most households namely: restrictions on consumption, a decrease in demand for credit resources and the low level of savings of most of the population. In their opinion, there was no transition of households to a savings strategy of behavior during the current recession of business activity.

In the context of a sample survey of household budgets by state statistics bodies in all constituent entities of the Russian Federation, covering only 48 thousand households and subject to their voluntary participation, the works of E. Medvedeva, A. V. Yarasheva, V. B. Toreev, and Kroshilin S.V. under the leadership of Rimashevskaya N.M., Balandin S.V., Ryabov S.G., Petryakov O.L. are valuable in connection with the study of regional statistics of incomes and expenditures of the population.

Foreign scholars Thaler R., Barro R., Zou Heng Fu and Wang Chong-yang study similar processes, establish an effect of tax increase for citizens on reducing household consumption spending and an effect of government actions on consumption which is independent on the method of financing government spending.

Materials and Research Methods

The research involved teachers and staff of Chuvash State Agricultural Academy. The scientific problem was studied on the basis of the Department of Economics, Management and Agro-Consulting throuth the use of available information resources, including reference networks, electronic library networks, official websites of government agencies of the Russian Federation and Russian enterprises. The objects of the study were households of the Russian population.

The used research methods: scientific search, analysis and systematization of statistical data, generalization of research results, forecasting and planning.

Research Results

Disposable household resources are the sum of household cash income, the amount of accumulated savings and borrowed funds and the cost of in-kind income.

In general, the indicator “household disposable resources” is interpreted as the amount of funds (cash and in kind) that households had to ensure all their expenses and make savings during the survey period.

An analysis of the structure of household disposable resources in Russia, according to the Federal State Statistics Service, showed that in 2018 disposable resources increased by 1,191.2 rubles compared to 2017, including 2,350.1 rubles in urban areas and rural areas by 879.4 rubles.

Table 1: Composition of household disposable resources of various socio-economic categories in the Russian Federation (on average per household member) in 2016-2017, rub. per month

	All households		including residents			
			in urban areas		in the countryside	
	2017	2018	2017	2018	2017	2018
Available resources, total	24926,5	26917,7	27206,8	29556,9	18309,1	19188,5
including: cash expenses	21220,9	22926,4	23428,0	25427,2	14816,2	15602,5
Cost of in-kind non-food items and services	177,2	177,9	195,5	190,0	124,2	142,3

Cost of in-kind food	585,0	589,6	395,6	381,2	1134,6	1121,6
Amount of borrowed funds and spent savings	2943,3	3232,9	3187,7	3548,7	2234,1	2307,9

The analysis of the structure of disposable resources of households in the Russian Federation showed that the share of cash expenditures tends to increase. The growth amounted to 786.3 rubles in 2018 compared to 2017.

Table 2: Composition of disposable resources of households of various socio-economic categories in the Russian Federation for 2013-2018 (on average per household member per month, rubles)

	2013	2014	2015	2016	2017	2018
	All households					
Available resources, total	21198,5	22890,1	23084,8	24209,8	24926,5	26917,7
including:						
cash expenses	18089,9	19447,2	19293,3	20583,5	21220,9	22926,4
cost of in-kind food	468,6	490,2	585,2	598,8	177,2	177,9
cost of in-kind receipts, non-food goods and services	148,7	149,5	208,9	167,8	585,0	589,6

	Urban households					
Available Resources - Total	23645,0	25347,5	25486,4	26719,7	27206,8	29556,9
including:						
cash expenses	20431,5	21788,8	21503,2	22974,5	23428,0	25427,2
cost of in-kind food	302,6	322,3	399,1	415,4	195,5	190,0
cost of in-kind receipts, non-food goods and services	165,9	164,3	241,9	186,6	395,6	381,2
amount of savings made	2745,1	3072,0	3322,2	3143,2	3187,7	3548,7
	Rural households					
Available Resources - Total	14191,7	15802,3	16639,7	16971,0	18309,1	19188,5
including:						

cash expenses	11383,7	12693,1	13313,0	13687,7	14816,2	15602,5
cost of in-kind food	944,1	974,7	1068,9	1127,8	124,2	142,3
cost of in-kind receipts, non-food goods and services	99,6	106,8	119,5	113,6	1134,6	1121,6
amount of savings made	1764,2	2027,7	2118,3	2041,9	2234,1	2307,9

Analysis of the data given in table 2 indicates that in the structure of disposable resources of households in Russia living in urban areas the largest share is occupied by cash expenses, the share of which in 2018 compared to 2013, that is an increase by 5719.2 rubles. The growth in savings in the total amount of household resources available in 2018 amounted to 29.8%, which is 741.7 rubles higher than in 2013.

Table 3 shows the structure of consumer spending in the Chuvash Republic for the 3rd quarter of 2016-2017.

Table 3: The structure of household consumer spending in the Chuvash Republic for the 3rd quarter of 2016-2017, %

	All households		**including residents**			
			in urban areas		**in the countryside**	
	3 quarter		**3 quarter**		**3 quarter**	
	2016	**2017**	**2016**	**2017**	**2016**	**2017**
Consumer spending, on average per household member per month, rub.	10098,8	9266,5	11303,8	10454,0	8190,1	7327,2
including percentage:						
for the purchase of food	36,5	38,3	36,2	35,7	37,2	44,3
eating out	2,6	3,2	2,4	3,0	3,0	3,6
for the purchase of alcoholic beverages	1,9	1,6	2,0	1,7	1,5	1,4
for the purchase of non-food goods	32,1	31,9	28,9	31,5	39,1	32,9
to pay for services	26,9	25,1	30,5	28,2	19,2	17,8

A sample survey of household budgets is one of the main sources of information on the level and quality of the population life. The importance of this survey lies in the fact that information is collected directly from households. The survey covers srata of the population whose main sources of income are wages, social payments and income from personal subsidiary plots.

In the Chuvash Republic the survey covers 500 households.

According to table 3 some changes took place in the structure of consumer spending. In the 3rd quarter of 2017 82.2% of income was spent by residents of the republic on the consumption of goods and only 17.8% on payment for services.

The average per capita consumer spending of households in the third quarter of 2017 amounted to 9266.5 rubles per month and decreased by 8.2% compared to the corresponding period of 2016, in

urban areas these expenses amounted to 10454.0 rubles and decreased by 7.5 %, in rural areas - 7327.2 rubles and 10.5% respectively.

Analyzing the data of Chuvashstat on a sample survey of household budgets for the third quarter of 2017, we can draw certain conclusions. In the structure of consumer spending there was a decrease in the share of expenses for the purchase of non-food goods, alcoholic beverages and payment for services, while an increase was observed in the purchase of food products (including lunching out).

The average per capita household spending on food (including lunching out) increased by 2.3% and amounted to 3839.6 rubles per month.

In urban areas expenses for these purposes amounted to 4042.2 rubles, in rural areas –3508.6 rubles.

The most expensive items of food for home use are meat and meat products (25.5%), bread and bread products (18.3%), milk and dairy products (16.8%).

Compared with the third quarter of 2016, household expenses for the purchase of potatoes increased 2.0 times, fruits and berries - 1.6 times, fish and fish products - 17.7%, meat and meat products - 2.7% .

Expenses for the purchase of non-food items amounted to 2,956.0 rubles per month, which is 8.8% lower than in the third quarter of 2016, in urban areas they amounted to 3290 rubles and increased by 0.7% in rural areas - 2410.5 rubles and decreased by 24.7%.

The cost of services amounted to 2325.2 rubles per month, which is 14.4% lower than in the third quarter of 2016, in urban areas they amounted to 2948.6 rubles and decreased by 14.4%, in rural areas - 1307.1 rubles and 16.7%, respectively. In the structure of household expenses for services the prevailing expenses are those for cultural institutions and recreation services (28.2%), public utilities services (28.1%). Communication services accounted for 10.9%, passenger transport services - 9, 3%, household services 9.2%, other services - 5.8%, services in education –5.3%. Costs of housing and public utilities services increased by 1.8%. In the third quarter of 2017 household expenses for communication services exceeded the level of the corresponding period in 2016 by 4.1%, household services - by 4.3%, other services - by 3.1 times.

Household expenses on cultural and recreational facilities, services in education, medicine and health and wellness services, passenger transport services decreased.

Conclusion

Thus, we can conclude that at present the household is becoming an active participant in the system of economic relations of the society, its importance in solving the most important socio-economic problems is expanding.

The due approach to the problems of household management will allow to establish a system in the money management of households, keep records of expenses and incomes, analyze and plan them, rationally make purchases, increase savings.

Rosstat presents the results of a sample survey of consumer expectations for the first quarter of 2019.

The consumer confidence index, which reflects the aggregate consumer expectations of the population, increased by 1 percentage point in the 1st quarter of 2019 compared to the 4th quarter of 2018 and amounted to (-16%).

Fig. 1: Consumer Confidence Index

The index of expected changes in personal financial situation increased by 3 percentage points and amounted to (-7%) versus (-10%) in the IV quarter of 2018.

The proportion of respondents who expect improvement in their financial situation over the next 12 months, compared with the fourth quarter of 2018, increased to 11% compared to 10% in the fourth quarter of 2018. The share of negative assessments decreased to 23% (in the IV quarter of 2018 - 26%).

The index of changes in the personal financial situation remained unchanged and amounted to (-14%) in the 1st quarter of 2019.

The share of respondents who positively assess changes in their financial situation during the year in the I quarter of 2019 compared to the IV quarter of 2018 increased by 1 percentage point and amounted to 10%. The share of negative assessments increased to 34% (in the IV quarter of 2018 - 33%).

Fig. 2: Assessment of changes in personal financial situation

The favorable conditions index for large purchases decreased by 4 percentage points and amounted to (-29%) versus (-25%) in the IV quarter of 2018. The favorable conditions index for savings decreased by 1 percentage point and amounted to (-37%) versus (-36%) in the IV quarter of 2018.

Fig. 3: Assessment of current conditions for large purchases and savings

The consumer confidence index by age groups in the Ist quarter of 2019 compared with the 4th quarter of 2018 increased by 1 percentage point among middle-aged people (30 to 49 years old), decreased by 2 percentage points among the younger generation (aged 16 up to 29 years) and remained unchanged in older people (50 years or more).

Fig. 4: Consumer Confidence Index by age group

Table 4: Consumer Confidence Index in Russia and EU Countries

	November 2018	February 2019		November 2018	February 2019
Russia	-16,6	-16,5			
Austria	0,1	-1,6	Luxembourg	0,1	-0,7
Belgium	-6,8	-11,1	Malta	9,3	6,4

Bulgaria	-27,2	-26,6	Netherlands	-1,8	-6,3
Great Britain	-8,1	-10,8	Poland	3,7	5,9
Hungary	-5,9	-4,4	Portugal	-4,5	-9,1
Germany	-1,1	-2,2	Romania	-12,9	-14,3
Greece	-32,7	-33,3	Slovakia	-7,8	-7,8
Denmark	5,6	3,1	Slovenia	-8,5	-6,8
Ireland	6,5	-1,3	Finland	2,8	0,4
Spain	-4,9	-5,4	France	-13,9	-11,6
Italy	-10,7	-11,8	Croatia	-5,4	-7,6
Cyprus	-5,8	-7,0	Czech	1,2	3,7
Latvia	-5,9	-6,6	Sweden	1,0	-1,0
Lithuania	2,4	5,2	Estonia	-2,8	0,6

The survey questionnaire includes questions of the subjective opinion of the respondent about the general economic situation and personal financial situation, about the situation in the markets for goods (services) and savings. Respondents' answers are distributed according to the following options:

- definitely positive or definitely negative (very good, very favorable / very poor, very unfavorable);
- rather positive or rather negative (good, rather favorable / bad, rather unfavorable);
- neutral (average, "pluses" and "minuses" are the same).

According to the methodology of the European Commission, the values of private indices and a generalized index of consumer confidence in the population are calculated.

Private indices are calculated based on the balance of respondents' ratings (percent) on the corresponding question of the questionnaire.

The balance of assessments is the difference between the sum of the shares (percent) of definitely positive and ½ rather positive answers and the sum of the shares (percent) of definitely negative and ½ rather negative answers. Neutral responses are not taken into account.

The generalizing (composite) index - the consumer confidence index - is calculated as the arithmetic average of five private indices: the actual and expected changes in personal financial situation (1-2), the actual and expected changes in the economic situation in Russia (3-4), favorable conditions for large purchases (5).

The information obtained as a result of a survey of consumer expectations of the population can be used, along with quantitative statistical data, to analyze the behavioral model of the population in consumer market, as well as to assess the impact of consumer activity on the state of economy as a whole.

Abstract

The article presents the main ways to improve tax policy of the Russian state, to solve the problems associated with the budget revenues formation, the main purpose of which is economic and social stability in society.

Keywords: taxes, tax policy, ways to improve tax policy, improvement of tax policy, tax policy of the state.

Introduction

Taxes have been an integral part of economic relations in society since the creation of the state. The transformation of the state device always occurs when the tax policy changes. The use of taxes serves as a link between the public and commercial interests of entrepreneurs, organizations, regardless of forms of ownership. Thanks to taxes, foreign business activity is audited, namely attracting foreign investments that increase the organization's profit.

The main goal of tax policy is to achieve fiscal sustainability and a balanced budget system. The tax policy of the Russian Federation should set certain goals and begin to quickly resolve urgent external problems, which, for example, include:

- Sanctions imposed on the Russian Federation;

- Low oil prices.

Materials and Methods

The research involved teachers and students of the Academy. The problem was studied on the basis of the Chuvash State Agricultural Academy, which provides access to open information resources. The objects of the study were the legal framework of tax and budget legislation. In the course of the work, widely tested reliable research methods were used. General scientific methods of dialectics, analysis, synthesis, induction, deduction and analogy, special economic methods were used to solve analytical problems: comparisons, analytical groupings, time series analysis, correlation and

regression. Statistical information is processed in the Microsoft Excel software environment.

Research Results and Discussion

Tax policy for 2019-2020 - this is public information that the Ministry of Finance places on its website (as a rule it happens before the beginning of the coming year). Based on this information, you can understand what fiscal conditions will be created for the development of private business, what set of tools will be used. We want to see if the shadow segment is able to fully balance the budgets and what legislative innovations will be adopted to solve such problems.

The shortcomings of tax policy of the Russian Federation are currently given quite special attention, since the stable functioning of the entire national economy depends on the extent to which the tax system is correctly developed and how the state's tax policy is thought out.

The basic forecast for medium-term economic development for 2018-2020, based on the budget parameters, is based on scenario conditions that assume a gradual slowdown in global economic growth from 3.1 % in 2016 to 2.8 % by 2020, due to the expectation of a slowdown in economic growth in both developed and developing countries. The resulting slowdown in energy demand growth, as well as the increase in the US shale oil production and the completion of the agreement on freezing oil production by OPEC countries will help to reduce the prices of Urals oil and reach the level of $ 40. In addition, the forecast is based on the hypothesis that financial and economic sanctions will continue until the end of the forecast period. (Table 1).

Table 1: Main parameters of the basic forecast of social and economic development of Russia for 2017-2020

	Years			
	2017	**2018**	**2019**	**2020**
Price of Urals crude oil, US dollar per barrel	49,9	43,8	41,6	42,4
Exchange rate of the ruble to the US dollar average annual, rubles per US dollar	59,4	64,7	66,6	68,0
GDP growth rate, percentage of the previous year	2,1	2,1	2,2	2,3
Nominal GDP, billion rubles	92224,0	97462,0	103228,0	110237,0
Consumer price index (average annual)	3,9	3,7	4,0	4,0
Exports of goods, billion US dollars	336,9	324,9	324,2	332,4
Imports of goods, billion US dollars	227,8	234,8	238,0	241,0

In addition, it should be noted that sustainable organizations include companies for power production, transmission and distribution, which have an autonomy coefficient at the level of 0.627 at the end of 2017. Whereas, it was 0.205, steam and hot water – 0.339 in the organizations producing and distributing gaseous fuels. This situation indicates a more favorable financial situation in power industry.

The baseline scenario predicts a gradual increase in the growth rate of Russian economy from 2.1 % in 2017 to 2.3 % by 2020. Sustainable development is expected without significant failures with the price of domestic oil at the level of $ 40-50. However, the dynamics of changes in prices for Russian oil in the world market shows a significant increase, exceeding the expected figure by almost two times. The price of Urals oil has been steadily rising since February 2018 and is currently at the level of $ 75-78 US $ per barrel.

Officials believe that the transition to the new budget rules will reduce the cyclical nature of domestic economy. Excess revenues from oil exports will be used to replenish reserves. As a result budget expenditures will be planned based on the cost of oil at the level of $ 40. This will increase the stability of Russian economy.

The high dependence of the state budget on oil and gas industry makes it necessary to constantly revise the tax policy depending on the cost of hydrocarbons. In addition, in recent years foreign policy conditions have increasingly influenced the formation of tax conditions.

The government of the Russian Federation has prepared the main areas of taxation policy for 2018-2020, which the State Duma will have to take into account in its work. It is planned to solve the following tasks:

1) to reduce the shadow business sector;

2) to further minimize the administrative burden;

3) to stimulate investment activity;

4) not to increase taxes for conscientious taxpayers;

5) to suppress various abuses in the application of tax benefits and special tax regimes.

In the next three years the state plans to adhere to the principle of fiscal neutrality and predictability (in particular, not to raise taxes for legal businesses). However, in order to create an incentive to whitewash wages, which otherwise move to the shadow economy, the possibility of changing the structure of tax burden is being considered, (namely, the rates of direct labor taxes (insurance premiums) may be reduced and the rates of indirect taxes (VAT) may be increased). The authorities also want to increase collection of taxes and non-tax payments, so they are improving their management [1]. Table 2. Shows the main areas of improvement of Russia's tax policy for 2018-2020.

Table 2: Proposals aimed at changing the tax system of the Russian Federation

Scope of changes	The planned measures
Tax administration	Expand the ability of tax authorities to independently clarify tax payments in order to avoid penalties - from 2018 to establish a moratorium on new benefits for regional and local taxes; - combine databases of extra-budgetary funds and the Federal tax service; - combine different information bases into one and automate its analysis in order to simplify interaction with taxpayers and prevent shadow schemes
Profit tax	- Allow to include in the composition of bad debts the debt of a citizen recognized as bankrupt; - provide reduced rates for companies implementing investment projects in the Far East region and create external infrastructure facilities for this purpose; - improve the procedure for taxation of profits of controlled foreign companies
Value added tax (VAT)	- Cancel the exemption from VAT on sales of scrap and waste of ferrous and non-ferrous metals <1> and recognize buyers of such products as tax agents for VAT

income tax on individuals	- Allow tax agents to inform individuals on the inability to withhold personal income tax from them using electronic services; - provide a standard personal income tax deduction for disabled children of group I or II, regardless of their age; - prescribe for income under the trust management agreement the same taxation features that are established for the trust management of securities
Uniform agricultural tax	- Recognize payers with the revenue of more than 150 million rubles as VAT payers. At the same time, despite the fact that they recognize expenses after payment, they will apply VAT deductions before payment
Unified tax on imputed income	- Provide a tax deduction in the amount of expenses for the purchase of cash registers
The patent system of taxation	- Provide a tax deduction in the amount of expenses for the purchase of KKT; - allow reducing the cost of a patent by the amount of insurance premiums; - limit the total amount of ownership; - specify the types of activities that fall under this regime
Insurance premium	- Tax payments under agreements on the alienation of exclusive rights and license agreements regarding any results of intellectual activity
State duty	- Differentiate the amount of state duty for issuing a license to trade alcohol depending on the number of points of sale; - allow individuals to pay taxes and state duties through multifunctional centers
Non-tax payments	- Complete the work on systematization of common rules for setting and collecting non-tax payments in 2017; - provide for the possibility of transferring certain types of non-tax payments to the local level; - if possible, reduce the number of non-tax payments and simplify their administration procedures

Conclusion

Thus, the development of Russian economy remains dependent on the dynamics in the oil market, which remains the main risk factor. A new decline in oil prices may cause another economic crisis, which will be much more difficult to overcome.

An effective stabilization economic policy will help ensure:

1. supporting stability of the budget balance;
2. achieving a stable surplus balance;
3. reducing the deficit balance;
4. the correction of macroeconomic imbalances;
5. reducing dependence on oil prices;
6. improving the economy structure , etc.

The main tax system flaws were attributed to the following:

1. Instability of tax policy.
2. Excessive tax burden imposed on the taxpayer.
3. Tax evasion by legal entities.
4. Excessive distribution of tax benefits.
5. Lack of incentives for the development of the real sector of economy.
6. Impact of inflation tax.
7. Excessive amount of payroll tax.
8. Single tax rate on personal income.

The following main areas for improving tax policy were listed:

1. Supporting stability of the budget balance;
2. Achieving a stable surplus balance;
3. Reducing the deficit balance;
4. Correction of macroeconomic imbalances;
5. Reducing dependence on oil prices;
6. Improving economy structure, etc.

Abstract

The article gives an assessment of agricultural development in the Chuvash Republic, which is of great importance, since the agricultural sector is one of the sectors that ensures food security of the region and the state as a whole. The aim of the study is to determine the ways of agricultural development in the region. The main objectives of the study are: assessment of the development of the main branches of agricultural production; analysis of types of agricultural products produced; analysis of economic entities engaged in the production of agricultural products. The presented indicators of agricultural development show the current trends in the development of the industry, which has a positive dynamic both in terms of types of business activities and in terms of types of agricultural products produced within the framework of the agricultural support program. Based on the conclusions of the study, it is proposed to support those activities that are in greatest demand on the market of agricultural products and to develop the social infrastructure of rural areas.

Keywords: Agriculture, Areas of Agricultural Development, Structure of Agricultural Products Production.

Introduction

Nowadays, the priority area of regional development is the development of agriculture, since it takes a key place in the development of rural areas. After all, it is agriculture that provides food security for

the regions and the country as a whole. Evidence of this direction is the current program of development of the Chuvash Republic "Development of agriculture and regulation of agricultural products market, raw materials and food of the Chuvash Republic" [1], the main goals of this program are:

- development of processing and sales of crop products;

- development of processing and sale of livestock products, meat cattle breeding;

- support of small businesses;

- modernization of equipment, innovative technical and technological development of the agricultural sector;

- comprehensive measures in veterinary medicine;

- sustainable development of rural areas in the region;

- carrying out land reclamation for agricultural purposes;

- scientific and information services for agricultural industries;

- vegetable and seed potato production;

- dairy cattle breeding;

- selection and seed production, support of breeding;

- infrastructure of the social nutrition system;

- general conditions for functioning of agricultural industry;

- export of agricultural products.

In addition, there is an increased interest of the head of the Chuvash Republic in agriculture as evidenced by the message of M. I. Ignatiev, who announced the strategic ways of the region's development, the main vectors of the work of the Government, the State Council, local authorities, enterprises and organizations of the Republic for the short and long term.

Materials and Methods

Teachers of the Academy took part in the study. The problem was studied on the basis of the Chuvash State Agricultural Academy which provides access to open information resources. The objects of the study were agricultural enterprises of the Chuvash Republic. In the course of work, widely tested reliable research methods were used - general scientific methods of dialectics, analysis, synthesis, induction, deduction and analogy; special economic methods were used to solve analytical problems: comparisons, analytical groupings, time series analysis, correlation and regression. Statistical information is processed in the Microsoft Excel software environment.

Research Results and Discussion

Thus, in recent years there has been a positive trend in the development of the agricultural sector of

the Chuvash Republic, as evidenced by the indicators of the development of livestock and crop production (Table 1).

Table 1 - Main indicators of agricultural development of the Chuvash Republic in farms of all categories for 2013-2017, billion rubles

	Years					Deviation (+,-)
	2013	**2014**	**2015**	**2016**	**2017**	**2017 from 2013**
Agricultural product, including:	30,9	37,1	44,0	43,4	45,2	14361,2
- plant growing	14928,6	19663,8	24510,9	23158,5	21955,7	7027,1
- farming	15933,7	17390,5	19444,0	20240,7	23267,9	7334,2

According to the results of the conducted research it can be noted that in general there is a growth of agricultural production in farms of all categories in the period from 2013 to 2017, the increase in agricultural production amounted to 14361,2 million rub, the largest percentage increase is recorded from 2013 to 2017, accounted for the livestock industry production volumes which increased by 7334,2 million rub, in crop production the increase was equal to 7027,1 million rubles, which is less than 307, 1 million rubles compared to farming over the same periods.

The analysis of specific indicators of agricultural production is presented in Table 2.

Table 2 - Indicators of the share of agricultural production in the Chuvash Republic, in farms of all categories for 2013-2017, %

	Years				
	2013	**2014**	**2015**	**2016**	**2017**
Agricultural product, including:	100	100	100	100	100
- plant growing	48,37	53,07	55,76	53,36	48,55
- farming	51,63	46,93	44,24	46,64	51,45

The largest share for the analyzed period falls on crop production, namely, crop production for three years accounts for more than 50% of the total share of agricultural products produced. Thus, the indicators show a positive trend in increasing the volume of agricultural production in the studied region. The Chuvash Republic is one of the regions where agriculture has moderate risks, in addition agriculture is the main type of production on the territory of rural settlements and as shown by the previous analysis the largest share of production falls on crop production (Table 3).

Table 3 - Indicators of gross harvest of crop production in farms of all categories of the Chuvash Republic for 2015-2017, thousand tons

	Years					Deviation (+,-)
	2013	**2014**	**2015**	**2016**	**2017**	**2017 г. from 2013г**
Grains and legumes (in weight after completion)	558,9	561,5	616,6	616,6	707,4	148,5

Sugar beet (factory) in the original registered weight	27,7	20,4	26,5	44,2	37,9	10,2
Potato	519,3	464,5	549,9	448,2	387,2	-132,1
Vegetables	124,7	123,8	130,2	140,2	121,9	-2,8

The dynamics of production volumes indicates that the largest share of production falls on cereals and leguminous crops, the second place is occupied by potato production and the third place is occupied by vegetable crops. We can say that if there is a tendency for grain crops to increase production volumes, then for potatoes and vegetable crops, as the analysis shows, production volumes are decreasing from year to year. Let's look at the situation in animal husbandry (figure 1).

Fig. 1: Indicators of livestock production in farms of all categories of the Chuvash Republic for 2015-2017

According to the results of the study during the analyzed period from 2013 to 2017 there is an increase in the volume of livestock and milk production. Thus, the production of livestock increased by 17.1 thousand tons, milk - by 6.5 thousand tons, the production of eggs and wool decreased, eggs- by 70 million, wool- by 33 tons, the reduction in wool production is associated with a reduction in the number of sheep during the study period.

The analysis of the agricultural sector development requires attention to the development of sectors that most contribute to the agricultural production, since these indicators provide a basis for making proposals for the development of species management in the territory of the Chuvash Republic (figure 2)

Fig. 2: Indicators of the structure of agricultural production by category of farms in the Chuvash Republic for 2013-2017

According to the statistics of the Chuvash Republic the largest share of agricultural production falls on households. At the same time, it can be noted that in recent years agricultural organizations have increased the volume of agricultural production but still, as of 2017, it is the households that occupy the leading positions. Thus, according to the results of the analysis the share of agricultural organizations in 2013 accounted for 35, 77% and in 2017- 41.71%. Farms accounted for 6.83% in 2013 and 9.96% in 2017. As the results of the study show the leading positions in the volume of agricultural production still fall on households, despite the fact that their production volumes in the overall structure decreased from 57.39% in 2013 to 48.33% in 2017. In our opinion, it is the households that are able to respond more flexibly to the interests of the region's economy, taking into account all conditions of production and sale of agricultural products.

Conclusion

Thus, based on the research materials, the following conclusions and suggestions can be formulated. First, there is a positive trend of an increase in the volume of agricultural production on the territory of the Chuvash Republic, so it is necessary to continue to support those activities that are most in demand on the market of agricultural products. Secondly, the existence of programs for the agricultural sector development has had a positive impact on the growth of production in agricultural organizations, which means that it is necessary to develop the social infrastructure of rural areas, which is still not at a proper level.

Abstract

The problem of ensuring the sustainability of development and growth of the sector of the national economy occupied by small and medium-sized business entities involves the search for conceptual approaches aimed at increasing the efficiency of functioning of both individual business entities and their collection. Moreover, tasks of this kind are often poorly structured, that is, based on many elements, factors, and functional interactions. This circumstance suggests the paramount importance of constructing heuristic-useful and least risky from the point of view of the possible consequences of various regulatory impacts of small and medium-sized business models, which allow adequately describing and predicting the behavior of this system.
The variety and evolution of types of entrepreneurial structures, due to the processes of complication of social and production systems in the modern world, including diversification and integration interaction, suggests the study of their comparative advantages in terms of opportunities and sustainable progressive development. In this case, a special place is given to the sector of small and medium-sized business structures as the driving force for the sustainable development of the entire national economy.

Keywords: Small and Medium Enterprises, Sustainable Development, System Analysis, Conceptual Approach.

Introduction

Obviously, system analysis is the most effective way to study issues related to ensuring sustainable growth and development of the system of small and medium-sized enterprises, which, as practice

shows, precisely because of the significant stochastic element, are difficult to be evaluated using other methods of assessment and modeling.
Given that the solution to the above problem ultimately comes down to making structural changes to a hierarchical system, this problem can be divided into a number of smaller sub-problems, which determines the semantic content of the system approach in this case: the processes of development and implementation of informed decisions here can be considered by analogy with the corresponding processes of the functioning of the systems, and the problem itself, in fact, is the difference between the desired and actual state of the improved system.

In view of the insufficient elaboration of issues related to assessing the influence of factors contributing to the sustainable development of entrepreneurial structures in the medium and long term, as well as the comparative advantages of various types of entrepreneurial structures in terms of their sustainable development and possible interaction, theoretical and methodological substantiation of the area of sustainable development management of small and medium-sized business structures and improvement of the efficiency of their activities, the proposed topic is quite relevant.

Research Results and Discussion

Today, the economy of the vast majority of countries has a pronounced two-level structure, the upper level is occupied by large monopolies subject to direct state influence, and the lower level is occupied by entrepreneurial structures of small and medium-sized businesses. Moreover, if the formation and development of the system of monopoly enterprises of the first level, as a rule, is determined by a number of natural geopolitical and socio-economic factors, and such a system, being associated with either natural or state monopolies, is in practice outside the competitive environment, then, in the case of the lower level, which includes the small and medium business structures (SMBS) considered in this article, the situation seems much more complicated, the number of influence factors is much bigger, and public administration and regulation mechanisms - mediated and not so unambiguous.

The number of monopolies of the first level in developed countries is usually within a few thousand, organizations of the second level are estimated at millions and tens of millions, in terms of shares, as a rule, exceeding 98-99% of the total number of economic entities operating in the state. At the same time, such important characteristics of the SMBS system as its competitiveness and dynamic development directly depend on the quantitative composition of this system, which in the Russian Federation, according to experts, should exceed their current value by more than 2-3 times.

The total number of small and medium enterprises operating in the country, in addition, is of great importance for ensuring the sustainable development of their system as such. So, the number of subjects of the system of small and medium-sized enterprises, providing the necessary minimum level of stability for sustainable development, in Russia is estimated as 6-7 million units (Fig. 1).

Fig. 1: Dependence of the sustainable development of the system of small and medium-sized business structures on the number of its entities

It is obvious that the dependence shown in Fig. 1 and the current state of the domestic sector of small and medium-sized business structures naturally lead to the conclusion that low number of business entities in the Russian Federation needs to be significantly increased, and this problem can be considered as one of the key problems (Fig. 2).

In this case, the development of set of control, stimulating and other influences that must be exerted on the SMBS system at the national level in order to transfer it from the current state to the desired state 1, characterized by a 2-3-times increase in the number of economically active economic entities of this system, and, in the future, to the desired state 2.

Fig. 2: Problems of transition to sustainable development of small and medium business structures in Russia

Obviously, the currently observed mismatch between the real scale of development of small and medium-sized business structures in Russia and the level required to achieve a stable and effective mode of functioning of this system suggests that the measures taken do not give the desired effect, which may be due to either their ineffective execution, or incorrect theoretical justification. This fact makes the application of a systematic approach to ensuring the sustainable development of the SMBS system even more relevant.

Based on the foregoing, it can be argued that the problems of ensuring the sustainable development of the SMBS system, regardless of the scale at which such problems are considered, implies shold be resolved step by step (Fig. 3).

The key goals assigned to small and medium-sized businesses, acting as an integral system-forming element of the national economy, are divided into meso- and macroeconomic. The main meso-economic goals, which are largely achieved at the level of individual constituent entities of the Russian Federation and associated not only with the state of entrepreneurship in a given territory, but also with many fundamental parameters of the regional economy, are: ensuring a high level of socio-economic development of the regions, smoothing out imbalance in development observed within the regionsraising of the quality of life of the population.

A systematic study of the problems arising from the comparison of the hypothetical state of the SMBS system with its current characteristics indicated by the above objectives can be carried out using system analysis and system synthesis. We believe that in the present case, given the significant complexity of the structural and functional organization of the systems under study, system analysis and system synthesis should be used together (within the framework of the methodology for the development of optimal regulatory influences). This requirement for the formation of appropriate methodological approaches is also confirmed by the complexity of the target management settings available here.
Assessing the effectiveness of regulatory impacts on the development of entrepreneurial structures requires formalization and measurement of both the actual and desired states of this system, each of which, being represented by a significant number of very diverse indicators, should provide an opportunity for their comprehensive analysis. Such indicators, which are essentially the evaluation criteria, must satisfy the functional adequacy requirement - otherwise (especially true for crisis systems with a complex embedded structure) evaluation procedure built on the basis of an incorrect and (or) incomplete system of indicators can lead to unsatisfactory results.

Fig. 3: The main stages of solving the problem of ensuring sustainable SMBS system development

The main function of the criteria for assessing the activities of the SMBS system is to be able to make informed and motivated judgments about the past, present and future states of the system and the causal relationships that exist here, which determine the processes of change of such states under the influence of certain factors. In addition, these criteria can be used to develop an adequate system of motivation and encouragement of the personnel of this system. In this regard, the need for typing such criteria according to two criteria is obvious:

- criteria to evaluate the results of past activities of the system (staff encouragement);
- criteria for forecasting future expectations (staff motivation).

In solving problems of evaluating business performance, regardless of its scale, as a rule, four groups of criteria are used:

1) financial performance indicators of the entrepreneurial structure;
2) non-financial performance indicators of the entrepreneurial structure;
3) criteria reflecting the position of the entrepreneurial structure in financial markets;
4) cost indicators.

The same average indicators can be used to assess the effectiveness of the functioning of the components of the SMBS system.

It should be noted that the use of criteria belonging to the 3rd group in the case of medium-sized and, especially, small businesses is limited, since most small and medium-sized enterprises are not allowed in the financial markets.

In our opinion, it is advisable to select indicators reflecting the effectiveness of the development management of the SMBS system without unduly complicating the model formed using them, using the criteria of various groups.

It is known that the justification and development of almost any system of criteria that describe the effectiveness of a particular set of interconnected objects is a rather complex and multi-stage process, which should be carried out taking into account regional, industry and other features of the structure being evaluated.

In particular, taking into account the significant heterogeneity of the entrepreneurial structures that make up the system of small and medium-sized enterprises in the region, only general, unrelated to their industry affiliation, system properties belonging to the first, second and fourth groups should be presented in such a system of criteria. An example of an organization that meets these requirements, a system of indicators is shown in Fig. 4.

Fig. 4: A system of criteria reflecting the effectiveness of regulation of the development of small and medium-sized business structures

As you can see, the system of criteria shown in Fig. 4 allows you to evaluate not only the characteristics of the relationships that exist between the internal and external environment of the enterprise system, but also contains indicators reflecting the degree to which the system reaches the development goals. It seems that an integral element in assessing the effectiveness of activities and the effectiveness of managing the development of the SMBS system should be indicators that objectively reflect the process of achieving the goals of the system, meeting the needs of external actors - customers of the system, as well as internal influences in the system that generate income and other economic benefits costs. Given that each of the assessment criteria corresponds to only a certain (usually not too large) part of the information about the state or dynamics of changes in the entire system as a whole, the proposed system of indicators presents the most identifying and informative indicators of the development of small and medium enterprises in the context of analysis. Moreover, the control procedures for this process also have a number of characteristic features that distinguish them from the set of algorithms aimed at making managerial decisions.

Significant activity and the ability to control the development of this system, naturally, implies the existence of intra-systemic capabilities to stabilize negative perturbations of the internal environment and level their consequences. This circumstance serves to actualize the change of the existing model of relations in the system to another paradigm based on a high level of business ethics, economic education and financial management.

Thus, from the standpoint of the general theory of systems development, the evolution of the SMBS system can be represented as a sequential change in its state from the current to the desired. The direction and trajectory of such a change essentially consists of modifications introduced into the system in response to the existing problem in it, a reduction in the number of small business structures that make up the system and the unsatisfactory efficiency of their functioning.

Conclusion

The most characteristic processes for socio-economic systems, creating a kind of foundation for all other events occurring here, are the processes of reproduction, that is, production, exchange, distribution and consumption. Therefore, the creation of a conceptual model of the socio-economic system (one of the particular cases of which, as was shown above, is the small and medium-sized enterprises of the region) precisely on the basis of representations that adequately show the characteristic features of these processes, it seems very logical and can provide powerful tools of influence not only on the structure of the socio-economic system itself, but also its inter-component relationships.

A concept is called one of the possible results of cognition, which is reduced to the interpretation and understanding of a particular phenomenon, realized by constructing conceptual models that allow characterizing various aspects of the integrity under study, highlighting its system properties, and predicting the assumed state, which is determined both by the intrinsic nature of such a phenomenon and the set of mutual influences within it exerted on each other by its constituent elements.

In our opinion, it is advisable to formulate a concept that meets the national paradigm of economic growth and development of small and medium-sized business structures, starting from the following principles:

1) small and medium-sized entrepreneurial structures must be considered in a system of different levels of orderliness of managerial relations, complex systems (national economy, regional economy, business sector);
2) study of the problems of the SMBS system should be carried out according to the principle of hierarchical concepts of the theory of entrepreneurship, taking into account the existence of several levels of knowledge of this phenomenon:
- small and medium-sized business structures are one of the elements of the national, regional economies and its lower level;

- the SMBS system is a complex independent system, which includes various subsystems, each of which can be represented as an independent system;
3) the identification of the laws and interconnections of processes occurring in the SMBS system is determined both by the internal features of this system itself and by various environmental factors, can only be achieved through the disclosure of the basic integration mechanisms that determine the behavior of entrepreneurial structures and its integrity;
4) criteria and indicators of the functioning and development of small and medium-sized business structures should be selected from the standpoint of ensuring its sustainable development;
5) a special place in ensuring the sustainable development of small and medium-sized business structures belongs to the state;
6) when determining goals and criteria, it is necessary to take into account not only economic, but also non-economic motives for the activities of business entities;
7) taking into account the advantages and disadvantages of small and medium business structures.
The purpose of the conceptual model of sustainable development of small and medium-sized business structures is the justification and subsequent implementation of a strategy based on the development of citizens' entrepreneurial initiative by attracting them to entrepreneurial activity, giving it impetus and support from the state, providing the state with a stable mode of development of its economy.

Thus, the creation of a conceptual model of sustainable development of the SMBS system, first of all, should be aimed at determining the set of boundary conditions that ensure:

- optimal regimes for the progressive development of national and regional economies;
- improving the common institutional environment for economic systems at all levels;
- involvement of the country's population in small and medium enterprises;
- ensuring the efficient use of resources and existing instruments of state regulation in this area.

Abstract

The Constitution of the Republic of Poland, through the provisions of Article 85, imposes an obligation to defend the homeland on all citizens. This obligation may be fulfilled by military service, service in militarized units, service in civil defense and performance of defense services. Benefits for the defense apply to all Polish citizens, they will be used in situations of natural disasters and as part of the defense of the homeland. The basic legal document regulating the issues of defense benefits is the Act of November 21, 1967 on the universal obligation to defend the homeland, which divides benefits into personal, material and special.

Keywords: State Security, Defense Services, Personal Benefits, Benefits In Kind, Special Benefits

Introduction

State security, defense of the homeland is the responsibility of all state organs and institutions, as well as every citizen of the Republic of Poland, because only the actions of all these entities can contribute to the implementation of this important task (Świerszcz, 2016). In relation to citizens, this obligation can be divided into two main groups, namely the obligation of personal direct participation in the implementation of defense tasks and the obligation of material benefit for defense, also called the obligation of benefits in kind (Wojnarowska-Szpucha, Wojnarowski, 2014). It is the duty of the authorities, if possible, to evenly impose tasks on all citizens. The provision of services is subordinated to tasks that result from the scope of Polish defense and security.

The use of benefits for defense and security-related purposes has been implemented for a long time, only their role, forms and scope of use have changed. Both in the past and presently, the benefits fulfil a service function in relations to entities creating or securing defense and security (Wojnarowska-Szpucha, Wojnarowski, 2014).

The purpose of this study is to attempt to answer the following research question: How can the use of defense services contribute to the performance of tasks related to national security and defense?

Legal Grounds for Defense Services

Before attempting to clarify issues related to the principles of using state defense services, the meaning of this concept should be clarified. According to the Dictionary of Terms in the field of national security (Pawłowski ed. 2009), "defense services are an integral part of system defense solutions. The scope, organizational forms and principles of benefits are set out in the Act of November 21, 1967 on the general obligation to defend the Republic of Poland and the executive regulations issued on its basis. Benefits are divided into personal, in kind and special".

Defense benefits are one of the forms of implementation of the general obligation to defend the Republic of Poland and will be used by various entities related to defense in the country, among others, by the armed forces, civil defense units and militarized units.

The basic legal document regulating the issues of defense benefits is the Act of November 21, 1967 on the general obligation to defense the Republic of Poland, where section VII is devoted to defense benefits. The Act has been amended many times, and issues related to benefits have changed. According to the original version of the Act of 1967, benefits were divided into personal benefits, benefits in kind and the transfer of transport means for the defense purposes. In 1979, the division of benefits changed and included: personal and in-kind benefits, the transfer of transport means for the defense purposes and the special benefits. The last significant amendment to the Act in 2004 divided them into personal benefits, benefits in kind – ad hoc and permanent, and special benefits, and such a division is currently in force.

The Act obliged the Council of Ministers to issue detailed normative acts regarding:

- personal benefits for peacekeeping defense.
- benefits in kind for peacekeeping,
- personal and in kind benefits for defense in the event of mobilization and during war.

The Minister of National Defense was obliged to issue a regulation on military records of defense benefits.

The above ordinances were issued in 2004 and regulate in detail the issues related to the use of services for purposes related to national security and defense.

In addition to the abovementioned tasks provided for the Council of Ministers, the Act also indicates tasks for voivodes, whose task is to coordinate the activities of local government bodies in scope of planning and imposing personal and in kind benefits in the voivodeship. These tasks are performed by the voivode by maintaining aggregate lists of personal and in kind benefits, planning financial expenses in the budget related to imposing the obligation to provide benefits, supervising tasks related to planning and imposing benefits, analysing the needs and possibilities of providing personal and in kind benefits by the municipality authorities in the voivodeship.

Tasks related to planning, imposing personal and in kind benefits are the responsibility of the head of the municipality, mayor (city presidents). The above-mentioned local government administration bodies, by way of administration decision, impose the obligation to provide personal services at the request of authorized bodies (military commanding officer, head of the organizational unit constituting the basis for the formation of a specially created militarized unit (Wojnarowska-Szpucha, 2019), head of the organizational unit performing tasks for the defense of the state, competent civil defense authority.

Issues related to the use of benefits are also regulated by the decree of March 23, 1953 on benefits to combat natural disasters and the Act of April 18, 2002 on the state of natural disasters. Both of these documents relate to the use of benefits during a natural disaster, which consist of (Journal of Laws of 2007, no. 89, item 59, art. 3-6), (Journal of Laws of 2017, item 1897, art. 22) providing first aid to persons who have suffered from accidents, providing access to premises for victims for the time necessary to provide first aid and shelter, receiving the injured and looking after the property of the injured or evacuated, securing the endangered animals (providing feed and shelter), guarding, executing specific works, active participation in the rescue operation or performing other tasks designated by the head of the rescue operation, commissioning of owned real estate or movable property, securing endangered plants or seeds, providing tools necessary for conducting actions, securing endangered cultural goods, securing own sources of drinking water and foodstuffs.

Individual types of benefits may be provided after the approval of the head of the municipality, mayor (city president) or his representative, starost or representative – by order of the ordinance or

administrative decision, voivode or his representative – by way of an ordinance or an administrative decision.

The issue of using benefits also appears in legal acts regarding martial law. The Act of August 29, 2002 on martial law and the competences of the Supreme Commander of the Polish Armed Forces and the principles of its subordination to the organs of the Republic of Poland determines the scope of restrictions on human and citizen freedoms and rights that can be introduced if the President of the Republic of Poland issues ordinances on introducing martial law (Wiśniewski, Szyłkowska, 2017). In the event of martial law, individual types of benefits are introduced and determined by means of decisions of government administration bodies (in the case of imposing tasks on entrepreneurs) or ordinances of the Council of Ministers (in the case of imposing tasks on natural and legal persons running agricultural holdings).

During martial law, a general obligation may be imposed on persons who are capable of doing so (their health condition as well as personal and family conditions allow it) and who are over 16 but not over 65 (Journal of Laws of 2017, item 1932).

Defense Benefits – Basic Aspects

Marian Laprus (1979) defined personal benefits as "a type of defense benefits consisting in the provision of various additional ad hoc work free of charge in the free time for the purposes of preparing national defense". Contemporarily, this term has been defined as "the type of services consisting in calling and including people to various types of work related to securing the mobilization of military units and institutions and achieving higher combat readiness" (Pawłowski, 2009). It follows from the above definition that benefits will be provided for the needs of the armed forces, however, the legal regulations regarding benefits extend the possibilities of using benefits by other entities performing tasks for the purposes of state defense and militarized units.

The obligation to provide personal benefits during peace applies to all citizens who are 16 years of age and under 60 years of age, with the exception of persons intended for other tasks or having a certain health category.

Personal benefits consist in performing, within a set time, various ad hoc works by people who have Polish citizenship for the state defense preparation or combating natural disasters and eliminating their effects (Ministry of National Defense, 2008). Pursuant to the provisions of the Act on the Universal Obligation to Defense the Republic of Poland, the duration of performing personal benefits in peacetime may not exceed 48 hours at a time for couriers and persons providing and entities of in kind benefits, and for other persons – 12 hours. A maximum of two hours is added to the time of performance of services, due to the time that the person performing the service must allocate to travel to the place of performance and return to the place of residence. In addition, the time for resting (8 hours) may be added, but only if you have performed the service for at least 12 hours.

In the event of mobilization and during the war, the duration of personal benefits may not exceed 7 days.

For the performance of personal benefits, remuneration is paid in the form of an hourly lump sum of 1/178 of the minimum remuneration for work in force in December of the previous year, determined on the basis of the provisions of the Act of October 10, 2002 on the minimum remuneration for work, for each hour of work time of performing the benefits. The remuneration is paid by the organizational unit for which the personal benefit was performed.

Among others, persons performing important functions in the state, soldiers, officers of services, guards and agencies are released from the obligation to perform benefits (Journal of Laws of 2019, item 1541).

Benefits in kind are a type of "defense benefits consisting in the provision of premises, means of transport, tools and other equipment as well as the supply of materials held for the purposes of the

implementation of the universal defense obligation, and in the event of a state of immediate security threat being announced, mobilization and during war – on commissioning for the benefit of the armed forces, civil defense formations or other state organizational units performing tasks for the purposes of state defense, for an indefinite period – real estate or movable property needed for the defense purposes" (Laprus, 1979).

Performing benefits in kind is the responsibility of state officers and institutions, organizational units, entrepreneurs and natural persons. The state administration authorities at the municipal, city and district level (by name request) are entitled to impose the obligation to provide benefits in kind. Benefits in kind will be performed for the Polish Armed Forces, organizational units constituting the base for the formation of specially created militarized units, civil defense organizational units and organizational units (among others the Police, Internal Security Agency, Intelligence Agency, Border Guard, State Protection Service, State Fire Service, Prison Service), performing tasks for the purposes of defending the state of combating natural disasters and eliminating their effects (Journal of Laws of 2019, item 1541).

Article 209 of the Act regulates issues related to the time of performing benefits in kind, which depends on the purpose of performing these benefits. In the case of collecting the subject of the benefit to check the mobilization readiness of the armed forces amounts to 48 hours, for tasks related to military exercises or exercises in units intended for militarization it amounts to seven days, and in connection with civil defense exercises or practical exercises in the field of universal self-defence, it lasts up to 24 hours. If the service is performed for 48 or 24 hours, it may be taken three times a year, if it is performed for 7 days – only once. Similarly to personal benefits, the legislator provided for an additional time of 2 hours, intended for delivering the subject of the benefit to the place indicated in the decision and the time of its return to the place of storage or owner. At the time of announcement of mobilization and during the war, the Act allows the armed forces to use benefits in kind until the need to use the objects of these benefits ceases, i.e. to the end of warefare.

As part of using benefits in kind, the Armed Forces of the Republic of Poland may collect from the national economy: motor vehicles, trailers and semi-trailers, machines, aircraft, sea vessels, railway stock, areas and premises necessary for full-time security (Wojnarowski, Wojnarowska-Szpucha, 2016) and ad hoc (Szandrocho, 2013) mobilization needs. Full-time needs are intended to supplement the organizational structures of war, after having been adapted for use by the armed forces. Ad hoc needs will be used during the mobilization development of the Polish Armed Forces, without including them in the organizational structures of individual units. Benefits in kind will be used as part of the development of elements of the mobilization base, evacuation of stocks, maintenance of armaments and military equipment, use of rooms and buildings as well as areas and real estate necessary for the implementation of the mobilization development (Wojnarowska-Szpucha, Wojnarowski, 2014).

Due to the need to ensure efficient, undisturbed functioning of the state, the Act on the universal obligation to defend the Republic of Poland releases certain facilities, premises, areas of means of transport from the obligation to provide benefits in kind. (Wojnarowska-Szpucha, Wojnarowski, 2014).

Payment for the use of items of benefits in kind is paid to the holders by an organizational unit for which the benefit was provided on the basis of a list of flat rates for the use of benefits in kind. The amount of the lump sum depends on the type of transport, the lump sum is subject to annual adjustment.

The last type of benefits are special benefits, which "include specific tasks and obligations carried out by public administration bodies, business entities and other organizational units for the defense and security of the state, including those related to the liquidation of the effects of a natural disaster, or achieving higher states of combat readiness in the armed forces" (Pawłowski ed., 2009).

This type of benefits applies in particular to local government administration bodies, state institutions, local government bodies, as well as entrepreneurs and other organizational units, which may be required to the paid adaptation of their real estate and movable property to the needs of the state defense, adaptation of constructed (rebuilt and expanded) building facilities and manufactured movable items

for the purposes of state defense, collection, storage and maintenance of items necessary to perform the above-mentioned activities (Journal of Laws of 2019, item 1541). Performance of special benefits is financed by the state budget.

The implementation of special benefits by entrepreneurs has been specified in detail in the Act of August 23, 2001 on the organization of tasks for the defense of the state implemented by entrepreneurs, where tasks for defense were defined that may be imposed on entrepreneurs by way of an administrative decision by the appropriate administrative body government.

Ending

Each country is exposed to various types of threats. They may be associated with armed aggression or destructive forces of nature, as well as technical and man-made disasters. In such situations, in order to remove the danger, the state must use the forces and means that perform their civic duties on a daily basis. An instrument that allows the state to deal with the above threats, while protecting the resources of state goods and society are various types of benefits, implemented for defense purposes and in the event of non-military threats, e.g. a natural disaster.

Because state defense in modern conditions is a complex undertaking and by its nature must cover all areas of state, private and social life. One of the elements of the defense preparation are the state and defense benefits. In order to use them properly, cooperation and coherence of all public administration bodies, recipients and service providers are necessary. For both planning and practical implementation of the obligation to provide services requires a willingness to cooperate and a certain understanding of the seriousness of the moment, both military, civilian and individual citizens. From the discussed substantive content of this publication, it can be concluded that the benefits play an important role, both in defense preparations and in the event of emergencies in the country.

Referring to the research problem presented at the beginning, which was: *How can the use of defense benefits contribute to the performance of tasks related to national security and defense?* It should be stated that they are indispensable for performing certain defensive or assistance tasks in the event of a state of natural disaster. Because the constitutional resources of the state in the form of forces and resources may be insufficient, as indicated by past crisis situations – military and non-military.

Abstract

The use of the European Union (EU) funds is an important part of development of innovative technologies of the engineering industry, including the metalworking sector. There is a strict connection between raising EU funds and the possibilities of purchasing modern technological infrastructure which is applied to optimize and improve production processes. An important constituent affecting the possibility of acquiring the EU funds is an overall innovative approach of enterprises to creating research and development (R&D) departments in which the purchased equipment influences the verification and improvement in the quality of manufactured goods and an increase in competitiveness of enterprises both in the domestic and international markets. The main objective of the manuscript is the analysis of the metalworking sector improvement with the support of the EU Structural Funds. The paper presents a case study of Polish metalworking SME enterprise which has implemented process innovation in the manufacturing of large size aluminium high-pressure casting molds by purchasing novel infrastructure, which allows improving the quality of the product and highly reduces costs and time of production. The innovation was financed as part of the European Union's financial perspective programme for years 2014-2020.

Key words: EU funds, metalworking industry, process innovation, OEE index

Introduction

Modern trends in management science strongly emphasize the openness of the organization to changes conditioning the possibility of its survival in a turbulent environment. Creating value for the customer and satisfying their needs increasingly is becoming the foundation for planning, design and implementation of many business activities, enabling the development and competition of the company in global markets. Among these activities there are also identified innovation activities. Innovation is the area of a particular interest of modern industrial companies. In the book by Lam (2004), among the areas of initiation and practical application of innovative solutions in industry there may be listed: products, technologies, organizational methods, improvements in manufacturing processes and products condition for satisfying customer requirements. It is widely recognized that development and innovativeness of the product portfolio determines success and creates the possibilities of survival and development of industrial companies. In a research study by Drucker (1994) the context of survival and development of the company corresponds with the need to achieve efficiency and flexibility in the area of the design of organizational solutions, also in the area of processes. The environment of the operation of the modern company implies the need for openness, dynamism and flexibility of organizational systems, creating unique competences, networking, maintaining social relationships, developing and implementing innovation Relationships and networking increasingly constitute the

specific "strategic motive of the company". Innovativeness as the strategic orientation leads to innovation and reflects the level of the company creativity and ability of initiation, development and implementation of innovative projects. Creating new knowledge, development of technologies, intensification of research and development activities and an extensive use of ICT are only the selected areas of interpretation of innovativeness. Mielcarek (2015) mentioned the environment favourable for innovativeness and innovation is evolving towards the search for opportunities to improve business models, sources and methods of financing, interorganisational cooperation strategies etc. Mobile sale channels and networking create modern business models. While facing the need to involve large financial outlays, particularly on development of breakthrough innovation and the potential investment risk, the basis for financing innovation activities is both public instruments (using public sources) and the market ones (i.e. capital instruments: stock exchange, private equity etc. and debt instruments: obligations, loans, bank loans etc.). The financing of innovation activities exclusively with own funds becomes just unachievable for many industrial companies. An alternative is to diversify the sources of financing towards the involvement of foreign capital and public funds under the Structural Funds and Operational Programs of the European Union. Sundbo (2001) mentioned that inter-organizational relationships, as the source of value creation, become the foundation for the strategy of modern enterprises, aimed at achieving competitive advantage due to cooperation in networks. Broadly understood innovativeness of enterprises is often associated with the problem of organizational intelligence and learning organization, discussed in management science, where there is emphasized the significance of learning processes for the development of organizational, process, product and marketing innovation. It should be pointed that the organizational reconfiguration takes place in an increasingly complex, vague and unpredictable environment, which in turn determines the decision-making process and achieving efficiency of the implemented changes. Research study by Krzakiewicz, Cyfert (2016) and Behnam et al. (2018) proved that in management science, the considerations on innovativeness are also taken into account in relation to the problem of imitative activities of enterprises. Imitation is treated in the category of the adopted operation strategy of the organization, however, the imitative activity does not replace but stimulates innovation activities. In this case, imitation and innovation constitute a harmonized space for the formation and use of innovative capabilities of enterprises and the creation of competitive advantage. In the description of innovativeness of enterprises, there is the concept of innovation activity and maturity. The subject literature by Enkel et al. (2009) and Werynski (2015) disposes of the model of determinants of innovativeness of the company, in which innovation activities and maturity are considered to be two levels of innovation. The basis for the identification of these levels is most of all the scope, nature and frequency of innovation activities undertaken by enterprises. The compliance of these projects with the adopted strategy for development and competition is extremely important as well as their impact on the ability to achieve the financial success. Therefore, innovation activities refer to a narrow range of projects undertaken occasionally. In turn, innovation maturity is understood as ensuring the continuity and complexity of innovation activity and the need to inscribe innovation in the strategy for development and competition. The subject literature by Slusarczyk (2018) and Baskiewicz (2019) indicates that the research into innovativeness of enterprises can be referred to the identification of innovation and its benefits, obtained as a result of its implementation, in the form of, among others, income, competitive advantage, customer satisfaction etc. From the perspective of the achievement of innovation maturity, a very interesting area of empirical considerations is the recognition and identification of the benefits from innovation in the context of the strategy for development and competition adopted by the company and whole sector of industry. The scientific inquiry towards the analysis of development of the process innovation, carried out in the paper, has been rooted in the environment of the exemplary company of the metalworking sector of industry. The objective of the empirical research has been to determine the results of the implementation of innovation in company's R&D unit in the form of an improvement in the final indices of performance, productivity, effectiveness and quality of the implemented manufacturing process and product.

Literature Review

One of the key instruments to support innovativeness and thus economic development of the European Union are the European Funds which Poland has benefited from since 2004. Klimczak et al. (2015) mentioned that due to the objective and thematic scope, an important part of the EU support for

enterprises were the European Funds for years 2007 – 2013 and 2014 – 2020, implemented under the National Cohesion Strategy (NCS).The key objective of the programs was to improve competitiveness and innovativeness of enterprises, including in particular the manufacturing sector of high value added and the development of the professional services sector. Among the operations directed to improving innovativeness of enterprises in the period of 2007-2013 there was, above all, the Operational Programme Innovative Economy 2007-2013 (OP IE) and selected components of Regional Operational Programs (ROP). Under the OP IE, an improvement in innovativeness of enterprises was reflected in products, services, technology and business processes and organization management. The structure of the share of beneficiaries of the Programme for individual innovation activities and the level of funds allocated for these activities is presented in Figure 1.

Figure 1: The level of implementation of innovation activities in enterprises in relation to the incurred expenditure in the period of Innovative Economy Programme 2007-2013, Klimczak et al. (2015)

As it can be observed, enterprises benefiting from the funds of the Programme most frequently purchased or carried out the modernization of fixed assets, simultaneously allocating most funds for this purpose under the OP IE (94% of allocations). Among the activities of which there was a significant disproportion between the frequency of implementation and the level of expenditure there was the purchase of software and the purchase of intangible assets in an intellectual form. Finally, in the period of 2007-2013, under the OP EI, 59.0% of the total funds of the Programme (more than 10 billion euro) was dedicated to support entrepreneurs, where, with the breakdown by the sectors, 10% of the total funding was dedicated to improve innovativeness of the metallurgical and metal industry. On the other hand, within the implementation of the priorities of Regional Operational Programs (ROP), in the field of supporting innovativeness of enterprises, there was expenditure of a total of 4.93 billion Euro, which on average amounted to 24% of the share in the total allocation of funds for the specific region (Ministry of Infrastructure and Development, Warsaw 2015, pp. 6 and 26). The most significant funds were allocated for the Opole Voivodeship (37% of the allocation of the specific ROP) and the Łódź Voivodeship (33% of the allocation of the specific RPO).The summary of the results of activities aimed at improving competitiveness and innovativeness of enterprises under National Strategic Reference Framework (NSRF) /NCS for years 2007-2013 is presented in Table 1.

Table 1: Selected indices of enterprises innovativeness under NCS for years 2007-2013

Indices	2007	2009	2011	2013
Expenditure of the corporate sector on R&D activities (% GDP)	0.17	0.19	0.23	0.38
Share of industrial companies incurring expenditure on innovation activities (as % in a total number of enterprises)	31.8	29.6	29.8	29.6
Share of products of high and medium-high technology in marketed production in industry (%)	31.5	34.0	33.6	32.8

Source: Annual report on the implementation of the Innovative Economy Operational Programme 2007-2013 in 2014, Polish Ministry of Infrastructure and Development, Warsaw 2015

As a result of the EU funds obtained in the period of 2007-2013, there was a twofold increase in expenditure of the corporate sector on R&D activities. At the same time, a slightly smaller number of entities allocated funds for innovation activities, which may result from a lower level of sales of products of high and medium-high technology in that period. The continuation of the EU financing of innovativeness of enterprises for years 2014-2020 is provided by the Smart Growth Operational Programme (SGOP) and Regional Operational Programs (ROP). The main objective of the programme is to boost innovation in the Polish economy primarily by increasing expenditure on R&D and innovation by businesses. The programme consists of five priority areas: support for business R&D, support for the environment and capacity of enterprise for R&D&I activity, support for innovation in enterprises, increasing the research potential and technical assistance. Resource efficiency measures can be funded, in particular, from Priority axis III Support for innovation in enterprises, which supports SME projects that involve implementation of technological innovations (Report of the Polish Agency for Enterprise Development, 2019, Statistics of Innovative Activity of Enterprises in the Years 2015–2017, Poland Statistical Office). Within the framework of the Smart Growth Operational Programme it is planned to finance the projects of a total value of 8.6 billion euro. The structure of the allocation of funds by the objectives of the 2014-2020 Smart Growth Operational Programme is presented in Table 2.

Table 2: The structure of the financing of innovativeness of enterprises in the period of 2014-2020

Priority	Objective	EU support [mln EUR]	Number of applications approved for financing	Percentage of funds allocation [%]
Support for R&D works carried out by enterprises	Strengthening scientific research, technological development and innovation	3 034	1644	73.47
Support for the environment and the potential of enterprises to conduct R&D&I activities		787	1367	70.41
Support for innovation in enterprises	Strengthening competitiveness of small and medium enterprises	1 929	1669	76.66

Source: Report of financial progress under the Smart Growth Operational Programme 2014-2020 according to August 2019

Under the SGOP, there have been approved the total of 4680 applications financing so far, among which there will benefit most the priorities concerning the support for innovation (77% of allocations of all funds of the Smart Growth Programme), although more than 90% of funds was allocated to enterprises from less developed regions of Poland. Objectives for of the regions under the Regional Operational Programs (ROP) for years 2014-2020 have been defined on the basis of the so called smart

specializations i.e. the areas of the greatest competitive potential of regions in the domestic and international market, including the ones concerning traditional industries. ROP's funds also support common areas of development, among which there is supported the development of entrepreneurship. The structure of expenditure on the development of individual regions in years 2014-2020 is presented in Figure 2.

Figure 2: The structure of expenditure under the Smart Growth Operational Programme 2014-2020 on the development of individual regions, including innovativeness and competitiveness of enterprises of the region

Under the ROP, a total of 31 billion Euro has been allocated for the development of individual regions of Poland, including 4.5 billion Euro to support competitiveness and innovativeness of enterprises. The highest level of support for entrepreneurship in relation to the other activities can be seen in the Kuyavian-Pomeranian Voivodeship and the Silesian Voivodeship (respectively 23% and 22% of allocation of funds). At the same time, the largest amount of funds for this purpose have been allocated for the Wielkopolskie Voivodeship – 467 million Euro, which amounts to 10% of all the funds allocated for an improvement in innovativeness of enterprises. The analysis of Smart Growth Operational Programme 2014-2020 data shows that in the years 2016-2018 almost 35.8% of companies operating in Poland were innovation active - they introduced or tried to introduce at least one innovation of any type. Whereas 32.4% of companies can be described as innovative – they introduced at least one innovation (Financial progress under the Smart Growth Operational Programme 2014-2020 according to August 2019)

Research Question

Regarding the subject analysed in the study, it should be considered which factors plays the most important role in the R&D development and innovation improvement of the companies. This issue requires a detailed examination and diagnosis base on the case analysis of such area of the company. The main purpose of the article is to analyze the impact of and purchasing advanced technology infrastructure (large size molds spotting press) from the EU funds for the R&D department of the metalworking sector company to increase the company's innovativeness through the possibility of manufacturing large-scale pressure casting molds (previously not manufactured by the company) for the automotive industry. The analysis of the subject could be realized and evaluated after answering the following research questions:

1. Which external conditions determine the implementation of process innovation in the company ?
2. Was the innovation introduced to the company's R&D department important in increasing the company's competitiveness and opening production to foreign markets ?
3. Has the purchase of the device had a positive impact on increasing the company's productivity and faster execution of contracts, and thus positive relationships with global suppliers and customers ?
4. Did EU funds raised by enterprise lead to the company's development and the acquisition of new funds and opportunities in know-how improvement ?

Research Design and Methodology

The metal industry, due to the support for almost all other production sectors, includes the vast majority of European cities and regions while simultaneously belonging to the most expansive industrial sectors in Poland. In spite of the fact that it concentrates many large enterprises its main driving force is the companies of the SME sector operating as subcontractors in the EU supply chain. According to study by Daron, Gorska, (2019) and Klar D. et al. (2016) nowadays, in the Polish market, there are almost 54 thousand enterprises of the metal industry, which is dominated by micro (about 91%) and small entities (over 6%). It is also one of few sectors whose structure is characterized by high flexibility and innovativeness. Depending on goods, processes and the region, the metalworking sector may implement the activities in the field of

- production of steel and steel alloys,
- distribution of steel and steel products,
- processing (incl metalworking).

The industry, in spite of a wide range of activities, faces the problems concerning both high fragmentation of small and medium companies and its close link with other industries, among others, automotive, construction or the machinery industry. On the other hand, this sector generates high level of employment and exceeds other production sectors in the category of relationship between gross operating production and turnover, it is therefore one of more attractive sectors among foreign investors. The basic raw material manufactured for the metal sector is steel. The world's top producers of steel are located in Asia, North America and the European Union. According to Steel Statistical Yearbook (2017) and BFI des VDEh, (2017) data, the EU countries steel production is dominated by Germany and Italy. Poland occupies the close fifth position in this ranking. The share of Poland in the world's steel production amounted to only 0.56% in 2018 and was almost at the same level as in previous years. At the same time, in Poland, there was observed a dynamic growth in the level of steel production (by as much as 15% in 2018 compared to 2012). In 2018 the level of marketed production amounted to more than 0,8 million EUR in all entities of the industry, however the vast majority generated sales at the level of PLN 0,5 to 1,25 million EUR (a total of 63% of enterprises). The entities manufacturing steel products generate 92% of the total sales in the industry. The companies producing metal indicate the highest level of sales ranging from PLN 0,5 million to 1,5 million EUR and 10 million EUR and more (a total of over 46% of these companies). The metal industry occupies the fifth position on the scale of innovation in the industrial processing sector in Poland. However Peters (2017) indicated the reasons for the unsatisfactory level of innovativeness of the entities of the sector can be seen primarily in limitation of own financial resources:

- too high innovation costs,
- lack of external funds,
- lack of qualified staff,
- lack information on technologies.

According to studies by Romanowska (2016) and Slusarczyk (2019) the development of the metalworking sector, due to rapid development, enforces a substantial increase in the demand for increasingly complex products manufactured using the high-tech infrastructure of tools (eg. for pressure die-casting technology), which satisfies new requirements of the supply chain and industrial trends. In analysed case, for the metal sector company significantly important is ability to manufacture large-size molds for pressure die-casting of light alloys, which weight more than 20 tons and are used for the production of complex and operationally durable parts in the automotive industry. In order to investigate the use of the EU funds in supporting of innovative technologies, there has been chosen the

research object which faced the problem of technological limitations associated with manufacturing of large-size molds, which resulted in a decrease in competitiveness of the company in the area of the provided metalworking services. The contracts and projects of complex molds manufacturing, due to their weight, dimensions and degree of the shape and structure complexity, required the proper technical preparation and development of the specific manufacturing technologies and above all the possibility of verification of technical assumptions, so that the final product meets precisely the customer requirements and maintain the high level of profitability. According to OECD manual innovation is a new or significantly improved production or delivery method. This includes significant changes in techniques, equipment and/or software, which has been definitely confirmed by the analysed company through the production improvement and changes in equipment to verify the molds. The overarching company's objective was the strengthening of the economic and innovation activity through implementation into the market, new high-tech products and services which are aforementioned large-size molds. The accomplishment of the formulated objective was also associated with the development and technical upgrading of the research and development (R&D) department with the unique in Poland infrastructure which is die spotting press machine for verification and control of large-size molds dimensions tolerance and quality (Figure 4).

Figure 4: Image of the die spotting press machine for large-size molds purchased by the analysed metalworking sector company with the use of EU funds total cost ca. 0.9 milion EUR, (Millutensil Company (2015)

The die spotting press machine purchased for the company's R&D department, allowed for realization of following technological stages:

- verification of molds closing and fitting during the operation and leveling the surface between individual components of the mold,

- testing the rotation of the upper movable part of the mold to the position required by the operator, specified at the stage of assembling the mold, its control and possible improvement,
- testing and checking of linearity – centering and collision between the movable part and the fixed part in the press,
- testing the modelling and simulation of alloy injection, also using wax composition in order to make measurements of the surface of the prototype part, determine its complementarity and possible porosity,
- shortening of the mold manufacturing by elimination of multiple repetition of fitting and final check of the mold,
- verification of manufacture technology parameters for the large-size casting mold so that the casted component meets all the parameters and functions in operating conditions.

Results

The implementation of the EU project results was mainly associated with the implementation of innovative solutions in the field of the process innovation related to improvement of the production process efficiency and quality control of final product. Research and development carried out by the company in the R&D department using the die spotting press machine allowed, among others for:

- verifying the correctness of geometrical parameters of prototypes and technical 3D documentation of large-size molds
- checking leak tightness of large-size molds in the conditions (temperature / closing force / casting pressure) adequate to the operating conditions of casting machines at the recipient,
- checking allowance on pads and other fitted elements of the large-size mold prototype.

The application of the die spotting press machine by the R&D department of the analysed company allowed for manufacturing more complex molds and, in cooperation with research units for knowledge and technologies transfer for mastering know-how and expanding the service of the demanding customers both domestically and abroad. Purchasing of high-tech infrastructure allowed also for a significant improvement in the competitiveness of the company in terms of technological capabilities of the large-size mold production and places the company in the position of the leader in the ranking of metalworking firms not only in Poland but also among the Europe. The implemented process innovation enabled also for reduction in time of large size molds manufacturing process. Significant decrease of the correction of shapes and dimensions stage is particularly worth pointing as factor determining the attractiveness of the realized implementation, which was possible to realize within the Smart Growth Operational Programme project. To sum up key results of the innovative infrastructure implementation were as follows:

Result 1. Duration of the process of die spotting of the mold with the correction of dimensions and operations of precise finishing grinding is 2 days / earlier: 14 days
Result 2. Production costs of large size mold were reduced by approximately 10 000 EUR per mold
Result 3. Reduction in mold production time by about 30% (duration of production according to the existing technology is approximately 5 weeks).
Result 4. Obtaining a high-quality casting, which is directly associated with ensuring leak tightness and precise linearity of the cooperating components.
Result 5. Significant improvement in the competitiveness of the company
Result 6. Cooperation with foreign markets (automotive, aerospace companies)

Discussion

Obtained results of the research showed that the assumed result index concerning the shortening of production technology was achieved. At the same time, there were calculated the indices of Overall Equipment Effectiveness (OEE) of the new production equipment. According to Oechsner (2003) the OEE index is calculated by multiplying three factors: availability A, performance P and quality Q

$$OEE = A \times P \times Q$$

The index is estimated on the basis of the time of availability of the machine for work, its performance and the quality of manufactured goods. The results of OEE for mold and press-forming die spotting are presented in Table 3.

Table 3: OEE index for the purchased die spotting press machine for large-size molds production

Indices [%]	2014	2015	2016	2017	2018	2019
A	89.2	89.8	90.8	91.2	90.8	90.5
P	92.5	94.0	93.4	94.1	94.3	94.2
Q	96.6	97.3	98.2	98.3	98.2	98.2
OEE	**79.70**	**82.13**	**83.28**	**84.36**	**84.08**	**83.71**

On the basis of the value of the OEE index it can be noted that its highest value was achieved in 2017 (84.36%), the lowest in 2014 (79.70%), which results from the first stage of the infrastructure implementation. The factors of availability, quality and performance confirm that the purchase positively affected both the quality of metal products (an increase by almost 2% in 2017 in relation to the initial year of implementation) and the optimization of the production cycle (an increase in the performance index to almost 2% in the research period). At the same time, compared to the period before the project implementation (2010-2014), the OEE index went up on average by 4.66 %. In the research into innovativeness of the results of implementation – the modern press machine, one may refer to the functionality formula by Stabryła (2015). The author, adopting the interpretation of functionality as the satisfactory degree of implementation of functions in the system – in this case, the process innovation, presents the basic formulas and criteria for assessment in the above area. There is highlighted the cost of performing the function (KF), determined by the following formula:

$$KF = \sum_{i=1}^{m} g_i + \sum_{k=1}^{n} y_k$$

where:

g_i – costs of extracted functions – innovativeness,
y_k - costs of integrated functions – production.

In further considerations, Stabryła (2015) indicates the possibility of calculating an increase in functionality – i.e. innovation and the cost of performing the function of the company, identified with the manufacture of products of increasing quality. As a result, with the implemented process of an increase in productive resources – the purchase of innovative equipment ensuring an increase in the quality of production and a new level of effectiveness of the company is achieved. In the assessment of effectiveness, achieved results arising due to the implementation of innovative technologies to the expenditure associated with the purchase of modern equipment are compared. An increase in the value of assets resulting from innovative processes have generally enabled an improvement in the financial results of the company. This was confirmed by the financial analysis of costs and profits from the production of one mold (the same product) before and after the implementation of process innovation (Table 4).

Table 4: Financial analysis of large size mold production costs (one mold, the same product) before and after implementation of process innovation

	Costs in 2014 [EUR]	Costs in 2017 [EUR]	Costs in 2018 [EUR]	Costs in 2019 [EUR]
Material (Steel 28 tons)	39 069.76	39 534.88	42 325.58	41 860.46
Machine use and depreciation	9 767.44	8 372.10	6 511.62	6 627.90
Tools	3 720.93	2 325.58	1 860.46	1 395.34
Return Logistics for Corrective Actions (Contractor from Belgium 2400 km)	6 046.51	----	----	----
Quality control	1 860.46	697.67	744.18	651.16
Total costs [EUR]	**60 465.10**	**50 930.23**	**51 441.84**	**50 534.86**
		Profit after implementation of innovation [EUR]		
		9 534.87	**9 023.26**	**9 930.24**

Source: own study base on the company's financial data

In the strategy of its operation there has been an improvement in the level of innovativeness, which will determine further directions of development based on detailed results of the project financed with the European Union funds. The purchased die spotting press machine for large-size molds, within the framework of the research of the R&D department, prospective and implemented so far, allowed for introducing the input data into the mold project software, taking into account the use of cyclic spotting as one of the final stages of mold production. The purchase and possession of the die spotting press machine created the conditions, for increasing operational durability of molds through the implementation of testing the correction of dimensions and shape also at the stage of inter-operational mold regeneration.

Conclusions

The environment favourable for innovativeness and innovation is evolving towards the search for the possibilities of improvements in business models, enforcing the need to involve large financial outlays, particularly on development of breakthrough innovation and the potential investment risk. In addition to own capital, an important source of financing is the use of foreign capital and public funds under the Structural Funds and Operational Programs of the European Union. The presented research study is a classic example of the EU support for knowledge and experience in acquiring and expanding the horizon of activities in terms of innovative technological, regional, social and environmental solutions. The use of the EU funds in the field of implementation of innovative technologies in the surveyed entity allowed for creating the conditions for development of a new operational strategy in the market of the metalworking industry with the opportunity to compete not only in the domestic market but also the foreign one. The most important features of innovation are: the strong relationship between market performance and new products means that new products help maintain market share and improve profitability, growth also through non-price factors, the ability to replace outdated products, process innovation that lead to shorter production times and acceleration developing new products compared to competitors. In addition, standards for the production of technological and quality products in the form of large-size molds were raised, which has a significant impact on the acquisition of new prospective economic markets, including automotive, aviation, metallurgy and foundry.

grazyna.dehnel@ue.poznan.pl

Abstract

Transport is one of the most important sections in the service sector. Recent years have seen a constant and dynamic growth in the sector of transport enterprises. Under these conditions, only companies with effective management are able to compete on the market of transport services. One crucial requirement in this respect is the ability to monitor the market situation by having access to detailed, regularly updated information. This task is particularly challenging for small companies, which also happen to be the category of companies which receive the least research attention. In addition, they have to compete against large transport enterprises. The use of non-standard methods of estimation that rely on administrative sources can help to extend the scope of information about the transport market. The purpose of the study described in this article is to apply Robust Generalised Regression to estimate characteristics of small transport companies. The estimation process involves delayed variables from administrative registers used as auxiliary variables and is based on small area estimation methods. The variables of interest are estimated at the province level, i.e. at a lower level of aggregation than currently available statistics.

Keywords: Robust Estimation, Business Statistics, Small Area Estimation, GREG

Introduction

Transport services play a very important role in the economy: in fact, they determine its effectiveness and efficiency. Transport is therefore one of the most important sections in the service sector**.** It is strongly connected with market activity (*transport of goods*) and with the the financial standing of the society *(transport of people).* In 2017, in the EU there were more than 1.2 million transport companies. They represented the relatively low share (about 5 %) of the non-financial business economy firms. The *Transportation and storage* sector employed almost 11.5 million persons and recorded value added of EUR 570.0 billion, which represented 8.0 % of those working in the non-financial business economy (Eurostat, 2020). Over 95% enterprises belong to SME, but above half (56 %) of the value added at factor cost in 2017 was generated by some 3 813 large enterprises and these employed 48 % of the total persons employed in the sector. Thanks to its central geographical location, Germany records highest levels in both employment and value added (about 23 %) among EU Member States. It is followed by the France, Italy, Spain and Poland (Fig. 1) (Eurostat, 2020).

Fig. 1: Concentration of value added and employment, *Transportation and storage* sector, 2017
Source: Eurostat (online data code: sbs_na_1a_se_r2)

Recent years have seen a constant and dynamic growth in the sector of transport enterprises, which is the result of the increasing mobility of the population and the growing volume of goods trade. This leads to the constant growth in the number of transport enterprises (Fig. 2). Although this sector includes some activities which are mainly the domain of very large enterprises, for example, postal services, air and rail transport services, the number of small and medium-sized companies is constantly on the rise (Eurostat, 2020). At present, the SMTE (Small and Medium-Sized Transport Enterprises) sector operates in the logistics chain by cooperating with large, international companies as part of capital groups
(Mańkowski, 2019).

Fig. 2: Number of *Transportation and storage* sector enterprises, EU - 28 countries, 2011-2017
Source: Eurostat (online data code: sbs_na_1a_se_r2)

The growth in the number of enterprises is accompanied by the growth in employment (though at a slightly slower rate). Increases can also be observed in turnover and value added (see Fig. 3, Table 1)

Fig. 3: Number of employed persons in *Transportation and storage* sector, EU - 28 countries, 2011-2017

Given the development of *Transportation and storage* sector, transport companies have to operate in the conditions of increasingly fierce competition, which forces them to look for other sources of competitive advantage and extending the scope of their activities. This is directly associated with the need to improve and change their offering and forms of transport services. Moreover, in the context of changes occurring in the national economy, transport companies are faced with the challenge of meeting the growing demand for transport services resulting from the increasing volume of production, which in turn depends on the growing degree of specialization and cooperation (Bujak, 2017). Without the development of transport, further output growth is not possible. One could even argue that the rate at which transport develops should actually be faster than that observed in other sectors of the economy (Luft *et al.* 2016). All this shows the importance of this sector and the crucial task of optimizing their operations that transport enterprises have to undertake. To achieve this goal, transport companies need to monitor the market situation and have access to the latest and detailed information. The particularly difficult challenge is facing small companies, which have to compete against large enterprises that dominate the transport sector. To make matters worse, the number of statistical studies devoted to small companies is rather limited as they are usually treated merely as part of the MSE sector. Very few separate analyses are conducted on small companies, especially at lower levels of aggregation.

The study described in this article is an attempt to apply a non-standard method of estimation to extend the scope of information about small transport companies. At present, basic characteristics of companies operating in EU countries are only published annually at country level. The following

study provides estimates at NUTS2 level by applying a *robust version* of Generalised Regression (GREG), which is a method used in small area estimation (SAE). The aim of the study was to estimate one of the basic indicators of entrepreneurship - *mean monthly revenue* in Polish small transport enterprises at the level of provinces. Lagged variables from administrative registers were used to improve accuracy and coherence.

The article consists of six main parts. The first part is devoted to description of the *Transportation and storage* sector in EU, the second part describes data sources used for the estimation. The third part provides more details about the empirical study. The fourth part includes methodological considerations of the analysis. The fifth part contains a summary of the results and their interpretation. The article ends with conclusions.

