse ways by which firms report their environmental impacts to the stakeholders. Corporate environmental disclosure or reporting is an instrument for communicating a firm's performance in terms of environment activities. According to Crowther (2002) the primary purpose of environmental disclosure is to examine and incorporate in the company annual reports, issues that bother on environmental hazard that are not taken cognizance of in traditional accounting. This information is utilized by stakeholders in decision making. Disclosure of corporate environmental activities highlight the necessity for a close monitoring of natural resources and the corporation's harmful effect on the society it operate.

The United Nations (UN) published the Systems of Integrated Environmental and Economic Accounting (STEEM), in 1993, spelled out guidelines and procedures for environmental accounting. The STEEM came after several efforts by UN, World Bank and European Union (EU) and other international organizations to develop a uniform framework and methodological approach to environmental accounting. Zakimi and Hamid (2004) posit that environmental disclosure is used by firms to express to the public the cost implications of their activities, which has impacts on the society.

Hassel *et al.,* (2005) singled out two perspectives on the financial and environmental performance link. The first perspective is the cost-concerned perspective which purports that extreme environmental impacts demand high monetary costs and will thus result to a reduction in the reported earnings and overall market value. The second perspective referred to creating worth. This perspective opines that environmental (green) approaches embarked upon by firms translates to an edge for the organisation over its competitors, which increases the pecuniary worth of the firm. The work of Hassel *et al* (2005) examined the relationship between market value and overall environmental performance. The study using a sample of 71 companies listed on the Swedish stock exchange found that environmental efficiency and equity value are inversely related. Therefore, it was seen that firms rated high in terms of environmental activities are not well rated by stakeholders. This is because firms that perform well environmentally attract huge cost and have an inverse effect on the reported earnings and overall market value.

Gozali, How and Verhoeven (2002) also examined the benefits of environmental disclosure in improving corporate value. Data for the study involved a collection of financial reports of top 500 firms quoted in the Australian Stock Exchange. The list of disclosing firms was arrived at after exploring the available annual reports for the period of January 1998 to December 2000. The results indicate that firms that have positive information to show perform a lot better than those firms that have little or nothing to disclose.

Aggarwal (2013) carried out a review on the association between environmental performance and profitability. The study revealed that most of the prior research found a positive association. King and Lenox (2001) conducted an investigation on the link between environmental performance and profitability performance measures. The research made use of a sample of 652 manufacturing firms quoted in the US covering a time frame of 10 years from 1987 to 1996. The study found profitability to be related to pollution reduction. There was also evidence to show that companies operating in

alleged cleaner industrial sectors have higher values for Tobin's Q, even though the study failed to control for corporate attributes. The result revealed a positive association between going green and profitability.

Flammer (2015) examined CSR and stock prices of quoted firms in the United States from 1980 to 2009. The study found firms that had been seen and perceived to have executed their operation in an environmentally friendly manner had a boost in their stock prices. The study utilized event study methodology and regression-based approach to analyse stock data obtained via relevant press coverage of wall street journal.

Cormier and Magnan (2007) presented arguments showing the association between environmental performance and financial performance to be contingent on the structure of the regulatory environment the company has to deal with. The data collected comprised 237 observations made up of French, German and Canadian firms. The result of the investigation revealed that the reporting context experienced by the firms affected the nexus between their stock performance and corporate social environmental disclosure. Jacobs *et al*., (2010) set out to identify catch words generally used in announcing environmental efforts, rewards, moves and certifications displayed in various publications in US and within Europe. The study covered 780 announcements for 340 distinct organisations. It was discovered that there were no signals from the market with respect to announcements tied to aggregate Environmental Initiatives exercised by corporate entities as well as awards and certifications for environmental activities. A number of cases of reactions occurring for certain CEI and EAC subgroups. In specific terms, announcing the donation of gift items to aid the pursuit of environmental causes are positively related to the occurrence of market reaction, voluntarily reducing emissions are related to an inverse reaction from the market, on the other hand, ISO 14001 environmental certifications provides for positive reaction in the market. In summary, it can be said that the market selects in the manner it reacts to announcements of environmental concerns. This relationship can be regarded as mixed or not significant.

The work of Gonzalez-Benito and Gonzalez-Benito (2005) investigated a sample of 186 firms in the industrial sector selected from a pool of 50,000 largest firms as provided by 2002 Dun & Bradstreet census possessing over 100 employees in their payroll. The research showed no association between proactiveness on environmental concerns and performance of business. The study opined that environmental consciousness and environmental activities embarked on by management could put the firm at an advantage over its competitors although some of these activities could influence the performance of the business negatively. On a final note, there was no proof to back up the claim that environmental proactivity thus enhances profitability in the short term.

Bramer, Brooks and Pavelin (2006) examined the association between CSP and stock market returns in the UK. The study utilised a number of items that aggregate into indicators that capture efforts towards the environment, employee welfare and community supporting activities, the study findings reveal that firms performing better with regards to their social performance scores achieved a much lower return, while those firms having extremely low of zero were outstanding in the market. The work of Benlemlih *et al*, (2016) investigated environmental and social performance and financial risk using data gathered in the UK. The results reveal that firms that made higher environmental and social disclosures exhibited distinct competitive advantages. These advantages included better recognition in terms of their contributions to the environment and society in general. In addition, maintaining a genial relationship with stakeholders which has an inverse relationship to the company's idiosyncratic risk.

Hamilton (1995) shows a significant inverse abnormal earnings for firms having toxic release inventory (TRI) emissions at the time of initial disclosure. Konar and Cohen (1997) observed that the companies having large reaction to the TRI disclosed also experienced large reduction in emissions in the subsequent years. Konar and Cohen (2001) employed the same measurement of environmental performance as the previous study and found that, a below par environmental performance inversely affects the value of the firm's intangibles.

Therefore an insight into the literature shows that most existing literatures have shown stock price and environmental disclosure to be positively related though there have been instances of negative, mixed or inconclusive results. In line with these discussions, the study hypothesises thus:

H_1: environmental disclosure has a positive effect on share prices

Earnings Management

The effect of earnings management (EM) on share prices has been discussed at international gatherings in recent decades. A study by Gill, Biger, Mand, and Mathur (2013) on firms listed in the manufacturing sector the Bahrain Stock Exchange (BSE), highlighted the effect of increasing EM on the profitability of the firm in the subsequent period and the resultant decline in the price of the stock in future periods as a consequence. They argue that investors have greater urge for shares that exhibit positive in relation to shares that exhibit negative earnings surprises varies with time. However, the study had methodological limitations in that it only utilized a small sample size.

Tabassum, Kaleem and Nazir (2013) carried out a study on the Manufacturing sector in Pakistan. The research studied the impact of real earnings management on subsequent profitability of the firm. The result found out that real activities manipulation and future financial performance relationship is negative. Hence, firms with steady increased earnings do not necessarily translate to better compensation for stockholders. This work was centered on the manufacturing sector and failed to utilize the panel regression, which has both periodic and cross-sectional dimensions. In addition, account for explicit individual-specific heterogeneity Similarly, the study of Tang and Williams (2014) found an inverse association between earnings manipulation and share prices.

An avalanche of previous studies has revealed another methodological limitation in the statistical technique adopted for measuring EM. Some of these studies failed to adopt robust statistical techniques like the Panel Regression analysis which is multidimensional in nature with both time or periodic dimension and also cross-sectional dimension. In addition, some of the studies failed to take account of individual-specific heterogeneity, and eliminate collinearity. For instance, Nuryaman (2013) examined the effect of EM and the return of stock as well as the role of auditor quality serving as a moderator. The study utilized a multiple regression analysis based on 149 manufacturing based companies quoted on the Indonesia Exchange in 2010. He stated that it was observed that earnings management has an inverse relationship with stock returns. The reliance on accounting information by stakeholders in the valuation of stocks encourages managers to influence earnings upwards to boost the share price. Management therefore pays attention to the response by participants when EM is discovered.

The work of Oraby (2017) which involved a sample of 113 companies quoted in Saudi Arabia Exchange market cutting across five years from 2012 to 2016 employed a panel data structure and panel regression analyses which revealed that accounting accrual-based EM was not significant on share price. Furthermore, investors in the Saudi Arabia capital market are knowledgeable enough not to allow the impact of Management manipulating real activities in an attempt to enhance income affect the net income of the firm. However, it was observed that the investors were knowledgeable about this feat and reacted by shrinking the earnings value.

Hashim, Salleh and Arif (2013) on the reasons why director manage earnings noted that directors are interested in the benefits of the company. They try to meet market expectations and show interest in corporate reputation. Yang, Chi and Young (2012) documents that the practice of manipulating earnings in China is influenced by shareholders holding majority of shares. They found that

management feel obliged to attain projected earnings as the market does not reward companies that do not meet such target.

Some other studies either utilized multiple regression analysis or survey method to assess the association between the practice of manipulating earnings and stock market behaviour. However, these studies are not recent and were done in more advanced economies such as the United States. For instance, Chan *et al.,* (2006) examined the relationship between Earnings Quality and Stock Returns. The sample consisted of quoted firms listed in the New York Stock Exchange, American Stock Exchange (AMEX) and NASDAQ markets. However only domestic, primary stocks were considered (including observations at the tail end of April between 1971 and 1995). The authors carried out the study on both US and UK stocks using Regression analysis and observed that poor reported earnings are associated with future returns.

Similarly, Sloan (1996) investigated whether information on Stock prices is fully reflected in Accruals and Cash Flows on subsequent earnings. The study documents that the level of standardized accruals is inversely associated to abnormal returns in the subsequent year. Hence the market tends to overreact to earnings with large accrual component (whether positive or negative accrual). When the market learns that reported earnings of the previous year are not real or cannot be sustained, the overreaction is subsequently reversed. His conclusion that shares with high positive (income-increasing) accrual in a particular year exhibits lower returns in subsequent year.

According to Graham *et al*., (2004), achieving or even going beyond targets is crucial. Their study involved a survey of 401 executive officers regarding indicators that could possibly influence the extent of reported earnings and disclosures in the organisations they operate. The study noted that management presented a trade-off between the short-term target to "deliver earnings" and the future objectives of embarking on investment decisions that increase value. In addition, management are of the opinion that arriving at earnings target provides for a credible position in the market and thus leads to a positive share price and increases the management team's external credibility. Management are always striving to catch up with and even surpass earnings standards to gain stance in the capital market amidst their competitors; to have a steady or even surpass share price; and boost the reputation of its management team in the eyes of the outside world. The findings revealed that 78% of the management staff surveyed showed an intention of sacrificing its economic value to manage outsiders' perception. In other words, poor performing firms face the temptation of utilizing earnings manipulation to meet market expectations (Wokukwu, 2015).

Park and Jung (2017) examined the relationship between the ability of management and the risk of future crash in the stock price in Korea. The study noted that the influence of managers is usually powerful in Korea when comparisons are made with more advanced countries. This is because management and ownership are usually the same in Korean firms. A sample involving 3944 listed firms' observations for the period of 2002 – 2014 utilized a logistics regression analysis which revealed a negative relation between managerial ability to disclose and subsequent stock price crash risk.

Consequently, there has been heightened interest in the quality of firm's earnings. (Chan *et al.,* 2006; Darjezi, 2015; Machdar *et al.*, 2017). Chapman and Steinburgh (2010) examined earnings target and the various marketing expenses used to arrive at it. The study which utilized the OLS and Logistic regression model involved data collected between 1985 and 1988 which revealed that managers sacrifice the long run earnings for the forecasted earnings. In other words, they found an inverse association between manipulation of firm's expense and future performance.

In another research on Impact of EM on Stock Returns, which was carried out on publicly listed firms in Philippine covering a five - year period (2009 – 2013). Cruz and Luiz (2015) found out that EM does not significantly affect short-term stock returns. Wokukwu (2015), using the plethora of literature found out that firms manipulate the market price by inflating profits via EM. The work of Luiz and Cruz, 2015 also revealed that investors see through real earnings management practices. Based on this literature, it can be inferred that the link between the practice of EM and Stock Market Behaviour is strongly connected to the reputation of these firms in the capital market or shareholders' perception. Following from the discussions above, the following hypothesis is specified

H_1: earnings management has a negative effect on share prices

Theoretical Framework

The foundation and structure of this research is premised on the Agency and Signalling theory. Jensen and Mecking (1976) defined the type of relationship existing in an agency theory as a contract under which one party (the principal) hires another party (the agent) to perform a certain service on their behalf. As part of this, the principal will delegate certain decision-making powers to the agent. Nevertheless, issues with the firm occur because of the difficulty of contracting ideally for every possible action of an agent whose decisions affect both his own welfare and the welfare of the principal. The big question therefore is how to convince the agent to act in the best interests of the Principal. There is no gain saying that information unevenness exists between the two parties. Similarly, the primary focus of the signalling theory is to reduce unevenness between concerned parties. (Spence, 2002). Spence demonstrates this theoretical concept by utilizing the labour markets to explain the manner in which job seekers with higher educational qualifications embellish their resumes to distinguish them from less qualified job prospects. This pattern creates a signal to employers on the suitability of the candidates. Thus reducing the information unevenness that obstructs the selective ability of employers.

In line with Jensen and Meckling's Agency Theory (1976), the management's most common goal is to maximize shareholder capital that should be expressed in the firm's valuation. The stock price could be seen as one of the primary objective measures of how effective management is in achieving this goal. Particularly, in situations where managers of bonus plan is tied to the performance of the firm's market value, managers have very high incentives to more likely choose procedures in accounting that improve reported earnings in the current period (Watts & Zimmerman, 1990) and thus improving investors demand for the firm equity, which pushes up the stock price values. In addition, such managers are likely to employ accounting methods that increases the income of the current period when their bonuses is tied to it (Setyorini and Ishak, 2012). Capital market motivation for earnings management is to generate positive stocks price increases by manipulating disclosed accounting information to reflect investor's preferences (Healy & Wahlen, 1999). Thus managers have the opportunity to exploit reported earnings which are released to pose the firm as a "delight to investors" and hence heighten the demand for the firm's stock prices which then increases the firm market value

Also, Following the Signalling theory attributed to Spence (1973), several scholars have premised the relationship between environmental disclosure and share price using the theory. King *et al*., (2005) argues that the practice of ED transmits a signal that conveys a firm's unobservable characteristics to stakeholders and investors. In this regards, ED could pass as a sign that presents more information to stakeholders concerned, particularly in developing countries. The adoption of CSER activities satisfies two criteria for a good signal (Spence 1973). Firstly, it requires a huge financial burden to engage in CSER behaviours for poor performing organisations than for better performing organisations. Secondly, the reward margin for organisations engaging in CSER is only adequate to cater for the expenses of high-performing organisations.

A firm that carries out CSER practices sends signals to stakeholders concerned that the internal qualities that provides the firm the capacity to fill institutional voids and satisfy the general society (Miller et al. 2009; Rivoli & Waddock 2011). If the stakeholders consider these qualities to be important, then stakeholders concerned could increase investments in the organisation that have taken to CSER practices (Ramchander *et al.,* 2012). Prior research have shown that by carrying out CSER, firm signal to stakeholders and hence these entities demand positive responses from the investors in the capital market, which can improve the firm's stock price (Luo *et al*., 2014)

Methodology

The study employed the ex-post facto research design which involves the researcher predicting the possible causes behind an effect that has already occurred. The design is suitable considering this research intended in finding the effect of environmental disclosure, earnings management on share prices. The sample comprised 70 firms randomly selected out of a population of 112 companies quoted on the Nigeria Stock Exchange for the period 2011-2017. This period was chosen because of the improved disclosure in financial reporting as a result of the issuance of the code of corporate governance in Nigeria in 2011 and the adoption of International Financial Reporting Standards in 2012.

This study argues that the behaviour of share prices cannot be accurately predicted using the traditional finance theories, hence certain accounting information on opportunistic behaviours by managers are required to further explain the pattern of share price. The information is contained in environmental disclosure and earnings management. Analyses of panel regression are used to check the hypotheses of the sample given that the collected data has elements of both the cross-section and the time series. The utilization of panel data has several advantages over cross-sectional and time series data. In particular, panel data enables the estimation of consistent parameters while controlling for non-observable cross-sectional heterogeneity, thereby avoiding biased results (Ahn, Lee & Schmidt, 2013). The use of panel data also allows for more insightful data, addresses the problems of multicollinearity among variables, greater volatility, greater degree of freedom and, in general, greater efficiency (Baltagi, 2005; Rustam, Rashid, & Zaman, 2013).

In addition, this statistical technique more efficiently measures effects that are not detectable in pure cross-sectional or time series data (Baltagi, 2005). The data is sourced from the annual reports of the sampled companies. Secondary data sourced from the annual report of selected quoted companies are utilized. Secondary data from annual reports of the quoted companies is preferred because in addition to providing the researcher with already audited corporate information, it has been described as a reliable and consistent medium in communicating with shareholders (Belal, Abdelsalam & Nizamee, 2015). Specifically,data on share prices is collected from the Nigeria Stock Exchange fact book. Data on environmental disclosure is collected from the director's report, environmental reports and governance reports, while data on EM, firm size and profitability are acquired from the entities financials and NSE fact book.

Research Model

The empirical analysis involves estimating the relationship between environmental disclosure and earnings management on share prices. The study also included some variables (firm size and profitability) that have been found in the literature to be related to share price to serve as control in the model. The functional specification of the share price model is as seen below:

SP=*f* (ED, EM, FSIZE, PROF)……..1
The explicit form of the model is expressed in equation 2 as follows
$SP_{it}=\beta_0 + \beta_1 ED_{it} + \beta_2 EM_{it} + \beta_3 FSIZE_{it} + \beta_4 PROF_{it} + \mu_{it}$.....2

Where
SP= share price
ED= environmental disclosure
EM= earnings management
FSIZE = firm size
PROF= profitability
μ is Error term that represents other independent variables that affect the model but not captured.
t is year or period
i is firm
β is the intercept

Measurement of Variables

The dependent variable share price is measured using the market price per share (Omoike, *et al.,* 2018; Ohlson, 1995). The independent variable of environmental disclosure is measured using content analysis disclosure index approach. This approach is selected because it is a valuable research technique for gathering and analysing environmental data. It measures the reporting value from the size of disclosure reported on specific topics or categories (Beattie, Mcinnes & Fearney, 2004). The study utilizes an unweighted disclosure index which incorporates a nominal coding scheme in quantifying the reporting of environmental facts in corporate annual reports (Hanniffa & Cooke, 2002, the 2005). A checklist is adopted and followed to allow for replicable performance of content analysis. The research adapts the Haniffa and Cooke checklist (2005) to suit the Nigerian case. The environmental disclosure index contains 3 items (environmental information, sustainability information and health & safety information). Where a firm report on a particular environmental item, a score is given. A maximum score of 3 is given to a company that reports on all 3 environmental items and a minimum score of zero to a company that did not report on any environmental item.

Dechow, Richardson and Tuna (2003) suggest "that a very common model for estimating discretionary accruals (DISAC) is the modified Jones model (MJM). They assert that DISAC clearly displays manipulation of earnings. and that companies with high DISAC earnings get lower future earnings and less future return on stock. Hence DISAC are obtained as follows:

DISAC is ToACC – NDISAC
ToACC is NDISAC+ DISAC
Where ToACC is Total accruals
NDISAC is Non-Discretionary Accruals
DISAC is Discretionary accruals
$ToACCit = a (1/ASSETSit -1) + a_1 (\Delta REVit - \Delta RECit) + a_2 GPPEit + \mu it$
Where ToACCit is the sum of accruals in year t for firm i
Δ REVit is revenues in year t -1 for firm i deducted from revenues in year t
ΔRECit is receivables in year t less receivables in year t -1 for firm i
GPPEit is gross property, plant and equipment in year t for firm i
μit is error term (residuals) in year t for firm I"

The control variable of firm size is assessed using the natural log of total assets (Ugwuanyi & Ibe, 2012) while profitability is measured using the ratio of return to total assets.

Results

Descriptive Analyses

Table 1 presents the descriptive statistics for the dependent variable share prices (SP) alongside the independent variables of environmental disclosures (ED) and earnings management (EM) as well as the control variables of firm size (FSIZE) and profitability (PROF). From table 1 below, the mean for the share price is 37.79, with a standard deviation of 126.32. The standard deviation is a sign of volatility in the stock prices data. The price of the share ranges from a minimum of 0.5 to a maximum of 1555.99. The quality of environmental disclosure is based on the index as used by Haniffa and Cooke (2005) which has been modified to suit the Nigerian context. On the average, the degree of disclosure on environmental issues by the sampled companies is 0.43 (43%). The mean value for earnings management as captured using discretionary accruals is -0.07 with a standard deviation of 0.13 also suggesting stability of the data. The description of the control variables are also shown in table 1. The mean for firm size (FSIZE) as measured using the log of total assets is 7.12, with a standard deviation of 0.78. The assets amount range from the minimum of 5.4 to a maximum of 9.2. The mean total asset is comparable to Che-Ahmad and Osazuwa (2015) that reported a mean total assets of 7.65. The average value for profitability is 0.03, with a standard deviation of 0.11, ranging from the minimum of -0.53 to a maximum of 0.54.

Table 1: Descriptive Statistics of Variables

VARIABLE	**MIN**	**MAX**	**MEAN**	**STD. DEV**
SP	0.5	1555.99	37.85	126.32
ED	0	1	0.43	0.22
EM	-0.63	0.54	-0.07	0.13
FSIZE	5.4	9.22	7.12	0.78
PROF	-0.53	0.54	0.03	0.11

SP=Share prices; ED= Environmental disclosure; EM =Earnings management FSIZE=firm size; PROF=Profitability

Correlation Analysis

The correlation analysis from table 2 below shows clearly that there is no problem of multicollinearity as the relationship between the variables are quite low, below 0.5 while the relationship between a variable and itself is 1 as expected. The variance inflation factor (VIF) also confirms this position as it shows that multicollinearity is not present among the variables under study with a mean VIF of 1.18 which is less than the maximum acceptable value of 10

Table 2: Correlation Analyses

	SP	**ED**	**EM**	**FSIZE**	**PROF**
SP	1.00				
ED	0.37	1.00			
EM	-0.02	0.09	1.00		

FSIZE	0.33	0.30	0.00	1.00	
PROF	0.26	0.24	0.40	0.19	1.00

Notes: SP= share prices; ED= environmental disclosure; EM= earnings management; FSIZE= firm size; PROF=profitability

Panel Regression Analyses

Table 3 below shows the output of the share price model estimation. The Breusch and Pagan Lagragian multiplier test with Chi 2 values of 839.71 and probability values of 0.00 clearly indicates that there is presence of effects in the model thus jettisoning the pooled OLS model. This indicates that we have to go further and test between the fixed effects model and random effects model. The output of the Hausman test with p- values of 0.96 indicates preference for the random effect model as against the fixed effect model. The model is then tested for the occurrence of the problem of heteroskedasticity and auto correlation. The result of the modified Wald test for group wise heteroskedasticity with probability values ($P<0.01$) and serial correlation test with probability values ($P<0.00$) shows the presence of both problems in the model. The panel model is then rectified of autocorrelation and heteroskedsaticity problems using the robust standard error estimates based on the stata command "xtgls" (Hoechle, 2007).

The robust random effect model shows that environmental disclosure is significant and positively related to share prices ($\beta=156.01$, $p<.01$). The result provides support for the prediction in hypothesis 1which states that environmental disclosure has a positive effect on share prices. The result suggests that an increase in the environmental disclosure leads to higher share prices. It suggests that environmental performance disclosures are relevant to the investing public and financial analysts, considering the effect it has on the value of the firm. Furthermore, an improved social and environmental performance could result in enhanced stock returns by means of cost reductions and improved productivity, or by way of improving the firm's position that would encourage analysts in recommending the stock and also making it attractive for investors to keep despite the expenses and what the firm will benefit (Brammer *et al*., 2005). The result also agrees with studies by Gozali *et al* (2002) that showed that firms having positive information performed better in terms of performance. Also, the study agrees with Flammer (2015) that found that firms that were perceived to have carried out their operations in an environmentally friendly manner had a boost in their stock prices. The result differs from the finding of Hassel *et al* (2005) that found environmental performance and value of equity inversely related. The results also agree with the signalling theory that show that by disclosing environmental information, firm signal to stakeholders and hence these entities may demand positive feed back from the investors in the capital market, which can improve the firm's share price (Luo *et al*., 2014).

Furthermore, from the results of the robust random effect regression analysis, earnings management was found to be significant and inversely related with share prices ($\beta=-127.33$, $p<.01$). The result suggests that as firms manage their earnings the lower will be the share price. The result is in tandem with Gill *et al.* (2013) that posited the more pronounced the occurrence of earnings management, the more the side effects on the company's return on asset in the subsequent year and also the market participants react by lowering the share price in the future period as a consequence. Also the results agree with Tabassum *et al.* (2013) and Tang and Wilson (2014) that found an inverse relationship between earnings manipulation and share prices. Lastly, the results for the control variables firm size and profitability were also positively related in line with prior studies (Che, Ahmad & Osazuwa, 2015)

Table 3: Results of the Regression Analyses

VARIABLE	POOLED	RANDOM EFFECT	FIXED EFFECT
C	-284.97 (0.0000)	-284.97 (0.0000)	-403.70 (0.005)
ED	156.01 (0.000)	156.01 (0.0000)	-5.31 (-0.33)
EM	-127.33 (0.003)	-127.33 (0.003)	6.07 (0.78)
FSIZE	33.45 (0.0000)	33.45 (0.00)	62.08 (0.002)
PROF	249.50 (0.000)	249.50 (0.000)	62.44 (0.097)

Conclusions and Recommendations

The research investigated the effect of environmental disclosure and earnings management on share prices in quoted firms from the Nigeria Stock Exchange. The panel regression indicates that environmental disclosure has a positive effect on share prices. Also, earnings management was found to have an inverse effect on share prices. The positive effect of environmental disclosure on share prices has theoretical implications for the signaling theory that purports firms using disclosures of good news such as environmental information to send signals to the market of good performance which would have a ripple effect boosting their share price.

Consequently, the study provides an understanding as to the combined effect of environmental disclosure and earnings management on share prices thereby extending prior studies on this relationship from an emerging economy. These findings are of relevance to investors (potential and existing), management, board of directors, government, policy makers and shareholders who wish to understand the dynamics surrounding the firm's share price. Policymakers need to push for mandatory reporting of environmental information, as well as enhanced standards to minimize earnings management and improve the quality of preparing financial statements. Also, addressing the issue of earnings management there is need for development of accounting standards by standard setting bodies to provide for standards that are geared towards improving the quality of earnings for proper guidance of all stakeholders who rely on the reported earnings for their decisions as they participate in the market.

However, this study has some limitations. First, the sample is based on companies listed on the NSE and thus due to unavailability of data for unlisted companies, they could not be examined. Also, the study considers only companies listed in the non–financial sector of the NSE. Therefore, the results from this study should be interpreted with caution.

Resumen

En los municipios de Girardot, Ricaurte y Flandes presentan, por su cercanía, unas condiciones estratégicas de interacción, permitiendo la generación inercial de condiciones de conurbación, al ser prestadores y generadores de bienes y servicios mutuamente, como son los de capital, tierra y trabajo como fundamento económico; a través de la historia cada una de estas concentraciones demográficas, han sido representativas y de importancia, al encontrarse asentados en las riveras del río grande de La Magdalena. El estudio muestra, a través del análisis de la información recopilada, la necesidad que las empresas, aprovechando las oportunidades de inversión de multinacionales y corporaciones llamadas holding, evidencien las bondades de la infraestructura y la disponibilidad de mano de obra calificada y no calificada, permitiendo a la región ser generadora de una gran dinámica de creación de valor, así como el establecer o dimensionar políticas y acciones ecoeficientes para propender por un desarrollo sostenible y en lo posible sustentable, amigable con la sociedad, los recursos renovables y el pensamiento en la reutilización o usos alternativos de los residuos, que es uno de los detonantes de las sociedades modernas, al generar grandes volúmenes de bienes que no son aprovechados y se disponen sin ningún tipo de reflexión ni preocupación, en usos alternativos o de reindustrialización.

Palabras Clave: Factores de ecoeficiencia, desarrollo sostenible, conurbación

Abstract

Due to their proximity, the municipalities of Girardot, Ricaurte and Flanders present strategic interaction conditions, allowing the inertial generation of conurbation conditions, being mutually providers and generators of goods and services, such as capital, land and labor. as an economic foundation; Throughout history, each of these demographic concentrations have been representative and

of importance, as they are located on the banks of the large river of La Magdalena.

The study shows, through the analysis of the information collected, the need for companies, taking advantage of the investment opportunities of multinationals and corporations called holding companies, to demonstrate the benefits of infrastructure and the availability of skilled and unskilled labor, allowing the region to be the generator of a great dynamic of value creation, as well as establishing or dimensioning eco-efficient policies and actions to promote sustainable development and, if possible, sustainable, friendly to society, renewable resources and thinking about reuse or alternative uses of waste, which is one of the triggers of modern societies, by generating large volumes of goods that are not used and are disposed without any kind of reflection or concern, in alternative uses or reindustrialization.

Keywords: Eco-efficiency factors, sustainable development, conurbation.

Introducción

Los procesos demográficos en la concentración de ciudades revelan el crecimiento de los asentamientos urbanos y la necesidad imperante de alianzas sociales y económicas dentro de los territorios. Estas dinámicas conllevan a repensar en formas eficientes de organización para estas ciudades encontrando las áreas metropolitanas, donde se establecen relaciones de empleo, generación de ingresos, consecución de recursos, planificación y desarrollo territorial y financiamiento.

Estas relaciones y su realidad generan fenómenos urbanos conocidos como conurbación, donde ciudades similares y cercanas generan alianzas para incorporar infraestructuras que garanticen las condiciones ambientales, económicas que permitan la sostenibilidad y uso de los recursos sin presentar costos ambientales que determinen la deficiencia en el desarrollo y crecimiento económico y social para la región.

El desarrollo empresarial es una de las preocupaciones existentes en los modelos de gestión del estado, academia y el sector productivo, al tener como condicionante, factores y fuerzas del mercado, en un escenario dinámico y de fuertes cambios dados por las diferentes variables de influencia al determinar la relación costo – beneficio en busca de la productividad y la competitividad.