Data

The study is based on data from the sample survey conducted by the Statistics Poland (Statistical Office in Poznan), which is the main source of information about Polish entrepreneurs. The survey is conducted in the form of monthly reports submitted by all large and medium-sized enterprises and a 10% sample of small enterprises. Its objective is to collect up-to-date information about basic indicators of economic activity of enterprises, such as *revenue from sales (of products and services), number of employees, gross wages, volume of wholesale trade and retail sales, excise tax, specific subsidies.* The sample frame includes 98,000 units, of which 19,000 are medium-sized and large enterprises (with over 49 employees), 80,000 are small enterprises (from 10 to 49 employees). In effect, about 30,000 units participate in the survey every month.

Description of the study

The empirical study was limited to small businesses employing between 10 and 49 people, which were active in 2012 (due to the data availability). The dependent variable in the model was *mean monthly revenue* obtained by small businesses in June 2012. Two auxiliary variables from administrative registers were selected: *revenue* and *the number of employees* in December 2011. The first variable was taken from the register maintained by the Ministry of Finance and the other one from the ZUS register (the Social Insurance Institution). The selection of auxiliary variables was motivated by data availability. The use of administrative data in statistical practice is associated with certain limitations. One of them is the time delay which often occurs when registered data are made available for purposes of official statistics (Dehnel, 2015). *Mean monthly revenue* of companies employing between 10 and 49 persons was estimated for *Transportation and storage* sector and 16 provinces (NUTS2).

The main idea of the study was to estimate the parameter of interest using Robust Generalised Regression Estimation approach. Direct estimates obtained with the classic Horvitz-Thompson estimator, further abbreviated as HT, were used as a point of reference for the results. By comparing direct (HT, GREG) and robust GREG estimates it was possible to notice the change in estimation of *mean monthly revenue* resulting from the modification of some units (outliers) of the sample.

Estimation Methods

The Robust GREG Estimator

The estimation of parameters for domain associated with business entities at the low level of aggregation poses a particular challenge owing to the characteristic distribution of units with respect to the variables of interest. A way of tackling this problem involves modifying sampled units which are classified as outliers. One example of this approach is winsorization (Chambers et al., 2000). The method consists in splitting the sample into two groups using cut-off points. One group contains observations used to build a model, which are left unmodified. The other group contains outliers, which are included in the sample after modification. Model parameters are estimated on the basis of the modified sample using the winsorized estimator. The winsorized estimator bases on direct

estimator. The study involved Generalised Regression (GREG) estimator. The classic form of the GREG estimator is given by the formula (Rao, Molina, 2015):

$$\hat{Y}_{\mathrm{GREG},d} = \sum_{i\in U_d} \hat{y}_i + \sum_{i\in s_d} w_i e_i = \sum_{i\in s_d} w_i g_i y_i \qquad \hat{y}_i = x'_i \hat{\beta}_d. \tag{1}$$

In addition to the variable of interest, the GREG estimator requires auxiliary variables x_i.
The winsorized estimator is given by:

$$\hat{Y}_{\mathrm{win}} = \sum_{i\in s_d} \widetilde{w}_i y_i^* = \sum_{i\in s_d} w_i g_i y_i^* \tag{2}$$

where modified values of study variable y_i^* are calculated by the following formula (Gross, Bode Taylor, Lloyd-Smith, 1986; Dehnel, 2014, 2018):

$$y_i^* = \begin{cases} \left({}^{1}/_{\widetilde{w}_i}\right) y_i + \left(1 - {}^{1}/_{\widetilde{w}_i}\right) K_{\mathrm{Ui}} & \text{if} \quad y_i > K_{\mathrm{Ui}} \\ \left({}^{1}/_{\widetilde{w}_i}\right) y_i + \left(1 - {}^{1}/_{\widetilde{w}_i}\right) K_{\mathrm{Li}} & \text{if} \quad y_i < K_{\mathrm{Li}} \\ y_i \quad otherwise \end{cases} \tag{3}$$

where:

g_i – the g -weight for unit i defined as:

$$g_i = \left(1 + x_i'\left(\sum_{i\in s_d} w_i x_i x_i'\right)^{-1}\left(t_x - \sum_{i\in s_d} w_i x_i\right)'\right),$$

s ($s\subseteq$N) – sample, s_d ($s_d \subseteq N_d$) – sub-sample from domain d,
$U = \{1, \dots, i, \dots N\}$ – finite population of size N
$\widetilde{w}_i = w_i g_i$, $w_i = 1/\pi_i$ – sampling weights
g_i – weights dependent on the value of the vector of auxiliary variables for the sampled units
$x_i = (x_{1i}, \dots, x_{ki}, \dots, x_{Ki})'$ – vector of auxiliary variables X
$t_x = \sum_{i\notin U} x_i$ – population total of x auxiliary variable
K_{Ui} / K_{Li} – upper / lower cut-off value:

$$\widehat{K}_{Ui} = \hat{\mu}_i - \frac{B_U}{(\widetilde{w}_i - 1)} \qquad \widehat{K}_{Li} = \hat{\mu}_i - \frac{B_L}{(\widetilde{w}_i - 1)}$$

$B_U = E\left[\hat{Y}_{winU} - \hat{Y}_{DIR}\right]$ / $B_L = E\left[\hat{Y}_{winL} - \hat{Y}_{DIR}\right]$ - the bias of $\hat{Y}_{winU}$ / $\hat{Y}_{winL}$,
$\hat{Y}_{winU}$ / $\hat{Y}_{winL}$ – the estimate of population total when only upper/lower winsorization is performed.
To estimate cut-off values $\widehat{K}_{Ui}$ and $\widehat{K}_{Li}$ one must determine the values of bias B_U i B_L and the $\hat{\mu}_i$ parameter. Methods used for estimating bias are described in in articles by Preston, Mackin (2002), Dehnel (2014).

In order to estimate the parameter of $\hat{\mu}_i$ various robust methods can be applied. Four of them were used in this study: *Trimmed least squares (TLS), Trimmed least absolute value (ABS), Sample Splitting(SPLIT), Least median of squares (LMS)* (Preston, Mackin, 2002). They were described by Rousseeuw and Leroy (2003).

a. The method of ***Trimmed least squares (LS)*** involves first fitting an OLS regression model to minimise the function:

$$F = \sum_{i\in s} (y_i - \beta^T x_i)^2 \tag{4}$$

Then fitted values and residuals are calculated. In the second step, units with the largest positive and negative residuals are removed. Finally, a new regression model is fitted to the reduced sample in order to estimate the value of μ_i^*.

b. The method of ***Trimmed least absolute value (ABS)*** consists in fitting a regression model to minimise the function:

$$F = \sum_{i\in s} |y_i - \beta^T x_i| \tag{5}$$

After evaluating fitted values and residuals units with the largest positive and negative residuals are removed. A new regression model is fitted to the reduced sample. It is expected that the *ABS* method is a more robust regression model than the *LS* technique because large residuals which are not squared have less influence on the regression parameters.

c. The ***Sample Splitting Technique (SPLIT)*** is based on OLS. It is applied to data that has been randomly split into two halves. A regression model is fitted to each half of the data while the residuals are calculated using the model applied to the half of the data that was not used to fit the model. Then, after merging the data, units with the largest positive and negative residuals are removed. The process is repeated until a certain percentage of data has been deleted. The *SPLIT* technique is expected to be more robust than LS because the residuals used to remove the 'outlier' units are not calculated from a regression model that has been generated using these 'outlier' units.

d. The ***Least median of squares (LMS)*** technique consisted of minimising the median of all sample squared residuals. It was described by Rousseeuw and Leroy (2003). It resembles the bootstrap method. It involves drawing subsamples of size $n-1$ from a sample of size n using *simple random sampling* with replacement. For each subsample trial regression model parameters are calculated and then their squared residuals, which are used to calculate the median. The model with the smallest median of squared residuals is selected. The *LMS* technique should be more robust than *LS* because an OLS regression model is fitted in the absence of "outlier" units, without totally removing these 'outlier' units (Preston, Mackin, 2002).

The LMS technique should be more robust than *LS* because the OLS regression model is fitted in the absence of outlying units, without totally removing them (Preston, Mackin, 2002).

Estimation quality was assessed with reference to estimates obtained using classical direct Horvitz-Thompson (HT) estimator - the most common estimator in survey methodology (1952). Consider sample s drawn from population U, where s_d is a sub-sample from domain d. Counties in domains meet the condition $n_d < N_d$, where n_d denotes the sample size in domain d and N_d is the population size of domain d. Under simple random sampling, each unit i in the sample has been assigned a sample weight – w_i. The estimator of the total in domain d is given by the formula:

$$\hat{y}_d^{HT} = \sum_{i=1}^{n_d} \frac{y_{di}}{\pi_{di}}, \qquad (6)$$

where:

$\hat{y}_d^{HT}$ is the estimated mean of the variable of interest y in domain d,

π_{di} – probability that the i-th unit belonging to domain d is in the sample,

y_{di} – value of the variable of interest for the domain d and i-th unit.

The direct estimator is design-unbiased and design-consistent assuming that $n_d \to \infty$. Nevertheless, it is very ineffective for domains in which n_d is very small and it is impossible to calculate direct estimates for non-sampled domains where $n_d = 0$ (Guadarrama, Molina, Rao, 2016).

Method of Assessing Precision

Precision of estimates was evaluated using the extension of standard bootstrap method, taking into account sampling method (Shao, Tu, 1995). Detailed discussions of this subject can be found in the monograph by J. Shao and D. Tu (1995: 238–250), J. Rao and C. Wu (1988: 231–241), E. Antal and Y. Tillé (2011: 534–543). Estimation efficiency was assessed using the coefficient of variation of the estimator based on results obtained in $B = 500$ samples ($b = 1, 2, ..., B$), following the approach described in (Bracha, 2004):

$$\widehat{CV}(\hat{Y}_d) = \frac{\sqrt{Var(\hat{Y}_d)}}{E(\hat{Y}_d)} = \frac{\sqrt{\frac{1}{499}\sum_{b=1}^{500}(\hat{Y}_{b,d}-\hat{Y}_d)}}{E(\hat{Y}_d)}, \qquad (7)$$

where:

$\widehat{CV}(\hat{Y}_d)$– the estimator of the coefficient of variation of the estimator,
$Var(\hat{Y}_d)$– the variance computed based on bootstrap iterations,
$E(\hat{Y}_d)$– the bootstrap estimator of the expected value.

This ratio indicates the share of the estimation error in the value of the target variable estimate. Smaller $\widehat{CV}$ values are desirable.

Additionally, in order to obtain a more thorough evaluation of the estimates, the analysis focused on differences between values of the estimators obtained from a specific sample and estimates obtained from tax return data filed in December 2012. It was assumed that the following relationship holds: the ratio of *revenue* reported in tax returns by companies in the study at the province level to the value of *revenue* from the monthly enterprise statistical survey is constant (see Fig. 4).

$$\frac{\text{revenue_AR XII2012}}{\text{revenue_XII2012}} = \frac{\text{revenue_est VI2012}}{\text{revenue_VI2012}} \qquad (8)$$

revenue_AR XII2012 - revenue in December 2012 obtained from Administrative Register
revenue_ XII2012 - revenue in December 2012 obtained from statistical survey
revenue_est VI2012 - estimates of revenue for June 2012
revenue_ VI2012 - revenue in June 2012 obtained from statistical survey

This approach made it possible to calculate the approximate value of *revenue* for June 2012.

Fig. 4: Value of revenue in June and December 2012 reported in the statistical survey and in tax returns (Administrative Register) for companies classified into the *Transportation* section

Results of the Empirical Study

The robust GREG estimator makes it possible to exploit information from a small sample or, in special cases, an empty sample, by supporting estimation with data from non-statistical sources - auxiliary variables - without additional costs to provide reliable estimates at a low level of aggregation.

The point of reference for the evaluation of estimation precision was the estimate obtained using the classic HT estimator. The measure of efficiency (CV) indicates that the GREG estimator based on the least median of squares regression and GREG estimator based on the SPLIT method are characterised by the highest variation, even higher than the HT estimator (see Fig. 5). The variation of the classic GREG estimator based on the auxiliary variables from administrative registers is comparable with the HT estimator. The reduction in variation (compare to the HT) is achieved by the application of the GREG estimator based on the ABS and the LS method. In some provinces for ABS and LS methods it can be observed a considerable decline in value of CV. The biggest difference between the HT and robust GREG estimates can be observed for the Pomorskie, Opolskie and Wielkopolskie provinces – a decrease in CV from 57% to 25%, from 28% to 6%, and from 31% to 18% respectively.

Fig. 5: Comparison of estimation precision for Transport

Source: based on data from the statistical survey and CSO (GUS, 2016)

Some kind of "accuracy" of estimation was also assessed. The reference values for the estimation of *revenue* were calculated using *the ratio* (8) described above. Additionally and as in case of precision assessment, the robust GREG estimator was compared with the HT estimator, see Fig. 6. The results of this comparison indicate that the application of robust GREG estimation has considerably improved "the accuracy" of estimates in comparison with HT or GREG estimation. For nearly all domains of interests (provinces), the HT estimates of *mean revenue* are significantly overestimated; in contrast, the GREG estimator underestimates the parameter of interest for some domains. The largest discrepancy between estimates for different domains can be observed for the provinces for which the auxiliary variables used in the model were characterised by the highest dispersion.

Fig. 6: Comparison of estimates of revenue in June 2012 for Transport

Source: based on data from the statistical survey and CSO (GUS, 2016)

Spatial variation in differences between the estimates and real values is illustrated in maps showing the level of deviation across provinces (see Fig. 7). The results of the study indicate that direct HT estimates for most domains are overestimated compared with values from administrative registers. The biggest discrepancies can be observed for the HT estimator. These conclusions confirm the properties of classical Horvitz-Thomson direct estimation. If the sample size is too small and if the sample contains outliers, the direct estimator is very ineffective and may grossly underestimate or overestimate the population totals. The estimation approach based on the robust GREG method has generally improved the estimates (in terms of comparison with tax registers), but the degree of gain varied.

Fig. 7: Spatial distribution of relative differences between values of HT estimator and GREG estimators of revenues for Transport obtained based on data from tax returns

Source: based on data from the statistical survey and CSO (GUS, 2016)

The final results - the spatial distribution of *mean revenue* estimates across provinces for Transport section obtained for the GREG estimator based on the LS method (with the highest estimation precision) is shown in Figure 8. The highest estimates of *mean revenue* were obtained for the Pomorskie (4,404 PLN) and Mazowieckie (3,987 PLN) Provinces. The lowest value of *mean revenue* was estimated for the Dolnośląskie (2,033 PLN) and Warmińsko-mazurskie (2,344 PLN) provinces –

which is almost half of the value calculated for the Pomorskie Province, despite the fact that these are neighbouring regions.

Fig. 8: Spatial distribution of the GREG estimator based on the LS method of mean revenue by province for Transport

Source: based on data from the statistical survey and CSO (GUS, 2016)

Conclusions

The analysis of the regional variation between small transport businesses was conducted using non-standard direct method of estimation - Generalised Regression Estimation. Additionally, the study made use of robust regression - winsorization. The application of delayed auxiliary variables from administrative registers improved estimation precision, both in the case of the classic GREG estimator and its modified version based on winsorization. Each of the four methods of robust regression were characterised by varied precision of estimation. The observed differences resulted from how resistant each method was to the influence of outliers. Besides, the reduction of CV was greater for domains of a relatively smaller size and when the correlation between the estimated and the auxiliary variable was stronger. The use of winsorization not only resulted in a precision gain but also improved "accuracy". The evaluation of estimation quality in terms of "accuracy" has revealed that sample modification using winsorization helps to reduce bias resulting from the presence of outliers. While the HT estimates of *mean revenue* are significantly overestimated and, in contrast, the GREG estimator underestimates the parameter of interest for some domains, the application of robust GREG estimation has considerably improved the quality of estimates.

Multi-Factor Model of Competitiveness of Business Services Subsector in Poland In Changing Economic Conditions

Magdalena MAJCHRZAK

WSB University in Poznan, Poznan, Poland
magdalena.majchrzak@wsb.poznan.pl

Abstract

In the 21st century, many changes took place in Poland, which positively influenced the ability to think about the need to adapt the business model of an enterprise to a specific phase of the business cycle. However, this did not translate into preparation of enterprises for changes in the economic situation. This fact and extraordinary events, initiated in China at the turn of 2019 and 2020, influenced the launch of research aimed at developing a concept for the model of functioning of business sub-sector enterprises in changing economic conditions. The choice of the research subsector was determined by its economic significance, measured by its share in GDP creation, value added and employment. The hypothesis was formulated as follows: In the opinion of business owners of the business services subsector in Poland, their entities are relatively poorly prepared for potential changes in economic conditions. The effect of the study, which was conducted on the basis of a questionnaire, is the proposal of a flexible business model of the business services subsector in variable economic conditions based on the principles of clinical economics of J. Sachs.

Keywords: competitiveness, business cycle, business services

Introduction

Competitiveness is the driving force of the global economy and the strategic priority of a business owner. The ability to maintain a good competitive position is also the biggest challenge of the 21st century. This statement is invariably true, especially in relation to the business services sub-sector enterprises, whose functioning is largely determined by the economic situation. The direct inspiration to write the article were extraordinary events, initiated in China at the turn of 2019 and 2020, the development of which clearly indicates quite significant changes in the economic situation. An additional argument for undertaking the study was the significance of the sub-sector, measured by its share in GDP creation, value added and employment. The main aim of the research is to attempt to develop a concept for the business model of the business services sub-sector in changing economic conditions. The hypothesis was formulated as follows: In the opinion of business owners of the business services sub-sector in Poland, their entities are relatively poorly prepared for potential changes in business conditions. The verification of the hypothesis and the implementation of the goal will be carried out thanks to theoretical and empirical research conducted among enterprises of the business services sub-sector.

Theoretical Basics

Along with the industrialization and development of the market, cycles in the economy began to be associated more with human economic activity than with natural phenomena. Wesley Clair Mitchell believed that business cycles appeared in Great Britain in 1790, in the USA in 1796, in France in 1847, and in Germany in 1857. After 1890, business cycles occurred in almost all economies of the world, including the communist economies [Mitchell 1951, pp. 187-198]. According to Nikołaj Kondratieff, these were long cycles and the reason for their occurrence was the wear of the infrastructure and its renewal under the influence of technical progress, as a result of which the development process proceeded in waves [Kondratieff, Stolper 1935, pp. 105-115]. Simon Kuznetz distinguished medium-range swings fluctuations. They were associated with demographic processes, waves of inflow of emigrants, and as a consequence - investments in infrastructure [Kuznetz 1930, p. 558]. Clement Juglar

isolated the classic cycles. The reason for their occurrence were fluctuations in investments in fixed capital. This was related to the activities of banks and an excessive propensity to grant loans during the period of economic expansion [Juglar 1856, pp. 555-581]. This point of view was later adopted by Hyman Minsky, who was responsible for the financialisation of the economy [Minsky 1986]. Józef Kitchin, distinguished the short cycles. The reason for their occurrence are changes in working capital (changes in inventories). They resulted from delays in the flow of information, which influenced entrepreneurs' decisions. These delays caused the fact that the production volume did not match the current demand, an excessive increase in inventories, and as a result a drop in commodity prices and production restrictions [Kitchin 1923, pp. 10-16]. The general economic fluctuations presented are largely of historical importance, although one can find contemporary works referring to them, mainly to the Kondratieff cycles. They arise from the development of theories by Wesley C. Mitchell, Arthur F. Burns and other economists (see Table 1). W. C. Mitchel and A.F. Burns distinguished three phases of economic fluctuations: expansion, recession and reconstruction [Burns, Mitchell 1946]. Joseph Alois Schumpeter referred the cycles of the business cycle to a state of equilibrium and distinguished: the phase of growth, recession, depression and recovery [Schumpeter 1939]. According to John R. Meyer and Daniel H. Weinberg, the business cycle phases (recession, revival, demand inflation, stagflation) are linked to inflation [Meyer, Weinberg 1975]. Ilse Mintz lists two phases of the growth cycle: the accelerated growth phase above the trend and the slow growth phase below the current trend [Mintz 1969].

The financial crisis of 2007-2009 revived the scientific discourse on business cycles. The effect is, among others financial cycle concept developed by Claudio Borio [Borio 2012] and Bernard Landais's Ocean Model [Landais 2017, pp. 97-155]

The cyclical nature of economic development tends to spread to individual world economies. Despite the views on a possible negative correlation of business movements between countries [Baxter, Kouparitsas 2004], most often it is a positive correlation. There is a synchronization of the cycles known as the "contagion effect". This is due to, among others progressing globalization, increased openness of economies, the spread of technological progress and often a common policy of governments and central banks. An example of growth cycle synchronization for the US and EU-28 [OECD 2020]. In many situations, the response of the EU-28 to the US economy may be slightly delayed, which may suggest the direction of the spread of change and the contagion effect. The changes in the activity of European and American economies correspond to classical cycles. This is due to the fact that changes in real GDP on a common basis correspond to data on real GDP values.

Similar synchronization of growth cycles can be observed for EU-28 and Polish economies [OECD 2020]. In many cases a slightly belated response of the Polish economy to the EU-28 economy can be observed.

Due to the "contagion effect" translating into cycle synchronization, the classic business cycle will be used for the Polish economy later in the analysis.

Research Material and Methodology

In March 2020, initial empirical research was undertaken, the subject of which is the competitiveness of enterprises in the business services subsector in Poland in changing economic conditions. The survey covered business services sub-sector companies. Due to the large multifaceted diversity of enterprises in the business services subsector, empirical research was directed to groups of internally coherent entities whose functioning and development are based on professional knowledge. Therefore, based on the targeted selection for empirical research, the following types of activity were qualified (Polish Classification of Economic Activity):

a) other financial service activities, excluding insurance and pension funds (section K, group 64.9),
b) other monetary intermediation (section K, class 64.19),
c) activities auxiliary to insurance and pension funds (section K, group 66.2),
d) legal, accounting and tax consultancy activities (section M, division 69),

e) advertising, market research and public opinion polling (section M, division 73),
f) employment-related activities (section N, division 78).

The choice of types of activities resulted from the fact that the types of services provided were often combined, e.g. accounting office's often also deal with credit and insurance brokerage.

The research was conducted in four randomly selected provinces (Masovia, Pomerania, West Pomerania, Warmia-Masuria), with different levels of GDP per capita.

The research was conducted in March 2020 based on a questionnaire, which gave the opportunity to conduct research in a relatively short time. To prevent any possible artifacts (the subject of the study may not be suitable for measurement using a questionnaire or the subject of the examination may affect the answers it provides), which may occur in the survey conducted on the basis of the questionnaire, significant actions were taken:

1. The questionnaire was designed based on the theoretically and empirically verified model proposed by M. Majchrzak, according to which the competitiveness of an enterprise is a resultant of mega-, macro-, meso- and microeconomic factors of competitiveness.
2. The structure of the questionnaire was prepared on the basis of brainstorming, in which representatives of the world of science and persons performing managerial functions in enterprises of the business services sub-sector were invited to participate.

The respondents were presented with a questionnaire consisting of 21 closed and semi-open questions (6 questions were a record). The survey was anonymous, which resulted from the specifics of the business services sub-sector. Most of them are micro-enterprises not required by law to publish financial data, and a study of this area of activity is also envisaged. There was a fear of reluctance to answer questions in this area.

In the questionnaire, next to the metric, two parts were separated shaping the model of the competitive enterprise's functioning in changing economic conditions:

1. Impact of cyclical changes on the operation of the business services sub-sector company.
2. Assessment of the competitive potential and instruments of competing by the enterprise in changing economic conditions, with particular emphasis on the recession phase.

The questionnaire was sent to 1,600 enterprises (average return rate 22.13%) from Masovia, Pomerania, West Pomerania, Warmia-Masuria Provinces. At the significance level of 0.1 and with an admissible error of estimation of 9%, the necessary sample size was obtained, which allows to generalize the obtained results to the entire enterprise group of the business services sub-sector.

A similar percentage of enterprises from individual provinces took part in the survey (Masovia-25.06%, Pomerania- 23.94%, West Pomerania-26.84%, Warmia-Masuria-24.16%).

In all provinces, enterprises of the business services subsector were mostly run by natural persons as part of sole proprietorship (the average for all provinces is 75.71%), but there were also civil law partnerships (19.22%) and limited liability companies (3.12%) and partner companies indicated by respondents (1.95%). The choice of the form of conducting economic activity was largely dictated by the size of the enterprise. In the studied population, micro and small enterprises dominated (99.78% in total). Medium-sized enterprises constituted 0.22%, while there were no large enterprises.

The size structure of enterprises was additionally verified in the question regarding net turnover from the sale of goods, products and services and financial operations. Over 95% of the analyzed enterprises achieved a net turnover of up to 500,000, and the rest in the range of 500,000. up to 1 million (in this group were mainly enterprises registered in the Masovia characterized by the highest level of affluence of the society). The analyzed entities are micro and small enterprises.

The majority of respondents were enterprises conducting legal and accounting activities, as well as credit and insurance brokerage (over 39%). A smaller group are companies operating in the marketing area (over 17%) and employment intermediaries (less than 5%). The sample surveyed was dominated by enterprises operating for over 10 years, they constituted over 78% of the population. More than 19% are enterprises existing from 5 to 10 years, and only slightly more than 4% are enterprises existing less than 5 years. A high share in the sample of long-existing enterprises (over 10 years) suggests that the study was carried out among people who know the sub-sector and the specifics of operations well, which significantly increases the quality of research. The dominant participation in the survey of enterprises that have been on the market for many years indicates that it is possible to maintain the market position in the sector, and the invitation to research of experienced entrepreneurs will show the ways to achieve competitive advantage, which makes the survey reasonable and confirms the proper structure of the target group.

Competitiveness of Enterprises in The Business Services Subsector in Changing Economic Conditions

Extensive empirical and theoretical research has led to the creation of an integrated ten-factor competitiveness model for the business services sub-sector. It was created based on the concept of a nine-factor competitive model of D. Cho and H. Moon [Cho, Moon 2000, pp. 223], which on the basis of further empirical research was expanded by another factor of competitiveness - threats from the environment (Figure 1).

Fig. 1: Integrated ten-factor competitiveness model of the business services sub-sector
Source: M. Majchrzak, Konkurencyjność przedsiębiorstw podsektora usług biznesowych w Polsce. Perspektywa mikro-, mezo- i makroekonomiczna, CeDeWu, Warszawa 2012, p. 183.

The model presented in Figure 1 was modified by the empirical research conducted in March 2020. In the first stage, attempts were made to determine the macroeconomic impact of cyclical changes on the enterprise's functioning model. In connection with ensuring the best possible quality of empirical material in the first part of this stage of research, entrepreneurs were asked to assess the significance of individual macroeconomic factors of competitiveness, assuming a deterioration of business conditions by giving them rank. To this end, entrepreneurs ranked the given factors from the most to the least important (Table 1).

Table 1: Assessment of significance of macroeconomic competitiveness factors in changing economic conditions

No.	Macroeconomic competitiveness factors	Provinces				
		Masovia	Pomerania	West Pomerania	Warmia-Masuria	Total
1.	Business environment	5	4	4	4	4
2.	Business conditions	2	1	1	1	1
3.	Legal regulations	9	9	10	7	9
4.	Stable political environment	11	11	7	11	11
5.	Size and quality of human resources	1	3	2	2	2
6.	Socio-economic infrastructure	10	10	11	10	10

Source: own study based on conducted research.

Among the macroeconomic competitiveness factors, the economic situation is the most important for entrepreneurs in the business services sub-sector. In the survey conducted in 2012, this factor was in second place. Therefore, the timing of the survey (pandemic and probability of recession) affected the assessment of the significance of this factor to a small extent.

According to earlier fragmentary research, there is a tendency of the clients to "escape" from the sub-sector in a bad economic situation, who provide services on their own in such a situation. The size and quality of human resources came second. This is explained by the fact that business services are largely based on the professional, extensive knowledge of service providers, and therefore high-quality, accessible, mobile human resources can be a key factor here.

Another important factor is taxes and other payments and the business environment, whose friendliness is rated by most entrepreneurs (87%) at 2 on a scale of 1 to 5, and others - even worse. The assessment of this indicator may be related to the moment of testing. Enterprises of the business services subsector are mainly micro enterprises whose existence and position are particularly at risk in the case of economic recession. Hence high expectations towards the business environment. The least-valued factors were the socio-economic infrastructure and political environment.

When asked about the subsector's resilience to economic changes, most entrepreneurs (87%) answered in the negative. This means that the sub-sector is not resistant to macroeconomic shocks, which may indicate the need to adopt various strategies in different economic conditions, as well as flexibility of actions. Entrepreneurs also see the changes that can be brought about by the economic recession. The task of the entrepreneurs was to assess the significance of the indicated factors on a scale of 1 to 5 (Table 2).

Table 2: Assessment of significance of changes (dominant)

Source: own study based on conducted research.

In the opinion of most entrepreneurs, a change in the economic situation (recession) may lead primarily to a change (reduction) in the number of buyers, which will necessitate a change in the company's operating strategy. The next places were: a change in competitors' strategy, a change in their number and closer cooperation in the sub-sector. When asked about the preparation of the business services subsector enterprises for economic changes, 87% believe that these enterprises are not prepared, 10% answer in the affirmative, and 3% have no opinion on this topic. Also interesting are the entrepreneurs' answers to the question about possible support in the event of economic downturn. 79% believe that they can only count on themselves, 12% count on the support of family / friends and other people running a business, and only 9% count on the support of the government.

In the second stage, research was carried out to assess the company's competitive potential in the context of changing business conditions. The first question was about the company having an operating strategy in the event of a change in business conditions. 92% of entrepreneurs surveyed do not have such a strategy, and 8% declared that in the event of a recession, their efforts will focus on market survival. Entrepreneurs who do not have a strategy in the event of a change in economic conditions declare its preparation within the next year.

Another task of representatives of the management level was to assess the significance of individual elements of competitive potential. Entrepreneurs ranked the given potential elements from the most important to the least important (Table 3).

Table 3: Assessment of the significance of individual elements of competitive potential (dominant)

1- the most important factor
19 - the least important factor
Source: own study based on conducted research.

According to entrepreneurs in all the provinces, the most important elements of a competitive potential, with changing economic conditions, are: the quality of employees, means of work (the ability to provide services remotely is important for business services) and financial capital (amount of equity, the possibility of financing projects with foreign capital and collection of receivables). Entrepreneurs also recognize the importance of a flexible organizational structure and having complete market information.

The assessment of the significance of individual potential elements may be supplemented by answers to specific questions regarding this aspect of the research. Managers in all provinces assess themselves as far more entrepreneurial and professional than their competitors. They estimate leadership, creativity and innovation at a similar level. The level of self-assessment of the management is the higher the more developed provinces. Employee evaluation is similar. Entrepreneurs believe that the substantive preparation of employees was lower on the day they started work than at the time of the survey. At the same time, entrepreneurs agree that their employees have the opportunity to expand their knowledge, with various forms of further training.

Lower, but at a level close to competition (with the exception of the Warmia-Masuria Province), entrepreneurs assess the equipment with the necessary means of work in changing economic conditions. In each province, shortages in equipment for labor were identified, which gave an indicator of over 27% across the entire surveyed population. The biggest deficiencies were found by the entrepreneurs of Warmia and Masuria Province, and the smallest by those of Masovia Province. No deficiencies were found for cars, telephones and other small office equipment. The greatest needs in all provinces occur in the area of relatively expensive and specialized equipment for marketing agencies. Individual deficiencies also occur in terms of computers, peripherals, software and furniture. This is worrying, given that the services of the business services subsector without access to modern technologies cannot be provided in changing business conditions (e.g. the need to work remotely).

Entrepreneurs also assessed the significance of selected competition instruments in changing economic conditions. To this end, entrepreneurs ranked the given instruments from the most to the least important (Table 4).

Table 4: Assessment of the importance of competition instruments in the business services sub-sector (dominant)

No.	Competition instruments	Provinces				
		Masovia	Pomerania	West Pomerania	Warmia-Masuria	Total
1.	Price of the service	2	1	1	1	1
2.	Quality of the service	1	2	2	2	2
3.	Personalizing the offer	4	5	5	5	5
4.	Enterprise image	8	6	8	9	8
5.	Timeliness of the service	3	3	3	3	3
6.	Comprehensive offer	5	4	4	4	4
7.	Innovation of service	6	8	7	7	7
8.	Service provider's availability	7	7	6	8	6
9.	Marketing activities	9	9	9	6	9

1- the most important factor
9 - the least important factor
Source: own study based on conducted research.

According to entrepreneurs, the most important competition instruments are: price, quality of service, timely delivery and comprehensiveness of the offer. In turn, marketing activities and the company's image are of the least importance. The distribution of responses slightly differed in individual provinces. In the Masovia Province, the quality of the service is more important than the price, while the comprehensiveness of the offer is less important than in other provinces. In the Pomerania Province, the image of the enterprise is more important than in other provinces, the availability of the service provider in West Pomerania Province and marketing activities in the Warmia-Masuria Province.

Redefining the business competitiveness model of the business services subsector using the assumptions of clinical economics

Most business service subsector companies do not have competitive models. The way they operate is often intuitive, and the competition models themselves are informal and imprecise. Perhaps this is the result of a lack of future-oriented thinking and consideration of possible actions in the short term. Direct control of the implementation of the model, possible quick implementation and possible change should encourage its introduction in the enterprise. Implementation of the solution while avoiding threats may also be facilitated by the application of Jeffrey Sachs' clinical economics solutions [Sachs 2005, pp. 74-98]:

Lesson 1. Enterprises/economies, like human organisms, are complex systems. All subsystems must function properly for the entire economy/enterprise to function well.

Lesson 2. Economists, like clinicians, must master the art of differential diagnosis. Clinical economics should teach a much more effective focus on hidden causes of threats and recommendations of appropriate countermeasures, well adapted to the specific conditions of each country (descriptive economics). Similar effects can be caused by various causes, and this requires the use of a different corrective instrument.

Lesson 3. Clinical economy should consider the treatment in terms of "family", not individuals. Tips given, for example, by the World Bank and the International Monetary Fund may prove ineffective if they do not harmonize with the actions of other countries. Similarly, enterprises, while maintaining competition in some areas, can cooperate in others.

Lesson 4. The effectiveness of clinical economics will depend on the control and assessment of the situation. In clinical economics, it is important to carefully compare goals and results. In the event that goals are not achieved, the important question is why, instead of seeking justifications for previously given advice.

Lesson 5. Economists should adhere to strict ethical and professional standards. The economist's work is not undertaken with a sense of responsibility. It is often superficial. Meanwhile, an economist dealing with economic affairs should also be familiar with the history, ethnography and politics of a given region. He/She should speak the truth, even if the solution to the problem lies outside the subject.

On the basis of theoretical and empirical research and principles of clinical economics of J. Sachs, it is proposed to use a model of flexible operation of enterprises in the business services subsector in changing economic conditions (Figure 2).

Fig. 2: Model of flexible operation in changing economic conditions
Source: own study based on conducted research.

Empirical studies have indicated the following boundary conditions, which must be met when introducing a model of flexible operation in changing economic conditions:

1. The model is introduced based on the ten-factor competitiveness model of the business services sub-sector enterprise.
2. The introduction of the model is preceded by a thorough analysis of competitiveness factors at all levels.
3. The model is recommended to enterprises at every stage of development, but this model will work more efficiently in enterprises that know the market and the rules that govern it well.
4. The model can be used by both enterprises operating in more and less developed areas.
5. Adaptation of the model in other countries is possible after examining the maturity phase of the business services subsector. In Poland, this sub-sector is at an early stage of maturity.

In addition to the existence of boundary factors for the introduction of the proposed model, the solution can be attributed to success factors that justify the success of the project. These are primarily dedicated

employees and professional managers who have the ability to take advantage of opportunities arising in the environment.

Conclusion

The fluctuation of the business cycles under the influence of many foreseeable and unpredictable threats means that enterprises should be prepared to operate in each phase of the cycle. This applies to sub-sectors particularly sensitive to changes in the economic situation, including the business services sub-sector. An attempt to prepare the enterprise for changes in the economic situation, including recession, may be the proposed model of flexible operation of the enterprise of the business services subsector in changing economic conditions, which uses the principles of clinical economics of J. Sachs. Characteristics of the model:

1. Economic changes may have a significant impact on the quality and diversity of services provided by enterprises in the business services sub-sector, as well as create new attitudes and solutions in the sub-sector.
2. The business services sub-sector is in a favorable growth phase for entrepreneurs, but the economic recession may disrupt their development and reduce competitiveness.
3. A favorable business and tax environment could be an important element of protecting the business services subsector against adverse economic effects.
4. The factor maintaining the company's competitiveness should be entrepreneurs and professionals at the managerial level who are able to take advantage of opportunities coming from the market and minimize the effects of threats.
5. Beneficial changes in the environment can be used to build a competitive advantage, and threats can result in the use of avoidance strategies in the sub-sector.

An inherent element of the model is compliance with clinical economics principles focusing on: perceiving the complexity and diversity of enterprise systems and subsystems, considering problems within the "family" (potential cooperation of enterprises in the business services subsector, also in the recession phase), controlling and ongoing assessment of the situation by ethical and professional economists.

Abstract

The informal economy in Nigeria is acknowledged to be one of the largest in the global economy, therefore, the dynamics of the informal economy should be central in the formulation of macroeconomic policies. However, evidence from the literature in Nigeria shows that there is scarce information pertaining to the cyclical characteristics of the Nigerian informal economy. Hence, this study attempts to document some of the business cycle facts of the Nigerian informal economy from 1992 to 2018 using the Hodrick-Prescott filter. The results from the analysis suggest that an expansion of the cycle of informal economy coincides with a rise in the level of unemployment and government interference.

Keywords: Informal economy, business cycles, Hodrick-Prescott filter

Introduction

The informal economy in Nigeria is acknowledged to be one of the largest in the world, particularly in relation to its contribution to total employment. According to the harmonised global and regional statistics on the informal economy in 2016 by ILO (2018), as a percent of total employment, informal employment in Nigeria averaged about 92.9 percent. Further evidence reveals that the share of informal employment in Nigeria is much larger than the average in Africa (72.3 percent); Sub-Saharan Africa (73.6 percent); and Developing and emerging economies (91.6 percent), thereby illustrating the importance of the informal economy in creating employment and income opportunities in Nigeria.

From the literature, there are a number of factors accountable for the large size of the Nigerian informal economy. For example, Ogunrinola (2011) noted that due to formal sector not being able to provide job opportunities, most individuals have had to find alternative opportunities in the informal sector. The findings from Ogbuabor and Malaolu (2013) indicated that an increase in state regulation, the unemployment rate and interest rates are among the major factors that have caused the informal economy to expand in Nigeria. Rising urban population growth rate and the number of people considered to be vulnerably employed were seen as the major drivers of the informal economy in Nigeria (Dell'Anno and Adu, 2020). According to Dell'Anno et al. (2018) one major consequence of an expanding informal economy is that it tends to undermine the effectiveness of macroeconomic policies towards maximising the welfare of the people. Hence, it can be said that in the formulation of structural policies, informality should be a major consideration especially for economies with a large size (Elgin et al., 2019).

However, despite the policy significance of the informal economy in the formulation of structural and cyclical policies, in the literature, the dynamics of the informal economy from a business cycle perspective remains largely unexplored. Hence, for a Nigerian economy where the informal economy is recognised to employ a distinct size of the labour force, it is imperative to understand the nature of its business cycles in relation to other key macroeconomic variables, such as inflation and interest rates. Therefore, the main objective of this study is to fill this gap in the literature and document some of the

main business cycle facts of the informal economy in Nigeria. In what follows, the rest of this paper is structured as follows: Section two presents some trend analysis of the Nigerian informal economy and Section three reviews the literature pertaining to the estimation of the size of the informal economy; Section four discusses the method of analysis; Section five highlights the results and discussion of findings; and the conclusion of the study is presented in Section six.

The Nigerian Informal Economy

In this section, we document some facts about the Nigerian informal economy based on the official survey carried out by the Nigerian National Bureau of Statistics (NBS) in 2017. The informal sector in the report is categorized as micro enterprises with an employment size of less than ten people and having an asset size worth less than N5 million (Naira). The survey was undertaken in all the states of the country including the Federal Capital Territory.

a. High presence of informality in Nigeria

The survey covered micro, small and medium enterprises (MSMEs) and from the survey findings, there were a total number of 41.54 million in 2017. Out of which, micro enterprises, representing the informal sector constituted about 99.83 percent (41.47 million). Further evidence shows that there has been a strong growth in the size of informality from 2010 to 2017 (Figure 1). In particular, the number of informal enterprises grew by about 12.11 percent from 2013 to 2017.

Figure 1: Micro enterprises in Nigeria

Source: SMEDAN and NBS (2019)

b. The informal sector is the largest employer of labour in Nigeria

The findings from the survey reveals that in terms of employment generation, the informal sector employs a larger proportion of the Nigerian labour force. In 2017, Nigeria's labour force was estimated at about 69.11 million, out of which the informal sector provided jobs for about 59.65 million people, implying an employment contribution of about 82.13 percent of the labour force in Nigeria.

c. Wholesale and Retail Trade is the Major Economic Activity of the Nigerian Informal Sector

The results from the report as presented in Figure 2 shows that, in terms of economic activity, a larger proportion of the participants in the informal sector engage in wholesale or retail trade. In particular, about 42.30 percent of micro enterprises engage in wholesale or retail trade. This is followed up by agriculture that accounts for about 20.90 percent. Also, the results indicates that about 9 percent of informal enterprises engages in the manufacturing activities.

Figure 2: Economic Activities of the Informal Sector

Literature Review: Measurement of the Informality

From a conceptual standpoint, the definition of informality plays a major role in which it is measured. Schneider (2012) asserts that by overcoming issues concerning the definition of informality, a lot of ambiguities can be avoided in relation to the way it is measured. Early descriptions of the level of informality were measured along the line wage-employment dynamics (Hart 1971, 1973; ILO, 1972). The wage-employment concept generalised the informal economy as one that provides low-income and self-employment opportunities to individuals. However, new evidence from empirical studies has shown that the informal economy has evolved encompassing other elements such as employment size and legality issues (Schneider, 2012).

Measuring the informal economy in relation to employment size has become more prominent because of the ease in determination. Often times, informality using the approach is defined in the context of the number of firms with an employment strength of less than ten workers (Amin, 2002; Angel-Urdinola and Tanabe, 2012). Another common, but complex method of defining and measuring the size of the informal economy is by focusing on the legality of economic activity. Schneider and Enste (2000) assert that informality in any economy is characterised by "all legal value-added creating activities which are not taxed or unregistered". Therefore, in terms of legality, the informal economy only focuses on productive economic activities that under normal situations would be included in the national accounts but are not, usually because of tax or regulatory burdens (Schneider, 2012).

From a methodological perspective, there is still an ongoing debate on the appropriate technique to be used. However, there are three major methods: the direct estimation method, the indirect estimation method and the estimation method (Becker, 2004; Schneider and Enste, 2000; and Schneider, 2012). The direct approach is a micro level means of estimating the level of informality. It usually involves the use of a survey method through a set of administered questionnaires or focused group discussions. The advantage of this survey approach according to Krakowski (2005) is that the method allows the researcher to reflect the perceived concept of what the informal economy should be. Conversely, the indirect approach of estimating the size of informality is mostly econometric in nature and involves the use of certain indicators that provide evidence about the growth of informality in an economy overtime. Some of these indicators include: the residual amount between national expenditure and income statistics; the gap between actual labour force and official labour; the transaction approach; the currency demand approach; and the electricity consumption approach.

The statistical approach is grounded on the statistical theory of unobserved variables. In this method, informality is determined based on a factor analysis approach where a set of structural equations

consisting of unknown coefficients are to be estimated within which the unobserved variables cannot be directly measured (Schneider, 2002). This technique is regarded as the Multiple-Indicators Multiple-Causes (MIMIC) approach. Ogbuabor and Malaolu (2013) state that the MIMIC model is used to explain the association that exists between the unobservable variables and the variables considered to be observable in the model by minimising the spread from the covariance matrix to be predicted as against the sample covariance matrix of the model.

The major advantage of the approach is that it allows for the incorporation of several factors that could be considered to influence the level of informality. For example, Ogbuabor and Malaolu (2013) used the approach to evaluate the level of informality in Nigeria using macroeconomic indicators like the tax burden, government spending, unemployment rate, inflation rate, trade openness and broad money. Schneider (2005) also adopted the approach to estimate the size of the informal economy for about 66 economies in Africa, South America and Asia using variables such as employment rate, growth rate of GDP, burden of government regulation, and share of direct and indirect taxation. Dell'Anno and Adu (2020) also made use of the MIMIC approach to evaluate the drivers of informality in Nigeria. The results from the study showed that in Nigeria, the urban population growth rate and the vulnerable employment rate are the major factors accountable for changes in the level of informality.

The study of Medina, Jonelis and Cangul (2017) likewise made use of the MIMIC approach to evaluate the degree of informality in Sub-Saharan Africa (SSA). The results from the paper indicated that there exists a striking difference in the level of informality across the selected countries. For example, in countries like South Africa and Mauritius, the degree of informality ranges from about 20 to 25 percent of GDP as against about 50 to 65 percent in economies like Benin and Nigeria. The MIMIC estimation also revealed that trade openness, rate of unemployment and size of the government are some of the major factors responsible for the increase in informality in SSA. Additional findings from the study also suggested that the degree of informality in SSA compares distinctively to the rest of the world.

In summary, all three approaches are used in the literature, however, each of them has its own limitations and drawbacks. For example, the direct approach has been criticised based on the notion that it only offers a size of the informal economy at the period in which the survey is carried out and undergoing several surveys may be costly. Also, it has been criticised on the grounds that the survey may reflect the researcher's personal bias. In relation to the indirect approach, most of the criticism is based on its rather limited scope, while the statistical approach has been criticised based on the assumptions concerning the calibration of the model. However, the statistical approach is seen as a rather more comprehensive approach in comparison to the direct and the indirect approaches (Dell'Anno et al., 2018). This is because the method is able to take into consideration the different factors perceived to be responsible for the growth of the informal economy.

Methodology: The Business Cycle Approach

Towards the actualisation of the main objective of the study: to document some of the cyclical characteristics of the informal economy in Nigeria, the method of analysis is based on a data filtering technique commonly used in the business cycle literature (Alege et al., 2017). This data filtering technique used for the purpose of this study is the Hodrick Prescott (HP) filter which enables the extraction of the cyclical component of a series from its trend component. Through the use of the HP filter, we study three essential characteristics of the Nigerian informal business cycle: the amplitude of fluctuations; the degree of contemporaneous correlation; and the phase shift as defined in Alege, Oye and Adu (2019).

a. **Amplitude of Fluctuations:** The amplitude of fluctuations reflects the level of volatility inherent in a variable. This is measured using the percentage standard deviation and the relative standard deviation. The former depicts the level of volatility, while the latter is used to compare the volatility of a variable with respect to the volatility of informal GDP. Typically, a relative volatility greater than one suggests that the variable in question is considered to be highly volatile.
b. **Degree of Contemporaneous Correlation:** The degree of contemporaneous correlation is used to determine the cyclical relationship with informal GDP. This is measured using a cross-correlation analysis, where a variable is considered to have either a pro-cyclical, countercyclical or acyclical relationship with informal GDP. A positive correlation coefficient depicts pro-cyclical,

while a negative correlation suggests a countercyclical relationship. On the other hand, a coefficient value closer to zero depicts an acyclical relationship.

c. **Phase Shift:** The phase shift is used in the determination of leading or lagging variables. This is ascertained by observing the absolute cross correlations between two variables overtime. In particular, when the maximum absolute value between variable x and y is on the negative (lag) side, then variable x is considered to be a lagging indicator. Alternatively, when the maximum absolute value between the variables are on the positive (lead) side, then it can be concluded that x is a leading indicator of variable y.

Annual data from the period 1992 to 2018 is utilised to achieve the objectives of the study. The data for the informal GDP in Nigeria is sourced from the study of Dell'Anno and Adu (2020), while for the remainder macroeconomic variables: Unemployment rate, Inflation rate, Government expenditure, GDP Per Capita and the Currency ratio, the data is derived from CBN (2018).

Results and Discussion of Findings

Table 1 presents the result of the business cycle characteristics of the informal economy. Examining the relative volatility of the macroeconomic variables in relation to informal GDP, the results point out that government expenditure, unemployment and inflation all have a relative volatility greater than one, thereby signifying a high degree of volatility. In other words, these variables are subject to a high degree of fluctuations in the advent of shocks to the economy. In contrast, the result shows that GDP per capita and the currency ratio are subject to less degree of volatility.

The contemporaneous correlation coefficient between informal GDP and GDP per Capita is given as 0.08, the 0.08 coefficient indicates that there exist a weak, but countercyclical relationship between the variables. This result implies that a rise in the cycle of informal output coincides with a fall in the average level of income of individuals in Nigeria. Although the strength of the relationship is weak, the negative sign follows expectations such that a rise in the GDP per capita, a measure for income per head, should bring about a fall in the level of informality in the economy. The weak relationship noticed could suggest that the GDP per capita is not strong indicator for the cyclical nature of the informal economy. The phase shift reveals that GDP per capita lags the cycle of informal GDP, hence suggesting that changes in the level of the GDP per capita precedes changes in the informal economy.

Government expenditure is seen to have a strong and pro-cyclical relationship with informal GDP given the contemporaneous coefficient result as 0.59. This result indicates that an increase in government spending or interference in the economy, there is the tendency for the size of the informal economy to expand. The findings from the study of Ogbuabor and Malaolu (2013) provide similar findings when using a regression analysis testing for the effect of government regulation on the size of the informal economy. The strong relationship observed is not surprising given the considerable level of government and state regulation in Nigeria which could drive more individuals into the informal economy to avoid regulatory issues. The result from the phase shift indicates that government expenditure is a leading indicator to the informal economy.

Similar to government expenditure, the results indicate that the unemployment rate has a pro-cyclical relationship with the informal economy. This result implies that a rise in the cycle of unemployment is typically accompanied by a rising level of the cycle of informality. The finding is not surprising as empirical evidence from Schneider (2012) provides similar result and theoretical justification that higher levels of unemployment tends to drive individuals to the informal economy in search of income opportunities, thereby leading to a rise in the degree of informality. From the phase shift, the result shows that rate of unemployment tends to lead the cycle of the informal economy. This implies that changes in the cycle of unemployment is a leading indicator for the behaviour of the informal economy.

The contemporaneous correlation between inflation and informal GDP is given as 0.38, thereby implying that a pro-cyclical relationship exists between both variables. The result implies that a rise in inflationary pressures, the cost of goods and services, the informal economy tends to expand by its facilitation of illegal markets. The contemporaneous correlation between the currency ratio and informal GDP also suggest that there exists a weak, but pro-cyclical relationship. The currency ratio is used to represent the level of currency outside the bank, which is a major driver of economic transaction

in the informal economy. Therefore, an expanding currency ratio should reflect an a rise in the degree of informality (Schneider, 2012). The phase shift result indicates that both the inflation rate and the currency ratio both lead the cycle of the informal economy.

Table 1: Cyclical Behaviour of the Informal Economy

Variable	V	RV	CC	PS
Production				
Informal GDP	10.21%	1.00	1.00	-
GDP Per Capita	3.93%	0.39	-0.08	Lagging
Expenditure				
Government Expenditure	13.74%	1.35	0.59	Leading
Labour market				
Unemployment	28.30%	2.77	0.52	Leading
Prices				
Inflation	42.41%	4.15	0.38	Leading
Monetary				
Currency Ratio	7.28%	0.71	0.03	Leading

Source: Researchers' computation
Note: V denotes Volatility, RV represents Relative Volatility, CC stands for Contemporaneous Correlation and PS indicates Phase Shift

Conclusion

This study attempts to empirically analyse the business cycle dynamics of the Nigerian informal economy with the aid of the HP filter, a data filtering technique. The results from the analysis shows that when unemployment rises, there is the tendency for the cycle of the informal economy to rise. Also, the findings also point out that an increase in government interference in the economy drives people into the informal economy. Although, evidence also suggests that the currency ratio could be a weak indication for the cycle of the informal economy given the low contemporaneous correlation between the variables. Therefore, as counter measures to limit the degree of informality, countercyclical measures such as provision of employment opportunities and ensuring price stability should be the primary focus of policymakers.

The Impact of Dividend Payout Policy on Stock Return Volatility Of Companies Listed on The Warsaw Stock Exchange

Ewa BLASZKE

Wroclaw University of Economics and Business, Wrocław, Poland

Abstract

The dividend payout policy has been the subject of extensive research for years. However, the issue of the impact of dividend payouts on the company's stock return volatility remains unsolved. The purpose of the paper was to examine whether the dividend policy of companies listed on the Warsaw Stock Exchange affects the volatility of stock return. The research sample concerns 60 firms included in the WIG20 and mWIG40 indices. Consistent with dividend signaling, it was proved that the dividend payout reduces the volatility of the company's stock return. However, no statistically significant relationship was found between the dividend yield and the firm's risk. The dividend yield illustrates the proportion of the benefits arising from owning the company's stock that the investor receives at the time of dividend payout. It could be expected that the greater the portion of the total value of the company's shares that investor receives instantly, the lower the company's risk. For this reason, the lack of any statistically significant link between dividend yield and stock return volatility seems to oppose the signaling theory.

Keywords: Dividend payout policy, stock return volatility, companies, Warsaw Stock Exchange.

Introduction

After many decades of investigation, the dividend payout policy remains one of the most controversial topics in corporate finance literature. The authors of the most important and influential studies tried to find an explanation for dividends payouts and clarify the effect of dividend payments on firm value. Despite countless research, the debate on this subject is still ongoing and no final consensus has yet been reached. In 1976 Black described this disagreement as a "dividend puzzle" and stated that "The harder we look at the dividend picture, the more it seems like a puzzle, with pieces that just don't fit together". Despite the passage of over 40 years, Black's statement remains valid. There are currently several leading theories explaining the relationship between dividend payments and the company's share price. Some of them take into account the occurrence of information asymmetry between the company's managers and shareholders. According to those theories, dividend payout is perceived by the market as a positive signal about a good financial condition and the company's prospects. Therefore, it can be expected that the dividend announcement will increase the demand for shares and, consequently, increase the share prices of the paying company. Hence the strong market reactions to the news of dividend payment might be translated into increased share price volatility. However, many authors dispute the validity of the signaling theory, arguing that dividends have no information content, so they should not be treated as reliable information about the company. The main purpose of the article is to present the preliminary results of empirical research on the relationship between the dividend payout and the volatility of share prices of companies included in the WIG20 and mWIG40 indices.

Literature Review

Although no definitive solution to the "dividend puzzle" has been found so far, some of the dividend theories are widely discussed and often cited in the literature. These theories provide inconclusive or even contradictory explanations concerning the effects of dividend payout policy and firm value (Al-Najjar, Kilincarslan 2018). Generally, in the literature three main different concepts can be observed.

The first one was proposed in 1961 by Miller and Modigliani (M&M) and is often described as "dividend irrelevance theory" (Miller, Modigliani 1961). According to this hypothesis, under the assumptions of a perfect capital market, dividend payments do not affect the value of the company or the price of its shares. Miller and Modigliani believed that shareholder profits depend on investment decisions made by company managers, not on how the profits are distributed. It means that no dividend payout policy is superior to another. The neutral approach to dividend policy was also supported by other authors, e.g. Black and Scholes (1974), who concluded that the dividend insignificance is also influenced by the so-called clientele effect. They argue that different investor groups have their preferences regarding dividend payments. Some investors particularly value current income, so they prefer firms paying out a high percentage of their profits. However, another group of investors will invest only in companies that reinvest the largest part of their income. This is due to, inter alia, unequal tax treatment between dividends income and capital gains. Investors receiving favorable tax treatment on capital gains would invest in companies that pay low dividends or do not pay them at all. Actions taken by groups of investors with different preferences offset each other, so the dividend payouts do not affect the share price.

A different approach was presented by Gordon (1959, 1963) and Lintner (1962), the authors of another leading theory of dividend policy commonly known as "bird-in-the-hand hypothesis". According to this theory shareholders' profits in the form of dividend payouts are less risky than capital gains, as dividends reduce the uncertainty associated with future cash flows. Investors, having the choice of shares of two identical companies, one of which pays dividends and the other does not decide to buy shares of the dividend company. Investment decisions taken by these investors cause an increase in the stock prices of dividend-paying companies. Thus, dividend payout increases firm value.

Other relevant dividend policy theories have been formulated based on the relaxation of MM's perfect capital market assumptions. Al-Najjar and Kilincarslan (2018) mentioned that most influential studies generally focus on the three big imperfections: the signaling theory, agency cost theory and tax-related explanations. At the core of the signaling theory is the belief that information asymmetry exists between a firm's management and outside investors. Managers are best informed on the company's actual financial condition and its prospects, while other market participants do not have access to such information. A dividend payout is perceived as a signal about a firm's current situation transmitted by managers to shareholders to reduce the information asymmetry. Dividend initiations or increases are considered to be particularly strong signals sent by managers, because such events suggest that the company is in good financial condition and will be able in the future to maintain a higher level of dividend payments. Therefore, receiving information about dividend initiations or increases may prompt investors to purchase shares of the company, which will result in higher share prices. Dividend omission or reduction may be read by the market as information about the deterioration of the company's financial condition and, as a consequence, may cause a drop in share prices. The origins of the signaling theory can be observed in research published by Lintner (1956), who conducted detailed interviews with managers of 28 companies selected at random and analyzed financial data of these companies for the years 1947-1953. Lintner argues that managers are concerned about dividend signaling and they tend to adopt extremely deliberate dividend policies. This is because shareholders care primarily for a stable dividend payout ratio and therefore they can pay an additional premium included in the share price for its stability or gradual increase. Accordingly, managers are very reluctant to cut dividends. Managers' tendency to maintain stable dividend policy in the literature is often referred to as dividend stickiness. Based on Lintner's research, the following conclusions were made:

- firms maintain long-term target dividend payout ratio,
- short-term changes in the level of profits generated by the company do not affect the amount of cash paid to the investors in form of dividend,
- when managers decide to change company's dividend payout ratio, they do so by implementing a policy of gradual, partial dividend adjustments to "smooth" dividend payment streams in the short run. This means that the change in current earnings is only partially taken into account in the level of dividends paid to investors in a given year. Further partial changes in dividends are introduced in subsequent years, provided that the upward trend in earnings continues as expected.

Lintner's conclusions were confirmed by other authors, such as Baker, Farrelly and Edelman (1985) and Baker and Powell (1999). Brav, Graham, Harvey and Michaely (2005) also attempted to verify the hypothesis about management's urge to maintain stable dividend policy. According to them, managers are trying to prevent a reduction in the dividend payout ratio because they are afraid of negative reactions from investors. However, the authors also stated that the relationship between company's profits and the level of dividend paid to shareholders is not as strong as in the time of Lintner's research, and maintaining the stability of the dividend payment ratio is no longer the most important factor determining the dividend payout policy. As far as emerging markets are concerned, the partial adjustment model has been tested, among others, on the Turkish capital market. Lintner's conclusions were confirmed by Al-Najjar and Kilincarslan (2017), who examined the dividend policy of 264 companies listed on the Istanbul Stock Exchange over a period 2003-2012. Earlier studies of the Turkish capital market covering years 1985-1997 demonstrated that companies listed on ISE did not smooth dividends and thus did not maintain stable cash dividend policies (Adaoglu, 2000). However, Adaoglu's research was conducted at a time when these companies were not able to make independent decisions regarding dividend payments. Before 2003, publicly-listed firms were obliged to distribute at least 50% of their distributable income as a cash dividend. This requirement was known as the first dividend. Since 2003, significant reforms have been carried out to the requirements regarding the mandatory payment of dividends. This reform initially introduced reducing the minimum percentage of mandatory dividend payments. However, at the beginning of 2009, another decision of The Capital Markets Board was implemented – the CMB decided not to determine a minimum dividend payout ratio. Thus from this moment, the mandatory minimum dividend payment has been abolished, which provided total freedom for ISE-listed companies to make their own decisions regarding dividend policy. Al-Najjar and Kilincarslan investigated the dividend behavior of publicly-listed companies in the post-2003, i.e. after the relaxation of the first dividend requirement. They find that current earnings per share ratio and lagged dividend per share ratio are positive and significant factors in determining the current dividend per share ratio of the companies listed on ISE. The authors believed that those findings provide empirical support for the validity of Lintner's partial adjustment model. Furthermore, after the introduction of the second mandatory dividend payout policy, which imposed on companies the obligation of a minimum dividend payout that ranged between 20% to 30% (between 2003 and 2009), managers of ISE firms tried to gradually adjust company's dividends payouts by a moderate level of smoothing. After the abolition of the mandatory dividend payment, in 2009-2012 companies listed on ISE tended to slightly reduce their target payouts but still moderately smoothed their dividends. Al-Najjar and Kilincarslan also observed that ownership structure affects the target dividend payout ratio and dividend smoothing of Turkish companies. Firms with family ownership concentration aim the highest payout ratios and they also display the greatest dividend stickiness. On the other hand, companies with non-family blockholders significantly decrease the target dividend payout ratios and abolish dividend smoothing. Empirical research conducted on the Indonesian (Baker and Powell, 2012) and Indian (Baker and Kapoor, 2015) capital markets also prove that there is a substantial evidence supporting Lintner's partial adjustment model and the signaling theory. Baker and Kapoor surveyed managers of 500 dividend-paying companies listed on the National Stock Exchange in India to learn their view on the determinants of dividend payout policy. According to surveyed managers, the most relevant factors affecting dividend payout are earnings (stability of earnings and the level of current and expected earnings) and the pattern of past dividends. Respondents also believed that maintaining an uninterrupted record of dividends is crucial.

Lintner's belief that dividends convey information gave rise to the signaling theory, which was also developed by other authors: Ross (1977), Bhattacharya (1979, 1980), Miller and Rock (1985), Bar-Yosef and Huffman (1986). Although Miller and Modigliani thought that dividend payout policy does not affect shareholder value, they noted that changes in dividend policy are accompanied by abnormal returns surrounding the announcement date. This is because of the so-called dividend information content, according to which investors interpret any changes in the level of dividends as signals that managers have changed their view of the company's future profits. The observations of Miller and Modigliani were therefore a development of the signaling theory initiated by Lintner. The literature on the subject also indicates many other studies confirming the validity of the concept of information

content of dividends. Healy and Palepu (1988) noticed that companies that initiate dividend payout note an increase in profit both after and before the change in the dividend policy. Moreover, they also proved that dividends forecast future earnings changes. Dividend information content is predominantly linked to signals about the company's future earnings. However, many authors show that dividend changes may signal other attributes as well. The research carried out by Yoon and Starks (1995) showed that the increase in the level of dividend paid to shareholders is associated with subsequent significant increases in investment expenditure within three years after the introduction of changes in the company's dividend policy. On the other hand, the reduction in dividend was associated with a significant reduction in investment expenditure. According to Jensen et all. (2010), reduction in the level of dividend paid to investors can be interpreted as a signal of reduction in real growth options. However, in the corporate finance literature there is considerable evidence that does not confirm the validity of the signaling theory. If the signaling theory is correct, then the decisions taken by managers regarding dividend payouts should reflect information on future profits, and therefore dividends and profits should change in the same direction. DeAngelo, DeAngelo and Skiner (1996) attempted to investigate whether this relationship exists on a sample of 145 companies listed on the NYSE. The research sample included companies that after at least nine years of increase in profits noted their decrease. The results obtained by the authors did not confirm that managers' decisions regarding the dividend increase should be perceived by investors as a credible signal of higher profits in the future. In the case of 99 companies whose managers decided to increase the level of dividend paid to shareholders, this decision did not translate into an increase in future profits. On this basis, the authors concluded that changes in the company's dividend behavior are not a reliable signal about the company's future profits and cannot be seen as a factor that distinguishes companies with good prospects from those firms, where profits can be expected to fall. Similarly, Grullon, Michaely and Benartzi (2003) believe that changes in dividend payouts do not contain any information about future profits. They also showed that changes in dividends are negatively correlated with future changes in the level of profitability (measured by the return on assets). Lie (2005) proved that after reducing or ceasing to pay dividends, the companies did not record a decrease in profits.

The separation of management from ownership and differences in the priorities of managers and shareholders formed the basis of agency cost theory – another hypothesis explaining the actual motivation for paying dividends, which also suggests that dividend payments can increase the company's value and shareholder wealth. It was developed by Jensen and Meckling (1976), Roseff (1982), Easterbrook (1984) and Jensen (1986). They argue that company managers (called agents) do not always act in the best interest of the principal (shareholders). In the case of firms with large free cash flow resources, there may be a risk of overinvestment that would reduce the company's value. In such cases, the high level of dividend payout decreases the internal cash flow subjected to management discretion and forces managers to seek outside capital, thus causing them to reduce agency cost as they subject to the scrutiny of the capital market. The use of external sources of financing is also associated with the supervision of outside professionals (such as banks, regulators or potential investors), which should also ensure that managers act in the best interests of the shareholders. The authors of agency cost theory perceive the dividend payouts as a mechanism that limits the freedom of managers to make investment decisions, they also believe that dividend policy may be used to mitigate the agency problems. Therefore companies with high free cash flows should pay larger dividends to reduce the amount of cash under the control of managers and thus enhance the company's value.

The dividend theories discussed so far suggested that dividend policy does not affect the company's value (dividend irrelevance theory) or that dividend payments have a positive effect on the company's value and shareholder wealth (bird-in-the-hand theory, signaling theory, agency cost theory). The last one of the three main contradictory concepts observed in the corporate finance literature claims that dividend payouts may have negative consequences for the company's value due to uneven tax treatment between dividends and capital gains. This theory, widely known as tax preference theory, states that investors are determined to avoid investments that increase shareholders' tax burden, so if the dividend tax rate is higher than the capital gains tax, they will prefer shares with none or low dividend payouts. In this situation, firms should avoid or at least reduce dividend payments to maximize their stock prices. Tax preference theory was developed by Brennan (1970), Elton and Gruber (1970) and Litzenberger and Ramaswamy (1979).

There are also theories in the corporate finance literature that do not fit into these three different concepts regarding the impact of the dividend policy on the firm's value, but they add more complexity to the dividend puzzle by taking into consideration other attributes of the company. These theories concern, among others, issues such as the hierarchy of sources of financing new investment projects, changing investors' preferences or the firm's age. One of them, known as pecking order theory, was proposed by Myers (1984) and Myers and Majluf (1984). This hypothesis posits that companies have a specific hierarchy of sources of financing new investment opportunities. Internal funds (retained earnings, free cash flow surplus) are at the top of the pecking order. After the depletion of internal funds companies resort to debt issuance and eventually to equity issuance. Such a hierarchy of the company's funds implies that better firms should have lower leverage, which is why firms should adjust their dividend policies to new possible investments. In other words, the amount of cash distributed to shareholders should be reduced to prevent external financing of the company's new investment projects. A relatively recent explanation of the dividend puzzle was offered by Baker and Wurgler (2004a, 2004b). According to them, investor preferences regarding dividend payouts may change over time. Therefore managers should recognize and respond by catering to those shifts in investors preferences for dividends. They should increase distributing dividends when investors put a premium on stocks of dividend-paying companies. Whereas at times when non-dividend paying stocks become increasingly popular among investors, managers will probably omit dividends. Catering theory implies that dividend payouts are relevant to the company's value, but in different directions at different times. The maturity hypothesis is another theory explaining the company's propensity to pay dividends. This explanation suggests that the amount of cash distributed to shareholders in the form of dividends is related to stages in the company's life cycle. There are five stages in the classic theory of a company's life cycle: start-up, youth growth, high growth, mature growth, mature stable and decline. In each of these phases, the company has different investment opportunities and a different demand for internal and external financing. In the first phase of the life cycle, the company builds its position on the market and mainly uses internal funds to finance new investments. In the expansion (youth growth) phase, the company implements investment projects with a high rate of return - the younger the company, the greater the range of available investment opportunities with a positive net present value (NPV). The company uses retained earnings and debt or equity issue to finance profitable investment projects. At the beginning of the second stage, dividends may be paid in the form of issued shares. At the end of the expansion phase, the company may pay low cash dividends. In the phase of high growth, the company still incurs large capital expenditure but shows a greater propensity to pay dividends, as external financing is cheaper and more available. As the company transits from growth to a more mature stage, free cash flows are becoming more stable and investment opportunities less profitable, which results in higher dividend increases. The maturity hypothesis (also known as life cycle theory) was developed by Grullon (2002), DeAngelo, DeAngelo, and Stultz (2006) and Bulan and Subramanian (2009). Finally, according to residual dividend policy, the firm should pay dividends only when its internally generated earnings are not completely exhausted for profitable investment projects (with positive NPV). The level of dividend paid by firms following this kind of dividend policy is usually highly volatile and often these companies do not pay dividends at all.

Many explanations of the dividend puzzle emphasize the importance of dividend as a tool for reducing information asymmetry. Scholars associate the high level of information asymmetry with high risk and significant volatility of the company's share prices. Therefore, if the signaling hypothesis is correct, the dividend payout should reduce the asymmetry of information between managers and the market and thus contribute to reducing the firm's risk. Such correlation was observed by many authors of pioneering research on the impact of dividend payments on the company's risk. Dielman and Oppenheimer (1984) stated that beta coefficients decrease for those companies that initiate dividend payout and increase after dividend omissions. Venkatesh (1989) showed that the total volatility of share prices decreases after the company initiates the dividend payout, and this change is primarily due to a decrease in specific risk. Grullon, Michaely and Swaminathan (2002) observed that companies that increase the level of dividend payout record a significant decrease in systematic risk. Lee and Mauck (2016) decided to investigate how initiating or increasing dividends affects the level of non-systematic risk. The authors tried to refer to the research carried out by Eades (1982), who put forward the hypothesis of Relative Signaling Strength hypothesis. The hypothesis proposed by Eades concerns the cost of the signal, which is sent by the company when the dividend is initiated or increased. According

to it, companies with higher volatility experience larger abnormal announcement returns when the dividend decision is announced than companies with the same market value but with lower volatility. When a company with higher volatility of returns initiates or increases dividend, it sends a signal to other financial market participants that is more important than information provided by companies with lower volatility. This is because in such firms there is greater information asymmetry and any information producing event is particularly awaited by investors. Lee and Mauck added that idiosyncratic risk is crucial for signaling strength because it is associated with the level of information asymmetry. They conducted an analysis of the level of idiosyncratic risk and dividend initiations/increases based on the data of U.S. companies (financial and utility firms were excluded) over the period 1963-2013. The research sample included 1 691 dividend initiations and 11 870 dividend increases. The results obtained by the authors were generally consistent with dividend signaling (and also with the Relative Signalling Strength hypothesis). The conclusions drawn by the authors are as follows:

- idiosyncratic volatility changes, not systematic risk changes best explain market reactions to dividends,
- companies with higher levels of idiosyncratic volatility are associated with higher announcement abnormal returns when initiating or increasing dividend payouts. It means that high information asymmetry and idiosyncratic volatility companies record a stronger positive market reaction after dividend initiations/increases,
- firms on average experience an ex-post reduction in idiosyncratic volatility following dividend initiations,
- idiosyncratic volatility declines can be observed after dividend increases as well. However, dividend increases are less volatility reducing than initiations. The effect of reducing specific risk was significant only in case of considerable dividend increases (greater or equal to 12,5%),
- dividend initiations and increases are particularly strong signals in times of high uncertainty (this effect was strongly visible over the period 2008-2009).

In the corporate finance literature a lot of attention is paid to factors affecting the volatility of stock prices, and dividend payout is often mentioned as one of them. D. E. Allen and V.S. Rachim (1996) investigated the impact of the company's dividend policy on the volatility of share prices based on a research sample consisting of 173 companies listed on the Australian Stock Exchange over the period 1972-1985. Using the regression function, they tried to show that the volatility of share prices is affected by factors such as the company’s size, profitability, leverage ratio calculated as the ratio of long-term debt to equity as well as dividend yield and dividend payout ratio. Their empirical studies have shown that earnings variability, leverage and company’s size have a positive relationship to stock price volatility, while there is a negative correlation between the dividend payout ratio and volatility. The dividend payout ratio did not show any significant correlation with the volatility of share prices. Hussainey, Mgbame and Chijoke-Mgbame (2011) published the results of research conducted on the British capital market. They also attempted to determine whether there is a relationship between dividend policy and share price volatility. The control variables included in the study were the company's size, long-term debt and profitability (measured by operating EBIT). The obtained results indicated the existence of a significant negative correlation between the volatility of share prices and the size of the company, which agrees with the generally held view that shares of large companies are associated with lower investment risk. Besides, the research showed the existence of a positive relationship between the amount of debt and the volatility of share price, which confirmed that as the company's debt increases, the risk of investing in its shares also becomes more serious. A positive relationship was also observed between stock price volatility and operating profit volatility. On the other hand, the dividend payout ratio was negatively correlated with the level of the company's risk. Similar studies were carried out by Nazir (2010). The research was intended to determine whether there is a significant statistical relationship between the variables used by Hussainey, Mgbame and Chijoke-Mgbame and the corporate risk. The research sample consisted of 73 companies and it included financial data for the period of 2003-2008. The author used fixed effect and random effect models to determine factors affecting the stock price volatility of companies listed on the Pakistan Stock Exchange. In the random-effects model, the dividend payout ratio, company size, and profitability

showed a positive correlation with share price volatility, while leverage was negatively correlated with the company's risk. However, none of these relationships were statistically significant at the 5% significance level. In the case of the model with fixed effects, the size of the company was positively correlated with the volatility of share prices, while the payout ratio showed a negative correlation with the stock price risk. Both of these relationships turned out to be statistically significant at a 5% significance level.

Characteristics of the Research Sample and Methodology

Companies of the WIG20 and mWIG40 indices were included in the research sample and analysis of the link between dividend payout and stock price volatility was conducted based on the financial data of those companies for the years 2008-2017. During this period, nine out of sixty companies included in the sample did not pay dividends at all. These were: 11 bit studio, Alior Bank, Am-Rest Holdings, CI Games, Dino Polska, Mabion, Play Communications and Play Way. However, it should be noted that these companies debuted on the Warsaw Stock Exchange relatively (among others, Play Communications S.A. and Dino Polska S.A. have been listed since 2017, Play Way S.A. since 2016). According to the results of previously published studies, companies not paying dividends are perceived as entities with a higher level of information asymmetry. Therefore, it can be assumed that shares issued by companies in this group will turn out to be highly volatile. Four companies paid dividends in each year of the analyzed period. They were: Asseco Poland, Eurocash, KGHM Polska Miedź, and WAWEL. None of the sixty companies applied the policy of increasing the dividend yield or maintaining it at an unchanged level. Asseco Poland SA can be perceived as the company with the most stable dividend policy because it paid dividends in each year of the analyzed period and additionally maintained an increasing dividend payout ratio (except for the dividend paid for 2014. However, in this period there was no significant decrease, as the payout ratio in 2013 was 5.2%, while in 2014 5.1%). Besides, the amount of dividend per share of Asseco Poland S.A. grew from year to year throughout the entire period considered. WAWEL also paid dividends every year and applied a policy of increasing dividend per share ratio, and in the years 2014-2017 kept it consistently at the level of 20 PLN per share. Considering the number of dividend payments made by each company in the analyzed period, it can be stated that the most common was the situation in which the company did not pay dividends at all (9 companies), or paid it 9 times in 10 years (also 9 companies). Only three companies paid dividends six or seven times during the entire period considered.

The main purpose of this paper is to examine the link between the dividend policy pursued by the companies included in the WIG20 and mWIG40 indexes and the level of stock return volatility of these companies. The data of the firms included in the research sample was obtained from the stock yearbooks published on the Warsaw Stock Exchange's website. On this basis, 12 econometric models were built. In each of these models daily stock return volatility was the dependent variable and it was measured in three different ways. The first approach was to calculate the relative volatility by the standard deviation of stock return divided by the standard deviation of the WIG index representing the volatility of the entire market (the dependent variable measured in this way was denoted by SD WIG). A second way of measuring the company's risk has been adopted from the paper published by Habib, Kiani, and Khan (2012), who computed stock price volatility using the following formula:

$$MMA\,VOL\,WIG\,SQR = \left(\frac{P_{max} - P_{min}}{\frac{P_{max} + P_{min}}{2}}\right)^2$$

Where P_{max} and P_{min} means the highest and lowest prices recorded during each year. Additionally, a third method of measuring the volatility of the company's stock returns was used. It can be described by the following formula:

$$MMA\,VOL\,WIG = \frac{P_{max} - P_{min}}{\frac{P_{max} + P_{min}}{2}}$$

Independent variables that characterized the dividend policy of the companies included in the research sample were the dividend yield and the dummy variable ANY_DIVIDEND, which takes value 1 if the firm pays the dividend in a given year and 0 in case of dividend omission. It can be assumed that the dividend yield is significant for the stock price volatility because this indicator illustrates the relationship between the investor's current income in the form of dividends and the total value of shares. The higher the dividend yield, the greater part of the benefits emerging from ownership of shares the investor receives instantly. That implies that dividend yield increase should result in a decrease in the company's risk. The size of market capitalization was used as an independent control variable, as well as P/E and P/BV ratios (in half of the models P/E ratio was used as a control variable and in other models P/BV was employed). Previous research shows that there is a clear link between dividend payout and the level of the P/E ratio. Krishnan and Chen (2017) based on the quarterly data of all companies included in the S&P 1500 index from 1995-2016 proved that the dividend payout ratio from the current quarter is positively correlated with the level of the P/E ratio from future periods in case of companies characterized by high market capitalization and firms belonging to the industrial sector. On the other hand, there was a negative relationship between the current dividend payout ratio and future levels of the P/E ratio among companies in the technology industry or consumer goods. According to the authors, the dynamic increase in the dividend payout ratio indicates a lack of development prospects for the company and increased risk and may also cause a drop in the P/E ratio. On this basis, a significant relationship can be expected between the level of the P/E ratio and stock return volatility of the companies included in the research sample.

Results

The results obtained based on an analysis of 12 econometric models are presented in the following tables. The first one of them applies to models using the P/BV ratio as one of the control variables, table 2 includes models employing the P/E ratio.

Table 1: Stock return volatility models employing the P/BV ratio as one of the control variables

Model	1	2	3	4	5	6
Dependent variable	SD WIG	MMA VOL WIG SQUARED	MMA VOL WIG	SD WIG	MMA VOL WIG SQUARED	MMA VOL WIG
const	3.31896 ***	0.63853 ***	0.42781 ***	3.17064 ***	0.62926 ***	0.42222 ***
DY	-0.00763	0.00567 *	0.00322	-	-	-
ANY_DIVIDEND	-	-	-	-0.34487 ***	-0.00065	-0.00108
LN_MCAP	-0.14861 ***	-0.06895 ***	-0.04569 ***	-0.11030 ***	-0.06600 ***	-0.04392 ***
P/BV	0.00747	−0.00414	−0.00264	0.01136 **	−0.00424	−0.00269
R-squared	0.08536	0.05534	0.05820	0.12044	0.05012	0.05411

* p-value<10%; ** p-value<5%; *** p-value<1%

As can be easily seen, the dividend yield (DY) turned out to be a statistically significant variable in only one case (at a statistical significance level lower than 10%). The dummy variable ANY_DIVIDEND was also important in one model. However, it should be noted that this is the model with the highest value of the R squared coefficient.

Table 2: Stock return volatility models employing the P/E ratio as one of the control variables

Model	7	8	9	10	11	12
Dependent variable	SD WIG	MMA VOL SQUARED	MMA VOL WIG	SD WIG	MMA VOL WIG SQUARED	MMA VOL WIG
const	2.63647 ***	0.56523 ***	0.41449 ***	2.60656 ***	0.55681 ***	0.40870 ***
DY	-0.00228	0.00502	0.00269	-	-	-
ANY_DIVIDEND	-	-	-	-0.18949 ***	-0.03305	-0.02530
LN_MCAP	-0.07765 ***	-0.05865 ***	-0.04272 ***	-0.06026 ***	-0.05325 ***	-0.03909 ***
P/E	0.00126	-0.00088 *	-0.00061 *	0.00106	-0.00098 *	-0.00068 *
R-squared	0.04004	0.04829	0.05476	0.06044	0.04452	0.05328

* p-value<10%; ** p-value<5%; *** p-value<1%

In the group of models with P/E ratio as one of the control variables, the dividend yield turned out to be of no statistical significance, while the dummy variable proved to be statistically significant (at a statistical significance level less than 1%) only in the model with the highest R squared coefficient. The P/E ratio was statistically significant in four models.

Conclusion

Based on the analysis of the 12 econometric models presented above, it can be stated that it was possible to prove the existence of a negative relationship between dividend payout and the stock return volatility. Therefore, the assumption that dividend payments reduce the company's risk was confirmed. Two statistically significant models containing dummy variables confirmed the existence of such dependence at a significance level lower than 1%. This is in line with the results obtained by Allen and Rachim (1996) as well as Hussain et al (2011), according to which the dividend payouts are associated with a decrease in the volatility of stock return. The results can also be considered as confirmation of the research published by Venkatesh (1989), Grullon et al (2002) as well as Lee and Mauck (2016). According to these authors, initiating dividend payouts translates into a lower level of risk, which is caused by a decrease in the information asymmetry that exists between shareholders and company managers. Almost all of the presented models did not confirm the existence of any relationship between dividend yield and the level of return volatility. This is in line with research carried out by Allen and Rachim (1996). On the other hand, lack of any statistically significant link between the company's risk and dividend yield (a ratio that determines the amount of benefits arising from ownership of shares that investor receives immediately at the time of dividend payout) seems to contradict the conclusions drawn by Lee and Mauck (2016). According to them, dividend increases also reduce the information asymmetry, which translates into a reduction in the firm's risk. However, they believed that this effect is not as strong as in the case of dividend initiation.