Dentro de este contexto, se desarrolla la propuesta de la creación de un centro de desarrollo empresarial, con capacidad para generar escenarios de diálogo de las partes interesadas para generar conocimiento y capaz de atender las necesidades existentes en la práctica del ejercicio profesional de los futuros profesionales, condicionados por el mercado laboral y las necesidades del sector productivo, teniendo como garante, las políticas y las normatividades en el componente ambiental, social, cultural y legal.

Girardot, Flandes y Ricaurte, como área conurbada, trae consigo situaciones problema no pensadas desde la planeación estratégica de los municipios en diferentes aspectos demográficos, sociales, económicos y de infraestructura, al presentarse la saturación de los espacios geográficos por el asentamiento, migración y visita de personas a esta área territorial y geográfica, como es los periodos de vacaciones, semana Santa, días feriados y hogar para personas de retiro de grandes metrópolis como Bogotá, Ibagué o Neiva y ciudades intermedias como Agua de Dios, Tocaima o Nilo, siendo el escenario para atraer inversionistas y garantizar la viabilidad económica de los proyectos de construcción como se ha venido presentando en estos municipios conurbados.

El centro demográfico está dado por situaciones como el alto crecimiento de construcción en los tres municipios, sin haberse dado los estudios y la planificación para la estructuración de unas condiciones

ajustadas a esa realidad en cuanto a infraestructura de movilidad para la zona, manejo de residuos sólidos, consecución de recursos, plantas de aguas residuales, manejo y disposición de escombros, gestión de impacto sobre el cambio de la vocación del uso de suelos, zonas dedicadas a la agricultura que pasan a ser utilizadas en la construcción de condominios, hoteles e infraestructura relevante para el sector turístico de la región y así atender la cantidad de habitantes de la zona y población flotante.

Fundamento Teórico

Antecedentes: Desarrollo Tecnológico, Innovación, Eficiencia Y Sostenibilidad

Colombia es un país eminentemente urbano. "Se calcula que alrededor de 32 millones de habitantes viven actualmente en zonas urbanas (representando el 72% de la población nacional), población que alcanzara los 40 millones en los próximos 10 años" (CONPES 3305. 2004)

El documento Visión Colombia 2019 brindó datos acerca de la importancia de estas, al establecer que "El futuro de los colombianos dependería, en buena medida, del futuro de las ciudades. Para 2019 cerca de 77% de la población colombiana viviría en los centros urbanos, y en ellos, en los próximos quince años, tendrían lugar importantes transformaciones a nivel económico, social y ambiental" (DPN 2005)

Es evidente la necesidad de la adopción de modelos de desarrollo que propendan por la sostenibilidad de las ciudades: iniciativas como la Agenda 21 Local son un ejemplo de ello (considerada el Plan de Acción Global para el Desarrollo Sostenible, consensuado y suscrito por 178 gobiernos en la Conferencia de las Naciones Unidas sobre el Medio Ambiente y Desarrollo, celebrada en Río de Janeiro, en el año 1992). Estas iniciativas persiguen como objetivo aplicar criterios de sostenibilidad en el ámbito local, propendiendo por una eficaz gestión municipal; concibiendo la sostenibilidad local como resultado del equilibrio entre la sostenibilidad ambiental, sostenibilidad económica y la sostenibilidad social.

A nivel nacional, la tendencia sigue a las disposiciones mundiales, ejemplo de ello es el Plan Nacional de Desarrollo "Pacto por Colombia, Pacto por la Equidad", que tiene un enfoque regional a través de nueve pactos regionales para atender de manera directa las necesidades particulares de cada región y cerrar las brechas sociales (Departamento Nacional De Planeación 2019).

El PND identifica las potencialidades de cada región así: Pacífico, potencia ambiental y logística; Caribe, transformación para la igualdad de oportunidades y equidad; Seaflower Region, región insular próspera, segura y sostenible; y, Central, para la innovación e integración productiva nacional e internacional. Incluye la región de Santanderes como eje logístico para sostenibilidad y competitividad; Amazonía viva con desarrollo ambiental sostenible; Eje Cafetero y Antioquia, conectando para la competitividad y el desarrollo; Llanos y Orinoquia, conectando y potencializando la despensa sostenible del país y, Océanos, Colombia como potencia bioceánica".

Estas nuevas realidades de la urbanización llevan a repensar la planificación de las urbes a mayor escala pensando en dinamizar la productividad, incrementar el crecimiento económico, mejorar los procesos ecoeficientes y así lograr la equidad en las aglomeraciones urbanas, teniendo en cuenta que la relación entre las grandes ciudades y los municipios cercanos a ellas son funcionales y superan sus límites político-administrativos. Sin embargo, el ordenamiento territorial no ha incorporado de forma efectiva la planeación y gestión a escala supramunicipal. (Departamento Nacional De Planeación 2019)

Área Metropolitana Y Conurbación

El término fue utilizado por primera vez en Estados Unidos a principios del siglo para referirse al territorio en el que aparece una ciudad de más de 200.000 habitantes que no incluye el área de influencia de ninguna otra gran ciudad.

Y aunque actualmente este término cuenta con cierta ambigüedad y amplitud en su uso, según la CEPAL "… surgió cuando el termino ciudad dejo de ser equivalente a urbano y fue necesario encontrar otro que diera cuenta de las áreas urbanizadas en torno de la ciudad central".

Este proceso urbano, característico de finales del siglo XX, es entendido como "…la intensificación de las relaciones físicas, económicas y sociales, entre entidades territoriales vecinas, como resultado del crecimiento de una ciudad, generalmente capital nacional o regional, que actúa como núcleo del fenómeno" (MONTAÑEZ 1998).

Dichas ciudades están en la capacidad de conformar Áreas Metropolitanas que se definen como "…entidades administrativas formadas por un conjunto de dos o más municipios integrados alrededor de un municipio núcleo o metrópoli, vinculados entre sí por estrechas relaciones de orden físico, económico y social, que para la programación y coordinación de su desarrollo y para la racional prestación de sus servicios públicos requiere una administración coordinada" (Ley 128 de 1994, ley Orgánica de las áreas Metropolitanas)

Esta descripción teórica se ajusta perfectamente a la dinámica socio económica que vive la ciudad de Girardot y sus municipios vecinos. La subregión del Alto Magdalena (Cundinamarca) y el Yuma y Sumapaz (Tolima), a la que pertenece la conurbación, se extiende 2409 km2, del que ésta comprende el 14% con una densidad de 469 habitantes / km2. En los 354 km2 de la conurbación habitan 165.981 habitantes. El acceso a la subregión es diverso. Desde Bogotá hay tres vías directas. 1: Fusagasugá – Melgar. 2: La Mesa – Anapoima – Tocaima y 3: El Colegio – Viotá – Tocaima. En la actualidad se encuentra en operación el eje vial Girardot – Cambao – Puerta Bogotá – Puerto Salgar como parte de la estrategia de desconcentración del crecimiento de Bogotá y como alternativa para la comunicación y salida de productos a la costa caribe. [Plan de competitividad de Girardot 2007 - 2019].

La influencia regional de la ciudad y el papel que cumple al ser foco de desarrollo económico y social, y que presentan una continuidad física, permite la extensión en actividades agrupadas por clúster como turismo, académico, infraestructura, entre otros, que alientan la competencia y la cooperación, extendiéndose a otros municipios aledaños y que transforman de manera importante dinamizando la economía, el desarrollo social, empresarial, ambiental de la conurbación.

Los procesos que viven las ciudades colombianas han aportado conocimiento a las problemáticas que presentan y el análisis de ellas. El alcance real y a profundidad de los fenómenos urbanos y su impacto en la problemática ambiental de una ciudad es indispensable para presentar soluciones efectivas y de largo plazo. Este entendimiento permitirá dar alcance a los objetivos propuestos y ver a las ciudades conurbadas como una entidad agrupada que mira hacía la misma dirección para crecer y desarrollarse de manera sostenible. La CEPAL 2001, realiza la siguiente afirmación: "Cuando la aglomeración sobrepasa los límites administrativos de la ciudad se generan suburbios autónomos y conurbaciones institucional y administrativamente fragmentadas. Esta fragmentación tiene repercusiones institucionales, políticas y económicas…"

Contexto metropolitano Del Desarrollo Económico Y Empresarial

Factores De Ecoeficiencia

La ecoeficiencia se entiende a partir del concepto de desarrollo sustentable, entendido como "el desarrollo que satisface las necesidades actuales, sin comprometer la capacidad de que generaciones futuras puedan satisfacer sus propias necesidades". La dinámica económica, social, ambiental, requiere el entendimiento del desarrollo sustentable bajo premisas que cumplan con los objetivos empresariales de desarrollo sustentable, generando el concepto de ecoeficiencia se obtiene como "el suministro de bienes y servicios a precios competitivos, que satisfagan las necesidades humanas y proporcionen calidad de vida, mientras progresivamente reducen los impactos ecológicos y el consumo de recursos a lo largo de su ciclo de vida, por lo menos hasta un nivel acorde con la capacidad de carga estimada de la Tierra" (LEHNI 2000).

Dentro de los factores de ecoeficiencia puede encontrarse la eficiencia económica relacionada con la disminución de costos y el incremento de ingresos, permitiendo la maximización de beneficios y el aprovechamiento de ventajas competitivas. La eficiencia ecológica hace referencia a los procesos de impacto medio ambiental que desarrollan las organizaciones y se incluyen el consumo de recursos naturales, consumo de energía, generación de residuos, generación de vertidos, generación de emisiones atmosféricas y las tasas de reutilización.

Los factores que influyen en la eficiencia funcional están directamente relacionados con la eficiencia y eficacia de los procesos que influyen en el producto a lo largo del ciclo de vida. Puede entenderse como la calidad que se imprime para el desarrollo de las actividades propias del negocio.

Inicialmente Ricaurte, demostrado al ser el municipio más antiguo, concentrando su relevancia en la producción agrícola, contando con una extensión territorial amplia y riqueza de suelos, siendo productora de Quina, tabaco, maíz, en las últimas décadas, algodón y sorgo. En la actualidad retoma su importancia en el crecimiento del contexto en la construcción al ofertar proyectos urbanísticos ajustados a las necesidades de vivienda para turistas con deseos de tener una propiedad tipo apartamento para los tiempos de descanso y veraneo como son fines de semana.

Flandes por su ubicación estratégica de acceso al sur y occidente de Colombia, para acceder a las rutas de Neiva, Caquetá y Putumayo, y la otra ruta importante, Ibagué, Armenia, Cali, Costa Pacífica y Tumaco, como también vía a Ipiales y Ecuador y malla vial de toda el área Andina.

Girardot, por su infraestructura de Comercio, financieros e infraestructura en Educación Básica y superior e instituciones prestadoras de servicios de Salud y turismo, demostrando ser la de mayor concentración demográfica y mayor dinamismo, por su relevancia en la mitad del siglo pasado, al contar con la ruta fluvial y férrea para proveer de bienes importados como también la exportación de productos agrícolas y manufacturas del país.

Metodología

El desarrollo de la investigación está fundamentado en la información suministrada por las instituciones gubernamentales y no gubernamentales, las personas inmersas en el fenómeno de estudio y la población ubicada en las ciudades de Girardot, Flandes y Ricaurte; donde se asume el riesgo de presentar posibles negativas de algunos de estos entes en suministrar información generando posibles márgenes de error o sesgos en el análisis y procesamiento de esta. Se optó por un enfoque de tipo

descriptivo, el estado actual de las variables ambientales y de ecoeficiencia que hacen parte de los municipios que pertenecen a la conurbación, procediendo a definir en términos claros y específicos las características del problema. Las observaciones se realizaron de manera técnica usando la estadística utilizando como instrumento el desarrollo de encuesta para la recolección de datos.

La metodología aplicada es de tipo cuantitativo, dentro de este componente se incluyeron la caracterización e identificación de problemáticas medioambientales de las zonas identificadas. El método analítico fue aplicado al presente estudio al buscar identificar las variables y dimensiones de las condiciones de ecoeficiencia que influencian la conurbación de Girardot, Flandes y Ricaurte; y presentar la sistematización, permitiendo servir de soporte para la formulación de la política y planes de desarrollo territorial requeridas. Para el desarrollo del presente análisis se obtuvo información de la población asentada en los municipios de estudio del Área conurbada según el DANE a 2018

El proyecto surgió dentro de la iniciativa por la creación del área metropolitana en el 2015 y los intereses de las diferentes comunidades como la académica en estudiar la dimensión, a través de los diferentes estudios realizados como el proyecto denominado “Fenómeno de conurbación y su impacto ambiental, área Metropolitana de Girardot, Cundinamarca” por los autores María del Pilar Pájaro M y Cesar Augusto Ramos R y la investigación “Identificación de las Variables socioeconómicas como aporte para la estructuración de la conurbación en Girardot, Ricaurte y Flandes” autores Marlén Deyanira Melo Zamora y Cesar Augusto Ramos R, haciendo énfasis en la identificación de los diferentes problemas e impactos ambientales y la incidencia en el desarrollo social y la proyección económica de la región.

En el presente estudio se retoman estas dimensiones y se recopilan las directrices e indicadores de ecoeficiencia establecidas por las comunidades y entes como la Organización para la cooperación y el Desarrollo Económico (OCDE), El Consejo Empresarial Mundial para el Desarrollo Sostenible (CEMDS), El Banco Interamericano de Desarrollo (BID), el Fondo Multilateral de Inversiones (FOMIN).

Resultados

Se desarrolló un instrumento aplicado a empresarios y comunidad académico-científica, propendiendo por el conocimiento de los diferentes factores que inciden en la ecoeficiencia de las empresas existentes en la conurbación de Girardot, Ricaurte y Flandes, arrojando los resultados que se relacionan a continuación:

Connotaciones sociales, económicas y ambientales de la conurbación:

El 62% de la población manifiesta no tener conocimiento de políticas o programas en las empresas de la región para uso eficiente de servicios públicos como el agua y la energía, por ejemplo el uso de baños con sistemas que permiten el ahorro de agua, reductores y limitadores de caudal, aprovechamiento de aguas grises, campañas de información y formación para promover el ahorro de energía, aprovechamiento de la luz natural en los puestos de trabajo, utilizar luminarias y artefactos con la máxima eficiencia energética.

Al analizar el diseño e implementación de estrategias de conservación y uso de los recursos naturales renovables, el 84% de la población encuestada considera que en el municipio es necesaria la formulación, diseño e implementación de planes de seguimiento y control al estado de recursos naturales renovables, formulando indicadores de desarrollo sostenible en los municipios, incluyendo éstos en los planes de desarrollo propuestos desde el gobierno local.

El 76% de los encuestados cree relevante la incorporación de planes, directrices, condicionamientos y

criterios ambientales en los planes y programas de vivienda y construcción, mejoramiento de barrios, renovación urbana, mejoramiento de infraestructura vial entre otros, presentada en los municipios pertenecientes a la conurbación, de manera que implementen y atiendan a la protección y el uso sostenible del espacio público.

La población objeto de estudio en un 76% considera que es conveniente unificar el sistema de manejo de residuos sólidos con un solo operador y así especializar la actividad, aplicando buenas prácticas para lograr disminuir la cantidad de residuos generados en su disposición final.

Para el 83% de la población encuestada reviste importancia sustancial el implementar programas, incentivos y estrategias para el aprovechamiento de residuos y su disposición final, así como la disminución de residuos de alto impacto y gran volumen como son los plásticos, empaques, vidrio, papel, entre otros.

Connotaciones políticas y empresariales del área conurbada:

Al consultar la percepción de si las empresas de Girardot y la región emplean mano de obra calificada para el desarrollo de las diferentes actividades productivas, el 48% relacionan que no lo hacen, al tener como referentes el incremento en los costos y gastos financieros que de ello derivara, así como la consecución y facilidad de mano de obra no calificada.

Las organizaciones empresariales consideran fundamental el tener como pensamiento dentro de las reglas del mercado para la competitividad, la dimensión ambiental e ir ajustándose a las condiciones del escenario en un mundo globalizado, siendo el 85% el nivel de percepción frente a esta dimensión estratégica para ser referente en los planes de desarrollo y políticas gubernamentales a nivel local, regional y nacional.

La utilización de tecnología de punta para el 71% de la población encuestada, es considerado como relevante, en especial en los bienes de capital, informática y bases de información comercial, son necesarios de ser fundamento en la filosofía de inversión en las empresas, al tener desigualdad para competir y estar en el ambiente de los cambios tecnológicos condicionados.

Gestionar la sostenibilidad ambiental en los procesos productivos desarrollados en las áreas urbanas de los municipios conurbados, es una variable de importancia a tener en cuenta para la sostenibilidad ambiental para el 61% de las personas, quienes aducen que las políticas por parte del gobierno local, deben estar claramente determinadas en los planes de ordenamiento territorial con programas y acciones que permitan el control en temas como la contaminación generada por las empresas en el desarrollo de su actividad.

Para el 72% de los encuestados, aspectos como la deficiencia en la adopción de prácticas de producción y consumo sostenible por parte de las empresas en los municipios de Girardot, Ricaurte y Flandes, afectan el desarrollo sustentable y la aplicación de la ecoeficiencia para la región, generando problemáticas directamente relacionadas con el sector productivo.

Conclusiones y Discusión

Es necesario formalizar la conurbación de Girardot, Flandes y Ricaurte, con el fin de establecer mecanismos de planificación y de orden territorial del área que atienda las necesidades futuras de esta población y su comportamiento de crecimiento y desarrollo, sin generar lesiones y daños a los ecosistemas y enrutados a los indicadores de ecoeficiencia establecidos, según las comunidades internacionales y la necesidad inherente de la gestión para evitar el agotamiento de los recursos y atendiendo la filosofía de la sostenibilidad ambiental y económica.

El crecimiento de la población y los residuos, está acortando el tiempo de vida útil del centro de disposición de residuos sólidos o relleno sanitario, requiriendo el incorporar prácticas de reciclaje y cultura hacia la sostenibilidad y sustentabilidad, que disminuyan la generación de diferentes tipos de residuos y repensar en crear modelos de aprovechamiento de los diferentes materiales usados como materias primas de muchos productos que en la actualidad se disponen como basura, a pesar de conocerse o tener desarrolladas tecnologías blandas para el aprovechamiento de diferentes tipos de materiales que son consideradas residuos en una cadena productiva pero que podrían aprovecharse en otra cadena productiva.

El uso del suelo debe ser asignado de conformidad con las actividades que se pueden desarrollar, debiendo ser clasificados como principales, complementarios, conexos y restringidos. Toda aquella actividad que no se encuentre acorde a esta clasificación deben ser denominadas actividades prohibidas, usos inadecuados o prohibidos

Generar las condiciones necesarias para que las empresas localizadas en el territorio de conurbación incrementen la productividad disponiendo de las ventajas específicas del territorio, dando la oportunidad en términos de creación y capacitación del capital humano acorde a las necesidades de la dinámica empresarial y económica existente, garantizando los factores de producción y dinamizando los entornos físicos y paisajísticos, acorde a la existencia de instituciones y propendiendo por la calidad de vida.

El aprovechamiento de las mesas de competitividad como escenarios para la disertación y orientación de las diferentes acciones y procedimientos para la generación de unas condiciones y escenarios de urbanismo ajustado a las condiciones de infraestructura de movilidad para la explotación de las vocaciones económicas y productivas de la región, propendiendo por la protección, conservación y recuperación de los bienes de valor patrimonial, basados en la creación y atracción de capital humano y empresarial acordes a las tendencias de innovación empresarial y la clasificación de las diferentes actividades de carácter social, ambiental y económica para un crecimiento inteligente en la generación de empleo, la promoción y fortalecimiento del turismo, con el propósito de la generación de valor agregado y la estabilización de la infraestructura para garantizar la vida urbana y rural en iguales condiciones de calidad.

Garantizar la capacidad de articular responsable y eficiente la ocupación y el proceso de crecimiento del área de conurbación, monitoreando y estableciendo la curva de crecimiento de la huella ecológica, permitiendo fortalecer y restaurar los ecosistemas y permitir el aprovechamiento de los recursos naturales en armonía con el desarrollo urbanístico, en busca de la resiliencia a través de las acciones fundamentadas en la gestión del riesgo y todos estos factores considerados como factores medioambientales de incidencia directa, en esencia las generadas por el cambio climático. La esencia es priorizar la calidad de vida actuales y por las siguientes generaciones la sostenibilidad ambiental bajo los lineamientos de establecer y modelar la ocupación del territorio diseñando condiciones de bajo consumo energético, estableciendo condiciones y compromisos en la gestión ambiental de las instituciones, las empresas y la comunidad como una cultura de sustentabilidad.

Abstract

There have been divergent views on the necessity for regulating financial reporting and with many cases of financial shenanigans in the recent years; the pressure from the public for more stringent rules and regulation became more prominent. Hence, the new legislative initiatives and other reforms came from the demands by the society. In Nigeria, FRCN Act 2011 replaced NASB Act 2003 to address corporate governance weaknesses, particularly in financial reporting and provide opportunity for the adoption of FIRS. Despite the various regulatory initiatives, the managers still play smart in managing earnings to the detriment of other stakeholders. The study investigated the influence of regulatory agencies on creative accounting practices in the pre and post FRCN Act 2011 in Nigeria. The paper covered the six-year period (2005-2011) before FRCN Act and six-year period (2012-2017) after FRCN Act. For the purpose of the study, we employed descriptive and survey research design. Data was collected from the primary source, using structured questionnaire. The study distributed questionnaires to 405 respondents and 241 copies were returned. The pair samples t-test was utilized to test the hypothesis. The results of the study showed that the effectiveness of the regulatory agencies in curtailing creative accounting practices was better in post-FRCN Act than in pre-FRCN Act. The FRCN Act 2011 facilitated the adoption of IFRS, the effect of the adoption is what is reflected in the outcome. The study, therefore, concludes that the enactment of FRCN Act 2011 has significantly improved the effectiveness of regulatory agencies in curtailing creative accounting practices in Nigeria. The study recommends that the regulatory agencies must do more in making sure that companies comply with the relevant legislations and standards, and the FRCN should be proactive in its approach to issues relating to weaknesses in the financial reporting in Nigeria. It is also imperative to consider the review of Companies and Allied Matters Act 2004 with aim of eliminating areas of conflict with IFRS.

Keywords: Creative Accounting Practices, Earnings, Regulation, Regulatory Agencies

Introduction

The corporate failures of recent years in the big companies like, Skye Bank, Cadbury, Intercontinental Bank (Nigeria), Dynegy (USA), Carrillion (UK), Nortel (Canada), Banco Espinto Santo (Portugal), Schlecker (Germany), Kingfisher (India) and Dick Smith (Australia) have given the subject of creative accounting a place of prominence than it used to be in accounting research. This is, first, because of its impact on the quality of accounting information and second, because most of the financial scandals are traceable to unethical accounting practices and bad corporate governance resulting from non-compliance and non-enforcement of relevant standards and rules due to weak institutional and regulatory framework (World Bank, 2004; Adegbite 2012). Corporate failures do not only undermine the value of the firm, but also the interest of other stakeholders. When they occur, the stability of the stock market is affected and by extension, they reduce foreign direct investments (FDIs). Current events reveal that the prevailing accounting practices create opportunity for social injustices through the existence of ill-informed capital market. The trust that arises from the properly informed capital market continues to be impaired by the manipulated accounting information (Clarke, Dean, Oliver & Oliver, 2003). Creative accounting refers to the accounting practice that follows the letter of rules of standard accounting practices, but certainly deviate from the spirit of those rules (Assif, Junaid, Yu & Md, 2016). It arises from the abuse of flexibility, which exists in the accounting regulations. While it may not be against any law, it is immoral because it often misleads the investors and other users of accounting information on the true economic performance of the firm.

Many reforms have taken place at both governmental and professional levels to address the weaknesses in financial reporting. High quality financial reports will facilitate international financial architecture, key in improving transparency, secure investors' confidence, mobilize investments and ensure the stability of the capital market (UNCTAD ISAR, 2012). However, high quality financial reports cannot be secured in an environment where earnings management exists and information is asymmetric and unreliable. The entrenchment of legal, regulatory and institutional frameworks are important to addressing imperfection in the market and fostering economic stability. Therefore, formulating and executing national financial reporting strategy is essential in preventing the companies from using distinct accounting rules or methods in preparing financial statements that lack uniformity and comparability. While regulation and regulatory agencies have been found to be good external mechanisms that complement corporate governance mechanisms, they have not been able to perfectly reduce unethical practices among the preparers of the accounts. Thus, frequent releases of accounting standards and rules and their mandatory compliance have not addressed the problem of accounting irregularities. Attempts at curbing the corporate failures in the form of more stringent legislations and regulation do not appear to have had the desired impact (KPMG, 2016). Iyoha, (2011) observed that the main concern of the various stakeholders is whether the rules and standards by the regulatory agencies create more transparency in reporting or whether they create a situation whereby the managers look for loopholes and the regulators have the task of frequently revising the rules and standards. Regulation can prevents certain type of behaviours and at the same time facilitates some activities. For instance, where there are stringent sanctions against unscrupulous behaviours, the culprits could device cleverer means of circumventing the rules or use cosmetic approach for compliance (Jamal, 2009).

The primary objective of the study is to empirically assess the influence of regulatory agencies on creative accounting practices in pre and post FRCN Act 2011 in Nigeria. The essence is to test the impact of FRCN Act, 2011 in assisting the regulatory agencies in reducing creative accounting practices and thus, improving the quality of financial reporting in Nigeria. The studies on regulatory agencies and creative accounting practices in Nigeria, particularly the impact of FRCN Act 2011 in Nigeria have been relatively few.

The rest of the paper is structured as follows: Section 2 discusses literature review and theoretical framework. Section 3 focusses on research methods. Section 4 presents data analysis and results, while Section 5 concludes the paper with recommendations.

Literature Review

Concept of Creative Accounting

Creative accounting is a pervasive phenomenon and it has become controversial following the collapse of many large companies around the world. There are arguments for and against it. For instance, Scott (2003) stated that it is good when it coveys appropriate information to the market and makes share price reflect future prospects of the company. Good creative accounting occurs when changes in the economic, social, and political environments are reflected in the financial statements to show a better fair view. This enhances the value and usefulness of accounting information. In the process, shareholders benefit from the price/earnings that are augmented through the reduction of uncertainty that often occurs and improved projection of future earnings (Beidleman, 1973; Lipe, 1990). On the other hand, it becomes bad and injurious when unethical practices are used in window dressing the accounts to deceive the providers of capital (Viadu &Matis, 2010). In this case, the preparers of the accounts are the beneficiaries, while the interest of the other stakeholders are jeopardized. Most of the financial scandals of recent years are traceable to the unethical behaviours of the directors who are the preparers of the accounts (Adedipe, 2004; Bakre, 2007).

Creative accounting describes a situation where the preparers of the accounts use their accounting skills to manipulate earnings without the breach of accounting standards and relevant legislations. Jameson (1998) affirmed that creative accounting practices do not usually contravene any rule or standards. In fact, such practices comply with the letter of the law, but fails to conform to the spirit of the law. For example, a review of the economic growth recorded by companies in the United Kingdom in the 1980s showed that the major proportion of the growth was manipulated, using creative accounting, indicating that the report did not reflect real economic growth (Smith, 1992). The current accounting practice that allows for the use of discretion in the choice of methods for measurement and criteria for recognizing costs and revenues encourages managers to engage in earnings management with the obvious consequence of increasing information risk for the users of accounting information.

In this study, creative accounting is examined from the negative perspective because most of the corporate failures have been attributed to the bad behaviours of the preparers of the accounts who use accounting numbers to mislead the users of accounting information.

Accounting and Regulation

The financial reporting provides useful accounting information to an extensive number of users in making complete, timely and reliable economic decisions (IASB, 2010). Most often, this information is asymmetric and unreliable. This phenomenon makes the regulation of accounting practice inevitable. However, the regulatory framework goes beyond the information to the directors who are the preparers of accounts. As such, the era of self-regulation by the accounting profession has been taken over by government regulation with the oversight supervision being given to the regulatory agencies (Iyoha, Ojeka & Ajayi, 2014; Gaffikin, 2005). Accounting also relies on subjective judgements and choices in the treatment of transactions. Accounting regulations in the form of rules, standards and legislations are introduced to enhance uniformity and comparability in the construction of financial statements. Baldwin and Cave (1999) expressed that rules are formulated to prevent ‘‘unexpected gains, profit skimming and free rider effect’’. Besides, most of the interventions by government and other relevant agencies were prompted by corporate failures (Banner, 1997; Reinhart & Rogoff, 2008). In his study, Lev (1998) defined the term ‘‘financial reporting regulation’’ to include all regulatory instruments such as laws, rules and standards. They have been instituted to increase the usefulness of accounting information to the users. Regulating financial reporting goes beyond prescribing disclosure requirements. It involves providing mechanisms for compliance with the disclosure requirements. In most countries, there are two ways of regulating accounting. First, by local legislations and second, by the accounting standards both local and international. This is what is obtainable in Nigeria before the adoption of IFRSs in 2012. The accounting profession was self-regulated for most part of 20th century. At the initial stage, accounting professional bodies did not favour the imposition of external regulation on the accounting practice. Consequently, they attempted to develop first, GAAPs and second, a conceptual framework which serves as basis for the formulation of accounting theory. There was

confidence in the operation of the market and the use of regulation was an exception to correct the slight imperfection in the market. On the other hand, some believe that rules, principles and standards should be used to develop accounting theory, while accounting practice only needs 'minor corrections' to work efficiently.