As for the additional explanatory variables, the most significant relationship can be seen between the stock return volatility and the size of the company (measured by its market capitalization). In each of the 12 models, market capitalization turned out to be statistically significant at a statistical significance level below 1%. What is more, this relationship is negative which is consistent with the prevailing belief that large companies with high market capitalization are entities with lower risk. As for the P /BV and P/E ratios, the first one of them proved to be statistically significant only in one of six models, while the four models confirmed the significance of the P/E ratio in explaining the stock return volatility. This can be considered as confirmation of the conclusions of Krishnan and Chen (2017), who believed that the dividend yield influences the future value of the P/E ratio and thus the company's

risk level. The low explanatory power (expressed by the low level of coefficient of determination) of presented models should also be brought to attention. The highest level of R squared coefficient amounts to 0.120435. In the model with the highest level of R squared coefficient the dependent variable, i.e. the company's risk, was expressed by the standard deviation of the company's rate of return corrected for the standard deviation of the WIG index. The independent variables were the firm's size (expressed by the market capitalization), the P/BV ratio and the dummy variable.

Abstract

Hospital-Based Health Technology Assessment (HB-HTA) tools seem to be effective in strategic planning in hospitals. The benefit they show in the decision-making phase of medical devices management, in their acquisition, implementation, or the whole life cycle is obvious. Health technology assessment more and more includes an application of the Total Cost of Ownership (TCO) method, but its systematic incorporation into HTA is not complete yet. TCO has many advantages, when the main benefit follows from the fact that it helps identify costs that otherwise would remain hidden. TCO can be applied e.g. in the case of supplier selection, when TCO can be included to the input criteria of the multiple-criteria decision analysis. TCO finds further utilization in investment assessment on the basis of a prediction of future cost items. The last discussed area of TCO application is within evaluations of projects that were already implemented using retrospective data. The paper opens three basic perspectives of the TCO method as a part of HB-HTA, and it systemizes suitable application of this approach providing five case studies. These examples offer procedures specific for healthcare facilities and draw attention to particular "hidden costs" of health technologies.

Keywords: Total Cost of Ownership, HB-HTA, Medical equipment

Introduction

Health technology assessment (HTA) can be viewed as a multidisciplinary approach comprising the analysis of safety, clinical effectiveness and cost-effectiveness of health technologies (Callea *et al.*, 2017) (Ivlev, Kneppo and Bartak, 2014). Recently, interest in applying HTA methods to the level of individual hospitals has grown, as they showed straightforward benefits in the phase of purchase decision-making, implementing, and even determining the end of the life-cycle of health technologies (Rogalewicz, 2015) (Martelli, 2017). The tools of the Hospital-Based HTA (HB-HTA) seem to be effective above all for strategic assessments and management planning of health technologies (Gagnon, 2014) (Avdeyev *et al.*, 2018).

Appropriate evaluation of health technologies using HTA methods depends considerably on the cost calculation perspective and on its adequate quantification. Currently, a real problem in medical device (MD) purchasing is an absence of considerations of further related costs during the whole life cycle. Hospital management may preferentially concentrate on the purchase price, which would lead to a large distortion of the result in MD selection. The purchase price sometimes represents no more than 20-25% of the total costs of ownership (Schmidt, 2019) (Hospodková and Vochyánová, 2019). If the cost-effectiveness calculations fail to consider such connections, the result of the whole study may be misleading. A constructive solution of this situation can be an application of the Total Cost of Ownership (TCO) method.

There are several approaches and methodologies of how to execute a TCO calculation. These approaches can be divided into several categories, when the main one is represented Elram and Siferd (Ellram and Siferd, 1998), Cavinato (Cavinato, 1991), Benett (Bennett, 1996) etc. These authors agree that what is decisive for an effective calculation of TCO is the way of cost items measurement. They consider an application of the TCO concept for effective not only for calculations, but also for the subsequent reduction of overall costs. There is an added value of this research in the classification of TCO models by type as dollar-based or value-based. TCO models can be further divided according to their primary use that can be e.g. supplier selection or supplier evaluation (Ellram, 1995). Other authors completed the findings introducing the idea of life cycle costing. Shields describes (Shields and Young, 1992) a connection between organizational cost drivers, organizational learning, managerial innovations, and product and process innovations. Moreover, he presents examples of how organizational cost drivers can reduce long term costs.

The results of the contemporary research in the healthcare field are focused on the directions shown in Figure 1.

Fig. 1: Possibilities of TCO application within HB-HTA

One of the fundamental problems in hospital management is selection of suppliers. It can be described as a multiple-criteria decision analysis (MCDA) process aimed at optimizing conflicting goals such as quality, price, or term of delivery. The problem of supplier selection is addressed in Chapter 2.1. Based on an estimation of future data, it is investment assessment that is usually applied in the initial phase of projects. A typical example are feasibility studies for purchase of expensive medical equipment. This group includes also provision of other technologies that are not directly related to healthcare performances, which is covered in Chapter 2.2. Further, TCO is often applied in the case of a retrospective assessment of projects. Generally, the results of this phase should be always compared with the original estimations, and possible differences should be explained. This is the only project approach that can guarantee that possible mistakes in the selection will not be repeated in the future. Such cases are discussed in Chapter 2.3.

In our opinion, the combination of rapidly developing HB-HTA and TCO can contribute to the creation of an effective managerial support. The main objective of this paper is to summarize possibilities of TCO application in the frame of HB-HTA, and to demonstrate these options on selected examples of good practice.

TCO applications in healthcare

This chapter gives a series of examples aspiring to show the wide spectrum of possible applications of TCO in healthcare or in facility management in hospitals.

Supplier Selection

This example compares and discusses healthcare costs calculations in different suppliers using a combination of the TCO approach with MCDA, namely the analytic hierarchy process (AHP).

Example 1: Supplier selection problem: a comparison of the total cost of ownership and analytic hierarchy process approaches (Bhutta and Huq, 2002)

While TCO looks beyond purchase price to include all other technology-related costs, AHP uses ratio scales to integrate and then use pair-wise comparisons and the eventual synthesis to find the "best" decision. The main benefit of the TCO method is above all that it helps identify costs that otherwise may remain hidden. On the other hand, it presents a kind of challenge, as it requires extensive tracking and maintenance of cost data. The authors used the primary data to carry out calculations of both approaches, while they compared three suppliers. The costs were divided into the following categories:

- Manufacturing (raw materials, labour, machine depreciations, etc.)
- Quality (quality inspection, rework, cost due to delay, etc.)
- Technology (designing, engineering, etc.)
- After-sales service costs (units shipped, etc.)

Four criteria were chosen to evaluate suppliers using AHP: manufacturing costs, quality, technology being used and service offered. The results both methods differ, however, according to the authors, both approaches can be used in negotiations and in optimizing and concentrating resources where they are most needed.

When suppliers are to be selected for a healthcare facility, nowadays it is usual to apply the MCDA methods. Generally, the "cost" item is one of input criteria. It is usually represented by total cost of (product) purchasing from suppliers including freight costs and product price (Fashoto, Akinnuwesi and Owolabi, 2016). If further cost data are available or if a qualified estimate can be done for further costs that arise during the product life cycle, it is appropriate to use TCO instead, and get an all-embracing view. Such an integration of the TCO results would lead to a considerable shift in the validity of MCDA calculation results.

Investment Assessment

Two following examples demonstrate application of the TCO method for investment decision-making in projects of a special character, where there was a requirement of minimizing the total costs.

Example 2: Analysis of TCO Applied to Processes of Biomedical Technology Acquisition Competitive Intelligence (Barreneche, Hernandez and Garcia, 2015)

Barreneche calls for a standardization (Barreneche, Hernandez and Garcia, 2015) of the process of expensive medical technology acquisition, and defines the variables that affect the total cost of a biomedical apparatus. According to him, the aspects that must be considered in the estimation of TCO of biomedical equipment include initial costs, training costs, warranty, import costs, maintenance, metrology costs, update costs, operation costs, accessories and spare parts costs, requirements for planning costs, and final disposal costs. The study further analyses five basic stages:

1. Indexes definition
2. Acquisition of preliminary information
3. Information reception and analysis
4. Indexes estimation
5. Results analysis and recommendations

The above-mentioned stages are subsequently verified on representative data in a 5-year time horizon for two producers of PET/CT, see Tab 1.

Table 1: TCO with consumables and insurance (Barreneche, Hernandez and Garcia, 2015)

Manufacturer	5-year TCO (USD)	Initial costs (USD)
A	6,583,071,206	2,176,550
B	6,574,699,209	2,584,000

The results prove the existence of significant hidden costs, which means that healthcare facilities should consider these aspects in order to choose a supplier that best adjust to their operation conditions.

TCO can be viewed as a complex analysis comprising technical, after-sale, safety-of-the-patient etc. aspects, and thus it is useful for decision-making about an investment in biomedical technology (Hospodková and Vochyánová, 2019).

Example 3: Proposal to increase efficiency of waste management in the General University Hospital in Prague

The study objective was to compare the current costs of risk waste disposal through a supplying firm with TCO in the case of waste converter acquisition, while the calculations were done over a 10-year horizon. The reason of the projection is an expectation of raising the disposal price in the outsourcing variant.

TCO over the investment´s life time was calculated using the modified formula (Dabbs, 2010) :

$$TCO = Ca + Cc + Co + Cm + Cd, \quad (1)$$

where Ca –acquisition costs, Cc - commissioning costs, Co - the costs of operation, Cm - maintenance costs and Cd - the removal and disposal costs. Selected cost items within the TCO model according Charkravarty and Morfonious (Chakravarty and Debnath, 2015) (A.Morfonious *et al.*, 2011) are shown in Table 2. A 4% discount rate was considered, as recommended for public investment projects co-funded from European funds. The calculation of the discounted TCO proceeds according to the formula (2):

$$dTCO = \sum_{i=0}^{t} \frac{TC_t}{(1+r)^t}, \quad (2)$$

where *dTCO* are discounted costs, *TC* - the expected TCO in individual years, *i* - years of investment, *t* - the lifetime period, and *r* - the discount rate.

It was shown that TCO over a 10-year period amounts to EUR 427,907 in the case of a convertor acquisition, which is unfavourable if compared with waste disposal outsourcing. The purchase of a convertor seems to be the favourable variant if the prices agreed with the third party increased by more than 20%. Table. 2 provides a detailed structure of TCO for the convertor.

Table 2: Discounted TCO of the waste convertor over a 10-year period

	CA	CC	CO	CM	CD	DTCO
EUR	164,445	10,783	155,673	95,466	1,540	427,907
%	38.43	2.52	36.38	22.31	0.36	100

Project Evaluation

The method can be used also for a retrospective evaluation of implemented projects.

Example 4: Problems with systems of medical equipment provision: an evaluation in Honduras, Rwanda and Cambodia identifies opportunities to strengthen healthcare systems (Emmerling, Dahinten and Malkin, 2018)

A good example of analysing retrospective data is the study published by Emmerling et al. (Emmerling, Dahinten and Malkin, 2018). They analysed 3421 pieces of medical equipment in five departments from 64 hospitals, and found that 575 of them were out of service or only partially functional. Marks claims (Marks *et al.*, 2019) that one reason of the low operationality of MDs in developing countries is the absence of serious reflections about TCO in the management, which supports Emmerling´s hypothesis. If the costs of spare parts, tools, attachments, consumables, as well as installations, preventive maintenance, etc. are not taken into consideration already in the time of decision-making about procurement, the following operation would be controversial. This assertion stays valid also in the case of acquisitions through a donation or subsidy, when the problem is often amplified by an unsuitable combination of technical parameters of health technologies (missing compatibility with the other equipment).

The combined costs of disposal of the useless donated equipment and non-warrantied support for useful donated equipment could exceed the cost of purchasing the same equipment new and with warranty support. Based on a literary review, Marks summarizes several key areas that must be taken into consideration in the case of MD acquisition through a donation, and simultaneously it highlights that any guidelines are missing. These areas comprise costs of human resources, environment costs, material resources (ancillary equipment supplied either locally or from overseas etc.), maintenance resources, educational resources, etc. (Marks *et al.*, 2019).

Discussion and Conclusion

Current utilization of TCO is only limited and its strategic potential is not always met, while TCO has a wide use, which is obvious from published results (Fabian, 2017). The current papers describing TCO are helpful, above all if they are outlined as case studies. They offer procedures specific for healthcare facilities that draw attention to particular „hidden costs“ of health technologies (Holckel and Kintner, 2014).

One of the new and current directions in the field of MDs and their evaluation is early stage HTA (eHTA), a method that deals with assessments of MDs that are in the development phase. Such evaluation is very broad and includes, inter alia, a calculation of all cost items that must be taken into account before the technology is purchased, input costs, as well as costs incurred during the operation phase and equipment life cycle (Simonova *et al.*, 2020). Thus, TCO can be a useful tool within eHTA, as it usually includes the purchase costs, costs of energy, installation, regular maintenance, repairs, upgrades, staff training, disposal and personnel costs that are necessary in such a prospective MD evaluation.

Another area offering large possibilities of TCO applications is eHealth a telemedicine. However, within information systems implementation in healthcare, not only that HTA is often missing, but the contractor even does not conduct a feasibility study. Thus, after e-prescription was launched in the Czech Republic, it is impossible to evaluate whether the system implementation was successful (Bruthans, 2019).

Our examples taken mainly from literature show some limitations that can be, however, overcome by slight suitable modifications. Mostly they were focused on a single hospital, no discounting was applied, and very often real data did not exist, so that they had to be replaced by a model or expert opinion. Nevertheless, there is already quite a lot of experience gathered, so that we can recommend calculation of TCO in all HTA studies focused on medical devices.

Organizational and Legal Aspects of Insurance Cover Acquisition In Municipalities in Poland

Marcin WOJTKOWIAK

Poznan University of Economics and Business, Poznan, Poland
marcin.wojtkowiak@ue.poznan.pl

Abstract

Local self-government units in Poland, and in particular municipalities, should be treated as specific clients on the insurance market. In such entities, the process of concluding insurance contracts and shape of such contracts require the solution of several organizational and legal problems. At the initial stage, it is necessary to specify which units in the structure of the local self-government unit (municipality) may be parties to the insurance contract (policyholders) and who may represent them in this legal act. Then it is important to decide whose property interest is insured, and therefore who should be specified in the contract as insured party. Finally, due to the extensive structure of local self-government units (municipalities), decision-makers must determine whether insurance cover will be purchased in a centralized manner (i.e. at the level of the main office of the local self-government unit comprehensive for the entire structure) or in a decentralized manner independently through organizational units. There are many advantages to a centralized acquisition of insurance coverage. The article discusses these all issues. All the above-mentioned problems must be resolved with the knowledge that errors and gaps in concluded insurance contracts may result in property loss in local self-government units. Such a situation may result in reducing the scope of activities carried out by these entities.

Keywords: Municipality, Property Interest, Insurance Policy

Introduction

Insurance coverage in a local self-government unit, and in particular in a municipality[1] as the basic entity forming local self-government in Poland[2], contributes (as a risk management method) to meeting the needs of the local government community as a whole and individual needs. Insurance as an effective method of protection against financial consequences of random events minimizes the disruptions in the implementation of municipal tasks that Ziółkowska (2002) divides into two groups: public services (e.g. maintenance of transport routes, ensuring safety) and social services (e.g. education and health services). Research study by Jastrzębska et al (2014) shows the significant degree of use of the insurance method in the risk management of municipalities[3]. For this reason, the sphere of the way and correctness of concluding insurance contracts by these entities should be thoroughly analysed. This article presents selected organizational and legal problems existing at the stage of acquiring the insurance protection of municipalities.

Identification of the policyholder in the municipality

The parties to the insurance contract are: the insurer and the policyholder. Orlicki (2002) indicates that the policyholder is a natural person, a legal person or an organizational unit without legal personality, which by concluding an insurance contract in its own name undertakes to pay an insurance premium in exchange for the insurance protection provided by the insurer.

In order to formally and legally assess the correctness of the policyholder's declaration of will it is necessary to determine whether:

- the declaration of will was made by an entity authorized to perform such an action (competent entity),

- the declaration of will on behalf of the policyholder was made by the competent authority/person (form of representation).

As Drzewicki (1996) claims "legal capacity for insurance rights and obligations is an issue of quite fundamental importance″ and decides on the existence of insurance capacity, understood by Orlicki (2002) as the possibility of concluding insurance contracts on your own behalf. According to Nowakowski (2004) lack of legal capacity on the part of the policyholder is the reason for invalidity of the insurance contract. In the book edited by Gniewek (2006) indicated that this invalidity is absolute, and the legal act may not be covalidated in any way.

The municipality's capacity to perform legal actions results from its recognition as a legal person under Article 33 of the Civil Code[4]. The legal personality of the municipality results from two regulations: Article 165(1) of the Constitution of RP[5] and Article 2(2)[6] of the Act on Municipal Self Government[7]. Unlike the government administration, which remains within the structure of the state and in civil-law relations acts in the name and on behalf of the State Treasury, the municipality performs civil-law activities in its own name. The municipality may therefore conclude insurance contracts in its own name and on its own account.

However, the issue of the insurance capacity of the municipality's organisational units (budget units, local government budget companies) is problematic. The municipal organisational units do not have a legal personality, as it has not been conferred to them by the Act[8]. As Radwański (2007) states they also lack legal capacity[9]. These units are therefore neither legal persons nor 'temporary legal persons'[10]. Radwański, Panowicz-Lipska (1998) and Kowalewski (1999) are in favor of the admissibility of concluding contracts by such entities, but among other authors Ciepła (1997) is in favor of the impossibility of concluding such contracts. However this discussion was held under the terms of the Act of 28 July 1990 on Insurance Business, which is no longer in force[11] and at the same time before the amendment of the Civil Code of 14 February 2003[12], which introduced art. 33^1. Current Act of 11 September 2015 on Insurance and Reinsurance Activity[13] does not contain a *lex specialis* to art. 33^1 of the Civil Code, and therefore the organizational units of the municipality do not have the insurance capacity.

The above considerations undoubtedly indicate the defectiveness (irregularity) of insurance contracts concluded by municipal organizational units (budget units, local government budget companies). However, the thesis on the invalidity of such contracts would be too radical. Assigning the function of *stationis municipii* to organisational units[14] is close to granting these entities legal capacity[15]. The fact that the municipal organizational units sometimes act as the contracting authority (policyholder) in public procurement procedures seems to confirm this situation[16].

It would also be socially difficult to accept the annulment of insurance contracts concluded by individuals such as schools, kindergartens and municipal institutions. The subject of insurance protection is municipal property, which, after all, contributes to the implementation of public tasks. What is more, on the part of the municipality there is a consent to conclude such agreements in case of allocation of financial resources in the financial plan.

Table 1 identifies particular types of organisational units in the municipal self-government structure in the context of insurance capacity.

Table 1: Policyholder in the organisational and legal structure of the municipality

Type of entity	Legal status	Does it have legal and insurance capacity?
municipality	legal person	yes
budget unit	an organisational unit without legal personality	no
self government budget unit	an organisational unit without legal personality	no
auxiliary unit (housing estate, district, village, town, other)	an organisational unit without legal personality	no
self government cultural institution	legal person	yes
limited joint-stock partnership	an organisational unit without legal personality	yes
holding company	legal person	yes
self-contained public health care facility	legal person	yes
union of municipalities	legal person	yes
poviat-municipality union	legal person	tak
association of local government units	legal person	yes
foundation	legal person	yes

Source: own elaboration

Representation of the policyholder in the organizational and legal structure of the municipality

Article 38 of the Civil Code states that a legal person acts through its bodies. The body is formed by natural persons (or one person). According to Dmowski and Rudnicki (2006), the action of an authority is the action of a legal person, but only if natural persons act in a specific case, explicitly or at least implicitly as an entity and within the limits of its competence[17].

Constitution of RP stipulates that local self government carries out its tasks through the decision making and executive bodies[18]. In the case of a municipality, detailed regulations specifying the manner of representation (organisation of the bodies) should be sought in the Act on Municipal Self-Government. It stipulates that declarations of intent on behalf of the municipality with respect to the management of property shall be made by the head (mayor, governor) or a deputy authorised by him or her alone or with another person[19].

Declarations of intent on behalf of the municipality may be made by the head of the municipal organisational unit. He or she acts individually on the basis of a power of attorney[20] and within its limits[21]. Therefore, the scope of the authorisation granted is important, in particular whether it covers activities related to the conclusion of insurance agreements. These, in turn, fall within the scope of ordinary management of the property transferred to a given organisational unit.

In fact, the circle of persons making declarations of intent on behalf of the municipality is wider. This state of affairs is confirmed by the judicature. The Supreme Court has ruled several times[22] that declarations of intent in the area of property management may be made by a municipal proxy acting on the basis of the power of attorney granted to him or her by persons who themselves had the right to perform the legal act covered by this power of attorney. Such action is based on a power of attorney issued in accordance with the Civil Code.

The institution of countersigning is an additional complication when concluding an insurance contract in the municipality. Namely, when concluding an insurance contract by a municipal body, a countersignature of the treasurer of the municipality or a person authorized by him or her is necessary. However, according to Korzeniowska et al (2004) and Murzydło (2007), the lack of countersignature does not result in invalidity of the contract, but only in its ineffectiveness. In the absence of a countersignature, the insurer may raise an objection of inactivity of the insurance cover, thereby releasing itself from the obligation to provide the insurance benefit, and the municipality is exempted from the obligation to pay the premium.
Murzydło (2007) is of the opinion that the conclusion of an insurance contract by an authority (or by a so-called "false authority") in excess of its powers has no legal effect. If the scope of the power of attorney is exceeded or while acting as a "false proxy", the insurance contract will be affected by the defect of suspended ineffectiveness and thus by the possibility of restoring legal effects by the municipality.

Property interest of the municipality as the subject of insurance

Article 821 of the Civil Code defines the subject of the insurance as any property interest which is lawful and capable of being assessed in money. Szymański (1962) recognizes as the interest such an attitude to an object, event or someone's behaviour that their improper change (course, incident), i.e. against the will, is felt negatively by the subject affected by the change. In Polish contemporary literature such as Byczko (2013) and Krajewski (2016), attention is drawn above all to the far-reaching "economization" of the notion of insurance interest, which makes it possible to accept the insurability of both legal relations and various factual states of affairs.

Adoption of the theory of interest as a determinant of the subject of insurance is very important for the municipality, as it defines very broadly the limits of using insurance as a risk management method. The municipality, in terms of the type of activity, combines the features of:

1) a public entity, i. e. the sphere of *imperium* defined by Skoczylas (2005) and Safjan, Matuszyk (2009) as the executive activities of the administrative law and organizational and ordering activities reserved for municipalities,
2) a private entity, i. e. the sphere of *dominium* including forms of activity in the organizational and ordering area which are not reserved for municipalities and are aimed at meeting the collective needs of the local government community[23].

For this reason, property interests not encountered in the private sector can be identified. The theory of property interest at least makes it possible to negotiate with the insurance company on the insurance of interests specific to the municipality, e.g. related to the risk of claims for:

1) taking administrative decisions,
2) lack of provision or inadequate provision of municipal services,
3) actions of the municipal police,
4) delays in the allocation of social housing to persons evicted from private premises[24],
5) shaping spatial order in the form of adopting and amending the local spatial development plan[25],
6) damage to person or property of members of the voluntary fire service[26]

Identification of the insured in the municipality

Kowalewski (1997) points out that the insurance interest in the context of identification of the object of insurance is subjective in nature as it relates to a specific person or entity. Orlicki and Pokrzywniak (2008) as well as Byczko (2013) conclude that the insurance coverage may be provided only for the account of an entity having an insurance interest.

Orlicki (2006) indicates that the insured may be a natural person, a legal person or an organizational unit without legal personality, but having legal capacity.

The property interest in the organisational and legal structure of the municipality should be related primarily to the right to own municipal property. The entities of municipal property include organisational units with legal capacity, as indicated in Table 1[27]. According to Łętowska (1994), legal capacity is also a condition for bearing material liability and therefore the property interest in liability insurance is dependent on this capacity.

Bearing in mind the comments made, it should be concluded that the practice of concluding insurance contracts for the benefit of organisational units of the municipality without legal capacity [28] is defective. An organisational unit without legal capacity may not be entitled to an insurance benefit. Drozd (1997) makes the thesis that there can be no subjective right (including the right to an insurance benefit) without the subject of those rights. Likewise, it makes no sense to take out liability insurance "for the account" of an individual who is not subject to civil law obligations.

However, a request for a defectiveness of insurance contracts concluded "for the account" of organisational units of the municipality which do not have legal capacity does not lead to a thesis of their invalidity. Such an effect would be too significant. By fulfilling the function of the *stationis municipii*, these units actually fulfil the rights and obligations of the municipality. The technical designation of such a unit as an insured person indicates the intention to insure the property interest of the municipality being "in possession" (disposition) of that unit. In the context of Article 65(2) of the Civil Code, the purpose of such a legal act is understandable.

Insurance policy of the Municipality

From the previous considerations it appears that the municipality is a complex, multidimensional unit. Różycki (2006) describes that from a technical and organisational point of view, it combines the characteristics of an authority, a distributor of public funds, a specific service company, an owner of large assets and a basic entity managing the local economy. These properties influence the complexity of organizational issues related to the way insurance contracts are concluded. The organizational solutions adopted by the municipality in terms of concluding and performing insurance contracts are manifested in the insurance policy.

In the Polish literature such as Handschke (1989, 1998) and Łazowski (1998), the insurance policy is mainly connected with the state, although as Handschke (1989, 1998) points out, the subjects of the insurance policy at the micro level are also recognized: policyholders, insurance agents, insurers. The same author indicates that the condition for considering the actions of the above entities as insurance policy[29] is the setting of insurance objectives and the selection of means and methods for achieving them. Later publications of such authors as Jedynak (1999), Dubiel (2011), Janowicz-Lomott and Łyskawa (2013) stress the role of the insurance policy of companies and local government units.

Taking into account existing views of doctrine described in the abovementioned publications, the insurance policy of the municipality can be defined as an orderly activity of the municipality aimed at satisfying its insurance needs. The subject of the municipal insurance policy is the municipality itself (as an entity insuring its and not only its property interest), being at the same time an object in the implementation of the state insurance policy (e.g. imposing an insurance compulsion on the municipality in specific situations). The insurance policy of the municipality should be determined by the basic objective of its functioning, which is to satisfy the collective needs of the local community, i.e. it should serve to shape the desired reality in the economic and social sphere at the municipality level. Thus, the implementation of an optimal insurance policy should not be the final goal, but only an element enabling the achievement of the basic goal. The implementation of the insurance policy includes such activities as the decision to centralize (decentralize) insurance activities, making employees aware of the scope of insurance cover and their role in the insurance policy, creating an insurance programme and updating it.

Różycki (2002) lists the following premises of the municipality's insurance policy include:

- the multiplicity and specificity of public tasks performed,

- the value of the assets held and their purpose,
- obligation to manage municipal property with special care,
- complex organizational structure,
- the quantity and scope of insurance products used,
- legal conditions, both resulting from legal acts (e.g. being subject to public procurement law, compulsory insurance) and the essence of the insurance contract (regulations of general insurance conditions),
- insurance obligations imposed by the municipality's contractors (e.g. banks).

Since the reactivation of the local self-government units in 1990, it has been common practice for the managers of individual organizational units to make insurance decisions. Nowadays, the insurance policy is conducted centrally by the municipal office and most often it includes the office and other municipal organisational units, but without municipal companies. Liwacz (2010) mentions the following benefits of asset insurance in a comprehensive manner:

- it eliminates gaps in protection (both in terms of coverage and subject matter),
- it eliminates duplication of protection,
- it contributes to the unification of insurance conditions throughout the municipality,
- it saves on premiums,
- it streamlines administrative procedures.

Comprehensive municipal insurance often requires a public procurement procedure when selecting an insurer, which will be discussed later in this article.

Summary and conclusions

The municipalities are characterized by an organizational structure including specific organizational and legal forms, whose functioning on the insurance market encounters certain difficulties. It is in the interest of both the municipalities as a legal entity and the self-government community to conclude insurance contracts without legal defects, while striving to optimize the price through appropriate decisions taken in the field of insurance policy. It should be borne in mind that any incorrect decisions made by municipalities in the area of concluded insurance contracts may constitute damage to their property, the occurrence of which results in limiting the performance of public tasks important for local communities.

Public Data Driven Decisions – Linked Open Data Case

Anna LAMEK

Faculty of Computer Science and Management, Wrocław University of Science and Technology, Wroclaw, Poland, anna.lamek@pwr.edu.pl

Abstract

The increasing complexity and amount of data has a significant impact on the functioning of modern organizations, which are increasingly called Data-driven enterprises. Effective data management in enterprises is currently crucial when it comes to formulating a strategy of operation and developing a competitive advantage. The article is an attempt to show why modern organizations should develop the right methodology for managing information resources (especially in case of linked open data) to find their place in contemporary economic reality and survive in the era of big data.

Keywords: Management, Data Driven Enterprise, Linked Open Data, Big Data

Introduction

This work present how useful can be public data and how much information is hidden in public articles which can be found in the Internet. The increasing complexity and volume of data has a significant impact on functioning of modern organizations so called data-driven enterprises. Issues related to data management have crucial importance when it comes to formulating strategy and elaboration of competitive advantage. The article attempts to show why nowadays organizations should develop a suitable methodology of information resources management, especially in case of public data. The paper also presents the use of logistic regression in the assessment of variables describing the quality of articles published on English version of Wikipedia by it's users. Classification of variables because of the results of information value indicator have been presented. Last, but not least benefits of the effective data management have been defined.

Linked Open Data and Information value characteristic

The spectrum of modern sources of business information is nowadays very broad - they are not only internal resources, but also (and maybe above all) data from the environment of the organization, its competition or directly from customers. It should be emphasized that this is not only information related to e.g. purchasing decisions, but also about interests or activities, which creates a complete customer profile, also enriched with behavioral context. Very interesting information can be found in case of public linked open data based on the RDF standards of the semantic web. Access to this data in very easy (many API plug-ins / browsers are available for users, which help to find relevant data). One of the very well-known example based on this vision is DBpedia. As their website says (source: wiki.dbpedia.org) "the English version of the DBpedia knowledge base describes 4.58 million things, out of which 4.22 million are classified in a consistent ontology, including 1,445,000 persons, 735,000 places (including 478,000 populated places), 411,000 creative works (including 123,000 music albums, 87,000 films and 19,000 video games), 241,000 organizations (including 58,000 companies and 49,000 educational institutions), 251,000 species and 6,000 diseases.

The full DBpedia data set features 38 million labels and abstracts in 125 different languages, 25.2 million links to images and 29.8 million links to external web pages; 80.9 million links to Wikipedia categories, and 41.2 million links to YAGO categories. DBpedia is connected with other Linked

Datasets by around 50 million RDF links. Altogether the DBpedia 2014 release consists of 3 billion pieces of information (RDF triples) out of which 580 million were extracted from the English edition of Wikipedia, 2.46 billion were extracted from other language editions. The DBpedia knowledge base has several advantages over existing knowledge bases: it covers many domains; it represents real community agreement; it automatically evolves as Wikipedia changes, and it is truly multilingual. The DBpedia knowledge base allows you to ask quite surprising queries against Wikipedia, for instance "Give me all cities in New Jersey with more than 10,000 inhabitants" or "Give me all Italian musicians from the 18th century". Altogether, the use cases of the DBpedia knowledge base are widespread and range from enterprise knowledge management, over Web search to revolutionizing Wikipedia search."

The growing popularity of Wikipedia has also contributed to the emergence of an increasing number of scientific papers on the issue of public data quality assessment of it's articles. Comparing different parameters of featured articles, one can infer the quality of other (invaluable) articles. On the basis of literature [Lih 2004; Stvilia et al. , 2005; Hu et al. 2007; Wilkinson and Huberman 2007; Blumenstock 2008b; Blumenstock 2008a; Dalip et al. 2009; Lipka and Stein 2010; Dalip et al. 2011; Anderka 2013; Warncke-wang, Cosley and Riedl 2013; Lewoniewski, Węcel and Abramowicz 2015] this research was concerned around what data about articles can be obtained and how one can assess their quality. It should be noted that all data - so. articles and their assessments are public data. Data on articles in the English version of Wikipedia were analyzed. There are two distinctions of articles: "Featured Article" (FA), which means very good publication. There is also a second distinction for articles that do not meet all FA criteria, but come close to their quality and is called "Good Article" (GA). The FA or GA distinction in any language version of the article can get as a result of a positive vote, which usually lasts about a month. However, there are very few such distinguished articles - on average in each language version their share is about 0.07%.

Unfortunately, each language version has its own article quality classification system, all of them use at least two classes for the highest quality articles - FA and GA equivalents. However, a large proportion of articles are not evaluated at all, e.g. in the Polish edition the share of such articles accounts for over 99%. It is therefore worth considering what added value public data assessment can bring, how to do it and what decisions can be made on this basis.

Information Value

In numerous works - including Brotherton, Lund (2013), Finlay (2010), Mays and Lynas (2011), Siddiqi (2006) describing scoring models regarding e.g. creditworthiness (where the explained variable is also binary - granting or not credit, same like good/bad article) to assess the examined features Information Value (IV) is key determinant of data quality. It can be determined by using the following formula:

$$IV = \sum_{i=1}^{n} (g_i - b_i) * ln\left(\frac{g_i}{b_i}\right), \quad (1)$$

where using the Wikipedia example, the interpretation of individual elements is as follows:

bi - is the number of articles assessed as incomplete (bad) taking into account the specific value or range of the value of the explanatory variable in relation to the total number of incomplete articles in the total set X (e.g. how many times articles containing a certain number (or range) of followers (variable followers) were assessed as incomplete in relation to the total number of incomplete articles);
gi - is the number of articles assessed as complete (good) taking into account the specific value or range of the value of the explanatory variable Xi in relation to the total number of incomplete articles in the total set X.
In the case when $(g_i - b_i) = 0$ or $ln\left(\frac{g_i}{b_i}\right) = 0$, the unit information value is zero (it does not matter for the total value). As a rule, the models strive to consider variables with a high IV factor, while

stating that this factor should not be too high, because such variables may dominate the model, which is associated with the risk of weakening the stability of the model and deterioration of its precision. Proponents of using logistic regression to evaluate variables use two approaches. The first is to choose those variables that are characterized by medium and strong predictive ability (ranges of IV values for individual categories are presented in the table below (Table 1). In the second approach, only those variables that are considered as "valuable" for advanced model building are are predictors with an average factor of IV. It is assumed that these are the variables that best characterize the given phenomenon and do not show undesirable features of dominance in the model.

Table 1: Interpretation of the Information Value IV

Information Value	The nature of the independent variable, predictive power
< 0.02	A useless predictor
0.02 - 0.1	Weak predictor
0.1 - 0.3	Medium predictor
0.3 - 0.5	Strong predictor
>0.5	Sometimes treated as still a strong predictor or suspect as a"too good" to be reliable, variable with dominating features

source: own study based on Finlay (2010), Mays and Lynas (2011), Siddiqi (2006)

Research sample and variable selection

Research area was English version of Wikipedia. To get data Wikipedia's API service that provides convenient access to data and metadata to articles via HTTP, via a URL, in various formats (including XML, JSON) was used. This service works for every language version and is available at the address specified according to the template: https: // {language} .wikipedia.org / w / api.php? Action = {settings}, where {language} is the abbreviation for the language version and { settings} are query settings. To assess information value of articles logistic regression was applied. The value of the information contained in the explanatory variables to describe the dependent variable reflects the quality of these independent variables as well as their predictive power.

The number of articles in the training sample amounted to nearly 20,000 articles (where 50% were "complete" and the rest "incomplete"). The test sample in each language is at least 3 times larger than the trainee, in which all articles from FA and GA classes are "complete" and the number of "incomplete" is slightly larger. In the English version - it's about 60,000 articles. The explained variable is the assessment of whether a given article is complete or not, in other words whether it is assessed as a good or bad article (binary review). The calculations concern several selected variables, which, can significantly differ in terms of their informative value and the role of the variable in building predictive models. Efforts were made that the variables were representatives of different types, both primary and complex, as a derived of the originals. Variables such as references, number of followers, number of editions, page views, pictures and derivative reference / number of letters were taken into account.

Research Results

Creating a pivot table allowed to determine the number of incomplete (0) or complete (1) articles. An example of calculation in case of variable *number of images* is presented in the table (Table 2) below:

Table 2: The number of complete and incomplete articles in the English version of Wikipedia depending on the number of images.

Number of images	incomplete (0)	complete (1)	Sum
0	144	0	144

source: own elaboration

It turns out that in case of *images* variable, the informational value is 2.33. The use of logistic regression allows detailed assessment of explanatory variables in terms of information value and, consequently, their importance in the model. Role of logistic regression in the assessment of data quality may be significant in the big data era, where we deal with many variables describing different phenomenon or users behavior that may affect decision making process. Wikipedia isn't the only example. Many Wiki websites, based on public Linked Open Data technologies allow us to follow behavior on the network, e.g. Google trends or Trends map, where we can follow current activity of users and find relevant content of their interest. Here are some examples:

(a)

(b)

(c)

Fig. 1: Users behavior on network can be easily followed based on Linked Open Data technologies, e.g: (a) Trendsmap.com; (b) Google trends or #brexit hashtag (c) popularity on 11th of July 2019 on www.hashtags.org

Conclusions

According to Gartner, in 2020 year information collected through data analysis will lead to transformation, further digitization or elimination of 80% of business processes or products. Data brokerage will further develop (30% of resources in 2017). The data analysis will be much more customer-oriented in the future. One thing is certain - further evolution of business models and management practices based on data monetization awaits us. Nowadays information takes a leading and crucial role for both - individuals and organizations. In the age of big data, where we are dealing with information overload, the ability to manage information effectively is very important. We are seeing more and more often data-driven enterprises phenomenon, which create innovative business models not only based on assumptions or good practices, but rather on real-time data, adjusted to the individual customer's needs. Much, however, depends on the information potential and analytical skills of the organization. Soon the largest "data warehouse" of every enterprise will not be network itself and a series of information and relationships between them, regarding consumer behavior. What seems to be characteristic in case of data-driven enterprises is the desire to create consistent customer profiles based on one or more data sources in real time. Linked Open Data resources are very broad and they certainly can be used to achieve this goal.

Effectiveness and Application of Assisted Technology in Italian special psycho-education: a pilot study

Giusi Antonia TOTO
University of Foggia, Foggia, Italy, giusy.toto@unifg.it

Pierpaolo LIMONE
University of Foggia, Foggia, Italy, pierpaolo.limone@unifg.it

Abstract

Assistive technology allows to remove a number of obstacles to the complex psycho-educational needs of students with disabilities. The purpose of this research is to collect information on the knowledge, skills and perceptions of assistive technology among teachers in the context of Foggia, as a pilot study for a wider national reflection. The data were collected through consultation of official databases and through a survey, submitting to a sample of teachers a questionnaire used in an international context, translated in Italian. The results suggested that teachers do not have an adequate level of knowledge and skills in the use of assistive technology and require pre-service and in-service training to increase their general knowledge on assistive technology implementation and to plan effective actions for students with disabilities.

Keywords: Assistive Technology, Special Needs, Disabilities, Learning Environments.

Introduction

The didactic planning of artefacts and educational environments to return meaningful learning to any student must propose solutions that can be used by everyone and to their full potential (Burgstahler, 2012). Assistive technology (AT) means any product, virtual or real, capable of increasing, maintaining or improving the functional skills of people with disabilities (Young, 2013). In fact, thanks to its primeval innovative nature, assistive technology has spread to the most disparate sectors of human life, not least in training. The use at school, therefore, of technological devices to support students with special needs in learning is a vexata quaestio, which clashes with objective environmental deficiencies and ambiguous cultural heritage, reinforced by actions of resistance to the use of technologies at school (Limone & Toto, 2020). The realization of a truly inclusive education concerns not only the design of personalized didactic interventions, but also through the development of facilitating learning environments. The definition of effective learning present in psychology is affected by the classical theory of Vygotskij (1995), reinterpreted in the light of recent research by Booth & Ainscow (2011), must leverage the social dimension of learning through active and participatory teaching proposals. Continuing to enhance the value of participation in training processes rather than inclusion, as stated in the I*nternational Statistical Classification of Diseases and Related Health Problems 11th revision* (ICD-11), all'*International Classification of Health Interventions* (ICHI), (WHO, 2018). Participation according to this theoretical model is expressed in the social and active dimension of learning. In the contemporary context, technologies are the subject of study of the psycho-pedagogy of special needs to favor the processes of social and educational inclusion.

Unlike the use of assistive technologies in the rehabilitation and medical field, more simply accepted for their main support for motor function, ATs in the school context as a support to cognitive activities still laboriously have free diffusion, although they are encouraged by a vast pedagogical literature (Bonwell & Eison, 1991; Limone, & Toto, 2018). Assistive technology provides students with disabilities the same opportunities to participate in active environments with predictive activities aligned with their abilities.

Table 1: Main technological tools for school disability support.

Disability	Motor	Visual	Auditory
Tools found in schools	- Keyboards (mini, expanded, virtual, etc.); - Pointing systems (trackball, joystick, touch pad, touch, screen); - Scan systems, voice commands, sensors.	- Adaptation of texts; - Sign recognition software; - LIM - Touch monitor - Voice / written conversion software	- Speech synthesis; - Screen reader; - Display and braille printer; - Portable braille devices - Enlargers and video ingraditors; - Scanner and OCR system; - Digital audiobooks and book readers

The technology for disability at school substantially consists of a PC equipped with a suite of software and specific platforms for the different special needs (a separate discussion must be made for visual disabilities where the ATs have reached a high degree of training in training contexts specialization). For example, even in the presence of severe motor disabilities, the use of keyboards, pointing systems, touch screens or voice commands allows to carry out didactic tasks (Limone & Toto, 2019). The software for hearing impairments is in a phase of rapid experimentation, in which the written text, while maintaining the role of the main access channel to external communication, is substantiated in a decrypted text and translated into LIS language through digital devices (van Niekerk, et al., 2018). The greatest results in terms of technology applied to special needs occurred for visual impairments; in addition to the aforementioned speech synthesis systems and screen readers, the research was directed towards specific technological artefacts and software offering a support during the learning process, such as braille displays and printers, video magnifiers, OCR scans and digital audiobooks. The introduction of compensatory tools into the classroom, including information technology and alternative learning methodologies for DSAs, has given a strong boost to the search for applications also in this area.

State of art

The international debate has been asking for more than twenty years on the effective presence of TA in schools and what is the current level of knowledge and skills of teachers in the use of assistive technology (Alkahtani, 2013), research questions that have also addressed the present study. Another dimension investigated is the teachers' perception of the use of assistive technology with their students. For this purpose, we selected and compared for their possible use in the Italian context two (questionnaires) surveys used in the international research context. The first one was drawn up by Chmiliar (2007), structured in its very complex final version on personal information, followed by 13 items on training on the subject of TA and on the type of training followed, a question that asks participants to evaluate the their TA skills and knowledge, (an open question asking participants to identify assistive technology funders, not relevant to this study), 12 questions about the use and satisfaction of using assistive technology, a list of 12 options to evaluate the barriers and obstacles to learning and a list of 10 items to evaluate the importance in the provision of services and in the financing of TA and, finally, numerous opportunities to provide comments. The study also replicated in other contexts (Kutlu et al., 2018) produced the following results: in two researches conducted by the team led by prof. Kutlu (2007, 2018), the support teachers involved (248 in the American context in the first study, 211 in Turkey in the second) said they had not received in-service training on assistive technology and that they did not feel sufficiently adequate in the use of assistive technology, neither software, nor hardware. The degree of dissatisfaction widened 50% of the participants in the research in relation to the contemporary skills and knowledge of technological tools for special needs. This result, according to the authors, is related to the effective availability of equipment in the

schools investigated, therefore the dissatisfaction depended on the environmental deficiency. Finally, in both studies, the teachers indicated innovative teaching strategies as the most important tools available to them in school educational practice.

The second questionnaire developed by Alkahtani (2013) was designed by integrating quantitative research strategies with qualitative interviews, according to the models of Fowler (2008) and Creswell (2008). It is, actually, the screening of quantitative research that naturally selects subjects to deepen the topics of qualitative interviews. The survey respects the guidelines of the Consortium of Quality Indicators for Assistive Technology (QIAT) and consists of a first part structured in six items for the collection of personal information and a second part of 13 items designed to evaluate the use and level of knowledge of assistive technology of by the teachers. Finally, in the first version there is a last question requesting availability to undergo a 15-minute telephone interview on the same issues. The results of this research, conducted on 127 teachers (only 3 of whom gave availability for a telephone interview), showed that the vast majority of the teachers involved do not have an inadequate level of knowledge.

Parte I: Informazioni demografiche
Si prega di completare le informazioni su di te.
1 - Qual è la tua età?
----- Meno di 30 anni.
----- 30-40
----- 41-50
----- 51-60
----- Più di 60 anni.
2 - Qual è il tuo genere?
----- Maschio.
----- Femmina.
3 - Qual è il più alto livello di istruzione che hai completato?
----- Laurea triennale.
----- Master.
----- Dottorato.
----- Altro (prego specificare).
4 - Qual è la tua posizione lavorativa?
----- Insegnante Curriculare.
----- Insegnante di Sostegno.
----- Altro (prego specificare).
5 - Quale degli aggettivi proposti descrive meglio la posizione della scuola in cui insegni?
----- Rurale.
----- suburbano.
----- Urbano.
6 - Quanti anni di esperienza hai nell'istruzione?
----- Meno di un anno.
----- 1-2 anni.
----- 3-5 anni.
----- 6-10 anni.
----- Più di 11 anni.
Parte II: Uso e conoscenza della tecnologia assistiva
Si noti che questo questionario si basa sulla definizione IDEIA 2004 della tecnologia assistiva che include dispositivi high-tech (cioè dispositivi di comunicazione alternativi) e include anche elementi che in genere non possono essere considerati "tecnologici" (vale a dire impugnature a matita).
1 - Hai mai usato o richiesto una valutazione della tecnologia assistiva per uno studente?
----- Sì
----- No
2 - Le esigenze di tecnologia assistiva sono prese in considerazione dal team GLH della tua scuola?
----- Sì
----- No

3 - Gli studenti della tua scuola hanno accesso alla tecnologia assistiva?
----- Sì
----- No
4 - Quali tipi di tecnologie assistive sono disponibili nella tua scuola (scegli tutte le risposte pertinenti)?
----- Dispositivi a bassa tecnologia (penna luminosa per migliorare area di scrittura, pinze, scrivanie adattive).
----- Dispositivi di media tecnologia (tasti appiccicosi, penna Iris, tastiera portatile Neo 2)
----- Dispositivi high-tech (apparecchi acustici e / o di ascolto assistito, programmi di predizione di parole, alternative da tastiera).
5 - Sei pronto a fornire servizi di tecnologia assistiva ai tuoi studenti?
----- Per niente preparato.
----- Scarsamente preparato.
----- Piuttosto preparato.
----- Preparati adeguatamente.
----- Estremamente ben preparato.
6 - Stima il tuo livello di conoscenza della tecnologia assistiva.
----- Nessuna conoscenza.
----- Poca conoscenza.
----- Qualche conoscenza.
----- Buona conoscenza.
----- Ampia conoscenza.
7 - Stima il numero di corsi universitari o di livello universitario che hai svolto in cui la tecnologia assistiva è stata trattata nel dettaglio (cioè più di una sessione di classe).
----- Nessuno
----- 1-2
----- 3-4
----- 5 o più.
8 - Stima il numero di workshop o di formazione in servizio riguardanti specificamente la tecnologia assistiva che hai frequentato nella tua carriera.
----- Nessuno
----- 1-2
----- 3-4
----- 5 o più.
9 - Sei interessato a ricevere formazione e sviluppo professionale nel settore della tecnologia assistiva?
----- Sì, sono molto interessato.
----- Non lo so, ci penserò.
----- No, non mi interessa per niente.
10 - Pensando al tuo stile di apprendimento e alle tue esigenze, indica il tuo metodo preferito per l'apprendimento dell'assistenza tecnologica (scegli tutte le risposte pertinenti).
----- Istruzioni individualizzate individuali.
----- Le istruzioni pratiche nell'impostazione di gruppo.
----- Frequentare workshop o sessioni di conferenze.
----- Corsi formalizzati (vale a dire per il credito universitario).
----- Altro (prego specificare).
11 - Lo studente deve apprendere senza l’uso tecnologia assistiva, dato che il suo utilizzo ne influenzerebbe negativamente lo sviluppo delle abilità?
----- Fortemente in disaccordo.
----- Disaccordo.
----- Neutro.
----- Essere d'accordo.
----- Fortemente d'accordo.
12 - Sei d'accordo che la tecnologia assistiva consente agli studenti di accedere alle attività del loro curriculum?

----- Fortemente in disaccordo.
----- Disaccordo.
----- Neutro.
----- Essere d'accordo.
----- Fortemente d'accordo.
13 - Sei d'accordo che l'utilizzo della tecnologia assistiva richiede così tanto tempo extra e rallenta il ritmo di apprendimento per la classe.
----- Fortemente in disaccordo.
----- Disaccordo.
----- Neutro.
----- Essere d'accordo.
----- Fortemente d'accordo.

Results and Discussion

The analysis carried out on data relating to 855 students with disabilities present in attending the schools of Foggia in the school year of 2018-19 (staff of law and derogations) propose a magmatic situation (Tab. 2).

Table 2 - Distribution of pupils in schools in the province of Foggia.

	Cognitive	Motor	Visual	Auditory
	696	80	49	30
Percentage	81%	9%	5.5%	3.5%

For both pupils with motor and with cognitive disabilities, the PC is the main support tool for those in difficulty; the major drawbacks encountered by the teachers are the slowness of didactic interventions conducted in the classroom and the easy distractibility of the group with respect to individual work. The didactic emergency of multimodal instrumentation for blind people (Tab. 1) has the advantage in the perception of the curricular teacher of not needing intermediaries and of involving the pupil in shared activities for the plasticity of the documents produced. Furthermore, the same type of advantage is found in pupils with hearing disabilities. Finally, almost all of the teachers involved manifest the pedagogical emergency of in-service training through courses for the use of AT in the school. The investigation, in this first pilot phase, did not map all the 427 support teachers in the province of Foggia, however the questionnaire was administered to a representative sample of 81 referents for the disability of local schools. The data presented in conclusion relate to this second sample interviewed.

Conclusions

The educational success of pupils with disabilities is strengthened through effective and proper use of assistive technologies by teachers (Caldin, 2006). The international literature (Laughlin et al., 2018) describes the implementation of skills and knowledge related to rapidly evolving TA as essential for the professional development of teachers, curricular and support. The results of this study confirm the researches conducted so far in this area, that describe on the one hand the inadequacy of skills in the use of assistive technology and on the other a need / need for training on these issues. Teachers' perceptions on the usefulness of training for the use of assistive technology in the school, influence the frequency with which they are used (Canevaro et al, 2011) and represent another vast field of investigation for future research.

The main positive functions of technologies in inclusive education relate, in relation to the specificity of the handicap, to three main purposes: communicative purpose (1) which facilitates access to

educational situations, that participation (2) at a distance, an increasingly used method in all emergency situations and personalization (3) which simplifies the cognitive aspects of knowledge. The technology facilitates the compensation mechanism. With this term we mean that strategy of adaptation to the context activated by technologies. The dialectical mechanics of compensation / insufficiency directs the deficient subject towards two antinomic pathways, one propulsive and the other pathological, both triggered by the context, which restructures all adaptive functions, structures and substitute processes, and creates conditions of proximal development (Vygotsky, 1995). In this perspective, special teaching becomes an element of extreme experimentalism and innovation (Kling et al., 2010; BouCk, 2011). It is precisely the situations of emergency and disadvantage that stimulate the professional growth of educators and pushes them to seek new teaching / learning strategies. The school context becomes a privileged environment in which barriers become accessible and peer collaboration develops. Technology, therefore, becomes the medium of interaction between the inside of the school and the outside of the socio-cultural context of the subject (Toto, 2017; 2018). To develop autonomy and equal opportunities in children with disadvantages, a planned and systemic use of technology is also necessary. The didactic design rethought in this perspective allows the acquisition of life skills.

Acknowledgement

Thanks to prof. Keetam D. F. Alkahtani, Dept. of Special Education, King Saud University, for giving permission (authorizations) to translate and use the survey he developed, in this and future studies. We also thank the USP of Foggia for the context data, which can be consulted at the link www.ustfoggia.it

Abstract

The article analyses the innovative development of the Russian Federation enterprises considering the statistical reporting data, as well as the results of researching dependence of industrial enterprise valuation upon different factors of its innovative development using methodologies of correlation and regression analysis. The obtained results could be applied not only to an enterprise valuation but to the innovation development strategies of an industrial enterprise.

Keywords: Industrial Enterprise, Enterprise Innovative Potential, Enterprise Innovative Development, Enterprise Valuation, Innovation Development Strategy.

Introduction

Under the current business environment conditions, one of the main factors of the efficient long-term functioning of an industrial complex is the constant innovation development as an indispensable condition to reduce the dependence of the domestic economy on world market conditions. Additionally, innovative potential and the innovation development pace influence the enterprise valuation as a business.

Currently, the researchers have not completely investigated valuation of the impact of an enterprise innovation development indexes on an industrial enterprise value; it necessitates its further improvement. The importance of this evaluation is due to the fact that the value of the company becomes an indicator of success; a company management obtains an additional motivating incentive to form, strengthen, and use certain indicators of innovation development.

The factors restraining the innovative development of industrial enterprises in the Russian Federation include the following:

- underinvesting technological and innovative development by private investors, associated with the uncertainty of the payback period and economic efficiency of projects in the field of innovative development (fig. 1);

Fig. 1: The cost share for technological innovation in the total volume of goods shipped, work and services performed in the Russian Federation,% [1]

- the deficiency of a systematic approach to stimulating the innovative activity of enterprises at the state level and the insufficient participation of the state in investing innovations (fig. 2);

Fig. 2: Financing science from the federal budget of the Russian Federation, billion rubles [1]

- low efficiency of the innovation infrastructure created as a part of the implementation of various development programs and, often, not fulfilling the functions assigned to them;
- the educational system lag from the global trends in high-tech production areas and, as a consequence, a reduction in the number of personnel engaged in research and development in industry (fig. 3).

Fig. 3: The number of personnel engaged in research and development in the Russian Federation, thousand people [2]

Decrease in innovation activity resulted in a number of the problems; this lead to decrease in the number of patent applications filed (fig. 4) and the share of domestic patents in the total number of patents granted in the Russian Federation (fig. 5).

Fig. 4: Patent applications filed in the Russian Federation, thousand items [2]

Fig. 5: Share of the domestic patent filed, in the total number of patents granted in the Russian Federation, % [2]

The current trends lead to a decrease in the competitiveness of domestic industrial enterprises and their products in the world market and, as a result, a decrease in the value of these enterprises as a ready-made business.

Choice of Innovation Development Factors Influencing an Industrial Enterprise Valuation

To develop the research base, forming a system of indicators will reflect an innovative development of an enterprise. Since the innovative development directly depends on the innovative potential, it is necessary to form a conceptual apparatus.

Several scientific research formulate the concept of "the innovative potential of an enterprise" (Kravchenko S. I., Kladchenko I. S. (2008), Merzlyakova E. A. (2015), Mingaleva Zh. A. (2013), Mylnikova L. A. (2014)), and M.F. Safargaliev (2011) understands the innovation potential as “a combination of various financial, industrial, technical, intellectual and labor resources that ensure the implementation of innovative activities leading to the creation of fundamentally new products or technology, or modifications to the innovations already proved”.

The concept of "innovative development" is connected to the scientific research of a number of scientists (Dubinin A. S. (2013), Kardash I. N. (2013), Mindeli L.E., Chernykh S.I. (2014), Mironova N. B. (2013)), while the authors share P.N. Dolzhnikov’s (2009) definition, who believes that “innovative development is a business process based on the continuous search and use of new

methods and areas to realize an enterprise potential in the changing environment in the framework of the chosen mission and accepted business motivation, coupled with the modification of existing sales markets and forming new ones".

The values within the composition of the innovative potential characterizing the innovative development of an enterprise are quantitative indicators, reflecting:

- enterprise product manufactured;
- enterprise fixed assets;
- enterprise technology used;
- personnel characteristics;
- finance;
- enterprise organizational structure.

Since the enterprise valuation allows identifying the most likely price, an independent informed customer is willing to pay to an independent informed seller in an open competitive market; the evaluation process itself can be reduced to solving a mathematical and economic problems, and acceptable methods to solve mathematical problems within mathematical modeling sphere of economic and statistical patterns and quantities (14. Bickel P.J., Doksum K.A. (2001)). The current statistical methods to process and analyze data used for the comparison can reduce the impact of subjectivity in the evaluation.

The effective sign in the used statistical model will be the enterprise valuation, and quantitative indicators of the innovative potential of an enterprise are chosen as key factors affecting the innovative development of the enterprise.

To conduct the study, the data are used for engineering companies engaged in research and development in the field of technical sciences. The data used are the annual statistical collections of Rosstat, thematic periodicals, the Unified Federal Register of Information on the Facts of Activities of Legal Entities, Rospatent, the websites of organizations, and annual reports. Some data are confidential, therefore, the authors have decided to conceal the organization names.

Since increasing the enterprise valuation is not feasible proportionally to changing the factors influencing it, it is possible to use a logarithmic model. This model provides a slowing growth of the effective attribute when the factor changes, which corresponds to the economic nature of the change in the enterprise valuation. In this occasion, the regression equation will look like:

$$\hat{y} = b_0 + b_1 \cdot \ln x_1 + b_2 \cdot \ln x_2 + \ldots + b_n \cdot \ln x_n$$

In logarithmic multiple regression, the parameters at *x* are called the "pure" regression coefficients. They characterize an average result change with a change in the corresponding factor by 1% while the value of other factors is kept unchanged and fixed at an average level.

To build a regression model, the following factors are selected:

- share of shipped innovative products of an enterprise in the total revenue (x_1);
- number of registered intellectual property objects owned by an enterprise, as well as used under licensing agreements (x_2);
- share of machinery and equipment aged up to 5 years in the total machinery and equipment cost at enterprises performing research and development (x_3);
- share of research and development cost in the total enterprise costs (x_4);
- share of employees performing research and development in the total number of personnel (x_1).

Table 1 presents the initial data of the model.

Table 1: The initial data of the model

Target of research	Enterprise valuation, million rubles.	Share of shipped innovative products of an enterprise in the total revenue,%	Number of registered intellectual property objects belonging to an enterprise, as well as used under license agreements, items	Share of machinery and equipment aged 5 years old in the total machinery and equipment cost at enterprises performing research and development, %	Share of research and development cost in the total enterprise costs, %	Share of employees performing research and development in the total number of personnel, %
	y	x_1	x_2	x_3	x_4	x_5
Enterprise 1	61,8	74,8	1	13	17,2	76,2
Enterprise 2	64,2	78,2	1	12	19,7	68,7
Enterprise 3	68,2	75,1	2	14	16,8	48,3
Enterprise 4	70,7	75,5	3	12	18,4	54,9
Enterprise 5	73,1	78,8	2	14	17,8	62,5
Enterprise 6	73,3	83,1	2	13	18,3	82,4
Enterprise 7	74,8	80,6	2	17	22,4	63,7
Enterprise 8	75,6	79,8	3	18	23,6	79,1
Enterprise 9	81,0	85,6	2	27	30,3	60,6
Enterprise 10	81,2	83,2	3	25	25,1	83,7

To quantify the degree of deviation of the initial information from the normal distribution, the ratio of the asymmetry index to its error and the ratio of the kurtosis index to its error are used. As a result of checking the initial data, the insignificance of the asymmetry and kurtosis coefficients is revealed; therefore, the data array practically corresponds to the law of normal distribution and they can be used for the correlation analysis.

For the final selection of factors to be included in the regression model, it is necessary to evaluate their multicollinearity using the correlation matrix (Table 2).

Table 2: Matrix of pair correlation coefficients

	y	x_1	x_2	x_3	x_4	x_5
y	1	0,8256	0,7436	0,8435	0,7896	0,1695
x_1		1	0,3107	0,5442	0,7905	0,4298
x_2			1	0,4271	0,3505	-0,0449
x_3				1	0,9085	0,1998
x_4					1	0,2324
x_5						1

The calculated values of the correlation coefficients indicate the following:

- factors x_1, x_2, x_3 and x_4 correlating with an effective attribute indicates their close relationship;
- factor x_4, however, is collinear to factor x_3, while the influence on the resultant trait of factor x_3 is greater, therefore, x_4 must be excluded from the regression model;
- factor x_4 does not practically affect the effective feature.

As a result, three factors should be included into the model:
- share of shipped innovative products of an enterprise in the total revenue (x_1);

- number of registered intellectual property objects owned by an enterprise, as well as used under licensing agreements (x_2);
- share of machinery and equipment aged up to 5 years in the total machinery and equipment cost at enterprises performing research and development (x_3);

Constructing A Regression Model of An Industrial Enterprise Valuation Depending on The Selected Factors

To calculate the coefficients of the regression equation, the initial numerical data should be presented in the form of logarithms (Table 3).

Table 3: Logarithmic initial data

Target of research	*y*	x_1	x_2	x_3
Enterprise 1	61,8	4,314817885	0	2,564949357
Enterprise 2	64,2	4,359269648	0	2,48490665
Enterprise 3	68,2	4,318820559	0,693147181	2,63905733
Enterprise 4	70,7	4,324132656	1,098612289	2,48490665
Enterprise 5	73,1	4,366912997	0,693147181	2,63905733
Enterprise 6	73,3	4,420044702	0,693147181	2,564949357
Enterprise 7	74,8	4,38949865	0,693147181	2,833213344
Enterprise 8	75,6	4,379523504	1,098612289	2,890371758
Enterprise 9	81	4,449685283	0,693147181	3,295836866
Enterprise 10	81,2	4,421247348	1,098612289	3,218875825

Table 4 presents regression statistics.

Table 4: Regression Statistics indicators

Indicator	Value
Multiple R	0,9876
R^2	0,9753
Standardized R^2	0,9605
Standard error	1,0976
Observations	10

Based on the table 4, we can draw the following conclusions:

- multiple correlation coefficient is close enough to 1, which indicates a close relationship of the selected factors with the result;
- coefficient of multiple determination of R^2 indicates that the change in the effective feature by 97% explains a variation of the selected factors.

To assess the statistical significance of the linear regression coefficients, the Student t-test is used (Table 5).

Table 5: Variance analysis indicators

	Coefficients	Standard error	*t*-Statistics	*P*-Value
Y intersection	-201,118157	55,77072014	-3,606160302	0,015442714
x_1	56,87787971	13,67740646	4,158528145	0,008836678

x_2	6,981678595	1,286419008	5,427219707	0,002878291
x_3	7,277529571	2,147457953	3,388904336	0,019484507

Student t-test verification allows highlighting the significance of regression equation coefficients with a probability of at least 0.98. Verification of the regression model adequacy by the Fisher test indicates the determination coefficient significance with a probability of at least 0.9998.

As a result, the logarithmic regression equation is as follows:

$$\hat{y} = -201{,}12 + 56{,}878 \cdot \ln x_1 + 6{,}982 \cdot \ln x_2 + 7{,}278 \cdot \ln x_3$$

Describing the equation requires to interpret correctly the coefficients of the equation during the logarithm. In our occasion, the coefficients b_1, b_2, and b_3 characterize the change rate of a productive attribute under the influence of factorial units while increasing the value x_i by 1% results in y changing by $b_i/100$ in their own units.

Based on the obtained regression model, we could see that an increase in the share of shipped innovative products of the enterprise in the total revenue by 1% results in increasing the enterprise valuation by 0.57 million rubles; with an increase in the number of registered intellectual property owned by the enterprise, as well as used under license agreements by 1%, the enterprise valuation will increase by 0.07 million rubles; an increase in the share of machinery and equipment aged up to 5 years in the total cost of machinery and equipment at the enterprise performing research and development will lead to the enterprise valuation increase by 0.07 mln. rubles.

Conclusion

The regression model constructed as a result of the research reveals the fundamental factors influencing the valuation of an industrial enterprise. Moreover, this approach can be used for any industrial enterprises. In this occasion, the analysis requires to consider a complete set of factors so that the most significant of them become apparent at the selection stage. The composition of factors may differ from the given in this research and will reflect the specifics of the industry. In addition, such a regression model allowing evaluating the enterprise valuation can also be used to develop a strategy for the innovative development of enterprises to determine key areas of the development and make effective management decisions during such a strategy implementation.

Abstract

Small and Medium-sized Enterprises (SMEs), like any other organization, face many risks, but tend to reactively perceive risk management activities, greatly reducing the capacity of available resources to mitigate risks. By implementing a structured approach to risk management within the operations of SMEs, benefits such as reducing global risks, reducing costs, organizational alignment with the mission and objectives of SMEs can be achieved. The purpose of this paper is to identify if there is a significant correlation between perception of the possible benefits obtained from implementation of risk management and integration of risk management into operating activities within Romanian SMEs. The results indicate that appreciating the importance of increasing profitability and revenues and identifying and controlling a greater number of risks at entity level, as potential benefits of implementing risk management, have a significant and negative contribution to the extent to which risk management is integrated into operating activities of Romanian SMEs. In contrast, there is a significant and positive association between the extent to which risk management practices are applied in the operating activities of Romanian SMEs and the importance of aligning risk management with company objectives and increasing stakeholder satisfaction and involvement in risk management.

Keywords: Benefits, Implementation, Romania, Risk Management, Small And Medium-Sized Enterprises.

Introduction

Small and Medium-sized Enterprises (SMEs) are essential for the growth of any economy, the advantages they offer consist of the contribution to the production of goods and services, the creation of jobs with relatively low capital, the reduction of income disparities, the formation of qualified and semi-skilled human resources and the reduction of poverty (Rogerson, 2001).

Currently, SMEs play an important role in the Romanian economy. They generate 52.7% of the total value added and 65.8% of the total employment, yet the percentage is lower than the EU averages of 56.4% and 66.6%. The average productivity of Romanian SMEs, calculated as an added value for each employed person, is about EUR 15.100, significantly lower than the EU average of about EUR 44.600. On the other hand, Romanian SMEs employ on average 5.5 people, exceeding the EU average of 3.9 (European Commission, 2019).

The peculiarities of SMEs that make them vulnerable are limited access to finance, inadequate capital, instability, lack of appropriate records, lack of technology, lack of entrepreneurial and management skills, small-scale operations with low growth potential (Mwaniki, 2006).

Like any other organization, SMEs face many risks, but their ability to treat them is lower compared to large firms (Agrawal, 2016). On the other hand, within SMEs it is very difficult to differentiate between the role of manager and owner in terms of managing business risks. (St-Pierre & Bahri, 2006). Risks specific to small and medium-sized enterprises according to the Risk Management Guide for Small Businesses, the first and only guide issued regarding risk management in small organizations, by the Global Risk Alliance (GRA) and NSW Department of State and Regional Development, Small Business Development Division, are: financial, organisational, compliance/legal, operational, commercial, security, strategic, equipment, reputation, service delivery, project, stakeholder management, technology (GRA, NSW, 2005).

The study aims to analyze the extent to which the decision-makers perception of the different benefits of risk management correlates with the implementation of risk management in operating activities. This type of operation was chosen due to the fact that, in general, risk management is frequently used in strategic decisions. The application of risk management at the level of operating activities denotes the fact that the company considers that it has a high importance for the effective conduct of the activities.

Literature Review

The late 1990s is characterized by the publication of several books and articles on enterprise/integrated risk management and the emergence of specialized publications that included the word "risk" in titles (Power, 2004). However, until 2009 there was no accepted global framework or standard that could be used to establish or evaluate risk management activities (Frigo & Anderson, 2011). In 2009, the ISO 31000:2009 standard was issued, which brought more rigor in the areas of risk management implementation and boosted studies on the implementation of risk management in SMEs.

Simultaneously, were studied benefits of implementing risk management in an integrated approach within the organization. The differentiation between the integrated approach of risk management and the traditional one is made in terms of design and effectiveness regarding the creation of value for the organization. While the integrated approach also focuses on opportunities to bring value to the entity, generic risk management aims to eliminate the risks perceived as threats (Acharyya, 2013).

In the literature, the concept of enterprise risk management (ERM) is sometimes replaced by synonyms such as holistic risk management (HRM), integrated risk management (IRM), strategic risk management (SRM) or total risk management (TRM). Enterprise risk management (ERM) has emerged as a new approach to risk management that aims to manage in an integrated manner the risk portfolio that an organization is facing. In contrast to the traditional risk management approach, where individual risk categories are managed from the “in silo” perspective, ERM involves a holistic risk approach, enabling companies to take into account the correlations between all risk categories. (Monda & Giorgino, 2013)

Louw & Com (2007) states, based on DeLoach's study (2005, p. 3), that the ERM focus is on integrating risk management with existing management processes, on identifying future events that may have positive or negative effects and on evaluating the effectiveness of strategies to manage the organization's exposure to possible events.

There are three ways ERM helps the organization to manage risks, so as to protect and increase the value of the company (Protiviti, 2006):

- Establishing a sustainable competitive advantage. ERM supports the transition of the organization from a “in silo” risk management to a strategic one, which concentrates and applies the risk management process to all the sources of value of the entity.
- Optimizing the cost of risk management by aggregating risk acceptance and transfer decisions, eliminating the redundant activities and establishing the level of risk that the organization is willing to accept when running the business model.

- Management support to improve business performance by reducing performance variability and exposure to losses by anticipating future events with major impacts, and developing responses regarding their management.

Institute of Internal Auditors (2009) defines ERM as a structured, solid and continuous process, carried out throughout the organization, in order to identify, evaluate, respond and report the opportunities and threats that have an impact on the achievement of the objectives. EY (2016) creates a scheme that includes the ERM features. This is shown in Figure 1.

ISO 31000 (2009) outlines the integrated risk management approach made up of interdependent components of ERM/IRM, these derive from the way the management administrates the organization and from the way the components are integrated in the management process.

Figure 1: ERM Features

Source: Adapted from EY (2016)

Implementation of integrated risk management is an exercise in change management, there will be people who embrace change and see it as a welcome improvement for the company, but there will be people who consider change as an unnecessary work. When the need for implementation is exposed to management, the focus should be on the benefits granted to the organization, few managers can dispute the benefits of risk management or if the performance of an entity is consistent with the volume of risks managed (Society of Actuaries, 2006). ERM can really reduce risk exposure, improve the decision making process and bring benefits on a large scale, but only if implemented correctly. ERM also allows organizations to become more entrepreneurial, because, once risk management is adequate, they will have the confidence and knowledge to carry out new activities (Howard, 2009). Figure 2 presents the benefits of implementing integrated risk management.

Figure 2: The benefits of implementing integrated risk management

Source: Adapted from Argyrou; Dr. Schanz Alms & Company, (2015), Ciocoiu (2015), COSO (2017), PwC (2016), Standards of Sound Business and Financial Practices (2011)

In practice, implementing risk management has offered organizations various advantages as well: reducing the total cost of risk out of turnover, from 2.7% in 2006 to 2.2% in 2010 (DLA Piper), reducing exposure to risk with 85% for 51 analyzed projects (Nestle), decreasing of financial exposure of significant risks by 70% (Government Agency) (Howard, 2009).

The specialized literature is characterized by a small number of studies in which the issue of perceiving the benefits of implementing risk management is addressed, either they are interpreted as results obtained from the implementation of the risk management program, or as reasons for the companies to engage in the risk management program.

For example, a study conducted on listed companies in Malaysia, evaluates, through exploratory factor analysis (EFA), the intensity and challenges of implementing risk management, but also its benefits such as: improving the clarity of the decision-making process throughout the organization, increasing the profitability of the company, awareness of the risk among employees, improving communication with stakeholders/shareholders, significant contribution to the achievement of the strategic objectives of company (Lai, 2014). Also, Hoyt & Liebenberg (2011) have researched the advantages of ERM in the insurance field, using data for 117 companies listed on the US stock exchange, from 1998 to 2005, and found that there is a positive relationship between the implementation of risk management and the performance of firms.

Methodology of Research

The purpose of this paper is to identify if there is a significant correlation between perception of the possible benefits obtained from implementation of risk management and integration of risk management into operating activities within Romanian SMEs. The benefits category includes a number of elements drawn from previous studies of various authors from Romania and abroad (Ciocoiu, 2015; COSO, 2017; Lai, 2014; PwC, 2016).

The questionnaire was adopted as a means of collecting reliable and quantifiable data at a reasonable cost. The target population was composed of owners, managers, risk managers, project managers of the Romanian SMEs. From a total of 390 owners and managers who were invited to complete the questionnaire online, only 185 representatives of the Romanian SMEs participated, and 164

questionnaires were validated. The first part of the questionnaire contains three questions regarding the size of the organization, the age on the market and the level at which it operates, in the form of checklists. The second part has 7 questions addressed to the extent to which the risk management is used in the operating activities of the company and the perception of its benefits as a factor underlying the implementation. The benefits listed in the questionnaire refer to: increasing profitability and revenue, increasing the efficiency of the decision-making process and the efficient use of resources, developing a culture of risk managemnet in the company,

aligning risk management to the company objectives, identifying and controlling a large number of risks at entity level, increasing satisfaction and stakeholder involvement in the risk management process. The second part of the questionnaire used interval rating scale measurement with three-point Likert-Scale.

To analyze the data was used descriptive statistical methods such as averages and standard deviation, and inferential statistical methods such as linear regression, at the level of statistical significance of 0.01. The following hypotheses will be tested in this study:

H1: There is a significant relationship between increasing profitability and revenues and the extent to which risk management is integrated within SMEs in Romania.
H2: There is a significant relationship between increasing the efficiency of the decision-making process and the efficient use of resources and the extent to which risk management is integrated within SMEs in Romania.
H3: There is a significant relationship between the development of a culture of risk management in the company and the extent to which the risk management is integrated within the Romanian SMEs.
H4: There is a significant relationship between the alignment of the risk management with the objectives of the company and the extent to which the risk management is integrated within the SMEs in Romania.
H5: There is a significant relationship between the identification and control of a greater number of risks at entity level and the extent to which the risk management is integrated within the Romanian SMEs.
H6: There is a significant relationship between increased satisfaction and stakeholder involvement in the risk management process and the extent to which risk management is integrated within Romanian SMEs.

For each hypothesis was defined the null hypothesis H_0: The analysed variables are statisticaly independent (there is no association between the analysed variables) and the alternative hypothesis H_a: There is an association between the analysed variables.

Results and Discussion

The results from the descriptive statistics as presented in Table 1 indicate an average of integrating risk management into the organization's operating activities of 0.216 for the SMEs under consideration. It represents an average percentage (%) distribution of approximately 21%.

On the other hand; increasing profitability and revenue, increasing the efficiency of the decision-making process and the efficient use of resources, developing a culture of risk management, aligning risk management with company objectives, identifying and controlling a greater number of risks at the entity level and increasing satisfaction and involvement stakeholders in risk management have an average distribution value of 0.263, respectively 0.257, 0.245, 0.238, 0.245, 0.237 for the sampled SMEs.

Table 1: Descriptive Statistics

	Mean	Std. Deviation	N
RM integration in operating activities of the company	2.16	0.824	164
Increasing profitability and revenue	2.63	0.638	164
Increasing the efficiency of the decision-making process and the efficient use of resources	2.57	0.710	164
Developing a culture of RM in the company	2.45	0.753	164
Aligning RM to the company objectives	2.38	0.778	164
Identifying and controlling a large number of risks at entity level	2.45	0.720	164
Increasing satisfaction and stakeholder involvement in the RM process	2.37	0.760	164

Source: Own calculations

Conversely, the review of empirical results from the Pearson correlation analysis, presented in Table 2, regarding the relationship between the variable of risk management integration in the operating activities of the Romanian SMEs and the variables represented by increasing the efficiency of the decision-making process and the efficient allocation of resources, developing a culture of risk management in the company, aligning the risk management with the objectives of the company, and increasing the satisfaction and involvement of the stakeholders, shows that the correlations are positive at a probability level of 1% with the following correlation coefficients (r): 0.259, 0.198, 0.324, respectively 0.266.

In contrast, between the integration of risk management in the operations of the analyzed SMEs and the increase of profitability and the identification and control of a greater number of risks at entity level, the correlations are insignificant, being higher than the 1% probability level established.

Table 2: Pearson correlations for selected SMEs

	RM integration in operating activities of the company	Increasing profitability and revenue	Increasing the efficiency of the decision-making process and the efficient use of resources	Developing a culture of RM in the company	Aligning RM to the company objectives	Identifying and controlling a large number of risks at entity level	Increasing satisfaction and stakeholder involvement in the RM process

Source: Own calculations

First, the multicollinearity test was performed before the analysis of the regression model, considering that this may affect the parameters of the regression model. Field (2009) suggests that a tolerance value of less than 0.1 indicates a serious multicollinearity problem between independent variables, and a

value of variance inflation factor (VIF) greater than 10 calls for concern. The regression model parameters in this study do not present problems of multicollinearity, considering that all tolerance values are greater than 0.10 and all VIF values are less than 10.

In Table 3, the results of the linear regression show that the correlation between the dependent variable, which is represented by the degree of risk management integration in the operating activities of the Romanian SMEs analyzed and the predictors represented by the perception of the importance of the benefits of the risk management implementation. (6 variables - increasing the profitability and revenues, increasing the efficiency of the decision-making process and the efficient use of resources, developing a culture of risk management in the company, aligning the risk management with the company objectives, identifying and controlling a greater number of risks at entity level, increasing satisfaction and stakeholder involvement in the risk management process) has a high value (0.479) and in the same direction.

Also, the results of the regression analysis for the selected SMEs, described in Table 3, show that R-Square, which is often referred to as the coefficient of determination of the variables, has a value of 0.230. R-Square indicates that the model is able to explain about 23% of the variability of the integration of risk management in the operating activities of the questioned SMEs. This means that approximately 77% of the variation of risk management integration within the sampled SMEs are accounted for by other factors not included in the model. This result is corroborated by the Adjusted R-Square of about 0.200, which is in essence the proportion of total variance that is explained by the model.

Table 3: Model summary

Model	R	R Square	Adjusted R Square	Std. Error of the Estimate	Change Statistics				
					R Square Change	F Change	df1	df2	Sig. F Change
1	0.479	0.230	0.200	0.737	0.230	7.795	6	157	0.000

Source: Own calculations

Similarly, findings from F-statistic test, as reflected in Table 3, it has a p-value less than 0.01; this clearly suggests that simultaneously the explanatory variables are significantly associated with the dependent variable, integrating risk management into the operating activities of organizations.

In Table 4, the results of the linear regression analysis show that, the perceived importance of the benefits of risk management implementation influences the extent to which the risk management practices are integrated in the operating activities within the analyzed SMEs, at the level of statistical significance of 0.01 are represented by increasing profitability and revenues (t-statistics = -3.178; p-value = 0.002), aligning risk management with company objectives (t-statistics = 3.512; p-value = 0.001) identifying and controlling a greater number of risks at entity level (t-statistics = -2.713; p-value = 0.007) and increasing satisfaction and stakeholder involvement in the risk management process (t-statistics = 2.916; p-value = 0.004).

The association between aligning risk management with company objectives (beta coefficient = 0.476), increasing satisfaction and involving stakeholders in risk management (beta coefficient = 0.318) and integrating risk management into operating activities within SMEs is significant and positive, indicating that the greater the importance attached to these benefits of implementing risk management, the greater the extent to which risk management is incorporated. In contrast, the association between increasing profitability and revenue (beta coefficient = -0.307), identifying and controlling of a greater number of risks at entity level (beta coefficient = -0.347) and integrating of risk management within SMEs is significant and negative, indicating that the greater the importance attached to these benefits of the implementation of risk management, the less the extent to which the risk management is integrated into the operating activities of the questioned Romanian SMEs.

Table 4: Coefficients

Model	Unstandardized Coefficients		Standardized Coefficients	t	Sig.	Collinearity Statistics	
	B	Std. Error	Beta			Tolerance	VIF
1 (Constant)	1.753	0.262		6.692	0.000		
Increasing profitability and revenue	-0.396	0.125	-0.307	-3.178	0.002	0.526	1.899
Increasing the efficiency of the decision-making process and the efficient use of resources	0.301	0.123	0.259	2.450	0.015	0.438	2.285
Developing a culture of RM in the company	-0.148	0.135	-0.135	-1.098	0.274	0.324	3.090
Aligning RM to the company objectives	0.504	0.144	0.476	3.512	0.001	0.267	3.749
Identifying and controlling a large number of risks at entity level	-0.397	0.146	-0.347	-2.713	0.007	0.299	3.341
Increasing satisfaction and stakeholder involvement in the RM process	0.345	0.118	0.318	2.916	0.004	0.412	2.428

Conclusions

This study analyzed the connection between the perceived importance of the benefits of risk management implementation and the extent to which risk management practices are integrated in operating activities within SMEs in Romania.