The divergent opinions on the essence and modality of regulation have always been contentious and with many cases of financial scandals around the world, the pressure for more stringent rules and regulation became more prominent. It is the concern by the public that paved way for new regulations. For example, in 2002, the USA introduced Sarbanes - Oxley Act following Enron's financial debacle and other corporate failures. In Nigeria, FRCN Act 2011 replaced NASB 2003 to address corporate governance weaknesses in the system and provide opportunity for the adoption of FIRS. However, it appears some of the prevailing practices of accounting require a critical look by a more critical eye than the regulators appear to have given them. The government plays an essential role in regulating the practice of accounting and this is more visible in an emerging economy like Nigeria, which does not have a matured political culture. The way government responds to the effectiveness of any profession will normally be determined by the type of government, societal demands and developmental needs, social interactions and the amount intellectual capital the profession possesses (Uche, 2000:472). It is therefore not out of place for the government to provide the necessary support to any profession with the intent of bringing it under the control of a state through the enactment of appropriate laws and regulations (Wallace, 1992:34). Thus, direct intervention by government in view of the financial malfeasances of the recent years becomes inevitable. Nevertheless, what is the extent of government intervention that will not jeopardize the efficiency of the market? This has become a controversial subject in literature.

Financial Reporting and Setting of Standards in Nigeria

Accounting rules and reporting are developed to limit choices in the treatment of transactions in the accounts. The choice, scope and responsibility for regulation varies between countries. The responsibility to set accounting rules is often delegated by government to an agency through the enactment of law to give the agency legal authority to operate. In order words, the government has the sole responsibility for setting standards as part its role for regulating the market. This is what is practised in Nigeria. For example, the defunct NASB was an agency charged with the responsibility for setting accounting standards. At the initial stage the ICAN midwife and accommodated NASB for ten years after which it became a parastatal of the Federal Government in May 1992. NASB received a full legal backing for all its activities through the enactment of NASB Act No. 22 of 2003. The Act empowers the Board to establish an Inspectorate Unit that monitors and enforces compliance with accounting Standards. In addition to the Act that establishes NASB, Section 335(1) of CAMA 2004 gives recognition to accounting standards issued by NASB. As such, all financial statements prepared by the companies must be in agreement with the standards. Between 1982 and 2011, NASB issued thirty accounting standards and this greatly improved financial reporting framework in Nigeria. However, to address the weaknesses in the NASB Act 2003 and pave way for the adoption of IFRS, Financial Reporting Council of Nigeria (FRCN) was established under the FRCN Act No.6 of 2011. The Act replaced the NASB Act 2003. The FRCN Act creates a quasi-governmental agency with main aim of ensuring that financial reports are timely, relevant, and reliable, and conform to the International standards. The Act also amalgamates the existing heterogeneous regulatory agencies hitherto in control of financial reporting and corporate governance.

Regulatory Agencies in Nigeria

The under listed regulatory agencies have been found most suitable and relevant for the study. Hence, regulatory agencies in Nigeria are not limited to those discussed in this section.

Securities and Exchange Commission (SEC)

The apex regulatory institution in Nigeria responsible for the capital market is Securities and Exchange Commission. This regulatory agency was established through the enactment of SEC Act 1979 (replaced by SEC Act of 1998), while the Investment and Securities Act 1999 (replaced by ISA

Act 2007) facilitated its activities (World Bank, 2011). The Commission specifies and regulates corporate reporting in the public companies in Nigeria. In addition, Section 63 of ISA 2007 empowers the auditor of a public company to review the internal system and report on the strength (World Bank, 2011). The ISA 2007 also gives SEC the right to regulate investments and securities business, and ensure the prompt filing of periodic and annual accounts.

Professional Accounting Organizations (PAO)

There are two professional accounting organizations in Nigeria. The Institute of Chartered Accountants of Nigeria (ICAN) and the Association of National Accountants of Nigeria (ANAN). The ICAN Act No. 15 1965 established ICAN, while ANAN received its legal status from the ANAN Act No. 76 1993. The establishment of ANAN broke the monopoly of ICAN. Although the two organizations were established at different times and by different Acts, they have similar charter. Their responsibilities include the regulating the accounting profession, educating and training of members, reviewing and issuing of auditing standards and discipline members for unprofessional conduct.

Financial Reporting Council of Nigeria (FRCN)

The FRCN came into existence by the enactment of FRCN Act No. 6 of 2011 after NASB Act No. 22 of 2003 was repealed. The establishment of FRCN among other reasons was to overcome the weaknesses inherent in NASB Act, harmonize the regulatory capacity, foster the adoption of IFRS and promote cross border listings. According to the FRCN Act, the council shall develop and publish corporate governance codes, accounting standards, enforce compliance with accounting standards and corporate governance codes, and promote compliance with the IFRSs issued by IFAC and IASB and for other related matters.

Corporate Affairs Commission (CAC)

The regulatory agency received its legal status through the CAMA 1990. CAC took over the responsibilities of the department of Companies Registry of the Federal Ministry of Industry, Trade and Investment. The Commission supervises the formation, registration, incorporation and winding up of companies. It is also responsible for the timely filing of returns, including annual reports and accounts. Where it is necessary, the commission may also conduct and investigate the affairs of any company.

Central Bank of Nigeria (CBN)

The BOFIA 2004 empowers the CBN to regulate the banking and non-banking financial activities in Nigeria. To complement the financial reporting requirements of CAMA 2004, the CBN Act 2007 requires the apex bank to ensure prompt submission of audited and periodic accounts, and to examine periodically the books and affairs of the banks. The banks cannot publish their accounts in the national newspapers, except the governor of the CBN has given approval. Where it is necessary, the governor can commission an investigation of the books and affairs of the banks. The auditors of banks are also to report cases of irregularities and non-conformity with the appropriate legislations and accounting standards to the Central Bank.

National Insurance Commission (NAICOM)

The Commission came into being in 1997 by the enactment of National Insurance Commission Act 1997. The NAICOM by the Act plays a supervisory role in regulating and controlling insurance business in Nigeria. The insurance regulator ensures timely submission of financial returns and audited financial statements, reviews them for compliance with minimum paid-up capital, liquidity and long-term solvency requirements. The commission also imposes sanctions, where there are deviations.

Review of Previous Studies

The previous works on the influence of regulatory agencies on creative accounting practices are relatively few. Nevertheless, the studies on related works have been reviewed and the empirical findings are presented below:

Okoro and Okoye (2016) studied the impact of IFRS on creative accounting in Nigeria. They used questionnaires to collect data from 120 respondents made up of investors, stockbrokers and auditors. From the Pearson correlation analysis, the study discovered that IFRSs could be used to curtail creative accounting practices. They also observed that negative creative accounting occurs because of the incompatible interest between the shareholders and the managers. However, Jamal (2009) observed that regulation could have both positive and negative consequences. Where there are strict penalties against unethical behaviours, the culprits can device cleverer means of escape and by so doing engage in more serious fraudulent practices. This proposition does not contradict the fact that many of the extreme financial debacles in the world (Enron, Worldcom and others) took place in a highly regulated environment like, the United States of America. Adetoso and Ajiga (2017) investigated effects of IFRS adoption on creative accounting practices in the banking sector in Nigeria. They used questionnaire to collect data from the 10 sampled commercial banks. They tested the hypotheses using multiple regression model and their results showed that the implementation of IFRS significantly constrains creative accounting practices in the commercial banks. Taiwo and Adegoke (2014) in their work concluded that the adoption of IFRS showed a positive impact on the quality of financial statements and inverse relationship with earnings management. Leventis, Dimitropoulous and Anandarajan (2011) reviewed European Union listed banks from 1997-2008 and observed that managing earnings through the provision for doubtful loans is reduced after the adoption of IFRS in 2005.

Chen, Li, Liang and Wang (2011) in their work concluded that government regulations (high political costs) have significant influence on earnings quality among companies in China. This is because Chinese companies engage in earnings management practices to reduce high political costs in the economic transitional period. Okoye and Alao (2008) in their work examined the ethics of creative accounting and the challenges of regulatory agencies in Nigeria. They used a survey research design and administered structured questionnaire to a sample of 80 firms. They tested the relationship between creative accounting reporting and corporate fraud using Pearson's correlation and the relationship between creative accounting reporting and regulatory control using bivariate correlation. Their findings showed that the manipulation of transactions and accounting policy choice abuses have significant effect on financial reporting. The outcome of their work also revealed that an effective regulation of accounting tends to limit earnings management. Guenther (1994) provided an empirical evidence of a decrease in the level of creative accounting practices among some large firms in the USA following a tax reduction policy by government. Almasarwah (2015) investigated the relationship between corporate governance and earnings management in Jordan. His work showed that government regulations greatly reduce earnings management among the firms, while increase in tax rates encourages manipulation of figures. The results also revealed that ownership structure exhibits greater influence in constraining earnings management than board characteristics or audit process. He also observed that Peasnell, Pope and Young margin model (2000) was stronger than accrual models in explaining earning management.

Iyoha, et al. (2014) examined state agencies and the practice of accounting practice in Nigeria. They used multiple regression analysis and concluded that state agencies have positive and significant relationship on the quality of accounting practice in Nigeria. They added that regulations alone could not guarantee high quality of accounting practice. Odia and Ogiedu (2013) studied the effect of corporate governance and regulatory agency on creative accounting practices in Nigeria. They employed survey research method and questionnaire to collect data. The data was analysed using linear regression. The outcome of their work indicated that NASB has a negative and insignificant relationship with creative accounting practices, while corporate governance has a stronger relationship. Naranjo, Saavedra and Verdi (2013) considered the impact of financial regulatory reforms on financing decisions, following the adoption of IFRS in financial reporting. They observed that modifications in the financial reporting template increases the firms' ability to access fresh funds due to improvement in transparency and, reduction in agency cost and information asymmetry. Madawaki (2014) studied

regulatory framework, environment factors and accounting practices in Nigeria. Using literature review strategy, he observed that regulatory and institutional framework have direct influence on accounting and reporting practices, while political factors indirectly affect accounting reporting practices, particularly during civil rule.

Hypothesis of the Study

The primary purpose of the study is to investigate the influence of regulatory agencies on creative accounting practices in the pre and post FRCN Act 2011 in Nigeria.

$\boldsymbol{H_0}$**:** The regulatory agencies have no significant improvement in their effectiveness in reducing creative accounting practices since the enactment of the FRCN Act, 2011.

Theoretical Framework

Public Interest Theory

The study adopts public interest theory because it assumes that regulation became necessary because of complaints from the public in respect of the inefficiency and inequality in the market, especially the problem of information asymmetry and the need to correct them. It has become foundation of the contemporary public economics and compass for the socialist politics. Shleifer (2005) attributed the growth recorded in the public ownership regulation in the 20th century to the theory. The key factor here is that, regulation is set to achieve public interest. This proposition is a normative view, which the positive accounting theorists will always object to because they believe that the aims of regulation are very difficult to determine. Consequently, the basis for objectively identifying the public interest is often not feasible. Other flaws against public interest include, issues relating to objectivity and competence of the regulators. This approach also underestimates the economic and political power that may influence regulation.

The theory is found suitable for this study because it holds the view that regulation becomes necessary when there is a market failure and the public interest is undermined. Thus, regulation is set to defend the interest of the public, who are the stakeholders.

Research Methods

The study employed descriptive and survey research design in fulfilling the purpose of the study. The study consists of three (3) sets of population and they are the preparers of the accounts, users of the accounts and the regulators. The study used a multi-sampling technique in selecting the sampled size of companies and preparers of accounts. The investments analysts represents the users because they are the primary users of accounting information (Clement & Tse, 2003; Mangena, 2004). The sample size of the investment analysts is determined by applying Kothari (2004) to the list of Capital Market Operators and the study purposively selected seven regulatory agencies based on their relevance to the financial reporting and corporate governance. Data was collected from the primary source, using structured questionnaire. The study distributed questionnaires to 70 preparers of accounts, 300 users of accounts and 35 regulatory agencies, making 405 respondents. The copies of questionnaire returned by the preparers were 56 (80%), users were 158 (53%) and regulators were 27 (77%), translating into 241 respondents (60%). A 5-point Likert type scale was used to measure the variables in the questionnaire. Reliability and validity tests were carried out to avoid measurement challenges and preserve the integrity of the data.

For the hypothesis, the study used multiple cross section. This is because the sample used was more than one sample of respondents and in this study, three sets of respondents (preparers of accounts, users of accounts and the regulators). In carrying out the hypothesis test, two tests were conducted. These tests are Levene's test and t-test. Levene's is a test of homogeneity of variance, while t-test is a test of significance.

Data Analysis and Discussion of Results

Analysis of Data

In carrying out the hypothesis test, two tests were conducted. They are test of homogeneity of variance and test of significance, using Levene's test and t-test respectively. Tables 1 and 2 presents the results of the two tests:

Table 1: Levene's Test of Equality			
Levene Statistic	df1	df2	Sig.
f 5.333	1	480	0.021

Source: Field Survey (2018)

The result from table 1 indicates that the f value is 5.333 with a significant value of 0.210, which is above 0.05. Hence, the variation in the variances is not significant. By implication, there is no deviation from the assumption of homogeneity of variance. Therefore, we conclude that the ANOVA test can be carried out on the data set.

Table 2: Paired Samples Test on FRCN ACT 2011

	Mean	N	Std. Deviation	Std. Error Mean	t –value	Sig
Before the legislation of FRCN Act, 2011 (under NASB Act, 2003)	3.53	241	0.803	0.052	-6.544	0.000
After the legislation of FRCN Act, 2011	3.90	241	0.876	0.056		

Source: Field Survey (2018)

The hypothesis is tested based on the paired samples test of significance and the results are shown below:

Decision

Hypothesis

$\boldsymbol{H_0}$**:** The regulatory agencies have no significant improvement in their effectiveness in reducing creative accounting practices since the enactment of the FRCN Act, 2011.

The post FRCN Act 2011 period has a mean of 3.90, which is higher than pre-FRCN Act 2011 period with a mean of 3.53. Since the t-value is -6.544 and p is 0.0000, the difference is significant at 1%. The null hypothesis, which states that the enactment of the FRCN Act, 2011 has not significantly improved the effectiveness of the regulatory agencies in reducing creative accounting practices is rejected. In other words, the regulatory agencies have significant improvement in their role of curtailing creative accounting practices since the enactment of the FRCN Act, 2011.

Discussion of Findings

The Hypothesis examined the impact regulatory agencies on creative accounting practices, since the enactment of FRCN Act 2011. From the findings, the null hypothesis is rejected. Thus, implying that the introduction of FRCN Act 2011 has significantly improved the effectiveness of regulatory agencies in reducing creative accounting practices in Nigeria. This does not come as a surprise because the FRCN Act 2011 was enacted to overcome the weaknesses in the NASB Act 2003, entrench National Code of Corporate Governance and pave way for the adoption of IFRS. The voluntary self-regulation by the professional accounting organisations ceased with the enactment of FRCN Act 2011 and marked

the commencement of formal, mandatory oversight by the quasi-government agency, which should have positive significant effect on quality of accounting information.

Conclusion and Recommendations

Conclusion

Following the results of the study, the impact of the regulatory agencies in reducing creative accounting practices was better in post-FRCN Act than in pre-FRCN Act. The FRCN Act 2011 facilitated the adoption of IFRS, the effect is what is reflected in the findings. The study, therefore, concludes that the enactment of FRCN Act 2011 has significantly improved the effectiveness of regulatory agencies in reducing creative accounting practices.

Recommendations

Sequel to the conclusion of the study, we recommend as follows:

1. Although the effectiveness of the regulatory agencies is better in post-FRCN Act period that in pre-FRCN period, creative accounting practices are still prevalent among firms in Nigeria. Therefore, the study recommends that the regulatory agencies should exert more energy in ensuring that companies comply with the relevant legislations and standards.
2. In view of the dynamics in the business environment, the FRCN should be proactive in its approach to issues relating to weaknesses in the financial reporting system in Nigeria, particularly to checkmate the activities of those who take advantage of the lapses in the existing laws and standards to cause infractions.
3. The Companies and Allied Matters Act (CAMA) 2004 should be reviewed with the aim of amending the areas of conflict with International Financial Reporting Standards (IFRSs) and accommodating major reforms on financial reporting and corporate governance.

Abstract

The paper presents an overview of trends in research and development in the field of laser scanning. The analysis of existing algorithms and methods for visualizing and storing the results of laser scanning and photography data is carried out. The features of methods for storing and visualizing the results of laser scanning and photography are revealed. A complex of high-performance algorithms for processing, storing and visualizing the laser scanning point cloud has been developed. Field and camera work was performed to obtain laser scanning data and take photos of cultural and historical heritage sites and road infrastructure. The features of data acquisition and further data processing of air, mobile and ground laser scanning are revealed. The system architecture and functional scheme were developed, and the software package was designed. On the basis of the developed set of algorithms, separate software modules of the software package were developed and their integration was performed. An experimental sample of the software package for cloud storage and visualization of laser scanning point cloud for natural and technical systems has been developed. Testing and refinement of an experimental sample of the software package for cloud storage and visualization of the laser scanning point cloud for natural and technical systems were performed.

Keywords: Laser scanning, Point cloud, Visualization, Software package.

Introduction

Currently, the field of application of digital technologies and creation of digital duplicates of products and processes is actively developing. The result of this development is the emergence of devices that allow one to collect spatial information about terrain objects, structures at a new level of quality. This information can be used to solve design, engineering, geodetic, surveying, and other tasks.

One of the most promising methods of collecting spatial information is currently laser scanning (hereinafter – LS). The main advantages of LS devices are high accuracy and the ability to automate the data collection process. Based on information about the scanner location and pulse direction coordinates of the point that reflected the pulse can be determined. The result of this process is a three-dimensional point cloud that describes the measurement object with high accuracy.

A significant drawback of LS, which certainly limits its use, is the non-converging gap between the rapid development of LS technology and the ability to process results (point cloud processing). Currently, there are almost no universal tools for processing point clouds. Thus, the task of increasing the efficiency of LS point cloud processing systems for building geometric models of natural and technical systems is urgent. In such systems new structural and algorithmic solutions in the field of LS data storage and visualization, hybrid processing of LS data and photography are used.

Problem Statement

The development of an experimental sample of the software package for cloud storage and visualization of LS point clouds for natural and technical systems was carried out in two stages.

At the first stage, algorithms for storing and visualizing LS and photography data were developed. The analysis of existing algorithms for visualization and storage of LS and photography data is carried out. Algorithms for storing and visualizing LS data have been developed, as well as a set of algorithms for processing, storing and visualizing LS and photography data.

At the second stage, an experimental sample of the software package for cloud storage and visualization of the LS point cloud for natural and technical systems was developed. For this purpose the architecture and user scenarios of the software package of the cloud service for storing and visualizing the LS point cloud were designed. In addition, a functional diagram of an experimental sample of a cloud service for storing and visualizing a cloud of LS points has been elaborated. Software modules and an experimental sample of the software package were developed, tested and refined.

Research Questions

The analysis of existing modern world-class developments affecting the scientific and technical problem studied in the following areas was carried out:

- visualization of LS and photography data
- storage of LS and photography data.

The analysis of trends in research and development in the field of LS was made in quite a large number of Russian and foreign scientific works. For example, Gorohova (2016), Gospodinov et al (2016), Klepko et al (2016), Guan et al (2016), Kukko et al (2012), Rudenko et al (2016), Sarychev (2014), Shevchenko (2016), Shevchenko et al (2016), Mukupa et al (2017), Lienhart (2017), Wang et al (2017), etc.

Currently, three-dimensional (3D) LS technology attracts a lot of attention due to its simplicity and speed. For example, it is discussed in the works of Yang et al (2017) and Dore et al (2014). This technology is used in a wide range of applications: road management, urban modeling, industry research, preservation of architectural monuments, monitoring not only the condition but also the construction process, etc. Some of the examples are given in the scientific works of Aljumaily (2015), Chen et al (2015), Kamnev (2017) and Soilán et al (2018).

3.1 Analytical Review of the Literature on the Topic of Research and Development

Ground-based LS is the most common and relatively cheap technology in which shooting is performed from ground objects or from the ground in discrete mode.

Mobile LS is one of the most technologically advanced and productive methods of surveying the area. To make measurements, a mobile LS consisting of several laser sensors and several cameras is used, which are installed on a car or any other vehicle.

Among the advantages of aerial LS, compared with other methods, we highlight the ability to perform mapping of hard-to-reach areas where the use of other methods of point shooting will be

time-consuming and expensive. Aerial LS is characterized by high accuracy of planned and high-altitude measurements that do not depend on the human factor.

The standard methods used for geoprocessing data and image analysis, as well as high requirements for computing resources, do not allow the full use of LS capabilities. Currently LS and processing of results are often associated with the developer/manufacturer of laser scanning equipment and software for processing results, and there are almost no universal tools for communicating and processing LS results from different sources.

In order to use scanning in various areas, it is necessary to develop data processing techniques that allow obtaining spatial information in on-line mode. This allows us to conclude that today there is an urgent and significant problem of bringing the speed and accuracy of LS technological operations in line with the requirements of storing, processing and presenting the results of point shooting. This problem can be solved by improving the theoretical and methodological foundations of LS technology.

The analysis of existing algorithms for visualization of LS and photography data was carried out. One of the dynamically developing areas of practical application of data visualization and pshotography is to provide full information about the building and the actual conditions (see, for example, Gao et al (2015)).
The combined visualization of LS data and photography allows to reach a compromise between obtaining a more complete set of geometric information by combining all the point clouds of interest and reducing the file size, combining only a subset of point clouds that can provide all the necessary geometric information for the components of interest.

Currently, fully automatic generation of a high-quality three-dimensional model is still difficult due to interference in both laser data and photos, as well as due to the strong change of lighting from image to image, especially when cars and trees are located in the area with the building, the fully automatic method can not provide a satisfactory result. Structuring the original 3D point data is an essential component of the visualization system, since selecting visible points and accessing specific details requires efficient spatial queries on the surrounding area.

Thus, while photogrammetry focuses better on small details, LS gives a more complete overview of the geometry of the entire scene.

One of the most interesting developments of the knowledge-based modeling tool is the ability to create the shape of an object, an organized structure of the corresponding dimension, as it is described by Pătrăucea et al (2015).

Generating accurate built-in parametric models of objects obtained from PM point clouds is a complex task that is of paramount importance for existing building projects. This problem was discussed, for example, in the work of Son et al (2015).

In order to ensure efficient operation of the created digital layout, the discussed approach provides for the organization of the model in parts and the identification of their mutual relations, in order to ensure compliance between the hierarchical description of the object model and its geometric representation. The structuring tool developed in this way is based on simple grouping operations using a graphical interface that allows you to visualize labels and connections between model elements. The method is described by Jung et al (2017).

Analysis of Existing Approaches and Problem Statement

The analysis of existing algorithms and methods for storing LS and photography data was carried out. Space partitioning algorithms can be used to implement technologies for efficient storage of large amounts of data and taking photos. Algorithms for splitting LS results that work with individual

points require significant computational resources. Another approach to building a spatial index for storing geometric primitives is the R-tree approach.

There are three main problems with existing approaches:

- very low performance due to the fact that the operation was completely manual
- low geometric accuracy of 3D model production due to reduced data applied to the source data
- the huge size of imported data often leads to system failure.

A semi-automatic procedure is offered that guarantees better performance, higher accuracy, and data reduction without loss of performance and accuracy.
The semi-automatic modeling system is designed to provide the operator with a reduced number of points required for manual modeling, without losing accurate geometric information.
Storing large-scale volume models requires a lot of memory, which implies the use of compression methods (see Reference 'Types of Cloud Computing' (2018)).

The analysis of approaches to the processing of photographic data is carried out. The considered features and functionality of special point detection methods do not allow making a reasonable choice of a method for forming a single image at different times of the day, so the main task of the experimental study is to obtain data for performing a comparative analysis of methods for detecting special points in images at different lighting levels.

To manage the results of LS and photography, a study was conducted to find ways to solve the problems of managing the storage system depending on the architecture of information systems of companies based on advanced methods and technologies for data visualization.

All elements of cloud-based applications are deployed and run entirely in the cloud. Applications are either created directly in the cloud or migrated from an existing infrastructure so that you can continue to take advantage of cloud computing. Cloud applications can be built on low-level infrastructure components, or they can use higher-level services that allow you to avoid thinking about the management, architecture, and scaling requirements of the underlying infrastructure.

For a more flexible organization of the structure of the computing center, which expands the capabilities of users, the integration of data storage systems into a local network is used. This organizational structure has high performance and scalability and can be expanded vertically (by adding additional disks and expansion shelves to a single disk storage), or horizontally with the addition of new storage to the network infrastructure).

The appeal of cloud storage is due to some of the attributes that define other cloud services: pay-as-you-go, flexibility, and ease of use and management.

The largest number of technical solutions in the field of research relate to the processing of scan data, and are aimed at optimizing the process by reducing processing time, reducing cost, and increasing efficiency.

The leading countries that develop new technical solutions are China (47%), the Russian Federation (17%), and the United States (6%). It should be noted that only computer programs were included in the search in the Russian database. If they are excluded, the second position in patenting in the field of research will be taken by the United States.
During the analysis of the relevant documents found, development trends in the field of research are identified. The largest number of technical solutions relate to the processing of data scanning, and are aimed at optimizing the process by reducing processing time, reducing cost, and improving efficiency. It is also revealed that the patenting dynamics reflect the growth trend during the study period. The largest number of patent documents for a priority application are filed in China.

It is recommended to use the results of patent research when planning further developments in the field of LS, as well as commercializing the results of the work.

Research Methods

In the field of visualization using three-dimensional LS data, many approaches have been proposed in the computer vision and computer graphics communities over the past two decades.

A widely accepted method for determining the surface model based on three-dimensional data is the marching cubes algorithm for scanning data. There is also an algorithm for reconstructing a three-dimensional surface from a set of unorganized points scattered on or near the surface, regardless of whether there is a boundary. The approach was based on the idea of defining a zero set of the estimated distance signal function (a set of levels).

In 2003 an automated method for reconstructing a textured three-dimensional model of the urban environment using a vehicle-based system equipped with a GPS navigation system was proposed, it was described by Zhao et al (2003).

An open graphics library (OpenGL) is used for visualization LS data. OpenGL is a software application interface (API) that has access to graphics hardware.

However, the above mentioned algorithms are not sufficient for processing the point cloud. There is a need for a set of algorithms and a system that implements it, allowing executing these algorithms on various computing devices, managing memory, loading and caching data, calling visualization subsystems and managing the point cloud.

The main features of such a system are as follows:

- Loading / saving the point cloud into common data formats
- Spatial partitioning of an unorganized point cloud that allows you to quickly search for neighbors and select points located in a specific region
- Point cloud data buffering that allows data to be mapped to a file, RAM, and video memory
- Support for various point representation formats in the cloud
- Creating and executing a processing algorithm in the form of a filter applied to a point cloud or a section of it
- Combining filters into a chain that is a point cloud processing pipeline
- Create filters that run on both the CPU and GPU, without affecting any other filters in the processing pipeline
- Control of the filter execution, its memory consumption, and stopping and restarting the filter.

Support for the above features allows to present a wide range of algorithms in the form of filters, and use it as a standard component of a LS data processing system. Standardizing the filter format will allow to add third-party algorithms.

One of the most well-known approaches for recognizing and representing surfaces and volumes is to process data based on a three-dimensional rectangular grid as a set of zero-level functions. In this approach, a three-dimensional grid can be rebuilt into a two-dimensional (2D) grid, where data is compressed and saved as a gradient.

Another option is the method of restoring surfaces from a given sampling point based on Delaunay Tetrahedralization and Voronoi diagrams, which has been used for a long time. This method was described by Xie et al (2017).

Currently, many automated grid generation methods cannot accurately place objects with complex typologies or curved shapes. To overcome this, Várady et al (2017) developed a shape reconstruction

algorithm consisting of the following elements of hierarchical complex segmentation, object skeleton construction, calculation area boundaries, surface structure creation, and surface fit.

LS collects three-dimensional geometric points of object surfaces, called point clouds. While point clouds are often used solely for visualization or simple measurement of distance or angles, their potential value is much greater, as can be seen from their use for road infrastructure mapping, emergency management, and building reconstruction.

In addition to these approaches, there are commercial programs specifically designed to transform the point cloud of LS. The examples of such software are described by Patil et al (2017).

Thus, when shooting buildings and structures LS is useful for working with objects of complex geometry or when you need to get measurements of many points visible from a single station.

Selection of the visualization algorithm is an important task for transmitting all essential characteristics closest to the real object.

Development of algorithms for storing and visualizing laser scanning data

Description of the Developed Algorithms for Storing Laser Scanning Data

In the course of the work, a comparative analysis of the main point cloud storage formats was performed:

- ASCII point cloud (xyz), a common point cloud file format where data is spatially represented with using three-dimensional coordinates
- LASer (LAS), the most common point cloud storage format that is supported by most point cloud-oriented software
- Compressed LAS is a variant of the LAS format obtained by lossless compression of the original LAS file
- Point Cloud Data (PSD), a data storage format used in the PCL library, which can be either text or binary.

Based on the prevalence, file size, and supported number of attributes, the LAS format was chosen for use in this work.

Development of a Memory Management Algorithm for Storing a Cloud of Laser Scanning Points

When scanning industrial objects, the point cloud is too large and cannot be placed entirely in RAM. At the same time, loading smaller cloud points can lead to excessive use of RAM if it is not controlled. In addition, the processing uses video memory, which is necessary for visualization and parallel processing, the size of which is even smaller than the operational memory. Moreover, a number of application tasks may meet requirements for maximum RAM/VRAM consumption, which also need to be taken into account.

If the processing algorithms used do not require random access to the data of the point cloud, the problem is solved by the introduction of streaming – sequential reading of points from the file and processing in small parts. But the situation is complicated if we cannot predict which points from the cloud we will need to perform calculations (i.e. random access to memory is required), and the cloud itself is not placed in RAM.

A solution to this problem was proposed by introducing a dedicated memory Manager in conjunction with the point cloud data caching system. The memory Manager is a simple system that contains a

pool of buffers in RAM/VRAM memory, and allows you to get or release a piece of memory on request. Moreover, the memory used by the Manager is strictly limited from the top.

The caching system (see Fig. 1) is designed to synchronize point cloud data between a file, RAM, and video memory (see Fig. 2). If the volume of the processed point cloud is too large, it makes sense to cache the intermediate calculation results in a file.