The results indicate that appreciation of the importance of increasing profitability and revenue as a possible benefit obtained from the implementation of risk management has a significant contribution on the degree of integration of risk management in Romanian SMEs. The study also shows, there is a significant negative relationship between identifying and controlling a greater number of risks at the entity level and the extent to which risk management is integrated. Contrary to expectations, the nature of the relationship between the two variables is negative, that is, an increase in the risk management integration measure will lead to a decrease in the importance of increasing profitability and revenue. This result may be possible in the context of the difficulty of measuring the risk management performances in relation to the resources allocated and the complexity of the specific risk management process.

The research also indicates a positive association between the degree of use of risk management practices and the importance of aligning risk management with the firm's objectives and increasing stakeholder satisfaction and involvement. Therefore, a robust risk management approach provides relevant information to decision-makers, contributing to increasing the possibility of selecting an optimal strategy, and improving communication and stakeholder involvement, by regularly providing reports and taking into account their requirements in the risk management process.

An important limitation of this paper is the size of the sample given the numerous SMEs operating in Romania. To address this limitation, the following research aims to increase the sample size.

Directions of Changes in Polish ICT Enterprises After the COVID 19 Epidemic - Results of Own Research[1]

Katarzyna JASIŃSKA

Wrocław University of Economics, Wrocław, Poland
katarzyna.jasinska@ue.wroc.pl

Abstract

In the knowledge-based economy circumstances, the Information and Communication Technology (ICT) sector is the driving force behind the development of virtually the entire economy. Technological solutions stimulate innovation, contribute to the creation of new business models, and have created a new phenomenon in the information society. This picture, which was still valid at the beginning of 2020, presented to the ICT sector participants perspectives of uninterrupted growth, dependent only on the company's ability to follow changing technological trends. The COVID-19 epidemic has shaken the global economy, which has faced technology providers with a natural question about the timeliness of development directions defined so far. The purpose of this article is to attempt to approximate the conditions to which ICT enterprises are currently subject, and to indicate how enterprises respond to changes. The first part of the article defines the concept of the ICT sector, then discusses its evolution and importance for the development of the economy. The general characteristics of changes taking place in the ICT sector are discussed further, and on this basis research hypotheses were formulated. These were subsequently verified in an in-depth interview among 52 managers from 20 companies in the Polish ICT sector. The last part of the article presents the results of research as well as formulated conclusions.

Keywords: ICT market, IT market, strategic directions, covid crisis

Introduction

The ICT sector is described as a driving force for the development of the global economy [Shamim 2007; Garcia-Muniz, Vicante 2014; Sassi, Goaied 2013; WEF 2009; WEF 2015]. Investments in development and innovation contribute to the increase in the effectiveness of enterprises and build their intellectual capital. Enterprises in stock market reports bid on development ideas related to the implementation of new technologies, building a vision of future profits for investors. There is even a new term for an enterprise that builds its competitiveness based on new technologies - the so-called digital leader. This picture presented the participants of the ICT sector perspectives of undisturbed growth, dependent only on the company's ability to follow changing technological trends. The COVID-19 epidemic has shaken the global economy, which has faced technology providers with a natural question about the timeliness of development directions defined so far. The purpose of this article is to attempt to approximate the conditions in which ICT enterprises currently find themselves, and to indicate how enterprises respond to changes.

It should be emphasized that there is currently no detailed data available on the impact of the epidemic crisis on the ICT sector. In the global context, the first forecasts are created in selected market segments, and in the local context preliminary research is being conducted [KIGEiT, 2020; IDC 2020]. They have an undoubted cognitive dimension, but in a practical context they do not have a broader meaning. The

[1] The project is financed by the Ministry of Science and Higher Education in Poland under the programme "Regional Initiative of Excellence" 2019 - 2022 project number 015/RID/2018/19 total funding amount 10 721 040,00 PLN

goal chosen in the article fits in with this trend, while maintaining concentration primarily on managerial rather than macroeconomic aspects, which is typical of most available studies.

The first part of the article defines the concept of the ICT sector, then discusses its evolution and importance for the development of the economy. The general characteristics of changes taking place in the ICT sector are discussed further, and on this basis research hypotheses were formulated, which were verified in an in-depth interview among 52 managers from 20 companies in the Polish ICT sector. The last part of the article presents the results of research and formulated conclusions.

ICT sector and its Economic Importance

ICT sector has already been the subject of many different scientific publications and numerous reports [Shamim 2007; Lombard 2009; Garcia-Muniz, Vicante, 2014; Sassi, Goaied 2013; PARP 2017; IDC 2020]. This has contributed to the creation of very different ways of defining this sector [OECD 2011; Central Statistics Office 2010; PARP 2017; Zuppo, 2012; UNSC 2002]. An overview of the available definitions is not the purpose of this article, therefore, the basic sector definition created by the OECD. According to which, the ICT sector is defined as a set of enterprises conducting production and service activities, which consists in intercepting, sending and displaying data and information by electronic means [OECD 2002]. ICT sector is a combination of the IT sector (Information Technologies) and the telecommunications sector. According to the Gartner report, the size of the global ICT market was $3.7 trillion in 2019. Over the past 10 years, the ICT sector has seen annual value increases of around 3%. Among the most important market segments are: telecommunications services, equipment supplies, software development, data centers, and professional service providers [Gartner 2019]. In Poland, the situation of the ICT sector was described as stable. Since the beginning of 2014, GDP has been growing at a rate of at least 3.1% per year, and the share of the ICT sector in GDP is about 8% [PARP 2017].
ICT solutions are also a significant element of the Fourth Digital Revolution, which was distinguished by the World Economic Forum and Klaus Schwab. According to her concept, the boundaries between the physical world and ICT are becoming blurred and the saturation of IT solutions is constantly increasing [Schwab 2017].

According to the PARP report, the development of information technologies is the foundation of growth not only of the ICT sector, but also of the entire economy and society. The competitiveness of enterprises is largely based on the ability to use ICT sector solutions in the area of providing their own services or products [PARP 2017]. The role played by the ICT sector has been recognized not only in Europe; The World Economic Forum in cooperation with the Business School - INSEAD (INSEAD - The Business School for the World) measures the NRI (Networked Readiness Index), which can be defined as an indicator of readiness to use information technology communication in the economy of states [Stecyk 2009].

In the case of the ICT sector, there is a phenomenon of stimulating the growth of other economic fields, practically regardless of the economic profile of a given country, because the use of information and communication technologies leads to an increase in the efficiency of enterprises. However, this conclusion was not obvious, and was based on observations of the economies of strongly developing countries. In 1978, it was recognized that the widespread use of ICT was a source of success for the Japanese economy, and similar solutions began to be used in France. These activities became the foundation for building European strategies aimed at the development of the ICT sector, which, however, were not started until the 1990s [Grodzka 2009 p. in: Biuro Analiz Sejmowych 2009]. The widening technological divide between Europe, and Japan and the US led to the publication in 1994 of a set of recommendations for Europe and a global information society. Recommendations to the European Council (Europe and the Global Information Society) became the basis for shaping long-term strategies for the development of the ICT sector in Europe [http://ec.europa.eu/archives/ISPO/infosoc/ ..., date of download: 16/12/11].

The importance of the ICT sector for the development of the economy has increased over time, as the ability of enterprises to use products of this sector has increased. At the beginning of 2020, the ICT sector had prospects of almost unlimited growth.

General changes taking place in ICT enterprises in connection with the COIVID - 19 epidemic

The difficult macroeconomic situation related to the COVID-19 epidemic, which became a global pandemic in March 2020, reduces the general willingness of enterprises to spend, instead inclining them to strive to accumulate cash and cut costs. According to The IDC, the situation is not dramatic, however, the increase in spending on ICT in Europe in 2020 will amount to only 1.4%, which, compared to the December forecast that assumed 2.8%, is a 50% decrease. The pessimistic scenario assumes an increase of only 0.2% [IDC 2020].

Quarantine and temporary stoppages of many enterprises caused a degree of stagnation of demand for goods and services. This negatively affects, above all, the sectors whose products are consumer in nature. In the case of the ICT sector, the situation is more complex because, although some development investments of enterprises have been frozen, other purchasing decisions have become even more meaningful during the crisis. This is due to the fact that the use of ICT in enterprises can also be a source of savings and lead to a reduction in human participation in the provision of services. This phenomenon places before the ICT sector not only threats but also opportunities, inaccessible to other sectors, which construct their products and services with a small share of intellectual capital. An important element of transformation will be the marketing strategy of enterprises. It can be assumed that there will be changes in the share of revenues in individual market segments.

Business models of services rendered may also be subject to change in adapting to changing demand conditions.

One of the most important areas of ICT enterprises' activity, thanks to which it is possible to provide services to clients, is project implementation.

One of the results of the aforementioned research conducted by the author in 2011 was to verify the impact of external factors on the success of projects in the ICT sector. Under stable environmental conditions in which the study was conducted, as many as 97% of respondents indicated that "the degree of stability of the environment in the social, economic and environmental dimensions" has a significant impact on the management of project implementation processes [Jasinska, Szapiro 2014]. It can therefore be assumed that the area of project implementation will undergo significant transformation in connection with the epidemic. Changes may include not only the way projects are implemented but also the management of entire portfolios and changes in the perception of value built by projects. The implementation of projects is based on teamwork, in which the competences of members play a special role.

Until now, the ICT market was definitely an employee's market, not an employer's one. The constant shortage of specialists led to above average wages and salaries recorded in the sector. So the natural question arises as to how the crisis will affect staff in the sector. On the one hand, one can observe an increase in the number of projects, and a growing demand for specialists. On the other hand, however, some projects may freeze, which will result in less demand for highly qualified staff.

Leading players in the ICT sector in times of stable development took care of building the image as a professional entity that customers could rely on while implementing key projects for their business. In a crisis situation, building the right image is important for ICT companies. It should be remembered that ICT projects are often high-budget initiatives, forcing large expenses on clients. In the face of the progressing crisis, there is a natural expectation of the involvement of a trusted business partner in helping to solve current problems. In the image sphere, this is related to, for example, the implementation of social responsibility activities by ICT enterprises. Therefore, the question arises as to what type of activities are undertaken by ICT enterprises in the area of shaping their image in a crisis.

In the area of internal organization, the crisis associated with COVID-19 has had an influence in all industries, forcing a change in working methods, e.g. the introduction of telework and transferring

some of the processes previously carried out in a traditional form to the digital environment. An important element for verification is, therefore, how to reorganize work in enterprises and prepare them to adapt to changes.

In summary, in Table 1, areas have been identified that are undergoing changes due to the impact of the COVID-19 epidemics. The areas have been assigned the forecast change trends. In this way, hypotheses were constructed and verified in empirical studies.

Table 1: Areas of the ICT enterprise and its surroundings susceptible to changes related to the COVID-19 crisis

	Area of change	**Hypothesis: expected change trend**
H1	Demand and willingness to spend	Stagnation while maintaining the growth of selected segments
H2	Market opportunities and development	The emergence of new market opportunities. Interruption of previously stable trends
H3	Employment and demand for specialists	Turbulence in the employment market
H4	Implementation of projects	Changes in the scope of projects and portfolios
H5	Company image	Take action to combat the epidemic
H6	Management and work methods	Digitization of processes and teleworking
H7	Willingness to implement changes	High readiness

Hypothesis presented in Table 1 ware built on the basis of market observations described in this part of article, because the article was constructed in beginning of epidemic period.

The Empirical Studies

Trends indicated in the Table 1, expressed in the form of a hypothesis, were verified in empirical studies. This study was conducted from April 10-17, 2020 and involved in-depth interviews with 52 managers representing 20 companies from the Polish ICT sector. Companies were selected form the Polish Agency for Enterprise Development's list, that was presented in report "IT/ICT sector in Poland" [PARP, 2019]. Whole list included 200 companies. Only 20 of them respond. The study consisted of two parts. In the first stage, general questions were asked about the characterization of changes occurring in a given area of the enterprise and the market, and verified probable trends of changes, which are described in Table 1. In the second stage, deeper questions were asked to induce the respondent to think about the opportunities and threats, the reasons for the changes, and long-term impact of the diagnosed events on the enterprise.

The survey was completed by respondents whose characteristics are presented in Table 2.

Table 2: Share of respondents in the knowledge broken down by type of enterprise

Company	**Number of companies**	**percentage share of companies [%]**	**Number of people surveyed**	**Participation of respondents [%]**
Telecommunications operator	2	10%	12	23%
TV and internet provider	1	5%	4	8%
Software - house	2	10%	4	8%

Professional service provider (employee outsourcing)	1	5%	8	15%
Service company	2	10%	4	8%
A technological start-up	3	15%	5	10%
Cybersecurity and software tester	2	10%	6	12%
Data center	2	10%	2	4%
Hardware and software supplier	1	5%	1	2%
Equipment distributor	1	5%	1	2%
IT systems integrator	2	10%	4	8%
Provider of teletechnical systems	1	5%	1	2%

The first stage of the research

The first stage of the research revealed that the situation for telecommunications operators seems to be relatively stable, especially taking into account the mass market. However, a drop in satisfaction can be observed among customers due to the increase in complaints regarding the decrease in the quality of services provided. This problem is associated with a significant load on the data transmission network caused by the widespread use of telework. Real-time audio and video transmission requires stable link quality parameters. Access services provided in the mass segment for the most part do not have guaranteed quality, which significantly affects the quality of transmission in the event of an increase in load. Due to overloading, there are also numerous failures, the removal of which is difficult due to imposed restrictions. In business customer segments, there are decreases in revenues related to the freezing of projects and the desire to accumulate cash for corporate clients. Many of the companies that are clients of the operators are currently struggling with the effects of the crisis because they themselves have seen a decline in revenues. Service enterprises that operate in traditional sectors based on human work at the service point are the worst in this respect.

Respondents indicate that telecommunications operators have the opportunity to develop domain systems that can be provided in the SaaS model, as various telemedicine systems are indicated here as an example. Operator representatives see this trend as a long-term development that will continue even after the crisis. According to the survey, those employed by operators, systems based on M2M and IoT also create development perspectives, because they allow the elimination of human participation in the implementation of services, e.g. they allow reading a specific parameter remotely. Considering teleconferencing systems, respondents are seeing a slight increase in interest. Among the clients, publicly available tools offered by Microsoft (teams), google (Zoom) or Cisco (Webex) are used rather than ordered dedicated project-implemented systems. In the field of project management, respondents estimated that around 70% of customer development initiatives were stopped. However, projects focused on rapid digitization of processes have gained in importance.

The employment situation with operators is assessed as relatively stable. However, staff reduction strategies are implemented which originate for reasons other than the COVID-19 crisis. In the area of sales, recruitment has been suspended, and temporary part-time employment is being implemented. Remote work methods were implemented immediately and readiness to change the mode of work according to respondents was high.

In companies that are television and Internet providers, respondents observed similar trends of change. Unlike operators, a temporary increase in the purchase of internet access services and television packages on the mass market was recorded here. In the business market, however, a significant decrease

in revenues was recorded due to the temporary closure of hotels and the reduction in the purchase of television services. Both television providers and operators have developed remote customer service through electronic channels. According to the respondents, the activities were primarily to increase the infoline throughput and minimize the time of customer service in the electronic channel. It should be emphasized that television operators and suppliers are large enterprises, therefore they undertook large-scale image-building activities. For example, campaigns were carried out to spread knowledge about methods of protection against COVID-19, protective equipment was purchased for hospitals, and subsidies of foundations and purposeful fundraisers for the medical sector were organized. Taking into account local activities, computer equipment was made available to children from rural areas, and free internet access was provided to the poorest.

Subsidiaries of operators are to a large extent service and teletechnical system providers whose mobility has been limited. Respondents emphasized that currently both individual and corporate clients are not willing to contact representatives of enterprises. Thus, service companies and installers are developing ways in which the end users can do some of the work themselves. Similarly, when it comes to equipment, tests are carried out to increase the possibilities of existing models of equipment and reduce the need to replace them. Service companies have modified their strategy and instead of installing, they distribute equipment and other goods (even from outside the ICT sector). On the other hand, in the business segment, due to the large number of telecommunications infrastructure failures, the service department is currently carrying out fewer but more complex orders. Therefore, companies need to acquire more qualified personnel and reduce the number of less qualified service personnel.

According to the respondents, working methods in service companies have hardly changed, while a larger share of work was observed on the basis of remote user support.

According to respondents, an increase in orders was recorded in software houses. A particularly large number of orders appeared in companies associated with one main customer for many years or in those enterprises that form part of the capital group. Representatives of software-houses assessed the situation and concluded that in the event of an epidemic they received a large number of orders aimed at digitizing and developing electronic channels, as well as upgrading programming to adapt to remote work. Due to the decline in the value of PLN, interest in orders from abroad was noted, especially in software testing companies. In one of the surveyed enterprises, the number of traders selling abroad tripled. Both software developers and testers are used to working remotely, therefore the crisis situation did not significantly affect the way the work was organized. According to the respondents, the number of projects related to cybersecurity was limited. This is quite a surprising conclusion because due to the transfer of a large part of the work of companies to the network, the interest in security should grow. Software development is also associated with creating solutions for monitoring the activity of people in quarantine. The applications are used for social monitoring to determine the potential contact of an infected person with other people. Modeling the course of the epidemic, however, is performed using big data and AI analysis, which is also of interest to software developers. However, start-ups that are largely associated with the development of a specific application are in a difficult situation. Currently, the interest of enterprises in new ideas has significantly decreased, due to the strong commitment to the implementation of routine activities related to counteracting the effects of the crisis.

According to respondents, equipment manufacturers and distributors are currently in a quite difficult situation, because orders for equipment were largely related to the propensity of customers to implement large projects. Currently, development efforts have been limited, which resulted in the freezing of orders. Distribution of equipment is not a high-margin service, therefore distributors are counting on the possibility of employment reduction. Orders for subscriber and computer equipment are quite stable, which remained relatively intact due mainly to public sector orders. Equipment distributors and manufacturers have established cooperation with IT systems integrators, striving to stabilize the revenue line by creating cloud-based products. In this way, projects and built environments requiring the purchasing of a large amount of equipment are carried out, while reducing the need for its distributed installation. Data centers benefit from this strategy, which provide disk space for the needs of the systems. Hardware and software suppliers carry out extensive image-oriented activities aimed at providing free tools for the hospital and education sector. This trend has also hit professional

service providers, especially the outsourcing of qualified personnel. Due to the suspension of production and the freezing of projects, there was limited demand for outsourcing employees. The contracts concluded are pronounced and employees employed in this form experience considerable uncertainty.

The results of the first stage of the study are collected in Table 3.

Table 3: Diagnosed changes in ICT enterprises and their environment related to the COVID-19 crisis

Area of change	Hypothesis: expected change trend	Description
Demand and willingness to spend	Stagnation while maintaining the growth of selected segments	The hypothesis was confirmed with a pessimistic forecast regarding future changes in revenues. 40% of respondents reported an increase in revenue, which they treat as temporary. Ultimately, they expect long-term declines in the business segment reaching even 20% - 30%, which is associated with the pursuit of capital accumulation and the implementation of crisis plans in clients' enterprises. Only 2% of respondents expect an increase in revenues (test companies). Companies see significant opportunities for development in foreign markets due to the decrease in the value of the Polish currency (5%).
Market opportunities and development	The emergence of new market opportunities. Interruption of previously stable trends	The hypothesis has been confirmed. Among the main trends in the Industry 4.0 area that have been discontinued are smart-city solutions (currently city investments are directed at co-financing hospitals). The growing importance of ICT enterprises trends will be in: IoT (71%), M2M (24%), specialist services (13%), AI (10%), telemedicine (8%), data protection (5%), non-contact systems (4%), use of robots (4%) biometric auditing (2%).
Employment and demand for specialists	Turbulence in the employment market	The hypothesis has been confirmed. There was a decrease in demand for outsourcing employees in the auto-motive sector (15%). Entire teams of specialists have appeared on the market to be taken over by ICT companies in connection with the freezing of projects (12%) and phenomena such as reduction of salary or full-time employment (6%). Respondents indicate an increase in the amount of current work and fatigue by telework (72%)
Implementation of projects	Changes in the scope of projects and portfolios	The hypothesis has been confirmed by way of observation: freezing of projects in the area of cybersecurity (41%), suspension of projects requiring investment in equipment (31%), reducing the scope of the project (12%), recomposition of project portfolios (10%), increasing the share of foreign projects (3%)
Company image	Take action to combat the epidemic	The hypothesis was confirmed, however, the activities largely concerned the IT area. The products and services were made available for free or at preferential prices (21%), a fundraising campaign was organized to combat COVID-19 (10%), programs aimed at supporting e-education and the medical sector were implemented (8%).
Management and work methods	Digitization of processes and teleworking	The hypothesis was confirmed, although the way of working during the epidemic did not differ significantly from the standards already adopted in ICT enterprises. In particular, the teleworking system was implemented (92%) and the

		digitization of internal processes was deepened (41%). It was indicated that teleworkers do not need special methods of supervision and control (100%). In the respondents' opinion, an important element of changes was the protection of personal data (11%).
Willingness to implement changes	High readiness	The hypothesis was confirmed. The ability to implement changes was rated very high (98%). The high degree of enterprise digitization and possession of IT equipment (100%) facilitated adaptation to new conditions.

The second stage of studies

The results collected in Table 3 were deepened in the second stage of the study. This stage revealed that in large part respondents perceive the current situation in a pessimistic way, practically freezing most development initiatives. At the same time, 72% of respondents confirmed that they must take measures aimed at further development and construction of new products and services that respond to the changing market demand. However, over half of the respondents could not name new solutions yet. Most of them used general terms related to the development of a given market area: e.g. development of SaaS solutions (47%), expansion of call-center services (15%), construction of virtualized environments (15%) and remote monitoring of own employees and clients (12%) or construction of cost control systems (2%). Respondents were asked to characterize the strategy adopted for the crisis. Unfortunately, for the most part, they were unable to provide detailed answers, rather describing operational activities that were a reaction to emerging problems. The answers included: cost cutting (28%), reduction of employees' working time (22%), freezing of development projects (21%), resignation from the organization of conferences (15%), resignation from organization of training, and implementation of on-line activities line (12%). Among the most important opportunities created in the face of the COVID-19 crisis, representatives of ICT enterprises indicated: international expansion (19%), resignation from part of the office space due to the development of telework, and the possibility of reducing current costs (12%), increasing awareness of the need to digitize processes for external clients, which may lead to market development (11%), building an offer related to consulting in addition to providing simple services (2%), and development of new services and specialized products (2%). Among the biggest threats, the respondents mentioned: loss of liquidity (68%), loss of sales opportunities for which they had worked for a long time (54%), loss of work by specialists (21%), sale of enterprises (14%), departure of key personnel (8%), loss of investors (8%).

Summing up the presented research results, it should be emphasized that they relate to a period of high uncertainty among the studies. In many companies analyzed, detailed results related to the loss of orders were not yet known. Opinions were based primarily on a quantitative analysis of contracts that had been lost, projects that had been suspended, and estimates of market segment transformations that had unexpectedly begun to increase. The first quarter in which the full picture of the effects of the crisis will be known is Q2 2020. At that point, it seems as though it will be valuable to repeat the tests on the same research sample. The conducted studies do not meet the criteria of representativeness, although they may illustrate certain trends in the ICT sector.

Summary

Due to the changing market conditions associated with the COVID-19 epidemic, enterprises, regardless of the sector in which they operate, must take remedial action. In the case of the ICT sector, which additionally plays the role of a stimulus for the development of other industries, the negative impact of the crisis may have secondary effects on the entire economy. In this context, it is important to attempt to analyze the scope of changes in the sector and to identify ways of dealing with alarming phenomena undertaken by ICT companies.

The purpose of the article was to attempt to approximate the conditions currently affecting ICT enterprises, and to indicate how enterprises respond to changes. The goal was achieved by analyzing

the results of empirical research conducted on a sample of 52 respondents from 20 Polish ICT enterprises. The research method used was an in-depth series of interviews, which allowed us to confirm seven hypotheses.

The main conclusions are not optimistic, because ICT companies are focused on investment reduction and expect similar actions taken by clients. Only some business segments do not show disturbances. It should be emphasized, however, that enterprises are open to seeking new business models based on SaaS. In addition, expansion appears on the international markets as a chance, which seems justified given the low value of the currency. Generally, enterprises are focused on undertaking anti-crisis measures.

A significant limitation of the research was the deep focus of managers from the ICT sector on dealing with the current crisis. In addition, the enterprises did not have detailed data, therefore the presented conclusions are a qualitative assessment of the situation by the management.

The analysis of changes taking place in the ICT sector is an interesting research area that can be continued as economic conditions continue to develop.

Key Performance Indicators – Proper Selection and Design from The Human Resources Perspective

Wojciech Dawid KRZESZOWSKI

Wroclaw University of Economics and Business, Wroclaw, Poland,
wojciech.krzeszowski@ue.wroc.pl

Abstract

Motivation. The connection between human resource management and company's performance is a subject of discussion in the literature. Some practitioners discussed areas in which performance measurement might be useful. However, no widely accepted guideline has been presented to manage business performance so far. There are publications about guidelines for KPI development but this problem is treated in the literature selectively. **Objective.** The objective of this paper is to attempt to integrate knowledge about KPI development guidelines and to propose guidelines for the development of the appropriate KPIs in the human aspect. **Design/methodology.** The objective has been achieved through the literature studies, its critical analysis and the author's practical experience. **Findings.** There are no universally accepted guidelines in the literature regarding the determination of KPIs for employees. The guidelines literature list should be supplemented by the following guidelines: a) the selection of assessment indicators should take into account these guidelines and include within its scope parameters affecting the increase of this value, b) the area that includes indicators should be narrower when determining KPIs for lower positions in the organizational hierarchy and include, for example, the volume of production and waste for direct production employees, c) the bonus percentage should be felt by the employee, d) the bonus should be a reward rather than a permanent salary supplement e) for all employees, and at least for the managerial staff, one of the KPIs should be the company's overall result such as net result, EBITDA, EVA, etc., which synthetically reflects activities at various levels, f) the payment of bonuses to everyone should be dependent on the implementation of a certain general synthetic indicator, such as: the overall result of the enterprise. **Limitations**. There is a study and critical analysis of the selected publication, limited to the SCOPUS database. **Originality/value.** Supplemented literature by guidelines the determination of KPIs for employees.

Keywords: Key Performance Indicators, Human Resources, Human Resources Management

Introduction

Performance control and monitoring is one of the most important management functions. Due to an evaluation of the enterprise's results managers know the current company's situation and they have a basis for making better decisions about a development path and ways to improve the enterprise's performance. Thereby, there is a close relationship between performance control and current goals of enterprises. However, it is not possible to measure all business activities and the measure of everything would be inefficient. Therefore, performance measurements should be prioritized and focused only on the key performance indicators of the enterprise (Wu 2012, p. 305). Employees are one of the most important resources of enterprises because they determine the company's development and activity results. The connection between human resource management and company's performance is a subject of discussion in the literature (e.g. Guest 1997, Wood 1999, Becker et al. 2001, Nankervis et al. 2005). The finding of this research shows that effective people management contributes to enhancing company's productivity, profitability and overall organizational efficiency and effectiveness (Cascio 2003, Zheng et al. 2007 p. 306). To achieve the company's goals, human management needs not only an appropriate organizational structure and shaping responsibility for tasks but also developing indicators that will be the basis of employee accountability. In practice, it turns out that the design of systems for assessing employee performance can be associated with numerous problems, including the selection of the measures themselves, the differentiation of responsibilities of individual persons and at the same time the difficulty in defining common KPIs for a given group, the possibility of their

unequivocal measurement, planning and accounting. There is also a “knowing-doing” gap in the field of explanation the cause-effect relationships on which the value of each KPIs is based (Taticchi 2010, p. 13). “The problem of how organizations should assess their performance has been challenging to management commentators and practitioners for many years” (Sangwa and Sangwan 2017, p.42). Some practitioners discussed the areas in which performance measurement might be useful but no widely accepted guideline has been presented to manage the business performance so far (Neely et al. 2000). The problem of performance measurement and management is also of interest to researchers. Although research on this subject seems to be mature in terms of citations and number of publications, the subject is still vivid (Taticchi 2010). There are publications about guidelines for KPI development but this problem is treated in the literature selectively. Bridging this research gap seems to be especially important in the human resources management area because employee’s activities enable an organization to achieve its goals.

In this context the aim of this paper is to attempt to integrate knowledge about KPI development guidelines and to propose guidelines for the development of appropriate KPIs in the human aspect. Achieving this objective is based on the systematic literature study (limited to the SCOPUS database) and the author's practical experience. First, the research methodology is presented. Secondly, there are considerations about the background of KPIs in the context of performance measurement, management and human resources. Third, there are considerations about the proper selection and design of KPIs. Finally, the discussion and conclusions are presented.

Research Methodology

In the first part of this study, a critical literature review of 43 research articles has been conducted to analyze the available literature on key performance indicators in the aspects of employees. The SCOPUS database was used as a search engine. The following keywords were defined: “key performance indicators” and “human resources management” or “human resources” or “human management” (in Article title, Abstract, Keywords). There were 161 documents results. They were limited according to the following criteria: a) the subject areas are “business, management and accounting” (39 documents), “decision sciences” (16 documents), “economics, econometrics and finance” (10 documents) b) the literature search was constrained to works available in English language only, c) the articles published in peer-reviewed journals as well as gray literature were included. There were 46 documents results. Citations were excluded from the literature search. Initially, papers were selected by assuring the relevance of the article to the subject of research through manual analysis and reading the title and abstract of an article and then through an analysis of the complete article. Additional articles were searched by forward/backward snowball approach to find more documents related to subject KPIs in the human aspects which do not contain the predefined keywords in the title, abstract or keywords of article. There were 43 documents results. The review methodology is presented in table 1.

Tab. 1: Review methodology

Filter type	Characterization	Results
Keywords (in Article title, Abstract, Keywords)	“key performance indicators” and “human resources management” or “human resources” or “human management”	
Keywords search	The SCOPUS database was used as a search engine Articles containing above mentioned keywords in the title, abstract, keywords of the article	161
Inclusion criteria	Topic: articles related to key performance indicators in the human aspects	
	Subject areas:	

	"business, management and accounting"	39
	"decision sciences"	16
	"economics, econometrics and finance"	10
	Language: English	46
Exclusion criteria	Citations are excluded	
Consolidation I	Elimination by manual filtering and reading the title and abstract of the articles to check the relevance of subject KPIs in the human aspects	30
Consolidation II	Further consolidation by reading complete articles	18
Snowball approach	Additional articles added by forward/backward snowball approach	25
Final sample size		43

In the second part of this study an exemplification of the part of the KPI system of one company has been conducted to present the practice of KPIs development in the human aspect. This presentation is the result of the author's work as a consultant.

Background of KPIs

Performance management is based on the goal-setting theory of Locke (1991) and is administered through performance assessment and feedback (Kairuz et al. 2015, p. 884). Performance measurement supports performance management (Keegan et al. 1989). These two activities cannot be separated. "Performance management precedes and follows performance measurement, in a virtuous spiral and performance management creates the context for measurement" (Lebas 1995, p. 34). It is generally accepted that performance is about past achievement but in the context of management it is also about the future, about the enterprise's capabilities to achieve future goals. Thus, two types of performance measurement can be identified: a) related to results, b) related to determinants of future results (Fitzgerald et al. 1991). There are five main reasons why managers want to measure performance. They are constantly looking for answers to the following questions: a) where have we been, b) where are we now, c) where do we want to go, d) how are we going to get there, e) how will we know we got there (Lebas 1995, p. 24, Pariba and Tretten 2017, p. 35). The answers for these questions are useful not only for managers but for many different stakeholders of the company, including its employees.

Many models or frameworks have been developed in the literature (Sangwa and Sangwan 2017, p.46, Korenkova et al. 2019, p.52-53). Bititci et al. (1997) considered a performance measurement system as a reference model and Neely et al. (2000) reported that a system approach theory and an organizational structure approach are two basic approaches for designing the performance measurement system. The first approach is used to measure the horizontal flows of information and materials within the organization. The organizational structure approach is used to measure the vertical flows. From a practical point of view, it can be assumed that the performance management system covers all aspects of performance that are relevant to the existence of an organization as a whole (Flapper et al. 1996).

Various models have been developed to measure the performance of companies such as the BSC, the BEM, the Capability Maturity Model (CMM), the Six Sigma and the KPI (Konsta and Plomaritou 2012, p.143). There are many examples that the use of these models resulted in the improved performance of different sectors of organizations but the KPI model is more popular with financial management practitioners (Meng and Minoque 2011).
The concept of performance must be operationalized before it can be measured (Lebas 1995, p. 24). Key performance indicators are an expression of this operationalization. Generally, KPI is a measure of performance that focus on critical aspects of inputs and outcomes.

KPI embodies a strategic objective and measures performance against goals that are multidimensional (Eckerson 2009, p.6). The strategic business goals need to be broken down into targets at an operational level and the operational outcomes link back with KPIs at the strategic levels (Aditya and Chattopadhyay 2007). KPIs are modern tools that help managers to keep the enterprise's performance at a high level (Kaganski et al. 2017, p. 283) but it doesn't mean that PKIs are constant. They are dependent on many contributing factors. For this reason, they can be changed (Bortoluzzi et al. 2018, p. 282).

KPIs have been categorized as a) leading or lagging, b), strategic or operational c) social or technical, d) quantitative or qualitative (Sangwa and Sangwan 2017, p.42-43), e) tangible or intangible (Kaplan and Norton 1992). Leading indicators are also called performance or value drivers and they measure activities in their current state or a future state. The leading indicators have a significant impact on outcome KPIs. The outcome KPIs that are known also as lagging KPIs measure the output of past activity. This type of KPIs are often financial in nature (e.g. revenues, margins, return on equity), but sometimes they are non-financial in nature (e.g. customer satisfaction, employee retention) (Eckerson 2009, p. 11). It should be emphasized that from the practical point of view a distinction between these two types of KPIs could be difficult. There isn't often a lot of difference between leading and lagging indicators in practice because one factor's outcome measure is another factor's value driver in a reall company's life (Eckerson 2009, p. 11). How performance indicators in one area affect performance indicators in other areas is displayed also in the literature (Aranda and Arellano 2010, Banker 2004).

In turn the identification of a strategic and operational category of KPIs is important and useful in practice. Eckerson distinguishes also a tactical type of KPIs. These three categories of KPIs allow to understand how the matrix of KPIs is integrated across different departments and levels within a company. The following conclusions can be drawn from the consideration about levels of KPIs: a strategic matrix comprises outcome KPIs, an operational matrix shows driver KPIs and a tactical matrix has a mix of outcome and driver KPIs.

Some KPIs are based on quantitative data and others are based on qualitative data. The first are the basis of financial KPIs ant the second are the basis of both non-financial and financial KPIs (Eckerson 2009, p. 12-13). The PM was based mostly on financial measures in the past. The balanced scorecard, with its four perspectives, focuses on financial aspects, customers, internal processes, and innovation and learning has changed the perception of KPIs (Kaplan and Norton 1992). Kaplan and Norton have pointed out that both tangible (financial) and intangible aspects of the business process are important. Consequently, both tangible and intangible KPIs are currently used.

KPIs could refer to social or technical dimensions of an enterprise's activities at last. KPIs of human resources are especially important because employees determine all aspects of the company's performance.

An enterprise's productivity is closely correlated not only with its strategy but also with its people (Tabassi and Abu Bakar 2009, p.471) because employees' activities and engagement determine the company's efficiency and effectiveness (Cascio 2003). There are many theoretical models that discuss the relationship between HRM and company's performance (e.g. Guest 1997, Wood 1999, Paauwe 2004, Nankervis et al. 2005). KPIs help employees better understand how they contribute to the overall achievement of the organization (Wu 2012, p. 307). KPIs translate the company's strategy and goals into concrete actions that employees can take on a daily basis. Employees should know what's being measured and how it's calculated (Eckerson 2009, p. 20). This is the basis of understanding KPIs. The understanding of KPIs determines the positive impact of employees on the company's performance. This is why managers should train employees on KPIs. It's also crucial that employees accept the KPIs that are to measure the results of their work. This acceptance requires a lot of talk and cooperation between managers and employees at the stage of KPIs design. The task of KPIs is not over-control over an employee but their focus on a daily improvement of the company's performance. Using KPI shapes performance-based culture in the company that can increase human resource efficiency and also benefit the company (Suseno et al. 2016).

The collected data of performance can be unmanageable when it is to huge (Aditya and Tretten 2017, p.35). Traditional methods have been proposed and new approaches are being proposed to prioritize KPIs in the literature (Shahin and Mahbod 2007). Enterprises should pay attention to identifying and selecting the right KPIs because measuring a wrong indicator wastes productive times in improving something that isn't important for achieving the company's goals (Addis and Beshah 2017, p. 380). Key performance indicators are a measure of performance that focus on critical aspects of outputs or outcomes (Kosta and Plomatitou 2012, p. 145).

Proper selection and design of KPIs

The proper selection and design of key performance indicators is important for the measurement and improvement of performance. Išoraitea (2010) suggests that the choice of KPIs have impact on the operation and the development direction of an organization. Selection of the wrong metrics for KPIs can significantly damage or destroy a performance management initiative and demoralize employees (Gabcanova 2012, p. 119). This proper selection and design require the application and compliance with given principles. KPIs are an integral part of PMS; this is why they must have the following characteristics (Maskel 1991):

1) they should be directly linked to an overall business strategy and the company's critical success factors,
2) they should combine both financial and non-financial measures,
3) they should use different measurements for different departments of the company,
4) they should be modified over time to reflect changes in strategy and operation,
5) they should be simple and easy to use by employees,
6) they should give a fast feedback to managers and other employees,
7) they should be intended to teach employees rather than monitor & control them,
8) they should enable benchmarking to set target characteristics of performance measurement systems found in world class companies.

It should also be noticed that a KPI should follow the SMART criteria, i.e. specific (S), measurable (M), attainable (A), realistic (R) timely (T) (Aditya and Kumar 2006, p. 245). "Specific" means that KPI should be clear and focused to avoid misinterpretation. It should also include measurement assumptions and definitions and be easily interpreted (e.g. cost/ton). "Measurable" means that KPI can be quantified and compared to other data. "Attainable" means that KPI should be achievable, reasonable, and credible under the expected conditions. "Realistic" means that KPI should fit into the organization's constraints and be cost-effective. And finally, "timely" means that KPI should be obtainable within the time frame given. SMART is a solid framework for making decisions about KPI selection.

Except that, KPIs should have the following characteristics (Parmenterg, 2007):

1) financial and nonfinancial nature,
2) frequently measured,
3) acted on by the CEO and the senior management team,
4) understood by all staff,
5) responsibility assigned to the individual or team,
6) has a significant impact on an enterprise's activity,
7) has a positive impact on staff engagement.

Wang and Hao distinguish the following basic principles of KPI design (Wang and Hao 2013, p. 894-895):

1) KPI must be able to effectively support the strategic objectives,
2) KPI should be timely adjusted to reflect the strategic shift,
3) KPI must have a clear definition and calculation methods,
4) KPI must be easy to obtain reliable and unbiased data,

5) KPI should be able to distinguish between objects of different performance evaluation at different levels to distinguish good and bad results of work of different individuals, the principle of refining,
6) the number of KPI should not be too high,
7) KPI design should be simple, refined, to the reasonable control of the number of KPIs,
8) the staff should be fully able to control the outcome of the index, if staff don't have this control, then this index can't be used as key performance indicators.

The problem of proper selection and design of KPIs was also taken up by Eckerson (2007). This author has described what characterizes "good" KPIs. Summing up Eckerson's considerations effective KPIs are:

1) "Sparse: The fewer KPIs the better.
2) Drillable: Users can drill into detail.
3) Simple: Users understand the KPI.
4) Actionable: Users know how to affect outcomes.
5) Owned: KPIs have an owner.
6) Referenced: Users can view origins and context.
7) Correlated: KPIs drive desired outcomes.
8) Balanced: KPIs consist of both financial and non-financial metrics.
9) Aligned: KPIs don´t undermine each other.
10) Validated: Workers can´t circumvent the KPIs" (Eckerson 2007, p. 18).

Literature studies indicate that there are no generally applicable principles for the selection and design of KPIs. Performance measurement is determined as specific to the company and to the situation factors (Lebas 1995, p. 27). The matrix of KPIs is therefore decision-maker specific. However, the design of KPIs isn't easy in practice. Many organizations struggle to define accurate performance indicators. It isn't possible to identify KPIs without cooperation between managers at different levels of an organization's structure and employees. The starting point in KPIs design should be a brainstorming session in which a group identifies desired outcomes and then asks "What behaviors or activities will drive or lead to that outcome?" Each time the group identifies a new driver, it should ask the same question: "What behaviors or activities will produce that result?" (Eckerson 2007, p. 11). Finally, the group will find root causes that have the most significant impact on the outcome or value driver. Further KPI design process will be discussed through an example presented in the next section of this paper.

Discussion and Conclusions

There are no universally accepted guidelines in the literature regarding the determination of KPIs for employees. Different authors pay attention to selected elements. Some of them are vague/ too general (for example: "they should be directly linked to overall business strategy…" or "acted on by the CEO...") or obvious (for example: "they should use different measurements for different departments of the company …" or "KPI should be timely adjusted to reflect the strategic shift..."). From a practical point of view, it seems that special attention from mentioned in literature should be given to the following KPI features / principles:

1) be simple, easy use by employees, understood by staff at particular levels of measurement / have a clear definition and calculation methods - indicators should be constructed so that they be determined in a relatively easy / fast way - both the values in the plan and realized for a given period. Their definitions must be precise to avoid data manipulation. This allows good communication and avoids potential disputes.
2) the number of KPIs should not be too high – The settlement of KPIs should not be too complicated, i.e. based on a maximum of several parameters for a given group of employees. Too many of them unnecessarily hinder both the planning and settlement processes.
3) follow the SMART criteria – for example setting goals that are unrealistic in advance deprives you of a motivation to achieve them. However, for the enterprise to grow, the indicators should be raised in subsequent periods.

4) give a fast feedback to managers and other employees - Employees must receive information on planned KPIs and feedback on the achievement of their goals. An example may be boards / screens on a production site informing about the volume of production, waste, time of performance of tasks, etc.
5) be not only financial but also nonfinancial nature in some cases – for example satisfaction of clients very important in the long term
6) have a significant impact on an enterprise's activity - One should strive to choose the most synthetic indicators that allow optimization of their quantity and scope. Often, to e.g. account for production, it is necessary to monitor many parameters, but most often the key ones that are most important can be identified. On the other hand, the individual parameters are dependent on each other and there is no need to include all quantities in the KPI, just choose the ones that are most important from the point of view of assessment. It is also important that indicators are not mutually exclusive, such as a production volume / deadline and quality.
7) must be able to effectively support the strategic objectives - indicators, where possible, should be directly linked to the financial plan and complement it. Consequently, it will facilitate their subsequent settlement.

In addition, this list should be supplemented by the following guidelines:

1) in the light of financial management theory and practice, the owner's goal is to maximize an enterprise's value. Therefore, the selection of assessment indicators should take into account these guidelines and include within its scope parameters affecting the increase of this value. An example may be the volume of production directly related to the different distribution of fixed costs, which is determined by the amount of waste, weight of products, speed of machines, their downtime, productivity of employees, etc. Regarding sales, it is the amount of sales, price, level of receivables collection, etc. Referring to the definition of free cash flow, key parameters shaping an enterprise value include: net result, changes in net working capital, level of investment outlays and cost of capital. Thus, the selection of KPIs that allows:
    a. an increase in revenues,
    b. lower costs,
    c. minimize working capital and the cost of obtaining financing sources,
    d. selection of investments characterized by the highest NPV

    and then their implementation allows the company to increase its value.
1) the area that includes indicators should be narrower when determining KPIs for lower positions in the organizational hierarchy and include, for example, the volume of production and waste for direct production employees. In turn, for the Production Manager / Director, in addition to the quantities listed, e.g. production cost per unit or departmental costs. An example for a Salesman is revenue and quantity of sales (also the price if they can shape it), and for the Sales Director - margin.
2) the bonus percentage should be felt by the employee. Setting it at 5% of the basic salary is a relatively low incentive to achieve the goals.
3) the bonus should be a reward rather than a permanent salary supplement. Therefore, assuming the feasibility of goals, it should be paid if they have been achieved. Of course, it is up to the Management Board to decide on its payment in cases where due to independent factors, the tasks have not been completed.
4) for all employees, and at least for the managerial staff, one of the KPIs should be the company's overall result such as net result, EBITDA, EVA, etc., which synthetically reflects activities at various levels. The discussed result will not always directly show all areas that affect the value of an enterprise, but it is one of its most important elements in the long run. This solution allows the introduction of shared responsibility for the overall results of operations.
5) the payment of bonuses to everyone, unless the Management Board decides otherwise, should be dependent on the implementation of a certain general synthetic indicator, such as: the overall result of the enterprise realized at the level of at least 80% of the plan, which is the determinant for its payment.

The above considerations indicate that the construction of KPIs is a complex process. It requires the ability to link the company's goals with tasks for employees. These indicators must fulfill a number of criteria to be effective.

Abstract

Short-term car renting is becoming an increasingly common form of realizing the need to move. It is especially popular in large urban agglomerations. As shown by the observations, drivers often drive in a dangerous way: exceeding the speed limit and using more fuel. The aim of the paper is to identify factors which has an influence of driving style of a people who rent a car for a short time period. To analyse the collected telematics data statistical methods which include correlation analysis, regression analysis and testing of statistical hypothesis using the ANOVA method were used. The analysis of the collected telematics data allowed to indicate the relationship among: difference between real fuel usage and declared by producer and capacity and power of engine; exceeding the speed limit and capacity and power of the engine. The conducted research allows to set guidelines for building a business model that encourages renters to drive in economic and ecological style. Thanks to the identified dependency, it is possible to build a more efficient business model, the offer of which will be targeted at those drivers who currently drive in the most dangerous way.

Keywords: Eco-Drivng, Business Model, Short-Term Rental

Introduction

The problems of excessive emissions of substances harmful to the atmosphere are one of the most frequently raised issues regarding the transport process. Due to the fact that car transport generates the largest quantity of carbon dioxide, countries belonging to the European Union are obliged to reduce emissions of harmful substances by 2050 (European Commission, 2011). Although the majority of transports performed in Europe is planned be transferred to other modes of transport, in particular railways, the issue of the harmfulness of road transport remains unsolved due to the huge amount of passenger transport. Due to the increasing number of cars, moving in particular in large cities, the problem, concerning not only the quantity of generated fumes, but also the intensity of traffic in large agglomerations, is a challenge for the European Community countries, whose one of the main purposes is to fulfil the requirements of sustainable development, in the European Union's understanding of the ability to execute the necessities of one generation in such a way that it is possible to ensure adequate living conditions to execute the requirements of future residents of the European Union.

The aim of the paper is to identify factors which has an influence of driving style of a people who rent a car for a short time period. Authors analysed the impact of engine capacity and power in a rented car on increasing fuel consumption (and thus CO2 emissions) and exceeding speed (increasing road risk). Based on the analysis of literature and own observations, four research hypotheses were developed:

H1: The larger the engine capacity in the rented car, the greater the difference between actual fuel usage and the declared by the car producer.
H2: The greater the engine power in the rented car, the greater the difference between actual fuel usage and the declared by the car producer.
H3: The greater the engine capacity in the rental car, the greater the number of exceeding the speed limit.
H4: The greater the engine power in the rental car, the greater the number of exceeding the speed limit.

In the next part of the paper, the research hypotheses presented above will be verified on the basis of data analysis. Data coming from sensors installed in cars rented by one of the companies operating on the European market.

Theoretical Background

The need to reduce the emission of harmful substances into the atmosphere arise clear from reports prepared by the European Union, showing that 25% of pollution is generated as a result of the transport process. The transport of goods as the only economic activity in Europe is characterized by an increase in carbon dioxide emissions into the atmosphere in the last 30 years (Cichosz and Pluta-Zaremba, 2019; Yu. et al. 2018; https://ec.europa.eu/clima/policies/transport_en, 21.08.2019). Limiting the quantity of harmful substances released into the atmosphere by vehicles traveling on European roads is also the subject of many EU directives constituting the legislative basis for the regulations on the intensity of road transport use. For example, these EU documents include: Green Paper on Transport – indication an access to modern technology and inappropriate driving style due to lack of awareness drivers as key factors affecting ecological and economic driving style (European Parliament, 2009) or White Paper on Transport – focusing on reducing the use of crude oil as fuel for motor vehicles which should be achieved by changing the approach of drivers and technological support (European Commission, 2011).

In addition, according to the European Commission regulation of March 2019, EU Member States are required to reduce their carbon dioxide emissions by 37.5% for passenger journeys and by 31% for freight transport by 2030 (Yang et al., 2018; https://europa.eu/rapid/press-release_IP-19-1869_en.htm, 28.08.2019).

The quantity of harmful substances emitted into the atmosphere in the case of road transport depends on several factors, which primarily include the level of technological advancement of vehicles traveling on European roads or the combustion standard that characterizes a given vehicle or the way of driving a car. The European Union distinguishes six basic standards, from Euro 1 to Euro 6, granted to vehicles depending on the quantity of harmful substances emitted into the atmosphere. These standards (see Harrison, 2014) also differ depending on the type of engine, gasoline or Diesel (Tietge et al., 2017).

The European Union, which indicates economic style of driving as important factor in emissions reduction, assumes that vehicles that do not fulfil the required standards will not be allowed for urban traffic because of their excessive harmfulness to the natural environment. In particular this is a matter raised for diesel cars that do not execute the Euro 6 standard. Therefore eco-driving should indicate both the economic aspect in terms of lower fuel consumption costs and the environmental aspect resulting from the reduction of emissions of substances harmful to the atmosphere. Compliance with eco-driving rules is associated with a change in driving style by training certain model behaviours resulting from the principles of economic and ecological driving style which, compared to the development of the market of electric or hybrid vehicles, is a much easier and more cost-effective solution to be implemented (Barth and Boriboonsomsin, 2009). The most important behaviours that influence the style of driving in relation to the principles of economic and ecological driving include: driving at a relatively constant speed. braking with an engine. taking care of aerodynamics or using the highest possible gear (Sciarretta and Vahidi, 2019; Padillaa et al., 2020). Research conducted so far indicates that by changing the driving style of drivers bestirring in a congested agglomeration fuel use

can drop by up to 10% (Barkenbus, 2010) while exhaust emissions can be reduced by 5 to 20% (Jeffreys, Graves and Roth 2018).

Due to the increase in the number of cars moving in urban areas (resulting from their development) problems related to excessive exhaust emissions arise not only from the combustion standards imposed on vehicles but also from the volume of traffic. It should be also noticed the analogy between eco-driving and safe-driving whose main purpose is to adapt the style of driving a car to the rules increasing the level of safety on the roads of the European Union. The use of an economical driving style allows you to reduce fuel consumption but also to reduce the number of accidents (Kacar et al., 2018; Leontyeva and Mayburov, 2017). The need to achieve the requirements of the European Union relates to both the use of modern technologies that help reduce emissions of substances harmful to the atmosphere the desire to change the behaviour and habits of both experienced and inexperienced drivers in accordance with the principles proposed by the concept of eco-driving but also the use of car rentals and car-sharing. The main purpose of car-sharing was to replace private cars with shared vehicles to which every resident of a given agglomeration had access (Arena, Azzone and Bengo, 2017; Skjelvik, Erlandsen and Haavardsholm, 2017).

The development of large urban agglomerations, the lack of traffic capacity on roads, the limited number of parking spaces or technological development have contributed to the growing interest in using both mobile car-sharing services and traditional rental companies offering short-term car rental services. Resignation of the very own car for short-term rentals can not only reduce operating costs (e.g. insurance) but also reduce congestion as part of using the same vehicle by many passengers which automatically translates into a reduction in the number of vehicles moving in cities and motion (Lei et al., 2017). Car rentals are able to execute the expectations of various customers. due to the wide range of vehicles available which also proves the flexibility of solutions to which car-sharing belongs. thus guaranteeing the efficiency of its use (Stajniak and Koliński, 2016).

According to research carried out in different countries one should notice the relationship between the use of short-term car rental companies and the reduction in the use of private vehicles, CO_2 emissions or fuel consumption (Wang and Boggio-Marzet, 2018). The use of car-sharing while maintaining the current level of mobility of residents translated into a reduction in the number of private cars by 33% in the US and by 10% in Portugal. Research conducted in Milan showed a decrease in the use of private vehicles by 30.000 while emissions of harmful substances to the atmosphere declined by 18%. In Paris, since 2011, the quantity of carbon dioxide released into the atmosphere has decreased by 15.000 tons while by 2023 it is estimated that the demand for private cars will decrease by about 36.000 which will translate into a reduction of CO_2 emissions by about 75.000 tons (Bondorová and Archer, 2017; Adamczak et al., 2019).

Research executed in Germany indicates that the use of mobile car rental companies will save about 800l of fuel per one car-sharing user while in Ireland CO_2 emissions have dropped by 86 kilotons per year. In the case of Switzerland short-term vehicle rentals have contributed to a 26% decrease in fuel consumption which translated into a reduction of CO_2 emissions by 290 kg per resident (Baptista, Melo and Rolim, 2015). In addition. J. Rifkin claims that the use of one vehicle for short-term rental allows the replacement of 20 private cars and saves about 44% of kilometres travelled by city vehicles (Rifkin and 2011). Shirazi and Keivani assume that depending on the region and research sample the use of car-sharing allows for a reduction in the number of cars traveling in large urban agglomerations with a value between 4 and 23 vehicles (Shirazi and Keivani, 2019).

Car-sharing has experienced a significant boom in recent decades (Zhou, Zheng, Whitehead, Perrons, Washington and Page, 2019). According to study developed by Mindur et al. (2018) number of users of rental cars (in whole world) will increase till 2026 6 times in compared with 2015 and more then 50% in compare with 2020. Not only number of users will increase. Expected revenue of car-rental companies will increase. In example in India increase of revenue of car-rental companies is forecasted on about 7,3% annually till 2023 (More and Rakshit, 2020).

However the effective use of both mobile and stationary rental companies providing short-term car rental services requires adaptation of the city's infrastructure e.g. increasing the number of parking spaces intended solely for car-sharing (Fiedler, Cap and Certicky, 2017).

The European Union strives to reduce emissions of substances harmful to the atmosphere especially in the road transport sector indicating both technological development and social aspects as elements necessary to be fulfilled on the way of a more ecological and economical transport process. Both EU regulations and the use of short-term rental of motor vehicles contributes to reducing congestion in European cities. and thus reducing CO_2 emissions to the atmosphere.

Methodology of the study

The aim of the research is to determine the relationship between: engine capacity, engine power and the difference between real fuel usage and the norm set by the car producer and exceeding the speed limit. Thus, four research hypotheses were developed:

H1: The larger the engine capacity in the rented car, the greater the difference between actual fuel usage and the declared by the car producer.
H2: The greater the engine power in the rented car, the greater the difference between actual fuel usage and the declared by the car producer.
H3: The greater the engine capacity in the rental car, the greater the number of exceeding the speed limit.
H4: The greater the engine power in the rental car, the greater the number of exceeding the speed limit.

The verification of the above research hypotheses will be carried out in accordance with the methodology presented in Figure 1.

Fig. 1: Research methodology

Data for verification of hypotheses was collected from sensors installed in cars rented by one of the companies specializing in short-term rental of vehicles. Data was collected in April and May 2019. Details on the collected data are presented in Table 1.

Table 1: Number of cars and kilometres driven during data collecting

	Fuel usage	Exceeding the speed limit
No of cars	618	248
No of km	5 955 872	1 722 608

The different number of cars from which data on fuel usage and exceeding the speed limit was cellected is due to the fact that the cars were equipped with sensors with different functionalities. Importantly, from the point of view of that research, all sensors had the same component responsible for collecting data on fuel usage.

As part of the analysis, the actual fuel usage was compared with the fuel usage declared by the car producer (according to the WLTP procedure). The normative fuel usage was assumed to be usage calculated on the basis of a weighted average, in which urban had a weight of 60% and extra-urban 40% (weight proportions were calculated on the basis of analysis of data on the actual position of vehicles).

For the aim of determining the relationship between exceeding the speed limit and selected factors, two weighted units were created: second kilometre per hour [s km/h] and second percent [s %]. A second kilometre per hour is a unit showing how many seconds the vehicle (and thus the driver) exceeded the speed limit. Therefore, if the driver exceeded the speed limit by 15 km/h for 20 seconds, then the value of this unit will be 300 s km/h. On the other hand, the second percentage [s %] shows how many seconds and how many percent of the driver exceeded the speed limit. So if the driver exceeded the speed limit for 30 seconds by 20% (compared to the current limit), the value of this unit was 600 s %.

Fuel Usage Data Analysis

In accordance with the research methodology, in the first step, a graph was drawn up of the relationship between the difference between the actual fuel usage (determined on the basis of data from sensors installed in cars) and the declared by the car producer and engine capacity. Figure 2 illustrates this relationship.

Fig. 2: Relationship between the difference between the actual fuel usage and the declared by the car producer and engine capacity

From the analysis of chart presented on figure 2, it cannot be clearly concluded whether there is any relationship between the two examined features. Although linear regression analysis has a positive directional coefficient. In addition, the value of R^2 remains at a very low level. It is therefore worth checking if the differences in fuel usage in cars with different engine capacities are different. For this purpose, ANOVA analysis (significance level $\alpha = 0.05$) will be used. For ANOVA analysis statistical hypotheses were made:

H0: The average values of the difference between the actual fuel usage and the declared by car producer for cars with different engine capacities are equal.
H1: The average values of the difference between the actual fuel usage and the declared by car producer for cars with different engine capacities are different.

The results of the ANOVA analysis are shown in Table 2.

Table 2: Results of ANOVA analysis (engine capacity vs difference in fuel usage)

Source	DF	Adj SS	Adj MS	F - Value	P - Value
Engine capacity	8	165.4	20.673	14.88	0
Error	609	846	1.389		
Total	617	1011.4			

The results of the ANOVA analysis presented in Table 2 show that the null hypothesis may be rejected. Thus, the average values of the differences in fuel usage in cars with different engine capacities are different. Grouping information using the Tukey method and 95% confidence has shown that it cannot be clearly stated that there is a relationship between difference in fuel usage and engine's capacity. Therefore, a correlation analysis was carried out using the Spearman rho coefficient (engine capacity data is not continuous). The value of the Spearman rho coefficient for the relationship between the difference in fuel usage and engine capacity is 0.014 (P-value = 0.734), which clearly shows that there can be no relation between the difference in fuel usage and engine capacity.

The second of the vehicle's features analysed for the impact on the difference between real fuel usage and declared by the car producer r was the engine power. Figure 3 presents the relationship between these two values.

Fig. 3: Relationship between the difference between the actual fuel usage and the declared by the car producer and engine power

As can be seen from the analysis of Figure 3, the relationship between the difference in fuel usage and engine power can be seen. R^2 coefficient value of the linear regression is really low. There is impossible to declare dependencies between these values at this stage. Therefore, it was checked whether the differences in fuel usage in cars with different engine powers differ from each other. For this aim, ANOVA analysis (significance level $\alpha = 0.05$) will be used. A statistical hypotheses were developed:

> *H0: The average values of the difference between the actual fuel usage and the declared by car producer for cars with different engine power are equal.*
> *H1: The average values of the difference between the actual fuel usage and the declared by car producer for cars with different engine power are different.*

The results of the ANOVA analysis are shown in Table 3.

Table 3: Results of ANOVA analysis (engine power vs difference in fuel usage)

Source	DF	Adj SS	Adj MS	F - Value	P - Value
Engine power [hp]	11	313	28,457	26,72	0
Error	585	622,9	1,065		
Total	596	936			

The results of the analysis presented in Table 3 show that the null hypothesis can be rejected. Thus, the average values of differences in fuel usage for different engine powers are different. What is important from the point of research is whether there is any relationship between these two features. Grouping information using the Tukey method and 95% confidence showed that only 200HP vehicles have a statistically significant biggest difference (on average over 4.7l more fuel consumed than declared by the car producer). To determine the relationship for other powers, a correlation analysis was carried out using the Spearman rho coefficient (engine power data is not continuous). The Spearman rho value shows that there is a relationship between engine power and the difference between the real and declared by the car producer fuel usage.

Exceeding the speed limit data analysis

Figure 4 shows the relationship between exceeding the speed limit and engine capacity.

Fig. 4: Relationship between the exceeding the speed limit and engine capacity

Analysis of chart presented on the figure 4 shows that the values of exceeding the speed limit expressed in both weighted units [s km/h] and [s %] are dependent on each other. The value of the Pearson correlation coefficient was 0.964 (P-value = 0.000). This clearly shows that these values are dependent on each other. It can therefore be concluded that speeding drivers exceed it in proportion to the speed limit. By determining the correlation between these two values, the analysis will be carried out only for the value expressed in the [s km/h]. The exceeding the speed limit from engine capacity graph shows that there may be a relationship between these two values (this is also indicated by the value of R^2 - relatively high compared to the fuel usage analysis).

In the next step, it was checked if the average value of the exceeding the speed limit for car with different engine capacities were different. For this purpose, ANOVA analysis (significance level α = 0.05) was used. A statistical hypotheses were developed:

> *H0: The average values of exceeding speed limit [s km/h] for cars with different engine capacities are equal.*
> *H1: The average values of exceeding speed limit [s km/h] for cars with different engine capacities are different from each other.*

The results of the ANOVA analysis are shown in Table 4.

Table 4: Results of ANOVA analysis (engine capacity vs exceeding the speed limit)

Source	DF	Adj SS	Adj MS	F - Value	P - Value
Engine capacity	5	1,80E+14	3,61E+13	9,74	0
Error	242	8,96E+14	3,70E+12		
Total	247	1,08E+15			

The results of the analysis presented in Table 4 show that the null hypothesis can be rejected. Thus, the average values of exceeding the speed limit for different engine capacities are different. Grouping information using the Tukey method and 95% confidence has shown that there are two groups of results, for capacities 1.3 and 2.0 and 1.0, 1.1, 1.5 (capacity 1.6 does not give the possibility of explicit assignment to the group). In order to determine whether there is a relationship between these values, a correlation analysis was made. The Spearman rho value (engine capacities are not a continuous value) for the relationship between exceeding the speed limit and engine capacity is 0.276 (P-value = 0.000). This shows that there is a relationship between exceeding the speed limit and engine capacity.

The second studied feature is engine power. Chart presented on figure 5 presents relationship between exceeding the speed limit and engine power.

Fig. 5: Relationship between the exceeding the speed limit and engine power

Analysis of graph presented on the figure 5 shows that there is a fairly clear relationship between the values exceeding the speed limit and engine power. The value of R^2 for linear regression is 0.535.
In order to ensure that the average exceeding the speed limit values for cars with different engine powers differ from each other, an ANOVA analysis (significance level $\alpha = 0.05$) was made. A statistical hypotheses were developed:

> *H0: The average values of exceeding speed limit [s km/h] for cars with different engine powers are equal.*
> *H1: The average values of exceeding speed limit [s km/h] for cars with different engine powers are different from each other.*

The results of the ANOVA analysis are shown in Table 5.

Table 5: Results of ANOVA analysis (engine power vs exceeding the speed limit)

Source	DF	Adj SS	Adj MS	F - Value	P - Value
Engine power	10	3,31E+14	3,31E+13	10,51	0
Error	237	7,45E+14	3,14E+12		
Total	247	1,08E+15			

The results of the analysis presented in Table 5 show that the null hypothesis can be rejected. Thus, the average value of exceeding the speed limit for different engine powers are different. Grouping information using the Tukey method and 95% confidence did not clearly indicate groups of results for different engine powers. In order to determine whether there is a relationship between these quantities, a correlation analysis was made. The Spearman rho value (engine power is not a continuous value) for the relationship between exceeding the speed limit and engine power is 0.335 (P-value = 0.000). This shows that there is a relationship between exceeding the speed limit and engine power.

Conclusions

The results of the analysis carried out allow to state that as the engine capacity increases, the difference between real fuel usage and that declared by the car producer does not increase. Thus, the first research

hypothesis *H1: The larger the engine capacity in the rented car, the greater the difference between actual fuel usage and the declared by the car producer*. can be rejected. However, engine power shows relationship with difference between real fuel usage and that declared by the car producer . Therefore, it is possible to confirm the second research hypothesis *H2: The greater the engine power in the rented car, the greater the difference between actual fuel usage and the declared by the car producer.*

In the case of exceeding the speed limit, both research hypotheses have been confirmed.

H3: The greater the engine capacity in the rental car, the greater the number of exceeding the speed limit.
H4: The greater the engine power in the rental car, the greater the number of exceeding the speed limit.

It should be noted that the relationships between exceeding the speed limit and engine capacity and power are much stronger than in the case of fuel usage.

The results of the presented study are an important guide for developing business models that encourage customers to drive in eco-friendly mode and respect road traffic regulations. The analysis clearly shows that these incentives should be targeted at customers taking out cars with a higher engine capacity and higher power. They consume much more fuel than the norm specified by the car producer (thus they generate more CO2) and they driving at a speed above the limit (they cause danger on the road). Achievement of the goals described in EU directives is also possible by consciously shaping offers for car rental persons. The short-term rental market is still growing. The number of rented cars driving on the road is also growing, which shows even more clearly what the importance of deliberately shaping the offer encouraging ecological and economic driving to reduce CO2 emissions and improve road safety.

Acknowledgments

This paper has been the result of the study conducted within the grants by the Ministry of Science and Higher Education entitled 'Development of production and logistics systems' (project No. KSL 2/17) pursued at the Poznan School of Logistics.

Abstract

Constantly increasing customer's requirements, more demanding markets and unstable social and economic situation forces organizations in recent years to care more about sustainable development and face both foreseen and unpredictable challenges. On the basis of such experiences term organizational resilience was developed. However, despite dozens of researches, still there is lack of knowledge in regards to solid definition of the term, way of measuring resilience or identifying particular resources which play role in increasing the resilience. This paper was developed to further explore knowledge within the area of organizational resilience and types of resources which can impacting the level of organizations' resilience. Therefore authors have defined following hypothesis which was checked within the paper: perceiving types of resources' influence on organizational resilience is different depending on employment level within the organization. Topic of organizational resilience is comparatively novel when being considered within the area of different types of organization's resources . Therefore the paper is complementing studies conducted hitherto. Within the paper authors are using both theoretical and empirical data. Main sources of data are researches so far available and author's broad literature review. As an empirical data authors are using results from survey which they have carried out amongst 216 business representatives from 13 countries across the world.

Keywords: Organizational Resilience, Organizations' Resources, Human Resources.

Introduction

Worldwide process of interaction and integration among people, companies, and governments – globalization and constantly increasing customer's requirements, more demanding markets and unstable social and economic situation are impeding organizations in recent years to stay competitive.

Therefore organizations are looking for effective and novel concepts which are supposed to support their business and management processes. Lean management (Kisiel, 2016, p.325), agile management (Aitken et al., 2002, p. 65) or tools defined as part of Industry 4.0 (Odważny et al., 2018) are only few examples of popular concepts which are being implemented by organizations in recent years. However on the market not only organizations are competing but also whole supply chains (Christopher, 2000, p.40). Out of the supply chain, producers are in very challenging position. They are leading their business in cooperation with wide variety of partners, both suppliers and clients. Turbulent market however is interfering smoothness and stability of the business. Therefore producers need to be able to react fast and follow all important changes. Unfortunately organizations very often do not identify all risks or can't predict upcoming changes. What is more, eventual consequences are not known or well described (Christopher, Peck, 2004, p.5; Pereira, 2009, p.375). In globally connected world organizations, societies and individuals are exposed to turbulent environment and threats appearing from outside and inside the group or organization (Gundel, 2005; Gibson, Tarrant, 2010; Bhamra, 2015).

Situation described above and desire to become stable as an organization led to developing the term of organizational resilience. Organizational resilience as an idea is getting more and more popular. Especially within the years of uncertainty, short-lived opportunities and unpredictable customers organizational resilience seems to be a very relevant topic which stimulates multiple scientists and entrepreneurs (Linnenluecke, 2017, p.23).

Review of available papers in Web of Science database has shown that after searching for the phrase "resource management" 44 379 results were found. Top five papers were referring to human resources, with more than 1000 citations each. Authors cross-checked results in Scopus database. Research has shown 15 808 results for "organizational resources" and 435 results for "organizational resilience" however when connecting two terms only 85 results were listed. What is more, in the context of organizational resilience most of the authors are focusing on immaterial resources (human resources, information resources) (Lengnick-Hall et al., 2011; Triatmanto, Nursyamsi, 2011; Ho et al., 2014; Wilson, 2016; Fatma, Zouhour, 2018; Al-Ayed, 2019, p.184). This is a common trend lately proven by authors of this paper.

Nevertheless authors would like to underline that material resources might be playing significant role in becoming resilient organization. What is more material resources are gaining importance due to the age of automation, robotics and artificial intelligence.

Organizational Resilience

Organizational Resilience Theme

Organizational resilience has not yet been defined in a unequivocal way and discussions in this area are constantly underway. It is still a relatively novel term however its origin is based on other well-known concepts. When one is aware about the context and source of organizational resilience it simplifies understanding of the term itself. Other terms which are referring to organizational resilience are:

- risk management (Engemann, Henderson, 2014);
- ERM (enterprise risk management) (Oh, Teo, 2009);
- financial control based on Turnbull report (Page, Spira, 2004);
- BCP (Business Continuity Planning), which mainly refers to organization's recovery after disruption (e.g. natural disaster or act of terror) (Sahebjamnia, Torabi, Mansouri, 2015).

Above listed terms are only examples of related with organizational resilience concepts. They are all however strongly connected with the topic of risk and organization's continuous functioning before, during or after disruption.

First attempt to define organizational resilience was made in 1973 by Holling who has described engineering resilience as a capability of organization to face disruption and recovery afterwards and ecological resilience as the magnitude of the disruption that can be adopted by the organization without major destruction (Holling, 1973). Afterwards numerous scientists and researchers have been elaborating on the topic of resilience including: Staw who focused on influence of uncertain disruptions on risk management (Staw et al.,1981) or Meyer who have extended Staw's thesis basing on hospitals case studies (Meyer, 1982, p.521). Following years were even more intense within this matter involving topics like risk management, crisis management, emergency planning, business continuity management (Smith, Elliot, 2006) or enterprise risk management (Siang Meng et al., 2017, p.44). Despite many attempts and wide researches focused on organizational resilience still the term is not defined unequivocally which is visible within literature review and confirmed by other researchers (Annareli, Nonino, 2016; Ribeiro, Barbosa-Povoa, 2018). Within this paper authors have chosen the definition provided by Bhamra (Bhamra, 2015) which seems to be describing well the essence of the term. Bharma is referring not only to the stage when organization is facing disruption but is also describing the stage before disruption has emerged as well as period of time when organization has overcame all difficulties (recovery phase). In authors' opinion such tridimensional definition should be seen as an essence of organizational resilience. What is more Bharma sees organizational resilience as a

constructive mechanism to build organization's competiveness which supplements well the general definition.

Independently from the definition and its interpretation, authors would like to draw attention to the fact of dependencies between organizational resilience and organization's resources which are defining, characterizing and building its strength (Barney, 1991; Penrose, 1995; Czerniachowicz, 2012; Flaszewska, Zakrzewska, 2013; Sładkiewicz, 2015). Main factors which are influencing organizational resilience are:

- culture of an organization and leadership (Farrar, 2017);
- partnership within supply chains (Spiegler, 2012);
- available resources and knowledge (Hills, 2015);
- organizational unity (Ates, Bittici 2011);
- planning strategies and change management (Crichton et al., 2009).

On the basis of Farrar's paper (Farrar, 2017) clear connection between organization's resilience (in this case UK police) and leadership exists. Farrar underlines in his conclusions that clear plans for both individuals and organization are required to strengthen resilience through leadership especially within times of diminishing resources and growing expectations. Not only leadership plays a key role in building resilience as other authors suggest supply chain (Spiegler, 2012) as one of the key factors influencing the level of organizations' resilience. It is important due to delays and feedback information in the system and also impacts costs of the organization. As of the list above it is visible that organization's resources are essential for building resilience within organization and sustaining its level throughout years, regardless of disruptions and uncertainty.

Ambiguity within defining the term is also leading to different concepts of measuring organizational resilience. One, universal scale was still not yet developed (Kantur, Iseri-Say, 2015). Hence several papers have been describing different approaches towards measuring the level of resilience. One of such examples would be OrgResTool build by New Zeland's government. The tool is using questionnaire and subjective evaluation of 13 different factors: leadership, staff engagement, situation awareness, decision making, innovation and creativity, effective partnership, leveraging knowledge, breaking silos, internal resources, unity of purpose, proactive posture, planning strategies and stress testing plan. Another worth mentioning approach amongst others was developed by Tierney (Tierney, 2003) and was based on September 11, 2001 events (World Trade Center attack). Tierney underlines four factors indicating organization's resilience: robustness, redundancy, resourcefulness and rapidity. She considers resilience as a matrix of four dimensions: technical, organizational, social and economic.

This leads to analogy to different types of resources: technical, human, financial and information resources.

Resources within resilience

Organizations nowadays are looking for tools and activities to prevent themselves from negative influence of the environment. To make the best out of the challenges of the market and emerging opportunities organizations are willing to integrate all departments inside. Connections between production departments and other departments supporting production indirectly (e.g. financial department) or directly (e.g. internal logistics department) is valuable to reassure stable process. This is also granted thanks to other integrated processes like preventive maintenance, predictive planning, stoppages management or materials management. All those processes are at least minimally connected with resources. Managing resources in an effective way is key to organization's success which means to drive a profitable business. To manage well resources each organization needs firstly to identify them, set up business targets and finally to control resources accordingly. It is also important to mind all the potential risks appearing throughout the process of resources management what is also emphasized within ISO 9004:2009 norms (Quality management systems – Guidelines for performance improvements).

Resources in an organization can be classified according to different criteria: types, source, area of interpretation, treating resources as a competitiveness factor or key strategical agent (Matwiejczuk, 2014). Typically resources are divided into two main types: (Godziszewska et al., 2011)

- material resources (understood as all goods posessed by an organization e.g. lands, real estate, machines, materials),
- immaterial resources (e.g. human resources, knowledge, know-how).

From resource based theory point of view, despite classifications, the most important resources are resources valuable (meaning which are improving efficiency and effectiveness of the organization), rare (usually described as resources are described as rare as long as the number of firms that possesses the resource is less than the number of firms needed to generate perfect competition dynamics) and difficult to imitate (due to unique historical conditions, social complexity or casual ambiguity). If those three categories are matched the next step is to organize the company in a way to exploit these resources. This was concluded within VRIO framework which a business analysis framework that forms part of the firm's larger strategic scheme (Barney, Clark, 2007; Keuper et al., 2011; Brem et al., 2016).

Resource-based theory suggests that resources that are valuable, rare, difficult to imitate, and irreplaceable can position a firm for long-term success. Whenever organization will identify key resources and start protecting and developing them, organizational resilience should be strengthen as well. Hereby an undisputed question appears which type of the resources is most critical for building resilience.

Study

Authors of the paper have carried out a survey to achieve following targets:

- check respondents' understanding and interpretation of organizational resilience term,
- identify key organization's areas and resources influencing resilience,
- check if there is a correlation between respondents' level of employment and chosen factors/resources important for organizational resilience.

Survey has been carried out between May and July 2019 on the basis of previously completed literature review. Authors have reviewed definitions of organizational resilience, so far described factors influencing organizational resilience as well as different approaches towards measuring resilience. Authors have also reviewed available papers referring to resources management and different types of resources in the context of resilience. On that basis questionnaire was built. 647 business representatives were asked to answer questions. Questionnaires were available in two languages: Polish and English and were distributed online. Authors received 216 answers coming mainly from Poland (157 surveys) and Germany (31 surveys). Other answers were coming from Ireland, Netherlands, Mexico, Austria, China, Iran, Serbia, USA, UAE and Romania. Survey has not checked however in which countries, represented organizations were registered. 168 respondents were representing big organizations (employing more than 249 people), 29 respondents were employed in medium-sized enterprises (between 50 and 249 people employed), 13 were representing small-sized organizations (10-49 employees) and remaining 5 respondents were representing micro-enterprises (less than 10 employees). Conducted studies served as pilot studies and helped finding out relations between different types of resources and organizational resilience. Further on, results can help defining the model that depicts how resources influence organizational resilience which is also suggested as one of next steps and following studies.

One of the questions within questionnaire focused on indicating types of organizational resources which are critical to organizational resilience. Respondents were asked to assign importance level (choosing from: very important, important, less important and irrelevant to organizational resilience) to four given types of resources:

- human resources,
- financial resources,
- technical resources,
- informative resources.

Each importance level had particular number of points assigned which helped in further mathematical analysis. Assigning "very important" was equal to 3 points, important – 2 points, less important – 1 point and irrelevant – 0 points.

On the basis of this question authors were able to check if perceiving of different resources' types strength influencing organizational resilience is different depending on employment level within the organization. Respondents were divided into three groups:

- first employment level - specialists level (consisting of other individual positions eg. specialists).
- second employment level - leadership level (consisting of mid-level managers and team leaders),
- third employment level - top management level (consisting of consortium and organization's top management).

Correlations between respondents' answers and their management groups were further analyzed.

Results

The test results were analyzed in accordance with the methodology presented in Figure 1.

Fig. 1. Methodology of the analysis

Source: ow□study

Step 1: In the first step of the analysis, a normality test was carried out for the significance levels of individual types of resources indicated by the respondents. Knowledge about the distribution of results will allow selection of appropriate methods for verifying statistical tests. Normality test was carried out using the Anderson-Darling method. For the significance levels assessments for each of the analyzed types of resources, statistical hypotheses were made:

H0: The data follow a normal distribution.

H1: The data do not follow a normal distribution.

Thus, four pairs of hypotheses were created for the answers given for each type of resource. Testing was carried out assuming $\alpha = 0.05$. The results of the normality test are presented in Table 1.

Table 1: Results of normality test

Type of resources	**Human resources**	**Financial resources**	**Technical resources**	**R&D resources**
P-Value	<0.005	<0.005	<0.005	<0.005

Source: own study

According to the results presented in Table 1 P-Value is smaller than the assumed α, thus the null hypotheses should be rejected. The distribution of significance levels for each type of resource is not normal. Therefore authors were in position to use nonparametric tests in the next steps of the analysis.

Step 2: According to the presented methodology, in the second step, the correlation analysis between the responders' employment level within the organization and the assessment of the significance of the impact of a given type of resource on organizational resilience was performed. To assess this correlation Spearman's rho index was used. Following statistical hypotheses have been made for each type of resource:

H0: There is a correlation between organizational level and chosen type of resources.

H1: There is not a correlation between organizational level and chosen type of resources.

Testing was carried out assuming $\alpha = 0.05$. The correlation test results are presented in Table 2.

Table 2: Results of correlation test

Type of resources	Human resources	Financial resources	Technical resources	R&D resources
Spearman rho	0.189	-0.115	0.030	-0.073
P-Value	0.005	0.092	0.661	0.284

According to the results presented in Table 2 statistically significant correlation between employment level within the organization and types of resources was determined only for human resources. It should be noted that the value of this coefficient is very low and in this situation it cannot be concluded that a correlation exists.

Step 3: On the basis of a conclusion from former, second step of the analysis (no simple correlation between perceiving types of resources influence organizational resilience on different employment level within the organization), authors have conducted a more detailed analysis of the results. It is necessary to check whether the perceiving of the significance of resource types on organizational resilience is the same for each of the employment levels within the organization. Authors took under consideration that data analysis might show a different results than expected. For the purpose of detailed analysis, the Kruskal-Wallis analysis was carried out assuming $\alpha = 0.05$. Following statistical hypotheses for each of the types of resources were made:

H0: All medians are equal

H1: At least one median is different

The results of hypothesis testing for human resources are presented in Table 3.

Table 3: Results of Kruskal-Wallis test for human resources

Organizational level	N	Median	Mean Rank	Z-Value
1	140	3	101,3	-2,30
2	58	3	117,5	1,29
3	18	3	135,4	1,91
Overall	216		108,5	

The P-Value for this test was 0.017, which allowed authors to reject the null hypothesis. This means that the median of perceiving strength of influence of human resources on organizational resilience is different depending on responder's employment level within the organization.

The results of the Kruskal-Wallis test for financial resources are presented in Table 4.

Table 4: Results of Kruskal-Wallis test for financial resources

Organizational level	N	Median	Mean Rank	Z-Value
1	140	1	113,3	1,55
2	58	1	101,6	-0,99
3	18	1	93,1	-1,09
Overall	216		108,5	

The P-Value for this test was 0.235, so the null hypothesis could not be rejected. This means that the median of perceiving strength of influence of financial resources on organizational resilience does not differ according to previously defined employment levels within the organization.

The results of the Kruskal-Wallis test for technical resources are presented in Table 5.

Table 5: Results of Kruskal-Wallis test for technical resources

Organizational level	N	Median	Mean Rank	Z-Value
1	140	1	107,4	-0,36
2	58	1	109,2	0,10
3	18	1	115,1	0,47
Overall	216		108,5	

The P-Value for this test was 0.871, so the null hypothesis could not be rejected as well for technical resources. This means that the median of perceiving strength of influence of technical resources on influencing organizational resilience does not differ according to previously defined employment levels within the organization.

The results of the Kruskal-Wallis test for R&D resources are presented in Table 6.