Fig. 1: Proposed structure of the caching system

The developed caching system splits the point cloud into pages (Point Chunk) of a fixed size, and allows you to display such a page on a file, RAM, or video memory. In fact, such a page must be in at least one type of memory at one time (usually in a file). If necessary, the page can be loaded from the file to RAM, and from RAM to video memory. When you change the page data, the result is saved down the chain accordingly. If the amount of allocated memory is approaching its limit, the pages that were accessed the longest time ago are the first to be unloaded

To improve the efficiency of the proposed caching system, it was proposed to use pagination according to the spatial location. This approach is necessary if the algorithms need to select points in a specific spatial region of the point cloud to work. In this case, if you divide the point cloud into pages sequentially (increasing the number of points in the cloud), then when you select points by spatial characteristics (for example, inside a parallelepiped), the affected points will be distributed throughout the point cloud, which will significantly reduce the efficiency of the caching system, since in the worst case, you will have to load the entire page for one point. In this case, it is advisable to use pagination according to the spatial feature (see Fig. 3). The point cloud is paginated depending on the hierarchy level in the structure used for splitting the space (Octree or K-d tree).

Fig. 2: Memory hierarchy in the caching system

Fig. 3: Pagination according to the spatial location of points

To implement control of point cloud parameters, a filter structure was proposed that has a set of inputs, a set of outputs, stop and start functions, and a number of diagnostic functions.

As described above, splitting the space of the LS point cloud into blocks is necessary for fast data sampling based on spatial features, which leads to faster computing and reduced memory consumption.

Based on the results of a comparative analysis of options, it is proposed to use the octar tree (see Fig. 4) to implement the possibility of caching points by spatial feature.

Fig. 4: Example of an octar tree

If an octar tree is used in conjunction with the caching system, the minimum number of points in the node will be set as *PS* * *N*, where *PS* represents the page size. A scale is a scaling factor for balancing the ratio between the number of octar tree nodes and the number of stored pages.

As a result of processing, the output should be a scan in the form of an image, as well as an index file for matching the pixel in the image to the source points from the point cloud. Working with the point cloud takes place in two passes. In the first pass, the program reads the original point cloud into an intermediate buffer. When reading the next point, it is projected onto a cylindrical surface, after which it is written to the file in the scan coordinates. In the second pass, the program reads the next cell from the file (already in the scan coordinate system), and converts the received points to pixels in the final image.

The main result of the work is developing of the high-performance algorithms set for processing, storing and visualizing the LS point cloud. The developed software package for the cloud storage and visualization of the LS point cloud for natural and technical systems consists of the following elements:

- Authentication service
- API Gateway service
- File upload service
- File download service
- File directory service
- Converter
- Queue of conversion tasks
- Inter-service communication message queue
- File storage
- User database
- File directory database.

The software module includes the following components:

- graphical user interface
- user authorization module

- point cloud storage module.
-

The program performs the following tasks:

- user authorization
- view the list and select a point cloud file
- creating a file with a point cloud
- deleting a file with a point cloud
- uploading a file with a point cloud
- download a file with a point cloud.

Conclusion

In the course of this work, algorithms for visualization and storage of LS and photography data were studied. The analysis of existing algorithms for visualization and storage of LS and photography data was carried out. Methods of visualization and storage of LS and photography data were studied, their features were identified, and options for recognizing and representing surfaces and volumes for visualization of LS and photography data were analyzed.

Algorithms for visualization and storage of LS and photography data have been developed. Methods of data import and export are defined, and an algorithm for memory management when storing the result of LS and photography data is developed.

3D models of cultural and historical heritage objects and infrastructure objects were obtained using data from aerial, mobile and ground-based LS and photography.

The software package for cloud-based storage and visualization of LS point cloud was developed. The proposed software complex can be used for natural and technical systems, it includes custom scripts and use of the service, system architecture, functional diagram.

Software modules for storing and visualizing LS point clouds were developed and integrated into a single cloud service. The software complex for cloud-based storage and LS point clouds visualization was tested. Based on the testing results the software was updated. to eliminate detected errors and to complement the functionality of the service.

Abstract

The current world of health is inseparable from computer technology and information technology. The processing of medical data that used to be done manually is now made automatic with information systems to speed up the work process of doctors in obtaining medical data. In hospitals, of course many have "Electronic Medical Record (EMR) Information System (IS)" but there are still many Puskesmas (the third level of Indonesian healthcare institution) that do not have such a system in Makassar City. Patient medical data at the health center at this time in the city of Makassar, is done manually or using a computer but has not been supported by the information system. The number of problems that often occur due to recording medical records is done by recording on the medical record card, resulting in human errors, searching medical records data that takes a long time and recording disease reports that are sometimes inaccurate. In addition to the patient's medical data, the illnesses suffered by patients vary greatly and the drugs recommended for each patient are also, in many cases, not the same between patients with the same disease. Based on the description above, it is considered very urgent to design and design an EMR information system at one of the Puskesmas in Makassar that can be used as a reference by other Indonesian's Puskesmas.

Introduction

To find out the level of accuracy of a drug for each patient, a system is needed to handle this problem, namely by creating an information system to make it easier for doctors to enter patient data, search for patient data, medical record data and others quickly. So it is expected that with a computerized information system for recording medical records that can facilitate the process of

recording medical records, search for patient data that checks at the health center. According to Bjering et al. (2018) The use of computers for electronic medic record services in public health services, especially for data processing in the patient registration section, recording medical records and patient examination sites is very appropriate, because it can provide several advantages and conveniences in patient services including: speeding up service, more accurate information, and faster data searching and searching.

Based on the description above, it is considered very urgent to design and design an EMR information system at one of the Puskesmas in Makassar that can be used as a reference by other Puskesmas. With the design of this system, it is expected to make it easier for doctors to find out patient information, diseases, drugs, know the level of influence of certain drugs on certain patients and get reports clearly and quickly and can make it easy for patients to find out personal data information, and check data.

Research Problems

1. What is the real condition (status) of the data management of road patient medical records at the Makassar City Health Center at this time?
2. How to design a patient's integrated EMR information system at the Puskesmas in Makassar City?

Research Objectives

1. Knowing the current status of patient data management to determine the EMR information system that suits your needs.
2. Analyzing and documenting the draft of the information system design of the target Puskesmas EMR in Makassar City.

Research Limits

1. Designing a web-based and also android-based EMR Information system (only for the doctor module), this is done so that the distribution and publication of information is quickly conveyed to those in need, so that health services are carried out properly and efficiently.
2. Information system which includes entering medical record supporting data such as patient, doctor, laboratory assistant, reference letters and also medical reports.
3. The patient queue process is also used to check whether the patient data that want to check already exists or not at the target health center.

Research Importance

Data management in all Puskesmas in Makassar City is one of the important components in realizing an EMR information system, where data management is still manual even though it is already using a computer (not based on information systems) has many weaknesses, besides requiring a long time, less accurate, so the possibility of error is very large. With the support of current information technology, the work of managing data manually can be replaced with an information system that is not only faster and easier, data management is also more accurate.

The increase of both inpatient and outpatient patients in all Puskesmas causes difficulties for staff in registering patients, both old patients and new patients so it is very helpful if in this case there is a special information system to handle the medical record system at the Puskesmas in Makassar City .
The benefits expected in this study are:

1. For the research team, this research is expected to be able to increase empirical research finding in healthcare domain based IT.

2. For university stakeholders, this research is expected to be able to add references for relevant further research.
3. For the target Puskesmas, this research can provide facilities for the development of an information system for the regestration of patient visits and to facilitate online reporting.

Theoretical Foundation

Basic Concepts of Information Systems

According to Jensen (2016), Information systems are a combination of four main parts. The four main areas include software (software), hardware (hardware), infrastructure, supported Human Resources (HR). Meanwhile, according to Bang et al. (2005) that the information system is a system within an organization that meets the needs of daily transaction processing that supports organizational operations that support managerial with the strategic activities of an organization to be able to provide reports needed by certain outsiders. From these two theories it can be concluded that the resolution of information systems is a relationship of various interrelated information and one linkage to another for specific purposes and objectives.

Benefits of Healthcare Information System

Users of information systems in this era are increasing along with the rapid development of computer technology (software, hardware), the internet and the awareness and interest of the public to use computers to facilitate their work. An information system provides many benefits including the following: (Jensen, 2016; Su and Shih, 2003):

1) Data centered.
2) Ease of Accessing Information.
3) Time efficiency.
4) The scope and dissemination of information becomes wider and faster.
5) Facilitating business and work processes.
6) Low cost for access and provision of information.
7) Cheap, economical and reliable communication solutions.
8) Data storage can be developed as needed.

Electronic Medical Records

Electronic medical records are files containing records and documents about patient identity, examinations, treatment, actions, and other services that have been provided by doctors to patients, both inpatients and outpatients (Ladden et al., 2013; Patwardhan, 2012; Jansen, 2016). These records and documents are very important for patient care, because they can provide information in making decisions, both for treatment, treatment and other medical measures. Patient medical record information must be kept confidential by doctors, leaders of health service providers, certain health workers, and management officers, but can be disclosed in certain cases. As regulated in the Minister of Health Regulation No. 269 of 2008 concerning Medical Records Chapter IV article 10, information on identity, diagnosis, disease history, examination history and treatment history can be disclosed in terms of:

1. For the benefit of the patient's health,
2. Fulfill the request of law enforcement officials in the context of law enforcement according to a court order,
3. Request and / or the patient's own consent,
4. Request for institutions / institutions based on statutory provisions, and
5. For the purposes of research, education and medical audits, as long as they do not mention the patient's identity.

Benefits of Electronic Medical Record Information Systems

The benefits of the EMR information system according to Joynt et al., (2011); Winpenny et al., (2016), can be mentioned, among others as follows:

1. Management can see reports issued by hospitals (Puskesmas), such as drug data reports, employee data reports, visit history reports, and medical record reports.
2. Administrative staff can manage patient data, manage head of household data, add visits, print queuing numbers, print medical treatment cards, and make reports.
3. Poly officers / nurses can manage the results of physical examinations.
4. Doctors can manage data from disease examination results (diagnoses and medical actions), manage prescription drugs and make referral letters.
5. Pharmacists can manage drug data, view prescription drugs, and ACC prescription drugs.
6. Patients can see the visit history and medical record of the patient himself.
7. Admin manages poly data, employee data, user access data, and view Hospital reports.

Research Methods

Framework

To assist in the preparation of this study, it is necessary to have a clear framework for the stages. This framework is the steps that will be taken in solving the problem to be discussed or a series of ideas arranged systematically, logically, clearly, structurally and regularly.

Plan for System Design Recommendations

In analyzing the needs of this outpatient service information system, researchers will use the basic method of developing the System Development Life Cycle (SDLC) system with the waterfall model reference for the benefit of recommendations.

This reference model can be explained in 4 (four) stages, namely:

First, the analysis phase. This stage is the process of identifying and evaluating the problems that occur, and the expected needs of the Type C Hospital in Makassar City. The ongoing system analysis process is described using:

1 Literature Study
At this stage a search for theoretical foundations is obtained from various books and journals to complement the vocabulary of concepts and theories, so that they have good and appropriate foundation and knowledge.

2 Data Collection
At this stage the data collection process is carried out by interview and observation methods to make observations and analysis of the actual state of management of outpatient information data in Makassar Type C Hospital so that data and information are needed by researchers for information system development needs.

3 Old System Analysis
At this stage identification of problems in the current system (manual or computerized) is carried out. Thus, researchers are expected to find solutions to problems and needs.

Second, the design stage. This stage determines the overall system architecture, design of making software programs, and coding procedures. At this stage system design is carried out which consists of designing ERD (Entity Relational Diagram), software architecture, interface design using UML

tools. After that the interface design for web-based information systems was carried out until the Beta version.

In the system design recommendation stage, follow these steps:

1 Process Modelling. Modelling information systems outpatient services using system use case and activity diagrams. system use case which is a more detailed description of what the actor does in the outpatient service information system. While the activity diagram is a detailed description of the procedures perfoEMRd in the outpatient service process.
2 Data Modelling. Data modelling in the outpatient service information system includes the description of entity relationship diagrams, designing the tables needed in the database, and making relations between tables. Entity Relationship that is made has a relationship between data one with the other data. The tables that have been designed are then realized between tables with one another to support the smooth processing of data.
3 The interface design, the application interface design is used to provide an overview of the outpatient service information system designed. Interface design Check function to enter patient check data. In the patient interface design check, the user can search data, add data, save data, edit data and delete data.
4 Implementation of the system, the hardware needed to develop an Outpatient Patient Information System is a desktop computer. The testing method used is black box testing, which is by giving input from the user to the system that is already running and observing the output of the system.

Third stage of coding. At this stage, software design is realized as a set of programs or program units. System implementation is done using the PHP, HTML, java script, and PostgreSQL database languages.

The fourth stage of testing. At this stage, software testing is carried out to ensure that all system requirements are met and ensure that the output gives results that match the needs. In this study system testing was carried out using black-box testing. To compare the test results according to the functional that has been determined.
The system development method that will be used on the recommendations of the analysis of information system development needs is the System Development Life Cycle (SDLC).

Conclusion

It is expected that the research finding will build a unique framework addressing the following issues (1) the existing conditions of patient data management, and (2) current manual registration system. By analysing the need assessment, EMR information system that beneficial for accessing information regarding to patients, doctors and pharmacies, will be more easy to be implemented. This conceptual assessment will guide the planning for identifying system development life cycle in the perspectives of modern outpatient information system.

Influence of Selected Internal Transport Technology in The Picking Area on Improving Work Safety and Picking Time

Katarzyna GŁODOWSKA, MSc

Military University of Technology, ul. Gen. S. Kaliskiego 2, 01-476 Warsaw, Poland,
E-mail: katarzyna.glodowska@wat.edu.pl

Abstract

The subject of work safety coupled with the reduction of working time work has been studied extensively for a long time. Every work is known to pose certain risks and hazards. Work in warehouse facilities particularly abounds in safety issues. There is no way to avoid risk situations at work completely, yet they should be kept away or their likelihood should be diminished. It is essential to be aware of possible threats and, above all, know what to do to reduce them. A standard warehouse facility has four functional zones, one of them being a picking area. The picking area is primarily served by internal transport. Most operations in that area are handled in this way. If a warehouse facility is expected to run properly, its picking area must be organized properly. This article attempts to prove that properly organized work of means of internal transport and the proper selection of internal transport technologies have a direct impact on expediting operations in the picking area of a warehouse and on reducing the likelihood of hazardous situations.

Keywords: Picking, Warehouse, Security, Technology

Introduction

According to reports by the Chief Statistical Office, there were 4433 accidents related to warehouse management and handling operations in the period from January to September 2019. Many of them affected staff working in the picking area. They are exposed to numerous risks due to the need to reach, lift, pick, move, work at heights, high intensity of warehouse traffic, use of inadequate equipment, etc. All threats that occur in warehouse processes also apply to the picking area. It is essential to reduce the possibility of undesirable incidents, i.e. accidents, damage or bodily injuries. According to the information from the Chief Statistical Office covering the period from January to September 2019, out of all 4433 accidents, as many as 16 were fatal and 13 were severe. It should be noted that a natural consequence of an accident at work is the affected employee's absence from work on following days. In the period mentioned above, absenteeism caused by accidents at work totalled 153,323 days. As a result, the efficiency of picking processes in the warehouse is reduced as some staff members may be missing. Consequently, the time needed to complete the same tasks shrinks. Nowadays, due to the rapidly growing logistics market where commodity flows are intense and regular, it is vital that goods are delivered to recipients as soon as possible. This situation has caused warehouse-internal transport to grow in importance, especially in the picking area. In many companies, manually operated pallet trucks are still the basic work tool. The time of operations and the burden of manual work are extensive. It is therefore important to select such a technology of internal transport that would best match the warehouse capabilities and processes with a view to streamlining operation time and the volume of manual work. There are three basic internal transport technologies: manual, mechanized, and automated.

- **Manual** - people's work is assisted by simple devices, and the human factor is decisive. This technology is marked by relatively low efficiency and effectiveness. It is mainly used in smaller warehouses where automation is not justified business-wise. The use of the manual technology generates lower unit costs due to the application of simple equipment that does not require advanced software. Such means of internal transport are easy to use. No permits or certificates are required to work with most devices. It reduces the need to hire certified personnel or to invest in extra training;

- **Mechanized** - in this technology, people are an important factor, but the means of internal transport are even more relevant. Truck and other wheeled equipment operators are required to have a permit or licence. The variety of equipment available in this technology is an advantage because it affords a wide range of possibilities. The efficiency and effectiveness of mechanized internal transport process is superior to those in the manual technology: the equipment used has greater capacity and carrying limits. More advanced tools are used, which requires the warehouse operator to hire highly qualified personnel and offer them specialized training. The use of this technology is justified in larger warehouse spaces compared to the manual technology and it must be justified business-wise;
- **Automated** - this technology relies on fully automated processes; people merely control operations but do not necessarily take part in them. Employees must be trained in advanced software and warehouse operations. Automation significantly increases process efficiency and effectiveness but increases costs. The use of this technology should be economically viable and should be preceded by a detailed analysis. A factor that must not be ignored is that storage space must be accommodated to fully automatic means of transport. Given the reduced human factor, the number of human errors diminishes significantly.

Thus, the selection of the most relevant technology in the picking area will have a direct impact on increasing work safety in the warehouse and the time of completing warehouse operations.

Warehouse Safety

The question of warehouse safety is of utmost importance. Where the internal transport technology is a warehouse is already established and no modification is possible, the existing internal processes should be examined. Such processes must be organized in a way that ensures work safety and efficiency. If no transport technology has been selected yet, then a series of analyses should help in making the right choice. Internal transport plays a very important role in the entire warehouse, especially in the picking area. It offers multiple benefits but also poses some hazards. To talk about safety, first, it is necessary to identify threats that can occur. The most frequently highlighted threats that are directly related to internal transport include:

- Lack of designated picking routes/paths. This can result in hitting a person, bumping into a rack when passing by quickly, colliding with another means of internal transport, and delaying operations.
- Inappropriate selection of a means of internal transport for picking operations. This can result in overloading the vehicle and its overturning; it poses a threat to life of the operator and other employees nearby and a risk of damage or complete destruction of picked goods.
- Inappropriate distances between racks. This can result in a difficulty in manoeuvring the means of internal transport, which significantly delays the time of picking and creates a risk of collision or personal injury.
- Poorly selected means of internal transport generating greater workload for warehousemen. In addition, the employee is exposed to excessive fatigue, forced to work in an uncomfortable position or lift too heavy packages, etc. It can result in an injury.
- Lack of targeted training for employees operating internal transport equipment. This may result in hitting a person, colliding with another means of internal transport, bumping into a rack or other object, etc.
- Incorrect use of forklifts for two-dimensional picking can result in a person's falling from height or dropping a load. Such threats may result in damage to other employees, means of transport or goods, etc.

Warehouse space also abounds in other life-threatening situations, risks of damage to the goods or internal means of transport. Each adverse event may lead to many dire consequences, including, for example, bodily injury, death, damage to the goods, damage to the storage facility, etc. All this has a direct impact on the time of performance of picking operations. The use of an appropriate technology adapted to a specific warehouse facility can significantly facilitate work, increase safety and minimize

losses. Based on market monitoring and analysis of materials from the warehouse industry, it becomes evident that the most commonly used internal transport equipment in the picking area is picking trucks operated by an operator and falling under the definition of mechanized technology. This does not mean that the use of this type of trucks does not carry risk or threaten the safety of employees and goods. As a result of analysis of many studies and reports, it appears that many personal injuries and damage to goods are caused by operating picking trucks. The presence of pedestrians or other internal transport equipment in the same areas can result in collisions and hits. Additionally, if more than one truck takes part in the picking process, congestion and hold-ups may occur. They may result in delays, downtime, nervosity, or distraction, which may additionally increase the risk of collisions, falls, hits, etc. Based on classification contained in the analysis of accidents and dangerous technical damages covered by technical supervision, the following are regarded as categories of causes of accidents related to internal transport means:

- Design/construction errors - this includes defects within the internal transport equipment, drive system, control system, braking system, improper selection of materials for specific components/devices, inadequate safeguards, etc.
- Manufacture defects - faulty connections, material processing defects, failure to comply with the conditions contained in the operation and maintenance documentation, etc.
- Material causes - this group includes hidden defects in materials, material fatigue, the action of corrosive substances or corrosion.
- Operating errors - improper maintenance or inspection of the device and its systems, poorly conducted repairs and alterations, improper organization of the workplace, failure to comply with the technical supervision requirements, poorly trained personnel operating the means of transport.
- External factors - natural disasters, fires, etc.
- Unexplained causes.

According to the analysis of the available literature on the subject, the most common causes of accidents are operating errors, followed by bad design and defects in manufacture. The following risk can be identified when working with a truck:

- Getting hit by a moving truck.
- Lifting a person on forks.
- Truck overload.
- Loss of truck stability during cornering.
- Collision with another truck.
- Getting burned while in a truck.
- Catching a fixed element with forks.
- Truck fall from a loading dock.
- Crushing with a truck or truck accessories.
- Hitting with transported load.
- Running over or hitting by a truck.
- Hitting by a reversing truck.

The main causes of accidents involving trucks include:

- Lack of skill or competence.
- Operator's inattention.
- Operator’s recklessness.
- Poor condition of equipment.
- Mechanical failure of equipment.
- Design defect of any part of equipment.

The most common threats to employees related to the use of trucks are:

- Getting hit by a truck.
- Crushing/hitting a truck operator/pedestrian by goods falling from height.
- Too quick or careless stepping out of the truck cab.
- Truck overturn.
- Truck collision with another truck or a fixed object along its route.

If is it already known what risks may occur, what their cause is and what consequences they may produce, all possible action should be taken to eliminate such risks or, if not possible, minimize them by increasing work safety and reducing picking operations time. If a warehouse facility is at the design stage, the designer should allow for all measures aimed to improve work safety, for example: design wider corridors, design routes accommodating internal transport means, determine the method of traffic management by, e.g. separating pedestrian and mechanized transport routes, reducing the number of intersections, etc., allow for more and more visible warning signs, spherical mirrors or sound and visual signalling devices. The basic measures necessary to reduce the risk of hazardous situations occurring in internal transport include, for example:

- Organization of pedestrian movement and internal transport.
- Setting the maximum possible speed of internal transport means in the warehouse facility.
- Reducing the number of truck meeting points including intersections.
- Limiting the number of blind spots to improve visibility: the use of spherical mirrors, reversing cameras, audio signals.

In internal transport, it is crucial to separate pedestrian traffic from wheeled transport completely. However, before such separation is made, the relevant transport routes must be carefully designed. According to the Regulation of the Minister of Labour and Social Policy of 26 September 1997 on General Occupational Health and Safety Regulations, a warehouse facility operator is required to:

- Label all traffic routes, transport routes, pedestrian roads and fire access roads in accordance with applicable Polish Standards.
- Roads must be maintained in a condition that does not pose a threat to their users.
- In places where hazards to pedestrians exist, e.g. gates, doors, passages, effective protective measures should be applied.
- There should be no thresholds or steps on carriage and storage routes.
- The dimensions of roads and passages must correspond to the potential number of users and the type and size of internal means of transport and loads.

The importance of picking operations time and the choice of internal transport technology

The need for fast handling of a large number of orders requires highly efficient warehouse processes, among them picking. This fact necessitates the use of more means of internal transport. The prevailing trend to reduce warehouse space translates into designing spaces with a maximum storage area at the cost of transport routes. Because of the need to handle a large number of orders, any warehouse facility is filled with numerous means of internal transport and pedestrians, which creates a serious risk of collisions, accidents involving pedestrians, hold-ups, etc. All this makes picking operation times significantly longer. This, in turn, causes delays in the handling of orders for customers. It can therefore be concluded that optimum and well-organized movement of personnel (pedestrians) and trucks in the picking area has a direct impact on the efficiency of the entire logistics chain in the enterprise. The picking process is not only vital but also consumes most time allocated to warehouse operations. Analysis of the share of individual activities in the total time needed for picking processes shows that nearly half of this time is spent on movement, as shown in Fig. 1.

Fig. 1: Percentage share of warehouse activities in the assembly process

Fig. 1 demonstrates that the time spent on movement in the picking area is incomparably long compared to other activities. A consequence of this is higher costs of operations. Therefore, it is essential to minimize this time by choosing the right technology and organizing the movement of all picking process participants in the most optimum way. This will not only reduce working time but also increase work safety. To ensure a proper, efficient, effective and safe functioning of a warehouse facility, selection of the best internal transport technology is a priority. This choice is closely linked to economies of scale. This means that high material flow rates in warehouse facilities justify the use of transport technologies that are expensive to acquire and maintain. These technologies prove efficient and effective not only in the processes that they support but also benefit the entire warehouse. If a large number of operations is carried out in a warehouse facility, even small time savings at each handling stage will generate measurable savings across the board. Expecting the top efficiency of the internal transport process, it is necessary to analyse available and necessary data to be able to make an informed choice between automated, mechanized, and manual technologies. Before making a decision, an in-depth analysis must be made of the structure and flow rate of load in the warehouse (or in a specific functional area) as well as the costs of human labour and equipment performance. Given the above, the selection of best internal transport technology is regarded as a complex and challenging process. However, a properly organized internal transport should ensure the handling of warehouse streams at reduced use and wear of means of transport and minimum time of operations along with streamlining operational and operating costs. The analysis of the selection of internal transport technology in a warehouse should cover criteria that are relevant from the viewpoint of operations in a logistics facility. Each enterprise has different possibilities and requirements. Sometimes, warehouse operators wish to get automated but after a careful analysis they realize that it is not economically viable. In order to gain a competitive edge, many companies streamline their operations through automation (wanting to reduce costs without compromising the quality of rendered services). Every customer expects their deliveries on time and at the right quality and expects transport services at the lowest possible price. Warehouses where goods are stored or transshipped are one of the links of the logistics chain. Therefore, before selecting the optimum internal transport technology, it is vital to perform an analysis based on a number of criteria. These criteria should also be chosen very carefully and should reflect the actual capabilities. They are:

- availability of technologies on the market;
- selection of the method of storage/picking/issuing;
- type of existing warehouse equipment;
- specifications, advantages, disadvantages and general guidelines regarding the use of specific technologies.

Some more criteria what should be followed are:

- technical:
    - warehouse area (large/small);
    - spatial dimensions the warehouse facility (small due to restrictions for low-rise buildings or large without restrictions);
    - capacity of functional areas;
    - process efficiency (maximizing the efficiency of processes carried out with a particular technology - storage, picking, internal transport);
    - level of process automation (determining which processes carried out within the facility need automation and to what extent).
- commercial:
    - investment in technology (profitability ratio);
    - operating and operational costs (costs related to the use of a specific technology in performing logistics operations, e.g. picking, movement, and others).
- additional:
    - selective character of stored goods (whether it is necessary to ensure access to each loading unit at any time or only to one type of assortment);
    - universal character of technology (whether it can handle multiple tasks, whether the means of internal transport can carry out different operations in the warehouse, whether the technology allows easy reconfiguration and expansion of the internal transport systems);
    - safety (of personnel and equipment).

Internal transport technology is a way of implementing the transport and storage process related to a logistics objective in logistics facilities. To do that, the following relationships must be taken into account existing between:

- load streams described by item, number, dispatch and collection points, available time and buffer locations;
- information streams related to material flows;
- efficiency of the transport and storage system components;
- unit operating costs of used resources;
- the facility and its surroundings.

Other means of transport selection criteria are also found in the literature on the subject. They are grouped into technical and commercial. The technical criteria are:

- external factors which cover: the type of load (properties, technical vulnerability, number, etc.), type of transport task, the extent of carriage contract between suppliers and recipients, dispatcher’s and recipient’s infrastructure, carriage time and cost;
- internal factors which cover: loading machines and their performance of required tasks, personnel and their qualification, work organization, technical facilities.

The commercial criteria are divided based on the perspective of each participant of the transport process:

- carrier's perspective: proper use of the vehicle's capacity/carrying capacity, adequate securing of load, ensuring the lowest transport costs;
- dispatcher’s and recipient’s perspective: to preserve the functional parameters of loads, to maintain desired quality at reduced costs;
- producer’s perspective: the volume of demand based on operations, minimization of inventory, delivery of components indispensable for operations, warehouse size, performance of transshipment equipment at the beginning and end of the process, daily delivery and dispatch volume, JIT deliveries, delivery time, etc.

Currently, there is a tendency to automate logistics processes. The same trend is reported in transport. However, it should be noted that before making a decision on the use of automated means, it should be preceded by an analysis of the structure of material streams within the logistics system. The basic conditions for internal transport automation are:

- logistic form of loads - unified, repeatable, standard sizes, packages properly and well protected;
- high-quality material carriers;
- material flow volume - the criterion of cost-effectiveness of using automation technology;
- justification for using automation in place of manual (human) work;
- high quality of logistics services - high price of handled goods, goods requiring special conditions (e.g. medicine or electronics);
- special working conditions, e.g. cold, required sterility, meaning impeded access;
- low assortment variability index;
- ability to integrate new solutions with existing systems.

The selection of internal transport technology can be shown as an algorithm.

Start.

Step 1 - Beginning of the process.
Step 2 - Modelling the warehouse process: describing how the warehouse process will be carried out in a specific logistics facility.
Step 3 - Identification of a single transport routine; many transport routines can be carried out simultaneously or one after another in a warehouse facility; chose one and analyse it to make it serve as a model.
Step 4 - Identification of conditions imposed by technologies for selected routines; the following parameters describing the logistics facility should be provided:

- width of working aisles;
- required lift height;
- method of operating wheeled equipment (control);
- work equipment;
- applied automatic solutions.

Step 5 - Identification of travel starting points; define factors closely related to a routine carried out at the logistics facility:

- single pick-up location;
- a list of warehouse locations where pick-up can take place.

Step 6 - Identification of travel end points; as in Step 4, specify routines carried out in the logistics facility:

- single drop point;
- a list of warehouse locations where drops can take place.