Table 6: Results of Kruskal-Wallis test for R&D resources

Organizational level	N	Median	Mean Rank	Z-Value
1	140	1	111,6	0,99
2	58	1	103,9	-0,66

3	18	1	99,3	-0,66
Overall	216		108,5	

The P-Value for this test was 0.559, which does not allow rejecting the null hypothesis. This means that the median of perceiving strength of influence of informative (R&D) resources on organizational resilience does not differ according to previously defined employment levels within the organization.

To sum up step 3 of the research methodology, it should be noted that the impact of employment level within the organization on perceiving types of resources influencing organizational resilience can be observed only in the case of human resources. Investigating this phenomenon, the authors have stated a scientific question: Are human resources perceived as more important in building organizational resilience by responders on higher employment level within the organization? In order to answer the research question posed in this way, two research hypotheses should be verified. Assuming that:

η_1: median of perceiving human resources' impact strength on the organization's resilience indicated by people employed on the first level within the organization,

η_2: median of perceiving human resources' impact strength on the organization's resilience indicated by people employed on the second level within the organization,

$\eta 3$: median of perceiving human resources' impact strength on the organization's resilience indicated by people employed on the third level within the organization.

The first research hypothesis is: perceiving human resources influencing organizational resilience is higher in case of people employed on the second level within the organization than by people employed on the first level.

H_0: $\eta_1 - \eta_2 = 0$

H_1: $\eta_1 - \eta_2 < 0$

The hypothesis was verified using the Mann-Whitney method assuming $\alpha = 0.05$. P-Value was 0.030, which means that the null hypothesis can be rejected. Median of perceiving influence strength of human resources on organizational resilience indicated by people employed on the second level within the organization is higher than people employed on the first level within the organization.

The second research hypothesis is: perceiving human resources influencing organizational resilience is higher by people employed on the third level within the organization than by people employed on the second level.

H_0: $\eta 2 - \eta 3 = 0$

H_1: $\eta 2 - \eta 3 < 0$

This hypothesis was also verified using the Mann-Whitney method assuming $\alpha = 0.05$. P-Value was 0.074, which means that you cannot reject the null hypothesis. Median of perceiving of human resources' impact level on the organizational resilience indicated by people employed on the second level within the organization is not significantly different than indicated by people employed on the third level within the organization.

Conclusion

Within the paper authors have defined following hypothesis: perceiving types of resources' influence on organizational resilience is different depending on employment level within the organization. Throughout the paper authors could not prove fully the thesis however the results of carried out analysis are leading to following conclusions. On the basis of conducted survey and tests authors found out that employees from 1st level of employment within organization (specialists and individual position) are perceiving human resources as less important for building and strengthening organizational resilience. This finding comes along the other conclusion which considers other employees working on leadership and top management level. Those two groups are perceiving human resources as more important in the scope of building organizational resilience. Growth of importance of human resources is however not in direct proportion to employment level so there is no real difference between 2nd and 3rd group of employment.

Despite authors' expectations, there are no evidence for existing a correlation between level of employment and perceiving strength of other types of resources for strengthening organizational resilience. This could lead to a conclusion that informative, financial and technical resources are evenly important on each level of employment however further studies on bigger group should be carried out. This paper was developed to assess resources which play a main role in building and increasing organizational resilience however such type can't be clearly indicated on the basis of carried out study even though human resources showed highest interest within leadership level.

Topic of organizational resilience is comparatively novel when being considered within the area of resources. The paper is complementing studies conducted hitherto. Despite presented analysis authors suggest further line of studies which should focus especially on the areas of:

- resources management methods to strengthen organizational resilience through more effective use of particular types of available resources,
- further analysis of correlations between level of employment and type of resources influencing organizational resilience,
- deep dive on specific types of human resources (eg. resources on different level of employment, skills, know-how) and how they are influencing resilience of an organization,
- further studies on specific types of material resources types in relation to organizational resilience,

What is more authors are recognizing a gap in the area of unification of resilience definition and measurements tools for organizational level assessment as well as benchmarking tools for organizations active in different branches. Broader studies focusing on those topics are recommended and should involve representatives of different branches as well as different employment levels.

Abstract

The turbulent environment in which production companies operate today has forced them to constantly improve processes. Fast-paced technological advancement brought us new and strong wave of disruption. Implementation of such solutions requires knowledge of not only the technological and IT areas, but also requires a broader insight into the management, finance and human resources. Based on the company's study, authors of the article present the rapid and repeatable method of assessment of all of the indicated areas above. Authors created the audit method based on lean management, six-sigma, change management and theory of constraints problem identification, using interviews and observation mixed with data gathering and analysis from the ERP class system. Considering speed and repeatability of the Automation Readiness Check method in data gathering and analytical areas, it brings clear view of constraints and risks that are presented to the enterprise in a manner, that gives a clear direction of the process and management improvement efforts.

Keywords: industrial automation, audit, process improvement, Industry 4.0, change management

Introduction

This article is presented as a business case. Business means that the organization is pursuing goals measured by its performance, for example using EBITDA or any other measure commonly related to profit (Paris, 2017). One of the key ingredients to become and stay profitable is to utilize the innovative technological advantage related to company's strategy goals (Bisack, 2013). Decision about technological advancement should be considered after ensuring that there is no other known option to reach company's goals in the quicker and more efficient manner, including: maintaining older technologies (Chambers, 2004), efforts targeted at internal operations, for example Six Sigma (Antony, Brennan, Dempsey, Farrington, Forthun, McFarlane, Trakulsunti, 2019) or meeting the market demands by changing the product portfolio. When company's management board comes to the conclusion that they should choose technological advancement instead (such decision can be accelerated by implementing OODA loop (Eisenbart, Ranscombe and Vettorello, 2019)), they should proceed with momentum and ensure that the decision is made considering finances, human resources, processes and IT readiness. The Automation Readiness Check method presented in this article gives the company fast and clear answer what and when should be improved to start efficient technological change and to achieve benefits in line with strategy goals.

Automation readiness check (ARC) method

Description of the method

The purpose of the analysis is to indicate what and when should be changed to achieve readiness for automation. Value for the entrepreneur is not only the assessment of the current state, but also the ability to verify progress and the possibility of comparative analysis with other companies. For this reason, the entire analysis has been reduced to one rating showing the current level of readiness for automation. This rate is the average derived from the assessments of five main areas studied by the ARC method: management, people, processes, IT and finance. Individual ratings are in the range of 0 to 5 with one decimal, where 5 is the top score indicating that organization is in the state of readiness to rapidly implement automation of processes and 0 means that organization has to work through the whole spectrum of organizational and management changes to be able to invest in industrial automation without losses in profit and without putting morale of the whole crew at risk (Band, Blanchard, Dressel, Korbelak, 2018). Description of each of the strengths and weaknesses of the company is attached to the assessment of each category. The next part of the article will present in detail the research methods used in each category. In addition to quantitative assessment, one of the main elements of the report's results is the automation road map. It indicates specific actions in the above-mentioned five main categories. Combining these actions in one document gives a holistic view of the required changes in the enterprise along with their placement on the timeline. The automation roadmap (Grünewald, Jürgensmeyer, Kohnke, Lier, Reise, Reitze, 2018) is prepared as the last element due to the required expertise of professionals involved in business transformation. Automation road map does not affect the assessment of mentioned above five categories.

Description of areas analyzed

Management

The rating on a scale of 0-5 in the area of management is calculated on the basis of the average of ratings of four sub-areas analyzed within this category: strategic goals, main problems, main initiatives and new opportunities (Wadström, 2019). The assessment of this area is based on the correlation between goals, problems and current and planned initiatives, as well as the presence of indicators assessing their effectiveness. Gathering information about new opportunities is done by means of unstructured interview and brainstorming, which results in a list of ideas for ways of using future automated production. The assessment of this area is based on a range of ideas that define the senior and middle management awareness of the benefits resulting from automation (Burduk, Grzybowska, Safonyk, 2019).

People

The key factor to any change is people. People have their own limits in regard to participation in a change (Georgalis, Kimberley, Lu, Samaratunge, 2015). Therefore, when launching subsequent initiatives, it is necessary to specify where the limit is, whether and when it will be exceeded, and how to regulate its level (Bridgman, Brown, Cummings, 2016). To answer these questions and assess people's willingness to change on a scale of 0-5 the study draws an average of the ratings of individual areas such as: the limit of assimilation of changes, method and frequency of communication, readiness to work with machines, readiness to change position and work mode, termination of employment process (Wyonch, 2018). In addition, to show broader perspective, ARC shows the type and impact of change resistance (Campbell, Carmichael, Naidoo, 2015) using the tree map chart. Each area is assessed during structured interview.

Processes

Processes are assessed in terms of: process automation potential on a 0-5 scale, the financial potential of automation on a 0-5 scale. The results are presented in form of a simplified layout of the hall with marked workstations. The average of ratings of both areas indicated above for each workstation is calculated. From the individual assessments obtained this way, an average is derived, representing the overall assessment of the process area. To assess the process potential of automation, each workstation is rated on a 0-5 scale for various elements, which are presented in Table 1.

Table 1: Description of workstation processes' elements analyzed

Value	Range of rating	Obtaining method	Description
Stability	0 - 5	Observation	Existence of a process management system such as: standards, change management, process maps, visual management, 5S, CI, TQM, WCM, Lean, 6S, PDCA, exceptions management. Result also consists of: number of failures, downtimes (Chassapis, Ibrahim, 2017).
Repeatability	0 - 5	IT system and observation	The number and duration of changeovers for another type of the same product and for another product.
Flow efficiency	0 - 5	IT system and observation	How long it takes to process stock (work in progress) accumulated before and after the workstation, determining whether the workstation was working during the observation. Inventory data is used in a comparative form between workstations, where a high stock of work in progress before the workstation indicates a potential bottleneck (Kot, Kovács, 2017).
Need for improvement	0 - 5	Observation and evaluation results of stability	Expert assessment regarding the need to introduce organizational changes to optimize work in a given work position (Antony, Dahlgaard, McLean, 2017).
The level of automation	0 - 5	Observation and interview with factory workers	Automated - no human intervention (rating 0-1). Semi-automated - human working with the machine (rating 2-3). Manual - no machine involved (rating 4-5). Data gathered was later used in the assessment of financial potential for automation: the number of employees per workstation and average employee cost.
Maintenance	0 - 5	Observation and IT production system import	Presence of KPI's (Maintenance Department), what do these KPI's indicate, how are they managed, ways of receiving information about a failure, time from failure to notification, queueing these notifications (including priority), response time, ability to operate automated workstations, whether the maintenance process is outsourced and if so, is there a fixed response time and how is it checked.
Process ergonomics	0 - 5	Observation, interviews and IT system import	Impact of the environment on employees' health (harmful body position during work, noise, dustiness, etc.), accidents in the production hall, the number of days on sick leave expressed as a percentage of available working days, salary supplements related to harmful working conditions. The better the conditions, the lower the rating of automation potential (Del Fabbro, Santarossa, 2016).
IT infrastructure (workstation)	0 - 5	Observation and interview	Presence of sensors, controllers, control cabinets, IT connections at the workplace. Assessment of the ability to connect IT infrastructure.

The results of the automation potential are presented on a matrix where columns represent the elements described above, and the rows represent specific processes. For better presentation of key areas to change, different colors corresponding to the rating scale were used, where: 0 - red, 5 - green.

The financial potential of automation for each workstation is assessed on the basis of variables:

- Data collected during the assessment of automation potential: number of employees, average salary of the employee and assessment whether the workstation may be a potential bottleneck.
- Data collected from the IT system: assessment whether products processed at the workspace constitute a high share in turnover (using pareto chart) or have a significant difference between the purchase price of raw materials and the sale price of the finished product.

The assessment of the elements above, together with expert assessment of the automation potential carried out in the previous step, enables assessment on a 0-5 scale of each of the analyzed workstations.
IT area

The assessment of readiness of the IT area for automation is based on the interview using three variables, included in Table 2.

Table 2: Description of IT elements analyzed

Value	Range of rating	Obtaining method	Description
System readiness for data acquisition and processing:	0 -5	Interview with the IT director	Existence and use of IT systems in the enterprise, efficiency and experience in the integration of existing systems with production machines and methods of data presentation are assessed (Nwankpa, 2015).
IT infrastructure	0 - 5	Interview with the IT director	Assessed are: speed and compatibility of cabling and hardware, existing security procedures, backup of the most important hardware components.
IT-Production-Maintenance Department cooperation:	0 - 5	Interviews separately with each manager of individual departments	The following are evaluated: the precision of determining the needs for data collection and presentation, meeting these needs during investments in equipment requiring data transmission via IT infrastructure.

Finance

The assessment of financial readiness is based on the assessment of two variables. The average of the following two values gives the final result of the finance area. The values are shown and described in Table 3.

Table 3: Description of financial elements analyzed

Value	Range of rating	Obtaining method	Description
Readiness to invest	0 - 5	Financial data and interview with the financial director	Two values are defined: the minimum and maximum amount of money the company is ready to gather with an acceptable level of return on investment (Frank, Shen, 2016). The minimum level is determined assuming that the engagement of employees whose knowledge of company processes is required to carry out the investment is not part of the calculated costs. The result is presented in the form of a graph, with lines of minimum and maximum investment cost estimated using the expert method based on a previous examination of the readiness of processes for automation. The higher the estimated maximum investment value exceeds the maximum level of readiness for investment, the lower the score.
Fundraising	0 - 5	Interview with the financial director	It is determined which investments over the last 3 years have been co-financed with the help of external sources, such as loans, leasing or co-financing from government programs. The greater the experience gained in raising funds, the higher the expert rating.

Automation Readiness Check report ends with automation road map. This is one-page blueprint for obtaining organizational readiness. Each category: management, people, processes, IT and finance represents separated pool of actions. Each step is designed to bring company closer to the point where investment in automation could be implemented rapidly, with strong economic value and correlation with strategic goals and people's development.

Results of the automation readiness check (ARC) – case study

Main Score

The company's main activity is producing and selling lighting products and sub-products. Production process includes among others: cutting, injecting, painting, assembling and packing. Some of the sub-processes are outsourced. Sales are international. The company is managed by two co-owners and is divided into 6 departments: sales, production, logistics, quality, marketing and finance with outsourced IT. The company's growth is stable and management is actively looking for new ways to accelerate their business. In ARC, analyzed company received an overall score: 2,7. Details of the score are presented on the figure 1.

Fig. 1: Overall score of main areas

Table 4 presents ratings for specific elements of each analyzed area. The reasoning behind those ratings is described in further sections (2.3. – 2.7.).

Table 4: Scores of specific elements

Area	Element	Score	Overall score
Management	Strategic goals	1,0	2,5
	Main problems	3,0	
	Main initiatives	2,0	
	New opportunities	4,0	
People	Initiatives impact on people	2,0	2,3
	Quality and frequency of messages	3,5	
	Readiness to work with machines	2,0	
	Readiness to change the workstation	2,0	
	Outplacement	2,0	
Process	Automation potential	2,5	2,5
	Financial potential	2,0	
IT	Readiness of systems to gather and process data	2,0	2
	IT infrastructure	2,0	
	IT - Production - Maintenance Department cooperation	2,0	
Finance	Financial readiness for investment	3,0	4
	Fundraising	5,0	

Strengths and weaknesses regarding potential automation

Strengths:

- Management – openness to changes and the ability to react quickly, ongoing process of delegating tasks and permissions, market knowledge and knowledge of processes within the company at all levels of implementation.
- People – a relatively large group of employees ready to take on new roles in the company, high frequency of messages about changes within the company.

- Processes – processes with high repeatability and stability, knowledge of processes among employees.
- IT - internal resources for developing hardware infrastructure inside the company, some of the workstations equipped with controllers.
- Finances - high readiness to invest in new technologies, experience in obtaining funds in the form of leasing, loans and EU grants.

Weaknesses:

- Management – lack of organizational structure consistent with the number and burden of implemented processes, different management styles of company's owners which create a sense of instability among employees.
- People – a sense of overload with implementation projects that are imposed by the management, lack of standard for effective implementation of new employees.
- Processes – lack of consistent method for assessing the effectiveness and profitability of processes, lack of maintenance structure.
- IT - little experience in designing IT solutions, the needs related to obtaining information at various levels of the organization do not translate into the IT systems used.
- Finances - lack of experience within the company with assessing the financial legitimacy of investments in integrated management systems.

Management Readiness Score

On figure 2 strategic development tree for analyzed company is presented.

Fig. 2: Strategic development tree

Strategic goals (score 1 / 5)

Strategic goals are expressed in measurable form (such as profit) and in the form of course of action. Measurable goals are not directly translated into individual management levels. Recommendations for strategic goals are: strengthening the structure of setting, delegating and monitoring strategic goals.

Main problems (score: 3 / 5)

High awareness of the company's problems. Lack of effective mechanisms indicating priorities in relation to the new projects. Recommendation for main problems is adding a processing index based on a bottleneck analysis to calculations based on revenues, costs, margin (sales price - production cost).
Main initiatives (score: 2 / 5)

Accurate selection of started projects to solve the main problems affecting strategic goals. The recommendation for main initiatives are: maintaining the direction of work on the roles and rights in the company; treating these changes as a priority, because most of the initiatives launched are based on the emerging coherent management system, employee involvement and new competences related to automation and IT systems; implementation of the internal project management method (including the resources assigned to them) due to project overload and lack of ownership of implementations by implementers, which affects the unused potential of initiatives and projects, and reduces the efficiency of operational tasks.

New opportunities (score: 4 / 5)

High awareness of senior- and middle- level managers about the benefits of automation. The benefits listed are:

- Quality and time repeatability of the product.
- Enforcing standardization.
- Processes easier to manage, organized.
- The crew is more competent.
- Changing the nature of the crew from production to maintenance.
- Changing the character of the production crew from more to maintenance.
- More people at middle management level (instead of senior level).
- A more balanced, multi-stage recruitment method - employing people with higher competences (people who have already worked in the company will be trained).
- Supervision of real efficiency (it is more difficult with a human).
- Easier determination of production capacity and capabilities, production planning.

Recommendation for new opportunities is using automation projects and understanding their benefits as tools of internal marketing (promotion of new technologies) as well as external (image of a modern company).

People readiness score

Initiatives impact on people (score: 2 / 5)
On figures 3-5 limitations of assimilation to change are presented.

Fig. 3: The limit of assimilation to change – impact on employees

Fig. 4: The limit of assimilation to change – impact timeline

Fig. 5: The limit of assimilation to change – stress point

Quality and frequency of messages (score: 3,5 / 5)
On figure 6 communication matrix is presented.

The colors of individual circles on the matrix determine the impact of a given initiative on people (same logic applied as on the previous graph). The frequency of messages regarding ongoing changes and projects in the company is at a high level. Employees regularly receive information about ongoing projects. Figure 7 shows the reasons, why automation may encounter resistance from workers' perspective.

Fig. 6: Communication matrix

Fig. 7: Resistance tree map chart

Orange color represents management resistance, dark blue: individual resistance, light blue: organizational resistance and green: technical resistance.

Particular attention should be paid to the resistance resulting from the management method. Seemingly obvious human fears of something unknown resulting from the fact that: they are not the authors of changes, their time commitment will increase or they will hear rumors about new initiatives that do not always coincide with reality, should not occur in the face of the upcoming change, if effective way of managing not only change, but also the entire organization is applied. Lack of this efficiency is manifested by imposing changes on employees, without determining the purpose and benefits of these changes, or by excessive interference in the activities of employees, especially resulting from their own initiatives. The change management should be based on a clear, understandable message for employees, which will limit resistance at source.

Readiness to work with machines (score: 2 / 5)

There is a high probability that people who will have to work with a new machine will not be satisfied by that. The employees themselves have the potential to undertake new initiatives, but their fear of taking responsibility and decision-making in connection with new tasks is limited. The company has people competent to operate new devices, willing to "absorb" new knowledge, but they only constitute about 30% of the crew - the rest would prefer to stick to simple work, as is the case today.
Readiness to change the workstation (score: 2 / 5)

The company lacks the preparation of employees to change positions and work mode. There is no specific standard for conducting operator training. Employees are implemented through initial training, during which they become acquainted with the threats and the basics of work in a given position. The advantage is the implementation of the employee through practice - the leader of the workstation gradually introduces a new person to the new position, starting with simple work, then implementing him in ever newer areas.
Outplacement (score: 2 / 5)

The company implemented the process of transferring employees to another position and provides dismissed employees with a security package. However, it lacks outplacement process and does not cooperate with employment agencies.
Processes readiness score
Automation potential (score: 3 / 5)

Figure 8 present the automation potential of workstations matrix.

Workstation / Parameter	P1	P2	P3	P4	P5	P6	P7	P8	P9		SCORE
W1	3	2	2	3	2	2	2	2		W1	2,2
W2	3	3	5	2	2	3	4	3	0	W2	3
W3	2,5	2	2,5	2,5	2	3,5	2	2		W3	2,3
W4	4	3	4	3	2	3	3	2		W4	2,9
W5	4	3	4	3	2	3	3	2		W5	2,9
W6	2,5	4	3	3	2	5	3,5	2	1	W6	3,2
W7	4	4	3	4	2	5	4	2,5	1	W7	3,6
W8	2	1	5	2	2	4	3	2	1	W8	2,7
W9	4	2	3	4	2	4	3,5	2,5	1	W9	3,2
W10	5	4	2,5	5	2	2	3	2	1	W10	3,2
W11	3	4	5	5	3	3,5	2	5	1	W11	3,8
W12	2	5	1,5	1	2,5	2	2	3		W12	2,3
W13	3	5	3	4	2	2	2	3		W13	2,9
W14	3	5	1	4	2	2	3	2	0	W14	2,7
W15	3	3	5	2	2	3	2	2		W15	2,7

Fig. 8: The automation potential of workstations matrix

Legend:

- P1 - Stability
- P2 - Repeatability
- P3 – Flow efficiency
- P4 – Need for organizational improvements
- P5 - Maintenance
- P6 – Process ergonomics
- P7 – IT infrastructure
- P8 - Transport
- P9 - Employees' knowledge about the process

Financial potential (score: 2 / 5)

Table 2 present the financial potential of automation per workstation

Table 2: Financial potential of automation per workstation

Workstation	Number of operators	Bottleneck score	Sale price - price of material Score	Turnover score	Arithmetic average
W1	3	1	-----	-----	1,4
W2	5	4	5	-----	4,7
W3	3	1	-----	-----	1,4
W4	1	3	-----	-----	1,4
W5	1	3	-----	-----	1,4
W6	1	1	5	-----	2,4
W7	1	1	-----	5	2,4
W8	1	0	-----	-----	0,4
W9	1	1	-----	-----	0,7
W10	1	1	-----	-----	0,7
W11	5	4	-----	-----	3,0
W12	3	0	5	-----	2,7
W13	3	1	-----	-----	1,4
W14	3	0	5	-----	2,7
W15	3	5	5	-----	4,4

Financial potential assessment logic is as below:

- Number of operators: range 0-5. If only one operator had been working at a specific workstation, this workstation got 1 point. If there had been two operators working there, it got 3 points and for 4 people operating at the specific workstation, it was rated with 5 points.
- Bottleneck score: range 0-5. Expert assessment, taking into account the stock before and after the specific workstation at the time of observation and management indications regarding potential bottlenecks. A rating of 0 means, that the workstation is not very likely to be a bottleneck, while a rating of 5 indicates workstations that are likely to limit production.
- Sale price – price of material score: 5 points were assigned to workstations which process products that had been indicated by the management as having the largest difference between the product sale price and purchase price of raw material.
- Turnover score: 5 points were assigned to workstations which process products that had been indicated by the management as generating the highest turnover for the enterprise.
- Arithmetic average: the sum of points from the previous 4 columns was divided by 3 (just for analysis in this specific enterprise): the rating of number of operators, bottleneck score and either price difference score or turnover score (whichever is rated). Additionally, the program that was used to calculate the score rounded it up to the first decimal place.

IT Readiness Score

Readiness of systems to gather and process data (score: 2 / 5)

There is readiness and need to collect and analyze data from production workstations. The existing ERP system is not integrated with existing machines, there is no information on the data exchange protocols used. The data is entered manually into the system at production stations. The MES class system is being implemented. Recommended is introducing competences related to the implementation and maintenance of integrated management systems focused on integration with machines.
IT infrastructure (score: 2 / 5)

High ability to prepare cabling, easy to connect to individual stations. Although, infrastructure should be strengthened in case of a failure (spare data transmission devices) and in the area of network security. For some of the workstations at which there is no infrastructure to collect and transfer data, the company will have to install sensors and controllers.

IT – Production – Maintenance cooperation (score: 2 / 5)

The company has a common understanding of the objectives related to data collection and analysis, and expectations in area of production are clearly defined (listed: determination of production capacity, capabilities, standards, a visible pool of orders assigned to workstations, scheduling and prioritization). Previous implementations of systems and new machines / production lines were based on the competence of external experts. There is also lack of experience within the company in the field of automatic data collection and analysis. Dedicated IT positions, maintenance department in the field of automation of technological processes and data processing are recommended to be created.

Financial Readiness Score

Financial readiness for investment (score: 3 / 5)

In a short time, the company is able to assign sufficient financial resources to prepare the organization for automation and introduce technological changes so that the return on investment is at a level acceptable to the management. However, it is not able to cover the maximum assumed investment cost from its own resources. The maximum assumed cost of investment is determined by the expert method of estimating the level of costs associated with technological changes that will not only ensure an acceptable return on investment, but will fully use the organization's ability to absorb changes.
Fundraising (score: 5 / 5)

The company is able to successfully raise funds for investments through loans, leasing, co-financing for infrastructure and machinery. Recently, funds for development have been obtained several times. In addition, the organization has experience in obtaining financial support from the European Union with an external company.

Automation roadmap

Last step of the methodology is developing an automation roadmap. Map is presented on the figure 11.

Fig. 11: Automation roadmap

Legend:

- M1 - Creating a one-card company status overview for owners.

- M2 - Preparation of company's development plan according to strategic goals: what and when to do, how to measure the result.
- M3 - Redefining management structure and standards.
- M4 - Implementation of a system for monitoring the realization of goals and projects at various management levels .
- MP1 - Analysis of the required resources to achieve the objectives, including required vs possessed skills and competences among the crew.
- MP2 – Creation of transparent method of communicating goals, progress, changes and rules for starting new projects.
- PP1 - Concept of monitoring process efficiency and rewarding employees.
- P1 – Automation of selected processes: W15, W11, W2.
- PI1 - Creation of positions with IT and Maintenance skills in the field of production and development of integrated management systems.
- PI2 - Continuation of implementations according to a coherent strategy: MES system, production standards and rewarding system.
- F1 - Financial preparation for the investment related to the change in the management structure.

Conclusive Remarks

The automation readiness analysis has been designed for companies that want to quickly:

- Diagnose the current state of the company in the context of preparation for automation processes.
- Assess financial and organizational costs resulting from process automation.
- Make the necessary changes to fully utilize the potential of automation.
- Reduce the risk of unsuccessful investments and a decrease in employee involvement and morale.

The ARC study involved employees of the company for eight hours and was conducted by three researchers. The transparent structure of the study allows to identify areas for improvement and simplifies business decisions. Expert, quality assessment requires knowledge of research and management methods, the ability to communicate and empathize, knowledge of process improvement strategies, tools and techniques in the form of work organization, material and information flow, as well as in the form of modern technologies. For this reason, the range of applications of the method is limited by the availability of experts with specific knowledge. A potential solution is to conduct the analysis by a company using a leading auditor in the person of an employee with high communication skills, who will gather a team consisting of employees from the area of senior level management, HR, finance, production, maintenance and IT.

Abstract

The rural labor market in Ukraine is characterized by limited employment, the spread of all forms of unemployment, and the concentration of a large part of the population in the informal economy. The diversification of the rural economy is one of the strategic priorities for creating new jobs in the countryside, creating an alternative to the dominant agricultural sector and ensuring productive employment for the peasants. Its promising directions are identified, among which, along with the diversification of the agricultural production itself, the accelerated development of the rural non-agricultural sector is equally important.

Keywords: Diversification, Labor Potential, Employment, Agricultural Sector.

Introduction

Employment is one of the key indicators, the level of which characterizes the development of not only individual territories, but also the national economy as a whole, and also reflects the degree of its social orientation. A characteristic feature of rural Ukraine is the dominance of the agricultural sector. Transformations in the agricultural sector of the Ukrainian economy in recent decades have led to a significant reduction in the scope of employment, which, in the absence of employment alternatives in rural areas, has caused intense unemployment and the concentration of a significant part of the economically active population in the informal economy. New threats to the rural labor market are associated with the formation of a free trade zone and the weakening of migration legislation with EU countries, which may lead to a weakening of the position of national producers in the domestic food market, a reduction in export volumes of uncompetitive agricultural products on the one hand, and an outflow of the most active and qualified labor - on the other. All this can lead to an increase in the rate of decline in employment in the agricultural sector of Ukraine and aggravate the already acute problem of unemployment in rural areas. The diversification of economic activity in rural areas is a strategic direction of creating new jobs, forming an alternative to the dominant agricultural sector and ensuring productive employment of the rural population in this regard.

A study of the theoretical, methodological and applied aspects of diversification, as well as an increase in rural employment on its basis, are in the field of scientific interests of a whole galaxy of domestic and foreign scientists and economists. The aggravation of rural unemployment, the reduction in the number of jobs and the spread of employment in the informal sector of the economy led to the intensification of scientific research on this important socio-economic problem and the development of mechanisms for its legalization, in particular, are devoted to work. (Libanova and Bandur, (2000); Bondarchuk, (2014) etc.). One of the key problems of the rural labor market of Ukraine, like most post-Soviet countries, is its traditional, over-reliance on the development of the agricultural sector of the economy. Studies are devoted to substantiating ways to resolve this issue and the need to develop non-agricultural employment in rural areas. (Vishnevskaya, (2011); Paskhaver, (2015); Sieczko и Parzonko, (2015)). It is noted that the development of diversification of the rural economy contributes not only to increasing the level of employment and solving the social and material problems of rural residents, but also guarantees the regularity of income generation and increasing the profitability of the activities of producers, the implementation of national priorities for ensuring the country's food security. That is why Yu.A. Lupenko and V.Ya. Mesel-Veselyak (2012) define the diversification of economic activity in rural areas by stimulating entrepreneurship in the productive and non-productive sectors as one of the strategic directions of agricultural development of Ukraine.

The objective need for further study of diversification, in particular in relation to the rural economy, is to determine the possibilities of its use as a tool to solve employment problems, create new jobs, ensure high social standards of rural development.

Aims

The purpose of the study is to evaluate the current trends in the formation of employment of the village's labor potential and to substantiate the directions of ensuring its productive level on the basis of diversification of the rural economy of Ukraine. Of particular relevance is the research and development of effective ways of solving this complex socio-economic problem in the context of a significant exacerbation of the problem of employment in rural employment, the spread of unemployment and informal employment, increasing social tension, the need for development and growth of rural economies.

Material and Methods

The theoretical and methodological basis of the research were the dialectical laws of knowledge of economic processes, theoretical provisions of modern economic theory, scientific developments of domestic and foreign scientists on the formation and use of labor potential, legislative and regulatory acts. The research is based on data from state statistical observations characterizing the socio-economic condition of agriculture in Ukraine and its regions (Agriculture of Ukraine 2018. Statistical Yearbook (2019)), indicators of enterprises on labor statistics (Labor of Ukraine in 2018 year. Statistical yearbook (2019)) and data on economic activity of the population obtained from a sample survey (households) on economic activity (Economical activity population of Ukraine 2018. Statistical yearbook (2019)). Abstract-logical, economic-statistical and other methods were used in the research process.

Results and Debate

The current state of the rural labor market

The crisis processes in the functioning of the economic mechanism and the economic management system of Ukraine, as a result of which the volumes of production and consumption of products and services of all sectors sharply decreased and, accordingly, the demand for labor fell, led to a decrease

in employment due to a reduction in employees. The largest volumes of the release of labor potential in rural areas occurred due to the reduction of employees of agricultural enterprises (Table 1).

Table 1: Economic activity of the rural population of Ukraine (thousands persons)*

Indicators	2000	2005	2010	2015	2018
Average annual population	16031,3	15161,7	14387,5	13215,9	12996,0
Economically active population	6894,6	6987,0	6967,7	5 667,5	5 604,7
Unemployed	465,3	400,9	493,5	533,3	515,5
Employed population	6429,3	6586,1	6474,2	5 134,2	5 089,2
Employed in agriculture, forestry and fisheries	4334,1	3986,3	3094,5	2 870,6	2 937,6
of which employees	2752,8	1418,1	794,7	568,5	533,6

** Hereinafter, information for 2015-2018 given without taking into account the temporarily occupied territory of the Autonomous Republic of Crimea and the city of Sevastopol, as well as without a part of the temporarily occupied territories in Donetsk and Luhansk regions.*

Source: Data of the State Statistics Service of Ukraine (calculated, developed and presented by authors)

The basis for it was a significant reduction in labor demand as a result of a sharp decline in agricultural production and a decrease in its saturation with labor-intensive types of products. Despite the growth of production in agricultural enterprises that has been outlined in recent years, the downward trend in workers continues. The production direction of most agricultural enterprises has become strongly oriented towards the development of those sectors that, with the lowest labor and capital costs, can guarantee guaranteed profitable activities. Such transformations in the industry structure, against the background of a rapid increase in labor productivity, caused not only a reduction in the need for labor, but also led to an increase in the seasonality of labor, and contributed to the spread of underemployment of workers in agricultural enterprises. In most cases, the bulk of the workers are part-time, they are hired for the period of seasonal work, and upon completion they are fired. So, in 2018, 55.1% of the average number of full-time employees were laid off from agricultural enterprises of Ukraine, and 53.9% were accepted (Labor of Ukraine in 2018 year. Statistical yearbook (2019). Thus, laid-off workers are deprived of a permanent source of income for a year and do not have guarantees of employment in the next season.

The situation in the rural labor market is aggravated by the rapid development of new holding-type agri-food structures in the agrarian sector of Ukraine in the last decade. This process is accompanied by a number of negative consequences, as capital-intensive and low-efficient agricultural sectors and enterprises are eliminated, the need for labor is reduced, and rural infrastructure is destroyed. The vast majority of agricultural holdings specialize in the production, processing and sale of highly liquid and low-cost crop products. Having the ability to apply the latest technology and highly productive equipment, they do not need significant amounts of labor. This makes it possible to widely use the practice of mobile mechanized detachments that carry out the whole complex of agricultural work from sowing to harvesting. At the same time, the local rural population is practically not involved in work.

An intensive reduction in labor demand has led to the spread of all forms of unemployment in the countryside. However, given the real volume of the reduction in labor, the current level of its fixation does not reflect the true dimensions of this phenomenon. Many peasants who find themselves unemployed do not apply to the employment service due to the lack of prospects for getting a job in the countryside, low unemployment benefits, difficulties in registering and the need for frequent re-registration, which is associated with the time and money spent in conditions of remoteness organs. The bulk of the peasants, freed from agricultural and other enterprises and organizations, are compelled to replenish the group employed in the informal sector of the economy. The number of

rural residents employed in this sector of the economy in 2018 amounted to 1941.7 thousand people, or 38.2% of the total number of employed rural population of Ukraine aged 15-70 years (Table 2).

Table 2: Employment of the rural population of Ukraine by type of economic activity in 2018 year

Indicators	In total	Including:	
		Formal employment	Informal employment
Employed population - total, thousand people	5089,2	3147,5	1941,7
including by type of economic activity,% of total agriculture, forestry and fisheries	39,7	21,8	68,9
Industry	10,8	15,3	3,6
Construction	6,9	3,4	12,4
wholesale and retail trade; vehicle repair	10,8	13,4	6,7
transport, warehousing, postal and courier activities	4,7	6,6	1,6
temporary accommodation and catering	1,6	2,0	1,0
other types of economic activity	25,5	37,5	5,8

Source: Data of the State Statistics Service of Ukraine (calculated, developed and presented by authors)

With the aggravation of the situation on the rural labor market, the informal sector of the economy, for a relatively short period of time, accumulated a significant part of the rural labor potential, acting as a depreciation factor (Libanova and Bandur, (2000); Bondarchuk, (2014)). It reduces to some extent the level of social tension and mitigates the negative impact of unemployment, primarily on the least protected layers of peasants. In the absence of employment alternatives, informal employment became the only way to generate income and provide livelihoods for the least competitive part of the rural labor potential - youth, people of pre-retirement and retirement age, people with a low level of education and qualifications.

Informal employment in rural areas covers unregistered production units of households, individuals and legal entities that work without concluding labor contracts in various areas of economic activity (Bondarchuk, (2014). However, the dominant part of the informal sector of the Ukrainian economy is employment in agriculture, which is implemented in the form of conducting personal peasant farming. In 2018, 68.9% of all informally employed rural residents were concentrated in it (Economical activity population of Ukraine 2018. Statistical yearbook (2019)), Based on low-productivity manual labor, with a low level of efficiency of production processes, such employment does not ensure the full use of labor potential and does not guarantee a sufficient level of income. Given this, the forced nature of informal employment and the absence of even minimal social guarantees, there is every reason to consider it one of the forms of hidden unemployment in the countryside.

Ways to Diversify Agricultural Employment

Among the strategic directions of creating new jobs, forming alternatives to the dominant agricultural sector and ensuring productive employment of the rural population, the leading place belongs to diversification of the economic activity of rural territories (Lupenko and Mesel-Veselyak, (2012). Diversification is the process of developing new production or expanding the range and range of traditional types of products that are produced by the enterprise, which allows to more fully realize the existing natural, biological, resource, labor, production potential and helps to strengthen financial, economic and environmental security, increases competitiveness and the effectiveness of business entities.

Among the directions of diversification of the rural economy we highlight the paths associated with the diversification of activities proper in the agricultural sector of the economy and the paths associated with the development of non-agricultural activities in rural areas (Table 3).

Table 3: Directions for diversification of the economy of rural areas of Ukraine

<table>
<tr><th colspan="4">DIVERSIFICATION OF THE ECONOMY OF RURAL AREAS</th></tr>
<tr><th colspan="3">DIVERSIFICATION OF ACTIVITY IN THE AGRICULTURAL SECTOR OF ECONOMY</th><th>NON-AGRICULTURAL ACTIVITIES IN RURAL AREAS</th></tr>
<tr><th>Diversification of agricultural production</th><th>Development of production services</th><th>The development of industrial sectors (industries)</th><td rowspan="2">industrial location (production of biofuels, building materials, furniture, containers, packaging materials, sewing clothes, shoes, etc.)</td></tr>
<tr><td>the development of crop production based on a rational combination of crops</td><td>the provision of land cultivation and crop care services, harvesting to other enterprises or the population</td><td rowspan="6">processing, storage and sale of agricultural products (production of flour, cereals, bakery products, butter, canned vegetables, fruits, juices, meat and dairy products, etc.)</td></tr>
<tr><td>livestock development on an efficient basis</td><td rowspan="5">provision of services to the population for the harvesting of agricultural products</td><td>development of industrial and commercial infrastructure, consulting and service organizations</td></tr>
<tr><td>growing energy crops</td><td rowspan="3">development of small and medium-sized businesses in the field of green tourism, local folk crafts, the creation of a system of services, in particular restaurant, hotel business, etc.</td></tr>
<tr><td>organic production</td></tr>
<tr><td>horticulture and vegetable growing</td><td rowspan="3">revival of the social infrastructure of rural territories (education, medicine, electricity, water and gas supply, communications, trade, utilities, transport, etc.)</td></tr>
<tr><td>production of non-traditional types of agricultural products</td><td>transport services, etc</td><td>material and technical providing and agricultural service</td></tr>
</table>

Diversification in the agricultural sector of the economy implies the effective development of large-scale agricultural production on an innovative investment basis with a rational combination of crop and livestock industries, the revival of the traditional beet, vegetable, horticulture, livestock, pig and sheep breeding industries in Ukraine. Naturally, this process is possible and advisable only under the condition of ensuring high efficiency and competitiveness of these sectors, which involves the use of intensive technologies with a high level of mechanization of production processes and high labor productivity. As B. Paskhaver (2015) notes, “in the historical perspective, farmers are a highly qualified, highly productive, and highly profitable professional group with a relatively low specific weight in the total population”. Therefore, the revival of large-scale production in agricultural enterprises should not be regarded as a panacea, since the need for labor, if it does increase, is not on the scale that guarantees full employment in the countryside. There are potential opportunities to expand the scope of services that agricultural enterprises can provide to the population or other enterprises. Among them are technological operations for cultivating the land and caring for crops, harvesting, transportation, etc.

Today, the question is urgently needed to change the raw material nature of the agrarian sector of the Ukrainian economy, and to orient it towards increasing the output of industrial processing of agricultural raw materials. This will allow not only to obtain greater added value, but will provide the creation of additional jobs, will contribute to the growth of incomes of the population, increase the income of budgets of all levels. In this regard, an important area is the organization and development in rural areas of activities for the harvesting, storage, sale and processing of agricultural products (the production of flour, cereals, bakery products, butter, canned vegetables, fruits, juices, meat and dairy

products, etc.).

We should not forget that a significant part of agricultural products is produced in the informal sector of the economy. According to the State Statistics Service of Ukraine, in 2018, 98.1% of potatoes, 85.6% of vegetables, 78.4% of fruits and berries, 72.6% of milk, 34.9% of meat, 44, 8% of eggs, 87.6% of wool and 98.8% of honey were produced in private farms of Ukraine (Agriculture of Ukraine 2018, Statistical Yearbook (2019)). Therefore, informal employment should be considered not only as a specific social shock absorber, but also as a kind of business incubator. When creating certain conditions for the legalization and support of private farms, ensuring their access to investment and credit resources, developing infrastructure for the procurement and marketing of products, these entities can become the basis for the development of rural areas. Naturally, small producers cannot compete with large enterprises in traditional agricultural sectors. Therefore, an orientation toward the production of products with a high level of laboriousness, environmentally friendly organic products, "niche" agriculture, and the production of non-traditional types of agricultural products may become a possible way of developing personal farms.

Non-Agricultural Rural Development

The strategic direction of diversification and ensuring productive employment should be the development of non-agricultural activities in rural Ukraine. This will minimize risks from adverse events of an agrotechnical and weather-climatic nature, unforeseen changes in market conditions and reduce the dependence of the rural economy on the results of agricultural production. Numerous studies and experience of advanced economies indicate a positive relationship between effective non-agricultural employment and growth of rural families' incomes, better diversification of income sources, and high labor productivity (Vishnevskaya, (2011); Paskhaver, (2015); Sieczko and Parzonko, (2015); www.ier.com.ua). Among non-agricultural activities, priority should be given to the deployment in rural areas of industrial enterprises for the production of building materials, furniture, containers and packaging, biofuels, the development of appropriate industrial and commercial infrastructure, and service and agricultural service enterprises. A significant source for the development of non-agricultural employment is the need for a radical improvement of rural living conditions, the creation of a modern social infrastructure in rural areas (education, medicine, electricity, water and gas supply, communications, trade, utilities, transport, etc.). There are great prospects for the development of small and medium-sized businesses in the field of green tourism in the countryside, the creation of a system of services, in particular sports, health, hotel, restaurant business, local folk crafts.

The proposed areas will contribute to the productive employment of the rural population, increase the level of its material well-being and improve social standards of living, and will also ensure economic growth and increase the investment attractiveness of rural areas.

Conclusion

The study found that the current state of the labor market in rural areas of Ukraine is characterized by a reduction in official employment, an increase in various forms of unemployment, the dominance of agricultural employment and the concentration of a significant part of the labor potential in the informal sector of the economy. The necessity of diversifying the economy of rural territories as a strategic direction for creating new jobs, providing alternatives to the dominant agricultural sector and creating productive employment of the rural population are substantiated. Key ways to diversify the rural economy are proposed, among which are ways to diversify the agricultural sector of the economy itself and, more importantly, ways related to the development of non-agricultural activities in rural areas.

The first group, along with the development of large-scale agricultural production with a rational combination of crop and livestock industries, provides for the expansion of services that agricultural enterprises can provide to the population or other enterprises and the organization of procurement, storage, sale and processing of agricultural products and production of industrial products (building

materials, containers, packaging materials, tailoring, shoes, etc.).

Stimulation of non-agricultural activities should be aimed at the location of industrial enterprises in rural areas, development of appropriate production and commercial infrastructure, service and service enterprises, social infrastructure, services, tourism, restaurant and hotel business, handicrafts.

Abstract

The article describes the main reasons that hinder the application of the cluster model in the region. Highlights the theoretical aspects of the formation fruits and berries cluster and identifies the main stages of its creation. It justifies the concept of development of innovative fruits and berries cluster and proposed it organizational structure. The advantages of clustering and generalized mutually beneficial relations between its participants.

Keywords: fruits and berries innovative cluster, members of the cluster, cluster structure, the advantages of clustering, the effectiveness of cluster.

Introduction

In today's environment, improving the efficiency of the gardening industry is possible by translating it into an innovative model of development, which would combine science and entrepreneurship into one balanced complex and contribute to improving the competitiveness of enterprises. The formation of integrated market-type structures in the industry plays a strategic role in implementing innovative processes. In this context, it is important to create a fruitful cluster that is not only a means of achieving economic development goals, but also a powerful tool for stimulating regional development, which, as a result, will increase employment, wages, budgetary contributions to various levels, increase competitiveness and sustainability of the domestic horticulture industry.

A significant contribution to the development of theoretical, methodological and practical aspects of cluster formation belongs to such scientists as T.V. Bozhidarnyk, V.I. Zakharchenko, M.F. Kropyvko, Yu.O. Nesterchuk, O.M. Odintsov, V.V. Rossokha, P.G. Sabluk, S.I. Sokolenko, V.I. Chornodon.

The issues of development of regional product clusters taking into account the peculiarities of individual territories of the country remain insufficiently investigated. At present, there is no single approach to the formation and efficient functioning of the fruit-bearing cluster, which has necessitated the need for a separate study.

Material and Methods

The methodology of the process approach to the development of a structural model of an innovative fruit-bearing cluster is applied in the study.

Aims

To substantiate the conception of formation and organizational structure of the regional innovation fruit-bearing cluster.

Results and Debate

Prerequisites and principles for the formation of an innovative fruit-bearing cluster

Based on the research of foreign and domestic scientific works, devoted to the creation of a comprehensive system of effective management of innovative activity of enterprises, we agree that its main components are now considered human capital and scientific and technological development, clusters, which are closely related to each other, since they act on a voluntary basis, characterized by a high degree of use of information and provide effective favorable conditions for the realization of human capital and innovation (Bakum, (2009)).This will contribute to the high economic and social performance of these associations, as well as the territories in which they are located. The formation of an innovative fruit-bearing cluster will provide an increase in the production of fruits and berries and increase the level of competitiveness of domestic gardening products.

An innovative fruit-bearing cluster is an amalgamation of different economic entities (horticultural enterprises, processing enterprises, research centers, public authorities), which envisages the benefits of two ways of coordinating the economic system - the intra-enterprise hierarchy and the market mechanism, which allows faster and to effectively acquire new knowledge, scientific discoveries and inventions (Tupchiy, (2013); Tupchiy, (2014)).

The stages of construction and development of the fruit-bearing cluster were determined (Fig. 1). It is important that each cluster participants made their contribution in making strategic and operational decisions, thus realizing the exclusivity of cluster initiatives.

A prerequisite for the creation of an innovative fruit-bearing cluster is the system of principles on which its activity is based. They reflect the experience of cluster formation and operation. The system of principles to be followed when organizing an innovation cluster is characterized (Chaliapina and Solomakhin, (2008)):

- Comprehensive support initiatives from below;
- advantages of private ownership;
- financial and legal independence of each cluster member;
- making optimal use of everyone's opportunities for successful implementation of joint projects;
- clear fulfillment of contractual obligations for project implementation;
- maximum interaction with local authorities, involvement of scientific potential in planning, development and implementation of modern technologies and materials;
- exceptional understanding, mutual support and trust in one another.

Fig. 1: Formation of conditions for creation of innovative fruit-bearing cluster

Formation of organizational structure of an innovative fruit-bearing cluster.

The formation of the organizational structure of an innovative territorial fruit-bearing cluster is a rather complicated process, encompassing not only horticultural, but also a number of other enterprises, organizations of territories and objects belonging to related industries (Fig. 2).

Fig. 2: Organizational structure of innovative territorial fruit-bearing cluster

In order to coordinate the work of the members of the fruit-bearing cluster, it is proposed to form the Coordination Council, as the highest management body, at its meetings strategic goals and tasks of regional production development will be solved. The work of the Council should be organized in the following areas: planning and innovation; monitoring and analysis; marketing and marketing; financial and accounting activities; information and counseling.

Implementation of cluster initiatives is possible only if the state regional policy in the field of clustering and formation of a favorable macroeconomic, information and legal environment is possible. There is a need to build a reliable information platform for cluster development, to carry out

a careful analysis and adjustment of cluster policy at each stage of the cluster process, to combine efforts of the state, private sector and public organizations to effectively develop regional and interregional clusters in Ukraine, and to take the following measures (Kropyvko, (2010):

- contribute to the revitalization of the process of approval of drafts of the Concept of Cluster Creation in Ukraine, the Concept of the National Target Program of Industry Development of Ukraine, the National Strategy for the Formation and Development of Transboundary Clusters and Cluster Development with the purpose of normative definition of the concept of "cluster", as well as the formation of institutional environment for the implementation of the cluster model of development in Ukraine;
- create conditions for increasing the productive capacity of enterprises through the introduction of tax incentives scheme cluster cooperation, including;
- development of projects, targeted programs and mechanisms for implementation of tax holidays for small and medium-sized enterprises within the cluster;
- provision of benefits, subsidies in taxation of the cluster, which provides funding for projects, programs that depend on the directions and strategy of the industry development;
- implementation of initiatives of private agricultural enterprises and state bodies on the functioning of the cluster by creating a mechanism for involvement of small and medium-sized business entities in cluster programs and projects, using public-private partnership models to increase the efficiency and competitiveness of agribusiness.

The benefits of using national and regional policy measures to create a fruit-bearing cluster are based on the fact that they allow a comprehensive analysis of the situation in a group of interconnected enterprises belonging to different industries. For the state it is the latest, most convenient tool in economic and tax policy. This is fully explained by the fact that one of the goals of the fruitful cluster is the formation and implementation of new technologies, products, services. Benefits for the members of the fruitful cluster are objective in nature, that is, they do not depend specifically on any of them, so they are potentially more resilient than mergers of another type.

Improved state and regional policy should become a solid basis for investment and innovation development, enhancing the country's competitiveness in foreign markets (Khabirov and Sitdikova, (2009). The decisive role in this process is the formation of regional and inter-regional clusters that will optimize the activity of production systems, will promote the development of high-tech and high-tech industries, will allow to take advantage of specialized companies, creating on this basis a strong synergistic effect of socio-economic growth, at the regionally and national level.

Benefits of combining enterprises into an innovative fruit-bearing cluster

Combining enterprises into an innovative, fruit-bearing cluster provides participants with numerous competitive benefits from collaboration and engagement. The main advantages of cluster integration are:

- improvement of the business reputation of the participants of the fruit-bearing cluster, creation of new brands, brands, advantages over competitors;
- increasing the pace of innovation that determines their direction, creating the foundation for future economic growth, that is, the benefits of access to the latest technologies, new components and equipment that will enable the production of fruit-bearing products by world standards;
- effective solution of urgent problems at the level of authorities and local self-government, lobbying of interests;
- improving the productivity of enterprises through better access to highly skilled workforce, specialized information, better motivation of managers and employees and, in particular, achieving social impact (employment orientation, welfare improvement, reduction of social tension, compliance with environmental standards, energy and resource conservation measures);
- joint research, use of managerial experience, information and resources, enabling the expansion of old markets, creation or development of new and effectively displacing foreign manufacturers;

- reducing costs due to the absence of intermediary organizations between cluster members;
- reduction of risk through the possibility of joint implementation of significant projects by participants of the innovation cluster;
- increased flexibility and large scale effect. The result of the creation of an innovation cluster is to improve production, increase the number of small and medium-sized enterprises and increase the competitiveness of enterprises in the domestic and global markets.

The benefits of merging into an innovative fruit-bearing cluster receive not only horticultural enterprises, but also other participants in it (Fig. 3).

Indicators	**State**	**Fruit-bearing cluster**	**Processing enterprises**	**Horticultural enterprises**	**Scientific and educational organizations**	**Financial, insurance, transport and trade organizations**
State	Government interaction in the process of clustering	Provision of conditions for the development of the region	Regulation of imports of processed fruit-bearing products	Regulation of imports of processed fruit-bearing products	Regulation of import of plant breeding achievements (fruit-bearing crops); support in the training of specialists	Supporting the development of small and medium businesses
Fruit-bearing cluster	Ensuring food security for the region's development	Inter-cluster competition	Ensuring conditions for balanced development	Activation of conditions for balanced development	Ensuring conditions for balanced development; support in the training of specialists	Supporting the development of small and medium businesses
Processing enterprises	Providing production of domestic products	Implementation of social programs	Collaboration within the cluster	Setting price parities	Realization of innovative developments; assistance in the training of specialists	Collaboration to protect competitive advantage
Horticultural enterprises	Providing production of fruits and berries from plantations of domestic plant breeding	Improving efficiency, implementing social programs	Providing production of fruit-bearing products	Collaboration within the cluster	Realization of innovative developments; assistance in the training of specialists	Collaboration to protect competitive advantage
Scientific and educational organizations	Providing production of domestic fruit-bearing plantations; effective specialists policy	Increasing innovation and economic activity; providing highly skilled specialists	Increasing innovation and economic activity; providing highly skilled specialists	Introduction of innovations in production and management; providing highly skilled specialists	Partnership within the cluster; assistance in the training of specialists	Cooperation in the development of investment projects; providing highly skilled specialists
Financial, insurance, transport and trade organizations	Ensuring sustainable development of cluster members	Ensuring sustainable development of cluster members	Provision of processing enterprises with sustainable development	Provision of processing enterprises with sustainable development	Ensuring sustainable development of cluster members	Assistance in training specialists

Fig. 3: The matrix of the target interests of the participants of the fruit-bearing cluster association

State administration bodies will be able to find a balance of interests and to establish the optimum relationship between enterprises and the government, creating conditions for sustainable socio-economic development. In addition, the functioning of the innovation cluster contributes to the creation of new jobs, and, consequently, increase employment, population income and reduce social tensions, increase the region's revenues by increasing budgetary contributions.

Research institutions and educational institutions within a fruit-bearing cluster will be able to practically reconcile the range of educational services and the level of training of personnel with the real requirements of enterprises, to restore the system of training and research execution system to the order of enterprises, which will now reflect the necessary combination of scientific and economic interests.

Benefits from participation of financial institutions in the innovation cluster are achieved through work with significant turnover from servicing numerous operations performed by entities of the fruitful cluster; reduction of interest rates on loans for members of the cluster; expansion of practical application of mortgage and leasing loans to enterprises; bringing European development levels to their own levels and sizes.

Small businesses will gain access to significant scientific potential and investment resources from cluster integration, and thus the ability to complete and implement even the most risky and effective projects that they are not always capable of on their own. In addition, they will be able to receive a large number of orders for the supply of raw materials, resources, complete programs and orders of large enterprises, strengthen positions in existing markets or access to new ones.

Mechanism of economic relations in a fruit-bearing cluster

The integration of farmers with processing enterprises and service organizations is a crucial step for the efficient and sustainable development of the horticulture industry. The economic mechanism of relations is based on the set of organizational, economic, motivational, legislative ways of interaction and coordination of interests of all participants of the cluster, so it should be created on the basis of organizational, economic, motivational, legislative mechanisms. The relationships between the cluster entities are governed by the terms of the contracts. They include: volumes, quality and delivery time, processing of raw materials, order of delivery and delivery of finished products, storage conditions, rights, obligations and responsibilities of the parties. Contracts between cluster members allow association members to set conditions for the production and sale of raw materials, to ensure the rhythm and production of high-quality fruit products (Fedorenko, and all (2008)).

The mechanism of economic relations in a fruit-bearing cluster should be based on the following basic requirements: to create conditions for the participants of the interest in expanded reproduction on the principles of equivalent exchange, self-sustainability, which will increase the efficiency of joint production; monitoring and control; creation of conditions for solving consumer problems, creation and maintenance of structure and volume of production, balanced and rhythmic functioning of the market of fruitful products; planned and validity of actions; proportionality of construction; motivational weapons; progressiveness; direction of production-economic relations for increase in efficiency (Yukhymchuk, (2013).

Assessment of economic efficiency of creation of innovative territorial fruit-bearing cluster is based on indicators of use of fixed and circulating means, labor and financial resources. This will ensure that sound management decisions are made to efficiently utilize the cluster's resource potential, optimize costs, and reduce risks. It is proposed to distribute the cluster profits from joint activities in proportion to the resources invested at all stages of production and delivery to the consumer of the final products.

Conclusion

It is advisable to form a fruit-bearing cluster as an inter-economic territorial association of legally independent enterprises and farms for the production of final competitive fruit and berry products, including infrastructure components - government bodies, scientific and research institutions, fruit and berry nurseries, transport and logistics companies, trade and logistic companies, organizations, financial institutions and enterprises of logistical maintenance of horticulture. Their joint activity should be carried out by prior orders and contractual relations. The economic mechanism of relations is based on the totality of interaction and coherence of interests of all participants in organizational, economic and motivational aspects and economic risks and achievement of synergetic effect. The mechanism of distribution of profit of a cluster from joint activity is offered to be carried out in proportion to the invested resources at all stages of production and bringing the final products to the consumer.

ABSTRACT

The role of women entrepreneurship in small and medium scale enterprises (SMEs) has received increased attention from academics and policymakers in recent years. SMEs have become a more imperative component of women entrepreneurship development. The number of woman-headed businesses and their entrepreneurial activities is quite significant, and this has made women entrepreneurs to be relevant for economic development. Women entrepreneurs have specific individual traits that prompt them to become entrepreneurs, but despite this, they are faced with challenges of identifying their innate abilities to achieve enhanced performance. Therefore, the paper examined the concept of creativity and women entrepreneurs and the resultant effect as it relates to the competitiveness of SMEs. The problem-solving and expertise-based theory of creativity and theory of competitive advantage was considered for this paper. The paper adopts an exploratory and causal study in which the researcher made use of the survey and descriptive design. Five hundred and twenty (520) copies of questionnaire were administered among the selected Nigerian women in Small and Medium-Scale Enterprise in Lagos and Abuja. Findings from the review suggest that creativity is an essential trait required to improve the competitiveness of an SME. Women entrepreneurs have a high tendency to initiate new ideas surrounding the improvement of their businesses. The government was also encouraged to create business enabling environments for women entrepreneurs. Also, managers should identify women in the organization and engage them in attending to creative assignments as this will help them improve on their creative ability.

Keywords: Women, Entrepreneur, Creativity, Business Competitiveness

Introduction

Small and Medium-Sized Enterprises have an essential place in the economic development of any country, which consists of the majority of private business which operates and are widespread from the most prominent cities to the remote areas of the villages (Alba, 2013). According to Temjanovski and Marjanova (2015), SMEs, being a primary critical elements of economic development is acknowledged to be responsible for increasing rate of employment, high living standard, poverty alleviation, production of useful services/products and generally the creator of several developed and developing economies (Agboli & Ukaegbu, 2006). In Nigeria, the importance and performance contributions of SMEs as a employment generation avenue, with reference to low-skilled and sometimes unskilled jobs, is very popular. According to Eniola (2014), Businesses in Nigeria classified under SMEs generates 98% of manufacturing sector, which provides a 76% workforce and 48% of all the industrial output in terms of value-added. In Nigeria, it revealed that SMEs absorbs 87.9% of the workforce in the private sector (Aladejebi, 2018) and 87% of the workforce in the sector are in the agriculture sector, SMEs also contributed about 47.8% to the GDP of the Nigerian Economy (Ebitu, Basil & Juliet, 2018).

The role and importance of women entrepreneurship in venture creation has received increased attention from academics and policymakers in recent years. Several studies, such as Kabir, Ibrahim, and Shah (2017) and Aladejebi (2018), have recognized the place of traits in ensuring effective operation and execution of the entrepreneurial activities demand of women. The study affirmed that women's performance in both business and home front could be attributed to their peculiar traits. In today's business world, entrepreneurs display a certain level of creativity, which will, in turn, culminate in business competitiveness. Creativity is essential because not only does it encourages upward thinking, it adds to the knowledge development that leads to business success (Ibrahim, Che, Mohd & Sharifah, 2015). Creativity is the ability and power needed to come up with new ideas, while competitiveness is a country's share of the world market for its product (Oluwadare, 2015). Hence, there is a need to study the effect of creativity of Nigerian women entrepreneurs on business competitiveness.

Creativity can be a significant determinant of business competitiveness, especially in cases of SMEs. In today's business world, being creative is an essential trait that an entrepreneur must possess which is often reflected in the ability to bring onboard new thinking patterns and develop new ideas, this, in turn, can affect business competitiveness (Geissdoerfer, Martin, Vladimirova, Doroteya, Evans & Steve 2018). Many women entrepreneurs in Nigeria, although motivated to start businesses, have not thoroughly identified the innate abilities in them, especially concerning creativity. The inability of entrepreneurs to identify and make use of their traits appropriately is a major issue as creativity has been identified as a trait that helps businesses to grow competitively and sustainably.

Literature Review

Women Entrepreneurship in Nigeria

Women entrepreneurship views both the societal conditions of women and their role as business owners. About 50% of the total population in Nigeria are women, NBS (2016), and they contribute both to their families and the economic growth of the country by creating jobs and generating revenues (Mahajar and Yunus, 2012). A study found out that women entrepreneurs often relates with customers with more patience and manages their business carefully (Moses and Amalu, 2010).

The study of Aderemi, Ilori, Siyanbola, Adegbite and Abereijo (2008) to examine why more women-run businesses in Nigeria, found out women who engaged in non-technological ventures were motivated by unemployment while the ones who engaged in technological businesses were encouraged by personal convictions and interests. Consequently, when a women's entrepreneurial capacity is developed, it helps greatly in harnessing their ability to identify and capitalize on business opportunities that they discover in their environment which empower them in economic and social perspectives (Eckhardt &Shane, 2003).

Women entrepreneurs are experiencing a constant increase in their market share and customers rapidly, but there is a gap between how men and women business owners operate (Sandberg, 2003). Hemalatha, Mohan, and Jasim (2013) posited few women participates in business in comparison to businesses owned by men and they are involved in specific sets of industries, which are mostly retailing and services. Women entrepreneurs in Nigeria contributes significantly to the economy, in their bit to create major landmarks in the socio-economic arena. Women entrepreneurs are also making an impact in their immediate environment by creating new ideas, and resources, and this leads to employment generation and increased business opportunities for suppliers and other business chains (Iyiola & Azuh, 2014).

Creativity and Business Competitiveness

Creativity is the act of converting imaginations into things that can be seen, and it is the ability to see the world differently, to discover hidden mysteries, to make connections between things that does not seem related to provide solutions to existing problems. The increased importance of creativity and innovation provides excellent ways in the production of goods and services, and this helps to strengthen their socio-economic development enhancing effective delivery to a higher number of people (Dimnwobu, Ekesiobi & Mgbemena, 2016). Competitiveness describes the position of an enterprise

in comparison with the qualities and results of activities that reflect either superiority or inferiority of another enterprise (Reiljan, Inrikus &Ivanov, 2000). Based on the opinion of Adebayo (2010), the main aim of competitiveness is to pin-point the productivity of a nation or business, being the original plan that creates sustainability.

Sustainability of a firm depends on the performance of the highlighted marketing strategies and competitiveness. Unfortunately, many enterprises are facing several difficulty of marketing due to the production of poor quality, unattractive packaging, lack of marketing skills, and tough competition. Sustainable growth of SMEs is as a result of best practices of entrepreneurship that are healthy in the economy (Ismail, Jafri, et al., 2012). It also indicates success for SMEs (Salojarvi, Furu, and Sveiby, 2005), and the overall economic growth. Kwan, Leung, and Liou (2018) posited that culture, creativity, and innovation enriches the findings that creativity is an integral part of innovation. The ability for women entrepreneur to be conscious that they are innovators have a long way to go in determining the business sustainability of an SME. This assertion was further supported by the findings of Barnard & Herbst, (2018) who asserted that pure or raw creativity by itself is certainly not a sufficient factor of entrepreneurship, but a combination of business education that generated good innovations.

Theoretical Perspective

The paper focused on the problem-solving and expertise-based theory of creativity and theory of competitive advantage. The problem-solving and expertise-based theory is rooted in the assumption that creativity is based on expertise (Kozbelt, 2010). This theory puts in perspective the creative person and the creative process, the person, emphasizing the level of expertise, which is a necessary condition to perform the creative act and the process (Kozbelt, 2008).

The problem-solving theory proposed by R. E. Mayer (1990), which explains that in situations where the solution procedure is not apparent, a cognitive process can be exerted on a given state to create a change in the final stage. According to Funke (2010), the ability to decipher the problem is the condition (given state) and the operations or activities introduced to the given state in order to bring up a solution (required final state) with the help of available instruments is defined as the problem-solving theory. This theory indicates that the entrepreneur should be able to identify the existing problems or challenges, suggest and investigate possible solutions, and implement the solution to get the desired result.

Methodology

The paper adopts an exploratory and causal study in which the researcher made use of the survey and descriptive design. Five hundred and twenty (520) copies of questionnaire were administered among the selected Nigerian women in Small and Medium-Scale Enterprise in Lagos and Abuja. The selected Small and Medium-Scale Enterprises considered for this study are registered of affiliated with Association of Micro Enterprise (AMEN), NASME Women Group (NASME), National Association of Small Scale Industrialist (NASSI) and NECA's Network of Entrepreneurial Women (NNEW). Out of five hundred and twenty (520)) copies of questionnaire distributed, only four hundred and sixty four (464) which accounted for 89.2% response rate as depicted in Figure 4.1.

Figure 4.1: Copies of Administered Questionnaire and Response Rate

The study adopted the convenience sampling and the data collected were analysed using the IBM SPSS version 23. The non-probability sampling techniques were used for this study; convenience sampling, judgmental sampling, and quota sampling were employed. The survey questionnaire designed for this study is made up of two parts. Part A consists of questions requiring respondents to answer about their background. Part B comprises of questions related to creativity and business competitiveness of women entrepreneurs. Entrepreneurs were required to indicate the level of agreement by circling on a scale 1 to 4 where 1= Strongly disagree 2= Disagree 3= Agree 4=Strongly agree for each of the respective statements.

Finding and Discussions

Hypothesis: Creativity of women entrepreneurs does not significantly stimulate business competitiveness of an SME.

Demographic Profile of Respondents

Tables 4.1 shows the demography profile of the respondents. This was done in cross-tabulation form with the organisation or association of the respondents. The participating association include Association of Micro Enterprise (AMEN), NASME Women Group (NASME), National Association of Small Scale Industrialist (NASSI) and NECA's Network of Entrepreneurial Women (NNEW).

Table 4.1: Demographic Profile of the Respondents

Variables		Selected Associations				Total
		Ass. #1 Freq. (%)	Ass. #2 Freq. (%)	Ass. 3 Freq. (%)	Ass. 4 Freq. (%)	Freq. (%)
Age	21 - 30 Years	2(2.4)	6 (7.3%)	4 (4.9)	70(85.4)	82 (17.7)
	31 - 40 Years	62 (31.6)	56(28.6)	49 (25.0)	29(14.8)	196(42.2)
	41 -50 Years	62(41.6)	37 (24.8)	34 (22.8)	16 (10.7)	149(32.1)
	50 year and above	-	21 (56.8)	16 (43.2)	-	37(7.97)
Marital Status	Single	7(7.0)	11(11.0)	9(9.0)	73(73.0)	100(21.6)

	Others	-	4(50.0)	4(50.0)	-	8(1.72)
Work Experience	Below 5 Years	7(8.9)	16(20.3)	10(12.7)	46(58.2)	79(17.0)
	6 - 10 Year	79(39.5)	47(23.5)	42(21.0)	32(16.0)	200(43.1)
	10 - 15 Years	40(29.6)	32(23.7)	30(22.2)	33(24.4)	135(29.1)
	15 - 20 Years	-	10(41.7)	10(41.7)	4(16.7)	24(5.17)
	20 -25 Years	-	6(54.5)	5(45.5)	-	11(2.37)
	25 Years and Above	-	9(60.0)	6(40.0)	0(0.0)	15(3.23)
Educational Qualification	SSCE	68(62.4)	19(17.4)	18(16.5)	4(3.7)	109(23.4)
	ND/NCE	52(47.3)	30(27.3)	28(25.5)	0	110(23.7)
	B.Sc/HND	4(2.2)	56(30.3)	44(23.8)	81(43.8)	185(39.9)
	Master	2(3.8)	15(28.8)	13(25.0)	22(42.3)	52(11.2)
	PhD	0	0	0	8	8(1.72)
Business Location	Lagos	126(29.4)	113(26.4)	98(22.9)	91(21.3)	428(92.2)
	Abuja	0	7(19.4)	5(13.9)	24(66.7)	36(7.76)

It was observed from the data presented that most of the respondents were within the economically active population. This implies that the selected associations that participated in the survey have concentration of young talented women that are less than 50 years old. Summarily, most of the respondent across the four selected Indigenous Women Entrepreneur Associations were married. Evidently, most of the respondents had between 10-15 years of work experience. However, the information provided by the respondents can be relied upon by virtue of their work experience. Most of the respondents had B.Sc or equivalent. This implies that the information provided by the respondents can be relied on because it is believed that they were highly educated. In a nutshell, most of the women business owners that participated in this survey were from Lagos.

Table 4.2: Mean Score Criteria for Four (4) Point Likert Scale

Scale	Mean Score Categorization	Level of Satisfaction
1	1.00 – 1.75	Strongly Disagreed
2	1.76 – 2.50	Disagreed
3	2.52 – 3.25	Agreed
4	3.26 – 4.00	Strongly Agreed

Table 4.2 above shows the mean score criteria for the four point Likert Scale which is used to depict the decisions made by the respondents. Table 4.3 below shows the descriptive statistics of creativity and business competitiveness. Each of the variable was measured with four (4) items as indicated in

the table. It is imperative to note that four (4) point Likert's scale that ranges from strongly agree (4) agree (3), disagree (2) and strongly disagree (1).

As depicted in Table 4.3, if the mean score is between 1.00 – 1.75, it suggested that the respondents strongly disagreed with the item on the research instrument, if the mean score is between 1.76- 2.51, it implies that respondents disagreed with the items on the questionnaire and if the mean is between 2.52 – 3.26 it suggests that the respondents agreed while the mean score that ranges from 2.27 – 4.00, it indicates that the respondents strongly agreed with the items. Going by the criteria presented in Table 4.2 and the average mean scores presented in Table 4.3, it shows that all the respondents across the selected associations agreed with the all the items of measurement of business competitiveness.

Table 4.3 : Descriptive Statistics of Creativity and Business Competitiveness

Creativity(C)	**SA**	**A**	**D**	**SD**	**Ass. #1**	**Ass#2**	**Ass#3**	**Ass#4**	**Ave Mean**
	Fre. (%)	**Fre. (%)**	**Fre. (%)**	**Fre. (%)**	**Mean**	**Mean**	**Mean**	**Mean**	
1. Adapt easily to new ideas	181 (39.0)	275 (59.3)	5 (1.1)	3 (0.6)	3.103	3.425	3.388	3.573	3.36
2. Discover new ways of looking at problems	119 (25.6)	335 (72.2)	10 (2.2)	0 (0.0)	3.134	3.266	3.242	3.304	3.23
3. Supportive environment to innovate	85 (18.3)	293 (63.1)	79 (17.0)	7 (1.5)	3.015	2.925	2.922	3.060	2.98
4. Consistently explore new ideas	136 (29.3)	313 (67.5)	13 (2.8)	2 (0.4)	3.039	3.250	3.213	3.539	3.25
Business Competitiveness (BC)									
5. Original outcomes from imaginations	123 (26.5)	312 (67.2)	25 (5.4)	4 (0.9)	3.000	3.141	3.106	3.539	**3.19**
6. Gather competitors information	128 (27.6)	279 (60.1)	48 (10.3)	9 (1.9)	3.047	3.183	3.165	3.147	**3.13**
7. Understand the threat	123 (26.5)	307 (66.2)	32 (6.7)	2 (0.4)	3.063	3.158	3.135	3.400	**3.18**
8. Leverages on the weakness of the competitors	104 (22.4)	313 (67.5)	38 (8.2)	9 (1.9)	3.103	3.041	3.077	3.191	**3.10**

The following findings were made based on the table above:

i. Most of the respondents which accounted for 72.2% agreed that women entrepreneurs discover new ways of looking at problems to sustain the business.

ii. Most of the respondents which accounted for 59.3% agreed that women entrepreneurs adapt easily to new ideas to boost their business.

iii. In order to establish if women entrepreneurs are consistently explore new ideas for their businesses, if we combine the respondents opinion of strongly agreed and agreed together, it shows that 449(96.8%) of the respondents were of the view that women entrepreneurs are consistently explore new ideas for their businesses

iv. This implies that most of the respondents which accounted for 63.1% agreed that women entrepreneurs have a supportive environment to innovate new things.

v. Table 4.2 also shows the mean score of the extent of respondents' opinion on each of the items of measurement. The mean scores were presented according to the association of the women entrepreneurs that participated in the survey. Going by the criteria presented in Table 4.2 and the average mean scores presented in Table 4.3, it shows that all the respondents across the selected associations agreed with all the statements or items that were used for the measurement of creativity of women entrepreneur except item 2 that most respondents strongly agreed.

vi. It was observed that 123(26.5%) of the respondents strongly agreed that women entrepreneurs imaginative activity is fashioned to produce outcomes that are original, 321(67.2%) agreed with the statement, 25(5.4%) disagreed while 4(0.9%) strongly disagreed with the statement. However, most of the respondents which accounted for 67.2% agreed that women entrepreneurs' imaginative activity is fashioned to produce outcomes that are original.

vii. It was also discovered that, 128(27.6%) strongly agreed that women entrepreneurs gather competitors information continuously to boost their business, 279 (60.1%) agreed with the statement, 48(10.3) disagreed with the statement while 9(1.9%) strongly disagreed that women entrepreneurs gather competitors information continuously to boost their business.

viii. However, most of the respondents which accounted for 60.1% agreed that women entrepreneurs gather competitors' information continuously to boost their business.

ix. In order to find out if women entrepreneurs seek to understand the threat associated with their business in order to stay ahead of the competitors, 123(26.5%) strongly agreed with the statement, 307(6.7%) also agreed with the statement, 32(6.7%) disagreed while 2(0.4) strongly disagreed that women entrepreneurs seek to understand the threat associated with their business in order to stay ahead of the competitors.

x. Most of the respondents which accounted for 66.2% agreed that women entrepreneurs seek to understand the threat associated with their business in order to stay ahead of the competitors.

Figure 4.2 : PLS Algorithm Model

C1= Adoption of new ideas, C2= Sustainable business via problem solving, C3=Supportive environment, C4= Exploring new ideas constantly. BC1= Imaginative activities, BC2=Competitors information, BC3=Understanding treats, BC4= Leveraging on weaknesses of competitors

Figure 4.2 shows the PLS algorithm model of creativity of women entrepreneurs and business competitiveness. The path shows the level of relationship between the two variables. R square (R^2) values which is categorised into substantial, moderate and weak with the following values ≥0.75, ≥0.50 and ≥0.25 respectively. Figure 4.1 shows that the R2 = 0.933 for creativity of women entrepreneurs and 0.395 for business competitiveness. This implies that all the factor loading items of business competitiveness substantially explain 93.3% of the variance in creativity of women entrepreneurs. In a related development, the figure also depicts that creativity of women entrepreneurs also explains 39.5% of the variability of business competitiveness. This implies that the items of creativity of women entrepreneurs weakly but significantly explain 39.5% of the variance in business competitiveness

Conclusion and Recommendations

The result from the analysis of the hypothesis shows that there is a significant positive relationship between creativity and business competitiveness. The components of creativity (adoption of new ideas, sustainable business via problem solving, supportive environment, exploring new ideas always) affects business competitiveness. This finding corroborates the study of (Kura, Abubakar & Salleh, 2020), who identified the need for creativity by entrepreneurs as an essential ingredient for business competitiveness. Meanwhile, the findings from the hypothesis also validate that having a supportive environment makes it easy for creative and constructive ideas to be generated, this is also true as it helps the entrepreneurs always to have the opportunity to explore new ideas.

The studies of Sánchez-Gutiérrez, Cabanelas, Lampón & González-Alvarado, 2019 indicated that the ability of entrepreneurs to create customer relations and the way they knowledge of customer needs is converted into specific choices in the market positively effect on customer value creation. Financial performance, optimization of cost, technology, are all indicators of competitiveness, which is a result of creativity. This assertion was supported by the findings where entrepreneurs agreed that they get the competitor's information continuously to boost their business. Likewise, entrepreneurs need to understand the threats, opportunities, strengths, and weaknesses associated with their business.

Understanding their SWOT will put them ahead of their competitors, encourage them to adapt to any upcoming changes, generate new ideas that will sustain their business, thereby culminating in increased performance of their business. This study concludes that women entrepreneurs do not have a supportive environment to create new things and ideas. However, this has also motivated them to discover new ways of looking at problems to ensure the survival of the business. The Nigerian government is encouraged to provide a creative enabling environment for business owners in the country. Based on the study, women have been discovered to have a high level of creative ability, which is a very pivotal entrepreneurial trait.

In essence, already established companies and institutions should encourage women to climb the managerial ladder as research has shown that women-managed business thrives better than men-managed businesses.

Innovative Educational Method at Practice-Oriented Studies at The Faculty of Logistics

Paweł ŚLASKI

The Faculty of The Security, Logistics and Management at The Military University Of Technology,Poland
pawel.slaski@wat.edu.pl

Abstract

The article describes an innovative universal educational method (form) developed based on modern methods, techniques, and tools supporting the educational process at the Faculty of Security, Logistics, and Management at the Military University of Technology (MUT). The original way of teaching concerns the application of lateral thinking and the so-called "questioning methods" (also known as 5W1H, Five Ws, or Kipling ones) in the process of ordering various goods from suppliers to customers with whom they cooperate in the supply chain. Teams of students in their logistics exercises using the "Six Thinking Hats" method, a concept developed by E. de Bono, analyze the complex problem posed by the lecturer. The key benefits the students received from this type of learning include verification of their existing way of thinking when solving a problem and taking a creative approach to solving the task. The advantage is also its simplicity and universality. Empirical research confirms that the learning methods not only increase the attractiveness of classes (93%), satisfaction with the acquisition of creative thinking skills but also bring contentment with the team solving a complex research problem (91%).

Keywords: Innovative Universal Educational Method, Six Thinking Hats, Reengineering

Introduction

Industry 4.0, where an intelligent information system controls all processes, is becoming a reality; thus, the capacity of universities to react quickly to changes in this environment is essential. Since change is stimulated by innovation, identification of the latter issue is crucial in solving engineering problems.

Peter F. Drucker (2005), the creator of modern management theory and practice, defines innovation as an opportunity to undertake new ventures and services, hence it is a new value or quality introduced to achieve better results. Innovation is, therefore, an integral part of a dynamic, complex world that responds to the growing demand for new technological solutions.

How to bring a university graduate into this world?

How to create or develop in them the skills and competencies necessary in the modern labor market?

The author attempts to answer those research questions in this article, which recommends a positive approach to effective and innovative education in the light of the research results.

The article aims to present an innovative method (form) of conducting practical classes with students at the Faculty of Logistics. It has been used to improve the traditional theoretical way of ordering various goods.

According to the author of the article, the critical aspect of using the developed method (form) in the education of a future engineer - logistician will be the creation of their own learning path. It is monitored by an academic teacher allowing, thanks to the student's involvement, passing to the area of independent work using the available research and academic potential. The future engineer-logistician

should learn about the possibilities, as well as be able to choose the right solution and a decision map in his or her future career. The teacher's role will be to indicate how to read the developed decision map without suggesting and imposing a solution.

In the further part, the article explains the empirical method of group ordering of goods alongside the stages of its realization in detail. Next, the essence, principles, and Business Process Reengineering (BPR) methodology by Hammer and Champy (1993) are presented, as well as a short description of E. de Bono's "Six Thinking Hats" method.

In the central part of the article, the author presents the concept together with instructions for the implementation of the developed innovative educational method (form) and its evaluation using the available research and academic potential and prepared props.

Literature Review

The author reviewed the literature on selected empirical methods whose stages of methodology were used to develop a hybrid innovative educational method. The literature review concerned the following methods:

- ✓ Reengineering (Business Process Reengineering),
- ✓ Group ordering method (Coverage analysis),
- ✓ Process analysis,
- ✓ Six Thinking Hats method.

The Reengineering method drafted by Hammer and Champy (1993) concerns the overall reconstruction of the process, which should be critical for company management. For the reconstruction, quantitative and qualitative auxiliary methods and tools such as benchmarking, the DMAIC cycle, Six Sigma, or SMED technique are generally employed.

Business Process Reengineering (BPR) can be defined as a method of a thorough transformation of overall processes in a company Hammer, Champy (1993). The starting point of this method is an in-depth analysis of customer needs, and the aim is to optimize three fundamental determinants: quality, cost, and cycle times.

Reengineering is based on four general principles:

1. starting with customer's needs,
2. analyzing company process,
3. considering existing constraints,
4. thinking creatively.