Step 7 - Identification of a transport routine repeatability; based on available historical data, determine the frequency of a transport routine:

- high daily/hourly repeatability;
- low daily/hourly repeatability;
- no daily/hourly repeatability.

Step 8 - Identification of the size of material streams on a given route (in Step 2 a single transport routine was specified). Next, specify what volume of material stream will be handled on the route:

- significant/minor/insignificant.

Step 9 - Identification of even material flows:

- even flows;
- repetitive grouped flows;
- irregular grouped flows;
- irregular flows.

Step 10 - Identification of the types of storage units (moved); specify what types of units will be handled by the means of internal transport:

- one type of standard unit (e.g. pallet);
- many types of units (custom - picking);
- bulk materials (liquid, loose, etc.);
- materials that require specialized manipulators.

Step 11 - Identification of automation requirements; determine the options of use and needs for automation solutions in the logistics facility in order to handle a specific logistics routine:

- high level of routine automation;
- low level of routine automation;
- mechanical routine;
- manual routine.

Step 12 - Selection of the method of operator's movement with the unit; determine how the operator will perform their routines in the logistics facility:

- device operator moved and lifted together with the unit (control and manual work, e.g. picking);
- device operator moved with the device (control);
- device operated remotely or automatically (without operator).

Step 13 - Identification of requirements concerning the universal character of technology (modification of the working area); determine the options of using various means of internal transport or limiting their use to a small number of more universal equipment; adapt to the area size and business capabilities of the logistics facility:

- universal technology with flexible applications and easy modification of the working area;
- specialized technology without the option of modifying the working area.

Step 14 - Requirements for method of movement - vertical/horizontal; define the type of equipment to be used:

- horizontal movement (lifting);
- vertical and horizontal movement (with lifting);
- vertical movement (lifting only by, e.g. lifts).

Step 15 - Identification of travel distance; determine how far the means of internal transport will travel in a specific routine in the logistics facility:

- large (travel between departments/sections);
- small (movement within the area/zone).

Step 16 - Identification of transport and safety conditions; define the basic conditions of operation of the means of internal transport in the logistics facility:

- temperature and humidity;
- precipitation and dust;
- surface type (if required) and inclination;
- employee and unit safety, exhaust emission;
- equipment maintenance conditions (poor/good).

Step 17 - Identification of the need to track material flow (automatic flow registration); determine whether it is necessary to track a load unit as it travels within the logistics facility:

- unit tracking required;
- unit tracking and identification required (mass, dimensions, label);
- no tracking and identification required.

Step 18 - Identification of the options of replacement of human work with automated work; in this step, the possibility of automating human labour (or vice versa) should be analysed. Based on the required data, decide on the right solution best matching the logistics facility where a specific routine is carried out:

- high/low human labour costs;
- availability of qualified staff.

Step 19 - Identification of available financial resources; in this step, carefully analyse all the above factors and determine the ultimate resources equipped with the knowledge about the financial capabilities of the logistics facility.

Step 20 - Choice of the selection criteria; each decision-maker will choose options based on other criteria, depending on the needs, financial resources and the volume of material flows.
Step 21 - End of the process.
Stop.
The algorithm is shown in Fig. 2.

Fig. 2 : Algorithm for the selection of internal transport technology

1. Simulation of the picking process

For research purposes, a computer simulation was designed with FlexSim to show how the selection of appropriate technology can help reduce the time spent on moving the means of internal transport in the picking area and increase work safety. The following assumptions were made (Fig. 3):

- The picking area is separated from the storage area; they are separate zones.
- The test case has nine racks in the storage area (R1-R9).
- The assortment weights are the same for each tested variant.
- Three picking orders are defined dropped on three intermediate storage places (PO1-PO3).
- Tested technologies: manual (human work with a pallet truck), mechanized (a human-operated truck), automated (AGV truck, with a human a controller and not the executor).
- An 8-hour work shift was adopted; one shift with breaks in accordance with the regulations.
- Movement speed for AGV: 1.5m/s; forklift 3.1m/s; operated pallet truck 1.4m/s.
- Distances between racks, width of transport aisles, etc. in accordance with the applicable regulations.
- Two cases for each technology were put to test:
    - The method of movement of the means of internal transport was determined (routing).
    - No method of movement of the means of internal transport was determined (no routing): every means moves in such a way so as to complete the routine as quickly as possible.
- During the simulations, there are also variants adopted in which there is no simultaneous movement of the human-operated pallet truck, forklift or AGV. For one simulation, only one type of means is used.
- Due to the fact that a human moves slower than a forklift, the following equivalent numbers were adopted: forklift type (mechanized technology) - 1, employee with a pallet truck (manual technology) - 6, AGV truck (automated technology) - 4.

Fig. 3: Model of the warehouse picking zone

The completed simulations yielded results for the first variant, i.e. lack of work organization and no hold up and collision avoidance system in place (collision of a means of internal transport with another means and hitting a standing object as a result of fast travel or a large number of vehicles at a time in one space). The results are given in Table 1. Table 2 shows the results of organized work for the same conditions as in Table 1.

Table 1: Work not organized – results

Number of means of transport	4	8	12	1	2	3	6	12	18
Technology	automated			mechanized			manual		
Working time [s]	18976	20536	21536	18240	18781	19231	19561	21550	21600
Number of collisions [pcs]	18	24	31	4	6	9	22	45	55
Number of hold-ups [pcs]	2	4	6	0	0	1	5	11	16

Table 2 : organized work – results

Number of means of transport	4	8	12	1	2	3	6	12	18
Technology	automated			mechanized			manual		
Working time [s]	17939	19158	19974	16890	17272	17670	18627	19082	20442
Number of collisions [pcs.]	10	13	16	1	1	2	14	21	31
Number of hold-ups [pcs]	0	2	3	0	0	0	3	5	8

Analysing the obtained results, proper organization of movement of the means of internal transport should no doubt be a priority as it significantly reduces the risk of hazardous situations, such as collisions, accidents, pedestrian incidents, etc. In addition, the choice of the most appropriate technology to satisfy the needs of the studied warehouse facility may not only improve work safety and minimize the risk of bodily injury or damage to transported and shelved goods but also minimize the time spent by internal transport means on movement. The results presented in Tables 1 and 2 and, above all, the time of movement of internal transport means are influenced not only by work organization but also by the number of collisions, hold-ups, etc. Therefore, the conclusion is that the selection of the best technology and proper work organization have a tremendous impact on the time of performed routines and work safety in the picking area.

Summary

Conducted simulation and analysis of literature on the subject demonstrate that despite the visible trend of improving work quality by employing measures to minimize risk in the workplace, in particular in logistics facilities, work-related risks and threats are still there. In the times of continuous upgrades and improvement of the means of internal transport, working with a forklift or AGV cannot be regarded as 100% safe and it still threatens the life of warehouse personnel due to pressure to reduce the time of performed operations. There is a noticeable reduction in the number of occurring threats and a significant improvement in the duration of completed routines. However, work in a warehouse facility still generates hazards for the personnel. Therefore, it is of paramount importance to try to avoid the risk of hazardous situations or, if not possible, minimize its occurrence. The simulation tests discussed in the article lead to the conclusion that good work organization is a key to success in terms of work safety and time of performed routines. It is noted that the more collisions, pedestrian incidents or hold-ups, let alone poor work organization, the more time is needed for completing picking operations. Ultimately, the final recipient will receive their goods later than scheduled. Such situations can entail to the loss of customers and may tarnish the company image, thus leading to financial losses. Well-

chosen technology, well-done preliminary and extensive analysis and appropriate work organization can contribute to the company's gaining of competitive edge on the market.

Abstract

The paper considers theoretical aspects of innovation concept, its common features and possible sources of financing in organizations. It studies innovative activity of enterprises in various sectors of Russian economy, the dynamics of indicators for 2010-2018, the volume of innovationactivity, the share of innovative products of economic entities as well as the costs of innovation, including technological. Priority financial sources are highlighted, suggestions are made to stimulate innovative activity of economy and improvement of innovationfinancingmechanism.

Keywords: innovation, funding sources, business entities, innovative activity, branches of economy.

Introduction

In today's dynamically developing world innovation is an integral attribute of successful functioning of any organization in all sectors of economy. A company's activities related to innovations is understood as a type of work at development and implementation of scientific and technological achievements, creation of new, more competitive products, their implementation at a high-tech level in order to obtain a maximum possible reward. At present, without innovations it is practically impossible to create competitive products with a sufficient degree of high technology and novelty. All this allows toconclude that innovationsare an essential element of anenterprise functioning, which ensures its survival and financial stability. They determine effectiveness of an industry as a whole, provide for a faster development.

In this regard,it is importantto understand whatis innovation. Some scientists formulate this concept as a process, some believe that it is an idea, practice or product that is perceived by an individual as new. The rest emphasize the use of innovation in human activities. All interpretations of innovationconcept share a common feature - a new value of a product created in the process of innovative activity.

Research Methods

The object of the research is an innovative processin Russian economy sectors, financial sources of its implementation. Sources of analytical information are the Federal State Statistics Service`s data, data of legislative and executive bodies of the Russian Federation, our own research. The methodological basis is formally informative, individual and is based on general approaches, deductive and inductive research methods. In the process of observing, collecting, summarizing and processing information various techniques of analytical, economic-statistical, graphical and other research methods have been used.

Research Results and Discussion

In the course of our study the analysis of innovative activity of Russian companies in various industries was carried out, which revealed its rather low level. Positive is the fact that in the period of 2011-2013 there was a noticeable upward trend in the share of organizations engaged in technological, organizational, marketing innovations in the total number of economic entities studied. At the same time, it can be seen that since 2014 the activity began to decline steadily and according to the results of 2016 stopped at the level of 8.4%. The growth of most indicators in 2017-2018 isdue to the refinement of Methodology for calculating criteria for determining innovation activity of an organization based on a new edition of the international manual on statistical measurement of innovations implemented by the OECD together with Eurostat. According to the Federal State Statistics Service`sdata calculated in accordance with the new methodology at the end of the study period (2018), one fifth of all organizations carried out technological innovations, marketing and organizational innovations were carried out on a small scale (Table 1).

Table 1: Indicators of innovative activity of organizations by type of economic activity of the Russian Federation for 2010–2018

Indicators	Years								
	2010	2011	2012	2013	2014	2015	2016	2017*	2018
1. The proportion of organizations implementing technological, organizational, marketing innovations in the reporting year, in the total number of organizations examined, total	9,5	10,4	10,3	10,1	9,9	9,3	8,4	14,6	12,8
- mining	7,8	8,4	8,2	7,6	7,5	6,9	7,4	8,9	7,9
- manufacturing industries	13,0	13,3	13,4	13,3	13,6	13,3	13,3	26,2	23,2
- production and distribution of electricity and gas	5,4	5,6	5,6	5,3	5,1	4,9	4,8	8,4	6,9
- activities related to the use of computer technology and information technology	10,0	9,2	9,4	9,6	8,8	8,0	6,3	7,1	5,0
- research and development	-	29,8	30,1	31,0	33,3	32,2	30,7	66,7	61,4
- agriculture	-	-	-	-	-	-	4,5	5,2	3,8
2. The proportion of organizations implementing technological innovations in the reporting year	7,9	8,9	9,1	8,9	8,8	8,3	7,3	20,8	19,8
3.Share of organizations implementing organizational innovations in the reporting year, in the total number of organizations surveyed	3,2	3,3	3,0	2,9	2,8	2,7	2,4	2,3	2,1
4. The proportion of organizations implementing marketing innovations in the reporting year, in the total number of organizations surveyed	2,2	2,3	1,9	1,9	1,7	1,8	1,4	1,4	1,3
5. Share of organizations implementing environmental innovations in the reporting year, in the total number of organizations surveyed	4,7	5,7	2,7	1,5	1,6	1,6	-	1,1	-

** In 2017, the data change was due to the refinement of the Methodology for calculating the criteria for determining innovative activity of an organization based on the new edition of the international manual on the statistical measurement of innovations implemented by the OECD together with Eurostat (fourth edition of the Oslo Manual).*

Analysis of innovation activity of organizations by type of economic activity showed that the highest level of innovation is seen in companies conducting research and development (more than 60%), in the manufacturing industry (about 25%). At the same time, it should be noted that for Russian economy, focused on the development of digital technologies in all areas of activity, 5% of organizations engaged in innovations in the field of computer and information technology are not permissible. The most difficult situation is in the agricultural sector, where only less than 4% of agricultural organizations introduce innovations.

Table 2: Indicators of innovative activity of organizations by constituent entities of the Russian Federation for 2010–2018

Indicators	Years								
	2010	2011	2012	2013	2014	2015	2016	2017*	2018
1. CentralFederalRegion	8,6	10,2	0,9	10,7	0,9	0,9	10,3	18,5	16,2
2. NorthwesternFederalRegion	9,4	11,2	11,0	10,7	10,3	9,6	8,3	15,9	15,9
3.SouthernFederalRegion	7,5	6,5	7,4	7,2	7,7	7,6	7,1	11,9	9,5
4. North Caucasus Federal Region	6,2	5,2	6,4	5,9	6,5	4,7	2,9	7,5	4,4
5. VolgaFederalRegion	12,3	12,7	11,9	11,7	11,4	10,6	9,4	14,3	13,3
6. UralfederalRegion	11,5	11,5	10,6	9,6	8,9	7,9	8,2	15,7	14,9
7. SiberianFederalRegion	8,2	8,8	8,5	9,1	8,8	8,0	6,9	12,3	9,9
8. FarEasternFederalRegion	8,6	11,2	10,8	9,5	8,9	7,2	6,4	10,5	8,9

In order to identify the most active regions of Russia in terms of introducing innovations the level of innovation activity in the regions was evaluated (Table 2). So, in the Central Federal Region the highest activity is observed in the Lipetsk Region, where the share of organizations implementing innovations is 23.6%. In the Northwestern Federal Region only the city of St. Petersburg stands out with a level of innovative activity of 28.3%, in the Southern Federal Region - Rostov Region - 13.2%. The lowest indicators of innovation activity were recorded in the North Caucasus Federal Region, where the highest rates were recorded in the Republic of Ingushetia - 10.5% and the smallest - in the Chechen Republic - 0.2%. Among all the regions the Volga Federal Region is noticeably distinguished, in which a fifth of all organizations carry out technological, organizational and marketing innovations. So, in the Penza Region innovative companies account for 20.9%, in the Republic of Tatarstan- 21.5%, and in the Chuvash Republic - 30.4% innovations.

Analysis of innovative activity involves an assessment of dynamics of volume of innovative productssales. As can be seen from the data presented in Fig. 1, during 2010-2018 there was a constant increase in the volume of shipped innovative products, which occurred mainly due to an increase in the volume of sold innovative products in manufacturing. As mentioned above, the role of the agricultural sector in the innovation process is very small, so by the end of 2018 agriculture

accounted for only 0.75% of the total volume of shipped products.

Figure 1 – Dynamics of the volume of shipped innovative products of organizations of the Russian Federation for 2010-2018, million rubles

As noted above, technological innovations prevail in the structure of innovations carried out by Russian companies despite the fact that their share fluctuated strongly from 73% to 33% during the entire study period from 2008 to 2011 and at the end of 2018 it amounted to more than 80%.

Due to the fact that the share of innovative products that have undergone significant technological changes or are newly introduced is significant, it seems interesting to study the costs of technological innovations. The costs of technological innovations increased from year to year, theygrew especially significantly in 2011 when they increased by 83% compared with the previous period, a slight decrease was observed only in 2015 (Fig. 2). In general, over the entire period of study the costs of technologically innovative organizations increased 3.7 times. Assessing the costs of innovation of organizations by type of economic activity, it should be noted that manufacturing industry accounts for the greatestcosts. Innovationcostsof agricultural organizations are small, their share being only

1.5%.

Figure 2 – Dynamics of costs of technological innovations of organizations by type of economic activity in the Russian Federation

for 2010–2018, million rubles

An assessment of the structure of sources of financing technological innovation showed that the main source of financing innovation in all sectors is organizations` own funds. Their share in all sources of financing in Russian economy in 2017 amounted to 53%, ranging from 68% in industry to 100% in construction. The share of budget funds has increased significantly in recent years and amounted on average to 27%. The highest share of budget subsidies for innovations is observed in the service sector, where it amounts to 56%, about 11% - in agriculture and 9% - in industry.

One of the most important constraints on the implementation of innovations by organizations is significant cost of research and development, unbearable for a significant number of business entities. In this regard, the study analyzes modern tools of state support for research and development available in Russia. We determined the most effective ones, among which:

- state assignments to scientific institutions subordinate to the Ministry of Education and Science of Russia;
- The federal target program “Research and development in priority areas of a scientific and technological complex of Russia for 2014-2020”;

- Fund for Innovation Promotion;

- Russian Science Foundation;

- RussianFoundation for Basic Research;

- Federal scientific and technical program for agriculture development for 2017-2025;

- Decrees of the Russian Federation Government of April 9, 2010 No. 218 and No. 220.

The largest amounts of funds to support scientific research during the study period were allocated to the federal target program, approximately the same amount of funds -to the Russian Science Foundation and the Innovation Promotion Fundtofinance scientific research.

Figure 3 – Structure of innovation financing sources, %

Difficult financial situation of organizations in most sectors of economy causes an urgent need to improve the mechanism of financing innovative processes in the real sector of economy. The analysis ofvarious scientists` points of view showed that the following development directions are most timely:

- development of the credit sector of economy;

- use of resources received in the stock market;

- use of funds of non-state pension funds (NPFs) and insurance companies;

- accumulation, distribution, coordination and setting restrictions on the use of financial assets through development banks; development agencies; financial corporations; investment, venture and sovereign funds; credit cooperatives; microfinance organizations; investment companies;

- development of financial market: stock market, banking services market, foreign exchange market;

- issue of infrastructure bonds, which can be issued in the following forms: corporate bonds issued by a special company, created to implement an infrastructure project; targeted public bonds, intended for implementation of specific projects, launched by public companies;

- development of a system of innovation financing and investment process (SFIIP), which is based on the mechanism of public-private partnership and provides for innovationfinancing and investment

projects in three ways - exclusively by the state, mixed way, on the basis of public-private partnership, on the basis of investment only on a private initiative ;

- development of targeted "operational" financing of the real sector of economy directly by the constituent entities of the Russian Federation;

- state support of innovative component of the real sector of economy by creating conditions tosupport development of innovative activities.

Conclusion

Thus, organization of innovation financing should be focused on a plurality of sources of financing and suggest a quick and effective implementation of innovations in terms of their commercial value, which ensures significant growth of financial returns from innovation. Additional sources of innovation financing may be funds of institutions which supportfinancial innovations, venture capital funds, business “angels” and banks. Improvement of mechanism of innovation financing in the real sector of economy has enormous potential and its realization will improve the overall efficiency of Russian economy.

Abstract

Inevitable succession of generations and necessity to preserve inner potential of the state presupposes the mandatory transfer of accumulated positive experience, knowledge, traditions, mentality from ancestors to their descendants. The state as a universal regulator of social relations plays a leading role in these processes, subject to the harmonious interaction of school and family, which contributes to harmonious development of personality. The study is devoted to the problems and prospects of developing a system of additional education for children in modern environment. The authors analyze the management activities of the region's administration to create the designated system; consider certain aspects of providing educational services as to relevant administrative decisions. The understanding of the system of additional education for children as part of a single educational environment has been updated.

Keywords: Educational Environment, System of Additional Education, Social Effect, Educational Policy.

Introduction

Human education is an extremely complex and controversial process that is directly related to learning, but at the same time it represents a focused activity on the formation of a personality through the perception of cultural traditions, spiritual and moral values, the implementation of communication skills in society. As the paradigm of teaching changes, the educational process should be aimed at achieving new pedagogical results, which will enrich learning, enhance its socio-pedagogical effect, unleash the potential of an emerging personality and adapt it in a high-tech, competitive world.

Traditionally, the organization of the educational process was the prerogative of the school, but in these times of change in our country, the "character-building component" gradually fades into the background, is shifted from secondary school to the institutions of additional education. Over the past decade, educational system has been largely modernized and the results of these modernization processes have been the subject of discussion by the general scientific community. Consideration and

prediction of social effects of such modernization, especially in part as they concern and affect parents, children, teachers, etc. are particularly topical.

The situation was complicated by the global algorithmization of educational activities. Such concepts as testing, performance monitoring, all-Russian tests, State Final Examination, and Unified State Exam have firmly entered into Russian reality and have focused the attention of educators on narrow subject-based instruction, which features a strict technological focus. Two decades of work of the reformed school resulted in not very pleasant, but quite pronounced trends:

– the authority of collective education has been largely discredited in the pursuit of the satisfaction of individual needs;

– excessive attention to the implementation of an individual approach in teaching, the growing role of the teacher, has several paradoxical consequences:

– on the one hand, it provokes the development of egocentric personality traits. Today, the opinion that young people are considered only as consumers, but not creators, has become commonplace. At the same time, the personality maladaptation in society results in infantilism in children and adolescents; the fact that significantly affects the effectiveness of the entire educational process;

– on the other hand, individual education is combined with the universal knowledge testing methods and the depersonalization of the process of monitoring learning outcomes, which often does not correlate with students' expectations;

– the transition to averaging monitoring technologies, including “calculating of the average grade”, is based on the automation of the process when the individual achievements of the child are no longer crucial, which partially eliminates the very attempts to achieve individual high results, which, in turn, reduces the motivation for learning and causes a number of psychological problems;

– the traditions of collective labor education have actually been lost, as a result of which the number of socially unadapted, psychologically immature graduates of educational institutions who are unable to independently and fully organize their living space, plan further education, start building careers, etc., is increasing.

Leading teachers and practitioners note negative trends that appear in Russian school, but are forced to obey the administrative decisions and have to comply with the requirements in their activities. Unfortunately, the educational component of pedagogical activity and character-building activities cannot be fully realized in the current conditions. In this regard, multidisciplinary institutions of additional education take much more responsibility for organizing a personality-oriented approach in developing a harmonious, valuable personality than before.

The purpose of the study is to determine the whole complex of organizational conditions that can ensure the integration of additional education of children into a single educational system.

Methods

The object of the research is the organization of the educational process in the period of reformation considering general and additional education as a single system.

The subject of the research is the organization of the educational environment in the region, the prerequisites for the formation of social effects as a result of implementation of general and additional education.

The theoretical basis of the research is scientific developments, philosophical concepts considering an individual to be the highest value of society and progressive ideas of humanistic pedagogy. The key points for this study are the propositions of the supporters of the general systems theory (P.K. Anokhin, I.V. Blauberg, etc.), as well as the theory and practice of pedagogical systems (V.P. Bespalko, V.G. Bocharova, V.A. Karakovsky, G.I. Legenki, A.V. Mudrik, L.I. Novikova and others). A significant contribution to the study of the theory of modeling pedagogical systems was made by V.P. Bespalko, I.V. Bestuzhev-Lada, B.S. Gershunsky, V.V. Kondratiev and others. V.A. Berezina, A.K. Brudnov, O.S. Gazman, V.P. Golovanov, V.A. Gorsky, I.P. Ivanov, M.B. Koval and others developed the theory of additional education. In the context of this study, the provisions of the theory

of personal development were applied (A.G. Asmolova, I.V. Abakumova, L.S. Vygotsky, P.N. Ermakova, A.R. Luria, A.N. Leontiev and others).

The methodological basis is the cultural, historical, systemic and activity-based approaches to education, a set of scientific concepts about the socio-historical conditionality of the educational process, the laws of creative activity as a factor in the upbringing and socialization of children.

Results and Discussion

A fairly long period of systemic changes in education has been accompanied by research and systematic assessment of the socio-economic consequences of its modernization and social effects produced. Theoretical understanding of even intermediate results is necessary for development of future scenarios for education evolution.

The Federal Law "On Education in the Russian Federation" states "the importance of additional education aimed at meeting individual needs of the population in intellectual, moral, physical improvement, health promotion and the organization of free time".

Considering the features of the organization of the educational process, it can be noted that one of the main features of the Russian education system as an object of management is the concentration of efforts on the management of individual elements of the educational system, and above all, educational institutions, as well as setting of standards for various types of activities. However, taking into account the diversity of reforms taking place in the sphere of education today, it would be irrational to single out only a specific outstanding process. Despite many years of tradition and rich Soviet experience in understanding the educational process as a cohesive whole from the perspective of a systematic approach, where the education and character-building of an individual were considered interrelated elements, the situation is different in the modern practice of providing pedagogical services while the system of additional education stands alone here. Today, at different levels of power, the necessity to integrate the system of general and additional education into a single whole is considered. Based on the need to solve the problems of managing the educational process in the Russian Federation, the implementation of additional education is considered as an integral part of modern education. The intellectual, spiritual development of an individual is facilitated by the activities of the network of institutions of additional education, which are actively developing and gaining new significance in the changed conditions of social contract.

So, the main social effect of the implemented educational policy and, accordingly, of all the ongoing modernization processes, is to achieve high quality and accessibility of additional education as a necessary condition for the likelihood of further social differentiation of society. This approach, having a political, strategic and ideological character, is recorded in the main documents of the Government of the Russian Federation, the Ministry of Education and Science of the Russian Federation.

According to the findings of V.V. Lobanov, the essential characteristics of the additional education of children, which determined its successful development in multidisciplinary extracurricular institutions, are:

– comprehensiveness, which is the focus of additional education on the education, character-building, development, enlightenment, wellness, socialization and vocational guidance of children;

– subjectivity, understood as providing children with opportunities to fulfill their individual needs, interests and needs, compensating for the insufficient variability of school education;

– self-government, understood as a variety of forms of children’s influence on the life of an educational association;

– humanism, which is organization of the educational space of an out-of-school institution, allowing children to choose the forms and level of their participation in the activities of the team.

Modern social contract, introduction of new education quality standards and financial and economic mechanisms for managing this system predetermine a significant change in the attitude to the organization of extracurricular activities for children by teachers, officials, recognizing the

importance of the work of additional education organizations, making their work important and relevant. This point was repeatedly mentioned by the President of the Russian Federation V.V. Putin both in official statements and speaking at various civil forums - the All-Russian Popular Front, the All-Russian Pedagogical Assembly, etc. It is necessary to note that it is impossible to achieve the goals set by the President of the Russian Federation and solve the designated strategic tasks without changing approaches to the formation of a new, progressive infrastructure of educational environment. This fully applies to both general and additional education.

Changing system of additional education began to offer a wide range of diverse programs designed for the widest range of children - additional programs of artistic and aesthetic, cultural, intellectually-developing, environmental orientation, programs for children with disabilities and a number of others. In 2018-2019, regions of the Russian Federation continued their efforts to create modern conditions for character-building and education in the system of general and additional education.

So, according to statistics, the share of municipal educational institutions that meet modern educational requirements amounted to 77.2% (compared to 2014 - 76.6 %) in the Tambov region. In modern conditions, when developing concepts for organizing the educational process, it is necessary to focus not on the requirements of today, but to take into account all the trends in the development of education that will require appropriate infrastructure in the future.

Today it is believed that the role of the additional education system, as the main institution of personality socialization, which can contribute to the weakening or elimination of the risks of social differentiation, will be recognized and appreciated by society in the event that every child will be able to maximize their potential, regardless of place of residence, health or material wellbeing. In this regard, one cannot ignore the positive experience of the administration of the Tambov region: the recently launched regional project “Equal rights for children to receive a quality education”, scientifically supported by the Higher School of Economics. This project has developed due to the need to support schools operating in complicated social contexts, thereby reducing the inequality of educational opportunities and differentiation in the quality of education between schools.

One of the reasons for differentiating of the quality of education in schools is the difference in the conditions of their functioning, human resources, and social characteristics of the contingent. If this situation is ignored and specially organized measures are not taken to change it, then there is a risk of a negative social effect: differentiation of schools will lead to differentiation of human capital and ultimately affect the investment attractiveness of individual territories. Of course, one cannot expect a quick change in the situation for the better, but the processes have started and now it is very important for schools not to stop, but to work systematically and purposefully to improve the quality of both general and additional education.

The system of general and additional education as full-fledged parts of the educational process can successfully integrate into each other, as it is mentioned in the fundamental documents providing for a plurality of options for every person, “in which his personal and professional self-determination is actively formed” - in the Law on Education, the Concept of Long-term Socio-Economic development for the period until 2020, the National Strategy for Children, the Concept for the Development of Additional Education, etc.

The system of institutions of additional education is controlled by municipal and regional authorities acting in accordance with federal and regional legislation. The activities of the Office of Education and Science of the Administration of the Tambov Region and the Education Committee of Tambov, as well as their subordinate organizations in recent years have been aimed at achieving goals and solving system tasks according to the decrees and instructions of the President of the Russian Federation, decisions of the heads of the Administration of the Tambov Region and the Administration of the city of Tambov. It should be emphasized that the tasks in the field of education were solved in accordance with the indicators of the socio-economic development of the region and the effectiveness of various levels of government, available potential and resources, taking into account changes in legislation in the field of education and strategic guidelines for public policy in the framework of the introduction of federal state educational standards for the new generation.

The Tambov Region Administration has created an organizational-functional model for managing the regional priority project "Accessible Additional Education for Children in the Tambov Region", which is currently functioning quite efficiently at the regional level (Fig. 1).

Fig. 1: Organizational and functional model for managing the regional priority project "Accessible Additional Education for Children in the Tambov Region"

In turn, the educational system of the city of Tambov is a developed network of educational organizations covering the following levels of general education: primary general education; basic general education; secondary general education and additional education. The municipal education system of Tambov has 35 institutions that do not only carry out educational activities, but also provide their support.

Obviously, the current educational system does not generate specific goals on its own (they are formed on the basis of external factors, ideally, a national doctrine of education, which takes into account both state and civil orders for education). Through standards, the social expectations of an individual, family, society and the state with respect to education are realized. Thus, taking the interpretation of the educational standard as a social contract, we can talk about the need to construct social norms of trust towards each other of various social, religious and national groups of the population. This is another social effect of the modernization of education, manifested as a result of increasing the openness of education, strengthening the social component in the management of educational organizations, the introduction of courses and subjects aimed at creating civic patriotism, tolerance, and peacefulness.

Often, at the level of a purely departmental approach, standards are perceived as a set of norms that determine the structure, content, results of the educational process, and the resources necessary for its implementation. But it should be noted that the social effect of the introduction of the standard is much deeper and wider. It consists in the formation of civic identity, which, in turn, is a prerequisite and condition for strengthening Russian statehood. It is the standards that act as a tool for constructing a civil (state) identity.

Indeed, new educational standards include programs aimed at creating civic, ethnocultural, and universal human identities. Considering the implementation of standards in terms of addressing organizational issues, training of personnel, logistics, the aspects of upbringing and socialization of the younger generation are often undeservedly ignored. In the new standards, qualitatively different meanings of educational activities are stated, which leads to an increase in the importance of extracurricular forms of organization of the educational process. However, no general standards for additional education were adopted in our country, and this, on the one hand, is a kind of positive point, as it allows children to be developed in accordance with regional specifics, to a greater extent find a personalized approach to a child, on the other hand, allow to properly unify the quality of the services provided. But without the implementation of the individual paradigm of personality development, it is impossible to get a harmoniously developed person, a member of society, capable of self-fulfillment in the future, to feel like a successful person and be valuable to society.

Therefore, today it is impossible to ensure a decent quality of education without attracting the resources of the additional education system. Of course, not at the same pace as in the system of general and preschool, but in additional education, significant infrastructure changes are also taking place that contribute to improving the quality and accessibility of additional programs. In accordance with the Decree of the President of the Russian Federation dated May 7, 2012 No. 599 “On measures to implement the state policy in the field of education and science,” the task was set to increase by 2020 the number of children aged 5 to 18 years studying in additional education programs up to 75 %. According to the results of a survey conducted among children and parents of the Tambov region last year, 96% of respondents are satisfied with the quality of additional education.

In the Tambov region, the integration of interdepartmental resources of education, culture and sports is actively developing: there are 417 “outreach classes” on the basis of schools, more than 30 network interdepartmental projects and initiatives are being implemented, such as “My Little Homeland” (educational tourism), “School Forestry”, “Tambov Region is the Territory of Ecological Culture” (nature conservation, ecology), “Youth Reserve” (work with leaders of the children's social movement). Today, socially oriented programs are extremely relevant, participation in which forms a sense of nationhood, legal and informational culture and tolerance among schoolchildren and students. Such programs and projects are actively implemented in the network of socially active schools, volunteer movement, and search activities. For example, last year 12 schools became participants in the All-Russian project “School of Literate Consumers” aimed at creating competent relations between members of the local community, including students and teachers, with the housing and communal services sector.

The conscious and objective choice of the future profession is also evidence of how successfully school contributes to the socialization of the individual, which is especially important for high school students. Pupils, and in particular graduates, must clearly understand not only the basics of the professions, but also how the economy of the country and the region is developing; know the priority, including high-tech industries; popular professions and specialties.

Very ambitious tasks set by the federal authorities for additional education teachers on involving children in early pre-vocational training at the level of interest groups, clubs, and study groups are being carried out quite actively today, with the annual growth rate. It has been repeatedly emphasized that the crucial importance of orienting a growing and emerging personality towards those professional areas that are in demand by the state today, is future oriented and will play a key role in the development of the country's economy. We have to admit that in the system of both general and additional education insufficient attention is paid to career guidance, in contrast to the system of vocational education. This is understandable: institutions of higher and secondary vocational education are interested in attracting applicants, so this type of work is vital for them. The time has come to change the situation in the general education system as well.

In this regard, the experience of organizing career counseling and pre-profile training for a number of constituent entities of the Russian Federation is very important, including the experience of Togliatti, in which for several years the organization of this activity has been extremely effective based on a specially developed automated information system. The expected effect of this work is to build organizational and technological ties between the school, vocational education organizations, enterprises and, as a result, students could make an informed choice of their future profession.

Particular attention in terms of socialization is required by orphans and children left without parental care. In general, in the Tambov region, a system for the prevention of social orphanhood has already been built, the development of which is ensured by:

– implementation of the project of creating a social cluster “Regional innovative system of child protection in the Tambov region”;

– reprofiling the network of orphanages into centers for family support and child care.

Another group of children that is constantly in the focus of public attention is children with disabilities and children with special needs. In 2018-2019, regions continued to create an accessible universal barrier-free environment and develop inclusive education as part of the implementation of the state program “Accessible Environment”. The organization of real, not pseudo-inclusive education is not an easy task, requiring special knowledge of school administrations and all teaching staff, and most importantly, the conscious adoption of the ideas and principles of inclusive education by all participants in the educational process, including children and parents. These principles are simple and understandable: children with health problems should receive comprehensive education, corresponding to their real capabilities, in order to live a full life. They have the right to communicate, they need support and friendship of their peers. However, the implementation of inclusive education raises many questions and problems regarding organization of such education, content of educational programs, relationship between children, and training of teachers for work with children with disabilities.

In the Tambov region, the Accessible Environment program will continue, the list of facilities for creating a barrier-free environment will include kindergartens, boarding schools and vocational schools. In each of these educational organizations, clear, well-founded plans for the organization of inclusive education should be developed, including, inter alia, work with parents and children. There is a category of disabled children who are educated at home for medical reasons. For these children, the implementation of the project “Distance Education of Disabled Children in the Tambov Region” continues, under which 161 disabled children studied at home in the academic year 2018-2019, and 145 network teachers worked with them. Along with mastering the educational program, children have the opportunity to study additional programs, they participate in contests, festivals, communicate with each other on the site and demonstrate very good learning outcomes.

In 2018, the implementation of an interesting experience of the city of Donetsk began - the new project “Live for Real”, aimed at preparing orphan graduates for independent life. During the project, participants take an interactive course to get acquainted with the basics of social project management, develop and implement their socially significant projects, and form a volunteer team for further activities. Now new projects are being implemented in the region aimed at: implementing a strategy for continuous spiritual and moral education and character-building, implementing an e-learning model, introducing a new model for vocational guidance for schoolchildren, updating school libraries turning them into information and library centers, developing a system of continuous professional growth for teachers, approbating professional standard “Teacher of additional education”. The implementation of a professional standard cannot be considered in isolation from the real activities of educators. Despite the high importance of introducing new approaches, changing the requirements for training and professional qualities of teachers, it is necessary to take into account that on average there is a leadership of 5-6 children's associations for each teacher, which indicates a sharply increased academic load on these institutions and their actual overload in the current situation. As in the general education system, aging and staff shortages are observed here, as well as an insufficient influx of young specialists.

Summing up and listing the positive aspects of the integration of additional and general education into a single educational environment, it is necessary to highlight the problems of organizing the activities of educational institutions. The activities of the Tambov Oblast administration in recent years have been aimed at solving this problems:

– insufficient level of access to quality supplementary education for children with various educational needs and opportunities (including gifted children, children from rural areas and children in difficult situations);

– insufficient level of competence of the teaching staff of the system of additional education;

– insufficient material and technical equipment of organizations for additional education of children;

– lack of competition mechanisms and lack of new approaches to the implementation of educational programs.

Despite the difficulties, primarily associated with the general problems of the development of the Russian state, the immediate prospects for the development of the system of additional education and its further integration in the modern educational environment are clearly visible:

– preservation and development of a network of organizations for additional education of children;

– updating the content of additional education;

– development of modern competencies of teaching staff;

– expansion of the private sector in the regional system of continuing education;

– participation in competitive events held by the Ministry of Education of Russia;

– attraction of extrabudgetary sources;

– formation of a system of early career guidance for children using digital technology;

– development of innovative models of continuing education (technopark, center of modern competencies).

Conclusions

The new realities of the Russian school provide for the formation of not just a creative personality, but a personality that can prove itself and achieve results in the modern world. Exploring the organizational conditions necessary for the full development of the system of additional education, we would like to note the following trends. The implementation of innovative approaches to the organization of the process of training and education in educational organizations is based on the analysis and forecasting of development trends in the system of general and additional education.

There is a departure from the management of individual elements of the educational system and the formation of the idea of the need for a unified educational system that allows you to get the planned results of professional pedagogical activity, where the child should not be perceived as the object of influence, the child in the new education system is a full-fledged subject of diverse educational activities.

Abstract

The article analyzes the state of the Russian market of audit services at the present stage; identifies the main trends of its development, summarizes the factors affecting its functioning. The author formulated directions for the development of audit based on the needs of customers of audit services, the competitiveness of audit entities and the increasing role of audit in the national financial control system. Proposals for improving audit activities will ensure the stability of the audit institution in our country.

Keywords: Audit Activity, Auditor, Financial Statements, Market of Audit Services, International Audit Standards (ISA)

Introduction

Audit, playing an important role in the national system of financial control, is at the same time a type of entrepreneurial activity, so its further development and improvement require in-depth study of the relationship between professional and entrepreneurial elements in this sector of the Russian economy. Despite the fact that the history of auditing in our country has been going on for more than thirty years, questions of the development of its theory are especially relevant at the moment in connection with the transition of Russia to the direct application of international auditing standards since 2017 and the problems encountered in their practical application. The inconsistency of the terminology in force in the legislation of the Russian Federation and international standards, the conceptual approaches to the audit methodology laid down in the ISAs, the imperfection of the self-regulation system in professional activities have caused existing problems in the development of auditing in our country and the need to solve them both from the theoretical and practical aspects.

Materials and Methods

The object of the research is the development of audit in Russia as a type of entrepreneurial activity and the field of scientific knowledge, the main problems and the most important directions for its improvement.

The subject of the research is the regulation of auditing in Russia, cause-effect relationships and the consequences of the state of the market for audit services at the present stage.

The theoretical basis of the study was the scientific development and concept presented in the works of R.Kh. Montgomery, R. Adams, J. Robertson. A. Arens, J. Lobbeck. The fundamental principles developed by these scientists are relevant at the present time and are the object of further analysis for modern researchers and specialists in the field of audit.

A significant role in the development of audit theory was made by Russian scientists K.K. Arabyan, M.A. Azarskaya, S.M. Bychkova, E.M. Gutzeit, Ya.V. Sokolov, V.Ya. Sokolov, A.D. Sheremet, V.P. Suits, etc.

A significant contribution to the field of theoretical and practical aspects of audit is made by modern research by E.V. Zubovoy, Yu.Yu. Kochineva, E.A. Lashchinina, V.F. Massaryginoy, E.L.Skvirskaya and others.

The methodological basis was the historical and logical, formal and substantial research methods. The research methodology also includes analysis, comparison, systematization and generalization of modern scientific literature on the topic of research, legislative acts in the field of accounting and auditing, international audit standards, standards in the field of accounting and financial reporting.

Research Results and Discussion

The situation in the market of audit services is largely determined by the general economic conditions in the Russian Federation. The development of audit in our country is generally characterized by negative trends. According to the Ministry of Finance of the Russian Federation, the market volume in 2018 amounted to 59.8 billion rubles. and over the past five years (2014-2018), its annual growth was from 1.8% to 5.5%, and in 2017 there was a negative trend. If we analyze the volume of audit revenue per 1 million rubles of customers' revenue, we can talk about a stable decrease in profitability in the audit market (from 313 rubles in 2014 to 276 rubles in 2018). The number of business entities in the audit market is declining annually. So, if at the beginning of 2016 there were 4400 organizations operating in the field of audit, as of 01.01.2020 only 3859 audit firms remained in the control copy of the registry. There is a high level of concentration in the audit market: Moscow and St. Petersburg account for 78% of the total volume of services rendered and 44.5% of the total number of audit organizations. Regional auditors have a much lower level of income per auditor.

The number of auditors is also steadily decreasing: from the figure of 38 thousand people at the end of the 90s of the XX century to 18826 people in January 1, 2020. The average number of specialists entering the profession is 250 people per year, which does not even compensate for the losses incurred due to leaving the profession for objective reasons (mortality and retirement). On the one hand, this indicates a decline in the prestige of the audit profession, and on the other hand, it can speak of problems in the current system of training auditors. It is possible that the new concept and procedure for conducting the qualification exam, which will be applied in our country from the second quarter of 2020, can positively affect the development and strengthening of the audit profession.

Undoubtedly, the factors that negatively affect this segment of the market include the state of the business and investment environment of the national economy as a whole, including a decrease in the

influx of new and outflow of existing customers, a decrease in the solvency of customers, and a reduction in budgets for attracting auditors and consultants. practice of holding open tenders for the procurement of audit services and price dumping. All this, ultimately, leads to a decrease or fixing at a constant level of prices for audit and consulting services.

However, in our opinion, the main factors affecting the functioning of the audit market include a low level of demand for audit services. Economic entities in most cases continue to consider mandatory audit as an excessive administrative burden imposed by the state. The low interest in audit services by the state, as one of the investors, often leads to the fact that owners and other users of financial information underestimate the value of audit services and their results. At the same time, government agencies do not take targeted actions to use the audit results to ensure the sustainable development of the financial system and the effective conduct of economic activity.

The Institute of Audit is developing in close connection with the theory and practice of accounting. In educational publications A.D. Sheremet (2014) notes that the subject of audit must be correlated with the subject of accounting. In our opinion, the development of the audit is also significantly affected by issues of the formation and presentation of financial statements, as well as modern corporate governance systems. Starting January 1, 2020, the state information resource of financial statements will be formed in the Russian Federation, the operator of which is the federal tax service. The structure of this resource, in addition to the financial statements themselves, includes an audit report regarding the mandatory audit. We believe that the effectiveness of this resource will directly depend on the quality of financial information and the reliability of the submitted statements. Despite the fact that, in October 2016, the legislation of the Russian Federation was amended to oblige to publish data on the conduct of the mandatory audit and its results on the Fedresurs website operated by Interfax, economic entities do not always comply with these requirements, as there is no liability for not posting this information. Therefore, in our opinion, the state should take measures to strengthen the administrative responsibility of economic entities for the reliability of their accounting (financial) statements, as well as evading the mandatory audit of these statements.

The publicity and accessibility of information contained in the state information resource will improve business transparency and will help reduce the risks of doing business.

A significant impact on the development of audit in Russia, in the author’s opinion, will have a change in corporate legislation from July 1, 2020 regarding the mandatory creation of audit committees that are part of the boards of directors (supervisory boards) of public joint-stock companies. One of the main activities of such a committee is interaction with the external auditor of the company, a preliminary review and assessment of its independence, the absence of a conflict of interest, an assessment of the quality of the audit of the company's financial statements by the external auditor. In the context of international standards, the audit committee refers to those responsible for corporate governance in the company. Auditing standards impose on the auditor a number of responsibilities for active interaction with the audit committee, with the aim of monitoring the implementation of the policy of public companies, which determines the principles for the provision and combination by the external auditor of the company of audit and non-audit services to the company. The application in Russia of the best world practices in the field of interaction between external auditors and audit committees will ensure the confidence of shareholders, as the main users of the audit report, the independence and quality of audit services. In addition, this practice can also be used by non-public joint-stock companies and other economic entities.

A limited range of services offered by audit organizations also has a negative impact on audit development. In our opinion, the functioning of the market for audit services is associated with the need to clarify the subject and scope of audit activities. For a long time, the development of this market segment in Russia was associated with a mandatory audit and the provision of consulting services in the field of accounting and taxation. According to the Ministry of Finance of the Russian Federation, 50% of revenues come from the mandatory audit of financial statements, almost 44% are consulting and only 6% are related services. Most of the tasks performed by auditors are associated with the audit of annual financial statements, the results of which give reasonable assurance of the

reliability of historical financial information. This understanding of the audit proceeded from the definition of the term "audit" is reflected in the law "On Auditing". However, in December 2014, lawmakers changed the definition of an audit to include "other financial information" as an audit object. It should be noted that the new wording did not lead to an actual expansion of the types of audit tasks performed in practice, since the concept of "other financial information" is too vague, and the implementation of audit services was regulated by federal audit standards that consider only audit of financial statements. An attempt to differentiate audit services in the absence of a methodology for their implementation and clear terminology in the legislation could not have a positive effect on the development of audit in our country.

From the point of view of K.K. Arabyan (2017) "the problem of the subject of audit is particularly acute in the audit activity and gives rise to numerous interpretations in terminology, the emergence of new types of audit, the subject field of which is also not clearly identified." The need to develop scientifically based approaches to the definition of audit was previously considered in the works of E.M. Gutzeita (2002), M.A. Azarsky (2009).

The current Russian law on auditing indicates that the types of audit and related services are established by the authorized federal body regulating audit activities. This list was approved by the Ministry of Finance of the Russian Federation three years later (in 2017), however, as the study shows, its adoption did not significantly affect the development and size of the audit services market in 2018-2019.

The recognition on the territory of the Russian Federation of international audit standards has further aggravated the problem of determining the composition of audit services, since the classification of these standards actually establishes the types of audit services. However, the list of services approved by order of the Ministry of Finance of the Russian Federation and the classification of audit and related services based on standards are not unified.

Undoubtedly, the development of audit activity is connected, first of all, with permanently changing information needs of users of audit services, and only, secondarily, depends on changes in legislation. However, the ambiguous formulations of the current Russian law on auditing undoubtedly hamper the development of this segment of the economy. In this regard, the author believes that the norms of the law on audit activities should be changed and the terminology regarding the definition of the nature of the audit and types of audit services brought into line with the provisions of international audit standards.

It is relevant to expand the subject of audit activity by completing tasks that provide limited confidence. Over the past six years, such services have been provided in the form of conducting reviews of interim consolidated financial statements of organizations prepared in accordance with international financial reporting standards. However, with regard to interim reporting prepared in accordance with Russian standards, such checks are practically not carried out. Users of such interim reporting most often use data not confirmed by the auditor, which increases their risk when making economic decisions. In our opinion, one of the tasks of professional organizations of auditors is to educate and inform the business community and users of audit services, aimed at improving the reliability and quality of financial information used in making business decisions.

The diversification of services provided by audit organizations can be carried out, in particular, by expanding the practice of completing tasks that provide reasonable or limited assurance regarding the reporting or its part containing financial information systematized according to special rules. We believe that such services may be in demand by economic entities in relation to tax reporting, including small businesses.

The expansion of the subject of audit activity may be related to the provision of services related to the confirmation of forward-looking financial information (business projects) and non-financial information. In recent years, outsourcing of accounting has become more widespread in our country.

Users of accounting services must be sure that their quality can be ensured only if the organization and effective functioning of the internal control systems of the accounting services provider are properly organized. The auditor's opinion regarding the controls of accounting companies may be provided as a result of the provision of services in relation to non-financial information. However, as the study shows, at the moment, audit tasks regarding the confirmation of non-financial information are practically not found.

The Ministry of Finance of the Russian Federation, as priority areas for the development of audit activities for the period up to 2024, also considers issues of improving the practice of auditors performing additional work during the mandatory audit of socially important organizations, in particular, checking statements of the management of such organizations on the effectiveness of risks and internal control management systems created and supported by them (based on normatively established criteria for such systems), checking the compliance of the activities of such organizations with their strategic documents (2019).

The basis of the institutional structure of the audit profession in most countries is its self-regulation. In the Russian Federation, the legislative obligation for the membership of audit entities in a self-regulatory organization of auditors arose after the adoption of the law of 30.12.2008 No. 307-FZ “On Auditing Activities”. Initially, 6 professional audit associations were created in Russia, but by 2017 their number had dropped to two. However, their activity, as practice has shown, was more focused on solving narrow corporate issues and tasks that did not have public significance. The main problems of the industry - the decline in the prestige of the profession, unfair competition, dumping and, as a result, poor quality of services, have not been resolved by the professional community.

Given the foreign experience and international obligations of the Russian Federation, the activities of this institute, in our opinion, should be focused on conducting research in the field of auditing and developing methodological materials aimed at improving the quality and effectiveness of audit services.

At the end of 2019, the country sharply raised the question of completing the process of consolidating the audit profession and creating a unified self-regulatory organization of auditors, which was supported by the Ministry of Finance of the Russian Federation and the largest 30 audit companies. It is difficult to predict what effect this situation will have on the further development of the market for audit services, given that at present more than 90% of audit organizations are small businesses.

One of the directions for the development of audit is the harmonization of the legislation of the Russian Federation with the unified principles for conducting audit activities in the territory of the Eurasian Economic Union (EAEU). At present, audit companies resident in the Russian Federation cannot provide audit services to economic entities registered in other countries of the former Soviet Union. This is due to different legislative requirements in force in these countries. If we analyze the practice of the European Union, it can be noted that directives have been adopted in the EU that establish uniform requirements for mandatory audit for EU member states. We believe that this practice can also be used in the EAEU, given that the preparation of a draft audit agreement has been completed, according to which it is assumed that from 2022 a single market for audit services in the EAEU will begin to function. To this end, over the next two years, the legislation of the EAEU Member States should be brought into line with this agreement. Removing barriers and restrictions on access to national audit services markets will undoubtedly have a positive effect on audit development in Russia. In addition, it is necessary to establish effective information exchange and cooperation between the auditing regulators of the EAEU member states, bodies supervising audit organizations and professional auditor institutes. This will contribute to improving the quality of audit services and the competitiveness of Russian audit companies.

Conclusion

The research shows that improving the fundamentals of the functioning of the market for audit services is associated with the implementation of a set of measures aimed at further developing the system of regulation of audit, supervision and responsibility in the field of preparing financial information. The recognition of international audit standards in Russia is, of course, an important step in the development of audit theory and practice, but does not solve all existing problems of the industry. The need to amend Russian legislation to clarify the conceptual framework and terminology, as well as the consolidation of the professional community within a single self-regulatory organization of auditors, are just the first step to solve existing problems in the industry.

Abstract

The paper deals with the issues of adaptation of first-year students to the conditions of higher education, socialization of students, the process of formation of a new system of values. It studies the process of adaptation of first-year students to the changes they face in the new social environment, development of a new strategy of behavior.

Keywords: Adaptation, Maladaptation, Adaptability, Maladaptivity, Adaptation of A First-Year Student at A University.

Introduction

The most important psychological task in working with first-year students is an active work of a psychologist and teachers, which is aimed at successfully adapting to the new system of education, to the new social status, social conditions. We can say that for a first-year student adaptation is a process of socialization. The process of socialization of children is a period of change in their lives, it is a process of assimilation and acquisition of new skills necessary for interaction within a new social role, which implies a range of certain adaptive situations that affect elements of a personal structure of a first-year student.

In this period the forming of a personality, getting aware of “self”, which is accompanied by feelings and finding the meaning of life take place.

Research Methods

The research was conducted by the teacher in collaboration with first-year students. This problem was studied on the basis of Chuvash state agricultural Academy, which provides access to open information resources. The objects of the study were first-year students of the faculty of Economics. In the course of the study, widely tested reliable methods of dialectics, analysis, synthesis and analogy were used. To solve analytical problems we used the following methods: comparisons,

analytical groupings and so on. The information received was processed by use of WORD and Microsoft Excel.

Research Results and Discussion

First-year students have life difficulties that can be attributed to: the level of claims to their social status, the discrepancy in communication styles that they face in higher school communicating with teachers and in the family communicating with parents, the contradictions associated with the fact that on the one hand there is a desire to be independent on the other hand the opinion of peers still remains important.

Therefore, a survey is conducted among first-year students, which is of practical value as it is necessary to develop strategies for higher school employees behavior for successful adaptation of first-year students.

According to Nikitin E. P., Kharlamenkova N. E. social adaptation is understood as a system of techniques and methods aimed at providing social support to people during their socialization or adaptation to new social conditions, in connection with changes in social status, life losses and failures as well as to unadapted individuals [1]. This concept fully reflects the process of adaptation of first-year students to the conditions of socialization in a higher educational institution, because the social environment into which a freshman gets is somewhat different from that in which he dwelt earlier in school, where he was a senior and had a higher status by age; getting into walls of higher institution he becomes a freshman almost like " the first time in first class ".

There are authors who consider social adaptation in two ways: on the one hand it is a process of integration of the subject into society and on the other hand they consider it as a result of this process [2]. Many authors who are engaged in studying the phenomenon note certain features of social adaptation: connection with the social environment, which is expressed in relationship of an individual with the environment, awareness of the need for adaptation by an individual himself which is aimed at entering an individual into a new group [3, 4-7]. Therefore, the socio-psychological adaptation of a first-year student can be understood as a process of an individual's entry into the system of social and psychological connections within the framework of emerging relationships in a new social environment.

Along with the concept of adaptation, most authors also distinguish maladaptation, which includes a loss of previously existing adaptation in a familiar environment. Exclusion is manifested in the form of dissatisfaction with the situation in which an individual is accompanied by anxiety and may be accompanied by violations of somatic health (F. B. Berezin, 1988; J. A. Alexander, 1991).

In the process of adaptation first-year students, according to T. A. Babakova, face the following problems:

- lack of free time;
- large amount of work, not convenient schedule;
- insufficient attention on the part of the Dean, curators;
- inability to organize oneself, lack of finance;
- lack of familiar circle of friends;
- lack of opportunity to choose an activity to one`s liking, an interesting occupation;
- negative sanitary conditions;
- difficulties in getting used to a new environment, to new people.

The main difficulties for first-year students are also related to the transition from the school system (lessons) to the university system (lectures). This transition assumes the presence of specific skills (quick note-taking, independent search for necessary information), without which a first-year student does not have enough free time [3, p. 32].

One of the probable ways of success of adaptation process is to solve the problems of productivity and quality of the educational process during the period of first-year students adaptation. The special role of educational process is also in the fact that teaching, being a reflective and transformative activity, is aimed not only at perception of the necessary material, but also at forming the first-year students` attitude to the educational and cognitive activity itself [3, p. 39].

But at the same time, educational process by itself even at the highest level of its organization, cannot ensure proper adaptation of students to the characteristic study conditions of higher education[4, p. 102].

A significant role in adaptation of students is assigned to the curators of the groups. From the first days of study at a university it is a curator who organizes work to establish a favorable socio-psychological climate in student groups. In most cases the success of student socialization is directly dependent on the nature of relationship between students. The systematic work of curators with first-year students is aimed at:

- study of individual psychological characteristics of an individual;
- assistance to students in adapting to a university;
- raising their cultural level;
- promoting students ' self-development;
- good performance of a group.

Student curatorship undoubtedly has certain advantages and can become one of the ways to ensure an educational resource of a university, which is expressed in the following functionality:

- integration of students into the corporate culture of a university;
- informing about legal acts and events in an institution;
- team building activities;
- assistance in self-organization of studying;
- assistance in planning and organizing time.

Student curatorial projects are mainly aimed at facilitating of first-year students adaptation to their new environment. And with proper careful support from the structure that carries out an educational function in a higher institution this version of curatorship, of course, allows to achieve positive results.

Psychological support of first-year students plays a special role in the success of adaptation. So, in order to create a favorable climate among students, it is advisable to conduct a variety of psychological trainings, where young people through simple games get to know each other better, learn to communicate, find a common language with classmates and older young people. Goodwill and attention of all participants help to reduce time of adaptation to the conditions of a university.

Conclusion

Thus, adaptation and non-adaptation reflects compliance or non-compliance of a certain set of goals that are achieved by an individual in the process of socialization of a first-year student to the new conditions of studying at a university. At the same time, adaptability is expressed in coordination of actions of a first - year student and a team and maladaptivity - in its mismatch.

Therefore, the main goal of psychologists and teachers is to build a system of complex interaction measures to adapt first-year students to the conditions of study at a university. To do this they must:

- surround students with care starting from the first day of study at a university as it is important that a first-year student joins the new reality in the walls of an educational institution as painlessly as possible;
- identify a student's aptitudes and trends that should be sought in the process of studying at a university – to prepare a first-year student for the first midterm examination session.

Abstract

Russia's transition to market relations has revealed the need to create new economic institutions that regulate the relationships between various business entities. Among them one of the leading places should belong to auditing whose main goal is to ensure control over the accuracy of the information reflected in the accounting (financial) statements. Data on the use of property, cash, commercial transactions and investments from economic entities can be objectively confirmed by an independent auditor. The analysis of practice and theoretical provisions indicate the need to create an effective system of civil law regulation of activities in the provision of audit services at the present stage. It is important to identify the features of the audit services agreement and determine its place in the system of Russian civil law contracts. All of the above determines the choice of the research topic, its relevance and significance from the point of view of theory, legislation and the practice of its application.

Keywords: Contractual Obligation, Audit Services, Principles and Norms of Audit.

Introduction

The most common and diverse type of civil legal relationship is an obligation. Obligations are important to ensure the normal functioning of commercial organizations; the rules governing them form the most important section of civil law - liability law. Russian civil law defines an obligation as a legal relationship by virtue of which one person (debtor) is obliged to perform a certain action in favor of another person (creditor) (for example, transfer property, perform work, provide a service) or refrain from a specific action, and the creditor has the right to demand from the debtor the performance of his duties.

The basis for the occurrence of obligatory legal relations between the auditor and his client is the contract. But in the current legislation there is no definition of contracts for the provision of audit services. Therefore, to determine the legal nature of such an agreement it is necessary to consider the general provisions on the paid services contract and determine the specifics of audit services.

Materials and Methods

The bulk of the total number of civil liabilities falls on obligations under transactions involving legal liabilities. Domestic legislation classifies the following as equivalent objects of civil rights: things, other property, intellectual property and intangible goods, the results of work and the provision of services.

Obligatory legal relations, in contrast to property relations, are characterized by the following features:

• circle of associates - legal relations connect only a certain creditor with a certain debtor, that is, an unlimited circle of persons is excluded;
• subject - the subject of legal relations is not the thing, but the actions of the obligated person;
• special expression of rights and obligations - legal relations presuppose the existence of a right – claim and an obligation – duty;
• special ways to protect violated rights - a claim for damages, payment of a forfeit and the performance of an obligation in kind;
• activity of the parties - the debtor is the active party to the legal relationship - the party opposing the other endowed with the right (the creditor).

From a legal point of view the provision of services differs significantly from the performance of work. In the theory of civil law the ratio of works and services was determined through their differentiation from each other on the basis of the presence or absence of a tangible material result of the activities of the obligated person (the idea of Roman private law). The legislation determines that activities involving the creation of a result and transferring it to the customer are the object of obligations to perform work, but if the object of the obligation is the activity of the contractor itself then such activity is the provision of services.