BPR is a typical process analysis whose first and at the same time key stage is to define the goal that the team involved in the process reconstruction pursues under the needs of the recipient for whom the reconstruction is conducted.

The pioneers of Reengineering were Hammer and Champy (1993), who proposed the following methodology:

1. the choice of the process to be reconstructed (it should be justified by the shortcomings of the processes carried out, their importance for clients, the probability of obtaining significant effects in the case of using Reengineering);
2. creating a working team (for only one process reconstruction);
3. understanding the process (one must put oneself in the role of clients and specify their requirements and real needs);
4. reconstruction of the process (using the benchmarking support method and three assumptions: the rejection of the established rules, application of Reengineering principles, use of new information technologies).

5. implementation of the reconstruction in practice (it can be realized wholly, or through pilot actions, with attention paid to monitoring implementation in both cases).

The conducted Reengineering process should bring effects in the form of, for instance, reduction of operating costs by 50%, increase of the company's profit by 60%, or shortening the delivery time from 3 (three) months to 2 (two) weeks.

The theoretical method of ordering various goods, the so-called "coverage analysis", is analyzed second. It allows obtaining a scale effect in the process of controlling stocks of assortment groups. Appropriate grouping of goods at suppliers' and delivery execution causes minimizing the average value of inventory at the customer's, and thus lowering the costs of inventory maintenance in the warehouse. Krzyżaniak (2002) and Sarjusz - Wolski (2000) defined the assumptions and limitations imposed on goods group orders:

1. Restrictions related to the supply process (a certain number of deliveries in the replenishment cycle, limitations of warehouse space, limited capital allocated for financing the stocks).
2. The required quality of customer service linked to the simultaneous availability of a group of goods.
3. The cost of ordering (creation - development and realization of delivery) is fixed and results from external limitations.
   Due to the complexity of the problem, the following research problem has been posed:

   How to control the stock of assortment groups to minimize the average value of the stock, on the assumption that the cost of ordering is fixed and results from external constraints? Ślaski (2017).

   The empirical method consists of five sequential stages the implementation of which makes it possible to solve the problem, Sarjusz - Wolski (1998), Krzyżaniak (2000), Murdoch (1965), Brown (1959), Lewis (1975):

1. Calculation of planned purchases for each assortment in the adopted period (1):
   $$W_i = P_i \cdot c_i \quad (1)$$
2. Determination of the square root of these values: $\sqrt{W_i}$
3. Calculation of the sum of square elements from the value of planned purchases of the goods group concerned: $\sum \sqrt{W_i}$
4. Calculation of the constant of coverage "k" (2):

   $$k = \frac{\sum \sqrt{W_i}}{l_d} \quad (2)$$

   where: l_d is the total number of deliveries

5. Determination of the so-called calculation number of deliveries for each good (3):

   $$l_{do} = \frac{\sqrt{W_i}}{k} \quad (3)$$

where: w_i − value of the *i-th* assortment; c_i − unit cost of the *i-th* assortment

In the final stage of the methodology, optimal volumes of supplies of goods for which the value of stocks, and thus storage costs, are minimal are determined.

The methodology is not tricky but labor-intensive. Moreover, it must be remembered that optimal delivery volumes are integers and, importantly, their rounding does not have to result from mathematical, but economic and intuitive rules.

The abovementioned methods are effortful, and their application is at risk of failure in a dynamically changing environment. The difficulty lies in the fact that the quantities determined in the empirical ordering method are not always optimal, and the selection of auxiliary methods makes it impossible for the Reengineering process to run optimally.

Innovation-Based Learning

The author's method is not to solve the problem based on the methodology of coverage analysis, but to propose a simple and less labor-intensive method using the Reengineering method and "Six Thinking Hats", and most importantly, to achieve an optimal effect. The classes conducted in this way will teach students process and creative thinking as well as making independent decisions.

Edward de Bono, the creator of lateral (creative, innovative) thinking, describes in his books how to free oneself from common and stunt thinking (De Bono, 1968), (De Bono, 1969), De Bono (1970), De Bono (1971), De Bono (1972), etc. He teaches conscious reasoning and its various variations, from critical appraisal, idea creation, analysis, and deduction, to the search for alternatives when solving a problem.

The creator's method called "Six Thinking Hats" De Bono (1985) can be helpful in the organization and conduct of the classes.

The objective of the method is to change the way of thinking from the so-called "argument mode" to the mode of developing a creative decision map.

Each of the thinking hats is a different color, which constitutes their identification. Hats, in a sense, reflect the way of thinking through entering into the role of the person wearing them. They are also a form of visualization and a way to distinguish them from each other. Hats have different colors: white, red, black, yellow, blue, or green. The white hat is neutral and presents a "photograph" of the problem in an objective, quantitative, and qualitative way. The red hat allows emotions and feelings to work. It provides a formal and precise way of bringing out the irrational aspects of thinking (e.g., hunch and intuition) in the form of fully-fledged elements of a decision map. The black thinking hat means an evaluation of the adverse effects of the problem. In terms of a black hat, thinking is used to assess the problem from experience gained in the past. The black hat puts harmful elements on the decision map being created to specify errors in the adopted methodology. Thinking in the yellow hat category is constructive and creative. The yellow hat is an evaluation of the positive effects of the problem, and its overriding goal is effectiveness. The blue hat is associated with the control and organization of the thought process. It is responsible for summarizing and reviewing the situation. The blue hat makes it possible to create a thought process leading to a decision map, monitor the process, and oversee the rules of the "game." The green hat is used for creative (lateral) thinking. Its primary role is to find alternative solutions to generate new and creative ideas.

Thinking in the Six Thinking Hats method is a two-stage process. In the first stage, while putting on the appropriate hats, the research teams decide on a map consisting of different types of solutions depending on the color of the hat. It enables them to choose the best way in the second stage.

What are the benefits of using the Six Thinking Hats method and how to use it in practice?

As Edward de Bono (1985) claims, this method provides the following advantages:

1. The ability to play a role. The hat helps to think and talk about issues and problems that are so-called inconvenient and not always addressed in a given environment.
2. The orientation of the attention. Hats help to orient the way of thinking on different aspects of a problem.
3. Simplicity and comfort. The symbolism of six hats makes it easier to perceive the problem in a positive, negative, or emotional way.
4. Possibility of establishing rules of conduct. Thinking hats set rules (games) of thinking, which stands as a decision map.

State of Research

The need to implement innovative educational methods was discussed and emphasized by the Ministers of Science at the Conference of Ministers of the European Higher Education Area (EOSW) in Yerevan in 2015.

The education at the university level is carried out using, among others, the PBL (Problem Based Learning) method, the so-called "seeking education," by the Aalborg University, Maastricht University, Polytechnic University College of Donostia - San Sebastian, Eindhoven University of Technology, Lodz University of Technology, or Warsaw University of Technology. Some of them have additional classes conducted in this methodology, some of the universities have included the seeking education in their curricula as courses, while others, like Aalborg University, have organized the entire training cycle based on this methodology. Aalborg, as one of two centers, has a Centre for Problem Based Learning in Engineering Science and Sustainability under the auspices of UNESCO. An example of the implementation of classes with innovative methods in Poland is the course realized at the Warsaw University of Technology by the Rector's team for innovative forms of education INFOX PW called *Creative Project Semester* (KSP). Students work in teams of 5-8 people and learn to solve real problems commissioned by the Warsaw City Hall and entrepreneurs. Each team is supervised by a lecturer who guides students through the process of task solving. The PBL method is divided into stages, as shown in Figure 1. The work is executed in small groups under the supervision of a lecturer. A team leader/moderator and a secretary who notes down the findings and the information worked out by the group so that nothing is left out, are chosen from among the students.

Figure 1: Stages of student group work using the PBL method

Source: Own study.

Stage 1 shows what the group work allowing the development of communication and discussion skills, brainstorming, identifying small tasks, goals, or problems is. Stage 2 is a joint identification of the real state of affairs, a kind of knowledge and experience the team has about the task, and causes and effects of the analyzed problem. Then the cognitive goals are defined, and the division of work is established. Stage 3 of PBL is characterized by searching for answers through individual work on all available channels: materials, library, experts, multimedia, institutions related to the problem, and so forth. Stage 4 serves the purpose of data aggregation during the mutual exchange of information aimed at finding a solution. This approach allows learning not only facts but also requires thinking, searching for solutions, cooperation, constructing conclusions, and feedback, due to which one can learn more through practice and cognitive sessions. It also gives the opportunity to get to know the opinions of others and learn to respect different views.

International experience indicates many variations of PBL: Design based learning, Active Learning, Collaborative Learning, Inquiry-based Learning, Cooperative Learning, Peer Led Team Learning, Team-based Learning, Peer Instruction, Inquiry Guided Learning, Just-in Time Teaching, Small Group Learning.

Organization and Way of Conducting Classes - Instruction for The Lecturer

The author of the method is an assistant professor at the Institute of Logistics at the Faculty of Security, Logistics and Management at the Military University of Technology (WLO WAT). He teaches the subjects of "Inventories in logistics systems" and "Designing logistics processes" at the third-year studies of a practical profile at the Faculty of Logistics.

Other lecturers can use the developed method to conduct classes at universities. Table 1 provides the instructions to follow.

Table 1: Instruction on organization and way of conducting classes

Phases	Stages	Instructions for conducting classes
Preparation phase	Gathering necessary props	The lecturer prepares hats made of paper in six colors.
	Preparation of the lab	Before the classes, the lecturer checks whether the computers have the Microsoft Office with the Excel spreadsheet (the educational version) installed.
		Installing the Solver optimization add-on in the Excel spreadsheet (it enables solving tasks related to operational research, i.e., linear and non-linear programming).
	Creation of research teams	The lecturer divides the student group into research teams. Each team consists of 4 - 5 students.
		The lecturer provides the teams with sets of six-color hats.
Initial phase	Reengineering Method	The lecturer discusses the Reengineering Method by Hammer and Champy.
	Group ordering method, the so-called coverage analysis	The lecturer discusses the empirical method of group ordering of goods.
	Six Thinking Hats	The lecturer explains to the students what hats are used for, what their colors mean and what is the order of putting on hats when solving a problem.
Main phase	Task presentation	Lecturer presents on slides the task to be solved to research teams and formulates the research problem.
	Practical activity in teams	The students in teams develop a thought map using prepared props and research equipment.
		Presentation in teams of the chosen thought path.
	Discussing the results of team work	The lecturer listens to the problem-solving proposals presented by the teams, and then summarizes the classes and presents the original solution.

Original Presentation of The Classes

The classes take place in the computer lab at the Institute of Logistics at WLO WAT in the 2x45 min lesson block in three student groups of 30 people in each. Students in groups are divided into six teams of five. Each team has a leader who presents the team's solution to the problem in the final part of the classes. The classes are held within the course: "Stocks in logistic systems." It is a specialist subject for the completion of which passing an exam is required. The theme of the classes is the process of group ordering of goods from suppliers in the logistics chain. Assistant Professor Ph.D. Paweł Ślaski – the author of the method, conducts the classes.

The teacher begins the classes with a discussion of their purpose and research problem. Then, during the presentation, the lecturer defines the input data, assumptions, and limitations concerning the subject matter, as well as explains how to use the Excel spreadsheet and the Solver optimization add-on. Next, students in teams analyze the task set. In the first stage, they put on white hats. The teams solve the task in Excel spreadsheets using the empirical methodology of coverage analysis, the stages of which are described in the literature review section Brown (1959), Murdoch (1965), Kumar (2007), Ślaski (2017), Krzyżaniak (2003). The characteristic feature of this stage is the reproducible application of the theoretical method of group ordering, while the effect obtained is objective and neutral. It is a practical approach to the problem posed and, at the same time, a starting point for the thought map that is being drawn up. Another hat that students wear is red hats. The critical way of thinking in a red hat is to make intuitive decisions. The mode of intuitive thinking applies to the last stage of coverage analysis and is related to determining the optimal delivery volumes. However, they are non-integer values. Therefore, when wearing red hats, the teams have the task of rounding these quantities intuitively (not mathematically) in such a way that their sum is consistent with the assumed annual delivery frequency. Intuitive thinking in red hats allows teams to search for such scenarios that will lead to an optimal solution to the research problem posed. Making optimal decisions based on intuitive thinking is not an easy task. The students have had short internships in companies and do not yet have relevant practical experience. They put on black hats and draw negative conclusions from their previous analysis. They ask questions: Is their delivery plan optimal? Has their intuition let them down? Does the obtained effect minimize storage costs? The lecturer observes the reactions of the students wearing black hats and suggests positive thinking while taking account of the risk of failure and teams' creating the wrong path of thought. The teacher suggests putting on a yellow hat. The students are aware that despite possible failures, they can count on support and guidance from the leader. In yellow hats, they draw definite conclusions from their previous activities and focus on the benefits of teamwork. They also pay attention to the possibility of choosing the right path of thought and, consequently, making the right decisions in their future professional work.

The teacher recalls that the green hat is next and should lead the teams to set the right path on the thought map. With a positive attitude after yellow hats, then came the time for creative thinking. The students put on green hats. The most significant thing in this mode is to change thinking from traditional, established during literature analysis to innovative (lateral). An essential part of lateral thinking may constitute the use of conscious "provocation". One of the effective ways of triggering provocation is the so-called "reversal". It consists in the fact that teams analyze the problem classically and then solve it starting from the last stage (from the end). Therefore, the lecturer suggests that, under the Reengineering methodology Hammer, Champy (1993), the teams should focus on understanding the process and choosing an effective optimization method. The students in teams, following the teacher's recommendations, move to the analysis of the ordering process from the final result, i.e., from determining whether the achieved total delivery volumes meet the expectations of the potential customer.

$$SWZ = 0{,}5 \cdot \sum_{i=1}^{n} \frac{w_i}{l_{di}} \rightarrow min \tag{4}$$

where:

SWZ – average value of stocks
w_i – value of the *i-th* assortment

l_{di} – total delivery volumes of the *i-th* assortment

Then the research problem defined by the formula (4), which is also a function of the target, is saved by the students in the Excel Solver Dialogs. Delivery volumes are treated in the Solver application as decision variables and the limitations and assumptions of the process concern the expected total annual delivery frequency and the adoption of variables as non-negative integers. Starting the application as a non-linear one determines the total optimal delivery volumes with minimum stock value. The students in green hats analyze the task with great interest and commitment. They note with satisfaction that solving the problem in a new way is much faster than traditional and more comfortable to apply.

The last hats that teams put on are the blue ones. In this mode of thought, the students monitor the course of solving the problem at each stage of the design and create a path for optimal decisions. The classes end with a summary and conclusions from the exercise.

Verification and Evaluation of The New Educational Form

Statistical evaluation of the conducted survey was related to the analysis of students' skills and competences of practice-oriented studies at the Faculty of Logistics.

The research focused on the assessment and proposal of organization and method of conducting classes based on the developed innovative method of education.

The result of the survey should be answers to the following questions:

1. To what extent does the educational process include the need to prepare students to be innovative, i.e., initiators and creators of change?
2. Does the academic community recognize the importance of the skills that are components of future innovative competence?
3. Has the new method applied during classes brought an effect in the form of:
   a. Increasing the attractiveness of classes?
   b. Students' satisfaction with the possibility to work in teams?
   c. Satisfaction with acquiring creative thinking skills?

Diagram 1 displays the analysis of the fundamental questions asked to the students in the survey.

Diagram 1: Analysis of a survey conducted among students

Source: Own study.

A Student's T-Test was conducted for independent tests before and after the implementation of the method into the academic process to verify the developed new method (form) of education. The statistical verification was based on the analysis of the questionnaire for the key question:
Has the new method applied during the classes brought the result in the form of satisfaction (contentment) with acquiring creative thinking skills?

It was assumed that the statistical data used for the verification are of normal distribution character. The survey covered a group of n=30 students of full-time practice-oriented engineering studies at the Faculty of Logistics. The test consisted in determining whether the difference between the obtained averages of tests is statistically significant.

To this end, two research hypotheses were put forward - the H_0 zero hypothesis for equality of averages and the H_1 alternative hypothesis for the diversity of averages (5):

$$H_0 : A_1 = A_2 \; ; H_1 : A_1 \neq A_2 \qquad (5)$$

Then the Student's t-test was carried out for two tests assuming equal variances that gave:

Averages A_1= 72%; A_2 = 93%

The results obtained were as follows:

$t = -1{,}88$
$df = 58$
$p = 0{,}06$
For $\alpha = 0{,}05$ it was determined:

$$t_{critical} = T.INV(\alpha; df) = T.INV(0{,}05; 58) = 2{,}0 \qquad (6)$$

and since $K = (-\infty;\ -2{,}0\rangle \cup \langle 2{,}0\ ;\ +\infty)$, it is justified to reject the H_0 hypothesis, i.e., the difference in averages before and after is statistically significant.

Conclusions

The method described in the article is universal. Although its verification was carried out in engineering studies in logistics, classes with its application can be conducted at various profiles and faculties. The author of the article believes that the developed method is innovative as it employs the mode of lateral (creative) thinking and is also a kind of hybrid. It is a combination of methods such as Reengineering, process analysis, and operational research. The statistical analysis of the questionnaires confirmed that the students solved the task much faster, and the organization and course of the classes were more interesting than reaching solutions in a standard way. An attempt to think creatively with the use of colorful hats and a simple, commonly used and cheap-to-use tool (Excel spreadsheet) enabled the students to develop the right thought maps and make optimal decisions. The current global situation and the dangers of coronavirus result in suspended classes for college students. The developed method enables distance learning, so-called e-learning. Students form groups and connect with each other via Skype. Using the internet platform, they share the conclusions developed in the field of using the thought hat. The Excel spreadsheet used as part of the method enables the transfer of online solutions, thus facilitating distance communication for students. Such classes do not require the use of complex applications and e-learning platforms. Students work at home using their private computer equipment and make the right decisions without much effort. In a situation of risk of being infected with a virus, focusing on interesting activities without the need for contact with the environment is crucial.

Albert Einstein's words: "Everything must be done as simply as possible, but not simpler" has become a fact.

E-Services in Managing A Territorial Self-Government Unit in Poland

Magdalena ROMAN

Czestochowa University of Technology, Czestochowa, Poland
E-mail: magdalena.roman@pcz.pl

Abstract

This article presents managing e-administration and e-services on ePUAP and SEKAP platforms in territorial self-government units. In the administration sector it is important to implement Electronic Documentation Management to facilitate, unify and accelerate the work of territorial self-government units. The catalogue of e-services in territorial self-government is growing, and services are becoming more and more mature.

Keywords: E-Service, Management, Territorial Self-Government Unit

Introduction

The need for management always appears during performance of joint activities for the given community. The ability to coordinate and properly manage tasks significantly affects achieving the defined goal. Management is a process conducted in every organized community. Management accompanies human activities. It is a process of impacting the organization's resources in order to achieve its goals.[1] Resources should be selected, collected and used in accordance with defined goals. A goal means a define state of affairs aimed at by the organization. Every organization strives to achieve the goals of owners, employees, as well as people and institutions in the organization's environment. Every organization sees the clash of various aspirations, and management may be seen as the process aiming at reconciling these aspirations, and providing a certain balance between requirements set by the above-mentioned entities.[2]

Management has the following characteristics:

- It has the nature of an informative/decision-making process;
- It combines the attributes of management work and team work;
- It is a system of actions that regulate the process flow in the given organization;
- It is a coordinating process, which harmonizes activities of various persons, institutions and business entities.[1]

The elements of the constructed concept of management may be defined as elements of the organization management system. It is worth noting that management has interdisciplinary nature, and its characteristics and components may be applicable to managing an organization such as a territorial self-government unit.

E-administration in a Self-Government

The concept of a territorial self-government is broad and includes the community of residents, the defined territory, the scope of authorizations, as well as the legal personality.[3]

A territorial self-government is to serve the purpose of building mechanisms of democracy and decentralization of public authority, therefore it includes democratically constituted decision-making

bodies, which enjoy broad autonomy. In legal and economic terms, a territorial self-government plays the role of both a body governed by public law, which has the ability to issue administrative decisions, as well as a body governed by civil law, which is separate from the State Treasury and has own assets. The essence of the process of managing territorial self-government units is that in legal and economic terms the territorial self-government has two roles.

The basic fundament of new management in a territorial self-government unit is to introduce a manager model of public management, which has the following characteristics:

- Citizen-client oriented administration;
- Emphasis on monitoring results and not only procedures;
- Strategic and operational functions are separated;
- Public functions are delegated to competing organizations from outside of the administration;
- Mechanisms of control over decentralized entities are introduced, e.g. through various types of social control; result-based management measured by indicators is introduced; support services are outsourced through public procurement, thus ensuring competitiveness of offers.[4]

Services provided electronically mean that a service is performed without simultaneous presence of both parties (at a distance), through a transfer of data on individual request of the client; the service is sent and receive using electronic processing devices, and it is fully transmitted or received through a telecommunications network.[5] [6]

Electronic services include services provided via the Internet or an electronic network, the provision of which is generally automated, due to their nature, and requires only minimum human participation, and which cannot be performed without information technology.[7]

To perform public tasks, a public entity uses public ICT systems which meet the minimum requirements and ensure interoperability of systems based on rules defined in the National Interoperability Framework.[8]

New rules of entrepreneurship and new technologies are strictly related in the electronic economy; they encroach upon one another and are interdependent. There are three most important entities in e-economy: enterprises, clients, and the administration. These relations should always be two-way. E-services distinguished in territorial self-government units include:

- A2A, meaning administration-to administration relations between public administration offices e.g. in a commune;
- A2B, meaning administration-to-business relations;
- A2C, meaning administration-to-consumer relations.[9]

The Electronic Documentation Management (*pl: EZD*) is implemented in public administration and it is setting the standard for this class of systems. The implementation of the Electronic Documentation Management is taking place within the scope of a project entitled "*EZD RP* – electronic documentation management in public administration". The system, being the final product of the project, will be distributed not-for-profit starting from 2022 to public administration entities. Installation of systems will be executed in own infrastructure of territorial self-government units. To increase the availability of the EDZ system, a possibility to provide it as a cloud service is considered. Public administration entities e.g. communes will use the Electronic Documentation Management system without the need to maintain own infrastructure and resources.

The system will enable preparing comprehensive documentation of the process of handling and resolving affairs in territorial self-government, as well as support:

- Creation, processing and flow of electronic and paper documents (including incoming and outgoing correspondence);
- Management of electronic and paper files and documents, including their transfer and archiving, information management.[10]

Project execution means, on the one hand – an ICT system, and on the other hand – a supra-regional range. Ties are formed within the scope of cooperation, and working on solutions and their possible modifications is supposed to make administration more effective as well as limit or eliminate bureaucratization. The goal of the project is to unify and adjust the system to the needs of public administration. The process is executed on not-for-profit basis, free of charge, using human resources and own means of offices, as well as the "know how" generated and published on the electronic platform at http://ezd.gov.pl. The system has been and is being implemented in, amongst others, thirteen voivodeship offices, in the central government administration, self-governments, universities, courts, and in health care. Currently it covers over 470 offices (status as at February 2020) and over 86000 public officials. The list of entities, which introduce the Electronic Documentation Management is growing, and expands the network of cooperating offices. [11]

E-services on ePUAP and SEKAP platforms

Communication between the citizen, entrepreneurs, and territorial self-government units or central administration can take place through the following platforms:

- ePUAP (Electronic Public Administration Services Platform) – a national ICT platform. [11]
- Regional platforms such as SEKAP (Public Administration Electronic Communication System in the Silesian Voivodeship). [8]

A citizen wanting to use e-administration services must create a trusted profile on ePUAP. The conditions for creating a trusted profile are defined in the Act on the computerization of the activity of entities performing public tasks. The profile includes identification data: first names, last name, date of birth, the number in the General Electronic Population Registration System (*PESEL*). During the profile verification procedure, data is verified automatically against the PESEL data. The ePUAP account is an electronic mailbox to receive official correspondence. The request should include an email address for correspondence with the public office. Creating a trusted profile requires visiting a Confirmation Point and presenting a personal identity card or a passport. The profile serves for logging into public administration systems and using public e-services. Approximately one million people in Poland use ePUAP e-services. After sending or receiving official correspondence, the user receives an Official Confirmation of Receipt; every territorial self-government unit is required to have an Electronic Correspondence Registry (*ESP*). [8]

The following sectors of e-services are available for natural persons on the ePUAP platform:

- Child – child birth, excerpts of birth certificates, child residence registration, the Family 500+ programme;
- General matters – official correspondence;
- Residence registration – permanent or temporary stay;
- Automotive and transportation – driving license, vehicle registration, international register and transport;
- Geodesy and cartography – building numbering, providing data from the central/ poviat/ voivodeship geodesy and cartography resources;

- Environmental protection – declaration about the amount of the fee municipal waste processing, grants for low emission source liquidation, product fee concerning packaging and products;
- Cultural activities, sports and tourism – accepting notifications about organization of a public gathering, entry in the register of facilities providing hotel services for entities which are not hotel facilities;
- Infrastructure – blocking of a road strip, permission to place an advertisement in a road strip, reporting a damage in the surface of roads and pavements, reporting a vehicle damage;
- Judicial enforcement – electronic transfer of titles of enforcement, overlap of enforcement.

The following e-services are available for entrepreneurs:

- Certificate of entry in the register of business activity;
- Conducting and establishing business activity;
- Entry in the Central Register and Information about Business Activity (*CEIDG*);
- Women Loan Fund, Innovation Voucher Programme;
- Registers and licenses for alcohol trading;
- Legalization of taximeters;
- Amount of real estate tax, information about local taxes;
- Permit to operate pharmacies, psychological therapy.

The above e-services are exemplary; not every municipality offers all e-services and this depends on the level of development of the given e-services in the given municipality office.

The goal of the SEKAP platform is to:

- Reduce the costs of providing public services;
- Raising the quality of public services;
- Expanding the offer of electronic services;
- Improvement of the conditions of commencing and operating businesses;
- Increasing the range of use of information technologies by region residents;
- Increase of the region's competitiveness in national and European scale. [12]

User of the SEKAP platform include: citizens, entrepreneurs, and public administration institutions that may communicate electronically with the Silesian voivodeship offices. There are approximately 700 service cards on the SEKAP platform.

The following catalogue of services is offered on the SEKAP platform:

1. Construction, architecture, urbanism – submitting notifications about constructions or construction works relating to advertisements, issuance of decisions on building permits, issuance of building logs, issuance of decisions on planning permits;
2. Personal identity cards, residence registrations, elections – issuance of personal identity cards to: children under 5 years, children aged 5-18, permanent or temporary residence registration, permanent or temporary residence deregistration, residence registration pursuant to an administrative decision, access to a register of voters, list of voters;

3. Business activity – entry in the register of regulated activity consisting in production of registration plates, submitting a request for an entry on the List of Traditional Products (the remaining part of the catalogue of services is identical with the ePUAP platform);

4. Geodesy and cartography – update of the register of land and buildings, soil-science classification of agricultural and forest land, acceptance of measuring documentation;

5. Municipal engineering – entry in the register of regulated activity in the scope of collection of municipal solid waste from owners of real estate, issuance of permits for routing non-standard vehicles;

6. Communication, roads and transport – the following subcategories are distinguished:

- Drivers training center – entries in the register of entrepreneurs operating drivers training centers, entry in the register of instructors / lecturers, and issuance of professional cards;
- Driving licenses – issuance of national, international and army driving licenses;
- Registration of vehicles – first registration of brand new vehicles purchased in the territory of Poland, registration of vehicles previously registered in other town/ starosty, deregistration of vehicles;
- Vehicle technical inspection centers – entries in the register of entrepreneurs operating vehicle technical inspection centers, issuing authorizations diagnosticians to perform technical inspections of vehicles;
- Road transport of merchandise and people, taxis – granting permits to perform the profession of a road carrier of people / merchandise;

7. Cultural activities, sports, tourism, education – Awards of the Marshall of the Silesian Voivodeship in the area of cultural activities, cultural/ sports scholarships, granting the title of a mountain guide, obtaining grants for execution of educational tasks, extracurricular activities for schools, granting or rejecting the title of appointed academic staff, on-line consultations in the psychological & educational clinic, school scholarships;

8. Real estate, residential and commercial premises – the following categories are distinguished:

- Real estate management – permit for construction within the border, update of the annual fee for perpetual usufruct of land, issuance of a decision confirming the division of a real estate;
- Municipal real estate management – lease of real estate owned by the municipality, lending of municipal or poviat land, purchase of real estate from natural persons and legal persons by the municipality;
- Management of State Treasury real estate – transformation of the State Treasury's perpetual usufruct of land into ownership;

9. Environment protection – the following categories are distinguished:

- Geology – providing geological data free of charge / against charge, granting licenses for mining deposits within the competence of the staroste and Marshall of the voivodeship;
- Water and sewage management – acceptance of water and sewer drainage connections, providing water from hydrants;
- Waste – information about products with asbestos, the location of their use or end of use, issuance of permits to generate waste, issuance of a permit for waste processing/ collection;

10. Air and noise – issuance of decisions on the admissible level of noise, issuance of permits to release gas or dust in the air;
11. Taxes and fees – the following categories are distinguished:

- Natural persons – reporting forest and agricultural tax obligations, electronic payment for taxes;
- Legal persons – reporting forest and tax obligation, electronic payment for taxes;
- Enforcement proceedings – request for discontinuation of enforcement proceedings, request for commencing mediation;

12. Citizen affairs – procedure regarding grants to non-government organizations, execution of public tasks within the scope of local initiative
13. Health and social affairs – register of medical doctors authorized to conduct medical tests of persons requesting a driving license, register of psychologists authorized to conduct psychological tests, additional financing from the State Fund for the Rehabilitation of the Disabled (PFRON) for construction works, sports, cultural activities, recreation and tourism for the needs of the disabled, equipping a work station for a disabled person
14. Regional development – the 2014-2020 Regional Operational Programme of the Silesia Voivodeship, Awards of City Mayor for gifted students and for activities in non-government organizations, cooperation with non-government organizations
15. Promotion and information about the region – issuance of materials and promotional publications, consent for using the city's coat of arms.

Each catalogue of services presents exemplary e-services on the SEKAP platform. The overall level of use of the e-service and the possible scope of handling individual matters electronically have been categorized according to a five-trade scale of e-service maturity:

- Maturity grade 1 on-line service - Information: general information about public services
- Maturity grade 2 on-line service – One-way interaction: possibility to download forms and applications
- Maturity grade 3 on-line service – Two-way interaction: processing of forms. Allows for transferring data both ways: from the service provider to the client and from the client to the service provider. A typical manner of execution is downloading, completing and submitting the form electronically.
- Maturity grade 4 on-line service –Transaction: handling transactions, making decisions on-line, provision of services and handling payments. Allows to fully resolve the given official matter electronically, including any payments.
- Maturity grade 5 services – Customization: organization of services in account of the needs of users. Level 5 allows performing tasks in such manner so that apart from the possibility to fully resolve the given matter it also enables to apply e.g. customization mechanisms, meaning adjustment of the manner of performing the service to the client's special conditions and needs (e.g. offering partially completed forms, informing the client in an SMS about the approaching deadline for certain actions). [13]

Various e-services in territorial self-government units achieve different maturity levels, measured in the five-grade scale. Due to applicable laws, some e-services will only reach level 1 or 2. Many e-services reaches full maturity and others are classified at levels 2-3.

Summary

The management of territorial self-government units in Poland entered the computerization stage about ten years ago and shifted many activities to the e-space. Territorial self-government units such as municipalities or poviats are offices that provide varied and complicated services. Moving these activities into the virtual reality as e-services is a long and time-consuming process. The implemented ICT system – Electronic Documentation Management is to help unify e-administration, and it is to be introduced in all territorial self-government units; the system will be offered not-for-profit starting from 2022. Currently units mat join the project entitled "EZD RP – electronic documentation management in public administration". This project aims at developing and introducing the best system solutions within the scope of EZD. According to the data of the Main Statistical Office (*GUS*) approximately 25% Polish citizens took advantage of e-services in 2016, and 35% in 2018. Many people, in particular 60 plus citizens, are excluded digitally, and do not use these services. Some services on ePUAP or SEKAP platforms are characterized by a low level of maturity, and the role of territorial self-government units is to raise this level. Certain services are not available at all as e-services. The level of the service itself sometimes varies between municipalities e.g. in different voivodeships; some services in are not available to citizens of certain municipalities. The territorial self-government in Poland must work on expanding the catalogue of e-services, and encourage citizens to take advantage of e-services, which take the burden off administration staff and are cheaper than traditional services provided in public offices.

Development of A Network Organization Based on Collaboration in A Supply Chain - How the Implementation of Supply Chain Standards Determines Network Connectedness

Marzena FRANKOWSKA

University of Szczecin, Szczecin, Poland
marzena.frankowska@usz.edu.pl

Abstract

Interorganizational cooperation is becoming increasingly important in the modern economy. The daily practice of enterprises is to simultaneously participate in many interorganizational systems, e.g. network structures and supply chains. At the same time, the interdependencies resulting from the impact of various interorganizational systems are, to date, a relatively poorly recognized cognitive and research area. This article aims to present the complexity of relations between enterprises, which are both network organization actors and links in many supply chains in the context of the increasing connectedness of a network. Operation within the network structure is the more attractive for enterprises, the greater its combinational potential, which is understood as the number of possible relations and ties connected to the actors of the interorganizational network. The article underlines that the conditions for the development of network connectedness may relate to the operational nature of cooperation. As a result of empirical research (135 manufacturing enterprises belonging to cluster organizations and cooperating within cluster supply chains), it was established that there is a positive relationship between the use of supply chain standards by enterprises belonging to an organizational network and the intensity of their cooperation in supply chains. Therefore, the use of supply chain standards by enterprises operating within a network organization is a factor determining the development of the network connectedness.

Keywords: Interorganizational Network, Network, Cluster, Supply Chain, Connectedness.

Introduction

A characteristic feature of the modern economy is the high complexity of market connections of enterprises resulting from, among others, adopting a networked form of cooperation. According to the literature, interorganizational relations, understood as an area in management and organizational theory, cover a wide range of socio-economic relations that are based on social networks (Gulati 1998; Toikka, Miettinen & Tuunainen 2016). The functioning of a network organization is described based on such parameters as cohesion, combinational potential, and method of activation (Strategor 1995) or in the latest conception as "3 Cs": cohesion (strong mutual influence among its members), connectedness (high number of ties), and conciseness (low redundancy) (Muller & Peres 2019). The network connectedness is a present number of ties between its actors, while the combinational potential is a possible number of actors relations resulting from all possible connections. The increasing number of relations between actors operating within a network organization results in a greater number of cooperating entities and contributes to the development of a given structure (Turkina & Van Assche 2018; Frankowska 2018, Zhang et al. 2013). That is the reason, why the network connectedness and combinational potential deserve special attention.

A sociological conceptual apparatus, connected to an analysis of relations, is often used to study interorganizational issues occurring in interorganizational networks. However, in order to explain the phenomenon of interorganizational cooperation, a deeper knowledge of the circumstances associated with the flow of physical and information streams is required. This allows multidimensional observation of the conditions of cooperation between entities, especially those belonging to various interorganizational systems. This paper focuses precisely on the situation where the company is, on the one hand, an actor of a network organization (e.g. cluster organization), under which it builds relations

with other entities and whose goal is to intensify these relations, and on the other, a participant in many supply chains.

It should be added that enterprises' participation in many interorganizational systems, for example, network structures and supply chains, is a daily business practice. At the same time, interrelations resulting from the impact of various interorganizational systems are, to date, a very poorly recognized area both from the cognitive and research point of view (Frankowska 2018). Therefore, there exists a research gap, the filling of which requires multidimensional research that takes into account the conditions of operational cooperation.

In today's turbulent environment, entities cooperating in supply chains are looking for different ways of more efficient coordination of cooperation. One of them is a convergence of operation, encompassing organizational, technological, and behavioural factors. Therefore, special initiatives are being taken to develop a common way of operating within supply chains. These include setting and implementing common standards to ensure consistency among enterprises. As already indicated, the literature on the subject uses a mainly sociological approach when conducting research in the field of network cooperation. Hence, the existence of research and a cognitive gap in recognizing the conditions of network cooperation at the operational level, including those covering supply chain processes, should be emphasized.

The article aims to present the complexity and explore relations between enterprises that are both actors of a network organization and links in many supply chains in the context of increasing the combinational potential of networks. In connection with the above, the research problem was formulated in the form of the following questions:

- What is the intensity of cooperation between enterprises belonging to an organizational network in supply chains?
- What is the scope of standards applied in supply chains of enterprises cooperating in supply chains with other organizational network actors?
- Can the possibilities of establishing or intensifying the cooperation of network organization actors be determined by the scope of standards applied in a supply chain?
- Is the use of network organization enterprise supply chain standards conducive to the development of combinational potential?

To achieve the research objectives, the following article structure was adopted. Based on the introduction, the second section describes the theoretical foundations of cooperation in network organizations, with an emphasis on exchange relations realized within supply chains. The third section describes the importance and areas of standardization in supply chain management. The following two sections present the research model and the results of research carried out among manufacturing companies belonging to cluster organizations and cooperating with other network structure actors in supply chains. In the empirical study, the condition of participation in two interorganizational systems was met. The article ends with a section presenting the conclusions of the research, as well as indicating the values obtained as a result of the research and their limitations.

Development of the network connectedness in the context of cooperation in supply chains

The issue of network organizations is characterized by high complexity, which is also evidenced by the fact that this concept is not precisely defined in the literature on the subject and has many synonyms, such as networked organization, network organizations, interorganizational network and network structure (Kiesler & Sproull 1992; Baker & Faulkner 2002; Higgins & Maciarello 2004; Gibson, Hardy & Buckley 2014). The multitude of views on the subject of networks resulted in the need to identify their main distinguishing features, which include, among others: striving for cooperation, use of market coordination mechanisms, increase in the innovation potential, unity of goals, lack of a dominant role of equity links, low level of vertical integration and hierarchy, as well as natural market flexibility (Niemczyk, Stańczyk-Hugiet & Jasiński 2012). A deeper analysis of individual definitions of a network

organization may lead to an understanding of the definition of the network in an operational and attributive sense. Interorganizational networks in an operational sense constitute a structure describing a specific form of cooperation between entities, whereas, in an attributive sense, they are understood as cooperation between entities who do not create a new form of activity at this stage. The subject of this paper is a network organization presented in the operational sense.

Network organizations consist of two main components: network participants also referred to as actors, and relations between them, also known as connections, ties, or dependencies. The literature indicated the following common features of actors in interorganizational networks (Niemczyk, Stańczyk-Hugiet & Jasiński 2012; Toikka, Miettinen & Tuunainen 2016):

- Creating relations based on resource and knowledge flows,
- Making independent decisions about entering or leaving a network independently,
- Achieving synergies as a result of cooperation (strategic, tactical and operational cooperation systems),
- Interdependence of actors, which is based on the implementation of both common and individual objective goal (which may be different in the individual approach),
- Flexible adaptability, based on the ability to enter modular interactions,
- Ability to actively learn from other participants and synergistically use innovation (the so-called teamwork skill),
- Communicating with other network members despite a high degree of heterogeneity,
- Mutual complementarity (mutual provision of competences),
- Ability to enter risky relations.

The analysis of the common features of network actors indicates the importance of exchanges between them. This makes it possible to refer to the concept of organization as an open system presented by E. Yuchtman and S.E. Seashore (1979), who showed that the effectiveness of an organization (a network organization actor) is its ability to use its environment to acquire rare and valuable resources (from other actors). This means that relations and connections between actors become particularly important. In terms of networking, relations can include any interaction, e.g. cooperation, conflict, trust, communication, exchange, or support (Koźmiński, D. Latusek-Jurczak 2014). Relations between network actors can take a different form, i.e. (Strategor 1995):

- Administrative – instructions, applicable standards and procedures,
- Economical – material and/or financial transactions,
- Operational – joint actions and decision making, using the same resources,
- Cultural – shared norms and values, a unity of opportunities and threats,
- Informational – information availability, exchange, and sharing of information.

Relations are the most important constitutive element of a network. Moreover, network analysis assumes that the relations between network participants affect their activities, although the perspective is not limited only to the actors themselves, but also covers the entire network structure. In literature, the importance of relations, connections and dependencies are particularly emphasized, and network organizations are often defined not so much by the actors themselves, but the exchange process taking place between them (Easton & Araujo 1994). This is closely related to the concept of network connectedness, which is a present number of ties between its actors, and the combinational potential understood as a possible number of actors relations resulting from all possible connections. In the development of a network, the number of actors is not as important as the relations between the largest number of actors in a given network structure. The interorganizational cooperation is implemented based on the capital of the social network that is being built and results in exchange relations in supply chains.

Cooperation and exchange as the subject of research of network organizations have so far focused mainly on the relations between network actors. In the analysis of connections in the supply chain system, this would mean focusing only on identifying the cooperation of entities belonging to a given network organization (supply chain links). However, it should be noted that the actors of a network

organization participate in many supply chains (supply networks), and that, at the same time, not all of them interact with each other. The issue is presented in Figure 1.

Fig. 1: Supply chains in a network organization

Source. Own elaboration.

In conclusion, the above observations may contribute to the development of the combinational potential of a network organization. It can be assumed that obtaining a higher network connectedness should be associated with the intensification of exchanges within the supply chains of entities participating in this organization.

The issue of cooperation in supply chains is complex, as it includes conditions related to the coordination of supply chains, and concerns, among others, the structure of supply chains, relations between partners, the specificity of physical flows in quantitative and time systems, and the implemented supply chain policy.

The importance and Areas of Standardization in Supply Chain Management

A standard can be characterized as a jointly established criterion that defines common, most desirable features of something, e.g. a manufactured object or human behaviour. In technology, a standard is a set of specific parameters ensuring an appropriate level of quality, safety, convenience, or compatibility with other elements (Fechner 2007). Standards are a voluntary agreement (except for security standards) that structure the activities of entities in both macro and microeconomic dimensions. Standardization is formal, and the scope and purpose of introducing standards result from the needs of a specific group of entities (for example, industry sector, transnational corporation, etc.). Furthermore, it is complementary to applicable law.

If the effect of introducing standards in a supply chain is convergence, i.e. unifying the ways of operation of the chain partners, then this mechanism can be justified on the ground of numerous research streams, including the transaction costs theory, resource-based theory, institutional theory and network theory, which is summarized in Table 1.

Table 1: Supply chain standardization in the light of selected theories of management science

Selected research streams	Description of distinguishing features
Transaction costs theory	Aiming at creating an internal (hierarchical) organization enabling greater control, limiting opportunism, and minimizing transaction costs.
Resource-based theory	Skills associated with socially complex procedures that determine the efficiency of the use and matching of resources play a significant role in the analysis of the value chain.
Institutional theory	The isomorphic mechanism is responsible for the convergence of organizations (partners) remaining in a common organizational field, which increases their effectiveness.
Network theory	The homophily mechanism is responsible for creating new relations between actors in networks that are similar to each other

Own elaboration based on: (Barringer & Harisson 2000; DiMaggio & Powell 1983; McPherson, Smith-Lovin & Cook 2001; Williamson 2002; Frankowska & Czyżycki 2018).

An analysis of the perception of the mechanism of similarity or convergence in selected management theories proves that standardization is a source of competitive advantage, as it increases the efficiency and effectiveness of supply chain management, as well as indicates mechanisms that facilitate the selection of partners. A particularly positive impact of the introduction of standards is indicated by logistics experts who claim that they enable improvement of operational suitability and coordination. The effect of standardization is the practical use of solutions that in consequence result in, among others, reduction in the costs of logistics processes, rationalization of transshipment work, facilitating commercial orders, etc. The logistic standard is a set criterion (series of criteria) that specifies the desired characteristics of, e.g. product or logistics service (Korczak 2013). Whereas, standardization in a broader sense allows connecting individual links (enterprises) into an efficient body, as it facilitates reaching an agreement on several activities that affect the production and movement of products. Thus, it has a significant impact on both the effective integration process and supply chain coordination. Similarly, the unification of solutions or actions allows understanding them better in direct contacts between enterprises and thus performing them efficiently and without errors, while avoiding potential conflicts, which frequently result from misunderstanding or a difference in approach to activities (Fechner 2007). N. Fabbe-Costes et al. (2006) prove that supply chain management standards are a source of information and a coordination mechanism that contributes to improving operational compliance, as well as connectivity, efficiency, and effectiveness in interorganizational supply chains due to clear and unambiguous communication between partners. The reasons for using standards are explained by F. Cafaggi (2016), who noted that setting standards are one of the main management tools in supply chains, especially of a global nature. This is due to the involvement of a large number of entities within the chain that operates on markets with different legal and market regulations. Hence, developing, implementing, and enforcing internal standards across multiple dimensions of the supply chain enables the creation of a common language and collaboration tools that partners use.

Processes of convergence in the context of cooperation in a supply chain are reflected in the issues of standardization and normalization. One of the effects of standardization is unification. The convergence of the behavioural patterns of supply chain partners can be beneficial since it aims at improving operational compliance and coordination. It is recommended that logistics processes and practices implemented within the supply chain should be unified in order to secure a smooth flow of materials from suppliers to customers (Stock, Greis & Kasarda 2000). The potentially wide scope of standard implementation results from the high complexity of supply chains, repeatability of operations, as well as problematic areas requiring the development of a specific permanent solution in the field of cooperation between entities. Thus the attempts to classify areas, where standardization is applicable, are of a framework and contractual character (Table 2). Based on the literature analysis, it was possible to identify three areas of the supply chain where standardization has a significant impact on achieving competitive advantage by enabling coordination and integration of partners in the supply chain. These areas include management, regulation, and logistics processes implemented within the supply chain.

Table 2: Selected areas of standardization in the supply chain

Criterion	Selected areas for setting standards
Functional areas of activity spheres	Supply, production, distribution, returns
Logistics tasks	Transport, inventory management, warehouse management, packaging, order processing, customer service
Management functions	Planning, managing, organization, controlling, coordination
Types of movements	Movement of goods, information, financial resources
Types of structures	Physical, information and communication structures
Entities subject to standardization	Supplier, distributor, supply chain leader, R&D unit, logistics operator
Stages of partner cooperation	Preparation for cooperation, start, maturity, conclusion of cooperation
Implementing a sustainable supply chain strategy	Acquisition and consumption of resources
Regulation	Command, control, compliance, monitoring

Source. (Frankowska, 2018)

a. Supply Chain Standardization Area: Management

The growing complexity of supply chains necessitates the convergence of their operations for efficient management. The response to this demand is developed reference models for supply chains, among which the SCOR (Supply Chain Operation Reference Model), created by the APICS Supply Chain Council (APICS, 2011), is of particular importance. The SCOR model allows the use of the same terminology and standard process descriptions to help all participants understand process management in the supply chain and best practices to improve the efficiency of supply chain management, and then effectively communicate using the reference model (Huang et al. 2005; Li et al. 2011). The SCOR model provides (Stefanović et al. 2009):

- Standard descriptions of supply chain management processes,
- Framework for shaping the relations between standard processes,
- Standard metrics for measuring process effectiveness,
- Management methods that ensure the best performance,
- Harmonization of the feature standards and functionality of the supply chain.

b. Supply chain standardization area: regulation

Regulation in supply chains is gaining importance by extending it to many areas of the chain's activity, from the social and environmental dimensions, through data protection, to customer safety and quality. It takes the form of the so-called transnational private regulation (TPR), which complements both national and international law. As part of this complementarity, it is often assumed that national provisions are mandatory minimum standards, while private regulations often introduce stricter standards for supply chain partners. Commercial contracts are, among others, implementing instruments in global supply chains (Cafaggi 2016). Therefore, private regulatory systems have a cross-border effect in many jurisdictions. Moreover, their goal is to harmonize public national systems. Thus, regulatory instruments enable coordination and ensure supply chain stability. Another goal of contracting is to provide forms of coordination among chain participants that reduce their opportunism while at the same time increasing trust and cooperation.

c. Supply chain standardization area: logistics processes

Movement processes involving the physical movement of all goods and the accompanying flow of information are a particularly important area of standardization of supply chains. Logistics standards have a key impact on the implementation of market transactions, mainly by facilitating the exchange of information, with the most important being (Fabbe-Costes et al. 2006):

- Packaging standards (e.g. EURO-pallet, ISO containers),
- Communication standards (e.g. EDI, RosettaNet, XML),
- Labeling standards (e.g. GS1, GHS),
- Product identification standards (GS1),
- Assessment tools (e.g. Standard Performance),
- Quality systems (e.g. ISO 9000).

In order to optimize supply chain processes, the information should be standardized, updated, and regularly available (Brüggemann & Hübner 2008). However, as the research carried out by Ch. Steinfield et al. (2011) suggests, these standards are necessary, although not sufficient, to solve supply chain transparency problems. On the other hand, according to I. Fechner (2007), the features that are the most important, as well as most susceptible to standard use, are information, communication, and movement of products.

Information standards include identifiers and means that enable automatic identification and acquisition of data. A variety of automatic identification techniques are used in logistics, including:

- Optical - barcodes, graphic and letter recognition, image recognition,
- Magnetic - magnetic ink recognition, magnetic tapes,
- Electromagnetic - RFID radio frequency identification and communication, electronic product code (EPC),
- Biometric - recognition of voice, fingerprints, iris, etc.,
- Voice – headphones, microphones, and IT synthesizers of human speech.

Communication standards are electronic messages that replace paper documents and other traditional forms of communication and information exchange of business partners, and allow them to send such documents electronically. Electronic Data Interchange (EDI) is a form of information exchange in the form of standardized messages between independent IT systems of business partners without direct human intervention.

Whereas, product movement standardization is based on a logistic dimensional chain comprising the following elements (Fechner 2007): warehouse areas, ramps, access roads, gates, cranes, warehouse equipment, internal transport and mechanical handling equipment, loading space of vehicles (railway wagons, lorries, ship, and aircraft cargo compartments, etc.), pallets, individual and bulk packaging, logistics units, packaging machines, packaging materials in sheets. The common element connecting all stages of the process is the design of the individual and bulk packaging, which is the result of dimensional relations. The benefits of using product movement standards include, among others, enabling the mechanization of warehouse and transshipment work, rationalizing transport and storage areas, transport safety, and cargo handling (Korczak 2013).

In conclusion, supply chain standardization can be a source of competitive advantage, like better coordination and greater integration of the chain result in higher efficiency and effectiveness. Thus, identification of the use of supply chain standards by the actors of a network organization can be considered a predictor describing the tendency of enterprises to enter into relations with partners, which in turn should contribute to increasing the combinational potential of the network.

Implementation of Supply Chain Standards and The Development of a Network Connectedness – A Research Model

The study aims to determine the relationship between the use of supply chain standards by companies operating within network organizations and the intensity of their cooperation in the supply chain, which in turn affects the development of the combinational potential of the network. The concept of the research model is schematically presented in Figure 2.

Fig. 2: The concept of the research model

Source. Own elaboration.

The following assumptions were made to conceptualize the research model:

- The application of standards in a supply chain improves the cooperation of partners and is a factor conducive to building cooperative relations and improving their coordination.
- For the study, three supply chain standards will be identified in the area of logistics processes, i.e. standards concerning information, communication, and freight movement.
- In line with the achievements of institutional theory, the emergence and structuring of the organizational field are favoured by the constant nature of cooperation between partners. Therefore, it is assumed that closer cooperation of partners may affect the increase of the network connectedness.

Fig 3: Research model

Source. Own elaboration.

The adoption of the above-mentioned assumptions results in the need to include categories of cooperation intensity (frequency) in the research. Therefore, the conceptualization of the research model should take into account the diverse frequency of cooperation (permanent/sporadic) as factors conducive to the development of combinational potential. The research model is presented in Figure 3. To achieve the research objective, the following research hypothesis was formulated:

H1: There is a relation between the use of logistics standards (supply chain) and the frequency of cooperation between enterprises in supply chains.

Characteristics of empirical research and study results

The study was carried out on a nationwide sample of 135 production enterprises declaring belonging to clusters organizations and simultaneously cooperating in supply chains with other cluster enterprises. Cluster organizations are an example of network structures. In turn, supply chains emerging as part of the cooperation of actors belonging to a cluster are referred to as cluster supply chains (Frankowska 2018). The research was performed using a quantitative research method (a standardized questionnaire comprising applied questions with a five-point Likert scale) and a computer-assisted interview (CAWI). The specific study was preceded by a pilot study among 20 companies.

The data collected during the research was subjected to an in-depth statistical analysis. To verify the hypotheses and the dependency analysis (correlation), a significance test of the chi-square statistic values (assuming that the level of significance for which a given result will indicate a significant dependence is p = 0.05) that is a part of statistical inference was applied, while the strength of such a relationship was determined based on Tschuprow's T, Cramér's V, Pearson's C correlation coefficients. The statistical analysis was carried out in the following order:

- analysis of the distribution of responses by individual research areas,
- study of existing interdependencies to verify the hypotheses presented in the paper.

Analysis of the distribution of answer structure

The respondents were asked about the intensity of cooperation with cluster partners in supply chains (Figure 4).

Fig. 4: Frequency of cooperation of partners in a supply chain

Figure 5: Frequency of applying logistics standards in supply chains
Source. Own elaboration.

Constant cooperation in a supply chain is a factor conducive to the process of its integration and structuring of the organizational field of partners. And so, more than 40% of respondents (42.22%) indicated "fairly often" or "very often" constant cooperation with contractors. About 1/4 of cluster companies declared occasional regular cooperation in supply chains (24.44%), and about 1/3 rarely or never conduct permanent cooperation with cluster partners (33.33%). At the same time, sporadic cooperation of high frequency (often and very often) was noted by about 1/4 of enterprises surveyed (25.93%). Almost 1/3 of respondents indicated that incidental cooperation occurs "sometimes" (34.81%), and more than about 40% that, "fairly rarely" or "never" (39.26%). These results show a large diversity of the scope of cooperation in cluster supply chains.

When assessing the scope of applied logistics standards in cluster supply chains, there is a noticeable similarity of responses characterized by a very low scope of application of individual supply chain standards (about half of the respondents) (Figure 5). Product movement standards are most common, as more than 20% of respondents indicate their very frequent and frequent use (23.71%). Furthermore, every fifth respondent declares the use of information standards in cooperation within cluster supply chains (20.74%). Whereas, communication standards are least frequently used by respondents. Only 15.55% declare their frequent or very frequent use.

Analysis of interdependencies

To verify the hypotheses set out in the article, there was conducted a study regarding the correlation between the degree of standards used by respondents in cluster supply chains and the degree of cooperation with these cluster partners. To detect significant links between the discussed phenomena, the Chi-square test of independence was used, for which *p-value* was determined, i.e. the probability for which there are no grounds to reject the hypothesis stating that there are no relations between the studied phenomena. For the study, it was also assumed that if *p-value* ≤ 0.05 is obtained, the interdependency between the studied phenomena will be considered statistically significant. Furthermore, the strength of this relation will be assessed using measures based on Chi-squared statistics (Tschuprow's T, Cramér's V, and Pearson's C correlation coefficients).

The distribution of assessments regarding the degree of application of standards in the field of information exchange, communication, or the way products are moved, is significantly dependant on the frequency of the respondent's cooperation with other enterprises (Table 3). However, this applies to respondents declaring permanent cooperation with other enterprises. The strength of this relation is moderate. On the other hand, in the case of occasional cooperation, there is no statistically significant relationship between the assessment of the degree of such cooperation and the scope of the standards used (except a positive relationship with the communication standard, whose strength is moderate).

Table 3: *P-value* and the values of basic measures examining the relationship between the assessment of the degree of cooperation and the application of standards in a cluster supply chain

Relation	*p-value*	Tschuprow's T	Cramér's V	Pearson's C
Constant cooperation and information standard	0.000026	0.30324	0.30324	0.51856
Constant cooperation and communication standard	0.000034	0.30106	0.30106	0.51583
Constant cooperation and product movement standard	0.003328	0.25662	0.25662	0.45661
Occasional cooperation and information standard	0.148554	0.20109	0.20109	0.37313
Occasional cooperation and communication standard	0.000348	0.28010	0.28010	0.48873
Occasional cooperation and product movement standard	0.088373	0.21105	0.21105	0.38887

Conclusions

In summary, the analysis of the obtained research results supports the research hypothesis. Therefore, it can be concluded that there is a relation between the frequency of cooperation between enterprises in the supply chains of network organizations (cluster supply chains) and the use of logistics standards (H1). However, it should be emphasized that a significant variation was observed in the implementation of logistics standards with a predominance of enterprises declaring the lack or very rare use of them in cooperation with partners in a supply chain. Thus, while enterprises prefer permanent cooperation with partners in a supply chain (Figure 4), the level of integration of these supply chains may be relatively low, as evidenced by the lack or little advanced in the implementation of logistics standards.

This paper fills the research gap and makes a valuable contribution to science by identifying important areas of interorganizational cooperation of network organization actors. Moreover, the paper showed significant deficits in the study area. The very limited scope of application of supply chain standards, including logistics standards, indicates a lack of, or even barriers to cooperation at the operational level. Thus, the development of the combinational potential of a network is blocked. The cognitive value of research indicates the need to raise the awareness of enterprise managers and facilitators of network organizations about the need to unify the conditions of operational cooperation by, among others, implementation of supply chain standards.

The restrictions that have been encountered when carrying out the studies should also be noted. This applies, above all, to the research sample covering only Polish enterprises, as well as the static nature of research. Furthermore, due to the adopted research technique, it was not possible to explore the studied subject. Therefore, it can be assumed that this study is initiating and encouraging further exploration of the issues of developing the connectedness of the network structures through increased cooperation in supply chains.

Summary

Standardization has a significant impact on achieving competitive advantage of a supply chain by ensuring its better coordination and integration of partners, which has its rationale grounded in theory. Thus, it is a determinant for the development of the connectedness of organizational networks, which in the strategic and operational dimensions takes the form of cooperation in a supply chain. This stems from the need to ensure consistency in the supply chain and to harmonize the terms of cooperation between partners. This issue concerns in particular the sector of small and medium enterprises. The literature on the subject proves that these enterprises have more difficulties in joining the supply chains than large companies. Lack of skills, financial resources, knowledge, infrastructure, and trust are identified as barriers for these entities to improve supply chain management in both developing countries and developed economies (Vaaland & Heide 2007).

Hence, further research is required. In the future, it would be particularly important to research the reasons for the relatively low degree of application of logistic standards and based on institutional theory, to deepen knowledge about the adaptive mechanisms of supply chain entities enabling them to cooperate more effectively, which will also contribute to greater efficiency in the functioning of enterprises within network structures.

Abstract

The spectrum of definitions of the notion "medical tourism" has been outlined based on the results of the original review, and the authors' vision of the said definition has been proposed. The WMA Statement on Medical Tourism has been analyzed and general principles for the functioning of medical tourism have been identified. The basic provisions for patients receiving services in the field of medical tourism and physicians involved therein have been crystallized on the basis of the said Statement. The experience of foreign countries in which the outlined sphere of tourism is actively developing, and which have the recognition of quality by WHO, has been covered. Authors' axioms for the development of medical tourism, which can be useful for any country that is willing to build legal medical tourism, have been proposed.

Keywords: Medical Tourism, Rights Of Patients, Medical Professionals, Medical Tourist, Cross-Border Health Services Provision, Economy.

Introduction

Nowadays, medical tourism as a type of tourism is especially economically attractive for the countries, because despite the main purpose of travel, individuals combine it with other goals, such as cultural, gastronomic, etc. Accordingly, these factors synergistically have a great impact on the economy and the growth of the local budget (for example, of a specific service provider), as well as nationwide/local. There is no unified understanding of medical tourism legal nature, as the variety of designations of this phenomenon can be met. For example, according to the results of various researches, it can be argued that foreign sources, in particular, use the following notions: "wellness tourism", "health care tourism", "cure tourism", "holistic tourism", "well-being tourism", "spa tourism", "medical tourism", "health and wellness tourism", etc. In the Ukrainian professional literature the terms "treatment tourism", "sanatorium tourism", "health tourism", "medical tourism", "spa tourism", "wellness tourism" and other designations are used (M. Sabat, 2012). As it does not have a proper regulatory basis, medical tourism is connected with a range of different issues: protection of personal data, personnel policy, and quality of services provided, in particular medical, legal liability, contractual regulation.

There are no official statistics for the medical tourism market today, and estimates and projections for its development differ from one research to another. Estimates from various experts range from USD 10.5 billion in 2012 to USD 32 billion in 2019 and USD 3 trillion. in 2025 (D. Myrhorodska, 2018). The study of some analytical data indicates that the volume of the medical tourism market will grow by 15.7% by 2022 compared to 2015, reaching in absolute numbers USD 143.8 billion. (K. Mokanov). According to other data, the market for research is already over USD 439 billion for now. By 2025, up to 3-4% of the world's population will travel the globe to improve their health, physiotherapy, and treatment (Visa, 2014).

According to the State Statistics Service of Ukraine, the analysis of the distribution of tourists served by tour operators and travel agents for the purpose of travel and types of tourism in 2018 looks as follows: the number of tourists for the purpose of treatment, served by legal entities and individual entrepreneurs was 61303 and 19003 persons respectively. This amount includes 3883 and 872 inbound (foreign) tourists, respectively, and 14554 and 1064 outbound tourists, respectively. Accordingly, Ukrainian statistics indicate that there are more tourists leaving Ukraine for medical treatment. As the researchers point out (L. Prodanova, D. Myrhorodska, 2017), the group of economic conditions and factors that affect inbound tourists include the level of socio-economic development of the country as a whole and the sectors of health and tourism in particular, the level of prices for goods and services, exchange rate, level of medicine and tourism financing, investment volumes in the said industries.

However, it is clear that the present conditions, caused by the COVID-19 pandemic, will change the conditions for medical tourism, since the virus has affected not only the healthcare system but also the economic situation in the world as a whole, creating many challenges for various industries, in particular tourism. The whole tourism industry is under COVID – 19 crisis conditions, therefore, a new map of medical tourism will be drawn at the stage of crisis exit. COVID - 19 clearly stated that it is medical conditions that can be decisive, be the factor that would change the paradigm of public life (political, economic, cultural, etc.)

Literature Review

It is important to analyze the sources of literature in order to clarify the definition of the concept, which would allow to understand the essence of the phenomenon and formulate conclusions to the strategy of development of medical tourism. Medical tourism is a specialty tourism destination, which provides for the organization and provision of treatment, diagnosis, disease prevention and other medical services both within the country (domestic medical tourism) and abroad (external one) (O. Hunchenko, 2014). Medical tourism can be also understood as a type of business activity aimed at providing services for the diagnosis, treatment and prevention of diseases outside the country of residence (K. Didenko, V. Zhuchenko, 2016).

Medical tourism is not only a journey to improve health, but it is an economic activity that involves trade in services, which is an amalgamation of at least two sectors of the economy - tourism and medicine (M. Bookman, 2007).

At the 9th National Conference on Health held in Rostock, Germany, in 2013, medical tourism was defined as a health and tourism industry that promotes the maintenance and restoration of health in general and well-being, in particular, through authorized medical services (N. Reznikova, O. Ivashchenko, O. Voitovych, 2018).

In our opinion, medical tourism is a type of business activity that combines tourism and medicine, aimed at creating a tourism product in the field of medicine, organization of providing and providing medical care for visiting and inbound medical tourist (patient).

Main part

In addressing the issue of medical tourism it is necessary to analyze the World Medical Association's Statement on Medical Tourism, adopted by the 69th General Assembly of the WMA in October 2018 (Reykjavik, Iceland) (hereinafter - the Statement) establishing a coordinate system for medical tourism worldwide. According to the Statement, medical tourism is defined as a situation where patients voluntarily travel across international borders to receive medical treatment, often at their own expense. Treatment covers a range of medical services and typically includes: dental care, cosmetic surgery, elective surgery, and fertility treatments. According to the Statement, the following cases do not apply to medical tourism:

1) the national healthcare system or healthcare facility sends the patient abroad for treatment at their own expense;
2) patients from EU Member States who are allowed to seek healthcare in another EU Member State, according to legally defined criteria, and their national health care system bear all the costs;
3) people are outside of their country of residence when they are ill and need treatment.
According to the Statement, it seems that intra-state tourists will not fall within the scope of medical tourism, although various definitions are found in the literature, as discussed above.
The general axioms established by WMA are the following:
1. It is necessary to develop a healthcare system in each country in order to prevent excessive medical tourism resulting from limited treatment options in the patient's country of residence. Financial incentives to travel to a patient for outpatient care should not limit diagnostic and therapeutic alternatives in the patient's country of residence, or limit treatment and referral options.
2. Governments are required to carefully consider all the health tourism implications of the country's healthcare system by developing comprehensive, coherent national protocols and legislation on medical tourism in consultation and cooperation with all relevant stakeholders. These protocols should assess the ability of each country to receive medical tourists, agree on the necessary procedures, and prevent the country's healthcare system from being adversely affected.
3. Governments and service providers need to be assured that medical tourism does not adversely affect the proper use of scarce health resources or the availability of appropriate care for locals in host countries. Particular attention should be paid to treatment with a long waiting time or due to scarce medical resources.
4. Medical tourism should not promote unethical or illegal practices, such as organ trafficking. The government, including executive agencies, should be able to stop selective medical tourism where it threatens the ability to treat the local population.
5. Admission of medical tourists should never allow distortion of the actual clinical need assessment and, where appropriate, the development of waiting lists or priority lists for treatment. After admission to treatment, patients should be treated according to the urgency of their medical condition. Wherever possible, patients should be referred to facilities approved by the national authorities or accredited by the relevant accreditation bodies.
As a result of this Statement, the key tips for healthcare providers and patients involved in medical tourism industry can be crystalised. It is they that can serve as the basis for national regulation and the fixing of these minimum safeguards, which should not be waived by countries. It is a system of safety coordinates for the patient and the activities of the physician in the field of medical tourism.
Therefore, the patients shall:
1) be aware that treatment methods and healthcare laws in host country may be different than in their home country and that medical care is provided in accordance with the laws and practices of the host country;
2) be informed by the doctor / service provider of their rights, including the right to medical care outside the country of residence, as well as information on legal assistance in the event of damage to the patient's health and possible mechanisms for compensation;
3) be informed of the potential risks of combining surgical procedures with long flights and vacations;
4) be aware that privacy laws are not the same in all countries and, in the context of the additional services they receive, their medical information may be provided to non-medical professionals (such as translators);

5) receive documentation indicating services provided by physicians and non-physicians, including translators, and an explanation of who will have access to their medical information;
6) agree that medical information may be disclosed that is necessary to provide them with health care;
7) be informed that a change in their clinical status may lead to a change in the cost estimation, as well as their associated travel plans and visa requirements;
8) be informed of a change in treatment plan arising out of a medical need other than the original agreed plan, the purpose of such change, and consent to any such changes in the treatment plan;
9) receive from a doctor in the host country information about the inability to improve his or her health if the patient suffers from an incurable disease, and the inappropriateness of traveling abroad for treatment;
10) receive information about their treatment in a language they understand, i.e.: a) the right to receive a brief report on the progress and discontinuation of treatment from the attending physician; b) translation of documents as needed;
11) agree on the transfer of test results and diagnostics to their country of residence before treatment starts;
12) receive a copy of their medical records for continued assistance and follow-up in their country;
13) receive, if necessary, a detailed list of medical guidelines and recommendations for the period after their departure, namely: a description of the expected recovery time and the time required for rehabilitation before returning to their country.
In their turn, the persons involved in medical tourism in the host countries shall:
1) develop a treatment plan, including a cost estimate and payment plan, before the medical tourist travels to the host country;
2) ensure that all activities are tailored to the patient's medical needs;
3) be aware of their ethical responsibilities regarding the protection of privacy. Translators and other administrative personnel who have access to the medical information of the medical tourist shall sign confidentiality agreements;
4) provide documentation indicating the services provided by physicians and non-medical professionals, including translators, and an explanation of who would have access to the patient’s medical information;
5) provide the patient who is suffering from incurable disease with accurate information about the treatment options, including treatment limitations, treatment options to change the course of the disease markedly to increase life expectancy and improve quality of life;
6) inform the patient about the impossibility to improve the patient's health, and prsude the patient to refuse from travel;
7) treat each person admitted for treatment, both local and foreign without any discrimination. All responsibilities specified by law and international medical codes of ethics also apply to the physician when trating medical tourists;
8) make medical decisions regarding the patients in cooperation with them;
9) not require the patient to undergo previously performed studies if the information is available and of good quality, unless there is a clinical need for re-diagnosis, but the evaluation is assigned to the attending physician;
10) confirm the diagnosis, prognosis and methods of treatment received by the medical tourist (concerning the doctor who prepares the patient's treatment plan);
11) communicate, as far as possible, with the doctor of the patient's country of residence in order to provide appropriate post-dispensary treatment and clinical monitoring of the medical problems of the patient.

Directive 2011/24/EU of the European Parliament and of the Council on the application of patients’ rights to cross-border healthcare of 09 March 2011 (with further amendments) (hereinafter referred to as the Directive) defines the principles of cross-border healthcare, which is not defined in the Statement as services within the scope of medical tourism. The Directive states that, despite the possibility for patients to receive cross-border healthcare in accordance with this Directive, Member States retain the responsibility for providing citizens with safe, high-quality, efficient and quantitatively adequate healthcare services in their territory. Moreover, the transposition of the provisions of this Directive into national law and their application should not lead to an incentive for

citizens to receive treatment outside their Member States of affiliation. As defined by the Council in its Conclusions of 1-2 June 2006 on Common values and principles in the European Union's healthcare system, the decision on the basket of public health services and the mechanisms used to the financing and provision of such health services, such as the extent to which market mechanisms and competitive pressures to manage health systems are appropriate, should be taken in a national context.

Within the framework of the provision of cross-border healthcare services, the obligation to reimburse the costs of such services is limited to the services to which the insured person is entitled under the law of the Member State of affiliation. For the purpose of reimbursement of costs for cross-border healthcare services, this Directive covers not only situations where a patient is provided with health services in a non-Member State but also prescriptions, leave and supply with medicines and medical devices, if provided in the context of healthcare. The definition of cross-border healthcare services involves the acquisition by a patient of such medicines and medical devices in a non-member Member State and the acquisition by a patient of such medicines and medical devices in a non-Member State, where the prescription was issued.

The wording of the European Court's of Human Rights (hereinafter referred to as the Court) case-law is interesting in the Directive. Member States may require prior authorization for reimbursement by the national system of eligible costs of in-patient care provided in another Member State. The Court ruled that such a requirement was both necessary and reasonable, since the number of hospitals, their geographical location, the way they were organized and the means by which they were equipped, as well as the nature of the medical services they were able to provide, were issues that could be raised. previous planning, which is generally intended to meet a variety of needs. The Court recognized that such planning was necessary to ensure that sufficient and consistent access to balanced high quality treatment was available in the Member State concerned. Additionally, it helps control costs and prevent, as far as possible, any waste of financial, technical and human resources. According to the Court, such a waste would be further detrimental as it is widely recognized that the hospital sector generates significant costs and needs to meet growing needs, while the financial resources available for health services are limited, no matter what method of financing is used.

EU citizens travel from richer countries such as the United Kingdom, Sweden, Germany, the Netherlands and Ireland to seek affordable healthcare in other countries, especially in Eastern Europe.
Until recently, the main healthcare areas for Europeans were the United Kingdom, France, Germany, Italy and Spain. However, as amendments to the Directive were adopted in 2014 (in particular that states that there should be free access to treatment for all EU citizens in the public space), a new market for medical tourism has emerged. Consequently, countries such as Hungary, the Czech Republic, Romania, Poland and Latvia have become popular destinations. According to the Polish Medical Tourism Association, in 2014, 488,000 foreign patients came to Poland for treatment. Medical tourism today accounts for about 5% of the tourism industry in the EU and contributes to about 0.3% of the EU economy. In fact, this is a higher percentage than traditional tourism. Therefore, increasing the share of health tourism may reduce the seasonality of tourism.

In Turkey, which has become a leading and popular destination for people seeking less sophisticated treatments, the government is offering discounts to patients flying Turkish Airlines. The government also plans to introduce tax-free health care facilities for foreign patients. More and more governments and companies are offering cheap flights, open borders and inclusive packages to further fuel this segment of the tourism market.

According to the research of medical tourism in the EU, the statistical data is the following (R. Fink, 2018):

- 64% of patients that traveled for care didn't have health insurance;
- almost 83% of patients traveled with a companion;
- 33% of patients traveled abroad for cosmetic surgery;

- almost 90% of patients or their companions engaged in tourism activities;
- nearly 80% of the demand for medical travel is driven by cost savings;
- medical tourists spend between €6,083 and €12,885 per medical travel trip;
- 48% of respondents would be interested in engaging in medical tourism again at some point in the future;
- the cost of medical treatment and quality were the most important factors in their decision to travel abroad for treatment;
- out of 49 participants that had previously traveled overseas for medical treatment, 36% used a medical tourism facilitator.

A large number of EU citizens (about 49%) are ready to travel for healthcare. This may be linked to the EU Health Directive, which states that Member States should reimburse their citizens for the cost of the services they could get at home (in order to protect the financial soundness of national health systems). This situation has some disadvantages for patients from poorer countries with less developed healthcare systems. For example, healthcare costs far less money in Croatia than in Sweden. Thus, a Croatian patient would have to pay out of pocket for a significant difference in the cost of treatment if he or she sought healthcare. At the same time, as a patient from a more affluent EU Member State can seek help in Croatia or anywhere without paying much of their own money for healthcare. This scenario is particularly advantageous for wealthy Member States as they achieve economic benefits if treatment abroad is cheaper. National policies in some countries, such as Turkey, promote the growth of medical tourism. This indicates that it is an important strategy in the overall tourism planning.

It is worth noting that for the development of medical tourism, it is important to institutionalize, bringing together professionals from different industries, determine the key basis for the development of the industry: from standards of services, protection of patients' rights and responsibility to the formation of legal boundaries of functioning. Nowadays, there exist World Medical Tourism Association, Global Healthcare Travel Council, European Medical Tourism Alliance, in Ukraine there is Ukrainian Medical Tourism Association, which is a member of the World Medical Tourism Association.

Medical tourism issues are regulated in Ukraine exclusively by the Law of Ukraine "On Tourism". Nevertheless, this legal act does not contain the definition of such notion. Art. 4 of this Law enshrines health tourism among the types of tourism. Therefore, for the effective development of the realm, it is necessary to clearly understand the legal essence of medical tourism by enshrining it in national law.

The law on medical tourism exists in Israel (Meidcal tourism law 5778-2018). It regulates the activity of medical tourism entities: it is proposed to create a register of medical tourism agents and determine the prerequisites for registration.

The law establishes ethical standards for medical tourism agents: - they are responsible for protecting the interests of medical tourists. They are also the body that represents the Israeli healthcare system to the medical tourist before their arrival to Israel. The law establishes a medical institution's obligation to comply with certain rules in order to provide medical tourism services. The purpose of these rules is to achieve certain goals:

a) preventing the deterioration of the quality of care for Israeli patients through medical tourism by ensuring that Israeli patients have priority in accessing all the healthcare facilities;
b) filling the health care system with funds for the well-being of Israeli patients, transferring medical tourism revenues there. To this end, there is a recommendation on several steps to increase the transparency of hospitals with regard to their financial activities, the source of which is medical tourism that allows to track hospital revenues from medical tourism and the use thereof.

The attention shall be drawn to the experience of those countries that successfully develop medical tourism. India is one of the key players in the medical tourism industry as it seeks to provide

healthcare with cutting-edge technology. Healthcare in India saves patients between 65% and 90% of the money compared to the cost of a similar services in the US, making India one of the most visited countries for healthcare. Patients visit India not only for the quality and availability of medical services, but also for the beautiful scenery and architecture of the country. In India, medical travel brings a blend of fun and quality health care to travelers.

Many hospitals in India are accredited by the National Hospital and Health Care Accreditation Council (NHHAC) and the International Joint Commission (IJC). Some private hospitals in India provide medical packages for foreign patients, such as airport transfers to hospitals, free Wi-Fi in the room and private chefs. In addition, there is almost zero waiting time in India as scheduling surgery or intervention is done as soon as the diagnosis is confirmed.

The WHO notes that Brazil has the best healthcare locations in Latin America. There are 43 hospitals accredited by IJC in Brazil, and it boasts of having world-renowned surgeons. Brazil is the center of cosmetic and plastic surgery, being the third most visited country, along with the US and China, by patients requiring these procedures. Brazil offers high quality cosmetic and plastic surgery services at affordable prices, bringing more and more medical tourists to the country. Florianopolis and São Paulo are two cities in Brazil best known for their advanced medical technology, medical advances and innovations. Brazil is also a favorite country for patients seeking special procedures such as Brazilian bracing or other special services from world-renowned surgeons. For example, medical travelers from the United States save between 20% and 30% on healthcare costs if they receive medical services in Brazil.

Malaysia won first place according to the International Journal of Medical Travel in the category of Health and Medical Tourism of the Year 2015 and 2016. Malaysia ranks as one of the best health care providers in Southeast Asia. Medical travelers visiting Malaysia save between 65% and 80% on health costs compared to US costs. Malaysia offers superior comfort for patients with five-star rooms that are more like a hotel than a hospital. For example, the Prince Kort Medical Center has indoor pools for hydrotherapy. Both at Penang International Airports and Kuala Lumpur Airports, the Malaysian Tourist Board for Health (MTBC) operates, providing leisure and concierge services to medical tourists to ensure their comfort from the moment they arrive to Malaysia.

The Central American country of Costa Rica has ranked high in dentistry and cosmetic surgery over the past few years, above Canada and the United States. The country is also making a name for itself in the field of ophthalmic surgery, cancer therapy and bariatric surgery. CheTica Ranch, located in San Jose, provides exotic treatments for medical travelers for patients who are enjoying a recovery in a relaxed atmosphere. The cost of medical services in Costa Rica is 45% to 65% lower than in the United States.

Singapore is one of the most developed countries in the world, ranking first in the field of healthcare by the WHO among Asian contries. Gleneagles Hospital is one of Singapore's best hospitals, offering excellent medical services, advanced facilities and well-trained professionals. Medical services in Singapore save the patient 25% to 40% of the similar services cost in the US.

Conclusions

To summaise the above, it is important to note that the common axioms for building legal medical tourism can be the following:

1. Medical tourism as a business shall be value-oriented, ethical, because it has life and health as key values in its essence.
2. The service provider needs to form a recognizable, unique product (for example, Kozyavkin International Rehabilitation Clinic).
3. Intra-state partnership is necessary for leadership, competitiveness of the state on the world map.
4. The service provided shall be of good quality and safe.

5. Multiculturalism, taking into account the diversity of services and specificities of cultures and religions of different countries.
6. Prohibition of illegal and unethical practices (for example, trade of anatomical materials).
7. Establishing clear and understandible intra-state regulatory boundaries with equal conditions for access to healthcare, a balance between the intra-state patient and the medical tourist regarding the quality of services.
8. Establish a proper legal basis for the vulnerable areas of medicine, such as embryo donation, surrogacy, abortion.
9. The vulnerability of the medical tourist in comparison with the national patient shall be taken into account, since it is necessary to remember that, as a rule, the lack of knowledge of the language of the service provider's country, there is often the need to involve a translator. Also, the foreign patient usually does not know the specifics of the law, contractual practice of the host country, etc.
10. A latent market for medical tourism intermediaries should be identified and regulated in order to ensure safety for patient tourists and to avoid unethical activities.
11. Medical tourism has a positive effect on other segments of the economy in the country, because in treatment the patient and/or their accompanying person: a) live in a hotel, in particular a patient dependent on the type of medical services (for example, dental, which do not require hospital care) ; b) visit restaurants, cafes, bars; c) visit the cultural heritage of the host country; d) often combined with rest.
12. Medical tourism activates competition, influences the flexibility of the market, because the patient has an unlimited opportunity to choose: better quality of services, better price, better transport route, better specialist, better medical infrastructure. Fighting for the patient should create a "natural" choice and stimulate states to improve services, and the benefit of this is the economic impact, the improvement of their own healthcare system, and the provision of better-quality medical services to national patients.
13. It is important for Ukraine to develop a national concept of medical tourism and to adopt the necessary legislation to catalyze this type of tourism.

Some Essential Considerations on the Phenomenon of Early Internationalization and Born-Global Firms

Katarzyna SZYMCZYK

Czestochowa University of Technology, Czestochowa, Poland

katarzyna.szymczyk@wz.pcz.pl

Abstract

Early internationalization and the phenomenon of born-global firms or global start-ups are a fascinating and evolving aspect of modern entrepreneurship. The literature on the subject certainly constitutes a rich collection of studies on the phenomenon of early internationalization, much has also been devoted to the phenomenon of born-global companies. This article supplements the current knowledge in this area and discusses the genesis of the theory of early internationalization, presents the essence and key attributes of the functioning of born-global companies, and discusses the core strategies for managing an early internationalized company. All theoretical considerations were based on scientific literature sources.

Keywords: Born-Global, Global Start-Ups, Early Internationalization, Management, Company

Introduction

Internationalization is, to a large extent, perceived in terms of a process. It is a phased, evolutionary and gradual sequence of activities of the company preparing it to enter foreign markets. Internationalization understood in this way requires time and, often, considerable experience of the enterprise on the home market. The stage concept of internationalization indicates that only proper and stable market position in their own country and measurable competitive advantage allow enterprises in subsequent stages of their operation to consider expansion into foreign markets, learn these markets, learn about their environment and then gradually plan to expand their activities abroad cautious ventures (Szymczyk, 2018; Otola & Szymczyk, 2017). However, the nineties of the last century proved to be a breakthrough in this matter, as the phenomenon of early internationalisation appeared (Blanke-Ławniczak, 2008). This new phenomenon forced a new approach to internationalisation and a departure from interpreting the internationalisation only in terms of the process.