According to Section 779 of the Civil Code of the Russian Federation, under a paid services contract the contractor undertakes to provide the services (to perform certain actions or carry out certain activities) upon the instructions of the customer, and the customer shall pay for these services. The application of the rules of the paid services contract includes contracts for the provision of audit services.

In the theory of civil law they usually distinguish 4 (four) constituent elements of the obligatory legal relations:

1) the object of the obligation;
2) the subjects of the obligation;
3) the content of the obligation;
4) the legal fact.

We shall describe these elements in relation to the contract for the provision of audit services. The object of the obligation to provide audit services is the audit services themselves. The subjects of the obligation to provide audit services are the auditor (debtor) and the customer (creditor), and the content of the obligation to provide audit services consists of a set of verification actions to study the financial and economic activities of the customer and issue him a specific document (for example, during audit reporting - audit conclusion). The legal fact provides the basis for the occurrence of the obligation, namely the concluded contract for the provision of audit services.

Research Results and Discussion

The legal experience in regulating audit activities in foreign legislation has a long history. Hence, it becomes necessary to study all the positive aspects in this area. The development of the Russian audit was influenced by many factors of a political, economic, social, legal and professional nature. Mostly it developed “vertically” (as an audit activity), in contrast to the countries of the Anglo-Saxon system of law and European countries in which financial control (audit) developed mainly “horizontally”.

However in recent years in Russia some work has been done to establish the institution of auditing. The adopted Federal Law "On Auditing" and other regulatory legal acts confirm the final formation of the Russian audit system and open up prospects for its further development. Today it can be stated with confidence that the regulation of audit activities is focused on international requirements since audit services are carried out in accordance with International Standards on Auditing.

Any entrepreneurial activity has common features enshrined in civil law. We shall consider these features on the example of audit activities.

Firstly, it is an independent activity. This feature means that no one can force the auditor to conclude an audit services agreement since the desire comes from the client (customer).

Secondly, the activity is carried out at your own risk and is aimed at making profit. This means that the audit services are fee-based in nature, but there is always the possibility that the auditor will incur a loss from his professional activities in connection with the presentation of claims by interested users of the accounting (financial) statements.

And thirdly, this is an activity carried out by persons registered in the manner prescribed by law. The legislation clearly articulates the range of entities that can carry out audit activities, and the conditions for doing business. So, this business is available to individuals and legal entities. Moreover, an individual must meet certain criteria, confirm their qualifications by passing the exam and obtaining the qualification certificate of an auditor. In addition, for individual auditors and audit organizations mandatory membership is provided in one of the self-regulatory organizations of auditors, where there are certain requirements for membership. Among the conditions for doing business it can be noted that subjects acquire the right to engage in audit activities from the date when information about them is entered in the register of auditors and audit organizations of the self-regulatory organization of auditors. In addition, the audit legislation does not allow any other entrepreneurial activity, except for conducting an audit and the provision of a certain type of service (services related to the audit, other services related to the audit activity).

For professions that are characterized by increased responsibility to society and certain specific manifestations of this responsibility, their own ethics of professional behavior are formed. For example, it has long been known about medical (medical) ethics, where the basic principles were formulated by Hippocrates. The oath of Hippocrates pronounced by doctors upon receipt of the document on education carries the fundamental moral and ethical principles of the their behavior.

The profession of an auditor is no exception. The activities of the auditor can be compared to some extent with the work of a doctor. In contrast to the latter, the object of the auditor's beneficial effect is not a person, but an economic entity (client organization).

The International Federation of Accountants (IFAC) has developed a Code of Ethics for Professional Accountants, which is used by professional associations of accountants and auditors from different countries to create national codes. In practice public professional organizations develop codes of professional ethics for auditors in great detail and scrupulously trying to foresee all the possible nuances of their behavior.

According to Russian audit legislation, the code of professional ethics of auditors is a set of rules of conduct that are mandatory for audit organizations and auditors to comply with when conducting audit activities. In any case the Code of Professional Ethics of Auditors revised and adopted in June 2019 is intended to maintain the high reputation of this profession and its moral image.

The analysis of theoretical principles and practice allows to compare the principles of audit activity with the principles of civil law, which in turn are reflected in the contract for the provision of audit services.

The most important principle in auditing is independence. When providing professional services the auditor should be independent of the audited entities and of any third parties, that is the auditor when forming an independent opinion should have no financial, property, family or any other interest in the affairs of the audited entity. Independence refers to:

• independence of thinking is a way of thinking that allows the auditor to make a judgment that does not depend on the influence of external factors and to act in good faith and objectively based on knowledge of the law;
• independence of conduct is the avoidance of such facts or circumstances when third parties could reasonably call into question the decency, objectivity of the auditor.

The independence of the auditor should be ensured both on formal grounds and in terms of factual circumstances. The principle of independence is implemented by audit legislation by establishing restrictions on the conduct of audit.

The principle of independence in auditing is closest to the principle of civil law on the inadmissibility of arbitrary interference in private affairs. The legislation provides a general focus on the maintenance and protection of private interests, which is expressed in the prohibition of state authorities and local self-government, as well as other, third parties, in any way interfering in the private affairs of participants in civil relations.

The next important principle in auditing is confidentiality. Confidentiality is the duty of auditors to ensure the safety of documents received or compiled by them during the audit, not to transfer these documents or their copies to any third parties and not to disclose the information contained in them without the consent of the person to whom the services were provided, except stipulated by Russian law. Respect for the principle of confidentiality remains valid even after the end of the relationship between the auditor and the audited entity or auditor and his employer, that is, without a time limit. In audit law, this requirement is referred to as audit secrets.

The principle of confidentiality has common features with the civil principle of non-abuse of civil rights. Most modern scholars consider the category of “abuse of law” based on the ideas of V.P. Gribanov. The essence of these ideas is as follows: abuse of the right is a special type of civil offense committed by an authorized person in the exercise of his right related to the use of unauthorized specific forms within the framework of a general type of behavior permitted by law.

In carrying out his professional duties the auditor should be guided by the principles of professional ethics of auditors. Among these principles can be noted honesty, objectivity, professional competence and integrity, professional behavior.

Honesty is an obligatory commitment of the auditor to professional duty and adherence to general moral standards. In providing professional services the auditor must act openly and honestly. Honesty means not only truthfulness but also impartiality and reliability.

Objectivity is the obligation of impartiality and resistance to any influence when considering professional issues and forming judgments and conclusions. The auditor must be fair, his objectivity should not be influenced by prejudice, bias, conflict of interest, other persons or other factors.

Professional competence and integrity. Competence is the compulsory possession of the necessary amount of knowledge and skills that allows the auditor to provide professional services in a qualified and high-quality manner. The audit organization should attract trained, professionally competent specialists and monitor the quality of their work to ensure qualified audit. Auditors should not provide services that go beyond professional competence and the limits of their authority. The auditor provides professional services with due care and diligence. His duties include the constant maintenance of professional knowledge and skills at a high level so that audited individuals or employers can take advantage of competent professional services based on the latest developments of practice, legislation and technology. Auditors should not exaggerate their knowledge and experience. Consequently, the auditor must approach in good faith in the performance of his professional duties.

In the framework of civil law, the term "good faith" does not have an official definition, but it can be found in the norms of individual sections. When considering the general principle of good faith in the exercise of subjective civil rights and the performance of duties, the content of the category in question can be determined only through ethical and moral components. Here, honesty is diligence and the necessary prudence of the subject of civil circulation. The principle of good faith can be compared with the civil law principle of the actual fulfillment of an obligation, which includes the execution by the proper entities, in the right place, at the right time, with the proper subject and in the proper manner.

Professionalism is the duty of auditors to comply with Russian law, to refrain from committing acts incompatible with the provision of audit services, and to avoid any actions that may discredit the profession or may reduce the respect and trust in the profession of an auditor, and damage its public image. The auditor must act in such a way that it is consistent with the good reputation of the profession. When offering and promoting his candidacy and services the auditor should not make statements that exaggerate the level of services that he can provide, his qualifications and experience gained, or give scornful comments about the work of other auditors or make unreasonable comparisons of his work with the work of other auditors.

The principle of professional conduct in audit can be compared with the method of permissible orientation of civil regulation. This method contributes to the development of a modern market economy by supporting initiative, enterprise, freedom of action and any form of activity in the realm of civil circulation. Moreover, this principle like all norms of civil law is based on the following general rule: "everything is allowed that is not prohibited by law and does not detract from the rights, freedoms and interests of other parties to legal relations".

Table 1: Comparison of the principles of audit and civil law

Audit Law	**Civil Law**
Independence	Inadmissibility of arbitrary interference in private affairs
Audit secrets	Inadmissibility of abuse of civil rights
Good faith	Proper performance of an obligation (subject, place, time, etc.)
Professional behavior	The principle of permissive orientation

We would like to draw particular attention to the observance by the auditor of the principle of professional skepticism since there may be circumstances that can substantially distort the accounting (financial) statements. Professional skepticism means that the auditor should question the accuracy of the statements if the audit evidence obtained contradicts the documents or statements of management. At the same time the auditor should not think that the management of the audited entity is dishonest but should not assume the unconditional honesty of the management.

Conclusion

The study showed that the main document governing the relationship between the customer (client) and the contractor (auditor) is the contract for the provision of audit services. The contract for independent verification (audit) has the following features:

1) the essence of the obligation - the commission of certain actions or certain activities;
2) the result of the fulfillment of an obligation - the result cannot exist separately from the contractor, its material form is missing (intangible nature);
3) the existence of a right to a result - the customer does not have a property right to the result.

Within the framework of the concluded contract for the provision of audit services the auditor is responsible not only to the individual client but also to other interested users of the statements. Acting in the public interest the auditor must comply with certain principles and norms of the audit as well as obey the requirements of professional ethics. The ethics of professional conduct of auditors determines the moral values that are affirmed by the audit community ready to protect them from all possible violations and encroachments. Therefore, there is an objective need to maintain in public opinion respect and trust in the profession of an auditor.

Abstract

In modern economic conditions, the formation of a favorable socio-psychological climate in the organization is one of the key conditions for its effective functioning. The authors considered the content and structure of the socio-psychological climate of the organization. Particular attention is paid to the consideration of factors that determine the degree of favorable climate in the organization. Using a number of methods for assessing the socio-psychological climate, the authors assessed the interests of the employees of the organization, the emotional, cognitive and behavioral components of the team under study. The assessment made it possible to generally assess the socio-psychological climate as favorable and highlight individual negative manifestations in the work of the team, as well as the factors that determine this condition. The following recommendations are formulated in the article to improve the socio-psychological climate in the organization's team, including the adjustment of the motivation and incentive system; effective allocation of responsibilities; work with a leader in informal groups; permanent diagnosis of existing relationships. Implementation of the proposed recommendations on the formation of a favorable socio-psychological climate will allow the team to maintain an even more friendly and productive atmosphere.

Keywords: Human Resource Management, Socio-Psychological Climate, Assessment Of The Socio-Psychological Climate.

Introduction

Currently, the effectiveness of the team depends not only on technical conditions, but also on the level of group development, the state of interpersonal relations, as well as the cohesion of its members. Each person is part of the team in which he is a member and influences his psychological climate.

Most authors who consider theories and approaches to determine the socio-psychological climate believe that the formation of a favorable socio-psychological climate in the team is a necessary

condition not only for the effective work of the organization, but also for the formation of self-sufficiency of a person, his success. These factors largely affect the work of an employee, since labor productivity depends on the interaction of a person with a team. Therefore, the socio-psychological climate is a key factor in both the professional and personal development of not only the individual, but also the organization as a whole.

The most relevant is the study and assessment of factors that have a key impact on the formation of the socio-psychological climate of the team with the goal of improving it (Figure 1).

Figure 1 - Factors that influence the formation of the socio-psychological climate of the team.

The structure of the socio-psychological climate is quite broad and diverse, it contains two main components: the attitude of employees to work and the attitude of employees to each other. In addition, the structure covers various aspects of employee relationships in the organization. Also, the structural components of the socio-psychological climate are closely related to its indicators, which are manifested in employee satisfaction with their colleagues, the process and results of work, and mood in the group.

Methods

The object of the study is the socio-psychological climate of the organization, which is engaged in the cultivation of cereals, legumes and oilseeds, and sugar beets, wholesale and retail trade.

The subject of the study is the managerial decisions made by the organization's leadership to create a favorable socio-psychological climate.

The methodological basis of the study was a systematic approach to considering the problems of creating a favorable socio-psychological climate in an organization, in which the socio-psychological climate is considered as a result of the influence of a system of factors of external and internal order.

The methodological basis of the study and the formulation of recommendations on the formation of a favorable socio-psychological climate are the results of its assessment and identification of factors that determine the presence of negative manifestations in the organization.

To analyze the socio-psychological climate, the staff was selected, the number of which is 32 people. A survey was conducted and the characteristics of respondents by age category and length of service were compiled, that are presented in table 1.

Table 1: distribution of employees by age category and length of service

Department	Position	Age, years	Work experience, years
1	2	3	4
Administration	General director	50	5
HR service and accounting	Head of human resources and accounting	51	11
	Chief Accountant	49	4,5
	Human Resources Specialist	37	1
	Accountant	52	21
Average		**47,25**	**37,5**
Agronomic. Service	Chief Agronomist	53	4
	Teller	58	18
Average		**55,5**	**11**
Engineering Service	Engineer	60	21
Warehouses	Warehouse manager	51	21
	Weigher	51	11
	Worker 1	40	1
	Worker 2	50	1
	Worker 3	57	21
	Worker 4	28	5
	Worker 5	61	1
Average		**48,3**	**11,7**
Machine workshop	Head of Machine workshop	54	1
	Electric welder	57	5
	Watchman	41	1
	Electrician	59	21
Average		**52,8**	**7**
Machine operators	Tractor driver 1	44	18
	Tractor driver 2	53	10
	Tractor driver 3	48	15
	Tractor driver 4	50	18
	Tractor driver 5	58	14
	Tractor driver 6	56	5
	Tractor driver 7	52	5
	Driver 1	38	21
	Driver 2	60	21
	Driver 3	27	9
Average		**48,6**	**13,6**

	Cook 2	55	17
Average		**55**	**19**
Vet service	Veterinarian	45	18
Organization average		**50,55**	**17,5**

To analyze the state of the socio-psychological climate in the organization, the authors used: the methodology of O. Nemov, the express methodology for assessing the socio-psychological climate in the workforce - a personnel book, the 'Express Methodology' for studying the socio-psychological climate in the workforce by O. Mikhalyuk and A. Shalyto, the methodology for determining the socio-psychological climate in the group by L. Lutoshkin.

Results and Discussion

As a result of the survey that used the methods specified in the methodological base of the study, the authors obtained the following conclusions.

Firstly, it was revealed that the organization's team has similar interests, since the personnel are in approximately the same age category.

Secondly, the emotional component of this collective is more likely favorable than uncertain. Such an assessment indicates that employees are more satisfied with each other and the emotional state of the group, most consider their team friendly and understanding. At the same time, one can say about certain instability in these judgments, i.e. team members believe that everything depends on the specific conditions and situation.

Thirdly, the results of systematizing the assessments obtained indicate that the cognitive component of the team can be called contradictory, unstable, some employees find it difficult to characterize each other's business or personal qualities, while others, on the contrary, are confident that they are well aware of the qualities of colleagues, can give them appreciation and know the qualities of a friend.

Fourth, the results of processing the questionnaire data obtained during the survey showed that the behavioral component of this team can also be classified as unstable, since most of the employees are not ready to meet with colleagues after hours or are indifferent to this, but at the same time it is interesting for the employees to know about the personal lives of colleagues.

The result of processing the data obtained as a result of applying the methods of L. Lutoshkin showed a result of 7 points. This result suggests that the climate in the study team is not the most favorable, but not openly hostile. Employees consider their team as a whole quite good, but, meanwhile, the team does not have a special friendship between employees.

The results of a survey of team members allow us to draw the following conclusions: the relations of department employees go beyond purely business, employees have known each other for a long time, quickly find a common language, and correctly evaluate the fairness of incentives. Conflicts in the team happen, but are resolved promptly and without consequences. Workers care about the reputation and status of the organization, and personal interests tend to subordinate to the interests of the team.

Answering the questionnaire, the department staff noted that they are well aware of the positive and negative aspects of the team's work, but, mutually complementing each other and interacting, strive to achieve great success in their work.

Workers spend their leisure time in different ways, but there is something that unites them - love for children, for flowers, needlework (there are almost only women in the team), and for car repairs in men. The team is distinguished by a respectful attitude not only to each other, but also to representatives of other units.

It can be concluded that in the analysis of the socio-psychological climate, evaluating the productivity of the organization and studying their relationship, it was found that the generally friendly atmosphere in the group, workers' tolerance for each other and a number of other factors contribute to the high performance of the department, which shows the great importance of a favorable socio-psychological climate and its direct impact on the effectiveness of the team.

Despite the favorable socio-psychological climate, the department has a number of the following problems:

1) although the employees work together quite successfully, they do not know and understand each other well enough;

2) conflicts that arise mainly on business issues are not often resolved to the end, employees harbor resentment and tension remains between some team members;

3) the team is indifferent to various joint activities;

4) inconclusive adaptation of new department employees to the work and team.

Recommendations

Having studied the data obtained in the course of the study, the authors formulated the following recommendations for improving the socio-psychological climate in the team of the studied organization.

When developing these recommendations, the authors took into account that improving the socio-psychological climate in the organization involves the development and practical implementation of a set of measures of a technical, economic and organizational nature. Moreover, most of these recommendations should be aimed not at eliminating the negative manifestations of an unfavorable socio-psychological climate in the organization, but at creating conditions for adjusting the influence of factors of the macro and microenvironment of the organization, improving the content and nature of labor. The important aspect is that the implementation of recommendations should be carried out taking into account the personal characteristics of all employees, which is one of the important factors.

The next aspect, which must be taken into account when creating a favorable socio-psychological climate, is a high differentiation of estimates of the prevailing parameters of the socio-psychological climate by subdivisions, categories of employees and evaluation parameters for the degree of unfavorableness.

In general terms, all the proposed recommendations should be grouped into areas whose content is determined by the composition of the factors determining the negative impact on the staff and determining the adverse nature of the socio-psychological climate in the organization (Figure 2).

Figure 2 – Directions for improving the socio-psychological climate in the organization.

Firstly, one of the conditions for improving the socio-psychological climate in the team is an effective system of motivation and stimulation. Particular attention must be paid to the relevance of the incentive system to the needs of employees. Particular attention should be paid to the creation of favorable working conditions, as well as to the formation of the career path of employees in the

overall value system of the organization. It is necessary to encourage all manifestations of employee activity in the field of training, retraining, training and self-education.

Secondly, it should be noted that for the effective distribution of responsibilities the manager needs to understand that the motives of all employees are different. This should be taken into account not only in the formation of a system of motivation and stimulation, but also in the formation of a collective and teams. This should be carried out taking into account the needs of the individual in communication and taking into account individual characteristics.

Thirdly, it is necessary to highlight the leader in the informal group, to identify the direction of the leader. It is necessary to identify an informal leader in the team with the aim of delegating authority, attracting him to arranging the events to improve the socio-psychological climate in the team. Identification of leadership qualities can be accomplished using the methodology “Leadership Ability” by R. Nemov. Then the level of development of the group and the causes of conflicts in the group should be determined and socio-psychological methods for their constructive resolution should be applied.

Fourth, it is necessary to diagnose the existing relationships using questionnaires and observation, to develop communication and empathy skills. For the development of empathy skills, you can use the book of F. Burnard "Training counseling skills."

To overcome the isolation of colleagues will also allow the use of methods of democratic leadership style. The most effective tool for this can be the organization of self-government days. This will unite workers under the pretext of a common goal, help to show them their hidden abilities and talents, which in the future can be useful in work. This will make it necessary for interpersonal communication of trainers, where their personal qualities will begin to appear, isolation should gradually be reduced to zero. But in this case, a person is needed who can soberly assess the situation and prevent possible conflicts, since the disclosure of characters can entail the manifestation of not only positive traits of workers, but also provoke the development of direct clashes or internal tension. This person may be the director of the organization, but he should only fulfill the role of a consultant and take managerial functions on the day of self-government, otherwise this event may lose its meaning.

To rally employees in the teams of the organization in which problems were identified, it is recommended to conduct team building - a set of measures that are aimed at creating and rallying a team, which includes various methods and techniques of rallying a team, such as team sports games and events, creative events, active trainings focused on teamwork, quest.

Holding team meetings will allow for the exchange of experience in overcoming unpleasant situations and stress management, which suggests the following:

- the opportunity to ask for advice;

- specify the goals and objectives;

- identify the needs of the target group to provide the most effective assistance that brings satisfaction to employees;

- conduct trainings on relaxation and increase stress tolerance;

- assess their own needs.

It is necessary to note the success of each employee in accordance with his expectations. Gratitude and various letters will be pleasant to the older generation, praise and recognition to young employees.

Next, you should turn to the problems associated with the value orientations of the leader, their assessment by members of the labor collective and the impact on the socio-psychological climate in the organization. The main problem is the distorted perception by employees of the manager’s value orientations, due to his short term in the organization. Employees believe that the number of the most significant values for the leader includes his personal interests and material benefits, but a survey of the leader showed that these values are not priority. In this situation, the most appropriate solution would be to expand personal contacts with employees in order to meet each other, during which the

opinion of the work collective should change and distortions in the perception of the image of the leader will be leveled. This will be possible in a democratized leadership style, where open discussion of issues and frequent face-to-face meetings are appropriate. Also, employees negatively relate to the manifestation of such a value orientation of the leader as creativity, expressed in his intervention in the work of the team. This problem is connected with the fact that each employee applies his own methods and ways of organizing work, his individual approach, putting all his knowledge and experience into it, that is, each of them shows his individuality in work and does not seek to unify his activities. The solution to this problem may be the non-interference of the leader in the activities of employees, which means introducing the features of an conniving style of leadership.

Thus, the solution of the problems identified in the team should be carried out through preventive measures and periodic studies, the results of which will help to improve the socio-psychological climate.

Carrying out the above measures to solve current problems and create a favorable socio-psychological climate made it possible to maintain an even more friendly and productive atmosphere in the team.

Conclusion

The structure of the socio-psychological climate is quite broad and diverse, it contains two main components: the attitude of workers to work and the attitude of workers to each other. In addition, the structure covers various aspects of employee relationships in the organization. Also, the structural components of the socio-psychological climate are closely related to its indicators, which are manifested in employee satisfaction with their colleagues, the process and results of work, and mood in the group.

In the analysis of the socio-psychological climate, evaluating the productivity of the organization and studying their relationship, it was found that the generally friendly atmosphere in the group, the employees' tolerance for each other and a number of other factors contribute to the high performance of the department, which indicates the great importance of favorable socio-psychological climate and its direct impact on the effectiveness of the team.

Despite the favorable socio-psychological climate, the department has a number of the following problems:

1) although the employees work together quite successfully, they do not know and understand each other well enough;

2) conflicts that arise mainly on business issues are not often resolved to the end, employees harbor resentment and tension remains between some team members;

3) the team is indifferent to various joint activities;

4) inconclusive adaptation of new department employees to the work and team.

Based on this analysis, recommendations were developed to improve the socio-psychological climate in the team of the organization under study:

- firstly, one of the conditions for improving the socio-psychological climate in the team is an effective system of motivation and stimulation. Particular attention should be paid to the relevance of the incentive system to the needs of employees;

- secondly, it should be noted that for the effective distribution of responsibilities, the manager needs to understand that the motives of all employees are different;

- thirdly, it is necessary to single out a leader in the informal group, with whom it is necessary to closely interact with the improvement of the socio-psychological climate, since he can give valuable recommendations and one of the first to contribute to the implementation of the proposed activities in practice;

- fourthly, it is necessary to diagnose the existing relationships using questionnaires and observation, to develop communication skills and effective communication skills, taking into account the characteristics of the personal space of employees.

All of the above recommendations aimed at solving current problems and creating a favorable socio-psychological climate made it possible to maintain an even more friendly and productive atmosphere in the team.

Abstract

Joint international educational programs are a complex form of cooperation that deals with a number of challenges: national legislation, institutional boundaries, lack of a clear internationalization strategy, linguistic and cultural problems. This also applies to quality assurance systems within programs. A special place in the development of the European Higher Education Area (EHEA) belongs to joint international educational programs. They are a complex form of cooperation and deal with a number of challenges: national legislation, institutional boundaries, lack of a clear internationalization strategy, linguistic and cultural problems. This also applies to quality assurance systems in programs, which are complicated by contradictions in national approaches. This study is aimed at analyzing approaches to ensuring the quality of joint educational programs and developing recommendations for implementing the provisions of the standards and recommendations of ESG and European Approach for Quality Assurance of Joint Programs.

Keywords: Joint International Educational Programs, Education Quality Assurance, European Standards and Guidelines (ESG).

Introduction

One of the effective export tools of the Russian higher education system is joint programs leading to two diplomas.

The increase in the number of joint international educational programs is due to various factors, the main of which, in our opinion, are as follows:

- changing the educational needs of applicants and students in the context of the globalization of higher education and science;
- formation of a single educational market and the development of international cooperation between universities, the increase in the import and export of educational services;
- increasing the flexibility of forms and methods of providing educational services (distance and on-line training, simultaneous training in various educational programs, parallel training in several educational organizations);
- increased mobility of students and teachers;

- development of new forms of educational services based on strategic partnerships and networking between organizations;
- expanding opportunities for introducing students to the cross-cultural learning experience;
- increase in the attractiveness and demand for higher education in a foreign university without a permanent stay abroad.

Joint international educational programs are a natural result of international cooperation between universities from different countries. In this context, the role of those international projects and programs is increasing during the implementation of which concrete results are achieved in developing innovative models and educational programs, a general conceptual field is developed, non-linear dependencies of the state of education on various cultural, social, economic and political factors are revealed [1] .

A study by the European Consortium for Accreditation in Higher Education (ECA) shows that quality assurance or accreditation of a joint program significantly affects the results of assessment and recognition of qualifications (92% of respondents answered in the affirmative) [2].

In this regard, the problem of creating effective quality assurance systems in the framework of joint programs is relevant for program developers and university officials responsible for the development of international activities.

Materials and Methods

Joint international educational programs as part of transnational higher education began to develop rapidly since 1980s based on the increased mobility of students and teachers, the growing number of educational organizations and programs, the emergence of new forms and methods of providing educational services (opening foreign campuses, the introduction of distance and e-learning, etc.) [3]. It should be noted that the main driver for the development of transnational higher education in general and joint international educational programs in particular is the massification of higher education. As studies show, admission of students to higher education institutions at the global level in 2000 amounted to 97 million people while in 2025 it is projected to reach 263 million people. [4].

The most complete description of all components of a joint educational program is given in the definition of O.N. Oleinikova. A joint program is a program in which:

- partners agree on all its basic elements (such as a curriculum, teaching methodology, quality assurance system, including the European Credit Transfer System (ECTS), assessment rules and principles, requirements for content, teachers and student enrollment);
- mobility is provided, with periods of study abroad (at partner universities) which are automatically recognized;
- joint program management is carried out;
- all partner universities recognize awarded diplomas / degrees.
- comparability is based on learning outcomes.

A similar approach to structuring the main characteristics of joint programs was proposed by the authors of the study “Innovation and transformation in cross-border education. Joint educational programs of universities of the EU and Russia” [4], in accordance with which seven blocks are proposed:

1) the institutional structure of partnership - from weak interaction to strategic partnership;
2) design and implementation of programs - from a fragmented approach to real integrity;
3) student mobility - from single visits to structured trajectories;
4) recognition of studies received abroad - from non- or partial recognition to full recognition;
5) types of qualifications and degrees - joint or double diploma, certificate;

6) program management - from individual (separate) management of a separate program to full integration into institutional activities;

7) quality assurance - internal and external subsystems.

An analysis of the scientific literature shows that quality assurance is the key to the successful implementation of joint educational programs.

In the Paris Communiqué of May 25, 2018, the Ministers of Education of the Bologna Process countries noted that quality assurance is the key to enhancing mutual trust, mobility and recognition of qualifications and periods of study in the countries of the European Higher Education Area (EHEA) [5].

In connection with the dynamic growth of transnational education offered by commercial and non-commercial providers as well as the commodification of higher education, quality assurance issues come to the fore [6]. Back in 2005 UNESCO developed a special document, "Guidelines for Quality Provision in Cross-border Higher Education" [7]. It defines the directions for reforming national systems of quality of education, accreditation and recognition of qualifications (assigned by foreign education providers) in the context of the globalization of the world economy and the development of transnational higher education for different groups of stakeholders: national governments; universities / providers of higher education; student governments; quality assurance / accreditation agencies; bodies (centers) for the recognition of qualifications (degrees); professional associations.

Quality assurance is recognized as one of the serious problems in organizing joint international educational programs [8]. According to J. Knight, quality assurance and accreditation are fundamental but in practice they can pose significant challenges. When universities have their own internal quality assurance procedures the requirements can be met only with respect to part of the joint program implemented in the relevant university. However, it is more difficult to ensure the quality of courses offered by a partner university. Common requirements for inputs and outputs are often used, but it would be more efficient to include in the agreement on a joint program the mutual recognition of relevant quality assurance programs [9]. Taiwanese scientists focus on the fact that joint programs are highly complex and their quality is formed and maintained on the basis of cooperation and coordination of efforts of all partner universities [10].

Research Results and Discussion

The space of higher education is characterized by a variety of approaches and models to ensure the quality of education, the most common of which are the following:

1. Model based on European standards and guidelines of ESG ENQA.
2. Model of a quality management system according to ISO 9001 /
3. The model of Total Quality Management (TQM)
4. Business Excellence Model (EFQM-European Foundation for Quality Management)
5. European model of Common Assessment Framework (CAF) for assessing the quality of the system.