The origin of the concept of early internationalisation

The concept of internationalisation as a phased process, which is identical to the Uppsala model (Johanson & Wiedersheim-Paul, 1975; Gorynia & Jankowska, 2007), has been criticised by many authors favouring the theories that in internationalisation some of the stages can be omitted using the so-called leapfrogging, i.e. skipping stages (Romanowska, 2009). This type of behaviour was observed by G. Hedlund and A. Kverneland among Japanese companies that were characterised by entry dynamics based on the use of increased resources for rapid expansion, which clearly proved, according to researchers, that internationalisation does not necessarily have to be a slow and gradual process. Three fundamental situations in which one or more stages are missed by an enterprise in the process of internationalisation occur when:

- the company has sufficient resources, especially financial resources, which will protect the company in the event of a disaster, thanks to which it will not feel the negative consequences of entering the foreign market,
- due to the stable situation on the target market, the company is able to operate based on its knowledge,

- the company, thanks to international experience, successfully uses for its expansion purposes into the selected foreign market analogous conditions that prevail in the markets within its operating range.

Skipping stages in the internationalisation process, as well as rapid entry strategies involving larger-than-usual enterprise resources, oppose the sequential, evolutionary internationalisation process in which each stage determines the next (Hedlund & Kverneland, 1983; Brezis et al., 1993; Goldemberg, 1998; Wang et al., 2010). O. Andersen or S. Reid criticised aforementioned Uppsala model, basically the excessive generality of its assumptions, as well as the fact that it is causally related (Reid, 1981, 1983; Andersen, 1993). S. Forsgren (2002) drew attention to the need to expand the scope of knowledge and to learn to explain the forms of internationalisation in the Uppsala model. A broader criticism of the Swedish model was presented by S. Bridgewater (2000), who first noticed that the model does not suit certain products, as well as services, which, in most cases, require the construction of a franchise network. He shared the concept of stages being skipped by national corporations. They, having the opportunity to use substantial resources and skills for expansion, often fail to implement stages in which the necessary involvement is smaller, and more stages will be overlooked by large corporations that use the Internet in the process of internationalisation. P. W. Turnbull (1987) stated that the model could not see clear boundaries between the stages of the process, and, also, that the export or distributor's involvement are not synonymous with less use of resources.

In the literature on the subject, one can also come across the concept of a simultaneous model of internationalisation. In the model, the attention of the so-called convergence of expansion markets in the global dimension, as a result of which national differences, are blurred, hence, customers' needs are unified, which gives enterprises the chance to enter several markets simultaneously, at the same time, bypassing the stages of the conventional Uppsala model. According to M. Gorynia (2007), the above concept is included in the definition of unconventional internationalisation.

The nineties of the twentieth century was a period of emergence of small and medium-sized enterprises that started operating abroad. Their presence in foreign markets was usually based on export of goods simultaneously in several countries. Firms occurred abroad either immediately from the start of the company's operations or up to three years from the establishment of the company. And what is interesting, among these companies were those that ignored their own country as an area of activity. That is how market observers and researchers started debating about born exporters or innate exporters (Ganitsky, 1989). At the turn of the eighties and nineties of the twentieth century, as many as 13% of American small enterprises in the first year of their operations entered international markets (Jarosiński, 2012). In Australia, it was noticed that some young enterprises started their activities on international markets very early, as the period of entering the markets did not exceed two years since the creation of these companies. A quarter of Australian companies turned out to function, according to the adopted literature on the terminology, as born-global firms. In Europe, this type of company had been observed primarily in Denmark. It was noticed there, in the period 1985-1993, an upward trend among companies that started exporting already in the first years of functioning on the market (Christensen & Jacobsen,1996; Christensen, 1991).

Underlying Assumptions of Functioning of Born-Global Firms

The main reason for the emergence of the concept of early internationalisation was the thesis that not all companies succumb to internationalisation processes along individual stages. Some companies are international by design. This means that they did not start their business from one, usually home country and later expanded it by entering foreign markets, but they entered foreign markets immediately, from the very moment of establishing the enterprise. The core business strategy of functioning was a foreign market and usually far away from the company headquarters.
There are many names and definitions for this type of enterprise in the literature on the subject: mentioned so far "born-global", or "global from the beginning", "international companies from birth", "international new ventures (INV)" "global start-ups" (Głód, 2008).

It is generally accepted that the concept of early internationalisation refers to companies operating in foreign markets from the very beginning, as well as companies that have developed or expanded their activities to international markets in less than two or three years from their establishment. However, S. Zahra, R.D. Ireland, M.A. Hitt (2000), as well as R.C. Schrader (2001) or N.E. Coviello and M.V. Jones (2004) also include a six-year period. Furthermore, P.P. McDougall and B.M. Oviatt (1996) consider being born-global the companies that needed up to eight years to enter international markets. Research on the phenomenon of early internationalisation in the literature has been divided into three separate periods (Jarosiński, 2012):

- until 1994 was the time when the first observations about the existence of early internationalised companies appeared,
- 1994-2000 was a period of research on the phenomenon, scale and premises for early internationalisation,
- the period after 2000 has been a time when early internationalisation is a fact, and researchers focus on searching for the most accurate theories explaining the premises for early internationalisation.

It is worth mentioning, the research on the phenomenon of early internationalisation gave birth to attempts to categorise new international enterprises based on the reach of companies in international space. B. M. Oviatt and P.P. McDougall (1994, 2005) developed a division of new international enterprises into four categories:

- new enterprises dealing with import and export within logistics activities in few countries,
- international intermediaries also operating in logistics but in more countries,
- geographically concentrated companies specialised in terms of clients from a given region of the world,
- global, new companies with a large spectrum of activities in a significant number of countries using the network of alliances (Ayadi-Frikha, 2014, 2015).

The observations of the above researchers have become crucial for further interpretations of both the categorisation attempt itself and the definition of the phenomenon itself. However, according to G.A. Knight and S.T. Cavusgil (2004, 2005) the category of born-global firms included the companies which undertook international activities within three years of establishing the company and achieved a minimum of 25% of revenues on foreign markets (see also Knight et al., 2004).

Attributes of Born-Global Firms

Born global companies have been international since the beginning and have a significant share in foreign markets resulting from the sale of products. They have advanced knowledge of international markets, excellent orientation and experience in functioning abroad, a kind of specialised business for a specific customer (Ayadi-Frikha, 2015). They often operate in a specific niche, in which they find the right recipients for their dedicated and selected products, and often use aggressive strategies to achieve competitive advantage. They use of several modern and advanced information technologies, and online communication and online commerce - on the Internet can be the most common form of business. High technology, product innovation, a strategy of intensive modernisation and improvement of goods for the customer, for born-global companies not only underlie the strategy of operation but very often constitute a kind of impulse to found a company. These companies have in-depth knowledge of the foreign market, know the potential of competition, the volume of demand, the scope of needs and preferences of consumers, the size of the niche and undertake business activities in selected foreign markets with a fully prepared, precise and specific product offer. Apparent born-global companies see foreign markets as an opportunity and merit of their functioning in the economy (Morawczyński, 2008; Hollensen, 2011; Sapienza et al., 2006). To emphasise the attributes of born-global companies, it is worth highlighting the differences between the classic and early model of internationalisation (Table 1). These, somehow fundamental, differences between the elements of internationalisation in the traditional evolutionary process and early internationalisation allow summarising the most important issues related to the essence of born-global companies.

Table 1: Classic (phased) versus early internationalisation

Classic Internationalisation (phased)		Early Internationalisation
well-established position and success on the domestic market determine the desire to expand operations beyond the borders of the country	**Domestic market**	local activity is of little importance the company focuses on markets outside the home country
gradually, knowledge is acquired as needed to go beyond the national market	**Knowledge about the foreign market**	knowledge is obtained quickly and often results from the experience of entrepreneurs
inexperience is not perceived negatively possession is not so valuable, it acquires skills by entering foreign markets	**Market experience**	experience in the overseas market determines the start of business often, knowledge of the market lies in the competence of the founder of the company
gradual, step-by-step, country-by-country method	**Entry into the foreign market**	dynamic entry to many countries at the same time often, the company skips the domestic market in its activities
it could be a barrier the company prefers foreign markets culturally similar to its country	**Culture of the foreign market country**	it is not a barrier companies enter markets with a diverse culture
it is crucial in the first stages of internationalisation, but on the further, the company is based on its own resources	**Binding network**	necessary for the speed of internationalisation an extensive system of links determines the activities of born global companies
negligible, insignificant for competitive advantage internationalisation itself is not a determinant of the success of the company	**Dynamics of internationalisation**	an essential and high, elevated degree of internationalisation determines the success of the company, usually achieved within two or three years

Source: Own elaboration based Chetty & Campbell-Hunt, 2004.

The above issues include many factors that characterise early internationalisation, such as market knowledge, financial conditions, innovations and technologies, and the role of managers. Additionally, for many early internationalisation researchers, the phenomenon should be considered in various approaches to strategic management and international entrepreneurship, in a similar way to the classic model of internationalisation.

Strategies of Management of Born Global Firms

The key to managing born-global company is having the right knowledge and skills to adapt, integrate or reconfigure depending on changes in the environment. Specific dynamics, flexibility and orientation towards information technologies distinguishes this type of company from other often hierarchical, bureaucratic or full internal dependencies (Jelonek & Turek, 2016). An important aspect conducive to the functioning of born-global companies in foreign markets is also their size, which facilitates the management and adaptation of the company to the environmental conditions in which it operates. Companies of this type due to their small size are more likely to change quickly and more flexible, because in most cases they are not affected by the problem of too bureaucratic structure. Flexibility and simplicity in the company structure and management allow faster responding to the needs and expectations of customers, a greater focus on innovation and developing more creative solutions to specialise a product or/and service for a specific recipient (Torres-Ortega et al., 2015; Szymczyk, 2018; Otola & Szymczyk, 2017; Blanke-Ławniczak, 2011, 2014; Ulewicz & Kucęba, 2016).

A specialised narrow portfolio of products or services is key in the activity of born-global firms because it completely changes the perception of the global market as a threat or risk but as an opportunity and profit. For many scholars, it turns out to be an accurate observation that born-global companies treat the whole world as one common international market, or as a global resource of opportunities and chances to gain and maintain a competitive advantage. This market is generally available and achievable and remains as the main goal of the company's management strategy. However, it is impossible not to get the impression that, to a large extent, born-global companies are successful in areas that are not within the scope of interest of large enterprises or corporations, because their operation is not essentially directed at mass recipients, expecting large-scale products and services and on a large scale.

A market niche, which is most often used by early-internationalised companies, for many long-term international companies with broad horizons and networks, can be less profitable and even generate unnecessary losses. Large companies, corporations or business conglomerates precede entering a foreign market with meticulous analysis and preparation for a long-term, if not a permanent period of operation. For this purpose, they usually transfer significant financial resources.

On the other hand, born-global companies operate on the basis of an up-to-date profit opportunity, previously well-established knowledge of the foreign market, and they use the existing demand for a specific product or service and knowledge of niches and consumer preferences while remaining flexible when it comes to the product itself. Due to considerable flexibility, born-global firms can dynamically change and re-adjust their portfolio of dedicated products or services due to current demand. Flexibility is certainly a big advantage of these companies. Undoubtedly, it is conditioned by having qualified managerial staff who can equally demonstrate skills swiftly and dynamically in the process of developing the appropriate strategies and methods of operation (Baronchelli, G., Cassia, 2014; Gabrielsson et al., 2008; Yli-Renko et al., 2002; Zucchella et al., 2007).

Conclusions

Summing up the theoretical considerations about the phenomenon of born-global companies and the concept of early internationalisation, it can be concluded that born-global firms are specific entities that conquer foreign markets dynamically, often find themselves in a niche and target the specific customer groups. They operate swiftly and equally quickly achieve market success largely due to the considerable knowledge of these markets, core competencies to use information technology for business purposes, and a range of ideas adequate to the current expectations of markets and their consumers. These are companies that to large extent capture opportunities and moments, in a sense, they catch up with the chances of success and profit without special planning and all stage preparation. Therefore, they also might have a short life span, often take risks and do not fully focus on long-term functioning. Of course, among them will remain on the market those that will be able to appear in foreign markets in a short time to develop further, expand the company and increase its operations. The question remains whether they still should be called born-global companies or already precisely-structured international corporations.

Abstract

In this the paper we present new methods, called OFCPM, OFPERT, for estimating a project completion time in the situation when activity duration times in the project are given in the form of Ordered Fuzzy Numbers OFNs. Extended Critical Path Method and Project Evaluation and Review Technique have been developed as new methods dedicated to project scheduling, preserving its basic concept. Ordered fuzzy numbers are used to project scheduling under uncertainty. The duration time of each project activity is estimated by experts (experts views of the activity duration time) based on their experience. These new methods will be verify on some examples. The comparison of our fuzzy approaches to existing deterministic sans stochastic ones is under study.

Keywords: Project Scheduling, CPM, PERT, Ordered Fuzzy Numbers.

Introduction

The transformation of business conduct and the differentiation between routine tasks and tasks that are unique (project driven orders treated as projects) in organisations, enterprises, production, logistics and supply chains become necessary. The project is viewed as a task-specific and time-limited form of working. Both the process approach, and the project approach are important for any enterprise or supply chain that wants to maintain its market position (Artto and Wikström, 2005; Artto and Kujala, 2008; Artto et. al., 2011; Blomquist et. al., 2010; Turner, 1999; Whitley, 2006). Project-based business is becoming increasingly more significant (Hartman and Skulmoski, 1998; Morris and Hough, 1987; Söderholm, 2008; Von Dran et. al., 1996; Turner and Müller, 2003; Turner et. al., 2010; Hällgren and Wilson, 2008; Ibbs and Kwak, 2000). In view of the continuously increasing importance of projects, including logistics projects, for organization and supply chains (often termed "projectification") (Midler, 1995; Maylor et al., 2006; Packendorff, Lindgren, 2014), competent project shaping, together with their social environment, are entering the spotlight.

One of the most important aspect of project management is the scheduling of project activities. There are many methods used in project scheduling. Most of the traditional tools for project scheduling are crisp, deterministic, and precise in character. Critical Path Method (CPM), Program Evaluation and Review Technique (PERT) are most popular project scheduling methods. They are usually used to determine the critical path. CPM and PERT play an important role in estimation the project completion time, and are the methods dedicated to modelling the execution of a given project. It has been demonstrated to be a useful tools in the planning and control of complicated projects. These methods have been applied to planning organization projects, software projects, logistics project, engineering projects, construction projects, innovative projects, etc. (Chen, Hsueh 2008; Malakooti, 2014). It is known that duration times of project activities are seldom satisfied. Precise information about the duration of the activities is seldom available in real world (Yakhchali, Ghodsypour, 2010). In project practice, activity duration times are often imprecise and have to be estimated subjectively. The project manager should rather subjectively evaluate the duration and determine a suitable commitment for project completion. The assumption of crisp durations of activities is unfeasible in real projects and these methods include considerable errors to calculations and results.

This paper is organized as follows. The second section provides a brief review of the relevant support state-of-art. The Section 3 is dedicated to the framework methods based on imprecise duration times

as the ordered fuzzy numbers. In next Section we present an illustrative example of applied the proposed methods to project scheduling. The last section includes conclusions and recommendations of the work.

Research Literature

The primary objective of project scheduling is to plan in time the sequences of all activities of a project such as that project duration is minimized and the sequences of all activities is feasible. Classical methods of project scheduling, like CPM, are deterministic and do not take into account the uncertainty related to the unavailability of reliable, precise information (Chen, Hsueh 2008). Methods based on statistics and probabilities such as PERT have been created to solve CPM problems and consider the effect of uncertainty on results. In the PERT, the durations of activities are assumed to be stochastic and they have a mean and standard deviation that covers the uncertainty (Habibi et al. 2018). Another method named Monte Carlo simulation is based on the probability theory have been developed. In the literature we can find many papers that have used these stochastic approaches and search on this area is still carried out (Łapuńka et al., 2016).

Critical Path Method was originally developed by Kelly and Walker in 1959. This method is used to find the minimum overall project duration and identify critical activities and critical paths. The Program Evaluation and Review Technique was developed by Booz, Allen, and Hamilton in 1959. It was developed in a joint with the U.S. Navy to deal with this issue of uncertainty of durations times in project management. In PERT the duration time for each activity is treated as a random variable, each having a random probability distribution (Malakooti, 2014). PERT is used as a tool for large project management. What is essential in the PERT method is that activity duration times in projects are probabilistic. In PERT we use three time estimates for each activity: the shortest - optimistic, the average - most likely and the longest - pessimistic. The objective of this method is to find the minimum project duration while considering probabilistic activity durations. PERT can also be used to provide probabilities associated with different project durations. The shorter the targeted project duration, the less likely the project will completed on the time.

In actual project control decisions, CPM and PERT have successfully been applied to business management, industry production, project scheduling control, logistics support, etc. These methods require a crisp duration time representation for each activity. In practice, this requirement is often difficult for the decision-makers due to the fact that they usually cannot estimate these values precisely.

As we can see, in recent years, some fuzzy CPM and PERT methods have been proposed based on fuzzy set theory for project management. Motivated by management practice in project environment and inspired by results of fuzzy set theory applied in science researchers employed the concept of fuzziness in project management. Fuzzy Set Theory, proposed by professor Lotfi Zadeh (1965), is interested in uncertain and fuzzy data, fuzzy environment including project environment. The uncertainty took significant place in the decision-making processes (Mazlum, Güneri, 2015). In almost every field of management, the widespread use of fuzzy set theory with the new perspectives is used in decision-making process for example in production, logistics, industry, services. The fuzzy set theory is widely used in game theory and network problems in operations research, linear programming, nonlinear programming, goal programming, dynamic programming, transportation models, inventory management (Kahraman, et al. 2006). The study of fuzzy scheduling has been initiated in research undertaken by Hapke and Slowinski (1993). Many techniques particularly the serial and the parallel scheduling schemes (Hapke and Slowinski, 1996), and the resource leveling technique (Leu et al., 1999) were generalized to handle fuzzy parameters. To decide the feasibility of a project schedule, the work load plan is established and compared to the available capacity. In the literature, the majority of authors who work with fuzzy sets in scheduling problems transform the fuzzy scheduling into crisp scheduling by applying either alpha-cuts or a defuzzification technique. Thus, they generate deterministic work-load plans (Hapke and Slowinski, 1996; Leu et al., 1999). On the other hand, Masmoudi (2011) use the possibility theory to define a new concept of fuzzy workload plan in operational level of planning.

In general, researchers use fuzzy numbers instead of crisp numbers in established formulas. For example, the deterministic activity duration times are replaced with the fuzzy activity times. Fuzzy CPM (FCPM) and fuzzy PERT (FPERT) are used in the fuzzy project management, and can be used to improve decision-making process and to plan the complicated, innovative project (Chanas, et al. 2002; Chanas, Zieliński, 2001, 2002, 2003, Kuchta 2001; Slyeptsov and Tyshchuk, 1997, 2003).

However, several authors reported problems connected with using fuzzy numbers. The papers (Gani, Assarudeen, 2012; Kosiński, 2002, 2003, 2009; Prokopowicz et al., 2017) discuss the drawbacks of convex fuzzy numbers. To overcome these issues Kosiński with team developed the concept of ordered fuzzy numbers (OFNs).

An ordered fuzzy number A (OFN) is an ordered pair $A = (f, g)$ of continuous functions $f, g: [0,1] \to R$. There is a great variety of ordered fuzzy numbers, wherein only a small part of them correspond to standard fuzzy numbers. The set of pairs of continuous functions, where one function is increasing and the other is decreasing and, simultaneously, the increasing function always assumes values lower or equal than the decreasing function, is a subset of the set of OFNs, which represents the class of all convex fuzzy numbers with continuous membership functions. We called them proper OFNs. So, the new interpretations offered by the ordered fuzzy numbers approach can be viewed as an extension of classical proposals. The concept of ordered fuzzy numbers has been described in papers (Kosiński, et al. 2002a,b 2003a,b,c; Chwastyk, Kosiński, 2013).

The key aspect of ordered fuzzy numbers is related to the notion of direction (in some papers it also called orientation). This additional kind of information is not represented by standard fuzzy numbers. Only the OFN model offers looking at imprecision from a new perspective. Using ordered fuzzy numbers, it becomes possible to describe a trend of imprecise value of the real-life processes (Kosiński, et al. 2002a,b 2003a,b,c 2013; Prokopowicz, et al. 2017) including durations time of project activities. The direction is a new kind of information and it is marked graphically with an arrow. It can be useful in many real-world scenarios, such as expressing diversity of opinions in social networks, modeling dynamics of financial data, simulating brain functions, and patient diagnostics (Prokopowicz et al. 2017). This aspect can be widely applicable to modeling reality under uncertainty, which makes them particularly suitable for the project environment. The direction of OFNs turned out to be useful in project management, especially in project scheduling. This additional information is very important for project manager. We obtain added information about the planning value - the duration time. According to duration time of the direction of an OFN can be related to the expert's opinion about the time characteristics in the analyzed project. Figure 1a presents a standard fuzzy number which constitutes the interpretation of the expert's opinion about duration time of a project activity – "ca. 60 days". Using ordered fuzzy numbers, it becomes possible to consider the expert's opinion about the dynamics of change in this value: "ca. 60 days with a decreasing trend" – negative direction (Figure 1b) or "ca. 60 days with increasing tendency" – positive direction (Figure 1c). This is an advantage over expressing the expert's opinion using standard fuzzy numbers.

Fig. 1: a) Classical fuzzy number "ca. 60 days", b) The membership function corresponding to the OFN "ca. 60 days with decreasing tendency" c) The membership function corresponding to the OFN "ca. 60 days with increasing tendency".

The proposed methods dedicated to project scheduling with imprecise data

We continue the research began in the work (Chwastyk, Pisz 2017; Chwastyk, Pisz 2018) which concerned the use of ordered fuzzy numbers to estimate activity duration times in a project. We converted the above problem from AOA (Activity On Arc) into AON (Activity On Node) network

and added PERT method with OFNs. The approach is based on idea of the classical Critical Path Method and extended critical path presented by (Chanas, Zieliński, 2001). We have developed the theoretical foundations of a new critical path analysis which can be an alternative to the conventional CPM and PERT method (Chwastyk, Pisz 2018). The duration times are estimated by experts. They estimated each value and expressed using OFNs. We add some basic information about of theory of OFNs in this paper. More we can find for example in papers (Kosiński, et al. 2002a,b 2003a,b,c Chwastyk, Kosiński, 2013, Prokopowicz, 2017).

A linear ordered fuzzy number (f, g) is a pair of linear functions and it is uniquely determined by a 4-D vector $[\mathrm{f}(0), \mathrm{f}(1), \mathrm{g}(1), \mathrm{g}(0)]$ composed of the real numbers. A proper linear ordered fuzzy number (f, g) is called a trapezoidal ordered fuzzy number. If we additionally assume that $\mathrm{f}(1) = \mathrm{g}(1)$ we get the notion of a triangular ordered fuzzy number. Let $A = [a_1, a_2, a_2, a_3]$, $B = [b_1, b_2, b_2, b_3]$ be triangular ordered fuzzy numbers ($a_i, b_i \in R;\ i = 1,2,3$). We distinguish two types of triangular OFNs: with negative direction ($a_1 > a_2 > a_3$) and with non-negative direction ($a_1 < a_2 < a_3$). The operations of addition and subtraction are defined as follows:

$$A + B = [a_1 + b_1, a_2 + b_2, a_2 + b_2, a_3 + b_3] \tag{1}$$

$$A - B = [a_1 - b_1, a_2 - b_2, a_2 - b_2, a_3 - b_3]. \tag{2}$$

According to project scheduling we consider a project model $S = (V, Ar, T)$ which is a directed and connected network, where $V = \{1,2, \dots, n\}$ is a set of n nodes – activities, $Ar \subset N \times N$ is the set of arcs – relations, T_i denotes the activity time of i-th activity. The duration times are represented by triangular ordered fuzzy numbers and crisp numbers $a \in R$ represented by OFN of the form $[a, a, a, a]$.

To draw the network diagram of the project, the precedence relationship of the activities are to be determined. The activities are represented by nodes. Nodes are numbered that for every arc (i, j) the relation is $i < j$. Let us denote by:
$P(i) = \{k \in V | (k, i) \in Ar\}$ – the set of predecessors,
$S(i) = \{k \in V | (i, k) \in Ar\}$ – the set of successors for the activity $i \in V$.

Idea and applied of Ordered Fuzzy Critical Path Method

The proposed algorithm of OFCPM consists of few steps. The steps are as follows:

1. Specify the individual project activities.
2. Determine the sequence of the each activities.
3. Select Zexperts to estimate the duration time.
4. Estimate the duration time using ordered fuzzy numbers by each expert $T_{ij,}$ $i = 1,2, \dots n, j = 1,2, \dots, z$.
5. Calculate average value of the duration time using ordered fuzzy numbers

$$T_i^{aver} = \frac{\sum_{j=1}^{z} T_{ij,}}{z},\ i = 1,2, \dots, n, j = 1,2,, \dots, z.\ , \tag{3}$$

6. Perform calculation of earliest start time of activities (denoted by T_i^e) for each activity $i \in V$ $(i = 2,3, \dots, n)$ according to the formula:

$$T_i^e = max_{k \in P(i)}\{T_k^e + T_k\}, \tag{4}$$

where addition operation is calculated according to the formula (1). Max denotes the choice of the activity time, where the crisp number $\phi_t(T_k^e + T_k)$ of a given activity is calculated according to the defuzzification formula:

$$\phi_t([a_1, a_2, a_2, a_3]) = \frac{a_1+a_2+2a_3}{4} \tag{5}$$

and the value is the biggest one. For the first activity it is equal $T_1^e = [0,0,0,0]$.

7. Use improved backward pass method to calculate the latest start times of activities T_i^l $(i = n-1, n-2, \dots, 1)$ using the formula:

$$T_i^l = min_{k \in S(i)}\{T_k^l\} - T_i, \tag{6}$$

where: subtraction operation is calculated according to the formula (2). Min in this case denotes the choice of activity duration, where $\phi_t(T_k^l)$ is the smallest one. It is assumed that $T_n^l = T_n^e$.

8. Estimate the slack time according to the formula:

$$Z(i) = T_i^l - T_i^e \tag{7}$$

9. Identify the critical path. The activity, where $Z(i) = [0,0,0,0]$ is called critical activity. Let P denote the set of all paths in the network S from the node 1 to n. The path $p \in P$ is called critical when the all activities belonging to this path are critical. The critical path is the longest sequence of activities carried out in a given project. It determines the total duration of the project $T_n^e + T_n$.

Now we will illustrate a numerical example of project scheduling using the proposed method OFCPM. Let us assume a project which consists of 11 activities. The sequences of activities involved in the considered project are listed out to draw the network diagram. The project in practice involves the unpredictable behavior of the market in the project execution timeframe, including weather conditions, prices and costs, availability of resources. We consider 11 activities $V = \{1,2,3, \dots, 11\}$. The relations are defined as follows:

$$Ar = \{(1,2), (2,3), (2,4), (2,5), (3,6), (4,6), (5,6), (6,7), (6,8), (7,9), (8,9), (9,10), (10,11).$$

Using the precedence relationship the network diagram of the project has been prepared and is presented in Figure 2.

Figure 2: The network diagram of the analyzed project

Table 1 contains the corresponding data of the given project. It presents project activities and their time characteristics. The activity duration time were estimated by group of experts ($Z = \{1,2,3\}$). They estimated each value and expressed using OFNs in Arbitrary Time Units [ATU]. The activities are complex and unpredictable. The duration times are imprecise. For example activity duration time of activity 1 estimated by expert 1 equals ca. 14 ATU with an increasing tendency described as [12,14,14,16] ATU. It means that activity duration time lower than 12 ATU and bigger than 16 ATU is impossible. In this case the activity duration time equal 14 ATU is the most possible, and the remaining values are likely to varying degrees, but the more the closer they are to 14 ATU.

Furthermore, more likely is 16 than 12 ATU. On the other hand some of activities in a given project are characterized by durations with an increasing tendency. In practice, this means that the duration of a given activity may be shortened to no more than the lower value of the ordered fuzzy number which is an interpretation of the activity time. For example activity duration time of activity 7 estimated by expert 2 equals ca. 13 ATU with a decreasing tendency described as [14,13,13,12] ATU. It means that activity duration time lower than 12 ATU and bigger than 14 ATU is impossible. In this case the activity duration time equal 13 ATU is the most possible, and the remaining values are likely to varying degrees, but the more the closer they are to 13 ATU. Furthermore, more likely is 12 than 14 ATU.

Table 1: Project activities with their time characteristics based on OFCPM

Number	Activity name	Expert	Duration time	Average duration time
1	A1	1 2 3	[12,14,14,16] [12,13,13,15] [12,15,15,17]	[12,14,14,16]
2	A2	1 2 3	[22,23,23,24] [22,23,23,24] [22,23,23,24]	[22,23,23,24]
3	A3	1 2 3	[2,3,3,4] [2,3,3,6] [2,3,3,5]	[2,3,3,5]
4	A4	1 2 3	[10,13,13,16] [11,13,13,15] [12,13,13,14]	[11,13,13,15]
5	A5	1 2 3	[12,14,14,15] [11,13,13,16] [13,12,12,14]	[12,13,13,15]
6	A6	1 2 3	[22,23,23,24] [21,23,23,25] [20,23,23,26]	[21,23,23,25]
7	A7	1 2 3	[15,13,13,12] [14,13,13,12] [16,13,13,12]	[15,13,13,12]
8	A8	1 2 3	[8,7,7,6] [9,8,8,7] [7,6,6,5]	[8,7,7,6]
9	A9	1 2 3	[32,33,33,34] [31,33,33,35] [30,33,33,36]	[31,33,33,35]
10	A10	1 2 3	[5,6,6,7] [5,6,6,7] [8,9,9,10]	[6,7,7,8]
11	A11	1 2 3	[15,16,16,17] [15,16,16,17] [18,19,19,20]	[16,17,17,18]

Now, we present applied of OFCPM step-by-step. According to the proposed approach we calculate the earliest start time for particular activity. This data should be determined first by performing operations on ordered fuzzy numbers representing uncertain durations of activities in the project. We present some initial calculations for network activities of the proposed method. According to the assumption of the fourth stage of the proposed method the earliest start time of the first activity is

equal $T_1^e = [0,0,0,0]$. From the project network, it follows that activities 2,3,4 and 5 have exactly one predecessor. Therefore:

$$T_2^e = max_{k\in P(2)}\{T_k^e + T_k\} = T_1^e + T_1 = [0,0,0,0] + [12,14,14,16] = [12,14,14,16],$$
$$T_3^e = T_4^e = T_5^e = T_2^e + T_2 = [12,14,14,16] + [22,23,23,24] = [34,37,37,40].$$

Activity number 6 coincides with the implementation of three parallel activities, i.e. activities 3, 4 and 5. Hence the earliest start time of the first activity is estimated as following:

$$T_6^e = max_{k\in P(6)}\{T_k^e + T_k\} = max\{T_3^e + T_3, T_4^e + T_4, T_5^e + T_5\} = max\{[34,37,37,40] + [2,3,3,5], [34,37,37,40] + [11,13,13,15], [34,37,37,40] + [12,13,13,15]\} = max\{[36,40,40,45], [45,50,50,55], [46,50,50,55]\}.$$

Because we have more than one value we should choose the time for which defuzzification value receives the greatest value. Therefore we calculate crisp value like:

$$\phi_t([36,40,40,45]) = \frac{36+40+2\cdot 45}{4} = 41.5,\ \phi_t([45,50,50,55]) = \frac{45+50+2\cdot 55}{4} = 51.25,$$
$$\phi_t([46,50,50,55]) = \frac{46+50+2\cdot 55}{4} = 51.5.$$

Thus, the earliest start time activity 6 is equal $T_6^e = [46,50,50,55]$. In a similar way we should calculate the values for other activities in the considered project structure.

Step 7 of the proposed approach of OFCPM allows to determinate the latest start times of activity. The calculations at this stage are carried out in the opposite direction (backward pass), according to the formula (6). The value of T_n^l is assumed to be the earliest start time of the last activity, i.e. $T_n^l = T_n^e$. In the present case it means that $T_{11}^e = [119,126,126,135]$.
The latest start times of individual activities in the considered project were subsequently calculated. Activities numbers 9 and 10 have one successor, so we calculate them like:

$$T_{10}^l = min_{k\in S(10)}\{T_k^l\} - T_{10} = T_{11}^l - T_{10} = [119,126,126,135] - [6,7,7,8] = [113,119,119,127].$$

Activity number 9 precedes the implementation of two parallel activities, activity 7 and 8. In order to obtain the latest start date we should select the time for which the defuzification value is the smallest one:

$$T_6^l = min_{k\in S(6)}\{T_k^l\} - T_6 = min\{T_7^l, T_8^l\} - T_6 = min\{[47,53,53,60], [54,59,59,66]\} - [21,23,23,25].$$

Because we have more than one value we should choose the time for which defuzzification value receives the greatest value. Therefore we calculate the crisp value like:

$$\phi_t([47,53,53,60]]) = 55;\quad \phi_t([54,59,59,66]) = 61.25.$$

Then $T_6^l = [47,53,53,60] - [21,23,23,25] = [26,30,30,35]$.

After determining the latest start times of activities, the slack time should be calculated for individual project activities (step 8). The earliest and the latest start times of the considered activities and their slack times are presented in the Table 3.

The critical path is 1-2-5-6-7-9-10-11. The total completion time of the considered project is equal: $[119,126,126,135] + [16,17,17,18] = [135,143,143,153]$ ATU. It means that the total completion time of the considered project is lower than 135 ATU and not bigger than 153 ATU is impossible. In this case the total completion time equal 143 ATU is the most possible, and the remaining values are likely to varying degrees, but the more the closer they are to 153 ATU. The project completion time is equal to 146 ATU (the crisp value) according to OFCPM considering states for the durations of

activities estimated by experts using ordered fuzzy orders with depicted tendency as an additional characteristics of the durations times.

Table 3: The earliest and latest times and slack times calculated with using OFCPM method

Activity	The earliest start times of activities T_i^e [ATU]	The latest start times of activities T_i^l [ATU]	Slack time $Z(i)$ [ATU]	$\phi(Z(i)$ [ATU]	Critical activity
1	[0,0,0,0]	[0,0,0,0]	[0,0,0,0]	0	yes
2	[12,14,14,16]	[12,14,14,16]	[0,0,0,0]	0	yes
3	[34,37,37,40]	[44,47,47,50]	[10,10,10,10]	10	no
4	[34,37,37,40]	[33,37,37,40]	[1,0,0,0]	0.25	no
5	[34,37,37,40]	[34,37,37,40]	[0,0,0,0]	0	yes
6	[46,50,50,55]	[46,50,50,55]	[0,0,0,0]	0	yes
7	[67,73,73,80]	[67,73,73,80]	[0,0,0,0]	0	yes

11	[119,126,126,135]	[119,126,126,135]	[0,0,0,0]	0	yes

$$\phi_t([135,143,143,153]) = 146 \text{ ATU}.$$

Idea and applied of Ordered Fuzzy Project Evaluation Review Technique

The proposed algorithm of OFPERT consists of few steps. Some of them are similar to the OFCPM. The difference is in estimating the duration times. The steps of OFPERT are as follows:

1. Specify the individual project activities.
2. Determine the sequence of the each activities.
3. Select Z experts to estimate the duration time.
4. Estimate the duration time using ordered fuzzy numbers by each expert $T_{ij,}$ $i = 1,2, \dots n, j = 1,2, \dots, z$. Each expert estimate three values (pessimistic T_i^p, $i = 1,2, \dots n$, optimistic T_i^o, $i = 1,2, \dots n$,, most likely T_i^m, $i = 1,2, \dots n$,) of the duration time using ordered fuzzy numbers.
5. Calculate average value of the duration time (optimistic, pessimistic and most likely) as ordered fuzzy number:

$$T_i^{o_aver} = \frac{\sum_{j=1}^{z} T_{i\ j,}^{o}}{z}, i = 1,2, \dots, n,\ j = 1,2,, \dots, z,$$
$$T_i^{p_aver} = \frac{\sum_{j=1}^{z} T_{i\ j,}^{p}}{z}, i = 1,2, \dots, n,\ j = 1,2,, \dots, z,$$
(8)
$$T_i^{m_aver} = \frac{\sum_{j=1}^{z} T_{i\ j,}^{m}}{z}, i = 1,2, \dots, n,\ j = 1,2,, \dots, z.$$

6. Calculate the expected time as ordered fuzzy number:

$$T_i^{\exp_aver} = \frac{T_i^{o_aver} + 4T_i^{m_aver} + T_i^{p_aver}}{6}, i = 1,2, \dots n. \quad (9)$$

7. Perform calculation of earliest start time of activities (denoted by T_i^e) for each activity $i \in V$ $(i = 2,3, \dots, n)$ according to the formula:

$$T_i^e = max_{k \in P(i)}\{T_k^e + T_k\}, \quad (10)$$

where addition operation is calculated according to the formula (1). Max denotes the choice of the activity time, where the crisp number $\phi_t(T_k^e + T_k)$ of a given activity is calculated according to the defuzzification formula:

$$\phi_t([a_1, a_2, a_2, a_3]) = \frac{a_1+a_2+2a_3}{4} \tag{11}$$

and the value is the biggest one. For the first activity it is equal $T_1^e = [0,0,0,0]$.

8. Use improved backward pass method to calculate the latest start times of activities T_i^l $(i = n-1, n-2, \dots, 1)$ using the formula:

$$T_i^l = min_{k \in S(i)}\{T_k^l\} - T_i, \tag{12}$$

where subtraction operation is calculated according to the formula (2). Min in this case denotes the choice of activity duration, where $\phi_t(T_k^l)$ is the smallest one. It is assumed that $T_n^l = T_n^e$.

9. Estimate the slack time according to the formula:

$$Z(i) = T_i^l - T_i^e \tag{13}$$

10. Identify the critical path. The activity, where $Z(i) = [0,0,0,0]$ is called critical activity. Let P denote the set of all paths in the network S from the node 1 to n. The path $p \in P$ is called critical when the all activities belonging to this path are critical. The critical path is the longest sequence of activities carried out in a given project. It determines the total duration of the project $T_n^e + T_n$.

Below we will present a numerical example of project scheduling using the proposed methods. Let us assume a project which consists of 10 activities. The sequences of activities involved in the considered project are listed out to draw the network diagram. The project in practice involves the unpredictable behavior of the market in the project execution timeframe, including weather conditions, prices and costs, availability of resources. We consider 10 activities $V = \{1,2,3, \dots, 10\}$. The relations are defined as follows:

$$Ar = \{(1,2), (2,3), (2,4), (2,5), (3,6), (4,6), (5,6), (6,7), (6,8), (7,9), (8,9), (9,10).$$

Using the precedence relationship the network diagram of the project has been prepared and is presented in Figure 3.

Figure 3: The network diagram of the analyzed project

According to OFPERT we present Table 4 which shows the experts' opinions about durations time of each activities in the optimistic, most likely and pessimistic states as ordered fuzzy numbers. The average of duration times in the optimistic, most likely and pessimistic states were then calculated as ordered fuzzy numbers. The expected value of each activities were also calculated. Table 4 contains the corresponding data of the given project. It presents project activities and their time characteristics. The activity duration time were estimated by group of experts ($Z = \{1,2,3\}$). They estimated each

value and expressed using OFNs in Arbitrary Time Units [ATU]. The activities are complex and unpredictable. The duration times are imprecise. For example activity duration time of activity 1 estimated by expert 1 equals ca. 4 ATU with an increasing tendency described as [2,4,4,6] ATU. It means that activity duration time lower than 2 ATU and bigger than 6 ATU is impossible. In this case the activity duration time equal 4 ATU is the most possible, and the remaining values are likely to varying degrees, but the more the closer they are to 4 ATU. Furthermore, more likely is 6 than 2 ATU. On the other hand some of activities in a given project are characterized by durations with a increasing tendency. In practice, this means that the duration of a given activity may be shortened to no more than the lower value of the ordered fuzzy number which is an interpretation of the activity time. For example activity duration time of activity 7 estimated by expert 2 equals ca. 6 ATU with a decreasing tendency described as [15,13,13,12] ATU. It means that activity duration time lower than 12 ATU and bigger than 15 ATU is impossible. In this case the activity duration time equal 13 ATU is the most possible, and the remaining values are likely to varying degrees, but the more the closer they are to 13 ATU. Furthermore, more likely is 12 than 15 ATU.

According to the proposed method OFPERT we calculate the earliest start time for particular activity. This data should be determined first by performing operations on ordered fuzzy numbers representing uncertain durations of activities in the project. We present some initial calculations for network activities of the proposed method. According to the assumption of the fourth stage of the proposed method the earliest start time of the first activity is equal $T_1^e = [0,0,0,0]$. From the project network, it follows that activities 2 ,3, 4 and 5 have exactly one predecessor. Therefore:

$$T_2^e = max_{k \in P(2)}\{T_k^e + T_k\} = T_1^e + T_1 = [0,0,0,0] + [2,4,4,6] = [2,4,4,6],$$
$$T_3^e = T_4^e = T_5^e = T_2^e + T_2 = [2,4,4,6] + [12,13,13,14] = [14,17,17,20].$$

Tab.4: Calculation of duration times with using OFPERT

Number	Activity	Expert	Duration time				
			Optimistic	Most likely	Pessimistic	Average optimistic/ most likely/ pessimistic	Expected duration time
1	A1	1 2 3	[1,3,3,5] [1,3,3,4] [1,3,3,6]	[2,4,4,6] [2,3,3,5] [2,5,5,7]	[3,5,5,7] [3,4,4,6] [3,6,6,8]	[1,3,3,5] [2,4,4,6] [3,5,5,7]	[2,4,4,6]
2	A2	1 2 3	[11,12,12,13] [11,12,12,13] [11,12,12,13]	[12,13,13,14] [12,13,13,14] [12,13,13,14]	[13,14,14,15] [13,14,14,15] [13,14,14,15]	[11,12,12,13] [12,13,13,14] [13,14,14,15]	[12,13,13,14]
3	A3	1 2 3	[1,2,2,3] [1,2,2,5] [1,2,2,4]	[2,3,3,4] [2,3,3,6] [2,3,3,5]	[3,4,4,5] [3,4,4,7] [3,4,4,6]	[1,2,2,4] [2,3,3,5] [3,4,4,6]	[2,3,3,5]
4	A4	1 2 3	[10,12,12,15] [10,12,12,14] [10,12,12,13]	[11,13,13,16] [11,13,13,15] [11,13,13,14]	[12,14,14,17] [12,14,14,16] [12,14,14,15]	[10,12,12,14] [11,13,13,15] [12,14,14,16]	[11,13,13,15]
5	A5	1 2 3	[12,13,13,14] [11,12,12,15] [10,11,11,13]	[13,14,14,15] [12,13,13,16] [11,12,12,14]	[14,15,15,16] [13,14,14,17] [12,13,13,15]	[11,12,12,14] [12,13,13,15] [13,14,15,16]	[12,13,13,15]
6	A6	1 2 3	[21,22,22,23] [20,22,22,24] [19,22,22,25]	[22,23,23,24] [21,23,23,25] [20,23,23,26]	[23,24,24,25] [22,24,24,26] [21,24,24,27]	[20,22,22,24] [21,23,23,25] [22,24,24,26]	[21,23,23,25]
7	A7	1 2 3	[14,12,12,11] [13,12,12,11] [15,12,12,11]	[15,13,13,12] [14,13,13,12] [16,13,13,12]	[16,14,14,13] [15,14,14,13] [17,14,14,13]	[14,12,12,11] [15,13,13,12] [16,14,14,13]	[15,13,13,12]
8	A8	1 2 3	[7,6,6,5] [8,7,7,6] [6,5,5,4]	[8,7,7,6] [9,8,8,7] [7,6,6,5]	[9,8,8,7] [10,9,9,8] [8,7,7,6]	[7,6,6,5] [8,7,7,6] [9,8,8,7]	[8,7,7,6]
9	A9	1 2 3	[31,32,32,33] [30,32,32,34] [29,32,32,35]	[32,33,33,34] [31,33,33,35] [30,33,33,36]	[33,34,34,35] [32,34,34,36] [31,34,34,37]	[30,32,32,34] [31,33,33,35] [32,34,34,36]	[31,33,33,35]

10	A10	1 2 3	[4,5,5,6] [4,5,5,6] [7,8,8,9]	[5,6,6,7] [5,6,6,7] [8,9,9,10]	[6,7,7,8] [6,7,7,8] [9,10,10,11]	[5,6,6,7] [6,7,7,8] [7,8,8,9]	[6,7,7,8]

Activity number 6 coincides with the implementation of three parallel activities, i.e. activities 3, 4 and. Hence the earliest start time of the first activity is estimated as following:

$$T_6^e = max_{k\in P(6)}\{T_k^e + T_k\} = max\{T_3^e + T_3, T_4^e + T_4, T_5^e + T_5\} = max\{[14,17,17,20] + [2,3,3,5], [14,17,17,20] + [11,13,13,15], [14,17,17,20] + [12,13,13,15]\} = max\{[16,20,20,25], [25,30,30,35], [26,30,30,35]\}.$$

Because we have more than one value we should choose the time for which defuzzification value receives the greatest value. Therefore:

$$\phi_t([16,20,20,25]) = \frac{16+20+2\cdot 25}{4} = 21.5,\ \phi_t([25,30,30,35]) = \frac{25+30+2\cdot 35}{4} = 31.25,$$
$$\phi_t([26,30,30,35]) = \frac{26+30+2\cdot 35}{4} = 31.5.$$

Thus, the earliest start time activity 6 is equal $T_6^e = [26,30,30,35]$. In a similar way we should calculate the values for other activities in the considered project structure.

Step 8 of the proposed approach allows to determinate the latest start times of activity. The calculations at this stage are carried out in the opposite direction (backward pass), according to the formula (12). The value of T_n^l is assumed to be the earliest start time of the last activity, i.e. $T_n^l = T_n^e$. In the present case it means that $T_{10}^e = [93,99,99,107]$.

The latest start times of individual activities in the considered project were subsequently calculated. Activities numbers 7, 8 and 9 have one successor, so we calculate them like:

$$T_9^l = min_{k\in S(9)}\{T_k^l\} - T_9 = T_{10}^l - T_9 = [93,99,99,107] - [31,33,33,35] = [62,66,66,72].$$

Activity number 6 precedes the implementation of two parallel activities, activity 7 and 8. In order to obtain the latest start date we should select the time for which the defuzification value is the smallest one:

$$T_6^l = min_{k\in S(6)}\{T_k^l\} - T_6 = min\{T_7^l, T_8^l\} - T_6 = min\{[47,53,53,60], [54,59,59,66]\} - [21,23,23,25].$$

Because we have more than one value we should choose the time for which defuzzification value receives the greatest value. Therefore:

$$\phi_t([47,53,53,60]]) = 55;\quad \phi_t([54,59,59,66]) = 61.25.$$

Then $T_6^l = [47,53,53,60] - [21,23,23,25] = [26,30,30,35]$.

After determining the latest start times of activities, the slack time should be calculated for individual project activities (step 9). The earliest and the latest start times of the considered activities and their slack times are presented in the Table 5.

Table 5: The earliest and latest start times and slack times obtained with using OFPERT method

Activity	The earliest start times of activities T_i^e [ATU]	The latest start times of activities T_i^l [ATU]	Slack time $Z(i)$ [ATU]	$\phi(Z(i)$ [ATU]	Critical activity
1	[0,0,0,0]	[0,0,0,0]	[0,0,0,0]	0	yes
2	[2,4,4,6]	[2,4,4,6]	[0,0,0,0]	0	yes
3	[14,17,17,20]	[24,27,27,30]	[10,10,10,10]	10	no
4	[14,17,17,20]	[15,17,17,20]	[1,0,0,0]	0.25	no
5	[14,17,17,20]	[14,17,17,20]	[0,0,0,0]	0	yes
6	[26,30,30,35]	[26,30,30,35]	[0,0,0,0]	0	yes
7	[47,53,53,60]	[47,53,53,60]	[0,0,0,0]	0	yes
8	[47,53,53,60]	[54,59,59,66]	[7,6,6,6]	6.25	no
9	[62,66,66,72]	[62,66,66,72]	[0,0,0,0]	0	yes
10	[93,99,99,107]	[93,99,99,107]	[0,0,0,0]	0	yes

The critical path is 1-2-5-6-7-9-10. The total completion time of the considered project is equal: $[93,99,99,107] + [6,7,7,8] = [99,106,106,115]$ ATU. It means that the total completion time of the considered project lower than 99 ATU and bigger than 115 ATU is impossible. In this case the total completion time equal 106 ATU is the most possible, and the remaining values are likely to varying degrees, but the more the closer they are to 106 ATU. The project completion time is equal to 108.75 ATU according to OFPERT considering the optimistic, most likely and pessimistic states for the durations of activities estimated by experts.

$$\phi_t([99,106,106,115]) = 108{,}75 \text{ ATU.}$$

Conclusions

The paper presents the theoretical foundations of new methods named OFCPM and OFPERT. Classical CPM and PERT methods were replaced by new ones. The OFCPM and OFPERT methods allow to define not precisely known duration time, ordered fuzzy numbers are shown to be relevant to the exact nature of the problem rather than deterministic CPM or probabilistic PERT.

These methods are based on classical CPM and PERT methods with using fuzzy logic. The ordered fuzzy numbers are used to estimate duration time of project tasks. The project tasks are estimated by experts on their experience and knowledge. The duration time expressed by experts on their opinions were obtained in the optimistic, pessimistic, and the most likely states and expressed as ordered fuzzy numbers. In according to OFPERT the final estimation was done after averaging data of each project tasks.

The comparison of new ordered approaches to existing deterministic and stochastic ones is under study. Future work will focus on applying these new methods and dealing with the complexity of time-constrained resource availability. The extended developed techniques based on ordered fuzzy numbers can be treated by project managers as a decisional support system to manage a project.

Abstract

Turnover intention is a personal condition where employees actively seek work opportunities in other organizations. One of the causes of turnover intention is work dissatisfaction and the inability of employees to manage work stress. This study aims to test the traditional turnover theory by analyzing work stress mechanisms in reducing turnover intention through job satisfaction. Using 101 employee samples, this study was conducted by distributing questionnaires as the main instrument. The collected data is analyzed using Path Analysis to test the proposed hypothesis. The findings showed all hypotheses were accepted. Work stress has a significant effect on job satisfaction and has a significant effect on turnover intention. Job satisfaction has a significant effect on turnover intention. Furthermore, job satisfaction significantly mediates the effect of work stress on turnover intention. The findings of this study support the traditional turnover theory that employees who feel satisfaction at work tend to prefer to remain in the organization.

Keywords: work stress, job satisfaction, turnover intention

Introduction

Employee turnover that is initiated by the existence of turnover intention has received attention from researchers and is a serious problem in all organizations because it can interfere with organizational performance (Choi et al., 2019). Normal employee turnover if it ranges between 5-10 percent per year and to be high if it reaches more than 10 percent (Gorrell & Langenbach, 1994 and Branham, 2009). PT. Fastrata Buana Denpasar is a distributor under Kapal Api Group which has a high employee turnover rate. Employee turnover data (Figure 1) in 2014 was 10.48%, in 2015 it was 11.27%, in 2016 it was 10.67%, in 2017 was 12.14%, and in 2018 it was 12.23%. Fahrizal and Utama (2017) state that employee turnover should not be above 10 percent in one year because it can interfere with organizational performance. Employee turnover intentions that are not handled properly can quickly lead to more employee turnover (Tripathi and Pandey, 2017). This shows that the intention of employees to leave the organization is in line with the level of employee turnover that occurs.

Figure 1: Employee Turnover

Turnover intention is also the intention of employees to leave the organization by showing a less friendly attitude towards the organization (Santhanam et al, 2017) so that it has an impact on the instability of work conditions. Sartika, (2014) stated that turnover can lead to high human resources management costs, such as training and recruitment costs. There are several factors that affect turnover intention, including job satisfaction (Sutanto and Gunawan, 2013). Most employees who wish to leave the organization due to dissatisfaction at work, thereby increasing the intention to leave the organization (Kristanto, et al., 2014). In addition to job satisfaction, work stress can also be a trigger for turnover intention (Siddiqui and Jamil, 2015). Stress at work is the main issue that is most difficult to avoid at work (Parvaiz et al., 2015). Hlatywayo et al. (2014) stated that stress is a condition in which an employee experiences changes in emotions, thought processes, and certain conditions. Employees who are required to work with high achievement often experience work stress. Ongoing work stress can reduce perceived job satisfaction and result in the intention to leave an organization.

Several research findings have indicated that work stress has a significant positive effect on turnover intention (Syahronica et al. 2015; Suciati et al., 2015; Manurung and Ratnawati, 2012). In contrast, research (Dewi and Netra, 2015; Tukimin, 2014; Adelia and Mujiati, 2016) found that work stress has a negative effect on job satisfaction. Other findings suggest that job satisfaction has a negative effect on turnover intention (Foon et al., 2010; Dewi and Wibawa, 2016). Furthermore (Basri, 2017; Indrayani, 2012) stated that the effect of work stress on turnover intention is mediated by job satisfaction. Satisfied employees tend to feel lower levels of work stress (Choi et al., 2019; Alam et al., 2019; Courtney, & Phelan, 2019). This study aims to analyze the mechanism of work stress reducing turnover intention through job satisfaction. In addition, this study aims to analyze the role of job satisfaction mediating the effect of work stress on turnover intention. This study also aims to examine the traditional turnover theory that predicts employee turnover behavior as a result of attitudes at work.

Literature Review

This study examines the traditional turnover theory (Harman et al., 2007) which stated that employees who leave an organization tend to have negative work attitudes. The traditional turnover theory also explains how employees feel dissatisfied with their work and thus find a new job. Zhao and Liu, (2010) asserted that employees who feel satisfaction at work are believed to not leave the organization within a certain period of time, but work stress can reduce job satisfaction. Robbins and Judge (2014: 429) stated that stress is an unpleasant psychological process that occurs as a reaction to pressures from the surroundings. Stress also arises when employees are unable to cope with perceived stresses in their work (Jamadin et al., 2015). Employees who have high work stress tend to experience lower job satisfaction (Dewi et al., 2014; Ariana and Riana, 2016). Research conducted by

(Usyal, 2019; Chichra et al., 2019; Lambert et al., 2018) found that work stress can significantly reduce job satisfaction.

Excessive work stress can also trigger the intention of employees to leave the organization, even potentially leaving the organization in the near future. This opinion shows that turnover intention is the intention to move but has not yet reached the stage of realization. Irvianti and Verina (2015) stated that turnover is a tangible manifestation of turnover intention which can be a serious problem for organizations, especially when employees who have the expertise, ability, experience and who are skilled are moving out of the organization. One of the factors triggering turnover intention is work stress as a result of the inability of employees to cope with work pressure (Jamadin et al., 2015). The high work stress of employees that result in employees' intention to leave the organization is increasing (Parvaiz et al., 2015; Mitchell et al., 2014). Research conducted by (Johartono and Thistle, 2013; Rai, 2015; Putra and Mujiati, 2019) found that work stress has a significant positive effect on turnover intention. Workloads that are felt to be too high can trigger the emergence of work stress that results in higher employee intentions to leave the organization.

In addition to work stress, another factor that can affect turnover intention is job satisfaction. As a work attitude, job satisfaction is an evaluation conducted by employees on the environment at work. Job satisfaction is a positive or negative feeling about a job that is generated towards evaluating job characteristics (Riana et al., 2018; Robbins and Judge, 2014: 46). Job satisfaction is one of the most important work attitudes because employee satisfaction can reduce the level of work stress and turnover intention (Wisantyo and Madiistriyatno, 2015). Research conducted by (Saeed et al., 2014; Candra and Riana, 2017) found that employees who are satisfied with their work tend to wish to remain in the organization.

Employees who feel pressured at work can increase feelings of dissatisfaction with the organization, and consider leaving the organization (Liu et al., 2019). Research conducted by Andini et al. (2018) found that job satisfaction mediates the effect of work stress on turnover intention. Employees who feel pressured in working indirectly feel dissatisfied with their work, which in turn causes turnover intention. Research conducted by (Sheraz et al., 2014; Tziner et al., 2015) suggested that work stress has a positive impact on turnover intention mediated by job satisfaction. Employees who experience high stress can reduce perceived satisfaction at work, causing a intention to leave the organization. Thus, job satisfaction is an important work attitude in reducing turnover intention as a result of work stress.

H_1: Work stress has a negative and significant effect on job satisfaction
H_2 : Work stress has a positive and significant effect on turnover intention
H_3 : Job satisfaction has a negative and significant effect on turnover intention
H_4 : Job satisfaction mediates the effect of work stress on turnover intention

Research Methodology

This study uses a quantitative design by distributing questionnaires using a Likert scale, from scale 1 show strongly disagree to scale 5 which shows strongly agree. The study population was employees of PT. Fastrata Buana Denpasar by using a questionnaire distributed to all employees at one-month intervals. A total of 105 questionnaires were distributed to all employees, 101 questionnaires were filled in completely and declared valid and 4 questionnaires were not returned. Turnover intention measurement was adopted from research conducted by Jehanzeb et al., (2013), work stress was adopted from research conducted by Qureshi et al. (2012) and job satisfaction refers to research indicators of Riana et al. (2018). Furthermore, the data collected was analyzed with Path Analysis to test hypotheses and Sobel Test to test indirect effects (mediation). The profile of research respondents is shown in Table 1 below.

Table 1: Respondent Profile

Age		Education	
21 - 26 years	19.8 %	Senior High School	11.9 %
27 - 32 years	52.5 %	Diploma	42.6 %
33 - 38 years	20.8 %	Bachelor	45.5 %
39 - 44 years	6,9 %	Work Duration	
Gender		< 3 years	30.7 %
Male	36.6 %	3 - 5 years	40.6 %
Female	63.4 %	> 5 years	28.7 %

Findings and Discussion

Validity and Reliability Tests

The validity test is conducted by analyzing the correlation between the scores of instrument items in a factor with the total score. Reliability shows the extent to which a measurement can produce a consistent analysis if it is measured several times on the same object (Sugiyono, 2017: 130). The results of the Validity and Reliability Test are shown in the following Table 2.

Table 2: Validity and Reliability Tests Results

Variable	Item	Validity		Remarks
		Correlation	Cut off	
Work Stress (X) α 0.856 (>0,60) (reliable)	($X_{1.1}$)	0,798	0,3	Valid
	($X_{1.2}$)	0,798	0,3	Valid
	($X_{1.3}$)	0,842	0,3	Valid
	($X_{1.4}$)	0,683	0,3	Valid
	($X_{1.5}$)	0,892	0,3	Valid
	($X_{1.6}$)	0,826	0,3	Valid
	($X_{1.7}$)	0,910	0,3	Valid
	($X_{1.8}$)	0,954	0,3	Valid
Job satisfaction (M) α 0.907 (>0,60) (reliable)	($M_{1.1}$)	0,968	0,3	Valid
	($M_{1.2}$)	0,932	0,3	Valid
	($M_{1.3}$)	0,930	0,3	Valid
	($M_{1.4}$)	0,970	0,3	Valid
	($M_{1.5}$)	0,948	0,3	Valid
Turnover Intention (Y) α 0.890 (>0,60) (reliable)	($Y_{1.1}$)	0,868	0,3	Valid
	($Y_{1.2}$)	0,846	0,3	Valid
	($Y_{1.3}$)	0,906	0,3	Valid

Table 2 informs that the model adequately meets the validity and reliability criteria. This can be seen from all correlation values (r) are showing numbers above the standard that is 0.3. Table 2 also shows the Cronbach's Alpha value is above the standard of 0.6. Based on these results, the model is said to be feasible because it meets the adequate criteria of validity and reliability (Sugiono, 2017).

Direct and Indirect Effect

Analysis of direct, indirect, or total effect, can explain the relationship between research variables. These variables are work stress, job satisfaction, and turnover intention. The direct effect is shown by a line coefficient, in contrary, the indirect effect occurs through the role of an intermediate variable.

Path Analysis

Path coefficient calculation is conducted by regression analysis and the results obtained are shown in the following table.

Table 3: Path Analysis Regression 1 Result

Model	*Unstandardized Coefficients*		*Standardized Coefficients*	t	Sig.
	B	Std. Error			
(Constant)	5,547	0,179		30,956	0,000
Work Stress (X)	-0,620	0,063	-0,706	-9,906	0,000
R^2					0,498
F Calculation					98,138
Sig. F					0,000
dependent	Job satisfaction				

The results of path analysis substructure 1 in Table 3 shows the structural equations according to the following formula.

$$M = \beta_1 X + e_1 \Rightarrow M = -0{,}706X + e_1$$

Table 4: Path Analysis Regression 2 Result

Model	*Unstandardized Coefficients*		*Standardized Coefficients*	t	Sig.
	B	Std. Error			
(Constant)	1,849	0,447		4,136	0,000
Work Stress (X)	0,716	0,067	0,667	10,615	0,000
Job satisfaction (M)	-0,356	0,077	-0,292	-4,643	0,000
R^2					0,805
F Calculation					202,897
Sig. F					0,000
dependent	Intention to leave				

The results of path analysis substructure 2 in Table 4 shows the structural equations according to the following formula.

$$Y = \beta_2 X + \beta_3 M + e_2 \Rightarrow Y = 0{,}667X - 0{,}292M + e_2$$

The coefficient of determination (R^2m) and error (e) calculation

Based on the substructure 1 and 2 models, the final path diagram model can be arranged. Before compiling the final path diagram, the default error value was firstly calculated as follows.

$Pe_i = \sqrt{1 - Ri^2}\sqrt{1 - Ri^2}$ => $Pe_1 = \sqrt{1 - 0{,}498}\sqrt{1 - 0{,}498} = 0{,}709$

$Pe_2 = \sqrt{1 - R2^2} = \sqrt{1 - 0{,}805} = 0{,}442$

Based on the effect of error calculation (Pe_i), the result of the effect of error (Pe_1) is 0.709 and the effect of error (Pe_2) is 0.442. The results of the total determination coefficient are as follows.

$R^2m = 1 - (Pe_1)^2 (Pe_2)^2$

$= 1 - (0{,}709)^2 (0{,}442)^2 = 1 - (0{,}503)(0{,}195) = 1 - 0{,}098 = 0{,}902$

A total determination value of 0.902 indicates that 90.2 percent of employee turnover intention variation can be explained by work stress and satisfaction, while the remaining 9.8 percent is explained by other factors outside the model. Based on Tables 3 and 4 it can also be concluded that the three hypotheses of direct influence are accepted. Furthermore, to analyze the indirect effect of work stress on turnover intention through job satisfaction, the Sobel Test is used as follows.

$$Z = \frac{ab}{\sqrt{b^2Sa^2 + a^2\ Sb^2\ + Sa^2Sb^2}}$$

Information:

a= 0,706; Sa= 0,063; b= 0,292; Sb= 0,077

$$Z = \frac{0{,}706\ \times 0{,}292}{\sqrt{0{,}292^2 0{,}063^2 + 0{,}706^2\ 0{,}077^2\ + 0{,}063^2 0{,}077^2}}$$

$$Z = \frac{0{,}2062}{\sqrt{0{,}0033}}$$

$$Z = \frac{0{,}2062}{0{,}057595}$$

Z = 3,5793 = 3,58

Hypothesis Testing Results

The analysis results of the work stress's effect on job satisfaction obtained are the value of Sig. t of 0,000 with a beta coefficient (ß) -0.706. Sig. Value t 0,000 ≤ 0.05 indicates that H0 is rejected and H1 is accepted. This result means that work stress has a significant negative effect on job satisfaction. The analysis results of the work stress's effect on turnover intention obtained are Sig. t of 0,000 with a beta coefficient (ß) of 0.667. Sig. Value t 0,000 ≤ 0.05 indicates that H0 is rejected and H1 is accepted. This result means that work stress has a significant positive effect on turnover intention. The analysis results of job satisfaction's effect on turnover intention obtained are Sig. t of 0,000 with a beta coefficient (ß) -0.292. Sig. Value t 0,000 ≤ 0.05 indicates that H0 is rejected and H1 is accepted. This result means that job satisfaction has a significant positive effect on turnover intention. Furthermore, the effect of work stress on turnover intention through job satisfaction with the Sobel Test obtained 3.58 results in which the number was greater than 1.96. Therefore, work stress has an indirect significant effect on turnover intention through job satisfaction.

Finding and Discussion

Turnover intention is the desire of employees to leave the organization by showing certain negative work attitudes (Santhanam et al, 2017). There are three indications that employees have the turnover intention (Jehanzeb et al., 2013), such as the intention to leave, find another job, and leave the organization in the near future. For employees to not have the intention to leave the organization,

employees must have a high level of job satisfaction (Wisantyo and Madiistriyatno, 2015). Job satisfaction is a positive or negative feeling about the employee's work environment (Robbins and Judge, 2017). Several indicators can be used to find out the level of job satisfaction (Riana et al., 2018) such as the job itself, salary, promotion opportunities, supervision, and satisfaction with colleagues. In addition to job satisfaction, employees are also demanded to be able to manage work stress levels so as not to cause the intention to leave the organization (Johartono and Thistle, 2013; Rai, 2015; Putra and Mujiati, 2019). Robbins and Judge (2017) stated that stress is an unpleasant psychological process as a reaction to pressures from surroundings. Employees who can control various pressures at work tend to be able to manage work stress thereby reducing the intention to leave the organization.

The findings of this study also found that work stress has a negative and significant effect on job satisfaction (Okumus et al., 2019: Courtney & Phelan, 2019). Employees who feel excessive work stress can reduce perceived job satisfaction, and vice versa (Lee & Kim, 2019). Employees who are given jobs outside their limits can cause various stresses for employees. When employees often feel pressured, the level of job satisfaction felt by employees tends to decrease. The results also found that work stress has a positive and significant effect on turnover intention. Employees who feel pressured at work can increase the level of work stress which leads to cause the intention to leave the organization. The intention of employees to leave the organization has the potential to harm the organization due to employees who have been trained are moving out of the organization.

Research findings also found that job satisfaction has a negative and significant effect on turnover intention. Employees who feel satisfaction at work can reduce turnover intention. However, employees who have low job satisfaction due to salaries and benefits that are not in accordance with the workload and are not satisfied with their work have the potential to have a stronger intention to leave the organization. In accordance with traditional turnover theory (Zhao and Liu, 2010), employees who have high job satisfaction are believed to remain in the organization. The results also prove that work stress can affect turnover intention through job satisfaction. Employees who feel work stress directly have the intention to leave the organization. However, when employees feel satisfied, the intention to leave the organization decreases (Rajamohan., 2019; Johnson & Yanson, 2018; Kim and Kang., 2018).

Conclusions, Implications, And Limitations

The work stress mechanism decreases turnover intention through job satisfaction can be proven. Employees who feel high work stress can reduce job satisfaction and lead to an intention to leave the organization. Furthermore, employees who feel high job satisfaction can reduce the intention to leave the organization, and vice versa if job satisfaction felt by employees is low, then the intention to leave the organization increased. The findings of this study inform that work stress felt by employees can reduce employee intention to leave the organization when employees feel satisfaction at work. In other words, job satisfaction plays an important role in reducing the effect of work stress on intention turnover. Satisfied employees tend to be able to manage work stress levels, reducing the intention to leave the organization.

The implications of this study indicate that work stress has a direct or indirect effect on turnover intention through job satisfaction. Theoretically, the results of this study confirm the Traditional Turnover Theory, that organizations that always pay attention to employee job satisfaction can reduce the intention of its employees to leave the organization. The findings of this study provide implications for human resource development strategies to pay more attention to indicators of work stress and job satisfaction. The high level of fatigue at work that is felt by employees of the existing workload, low satisfaction with colleagues must be a serious concern of management to reduce employee intentions to leave the organization. This research has limitations because it is done in one organization so it must be tested again in another organization. Also, perception research using cross section data tends to experience changes in respondents' perceptions of the statements in the questionnaire.

Abstract

The activities of the European Union (EU) in regard to occupational health and safety have its legislative foundations in Article 153 of the EU Treaty (Asfaw at el 2013; Besnard and Hollnagel, 2014). In the 28 member states of the EU (EU-28), 2015 recorded over 3.2 million workplace accidents which invoked at least 4 day work leaves and 3,876 deaths. The authors of this analysis present the issue of workplace accidents based on the examination of incidents in large foodstuff plants of the Lodz voivodship i.e. food processing businesses that have been continuously active for the five year period of 2008-2012. The analysis determines the correlations between months, hours, seniority, workstations, and workplace accidents. In the examined five year period (2008-2012), the incidence of workplace accidents in the foodstuff industry rose by 29%. The analysis results indicate that most workplace accidents occur in March, May and July i.e. the months when the foodstuff sector has its most intensive activity. The majority of accidents occurred to people who were employed at a given position for less than a year. The results further indicated that those workplace accidents happened to individuals employed in physical work positions.

Keywords: Occupational Safety Management, Foodstuff Industry, Workplace Accidents, Sustainability

Introduction

The EU strategy in the area of health protection in the workplace declares that occupational health and safety is one the most important and most advanced aspects of EU policy (Zielińska, 2017).

In the book by Zielińska (2018) in 2015, there were just over 3.2 million non-fatal accidents that resulted in at least four calendar days of absence from work in the EU-28 (Eurostat Statistics Explained). There was a decrease in the total number of non-fatal accidents at work in the EU-28 between 2010 and 2015, some 370 thousand fewer (equivalent to an overall reduction of 10.3 %). A closer examination reveals that the decrease was in fact recorded between 2010 and 2012, after which the number of non-fatal accidents at work was relatively stable, with changes between -1.2 % and 3.0 % each year during the period 2013-2015 (Bellamy, 2015). The decrease in the incidence rate (number of non-fatal accidents at work for every 100 000 persons employed) between 2010 and 2015 (down 10.9 %) was slightly greater than the decrease for the number of non-fatal accidents, reflecting modest growth in the total number of persons employed. In absolute terms, non-fatal accidents in the EU-28 were most common in manufacturing, where 625 thousand people had non-fatal accidents in 2015, 19.5 % of the total (Zielińska and Bajdur, 2019).

Fig. 1: Fatal accidents at work, by economic activity, UE-28, 2010-2015

In absolute terms, fatal accidents were most common in construction, where 815 people in the EU-28 had fatal accidents in 2015, 21.0 % of the total. Manufacturing (17.0 %), transportation and storage (16.5 %) and agriculture, forestry and fishing (13.2 %) also accounted for more than one tenth of all fatal accidents at work (Eurostat, 2013). In 2015, the highest incidence of fatal accidents at work was observed in mining and quarrying, with 73 fatal accidents, equivalent to 9.5 per 100 000 persons employed. Construction (6.2 per 100 000), transportation and storage (5.8 per 100 000) and agriculture, forestry and fishing (5.7 per 100 000 persons employed) were the only other NACE sections with incidence rates above 2.0 per 100 000 persons employed (Eurostat Statistics Explained). Among the activities shown in Figure 1, the lowest incidence rate was for human health and social work activities, which also recorded the largest decrease in its incidence rate between 2010 and 2015.

The Employers of Poland association has developed a Responsible Business Code which contains the principles of a responsible business (Barwickam, 2011). In it the association stresses the business' responsibility to the community for decisions and activities in reference society and the environment which should be guided by transparency and ethical behaviour (Bird and Germain, 1996). The activity of these companies should take into consideration the opinions of interested parties, act in accordance with the law and international norms and participate in the sustainable development of society (Carrillo-Castrillo et al 2016; Maciołek and Zielińska 2012).

The issue of workplace accidents is current in spite of technical progress and better training of OHS personnel to intercede in order to prevent these events, and the incidence of accidents continues to remain high (Dziekoński and Zielińska, 2017; Zielińska 2017). Workplace accidents are the primary measure of occupational danger occurring in inappropriate environmental conditions (Ordysiński, 2013). They also occur through not observing what is widely considered 'safety culture' i.e. improper employee behavior and poor work organization as defined by OHS [Norimitsu, 2015 and Pracodawcy, 2012).

Proper work conditions and preventive efforts in the area of OHS have a direct impact in reducing the number of workplace accidents (Dziekńsk and Zielińska 2017; Ślawska, 2010). They also serve to protect the health and life of individuals hired in plants (Cellier et al, 1995).

For many years, various plants have applied various material and moral incentives to encourage active participation in forming safe work conditions (Dziekoński and Zielińska, 2017). There are also legal codes defining disciplinary responsibility – official and punitive – for not observing OHS regulations and fulfilling responsibilities in this area (Bräunig, and Kohstall, 2013).

Materials and Methods

The study focuses on the correlations between months, hours, seniority, work station and workplace accidents, which occurred in large foodstuff plants in the Łódź voivodship. The plants considered were those continuously operated during the five year period of 2008-2012.

The research was carried out on large food processing companies that operate in the Łódź province which operated continuously between the years 2008-2012, in which only companies employing more than 50 employees. The main criterion for selection was that the companies' business activity was conducted within the Łódź province in the food industry. Complete data for 116 food industry companies was obtained through questionnaires. The information and source materials were collected during visits to the selected companies with the use of the questionnaire generated by the author, together with observations of labour in the production lines. Verification of collected information was carried out during similar interviews and conversations with OSH specialists at the studied companies.

Analysis of the Results

For the selected group of businesses, there is a marked increase of workplace accidents – from 258 in 2008, to 333 incidents in 2012 – for the study period in that the lowest incidence occurred in 2009 (211 accidents), and the highest in 2011 (358 accidents).

During the study regarding workplace accident tendency rates in the selected plants, a number of external factors were determined which may have impact on the accident rates in said plants. Correlation assessment was made between months of the year, worktime of employees, seniority and length of time at a given workstation, and the number of workplace accidents. Firstly, the dependency between number of workplace accidents and month of said accidents (figure 2).

Fig. 2: General Workplace Accident Incidence Structure at Selected Foodstuff Industry Plants by Months (2008-2012)

As shown in Drawing 2, workplace accidents in foodstuff plants most frequently occurred in March, April, May, June, July and August i.e. the months of most intensive production.

Fig. 3: General Workplace Accident Incidence Structure at Selected Foodstuff Industry Plants by Shift Hours (2008-2012) in average %

The next factor analyzed was the hours worked by an employee during the day. Results indicate (shown in Drawings 3 and 4) most accidents occurred during the early hours of the shift i.e. hours 1 to 4. This may be a result of the preparatory activities of employees during the initial hours of a shift which activities demand a high degree of concentration and attention. However, noticeable is the rise of accident incidence at the end of the shift – hour 7 and up. This may be a result of fatigue after seven hours of work when mistakes in servicing and operating machines are easier to make.

Fig. 4: Workplace Accident Incidence Structure at Selected Foodstuff Industry Plants by Hours (2008-2012) in average %

As shown in Drawings 3 and 4, most workplace accidents in the selected industrial sector occurred between shift hours 2 and 3, which may indicate a need to establish a break so employees may refresh themselves after 2 hours of work.

The next correlation analysis pertained to hours at work, the number of workplace accidents per 100 employees in the selected plants. In plants concerned with processing and preserving meat, and meat

production, there was no observable rise of incidence in any of the hours, whereas the results of Table 1 indicate that all shift hours noted high accident incidence. This condition may be caused by the specific production and preserving processes of the job(s) in the use of sharp tools.

Table 1: Workplace Accident Incidence per 100 Employees in Selected Meat Processing and Preserving and Other Meat Products Plants (2008-2012) on the Basis of Initial Shift Hours

Year	Initial Shift Hours							
	from 0 to 2	**above 2 to 3**	**above 3 to 4**	**above 4 to 5**	**above 5 to 6**	**above 6 to 7**	**above 7 to 8**	**above 8**
2008	0,19	0,34	0,31	0,22	0,36	0,19	0,24	0,22
2009	0,25	0,35	0,23	0,20	0,27	0,07	0,13	0,15
2010	0,25	0,31	0,28	0,23	0,25	0,28	0,21	0,30
2011	0,26	0,37	0,41	0,36	0,45	0,47	**0,49**	0,47
2012	0,26	0,47	0,28	0,26	0,26	0,26	0,31	0,42

Table 2: Workplace Accident Incidence per 100 Employees in Production of Bakery and Cereal Products (2008-2012) on the Basis of Initial Shift Hours

Year	Initial Shift Hours							
	from 0 to 2	**above 2 to 3**	**above 3 to 4**	**above 4 to 5**	**above 5 to 6**	**above 6 to 7**	**above 7 to 8**	**above 8**
2008	0,23	0,23	0,16	0,31	0,08	0,16	0,23	0,39
2009	0,08	0,46	0,15	0,31	0,31	0,15	0,23	0,08
2010	0,16	0,31	0,47	0,16	0,08	0,00	0,08	0,31
2011	0,00	0,45	**0,53**	0,30	0,38	0,45	0,08	0,15
2012	0,07	0,00	0,29	0,22	0,07	0,51	0,22	0,37

The subsequent branch to be considered is the bakery and other grain products branch where analysis results show – as presented in Table 2 – that most accidents were noted between the 3rd and 4th hours of the shift. This may be caused through starting-up machinery after an extensive preparatory to production phase by employees. The fewest accidents occurred during the 2nd hour of the shift when preparation and production organization was undertaken.

Table 3: Workplace Accident Incidence per 100 Employees in Production of Dairy Products (2008-2012) on the Basis of Initial Shift Hours

Year	Initial Shift Hours							
	from 0 to 2	**above 2 to 3**	**above 3 to 4**	**above 4 to 5**	**above 5 to 6**	**above 6 to 7**	**above 7 to 8**	**above 8**
2008	0,39	0,33	0,29	0,36	0,10	0,00	0,23	0,10
2009	0,26	0,03	0,03	0,16	0,00	0,20	0,46	0,53
2010	0,22	0,19	0,51	0,51	0,22	0,06	0,03	0,13
2011	0,12	0,22	0,25	0,43	0,22	0,25	0,34	0,09
2012	0,31	0,18	0,25	0,15	0,18	0,18	**0,65**	0,40

In the segment of dairy product production, results of the analysis indicate (Table 3), most accidents occurred between the 4th and 5th hours of the shift, caused by the very specific nature of the segment.

Table 4: Workplace Accident Incidence per 100 Employees in Production of Dairy Products (2008-2012) on the Basis of Initial Shift Hours

Year	**Initial working hours**							
	from 0 to 2	**above 2 to 3**	**above 3 to 4**	**above 4 to 5**	**above 5 to 6**	**above 6 to 7**	**above 7 to 8**	**above 8**
2008	0,15	0,30	0,30	0,15	0,08	0,15	0,15	0,08
2009	0,08	0,00	0,23	0,08	0,30	0,15	0,00	0,00
2010	0,22	0,22	0,22	0,15	0,15	0,22	0,15	0,07
2011	0,00	0,40	0,16	0,40	0,57	0,16	0,40	0,65
2012	0,08	0,41	0,33	0,08	0,08	0,08	0,08	**0,82**

In the segment tied to processing and preserving fruits and vegetables (Table 4), it bears notice that most workplace accidents occurred during over-time i.e. beyond the 8th hour of the shift, potentially caused by intensified production during the shift.

Table 5 presents the data of the beverage segment and its accident rates where most accidents occurred between the 3rd and 4th shift hours potentially caused by the timing of certain activities by employees' i.e. the preparatory phase for production took up to three hours and then production was initiated which start-up then may have raised concerns indicating that production raised danger factors more than the preparatory and shutting-down phases.

Table 5: Workplace Accident Incidence per 100 Employees in Beverage Production (2008-2012) on the Basis of Initial Shift Hours

Year	Initial working hours							
	from 0 to 2	above 2 to 3	above 3 to 4	above 4 to 5	above 5 to 6	above 6 to 7	above 7 to 8	above 8
2008	0,00	0,00	0,09	0,24	0,05	0,09	0,28	0,24
2009	0,00	0,15	**0,31**	0,10	0,26	0,15	0,00	0,00
2010	0,05	0,05	0,00	0,05	0,05	0,10	0,05	0,05
2011	0,00	0,14	0,29	0,14	0,14	0,10	0,05	0,14
2012	0,18	0,13	0,09	0,22	0,13	0,22	0,18	0,09

In the case of the last examined foodstuff production segment – other food products (such as cocoa, chocolate, coffee, fish, etc.), there was no indication that a relation existed between accident incidence and the shift hours which is shown in Table 6. This may be a result of the variations between the producers and the product production character of the companies qualified for this foodstuff segment.

Table 6: Workplace Accident Incidence per 100 Employees in Remaining Food Products (cocoa, chocolate, coffee, fish, etc.) (2008-2012) on the Basis of Initial Shift Hours

Year	**Initial working hours**							
	from 0 to 2	**above 2 to 3**	**above 3 to 4**	**above 4 to 5**	**above 5 to 6**	**above 6 to 7**	**above 7 to 8**	**above 8**
2008	0,13	0,00	0,00	0,00	0,13	0,00	0,00	0,00
2009	0,00	0,13	0,00	0,26	0,26	0,13	0,00	0,00

2010	0,00	0,12	0,00	0,12	0,00	0,00	0,00	0,00
2011	0,00	0,12	0,12	0,12	0,24	0,00	0,35	0,00
2012	0,00	0,45	0,11	**0,57**	0,11	0,23	0,34	0,23

An interesting correlation surfaced after analysis of accident number in relation to employee seniority for a given workstation, namely the greatest number of workplace accidents happened to people who had the lowest seniority (less than one year) at a given workstation (Drawing 5) indicating that they had the least experience in carrying out their tasks. Conversely, those who had more than 20 year seniority had almost no accidents.