All these models are criticized to one degree or another by specialists in the field of education quality. For example, experts note that the TQM, ISO 9001, and ESG ENQA models focus on the teaching process. However, it is research which is of paramount importance to university. The authors further note that the ESG model [11] pays insufficient attention to systematic improvement. Despite this this model is currently the most common and its development was carried out in the context of the Bologna process. Given the specifics of joint programs, it is advisable to use the European Approach for Quality Assurance of Joint Programs as the basis for the formation of a joint quality assurance system. The demand for the European Approach in the countries of the Bologna process is currently increasing. Its provisions correlate well with ESG ENQA standards and guidelines and take into account the particularities of joint programs. The interrelation of ESG ENQA and the European approach is presented in the Table.

Table - Key elements of a joint quality assurance system according to the provisions of Standards for Quality Assurance of Joint Programs in the EHEA and ESG ENQA

Standards for Quality Assurance of Joint Programs in the EHEA	Standards and guidelines of ESG ENQA
1. Eligibility	-
2. Learning Outcomes	ESG 1.2 Design and approval of programmes
3. Study Programme	ESG 1.2 Design and approval of programmes
4. Admission and Recognition	ESG 1.4 Student admission, progression, recognition and certification
5. Learning, Teaching and Assessment	ESG 1.3 Student-centred learning, teaching and assessment
6. Student Support	ESG 1.6 Learning resources and student support
7. Resources	ESG 1.5 Teaching staff ESG 1.6 Learning resources and student support
8. Transparency and Documentation	ESG 1.8 Public information
9. Quality Assurance	ESG 1.1 Policy for quality assurance ESG part 1 Standards and guidelines for internal quality assurance

From the Table, we see that the European approach to ensuring the quality of joint programs is fully based on ESG standards, supplementing them with the Eligibility standard. For joint international educational programs this standard is extremely important in determining the legitimacy of the program and the qualifications awarded.

Standards for external quality assurance in the framework of the European Approach to Quality Assurance of Joint Programs and ESG also correspond to each other (Table).

Table – Key elements of external quality assurance according to the provisions of Standards for Quality Assurance of Joint Programs in the EHEA and ESG ENQA

Standards for Quality Assurance of Joint Programs in the EHEA	Standards and guidelines of ESG ENQA
1. Self-Evaluation Report	ESG 2.3 Implementing processes
2. Review Panel	ESG 2.3 Implementing processes ESG 2.4 Peer-review experts
3. Site Visit	ESG 2.3 Implementing processes
4. Review Report	ESG 2.3 Implementing processes ESG 2.6 Reporting
5. Formal Outcomes and Decision	ESG 2.5 Criteria for outcomes
6. Appeals	ESG 2.7 Complaints and appeals
7. Reporting	ESG 2.6 Reporting
8. Follow-up	ESG 2.3 Implementing processes
9. Periodicity	ESG 1.10 Cyclical External Quality Assurance

As noted above, the formation of a quality assurance system for joint international educational programs in the countries of the Bologna process is increasingly carried out on the basis of the European approach to ensuring the quality of joint programs. However, not all countries have integrated the European approach into their national legislation (Table).

Table - Integration of the European approach to ensuring the quality of joint programs in the national legislation of the countries of the Bologna process

Integration of the European approach into national legislation	Countries
1. European approach is available for unlimited use by universities	Armenia, Belgium, Bulgaria, Denmark, Finland, Kazakhstan, Liechtenstein, Malta, Moldova, Netherlands, Poland, Switzerland, United Kingdom (13)
2. European approach is available for use by universities with restrictions	Austria, Bosnia and Herzegovina, Cyprus, Estonia, France, Georgia, Germany, Ireland, Lithuania, Luxembourg, Norway, Portugal, Russia, Serbia, Slovenia, Spain (16)
3. European approach cannot be used	Albania, Andorra, Azerbaijan, Belarus, Croatia, Greece, Vatican, Hungary, Iceland, Italy, Kosovo, Latvia, Montenegro, Northern Macedonia, Romania, Slovakia, Sweden, Turkey, Ukraine (19)

Based on: National implementation of the European Approach // https://www.eqar.eu/kb/joint-programmes/national-implementation/?cn-reloaded=1

At the level of educational programs, an important guideline is the concept of Compliance with Clear Goals. It involves a clear statement of the goals of the program, development of its concept, its implementation, monitoring and continuous improvement (Figure 2).

Figure 2: Scheme for the implementation of the concept of Compliance with Clear Goals

The steps presented and the questions related to them should be reflected in any educational program. Joint programs should have common goals and approaches to their achievement. In this regard, from the point of view of the life cycle, educational programs go through the following stages: preliminary assessment of the appropriateness of the program, development of the program, implementation of the program, termination of the program.

Stage 1: preliminary assessment. The goal - together with the selected partners to determine: comparability of the existing areas of training in terms of learning outcomes / competencies and the structure of training; the feasibility and attractiveness of the educational program due to structured mobility between partner universities. The following factors should be taken into account: the main educational programs existing at the university must have proper state accreditation; partner universities should have the legal right to issue relevant education documents; it is necessary that the national legislation and internal rules of partner universities allow entering into partnership agreements, recognize education received abroad and issue education documents; the calendar curriculum of partner universities should allow the implementation of mobility; partner universities should have the support of the administration; it is necessary to determine the financial resources for the development of partnerships, namely for organizing meetings, preparing documents (in different languages), paying for transportation expenses, tuition and other expenses.

Stage 2: program development. The development and approval of a joint educational program includes the following steps:

1. Formation of temporary working groups which include representatives of partner organizations.

2. Joint development by partner organizations of the structure of the educational program with included academic mobility and using distance learning technologies. It is necessary to take into account such conditions for the implementation of a joint program, as material, technical, educational, methodological, informational, personnel and other types of support for educational activities.

3. When developing a joint educational program it is recommended to use a modular structure.

4. It is necessary to develop a procedure for submitting documents, admission and selection criteria, as well as procedures for enrolling students for the program;

5. It is necessary to prepare a Partnership Agreement, which describes in detail the rights and obligations of partners and students, as well as the process of implementing the program with mobility windows and working languages.

Stage 3: program implementation. At this stage, it is extremely important to monitor the quality of the curriculum, as well as the administrative support provided to students and teachers. Particularly noteworthy are aspects such as the attractiveness and sustainability of the program which guarantee a sufficient number of students in each program.

In connection with the recognition and prevalence of ESG standards and the European approach to ensuring the quality of joint programs, we have formulated key priorities for the formation and development of education quality assurance systems in Russia in relation to joint international educational programs in the context of the implementation of these standards.

1. Quality assurance policy. An effective policy should be developed and implemented at the university to improve the quality of education taking into account the resources necessary for it. This policy should be integrated into the overall strategy of the university, including the convergence of educational and research activities.

2. Development and approval of programs. Educational programs should be developed on the basis of dialogue and partnership with teachers, students, graduates and representatives of the labor market. Programs should be based on new learning and teaching methods, so that students receive the most demanded competencies and increase their own competitiveness.

3. Student-centered learning and performance assessment. The state and universities in partnership with all interested parties should improve the system of training, support and counseling of students.

4. Admission, academic performance, recognition and certification. Student performance and progress should be assessed on the basis of clear criteria and consistent learning outcomes, with the full involvement of teachers and students. Universities should introduce a cross- and interdisciplinary approach to learning, develop entrepreneurial skills and innovative thinking among students.

5. The teaching staff. All teachers must undergo continuing education. Continuous improvement of staff competency is a must. The system for assessing the activities of the teaching staff should take into account various factors (possession of modern competencies, the availability and preparation of high-quality teaching materials, the level of social skills, etc.). Talented teachers should be encouraged, educational and research grants should be provided for them.

6. Educational resources and student support system. Universities should develop the competencies of teachers in the field of ownership of various forms and technologies of education in the digital age and provide an improvement in the quality of education based on modern technologies. Universities should provide all kinds of support to students in the face of increasing international mobility.

7. Information management. Universities should provide effective feedback to students in order to identify problems in all aspects of the quality of education and its improvement.

8. Public awareness. Universities should provide stakeholders with complete and objective information about educational activities, the proposed educational programs and learning conditions.

9. Continuous monitoring and periodic evaluation of programs. Universities should ensure the monitoring, analysis and evaluation of their programs in accordance with clear criteria and in a systematic manner.

10. Periodic external quality assurance procedures. Educational programs should be systematically subjected to an independent external quality assessment. Along with compulsory state accreditation, it is necessary to develop new mechanisms for the independent assessment of education (public accreditation, professional accreditation, international accreditation, external examination / audit, etc.).

A description of the above standards within the framework of international joint double diploma programs should be presented in the quality manual. This manual is a system document and contains a description of all procedures, tools and structures of the quality assurance system for partner universities. In the framework of the project "Improving Russian Creative Education: A New Master's Program in Digital Art", a quality manual was prepared, including a description of the implementation of ESG standards in the general part of the document and quality assurance procedures in a particular university, taking into account the peculiarities of internal processes at partner universities. Such an approach allows to take into account both European standards and the best practices of ensuring the quality of specific partner universities.

Conclusion

Thus, the quality assurance system of joint international educational programs requires, on the one hand, the development of a common strategic approach to quality assurance based on recognized and comparable models and, on the other hand, the Russian regulatory framework, as well as the national legislation of the partner university and its local documents.

Annotation

The scale, number and quality of the problems that companies have to solve today are significantly different from the problems of the past. Particularly acute are problems such as global competition, which intensifies against the backdrop of the ongoing escalation of sanctions wars; breakdown of economic integration with Western partners, forcing Russian companies to seek new business contacts; onset of a new technological revolution stimulating the innovative activity of all subjects of economic relations and development of management of the virtual work environment, etc. An operational response to environmental disturbances and an adequate solution to emerging problems, far from exhausting their complete list, is possible on the basis of increasing the resource potential of companies as a result of a synergistic effect from various kinds of cooperation relations between partner companies.

The solution of these problems is most promising in the conditions of transition of the economy to a model of sustainable development. The emphasis of economic policy should be placed on the innovativeness of all spheres and sectors of the economy, which are based on the generation, assimilation and diffusion of new knowledge.

Keywords: corporate strategies, corporate construction, management paradigm, technological paradigm.

Introduction

The beginning of the 21st century was marked by a cardinal transformation that the entire world community is undergoing. There is a growing awareness of the global threat and responsibility for planetary survival, the preservation of the noosphere and the sustainable development of society. The anthropogenic impacts of recent decades are so great in scale that the natural compensation mechanisms developed during the evolution of society have become inadequate. Problems have arisen, their elimination can be ensured only by joint efforts.

Globalization of threats and increasing responsibility for the sustainable development of society require solving urgent problems in the field of transition of the economy into a model of sustainable development. The emphasis in the economic policy of companies is placed on the search for new forms of intercompany cooperation that can consolidate intellectual capital and create conditions for the development of new technologies in order to create competitive advantages in the national and world markets. An important place in the process of moving the economy towards sustainable development and raising the standard of living is occupied by technology transfer, which can be considered a kind of tool for creating companies' value in the form of intellectual capital.

Materials and Methods

The object of research is the process of building strategically oriented corporate strategies based on the integration of management and technological paradigms.

The subject of the study is the organizational and economic relations that are built between corporate structures in the process of choosing strategic development priorities in the context of the large-scale impact of new technologies and other global environmental challenges.

The theoretical basis of the study was the scientific work, which sets out the theoretical and methodological approaches to the organization of corporate development, including on the basis of the consolidation of cooperative ties, improving the quality of corporate governance, improving the activities of corporations in stable conditions of national economies. These works include, first of all, the scientific works of foreign scientists: Mallin C., Goffin K., Kanji G.K., Reidenbach R.E., Robin D.P. A great contribution to the development of approaches to adapting corporate governance to conditions of instability was made by scientists: Hickson D.J., Pugh D.S., who studied the impact of globalization processes; Mendell S., Ennis D., Sawhney M., Wolcott R.C., Arroniz I., Santo B. analyzing the active penetration of innovative ideas in all spheres of life; Lang J.C., who studied the transformation of intellectual assets into increased productivity and efficiency.

The value of scientific works of domestic scientists, such as: Asaul A.N., Dementieva A.G., Belikov I.V., Vinslav Yu.B., Pivovarova M.A. etc., are in the fact that the focus of research is aimed at identifying corporate development problems in modern conditions associated with the instability of the economic situation caused by factors of different genesis, including non-economic one.

To formalize and summarize the results of the study, we used the historical method, methods of comparative and abstract logical analysis, as well as the following methods: general logical, formalization, inductive-deductive, statistical and data visualization method.

Research Results and Discussion

The rapid growth of new technologies against the backdrop of increased competition on a national and global scale has made significant adjustments to all areas of the economic life of companies. At the forefront are the problems which can directly influence the future of companies. Such problems include the construction of a strategic development route for companies that are adequate to the requirements of the market environment and future guidelines, the search for new forms of intercompany cooperation with the goal of creating unique competitive advantages, including those based on innovative proposals.

The choice of the type of organizational transformations of companies is determined, first of all, by their necessity and prospects in relation to building up intellectual capital as a planned result of transformations. In this regard, the most significant mergers and acquisitions, which lead to a long-term increase in the size of the business, including intellectual resources, while the joint venture may exist for a limited time. With a simple takeover, the acquired company becomes a part of the acquiring company, while many of the processes, traditions and culture of the acquired company are usually replaced by the processes, traditions and culture of the acquiring company, although such an outcome does not always occur. Mergers and joint ventures require tighter integration.

Mergers and takeovers have already become a universally accepted method for implementing corporate strategies and redistributing resources in the global economy. Today, many companies believe that it is faster and cheaper to acquire the necessary intellectual resources (or at least get access to them) in this way than to create them by yourself in the process of your own growth. In the past, the motivation for such transactions was related to monetary or material resources, but today they are increasingly aimed at transferring knowledge (with or without their human element), relative resources, strategic capabilities and technologies that bring profitable competitive firms opportunities as they go beyond their current strategic, organizational, and cultural context.

The ability to anticipate a favorable outcome for a merger, takeover, or joint venture is today becoming the chief quality of a leader. The ability to predict success or failure of a union is a rather difficult task. By virtue of this, appropriate reliable tools and methods should be created. They will allow us to analyze such situations when it is expected that key opportunities for creating value should grow out of the effective use of new integrated intellectual resources. Conventional due diligence schemes and methods, as a rule, do not take intellectual capital into account, because it is more difficult to identify and evaluate than tangible assets. Often this is due to the causal uncertainty associated with intangible resources and the time constraints imposed by the upcoming transaction. For this reason, in the event of a merger, takeover, or creation of a joint venture, intellectual capital is at the greatest risk of loss, damage, or failure to achieve its goals.

The strategic importance of mergers and takeovers in a competitive environment requires the creation of a conceptual framework to identify factors that determine their viability or success. Looking through the prism of intellectual capital in such situations is priceless, since it structures the difficulties that arise at such moments and, focusing the analysis on the level of resources, makes the process clearer thanks to which integrating organizations can successfully use the results arising on the basis of their synergy resources. This extends the scope of the traditional legal and financial audit, usually carried out in the course of mergers, takeovers and joint activities. By focusing their attention on the unique intellectual capital which is the basis of the competitive advantage of the companies involved in the transaction, managers are given the opportunity to link the desired results with the processes by which these results should be achieved in the future. Moreover, a look through the prism of intellectual capital can help identify and take advantage of the benefits of synergy, which are not so easy to identify and explain in the process of traditional due diligence. Since both tangible and intangible assets are important from the point of view of intellectual capital, new ways of obtaining value can be discovered. The concept of intellectual capital is fundamentally more comprehensive and more connected with long-term potential.

In this regard, the interconnectedness and interdependence of the concept of intellectual capital and the new technological paradigm of the present century should be assumed.

In modern conditions, the development of technology is carried out under the influence of two processes. On the one hand, they are developed in the course of scientific research and the production of innovations - processes whose course is based on the use and increment of intellectual capital. On the other hand, the needs of society make it necessary to generate and / or acquire, assimilate and disseminate new knowledge - the effectiveness of these processes increases many times in the context of the integration of business structures (Table 1).

Table 1 - The interaction of scientific advances and new needs on technology change

Needs / Inventions	Out of date needs	New needs	Actual needs
Major inventions	Basic innovations → new technological principles	New generation of technology, fundamentally new products	Basic improvement
General inventions	The combination of	New models of	Technology

	well-known goals with new tools	technology	modifications
Small and smallest inventions	Microinnovations	Pseudo-modifications, imitation, improvement of individual technology parameters	Improvement of obsolete technology

Thus, technological innovations can be represented by new combinations of production factors, a new production method, technologies of using a new type of raw materials or semi-finished products, a new organization of business processes, etc. They can correspond to different levels of novelty, international standards, be new to the company or updated, etc.

The innovative technologies that form the basis of the sixth technological structure include, first of all, nanotechnologies, the practical application of which began in the mid-90s. XX century, and the state of which will determine the level of development of the world community in the middle of this century. In addition, the modern technological field is based, in particular, on computer and fiber optic technology, software, telecommunications, information services, robot manufacturing, genetic engineering, biotechnology, and “green” technologies for the production of environmentally friendly energy sources (Fig. 1). Moreover, the share of work performed by man is already steadily declining and by 2025 it will occupy a smaller part - 48% against machine performed work (52%). Turning to the problem of using robots, it should be noted that in the modern world not only the word "robot" does not surprise anyone, but the use of robots has become widespread - from conveyor packaging and mine neutralization to minimally invasive surgery - and the robots themselves have overcome a huge distance from primitive devices to sophisticated devices endowed with artificial intelligence. By 2022, companies equipped with robots will be at their maximum for stationary and industrial robots in the automotive industry, the space sector, and supply chains. Equipment with air and underwater robots is expected in the oil and gas sector. In the financial sector, humanoid robots will be most in demand.

Figure 1: Basic technologies of the sixth technological structure

Characterizing these technologies, two general characteristics should be distinguished - universality and the reduction and / or elimination of market entry barriers.

The universality of new technologies is determined by the possibility of their use in various industries and fields of activity. For example, based on the achievements of nanoelectronics in the form of the production of nanostructured metal, ceramic and polymeric materials with desired properties and the

necessary shape, promising areas for the application of nanotechnology are manufacturing industry, medicine, aeronautics and space exploration, energy and environmental protection, technology in agriculture, etc. (fig. 2).

Figure 2: The expected benefits of investing in IT technology

Consequently, the effect of scale characteristic of traditional technologies is complemented by the effect of diversity. Expanding the scope of technology, diversification of offers to the market in the form of various products based on the same technology, are the main means of obtaining savings. According to experts, in high-tech industries such as electronics and telecommunications, savings can increase by expanding the scope of activities, while traditional savings are achieved by expanding the scale of production.

The reduction and / or elimination of entry barriers to markets that provide new technologies are manifested in several aspects:

1. The time barrier of market functioning is being overcome - the use of information and telecommunication technologies allows you to remove time limiters for doing business (you can do it around the clock, any day of the week). So, according to a study conducted in the USA, remote work will continue to remain in trend. So, about 53 million people perform their work remotely, and this is about 34% of the people represented on the global labor market. This indicator will rise to 50% by 2020. Companies will have to learn how to find the right employees and think about creating suitable remote employee management systems.

2. There are types of activities that are partly or in full carried out on the basis of Internet technologies. These activities include: planning and forecasting development, financial management, customer service, business partnerships, marketing research, advertising campaigns, hiring, personnel management, research and development, etc. For example, Internet banking technology has recently gained popularity, which allows you to remotely consult bank customers using the capabilities of the Internet. This system allows you to make non-cash internal and interbank payments and operations with non-cash currency, pay utility bills and Internet service bills and mobile communications bills, transfer funds and monitor all banking operations on your accounts. According to experts, in 2017, 94% of customers of American banks are already conducting transactions on-line, while the annual growth rate of mobile payments in the US is 68%. In Russia, the share of banks offering their customers (individuals) the Internet banking service in 2017 amounted to 86%.

3. Territorial restrictions in conducting market operations are eliminated — based on the use of Internet technologies, the opportunities for companies to quickly enter not only local, but also remote markets with different geographies of the world are expanding.

4. Institutional barriers to entering the markets have been overcome - this is true both for individual companies and the national economy as a whole. The formation of a global electronic environment for economic activity has occurred. The interconnection and interdependence of the active total introduction of new technologies into the business processes and the globalization of the economic space is determined, on the one hand, by the fact that the new technological paradigm stimulated the process of bringing industries and markets to the level of their globalization, and on the other hand, globalization helps increase economic efficiency through the use of new technologies.

5. Decreased logistical barriers. According to experts' forecasts, with the development and spread of nanotechnology, significant progress can be achieved in miniaturization and in increasing the speed and productivity of information processing devices.

But at the same time, the new technological paradigm gives rise to certain problems. The rapid development of new technologies can lead to unexpected effects that have both positive and negative significance for companies and society as a whole.

The first two problems are related to the use of Internet technologies.

First problem is increasing dependence of Internet technology users on the operation of their information systems and the need for their reliable protection against cyber-attacks by hackers and other interested structures. Despite the fact that cybercrimes occupy only fifth place in Russia among the main types of economic crimes, the leaders of Russian companies put cybercrimes in second place among all types of fraud that could potentially harm their business in the next two years. This is an explanation of the fact that the number of companies that have developed operational plans for protection against cybercrime has increased (from 26% in 2016 to 62% in 2018). In addition, every year the problem of reducing the effectiveness of the implementation of Internet technologies becomes acute due to losses caused by malware and unauthorized mailing lists (spam). Experts admitted that in 2008, for the first time, Russia ranked second in the world in the list of countries distributing spam, while the losses of Russian companies from spam in the same year amounted to about $500 million. The most relevant trends are the increase in the number of attacks on platforms other than Windows, diversification of malicious programs introduced in social networks, as well as the steady interest of hackers in mobile payment services. The efforts of business entities of the micro-, macro- and mesoscale levels are aimed at solving this problem, since the problem has turned into a global one.

Secondly, to achieve the real effect of the modernization of business processes based on Internet technologies, certain conditions are required. So, it is necessary that at least 2-3% of the bills should be paid using these technologies. Therefore, the realization of the advantages of new technologies depends both on the number of partners (network external effect) and on the use of "electronic money", which are funds on computer accounts in virtual banks.

The third problem covers the security sphere of all mankind and is manifested in the growing risk of man-made disasters that threaten the safety of both current and future generations. This is due to the fact that almost any technology, along with its advantages, is accompanied to a greater or lesser extent by negative impact on society and the environment. Particularly acute are problems of a non-economic nature affecting the field of psychology, the sphere of moral and ethical values, etc.

Therefore, we can conclude that, in general, the new technological paradigm of the beginning of the XXI century has a significant impact on the object and channels of technology transfer, as well as on the establishment of intercompany interaction in the field of scientific and technical cooperation.

The trend of technology transfer based on intercompany agreements within the framework of scientific and technical cooperation, including the international level, took shape in the late 80sof the XX century. The advantages of scientific and technical cooperation are obvious - it helps to reduce

the degree of uncertainty of the environment, the level of risk and the size of the costs of its participants, makes it possible on the principles of reciprocity to introduce the latest scientific and technical developments, use the potential of highly qualified personnel, removes the problem of obsolescence of knowledge, creates conditions for the dynamic promotion of innovative products.

The development of scientific and technical cooperation is based on long-term inter-company agreements of a strategic nature. In contrast to unidirectional relations in the transfer of technology under license, subcontract, or franchising agreements, this form of cooperation involves cooperation on an ongoing basis, throughout which its participants improve the methods used in research and production. This is made possible through the implementation of personnel exchange programs, allowing the dissemination of best practices.

The evolution of scientific and technical cooperation, starting with the exchange of information, co-production and marketing, begins to gradually cover a fairly wide range of industries. Today, scientific and technical cooperation is aimed at achieving a number of goals: the joint conduct of R&D and other types of innovation; aggregation of disparate technologies and knowledge; improvement of the innovation process; forecasting the prospects of cooperation on the basis of information exchange; expanding the range of technological capabilities within the company and at the national level. Especially observed the active development of scientific and technical cooperation in the sectors of the new economy.

Scientific and technical cooperation is implemented in a wide range of forms, such as strategic alliances, including scientific and technical, technological cooperation, strategic partnership, technological partnership, etc. Of all these forms in the last decade, the most widespread are scientific and technical alliances that are formed to create a fundamentally new technology, product (product, service) or solve priority problems of participating companies. Alliances of this kind are an integral component of the global strategy of TNCs.

World tendencies in weakening trade barriers, which led to an increase in the mobility of factors of production (primarily capital), have led to the expansion of the capabilities of small and medium enterprises in the field of scientific and technical cooperation. Such a form as technological partnership began to actively develop. If earlier scientific and technical alliances were observed exclusively in developed and new industrial countries, recently, agreements on scientific and technical cooperation have been actively concluded between enterprises of developing countries.

Numerous and diverse actors are involved in the field of scientific and technical cooperation - the company interacts with suppliers, customers, and possibly competitors, as well as with educational institutions of higher education and research organizations.

One of the features of this institutional form of intercompany technology transfer is the inclusion of competitors of companies among its participants. This is primarily due to the desire of companies, regardless of their size, to avoid confrontation and to establish cooperation in a hyper-competitive environment and rising costs for research activities. Predicting the stability of this form of cooperation, we can assume two opposite results: 1) similar forms can disintegrate at any moment, and, as practice shows, approximately 50-60% of all strategic alliances do not achieve their goals; 2) such forms can develop into quasi-mergers.

In modern conditions, cross-border mergers and takeovers of companies, including world leaders, are becoming a form of intercompany technology transfer. One of the results of the acquisition of a potential competitor or merger with it is the acquisition by the corporation of the respective research units. In the high-tech field, this is characteristic of industries such as pharmacology, communications, and biotechnology.

Thus,

Conclusion

In a modern society with a knowledge-based economy, an important place belongs to the creation, assimilation and diffusion of new technologies. The invention of innovations, being important from a scientific and technological point of view, may result in a commercial failure in a single company. But at the same time, under other circumstances, it can be very cost-effective and make a tangible contribution to economic growth and development. Therefore, considerable attention needs to be paid not only to the process of creating, mastering and disseminating new technologies, but also to the right choice and development of an appropriate company strategy aimed at increasing the company's intellectual capital using all appropriate methods, including expanding the range of forms of intercompany cooperation and establishing cooperative ties.

Abstract

Currently, households are the largest subject of economy, as they through their finances participate in all macro-regulatory processes of our society and represent the main force in the production and distribution of goods and services. The problem of housekeeping is becoming increasingly relevant due to the constant increase in food prices and other expenses. You must be able to properly allocate your budget to satisfy not only the required benefits, but also other needs. Thus, the importance of proper cash allocation is currently the foundation of housekeeping and requires careful study.

Keywords: households, disposable resources, consumer spending.

Introduction

In recent years, interest in household statistics has increased markedly. Survey data from household budgets are used to analyze the standard of living of the population, calculate the subsistence level, build an index of consumer prices, compile household sector accounts in the system of national accounts.

A household is a group of people living in one or part of a residential building, jointly providing themselves with food and everything necessary for life, that is, fully or partially combining and spending their money. These people may be related by kinship or relationship arising from marriage, or not be relatives, or both. A household can consist of one person living independently and providing himself with food and everything necessary for life. Households are one of the important subjects of economic activity on the results of which not only the welfare of an individual economic

unit, but also the entire population of the country as a whole depends. Having become the largest subject of economy, along with commercial enterprises and the state, households participate in all economic processes. The deep economic crisis and, as a consequence of this, the difficult financial situation of most of the population lead to vigorous activity of the household. Regular surveys of household budgets were organized on the basis of Decree of the Council of Ministers of the USSR of November 3, 1951 No. 4354 “On improving statistics of budgets of workers, employees and collective farmers.

Since 1988 the survey covered all sectors of the country's economy, in addition, the households of retirees who were not able-bodied were examined.

Currently, a sample survey of household budgets is carried out in all subjects of the Russian Federation, it covers 49.2 thousand households on a quarterly basis and is based on the principle of their voluntary participation. The data obtained from household budget surveys have a wide and ever-increasing range of uses. By its nature the survey is multi-purpose and its main tasks were initially defined as studying the level of material well-being of the population. Currently, the main objectives of the survey are: a) obtaining indicators for building a consumer price index; b) obtaining data on cash expenditures and consumption of household groups of different levels of well-being and socio-economic characteristics, sources and structure of food consumption by them; as well as data on income distribution and estimates of the poverty level of the population;; c) providing data for billing of the household sector in the system of national accounts.

The state program of the Chuvash Republic "Development of agriculture and regulation of the market of agricultural products, raw materials and food of the Chuvash Republic" (hereinafter referred to as the State program) provides for the comprehensive development of all areas of activity of the agro-industrial complex of the Chuvash Republic. At the same time, two priority levels are identified. The first level of priorities includes: environmental safety of agricultural products and food; in production - livestock breeding (milk and meat production) as a system-forming area of activity that uses competitive advantages of the republic, primarily the presence of significant areas of agricultural land, as well as crop production as the basis for the development of animal husbandry; in the economic sphere - increasing income of agricultural producers; in the social sphere, the sustainable development of rural areas as an indispensable condition for the preservation of labor resources, the creation of conditions for ensuring the economic and physical availability of food based on rational food consumption standards.

The implementation of measures of the State Program at the 2nd stage should ensure the achievement in 2030 of the following target indicators:

- the volume of agricultural production per capita - 103.4 thousand rubles;
- the index of agricultural production in farms of all categories (in comparable prices) is an increase of 42.1 percent compared to 2018;
- profitability of agricultural organizations (including subsidies) - 18.0 percent;
- labor productivity index - 1.8 times growth in relation to 2018;
- the number of high-performance jobs - 970 units;
- an increase in agricultural exports by 1.9 times in relation to 2018;
- the share of costs for the purchase of energy in the cost structure for the main production of agricultural products is 9.3 percent;
- disposable resources of households (on average per 1 member of a household per month) in rural areas - 21,311 rubles.

Based on the available literature, it can be concluded that economists have different approaches to the issue of households, namely to the issues of disposable resources, consumption, savings, investment and lending.

The most interesting for science is the research of S. Muravyov and Peck T.N. They give arguments explaining the decline in consumption by the presence of adaptive mechanisms used by