Fig. 5: Workplace Accident Incidence Structure at Selected Foodstuff Industry Plants by Months (2008-2012) in average %

It also bears noting that among the examined plants, over 65% of the workplace accidents occurred to people whose seniority was less than 3 years. This indicates a need to maintaining intensive preventive activities related to performing tasks by relatively new employees as they relate to any given workstation.

Table 7: Workplace Accident Incidence (by count) in Selected Foodstuff Industry Plants in Relation to Employee Seniority (2008-2012)

Year	Initial working hours								
	1 year and less	above 1 years to 2 years	above 2 years to 3 years	above 3 years to 5 years	above 5 years to 10 years	above 10 years to 15 years	above 15 years to 20 years	above 20 years to 30 years	above 30 years

2012	131	80	45	29	19	19	4	6	2

Considering both the results of Drawing 5 and Table 7, it remains to be said that the greatest need is employee training before starting any particular job and supplementing same during initial months on

the job. Furthermore, employees with low seniority should experience intensified oversight with the intention of workplace accident risk reduction. It is also essential to minimize employee turnover at given job stations which could be a contributing factor to accident rates.

Table 8 gives the breakdown of the relation between employee work seniority and accident incidence per 100 employees in the various branches.

Table 8: Employee Work Seniority and Workplace Accident Incidence Count per 100 Employees in Selected Branches (2008-2012)

Branch	Year	Initial working hours								
		1 year and less	above 1 years to 2	above 2 years to 3	above 3 years to 5	above 5 years to 10	above 10 years to 15	above 15 years to 20	above 20 years to 30	above 30 years

Table 9: Number of accidents at work [pcs.] depending on the position held in the meat processing and preserving industry and the production of meat products (2008-2012)

Year	Position																				
	Packer	Sausage	Slaughterhouse worker	Butcher - sausage (student)	Employee inside the factory	Dealer	Destroyer, cutter	Mechanic	Garmazer	Electrician	Storekeeper	Storekeeper	Butcher	Sales Representative	Conservator	Archivist	Smoker	Auxiliary worker	Driver	Smoker's helper	Smoker of industrial boilers
2008	10	28	23	0	5	24	27	3	3	0	3	0	7	2	0	0	1	1	0	0	0
2009	6	15	14	2	4	23	19	1	2	1	2	0	7	1	0	0	1	0	0	0	0
2010	5	28	**32**	5	2	16	18	0	3	0	3	1	9	2	0	0	2	2	0	0	0
2011	17	27	29	2	6	24	24	6	17	0	6	2	12	11	3	0	3	4	3	2	2
2012	12	20	17	3	6	22	17	1	8	2	7	1	12	8	1	1	8	5	4	0	0

Table 9 presents workplace accident incidence in the meat processing and preserving, and meat products segment. The most frequent incidence of injury were individuals working in meat curing, slaughterhouse, sales, packaging, and meat cutting. The most reasonable explanation for this is the fact that these employees use sharp tools, especially knives.

Table 10: Number of accidents at work [pcs.] depending on the position held in the Production of Bakery and Cereal Products (2008 – 2012)

Year	**Position**												
	Dealer	**Mechanic**	**Sales Representative**	**Conservator**	**Auxiliary worker**	**Driver**	**Smoker's helper**	**Smoker of industrial boilers**	**Economic administrator**	**Production worker**	**Baker**	**Machine and equipment operator**	**Confectioner**
2008	0	0	3	0	1	0	0	0	1	3	11	0	3
2009	0	0	2	2	1	2	0	0	0	3	7	1	5
2010	0	0	0	0	0	2	0	0	0	1	**17**	0	2
2011	2	3	5	0	1	3	1	0	0	6	10	0	2
2012	0	0	0	0	0	4	1	1	1	4	12	1	4

Table 11: Number of accidents at work [pcs.] depending on the position held in the Production of Dairy Products (2008 – 2012)

Year	Position																					
	Employee inside the factory	Dealer	Mechanic	Storekeeper	Electrician	Sales Representative	Conservator	Auxiliary worker	Driver	Smoker's helper	Smoker of industrial boilers	Serovar	Camera powder	Pickup raw material	Operator of dispensing and packaging machines	The driver of the transport trolley	The instructor of raw materials service	Lab	Milkman's assistant	Economic administrator	Production worker	Machine and equipment operator
2008	0	0	2	2	0	0	0	0	**17**	4	3	7	2	4	4	0	0	2	7	1	0	0
2009	0	0	0	5	0	0	0	0	0	4	4	10	5	7	2	0	0	4	6	0	0	0
2010	1	0	3	1	1	3	1	2	7	0	0	4	2	4	7	0	0	1	9	1	6	6
2011	0	0	2	1	0	2	0	0	8	0	0	9	8	6	5	3	1	0	5	2	3	2
2012	0	3	2	3	1	7	1	3	12	0	1	8	1	2	2	1	1	2	2	0	13	10

The milk processing segment shows injuries to drivers, cheesemakers, production workers, and machine and equipment operators more so than those employed in internal transportation or sales.

Table 12: Number of accidents at work [pcs.] depending on the position held in the Processing and Preserving Fruits and Vegetables (2008 – 2012)

Year	Position																
	Packer	Slaughterhouse worker	employee inside the factory	Mechanic	Storekeeper	Electrician	Sales Representative	Conservator	Auxiliary worker	Driver	Smoker of industrial boilers	Pickup raw material	Operator of dispensing and packaging machines	Economic administrator	Production worker	Machine and equipment operator	Fruit and vegetable processing worker
2008	1	0	0	0	0	0	0	0	0	0	1	1	1	0	4	2	8
2009	0	0	0	0	0	0	0	0	0	0	0	0	0	0	2	2	7
2010	0	0	1	2	0	0	1	0	0	1	0	0	0	0	3	3	8
2011	1	1	0	0	1	0	0	0	0	0	0	0	1	0	7	8	**12**
2012	1	0	0	1	2	1	2	1	1	0	0	0	0	1	6	5	3

When considering the segment of processing and preserving fruits and vegetables (Table 12), the most frequently injured workers were those who operated machines and equipment and those who were directly involved in the processing of said fruits and vegetables. As in most previous segments, those having direct contact with machines and equipment were most frequently injured.

Table 13 presents the workplace accident incidence in the beverage segment which indicates that injuries occur most frequently to sales representatives, drivers, production workers, machine and

equipment operators and filling machine operators. The table indicates a high risk in the case these workstations and the need to refit equipment with additions to insure health and life safety.

Table 13: Number of accidents at work [pcs.] depending on the position held in the Beverage Production 2008 – 2012

Year	Position										
	A transport employee inside the factory	Mechanic	Magazynier	Sales Representative	Konserwator	Driver	The driver of the transport trolley	Economic administrator	Production worker	Machine and equipment operator	Operator of bottling equipment
2008	0	0	0	2	1	5	1	0	3	6	3
2009	0	1	2	1	1	4	0	0	3	4	3
2010	1	1	1	2	0	2	0	0	1	0	4
2011	0	0	0	5	0	5	0	0	5	4	2
2012	0	1	3	3	1	6	2	2	**10**	1	4

Table 14: Number of accidents at work [pcs.] depending on the position held in the Remaining Food Products (cocoa, chocolate, coffee, fish, etc.) 2008 – 2012

Yaer	**Position**									
	Employee inside the factoryzakładowego	**Dealer**	**Mechanic**	**Storekeeper**	**Electrician**	**Sales Representative**	**Konserwator**	**Driver**	**Production worker**	**Confectioner**	**Operator of bottling equipment**
2008	0	0	1	0	0	1	0	0	0	0	0
2009	1	0	1	0	1	1	0	0	1	0	1
2010	0	0	1	0	0	0	0	0	0	1	0
2011	0	0	1	1	0	0	0	1	4	0	1
2012	0	1	2	2	1	1	2	3	**6**	0	0

The last production segment analyzed is titled 'other food products' (cocoa, chocolate, coffee, fish, etc.) and here the greatest number of accidents occurred to mechanics and production workers i.e. people directly connected with servicing machines. As shown in Table 14, other workstations in this segment showed little injury and may have not been tied to any workstation. Therefore, in the case of plants in this segment, particular attention should be directed at training of personnel operating said machines.

The association analysis between workstation and workplace accident incidence suggests that injury risks depend on, among others, which industry segment. Furthermore, it was confirmed that regardless of industry segment, the highest risk was tied to workstations directly involved in machine and equipment operation. As a result, additional and focused attention should be made to these positions when considering preventive measures. In the industry segment of bakery and grain products, accidents occurred most frequently to individuals working as bakers, confectioners, production worker, and drivers.

Conclusions

The issues of workplace accidents and prevention have, or should have, essential attention the world over in terms of safe production of products, health protection and work environment development. Union members must strive to realize stated strategic goals including endorsing the general culture of respecting health and minimizing dangers through supporting change in the way employees behave while at the same time encouraging employers to adopt efforts concentrating on health and applying at state and Union levels appropriate economic premiums.

In 2015, there were 3 876 fatal accidents in the EU-28. There was a decrease in the total number of fatal accidents at work in the EU-28 between 2010 and 2015, some 573 fewer (equivalent to an overall reduction of 12.9 %). During this period the number of fatal accidents initially decreased from 4 449 to 3 674 by 2013 (down 17.4 %) before increasing 5.5 % between 2013 and 2015. The decrease in the incidence rate (number of fatal accidents at work for every 100 000 persons employed) between 2010 and 2015 (down 13.3 %) was slightly greater than the decrease for the number of fatal accidents. As such, the number and incidence of fatal accidents fell faster between 2010 and 2015 than did the equivalent indicators for non-fatal accidents.

In the five year period of the study (2008-2012), examining selected foodstuff plants, an increase of workplace accidents was noted of 29%. The study assisted by a survey indicates that the most accidents occurred in March, May and July – the months of highest production in the foodstuff sector. The highest occurrence of accidents was between the 2nd and 4th hours of a shift, which trend continues. This observation may be significant in encouraging a break during this high risk injury period. Most injuries occurred to people who lad less than 1 year's seniority at a given workstation. This may signal the importance of experience in the performance of employees and training new cadres in OHS procedures with additional attention in the first year of employment. The study also indicated that workplace accidents occurred to those employed in physical labor. With this in mind, special attention should be drawn in insuring these employees appropriate work conditions and comprehensive training pertaining to operating and servicing machines, equipment and tools.

Abstract

Precision Healthcare offers an approach to a personalized and patient-centered care that increases the impact and the adoption of evidence-based preventive interventions. Based on individual patient genetic profile in convergence with clinical, societal, environmental and lifestyle-related data, Precision Healthcare takes fully advantage of the advancements in digital technology and health research to reconfigure the traditional medicine approach by providing customized comprehensive healthcare managements at the right time. Moreover, it encompasses the shift of the patient into an active actor involved in most of the medical procedures and services that target him/her, highly-aware about the importance of personal data and personalized healthcare. In this context, Customized Disorder Detection and Prediction Healthcare Systems are becoming indispensable drivers for leveraging the quality and accuracy of early diagnostic, appropriate therapeutic protocols, prevention strategies and prediction models. This paper aims to present the most important features of Precision Healthcare that sustain Customized Disorder Detection and Prediction Healthcare Systems that are demanded by the current empowered patient. As a practical illustration of the above-mentioned key elements, RO-SmartAgeing system is presented as a case study. As a novel approach, the architecture of a further extension of this system using chatbots is included.

Keywords: Precision Healthcare, Wearables, Chatbot, Patient Monitoring, Disorder Detection, Prediction.

Introduction

Taking into account the enhanced requests for material and financial resources in healthcare systems, as well as the growing and improved engagement of citizens in the self-management of health, it has become necessary to implement a new model of patient-centered healthcare that it is based on patients' tailored services that takes into consideration their specific needs and expectations and the necessity of real communication between the health care professionals and the patients involved in conducting their own health.

Healthcare services are nowadays subject to a dynamic shift from "one-size-fits-all" approach towards a customized one that targets an individualized patient by integrating and connecting information and data about his specificities, needs, and lifestyles, in order to provide and support personalized care and healthcare decisions.

Traditional medicine is based on healthcare services and therapeutic protocols established on large population averages (i.e. “one-size-fits-all”); unfortunately, it is proved that some patients might react unexpectedly bad to the same disease or treatment, mainly because of their personal genetic profile, which it hasn’t been taken into consideration.

The late exponential increase access to huge amount of different data that can be integrated, analyzed and processed, together with the current worldwide societal, economic changes, and digital technology and medicine advances have been leading to the setting of a new type of healthcare: The Precision Healthcare.

Precision Healthcare aims to tailor healthcare services taking into consideration the differences and singularities that may arise among individuals from the point of view of their genes, medical history, way of living, clinical and environmental factors. By consolidating, integrating this data and with the help of analytics tools, each patient has bigger chances to have better evaluated risk factors, more accurate diagnoses, customized disease managements and adapted prevention strategies, at the right time.

The Precision Healthcare is based on the convergence between innovative digital technologies and new healthcare services, having the ability to support and provide better access to care and to offer new opportunities for customized and patient-centered medical acts.

New smart devices and technologies that allow real-time medical / environmental data and information collection, and the availability of massive amounts of patient-related data provide new approaches to customized health care delivery and new health care services.

One way to support the migration to Precision Healthcare is the deployment of heath care systems that gather and integrate a patient's medical data from in and out of a clinical environment in treatment protocols, remote monitoring programs, and preventive actions and measures.

The gradual shift from reactive to preventative healthcare implies not only the way disease detection, diagnosis, therapeutic protocols are changed due to the emerging technologies and tools, but also a dynamic transformation of the patient demands. Placing the patient in the center of the healthcare ecosystem and directions has imposed the burst of tailored medical services, as health applications for a personalized remote support or Customized Disorder Detection and Prediction Healthcare Systems.

This paper aims to highlight the strong impact of the main features of the Precision Healthcare in developing Customized Disorder Detection and Prediction Healthcare Systems. The paper is organized in three main sections:

- “Precision healthcare, the next generation of digital healthcare” – where a comprehensive presentation of the basic concepts of Precision Healthcare together with its benefits, opportunities and constrains are performed;
- “The patient-centered approach driving high request for tailored healthcare services”- the particular features of the current patients that empower them regarding their own health management are briefly reviewed in order to justify the need for developing appropriate healthcare services. The presentation of the key elements of the remote patient care represents a demonstration of the necessity for tailored healthcare services.
- “Customized Disorders Detection and Prediction Healthcare Systems” – after underlining the main characteristics and potential functionalities, the section briefly presents some up-to-date technologies used in precision healthcare as: smart wearables, chatbots, and Big healthcare Data Analytics. The main contribution of the authors is presented in the Case study: RO-SmartAgeing system, an ongoing project that can be classified as a Customized Disorder Detection Systems. Some specific aspects of RO-SmartAgeing that demonstrate its belonging to this category of systems are emphasized. A novel approach discussed in the paper is related to the use of chatbots as personal assistants of elderly people and an architecture is proposed. The authors

plan to provide this facility as a further extension of the system, aiming also at the decrease of related cost associate with seniors' healthcare.
- The paper also includes Conclusions, Acknowledgements and References.

Precision Healthcare, The Next Generation of Digital Healthcare

Digital Healthcare can be defined as an interaction among "mobile computational and connectivity capabilities, genomics, information systems, wireless sensors, cloud computing" (Gouda and Steinhubl. 2018) and Artificial Intelligence (AI) used for supporting the healthcare service delivery. It enables and facilitates more efficient, effective, accurate, safer medical procedures and actions, allowing them to be more personalized and patient-centered.

A person's health is determined by the conjunction of his/her genes/family history, daily behaviors, ambient factors, environmental interactions. Therefore, as each person reacts differently to an event, he/she also has distinct reactions to a specific disease and, consequently, varied responds to the same treatment.

Precision Healthcare acknowledges the unicity of each individual and the fact that all the issues above mentioned have a strong influence on his/her health status. Precision Healthcare is sometimes perceived as another face of Personalized Healthcare. Although they are both patient-centered, there are slightly differences between them: *Personalized Healthcare* aims to provide tailored medical management to a particular patient, considering his/her genetic profile and social context, whereas Precision Healthcare, also fundamentally based on genomics and patient's directly related daily life issues, goes further by building-up improved healthcare models (based on data, informatics, analytics and other computational tools) that go beyond the individual patient.

Precision Healthcare takes all the advantages established by Digital Healthcare (for instance, considering a broad range of digital health data) and expands them towards the most veracious prediction of the most appropriate therapeutic protocol and medical management for a specific disease, both for an individual and category of patients.

Basic Concepts

Traditional medicine relies on standard health related investigations, standard symptoms and drugs. Digital Healthcare has brought the access to huge amounts of processed data and information, due to digital technologies and computational tools.

Precision Healthcare (PH) adds the approach of a tailor-made healthcare service (H. Zhu *et al.*, 2019). Taking into account that each person is uniquely defined from the point of view of genes, relationships with environmental and societal factors and personal responses to the growing numbers of diseases, the core of PH is the vision of the individual patient to which all the healthcare processes and services are directed.

The improved health status and management of a particular patient is also a dynamic driver for PH for identifying better customized healthcare services for specific groups of patients, for preventative strategies and protocols, for supporting decision-making at the public health level by developing prediction models.

Taking into consideration a greater variety of personal determinants of a patient, like his genetic profile, daily routines or habits or interactions with past and current environments, better outcomes of the targeted medical acts undoubtedly lead to a significant cost-efficiency of the healthcare systems, improved access to the best services for larger categories of population.

The rapid advances and transformation for the healthcare system fueled by the outstanding and continuous explosion of the development of new digital technologies have marked out specific

features of Digital, Personalized and nowadays Precision Healthcare, starting with the "3P model" and "4P model" till "7P model" (Horn. 2017), (H. Zhu *et al*., 2019).

An "8P model" can be conceptualized for Precision Healthcare with these specific features: Precision, Personalized, Participatory, Predictive, Preventative, Persuasive, Programmable, and Perpetual:

- *Precision* – the ability of clustering particular patients and diseases into different categories that may have important manifold outcomes to a specific healthcare management (Gameiro et al., 2018);
- *Personalized* – a patient-centered approach that involves distinct medical acts and services adapted according to the health-related determinants of an individual patient;
- *Participatory* – the empowered patients and increased access to health data, information and services due to the broad spreading of digital technologies lead to sharing data, better communication and engaging of medical staff and population;
- *Predictive* – the capacity of envisaging different responses and strategies to therapeutic protocols, disease spreading or evolution through predictive models (Ramos et al., 2019);
- *Preventative* – the stronger accent put on prevention approach and methods, for narrowing the decreased quality of life of the patient and higher cost-efficiency of the healthcare systems;
- *Persuasive* – the ability of persuading the patient to improve his lifestyle and better involve in his/her health management with the help of new emerging tools and smart applications;
- *Programmable* – the competence to involve the digital technology as a main driver for implementing newer, adaptable and improved healthcare processes, decisions or strategies;
- *Perpetual* – the capacity of ensuring a permanent access to health data and information through continuous monitoring, ubiquitous sensing, worldwide data sources, facilitated by technologies like cloud computing, Big Health Data Analytics (BHDA) and AI (Alexandru and Coardos, 2018).

Precision Healthcare wouldn't be possible without the intensive sustain of impressive late advances in domains like sensing technology, networking and communication technologies (Chen et al., 2017), molecular diagnostics, genetic sequencing, BDA, AI, machine learning algorithms that are able to identify as soon as possible and in the most efficient and precise way, the most appropriate diagnosis and treatment options.

In Figure 1 are illustrated the relevance of health data and the most prominent health information technology that provide the power to harness its potential to optimize the patient care.

Figure 1: Relevance of health data and health information technology for PH (Ginsburg and Phillips, 2018)

As advancements in medicine and information technology are continuously proving their potential and applicability, it is expected that new opportunities for improved and enlarge capabilities for PH to appear.

Benefits

Precision Healthcare, relying particularly on every patient's genetic profile and the potential of outlining both the individual and specific group specificities, brings important benefits to healthcare services by:

- Identifying the most appropriate and tailored healthcare management;
- Reducing drug adverse reactions, trial-and-errors prescribing, high-risk invasive testing procedures, and cost of healthcare services and treatments;
- Reshaping the reaction approach of the traditional medicine to the preventative one;
- Predicting the probability of getting ill and the disease spreading;
- Improving the capacity of using the patient's genetic information in the daily practice of health practitioners;
- Supporting an improvement of a disease detection at an early stage, both at individual and group level;
- Classifying patients in well-defined groups appropriate for tailored therapeutic protocols and disease-prevention strategies by collecting the genetic profile of individuals;
- Tackling a disease at the molecular level in order to better understand the mechanisms of its occurrence and afterwards generating new drugs and strategies to better control or eliminate it.

Briefly, PH improves many aspects in the healthcare area: *at patient level* through a tailored approach for preventing, diagnosis, treating and sustaining a healthy life, *at medical staff level* through providing capabilities for better manage the health procedures and mitigate side-adverse effects, and last, but not least, *at healthcare systems level* through reducing cost associated to many healthcare processes, trials or error procedures.

Opportunities

Digital technology and research in healthcare domain are continuously evolving; therefore, the opportunities brought by Precision Healthcare are evolving and expanding consequently. Among the most relevant opportunities of PH are:

- Classification of patients into groups with a common biological and molecular basis of disease can enhance the best available medical care, optimize the cost of adverse reactions and treatments by eliminating the errors and the inefficient use of resources;
- More adequate and accurate structuring of diseases into subtypes combined with the use of analytics tools and detection methods have the potential to allow the physicians to foster a much better understanding of the causes, diagnosis, evolution and management for a specific subtype;
- Tailoring the treatment for a particular patient taking into consideration the genes profile, lifestyle, clinical and environmental factors implies augmenting the safety, tolerability of it, together with the best possible outcomes and responses. All these provide knowledge and information that allow a further integration of the patient in a related group that can be better managed inside the healthcare system;
- Provided access to continuously gathered data from a greater variety of sources, comprising the genetic ones, wearables, mobile health applications have enabled powerful technologies like AI, BDA, machine learning, or blockchain to analyze and process it. For instance, AI can be used to predict the drug interaction, to provide insights about hidden patterns, about new correlations among vary data, or for genome sequencing. Blockchain can bring a reliable solution for ensuring the security of data. Machine learning algorithms can be used to find out the genetic risk for individual patients or groups.

Constraints

Besides the benefits and opportunities of Precision Healthcare, there are also some constraints that have to be tackled:

- PH relies strongly on data implies that the quality, the large amount and diversity, the accuracy and privacy of it have a crucial importance;
- Availability of ubiquitous data sources is closely related to security issues and comprehensive IT platforms and technologies able to store, analyzed and provide insight;
- Enlarged computational capabilities and optimized algorithms should be adapted continuously for providing faster and reliable knowledge-based decision-making support;
- Regulatory infrastructure and legal frame can restrain a quick development both at the levels of research and practice in PH (Prince, 2017);
- Ethical issues regarding personal data together with a deeper involvement of the patients in their own health management and awareness about how and where their personal data will be used are critical for the broad adoption of PH;
- Lack of health and IT literacy represents a significant barrier for a constant and appropriate commitment of the patients in providing and giving access to personal health data.

Summarizing, Precision Healthcare is a powerful upgrading of Digital Healthcare, having the patient in its core and sustaining that comprehensive personal, genetic, societal, clinical, environmental data is collected, analyzed and processed with emerging computational tools and technologies, in order to guide healthcare decisions, to detect keenly the health and disease factors and determinants, and most important, to implement tailored health services both for individuals and groups of people.

The patient-centered approach driving high request for tailored healthcare services

The traditional physician-patient relationship, in which the former leads, and the latter subordinates, has been changing in the last years mainly because of a growing number of people with chronic disorders and multiple morbidities – as a consequence of worldwide ageing of population -, because of an increased healthcare literacy of larger numbers of patients and because of the digital society.

Current patients, highly aware of personal needs and expectations

Digital technologies and smart devices have underlain the occurrence of current patients that are characterized by features that make them:

- *Information-savvy*: patients are used to look often for appropriate information and data, thus updating constantly their levels of healthcare knowledge;
- *Empowered*: the expanding availability of health information increase their health literacy, hence the role in the relation with their physicians and health providers;
- *More willing to try out*: patients are more open to adopt in their lifestyle healthier behavior rules and health-related resources;
- *More demanding*: being more aware about a broader range of options, patients are more and more accustomed to ask for personalized, affordable qualitative healthcare services;
- *Better engaged*: being actively involved in the management of their own status of health, current patients are far keener in collecting personal health data, pursuing the healthcare outcomes and diversify the use of personal health devices and tools;
- *Digitally involved*: patients use smart devices, mobile health apps, wearables and online consultations on regular basis.

Appropriate Tailored Healthcare Services

Current patients with the above-mentioned characteristics expect to have better access to patient-centered tailored healthcare services able to provide:

- Affordable, improved and personalized healthcare options;
- The best use and control of their personal data;
- Improved emphasis on prevention methods and protocols;
- Improved dynamic of the patient-healthcare provider relationship;
- Access and openness to healthcare solution based on emerging technologies like: Internet of Things, AI, smart monitoring devices, BDA, Virtual and Augmented Reality.

Remote Patient Care, A Key Trend

The worldwide ageing population and the growing prevalence of chronic disorders have been bringing a serious burning on the healthcare systems from the point of view of financial and specialized human resources. Therefore, the remote patient care has become a reliable alternative for providing qualitative cost-efficient healthcare services (Alexandru et al, 2017), (Manteca et al., 2016).

A remote patient care involves the delivering of appropriate healthcare to patients located in their homes or nursing homes, with the support of digital technologies and smart devices (Dobre et al, 2019).

The *basic elements* of a remote patient care are:

- Appropriate monitoring of health parameters, environmental factors and daily behavior;
- Early recognition of health dysfunctionalities, disorders and deteriorations;
- Quick response to different changes that might appear in the life and status of health of the patient;
- Reduced institutionalization and frequent hospital readmissions;
- Increased quality of a healthier life, independence, self-esteem of the patients;
- Triggered alerts in case of emergencies;
- A reliable smart environment, which is as much as possible non-invasive, that includes sensors for collecting data, technology for communication with physicians, hospitals, caretakers, healthcare providers and for apply analytics in it in order to get adequate insight for supporting tailored healthcare services, (Ianculescu et al, 2018);
- Decreased cost at patient, health and social systems.

Customized Disorders Detection and Prediction Healthcare Systems

Beside personalisation, the enhancement of patient disorder detection combines research in biology, environmental studies and digital technologies in order to facilitate the driving towards “highly accurate predictions” in patient health, costs and necessary resources within hospitals.

Huge integrated data sets are needed for such predictions. In order to put into practice the open medicine paradigm, such data represents a central pillar, attracting and connecting people involved in healthcare systems research and development, public authorities, and patients.

Main Characteristics and Potential Functionalities

The main characteristics of Customized Disorders Detection and Prediction Healthcare Systems are:

- Capabilities to collect data from different data sources such as wearable devices, telematics, social media systems and legacy sources (medical history of the patient, diagnostic and clinical data, etc.);
- Provision of accurate, consistent and relevant and valuable information for healthcare care personnel and patients that is a result of the process of data collection, management, analyze, interpretation and transformation;
- Employment of efficient platforms for data acquisition, processing and presentation, smarter new technologies for data gathering, intelligent computational analysis, storage and visualization techniques towards attaining new knowledge and efficient decision support strategies for different issues in healthcare;
- Use of a web-based architecture with the following characteristics: smart (adaptive, configurable, dynamic, and reactive), context-aware, hierarchical, and secure;
- Assurance of data privacy and security with obligations of responsible parties to avoid accidentally data damage and/or loss.

The potential functionalities of the customized system for disorders detection and prediction are:

- Real-time data acquisition from sensors/wearables devices as well as data gathering from medical and social media documents and data collections;
- Data transformation and transmission;
- Large volumes of data (Big Data) storage in DBMS or NoSQL data bases (Alexandru and Coardos, 2016);
- Data processing and interpretation using BDA;
- Data presentation using up-to-date data visualization techniques and presentation on fix and smart mobile devices.
- Real-time access to data by physicians and other medical personnel.

Types of used technologies: Smart Wearables, chatbots, Big Healthcare Data Analytics

The following types of technologies are largely used in Customized Disorders Detection and Prediction Healthcare Systems:

a. Smart Wearables

Internet of Healthcare Things (IoHT) is a mixture of" medical devices and applications that can connect to healthcare IT systems using networking technologies" (Alliance of Advanced Biomedical Engineering, 2020). According to (Fronst & Sullivan. (2017), the number of IoHT devices is expected to grow to 20-30 billion by 2020.

In healthcare, Smart Wearables SW) are wireless real-time sensors used remotely for acquisition, monitoring and controlling of healthcare data for advanced evaluation and intelligent decision support. Current applications of SW systems work for monitoring patients' vital signs, body movement, location, and fall prevention (Li et al., 2019).

In recent years, due to SW devices and remote health monitoring systems, the patients are empowered with new tools and technologies and are able to continuously monitor and manage their health (Alexandru et al., 2019).

b. Chatbots

"Intelligent virtual agents" (IVAs) or chatbots are now an exciting topic in solving eHealth related problems. A chatbot is a computer program that serves as both an educator and motivator, automatically providing services by conversing and interacting with the patient (using spoken, written,

and visual languages) by various communication channels such as messaging platforms, mobile apps, etc. In the last years, due to the amplified use of AI and of messaging platforms, chatbots have been agreed by the physicians and obtained positive results in being used as virtual assistants helping patients with chronic diseases and comorbidities by playing various roles: symptom checkers (collecting self-reported signs and symptoms) (Symptomate,. 2020), medication reminders (Florence, 2020) or personal data acquisition tools (Forksy. 2020https://getforksy.com/). Chatbots are interacting with chronic patients in the same way that patients communicate with their friends and relatives through their favourite messaging platforms being active chronic patient support.

AI-chatbots are used in order to improve chatbots efficiency of healthcare delivery. Chatbot software architecture should be based on three main columns (Roca et al., 2020):

- Scalability, that enables easy growing of the available services adapted to patients with rising comorbidities,
- Standard data models that support data sharing and reusability,
- Standard conversational modeling that make easier the dialogue between the patient and the chatbot.

c. Big Healthcare Data Analytics

In healthcare sector, data are classified as*: Structured data* (with defined type, format, and structure, such disease terminologies, laboratory results, patient info, etc.), *Semi-structured data* (with a minimal structure, such as data generated from sensors used in patient vital signs monitoring) and *Unstructured data* (with no specific structure such as medical prescriptions, clinical letters, biomedical literature, etc.). There is an enormous *Variety* of data emerging from diversified stakeholders (clinicians, patients, hospitals, pharmacy etc.). Health related data are mainly characterized by *Volume* (big amount of available data), *Velocity* (increased data generation rate from emerging technologies), *Variety* (diverse and multiple biomedical sources) (Palanisamy and Thirunavukarasu, 2017).

Health data analytics aims to analyze data using quantitative and qualitative techniques in order to determine trends and patterns and to create the possibility of obtaining actionable insights and driving long term development for enhanced the management, diagnosis as well as patient involvement in health sector.

There are three types of analytics: Descriptive analytics (that analyze real time and historical data in order to estimate the further evolution), predictive analytics (analyze past data trends in order to predict the future) and prescriptive analytics (advice on predictable outcomes and how act to maximize the results) (Ransbotham et al., 2015).

Case study: RO-SmartAgeing system

a. Short Presentation

"*Non-invasive monitoring and health assessment of the elderly in a smart environment (RO-SmartAgeing*)" ongoing project has as main objective to assist a senior to continue to have an active and independent life in his/her own environment, to delay as much as possible the age-related dysfunctionalities, to prevent disorders and health deterioration and to provide a broader access to improved personalized healthcare.

RO-SmartAgeing is a Disorders Detection Healthcare System that is intended to monitor and assess the health status of the senior by integrating non-invasive motion and physiological sensors for the gathering of health parameters in a smart environment to monitor daily activities and lifestyle. A cloud platform is used for storing and aggregating data, including the presentation of the results of advanced data analysis. The use of the RO-SmartAgeing system creates the possibility to monitor the health

parameters of the senior and to generate alerts when one of these parameters is outside the normal values.

The capabilities and functionalities of this system improve home-based integrated care, having a senior-centred approach sustained by personal physicians, caretakers and senior himself. Personalized interfaces will allow the users to access RO-SmartAgeing system on their personal computer, tablet or smart phone, as suggested in Figure 2.

The amount of heterogeneous data collected inside the senior's smart environment can be used not only for continuously remote monitoring of health and life style, but also for establishing customized predictive models with a strong preventative feature.

b. An example of using a chatbot system architecture as an extension of RO-SmartAgeing system

For a further extension of the RO-SmartAgeing System, a concrete work scheme for a chatbot based solution, suitable for the situation of seniors who need advising and monitoring is presented below.

As mention before in section 4.2, a chatbot is an AI program that "speaks" to the users and informs them about all the things they need to know, acting as a personal assistant of an elderly person. The senior user connects to the chatbot either through a text channel or through a voice channel: In the case of the voice option, from the software point of view, there are two more internal levels that deal with speech recognition and its transformation into text for input and synthesis of text in speech for answers:

– The NLU (Natural Language Understanding) component helps to extract the purpose of the discussion and the entities from the user's request. The NLU component consists of a supervised

Figure 2: Conceptual architecture diagram of the RO-SmartAgeing System

intent classification model that is driven by a multitude of input sentences and the purpose of the target discussion, and an entity extraction model that can be pre-trained similar to the Spacy model or StanfordNLP libraries. It can be trained using probabilistic models such as CRF (Conditional Random Fields);

- The NLG (Natural Language Generator) component produces responses of the chatbot. The easiest way to achieve this is by using a template mechanism. A more complicated method is to use sentence generators through deep learning.

Dialogue Management Component

It is one of the most important components of the architecture of a chatbot. The basic idea is that the user has to understand what the chatbot has just said.

Missing information: When a user requests something, the chatbot may not have enough information from the user to process the request. The solution is to ask the user for this information. So instead of deciding on the spot what was the user's intention, the system recognizes that certain entities need to be present. If the entities are not present, the chatbot must query the user about these entities until it has all the necessary information. Each purpose of the discussion is a template / pattern that may or may not need certain positions to be filled in with information.

Context of the conversation: In the conversation with a user, all kinds of information must be collected and managed. This is the context of the conversation. The context is built during the interaction with the user and contains all the information needed in the long and short term to manage the conversation.

Initiative: When two people communicate, one of them has the initiative. When does anyone have the initiative? Depending on the intention, a user can signal that he wants to take the initiative. Then a chatbot can decide whether to leave the initiative to the other dialogue partner or take the initiative. The purposes of the discussion can be classified according to the presence or absence of the initiative.

Training Component

Although chatbots can bring significant growth to a people category, they do not appear in context all of a sudden and are very well educated. A chatbot must be created and trained based on a data set. There are several ways to train chatbots:

- Collecting data through all input channels;
- Collecting analytical data in real time;
- Training it to understand semantics. This allows programmers to understand how they can achieve better results by finding what is not working and aligning the purpose of the data with the input;
- Training it to be more personal. A chatbot will interact with many people. The answer must be adapted to the specifics of the transaction, whether it is positive or negative. For example, we can train the data to meet the needs of different groups satisfactorily and productively or for obtain improvements frequently. This training is a long-term process and must be for at least the next few months to one year after launch.

The chatbot architecture example used to assist senior persons is represented in Figure 3.

Discussion

RO-SmartAgeing system is in its third phase of development, i.e. the design of the general architecture. In order to frame it properly in the Disorders Detection Healthcare Systems' category, the main age-related features associated with the system's functionalities are taken into consideration even from this stage of development. In order to obtain a practical supporting digital tool, comprehensive researches and studies have been done in the first phase of development, aiming to frame the current and envisaged future needs and requests concerning the seniors' healthcare, and also the trends of Customized Disorder Detection and Prediction Healthcare Systems for a proper integration in

Precision Healthcare domain. The second phase of the RO-SmartAgeing project targeted to identify the functional, technical, communication and security requirements for the system.

Figure 3: A possible solution for a chatbot architecture used to assist senior persons

Smart wearables, the main part of the smart environment, should be chosen so as to monitor the senior in the least invasive possible way, but in a controlled one, in order to provide accurate and reliable data. As health data has a very sensitive characteristic, a specific attention is given to measures and functions able to ensure the security, privacy and confidentiality of it. A proper senior's remote disorders detection and healthcare monitoring implies considerable amounts of (un)structured, heterogeneous data that come from a great diversity of wearables and from other types of sources – like those in Cloud. For getting the best insights of it, the use of *Big Healthcare Data Analytics* is compulsory. The data collected by the smart wearables and devices is filtered, aggregated, stored, analysed, processed and integrated in personalized applications, such as Behavioural Management, Diagnostic Support, Preventative Lifestyle Assistant, Disorders Detection Support, Predictive Models, etc.

As the seniors are very likely to have mental disorders in different stages and evolution, together with deficiencies and fears concerning the use of digital technology, *chatbots* are taken into consideration in the development of RO-SmartAgeing. They can act like virtual assistants that can be easily accepted by the seniors for supporting them in daily activities and self-healthcare managements.

Till now, some limitations of the chosen solution have been identified, like: the costs associated with the smart environment, the homologation of emerging smart wearables and devices within the Romanian healthcare system, the lack of interoperability among healthcare systems and applications that might be suitable for health data exchange, the lack of well-established standards in eHealth, some legal and ethical aspects related to the involvements of seniors in the next developments phases of RO-SmartAgeing system, a better collaboration with a broader range of doctors from more medical domains.

The diagnostic and monitoring capabilities supported by smart wearables, Big Healthcare Data Analytics, assistive devices that are embedded in Disorders Detection Healthcare Systems (as RO-SmartAgeing system is) represent important issues that clearly contribute to a sustainable implementation of Precision Healthcare.

Conclusions

Precision Healthcare has evolved from Digital Healthcare, taking advantages of computational tools and emerging technologies combined with a patient's genetic, personal medical records and history for developing tailored healthcare strategies, procedures, treatments, preventative methods and prediction models. Customized Disorder Detection and Prediction Healthcare Systems are a response to the expectations of the highly aware and empowered nowadays patient regarding an improved accessibility, efficiency, affordability of personalized healthcare services.

RO-SmartAgeing system is an example of such a system that has the potential to enhance the outcomes of a senior's home-based healthcare by providing personalized monitoring of health, ambient and lifestyle factors in a smart environment, trigger alerts in case of emergency, and preventative measures. Last, but not least, it can be further used in correlation with the senior's genetic profile to tailor better healthcare and more appropriate and efficient medical procedures.

The novelty within the Romanian healthcare domain of the ongoing RO-SmartAgeing project is mainly given by the integrated approach of IoHT, smart wearables, cloud computing technologies in monitoring the physiological and environmental parameters, in order to provide innovative support for personal medical assistance. Cross-cutting patient-centered approaches sustain the effective management of a variety of medical conditions, a greater awareness of a senior regarding his / her own health status, an active and healthy ageing, and a special framework for health professionals in Romania, favourable for further developments of new tackling and therapeutic protocols.

Among the socio-economic effects of implementing RO-SmartAgeing system are:

- Relieving the burden of the social and health systems by reducing the costs associated with short-term or long-term institutionalization of patients, due to the home-based monitoring;
- Improving the quality of life, safety, self-esteem and independence of a senior;
- Improving the range of timely services provided by health professionals;
- Increasing the quality of life of the senior's family members due to the possibility of remote monitoring and preventing his / her health deterioration;
- Increasing the quality of the medical act by detecting, processing and reporting in real-time personalized medical parameters and data, which will allow the current physician to adopt a pro-active and preventative healthcare management instead of the traditional reactive one.

In the next phases of the project, the development of RO-SmartAgeing system will be continuously adapted to the new technologies that are considered the most appropriate for the seniors and thus, due to agility, scalability and flexibility associated with the system, the possibility of an easy customization for seniors' needs will be provided.

Abstract

This paper focuses on the analysis of the link between time spent online and willingness to take into account recommendations of friends when shopping online (e-commerce). The basic sample for the purpose of the survey is the generation of Millennials of the region of East Slovakia. The total number of respondents (returned questionnaire) in the sample is 484, of which 88 were removed because the findings did not meet the age (generation Y) and smartphone use requirements. Data collection was conducted through simple random sampling in September and October 2019. To verify the hypothesis, we used StatSoft SPSS software. Due to the nature of the analyzed variables we used Kendall's tau-b test. Based on the research findings, most Millennials spend two to six hours a day on their smartphone, and over three-quarters of Millennials take into account recommendations of friends when buying goods online. Based on the result, there is no significant link between the time spent online using a smartphone and the willingness to take into account recommendations of friends when shopping online.

Keywords: M-Commerce, Online Shopping, Time Spent Online, Recommendations of Friends

Introduction

Mobile marketing is a new form of marketing communication that uses mobile communication methods to promote ideas, products and services. Marketing tools provide targeted customer reach, interaction, placement and custom measurement of campaign effectiveness anywhere, anytime (Wiedemann 2010). Mobile devices have tremendous potential for any business, allowing it to reach new customers in a very efficient way (Thangadurai 2016). Mobile marketing is a phenomenon that has been created gradually with the development of networks of mobile operators (Čorba and Nastišin 2015). The progress has been sped up also by a desire of marketers for the most interactive and fast communication with customers (Jakubíková 2012; Litavcová and Vašaničová 2019). Mobile marketing is a new term for one of the methods of direct marketing. The method focuses on the use of mobile devices (mobile phones, smartphones, PDAs, MDAs, rarely laptops) and distribution of both commercial and non-commercial content (SMS, MMS, YAPs, Infrared (IRDA), Bluetooth, WLAN). The popularity of mobile devices continues to grow as mobile marketing is one of the fastest growing marketing methods (mSolutions 2016; Jenčová and Vašaničová 2019). Mobile marketing is a tactical tool of marketing communication that uses mobile technology to present ideas, products or services (Bačík, Mihal and Fedorko 2015). Its advantage is that it enables immediate interaction with the target audience or customers, depending on location or situation in which it is at the time of receiving marketing information. Mobile marketing is an effective tool for self-measuring the effectiveness of mobile campaigns, making it an ideal means of building a true customer relationship, all in terms of accepting individual customer requirements (Štefko and Butoracová Šindleryová 2009). It was created gradually, with the development of networks of mobile operators,

and at the same time with regard to the desire of marketers to create the fastest and most interactive communication tool (Quirk 2017). Mobile marketing can also be defined as a set of procedures that allow organizations to communicate and connect with customers in an interactive and relevant way through a mobile device or network. Mobile marketing creates a connection that blends traditional media and digital marketing (Dodson 2016). Mobile marketing connects stores and their customers on mobile devices at the right time, in the right place and with the right content. At the same time, it requires customers to be actively connected or them to allow specific actions to be carried out (Fvanski 2009; Möslein-Tröppner et al. 2020). Peterson (2014) states that mobile marketing is one of the fastest growing tools of marketing communication. We understand it as a form of marketing that serves to promote sales through mobile communications. Vaštíková (2014) characterizes mobile marketing as a modern form of direct marketing, which cannot exist alone, but is linked to company databases about clients. Communication with customers is then carried out via SMS or MMS, thus helping build a long-term relationship with customers. A great example is notifications of forthcoming events of the company or congratulations on birthdays etc. This marketing communication tool is especially suitable for small businesses (Štefko, Bačík and Fedorko 2014). Mobile marketing or m-marketing is defined by Miklošík (2013) as all marketing activities that are focused on the active use of mobile devices (mostly smartphones and tablets). In addition, however, we must agree with what Sasko (2015) mentions in his video blog and that is the current state of mobile marketing. It is true that users are already part of the modern phenomenon of "second screen" which means they still have another device in their hands when watching TV or working with a computer (mobile phone or tablet). People do some of these activities somehow simultaneously. It is also important to underline the fact that Sasko (2015) reveals that over 60% of all mobile phone users have smartphones. So, there are opportunities to move forward by creating mobile applications and using advanced systems that these modern mobile phones can already handle. The interest in smartphones and tablets is evident from the current statistics, where it has been shown that people access the Internet from mobile devices more often than from computers. It can be said that this shift will have an upward trend in the coming periods (Etherington 2016). The goal of mobile marketing is to provide customers with information that promotes products, services and ideas with the help of wireless media at a given time. This process benefits all parties (Thangaduraia 2016; Shpak et al. 2020). According to Adamek (2013), mobile marketing is an interactive form of marketing that enables an immediate response to customer interest and further communication. In this respect, we talk about any form of marketing, advertising, or activity that is used to raise awareness and promote brands (Mura, Marchevská and Dúbravská 2018). Mobile marketing is also risky to a certain extent, as a mobile phone is seen by people as a private medium. Therefore, marketing communications via mobile devices can also trigger negative responses. However, the answer to this may be localization. This means that an ad text message will only be sent to those customers who are currently in the store (Karlíčka and Král 2011). National and international marketing and advertising associations are now incorporating rules for mobile advertising and mobile marketing into their codes of conduct. Some governments are beginning to outline the legal framework for mobile marketing in new legislation because of the rapid increase in the popularity of mobile marketing (Hagyari, Bačík a Fedorko 2016). However, there are no precise criteria for using mobile devices for advertising. This results in cases of negative use of mobile marketing (Bucko, Kakalejčík and Nastišin 2015). When using mobile marketing, it is necessary to maintain generally applicable moral criteria and principles, and it is also important to respect existing legislation in the country which could indirectly affect the use of the mobile marketing methods (mSolutions 2016). An increasing number of new companies in the world try to use mobile marketing to reach new customers, streamline forms of communication, expand their business and so on (Fedorko 2018). The most important question is which form of mobile marketing can use the potential of mobile marketing to the fullest (mSolutions 2016). According to Vysekalová et al. (2014), mobile platforms (mobile phone or other mobile electronic device) provide one major advantage to marketing research - real-time data collection (štefko and Pollák 2016). Research carried out through mobile devices gives the opportunity to engage customers in research in a variety of situations and get real feedback on how customers experience the situation. It is a unique opportunity to engage respondents in research in a fun way (Štarchoň et al. 2018). The advantage of mobile marketing according to the author Adamko (2013) is especially its efficiency and quick preparedness for various events. We can also use mobile marketing as a more effective alternative to other marketing communication techniques, as it is aimed at stimulating purchases or visits to a point

of sale. Jakubíková (2012) presents two advantages of mobile marketing in terms of communication campaigns. As Adamko (2013) states, one of them is efficiency and quick preparedness for various events. Another advantage is the ability to respond more flexibly to market needs (Mura and Kljucnikov 2018). In addition, mobile marketing also complements and strengthens traditional forms of communication, creating synergies and bringing effective marketing elements to traditional media. Frey (2007) considers flexibility and personality to be an advantage of mobile marketing because mobile phone is a versatile and adaptable medium allowing a wide range of activities. Here are some of the benefits of mobile marketing:

- targeting accuracy,
- speed of preparation,
- interactivity and speed of communication,
- instant measurability of campaigns,
- lower entry and operating costs,
- building a database.

Methodology

The main purpose of this paper is to find out whether there is a significant degree of association between time spent online using a mobile device and willingness to take into account recommendations of friends when shopping online. Based on this objective, we formulated the following research question:

Q: There is a significant degree of association between the time spent on the Internet using a mobile device and willingness to take into account recommendations of friends when shopping online?

The research hypothesis is formulated on the basis of this research question:

H: We assume a significant degree of association between the time spent on the Internet using a mobile device and willingness to take into account recommendations of friends when shopping online.

The first part of the research was devoted to descriptive statistics (abilities, averages, medians, modes, standard deviations, minima, maxima, as well as the 25th and 75th percentiles). This section highlights the preliminary findings of the research. Deeper relationships are shown in inferential statistics, i.e. analysis. In this section, the Kendall's tau-b test was used to analyze the context according to the data type.

For the purpose of this research, the research sample was defined as a new generation of customers represented by the Millennials. As for the definition of the age group of the Millennials, the article follows the methodology of Young (2017) in Ogilvy & Mather. The Millennials are referred to as “Generation Y” from the age 20 to 36.

- C Centennials (2001-2009),
- Y Millennials (1984-2000),
- X Generation (1964-1983),

- S Generation (1963 and earlier).

The inputs were obtained from the primary research carried out using the CAWI (Computer Assisted Web Interview) method. Data were collected through an electronic questionnaire in September and October in 2019. The link to the electronic questionnaire was posted on relevant Facebook pages and was also distributed by e-mail. The sampling method is based on the availability of participants and the voluntary nature of the research project. The processed data were adjusted for the age of respondents not belonging to the given generation (generation Y – the Millennials (20-36 years olds) as well as respondents preferring a device other than a smartphone.

The following table outlines the assumptions:

Table 1: Items determining suitability of respondents to be included in the research sample

Age	Which device do you use most often to connect to the internet?	Which device do you use most often to shop on the internet?
19 and below 60	Smartphone 412	Smartphone 405
Between 20 and 36 396	Tablet 19	Tablet 33
37 and above 28	PC 53	PC 46

The total number of respondents (filled-in questionnaires) was 484, of which 88 were removed because the findings did not meet the requirements of age (generation Y) and smartphone use habits.

Results

The following part of the article presents the outputs of frequency analysis and descriptive statistics. The results only show the outputs of mobile communication platforms used by Millennials. Selected characteristics of descriptive statistics were chosen universally so that they could offer the reader the most accurate picture of the given variable.

Table 2: Time spent browsing the web on a smartphone

	Number	%	Cumulative %
I do not use a smartphone	3	0.8	0.8
An hour a day	99	25.0	25.8
Up to 2 hours a day	132	33.3	59.1

Up to 6 hours a day	96	24.2	83.3
Up to 8 hours a day	30	7.6	90.9
More than 10 hours	63	9.1	100.0
Total	**396**	**100**	

99 respondents (25%) reported they spend an hour browsing websites on the Internet through a smartphone. 132 respondents (33.3%) spend up to 2 hours, 96 respondents (24.2%) spend up to 6 hours, 30 respondents (7.6%) spend up to 8 hours, and 36 respondents (9.1%) spend more than 10 hours. 3 respondents do not use their smartphones for this activity (0,8 %)

Table 3: See reviews, friend recommendations, and more when buying goods over the Internet

	Number	**%**	**Cumulatively %**
2	12	3.0	3.0
3	84	21.2	24.2
4	153	38.6	62.9
5	147	37.1	100.00
Total	**396**	**100**	

This item uses the Lickert scale, where 1 stands for "I do not take into account at all" and 5 "I definitely take into account." On this scale, respondents most often rated their experience as 4 (N = 153; 38.6%). Furthermore, respondents most often chose 5 (N = 147; 37.1%) and 3 (N = 84; 21.2%). Least number of respondents (N = 12; 3%), 2, say they disregard reviews, recommendations of friends and so on when buying goods over the Internet. The option “I do not take into account at all” was not selected by anyone.

Table 4: Descriptive statistics of taking recommendations into account when buying goods over the Internet

Average	**Median**	**Modus**	**St. deviation**	**Minimum**	**Maximum**	**Percentile**	
						25	**75**
4.0984848	4	4	0.8346288	2	5	4	5

From the values of the central tendency, it can be concluded that the willingness to take into account recommendations of friends when shopping online reached an average value of o 4. The deviation is approximately 0.84. This variable does not include the full range of responses, i.e. a minimum of 2 and a maximum of 5. Looking at the 25th percentile, it can be said that 25% of the answers were choices below the level 4 and 75% of answers cover levels between 2 and 5.

H: We assume a significant degree of association between the time spent on the Internet using a mobile device and willingness to take into account the recommendations when shopping online.

H0: There was no significant correlation between the variables analyzed.

H1: There was a significant correlation between the variables analyzed.

Table 5: Link – time spent on the Internet and recommendations

	Value	Asymptotic Standardized Error	Approximate T	Approximate Significance
Kendall's tau-b	-0,037	0,049	-0,745	0,456
N of Valid Cases	396			

In this case, the value is clearly higher than the acceptable α levels (e.g.: 0.1), i.e. we reject the alternative statistical hypothesis H1 and accept the hypothesis H0, as there was no significant correlation between the variables analyzed. Overall, we accept that there is no significant association between the time spent on the Internet using a mobile device and the willingness to take into account recommendations of friends when shopping online.

Conclusion

Mobile devices are a perfect tool that brings products and customer together. Mobile marketing offers high real-time operability, high user convenience, is cheaper, more portable, faster, has personal ad targeting, and even has its own position in the payment networks.

However, there are a number of limiting factors that will prevent customer conversion in terms of mobile marketing, such as a small mobile screen, that people are not yet accustomed to a smartphone interface, the issue of credit card security on a mobile device, smartphone, inconvenient typing on the screen of a smartphone, inconvenient price / purchase comparison, inability to view detailed product or service information, or it takes too long to load a website. Some of these barriers cannot be influenced by the seller, for example the dimensions of the mobile screen. What they can influence, however, is campaign optimization, content, and the overall shopping cycle and user experience (Haringová 2015).

Based on the above analysis, we can conclude that most Millennials spend from two to six hours a day on a smartphone, and over three quarters of Millennials take into account recommendations of friends when buying goods online. Our analysis has shown that there is no significant association between the time spent on the Internet using a mobile device and the willingness to take into account recommendations of friends when buying goods online.

Based on our research, it is possible for the purposes of management and practice to state that traders should pay attention to the quality of products and services they offer. Quality is the basis of business success. Subsequently, it is important to offer customers quality customer care or service. This fact also follows from SEE THINK DO CARE's marketing strategy, in which this necessity follows from the last phase.

The above facts are followed by customer satisfaction, who further reports it to their family and acquaintances through word of mouth in the form of a recommendation, or online in the form of reviews, directly on the website or other portals of sellers.

A similar research was carried out by the authors Stefanska, Knezevic and Stojkovic (2018). The research results are very similar to ours, but limitation of our study is that we focused only on Slovakia. Authors above have compared the online purchase consumer experience through mobile in Poland, Croatia and Serbia as well.

Other limitations of our study can be summarized in the following points:

- our study was conducted on a sample of students
- gender distribution was not even,
- our study was performed on a generation Y sample only,
- in our study, the products that respondents buy were not specified.

As for the possibilities of future research, it is possible to build on the results of our research in terms of the correlation between online reviews and customer shopping behavior as well as the correlation between word of mouth and customer shopping behavior.

There is still the possibility of verifying the correlation between a verbal recommendation from a family and acquaintances versus a verbal recommendation from a stranger and the shopping behavior of buyers.

Acknowledgment

This paper is one of the partial outcomes of the current research under the research grant 1/0609/19 - VEGA "Research on the development of e-commerce and mobile commerce and the impact of modern technologies and mobile communication platforms on consumer behavior and consumer preferences "

Abstract

Motivation. Pandemics on a scale like the SARS-CoV-2 have never before affected humanity and the economy in times of globalization. This is why the following question seems to be interesting: what is the situation of business entities during this pandemic?
Objective. The objective of the article is to identify the situation of enterprises operating in Poland during the SARS-CoV-2 pandemic in the context of the VUCA environment.
Design/methodology. The objective has been achieved through the literature studies with critical analysis and empirical research.
Findings. Research results have shown the SARS-CoV-2 pandemic poses serious implications for businesses in Poland. The results show that as many as 62% of enterprises are not able to stay on the market for more than 2 months without generating revenues. The most frequent strategies, the entrepreneurs had chosen was to minimize all costs related to operations (53.9%), implement "safe" actions, for example switching to remote work or selling via the Internet (52%) or looking for new business opportunities and market opportunities (44.1%). Interestingly, as many as 25% of the surveyed enterprises decided not to take any action and apply the strategy of waiting and observing the development of the situation. Results also have shown that the kind of support Polish entrepreneurs expect from the government are:, Social Insurance Institution (ZUS) exemption (85.9%), income tax exemption (69.7%), employees' salaries subsidies (49.3%) and subsidies to other fixed costs of the enterprise (47.9%).
Limitations. Selected findings of empirical research only in the field of the situation of enterprises operating in Poland during the SARS-CoV-2 pandemic have been presented.

Keywords: VUCA world, VUCA environment, SARS, SARS-CoV-2 pandemic, Polish company, crisis, globalization

Introduction

For many years, researchers and practitioners have been saying that turbulence is an immanent feature of the environment. Therefore, you can have the impression that all market participants have become accustomed to this situation and have learned - better or worse - to operate in these conditions. Talking about the fact that modern enterprises operate in conditions of constantly growing uncertainty and complexity of the environment may even seem a truism. However, the beginning of 2020 shows that this is not a truism, but the most important feature of the modern market. Reality shows to us that the global economy may find itself in a crisis that has been initiated by a factor independent of business people. This factor is the SARS-CoV-2 pandemic. It can be said that the SARS-CoV-2 pandemic is nothing extraordinary because humanity has been experiencing epidemics for centuries, e.g. pneumonic plague, Spanish-flu and bubonic plague and not so long ago severe acute respiratory syndrome (SARS). However, pandemics on such a scale have never before affected humanity and the economy in times of globalization. We are witnessing the "butterfly effect", which causes companies in the world face up to the consequences of the pandemic. Thus, the question arises: what is the situation of business

entities during the pandemic? The search for answers to this question has also become an inspiration for the authors of this article.

In this context, the objective of the article is to identify the situation of enterprises operating in Poland during the SARS-CoV-2 pandemic in the context of the VUCA environment. The article is empirical and it is prepared based on our own empirical research. The theoretical considerations are based on a critical literature study. First, there are considerations regarding the VUCA environment with particular regard to the SARS-CoV-2 pandemic. Secondly, research methodology and date sources are described. Next, we show empirical results. Finally, the discussion and conclusions are presented.

The VUCA World

Organizations should continuously balance between "exploration" and "exploitation" activities (March 1991). However, many organizations are concentrating on "exploitation" activities at the cost of "exploration" (Kotter 2001). The concentration on "exploitation" activities renders organizations ill-prepared for unexpected future events and therefore plunge into crisis when such events arrive (Rowe 2010). Enterprises must continuously "explore" their environment because environmental scanning is critical to the survival of an organization in today's world.

The modern world is volatile, uncertain, complex and ambiguous. That is the VUCA world. The acronym VUCA refers to the volatility, uncertainty, complexity and ambiguity of a company's internal and external environment. The acronym VUCA originated in the U.S. military to define conditions military leaders encounter on the battlefield (Whiteman, 1998). Bartscht imagines "VUCA environments as akin to being in a fierce winter blizzard at night; everything is always shifting and one cannot properly see what lies ahead" (Bartscht 2015, p. 254). The VUCA seem to occur together in inseverable combinations (Mason and Mitroff 1981). Volatility, uncertainty, complexity and ambiguity (VUCA) cause that strategic decision making is difficult (Bennett and Lemoine, 2014a). VUCA conditions make that any efforts to understand the future and to plan responses are often ineffective (Bennett and Lemoine, 2014b, p. 311).

Volatility refers to the nature, magnitude, rate and speed of change that occurs within a company's internal and external environments. "The nature of change occurs in the political environment (political instability, terrorism, (de) globalization), the economic environment (financial crises, global shifts in power, emergence of new and decline of established markets), the social environment (demographic changes, ageing society), the technological environment (digital transformation, big data, artificial intelligence, robotization), legal environment (immigration law, discrimination law, health and safety law) and the ecological environment (climate change) with increasing magnitude and speed" (Bader et al. 2019, p. 129-130).

A volatile situation can be defined as one that is unstable or unpredictable although this situation is one in which change is likely. Moreover, change may come quickly and at varying magnitudes (Bennett and Lemoine, 2014b, p. 313-314) and may be of unknown duration. In the opinion of Bennett and Lemoine (2014a) knowledge about it is often available. Volatility also refers to the rate of change. "When volatile change is expected, the best way to prepare is to devote resources toward developing agility" (Bennett and Lemoine, 2014b, p. 314) but investment should match the risk (Bennett and Lemoine, 2014a).

It is increasingly hard to predict the future with increased volatility of the environment (Mack and Khare 2016, p. 6). Thereby, it is problematic to correctly identify enterprises challenges, threats and opportunities. This situation causes enterprises to operate in uncertain conditions. The uncertainty drivers are a high degree of unpredictability, unknown outcomes and potential surprises (Bader et al. 2019, p. 129-130). The cause and effect of some event and factor is known in the case of uncertainty situation but there is a lack of knowledge about the importance of a given event or an influence of a given factor upon the enterprise's activity at present and in the future. (Bennett and Lemoine, 2014a, p. 314). Change mechanisms are also unknown and often unpredictable (Bader et al. 2019, p. 130).

There are three diversities of an environmental uncertainty: a) state uncertainties (parts or the whole business environment is unpredictable), b) effect uncertainties (effects of these uncertainties influence parts of the business or a company as a whole), c) response uncertainties (the consequences of choice in decision making can't be judged) (Nandakumar et al. 2012).

Enterprises should collect, interpret and share information constantly to reduce uncertainty. This is why companies should obtain information from many different sources, both inside and outside the firm. They should create information networks that can reduce ongoing uncertainty (Bennett and Lemoine, 2014a). But, the real business world shows that information is often incomplete or the understanding of available information is inadequate. This situation makes uncertainty a serious problem in the company's decision making.

The identification of cause-effect relationships becomes increasingly more difficult in an interconnected and networked environment (Mack and Khare 2016, p. 6). Some information about the environment is available or can be predicted, but the volume or its nature can be overwhelming because of many interconnected variables. This phenomenon illustrates the complexity of the environment. Thus, complexity can be defined as a situation where the interconnectedness of variables is so high that the same external conditions and inputs can lead to very different outputs or reactions (Mack and Khare 2016, p. 6). This situation relates to the structural dimension of an environment complexity. The second aspect of an environment complexity is the complex behavior (Dittes 2012, p. 3). Complex behavior is characterized by emergence that means "the action of the whole is more than the sum of the actions of the parts" (Holland 2014, p. 1). Thus, complexity refers to the task correlation, multifaceted effects and influencers (Bader et al. 2019, p. 129). The environment complexity has two aspects: the complex structure and the complex entities' behavior.

The level of complexity is constantly growing due to more and faster availability of data (Bader et al. 2019, p. 129). Social media also contributed to increasing the complexity of the business environment. Another area that has contributed tremendously to increased complexity are the social media. In the days of Twitter, Instagram or Facebook information about every company is available all over the world. Finally, knowledge transfer between people and companies has increased complexity as well.
Ambiguity refers to the lack of clarity and misinterpretation. Ambiguity is associated with the equivocality of the situation (Daft and Lengel, 1986) and the interconnection of environmental factors. Situations and environmental factors can be interpreted in a variety of ways and even interpretations could be conflicting. This phenomenon can create confusion (Thorén and Vendel 2019, p. 301). Therefore, the understanding of cause-effect relationships is difficult and this situation has just created ambiguity (Bennett and Lemoine, 2014b, p. 316). In this context, business decision-making is increasingly more difficult. There is more than one possible solution to resolve a problem and there isn't often known which one option should be chosen. (Mack and Khare 2016, p. 6).

The four VUCA elements were structured by Bennett and Lemoine (2014) in a portfolio with the two dimensions concerning knowledge about the situation (How much do you know about the situation?) and the predictability of the results of possible interventions (How well can you predict the results of YOUR actions?). Bennett and Lemoine (2014) assume volatility, uncertainty, complexity and ambiguity are different context types and require different approaches. The perception of these four elements as separated seems to be unreasonable and even wrong in the current conditions because in the economic reality they occur simultaneously. Mack and Kahre (2016) present a more interesting point of view corresponding to real environmental conditions. In their opinion, complexity is the key concept and volatility, uncertainty and ambiguity are the consequences of complexity (Mack and Khare 2016, p. 6). They base their opinion on the Systems and Complexity Theory. From this point of view volatility can be seen as an observable output of a complex system that cannot be easily interpreted any more. The so-called deterministic chaos is in the contemporary world. "Today's economy and environment seems to be more and more in a state "at the edge of chaos"" (Mack and Khare 2016, p. 9). In this state, even small environment changes can cause large and unexpected effects, the so-called "butterfly effect" and an environment behavior anticipation isn't possible anymore (McMillan 2004, p. 54f). This situation makes it impossible to predict the results and this is a sign of uncertainty. Moreover,

it is impossible to find the only “right” solution. Enterprises have to make decisions in ambiguous situations every day.

The current VUCA environment makes organizations continually take advantage of the evolving market along with its opportunities and threats and react very quickly to any change or evolution in the market (Dhir and Mital 2013).

The VUCA world in the SARS-CoV-2 Pandemic Time

The SARS-CoV-2 pandemic shows that we operate in a world that really is a "global village". Unfortunately, this pandemic has proved to us the following: how the economies of individual countries and individual enterprises are strongly dependent on each other, how changes in the economy of one country affect the activities of enterprises in other countries, and how one factor, which is the coronavirus, can have multiple and strong economic and social effects. The environment and global economic complexity are the key factors of huge problems of almost all businesses these days. The reason for this situation is the interdependence and interaction of all economic entities, regardless of whether they are small, medium- or large - sized enterprises or whether they are operating only locally or on an international or global scale.

The duration of SARS-CoV-2 pandemic shows that enterprises can face the extreme volatility of the environment. The change came very quickly and in very different environment dimensions. The SARS-CoV-2 pandemic is extremely painful for many companies in the whole world and how long it will last is unknown. It is also uncertain what path companies will take towards the crisis and how deep it will be.

The general rule is that the further into the future it aims the higher the level of uncertainty (Gordon, 2009). However, the developments of the beginning of 2020, when the SARS-CoV-2 pandemic started across the world, show that uncertainty can occur at the highest level in a very short time. We observe uncertainty in all three dimensions. First, there is a state uncertainty because the whole business environment is unpredictable. Secondly, there is an effect uncertainty. The results of the pandemic are affecting every company. We don't know how a change to the condition of every company will influence the crisis in large. Finally, there is a response uncertainty because the consequences of decision making of companies can’t be predicted. The SARS-CoV-2 pandemic results in the lack of clarity about what decisions enterprises should make about their future. Enterprises expect state aid, report their needs and governments will chaotically respond to them as far as it is possible. Enterprises don’t know if the government’s aid will be sufficient to stay afloat. Thus, enterprises have a dilemma whether they should try to save the company or should declare bankruptcy. The current situation of enterprises is extremely ambiguous.

Research methodology. Data sources.

The research was carried out on a sample of 690 companies, using the online questionnaire. The study lasted for two weeks, in the second half of March 2020 and covered enterprises operating throughout the country. The study used convenient selection using a "snowball sampling", i.e. respondents sent a survey via social media and messengers. The studied sample can be considered quasi representative, due to the diversity of the enterprises participating in the survey and their size (Fig. 1). The most strongly represented are: IT (76), marketing (60), construction (58), consulting (48), traditional trade (47), gastronomy (44), finance (38), beauty (35), education (32) , tourism (29), transport (23), medical and psychological services (21), automotive (18), events (16), e-commerce (15), film and photography (14), other services (31), others (61). The "other" category includes, among others: law firms, logistics companies, manufacturing and telecommunications companies as well as light and heavy industry.

Fig. 1: Percentage representation of individual industries in the research sample

Source: own research

The surveyed enterprises represent almost all areas of activity, 39% operate locally, 40% nationwide, and 21% internationally (Fig. 2). As can be seen from the figure (Figure 3), the research sample includes sole proprietorships (17%), companies cooperating with 1-2 people (19%), with 3-5 people (20%), 6-10 people (15 %), 11-20 people (14%), employing from 21 to 50 employees (7%) and above 50 (8%).

Fig. 2: Area of activity of surveyed enterprises

Source: own study

Fig 3: Number of employees/ people cooperating surveyed enterprises
Source: own study

The surveyed companies also had various experience on the market. 8% of surveyed companies have been operating for less than a year, 15% have been present for 1-2 years, 26% have been operating for 3-5 years, 22% have been operating for 6-10 years, and 29% have been on the market for more than 10 years (Fig. 4) .

Research results

Possibility of running a business in "new conditions"

An important issue in the context of the coronavirus pandemic was to check whether companies are able to conduct their business without direct contact with their clients, and to what extent they are able to switch to remote work mode. Therefore, the respondents were asked whether their activity requires direct contact with recipients, 56% of entrepreneurs answered yes (yes, my activity requires direct contact) (Fig. 5). Most often it concerns entrepreneurs from the beauty services sector, in large part of gastronomy, tourist industry or traditional trade.

Fig 5. The need for direct contact with clients of the surveyed enterprises
Source: own study

Fig 6. The possibility of switching to a work system in the surveyed enterprises
Source: own study

The next question concerned the extent to which respondents are able to change the mode of their work so that they can work remotely. Only 23% of entrepreneurs declared that they are able to work remotely full-time. 45% of respondents said that they were able to partially switch to remote work mode, and 32% said that in the case of their business it is not possible (Fig. 6). Enterprises which, due to their specificity, are not able to change their mode of operation may be at the highest risk of bankruptcy in the current situation.

Financial Cushion

One of the most important information, on the basis of which one can infer the future of many enterprises in the current situation, is their financial cushion, which is a financial reserve that will allow them to stay on the market without generating revenues. The results show that as many as 62% of enterprises are not able to stay on the market for more than 2 months without generating revenues, of which 20% are not able to stay at all anymore. 22% of the surveyed enterprises will survive for 3-4 months, and only 16% are able to survive over 5 months (Fig. 7). In the context of a protracted pandemic, these results seem to be very worrying.

Fig 7. Financial cushion of the surveyed enterprises

Source: own study

Analyzing these results by cross-sectoral sectors, it can be seen that the catering industry seems to be in the worst situation. No company in this industry has declared that it is able to survive for more than 4 months, of which 37% are not able to survive without generating revenues, and 49% will survive 1-2 months. The following industries are also in a very difficult situation: tourism (32% will not survive at all, 43% 1-2 months), beauty (41% will not survive without income, 41% will last 1-2 months) and interestingly medical and psychological services (20% will not last at all and 65% will last 1-2 months). The IT industry seems to be in the best position, in which only 8% of enterprises declare that they will not survive without revenues, and 26% are able to survive for more than half a year. The financial industry is also in a good situation, in which only 11% of companies declare that they will not survive without revenues, and 16% are able to stay longer than half a year. The sectors of e-commerce, consulting, marketing and traditional commerce are also in a relatively good situation (Fig. 8).

Difficulties and problems faced by Polish enterprises during the coronavirus pandemic

Another important aspect in the study was the identification of problems and impediments associated with coronavirus pandemic noticed by enterprises. The greatest threats are identified by enterprises in the following areas: postponed or canceled orders (375 enterprises), fewer customers than before (369 enterprises), fewer requests for quotations (329 enterprises) and the need to suspend or limit production or provide services (276 enterprises). The enterprises see the least problems in the following areas: the need for cash payments for deliveries (373 enterprises), the lack of competence of employees in the field of remote work (347 enterprises), the refusal or evasion of work by employees (316 enterprises) and the lack of willingness of employees to take leave (313 enterprises). These results show that the problems faced by enterprises are not due to problems in the field of human resources, but rather to problems occurring in other enterprises, due to the interaction and dependence of companies (Fig. 9).

Fig.9: Assessment of the impact strength of the problems faced by the surveyed enterprises during the coronavirus pandemic

Source: own study

Strategies chosen by enterprises during the coronavirus pandemic

An important issue for a full picture of the situation, was to check what actions companies are taking to survive the pandemic. Therefore, entrepreneurs were asked what strategy they had chosen at that time. The most frequently repeated response was to minimize all costs related to operations (53.9% of enterprises). Many enterprises (it can be assumed that those that had such an opportunity) decided to implement "safe" actions, for example switching to remote work or selling via the Internet (52% of surveyed enterprises). A significant group is also looking for new business opportunities and market opportunities (44.1% of enterprises). Interestingly, as many as 1/4 of the surveyed enterprises decided not to take any action and apply the strategy of waiting and observing the development of the situation (Fig. 10). It is also worth mentioning other ideas of enterprises that appeared in individual cases. It was, inter alia: withholding payment of corporate liabilities, reducing full-time jobs, reducing salaries by up to 60%, or taking sick leave.

Fig. 10: Strategies implemented by the surveyed enterprises during the coronavirus pandemic
Source: own study

Entrepreneurs' Concerns about the Coronavirus Pandemic

Entrepreneurs' concerns related to the coronavirus pandemic mainly concern: loss of liquidity (514 enterprises), loss of clients (414 enterprises), failure to implement strategic plans (401 enterprises) and the need to reduce jobs (281 enterprises). Moderate fears can be seen in the reduction of labor productivity (275 enterprises). On the other hand, most enterprises are not afraid of: withdrawal of investment from Poland (456 enterprises), employees' demands to remain in remote work after the cessation of the epidemic (424 enterprises), difficult recruitment (382 enterprises) and loss of suppliers (365 enterprises) (Fig. 11).

Fig.11: Concerns of the surveyed entrepreneurs related to the coronavirus pandemic
Source: own study

The kind of support Polish entrepreneurs expect from the government

When asked about the help entrepreneurs expect during the coronavirus pandemic, 85.9% declare that it is a Social Insurance Institution (ZUS) exemption, 69.7% expect an income tax exemption, 49.3% would like employees' salaries subsidies, and 47.90% subsidies to other fixed costs of the enterprise. Polish entrepreneurs expect the least real help from the State Treasury guarantees of loans for a short-term improvement in financial liquidity (14.9% of enterprises) and enabling the entrepreneur to consult experts in building a new strategy or restructuring of existing businesses.

Positive Effects of Coronavirus Pandemic on Polish Entrepreneurs

Despite the fact that the coronavirus pandemic is associated with a huge crisis for most businesses, it's worth considering whether it also has any positive effects on business. Research results show that 35.8% of enterprises have noticed the emergence or increase of employees' sense of shared responsibility for the company. 32.10% of entrepreneurs experience time savings due to canceled meetings. 26.40% experienced an increase in the competences of their employees in the field of remote work, and 23.60% an improvement in internal and external interpersonal relations (Fig. 12). These results may confirm the assumption that one of the effects of a pandemic will be transformation from the employee's market to the employer's market.

Discussion and conclusions

In 2004 Day B., Mckay R., Ishman M., Chung E. wrote that "the world was caught completely off-guard by the SARS outbreak" (Day et al. 2004b, p. 794). At that time, they were right: "As devastating as it was for many businesses, strategic planners would have to be psychic to have anticipated the disease and to incorporate it in the planning process" (Day et al. 2004b, p. 794). But 16 years later, it seems that governments and enterprises should have projected epidemics as an important factor determining the functioning of the world's economy and individual enterprises. However, our research shows that companies still haven't included the epidemic in the business definition of the crisis. Enterprises must include a pandemic to broaden the scope of crisis planning.

In the volatility context, the SARS-CoV-2 pandemic was unpredictable and its duration is unknown. The rate of change is dramatically high across the world. However, a volatile change was expected by enterprises in Poland and an economic crisis had been coming for months. However, most of them did not prepare sufficient financial resources to survive.

Our research shows that lots of companies in Poland have been concentrated on exploitation activity. They have been highly optimized to achieve their goals and very vulnerable and unprepared for future changes in the last few years. Thus, when unexpected future events (the SARS-CoV-2 pandemic) "come" in the present, these enterprises are thrown into crisis that significantly reduces their performance and at worst leads to an organizational collapse in many cases.

Our research has shown the SARS-CoV-2 pandemic poses serious implications for businesses in Poland. The recent SARS-CoV-2 pandemic outbreak has shown how quickly enterprises in Poland can be adversely affected by the global market problems. We have also identified that companies in Poland (very much similar to organizations in other countries) are expecting their government's aid without which they will most likely collapse.

Current events show that future epidemic threats should be considered by enterprises. Organizations should have plans to reduce the impact of the epidemic on their activities, including a "financial cushion". Enterprises should also have procedures to be followed in the event of an epidemic crisis. "There should be no excuse for being caught off-guard" in the future (Day et al. 2004b, p. 802).

We have been observing the development of ICT for years. The pandemic has caused a mega acceleration of their widespread use in work, education and private life. The impact of the technological environment has already had social effects but the scale of this impact (global) and the rate of changes (in Poland within one month) have not been observed so far. What will be the long-term effects of the SARS-CoV-2 pandemic in the technological dimension is certain: we will observe further development of ICT. However, the question remains as to what effects this pandemic will have in the case of private and professional social relationships. It seems highly likely that where home-office work is possible employees and employers will want to maintain this way of working. This requires enterprises to make appropriate changes in their organizational structures, processes and culture.

Unfortunately, now, in 2020, the following opinion: "It may not be SARS next time, but we can safely bet on similar health crises happening in the future. In whatever guise and labeled in whatever name, it will happen again. The question is whether the business community will be better prepared the next time it is around, and based on what we have found, the answer appears to be a resounding no" (Day et al. 2004a, p. 833-834) turned out to be true. Enterprises in Poland are experiencing the negative effects of the SARS-CoV-2 pandemic on the economy. They are not prepared to deal with this problem and the survival of most of them depends on the government and the European Union aid.
The world of today seems to become more VUCA than ever before (Bader et al. 2019, p. 132).

IT System Implementation from Clients' and Supplier's Perspective – A Case Study

Ewa PRAŁAT

Faculty of Computer Science and Management, Wroclaw University of Science and Technology, Wrocław, Poland, ewa.pralat@pwr.edu.pl

Magdalena MARSZAŁEK

Faculty of Computer Science and Management, Wroclaw University of Science and Technology, Wrocław, Poland,

Abstract

As more and more enterprises decide to introduce or to change IT systems, the implementation process becomes an important undertaking in many organizations. However, not all implementations are uniformly successful. The reasons behind problems vary and should be analysed from the perspectives of technology and management. Hence, it is important to understand what is necessary to ensure a successful IT system implementation. The paper takes an in-depth look at the issues behind the process of IT implementation via a case study methodology. It examines four cases of implementation of the fine recovery system, that were successful but not equally assessed by clients. The authors compare these implementations from both the client and the supplier perspective using data collected with a questionnaire survey and interviews. They try to explore the differences between these implementations and to identify their core issues. Some actions that can help improve troublesome implementations are recommended.

Keywords: System, Implementation, Client Perspective, Supplier Perspective

Introduction

A failure of new technology implementation is often caused by treating the implementation process as a technological problem only, while human and organisational issues are not fully born in mind (Eason, 1988). The new technology is likely to change the work processes and, according to Carayon and Haims (2001), to have both positive and negative impacts on job characteristics. An implementation of new technology can, on the one hand, facilitate and accelerate the work but, on the other hand, a technology with usability shortcomings can make the users overloaded by work and hence frustrated.

The nature of the issues that may affect implementation of the IT system can be examined on three levels: macro-, meso- and micro-level. These levels pertain to the inner and outer contexts of the implementation (Greenhalgh et al., 2008). For instance, the macro-level concerns national or regional policies, the meso-level refers to organisational culture, work routine in the client company and support strategies from its board, the micro level touches a behavior and habits in the work place, staff skills concerning IT use, differences between the new system and the previous one (if it existed), users' motivation for the implementation process and use of the new system (Carneiro Mussi et al., 2018). Implementation project can be also described from three main point of views: technology transfer perspective, innovation diffusion perspective, organisational change perspective and project management one (Xu & Cybulski, 2004).

According to Filip (2012) the process of an information system implementing (as well as designing) can be influenced by following factors: people involved, system orientation and its purpose, organizational setting, adopted standards, etc. The management of the client company, just like the

system supplier, should take account of those factors while making a decision on introducing a new system.

Successful IT system implementation cannot be perceived only as a software installation effort. Such an initiative, especially in the case of the ERP system, may affect the whole organization and may involve processes that lead to its broad transformation. It can result in significant changes of the organizational structure and management model (Chang, 2006), but also has implications for employees (Wood & Caldas, 2001). The IT implementation can cause conflicts encompassing the intra- and inter-department levels. Meissonier and Houzé (2010) distinguish five types of such conflicts: the conflict about the system itself, the conflict about definition and execution of the tasks to be fulfilled by the users, the conflict about new required professional skills, the cultural conflicts and finally the conflicts resulting from a loss of power. Several problems may be also caused by the "legacy IT systems" and the operating procedures permitted within the organization (Filip, 2012).

Many authors have analyzed the issues necessary to ensure a successful implementation, often focusing on the ERP system, however most of their findings could be applicable to all types of systems. In consequence, lists of critical factors for a successful implementation have been developed. As an example, Wu (2007) presents 14 factors that can be addressed to three main phases of implementation process: pre-implementation phase, implementation phase and post-implementation phase. The compatibility of system's and company's needs as well as ease of customization are the aspects important during the first stage. The success in the implementation phase can be provided by effective project management from the organizational perspective, and by data and IT infrastructure accuracy from technical point of view (Govindaraju, 2012). User training and education (Wu, 2007) as well as users experiences in their job functions (Krairojananan et al., 2013) are regarded as important factors in post-implementation stage.

According to Calisir & Calisir (2004) perceived usefulness and learnability increase the satisfaction and knowledge level of end-users and determine their acceptance. However, resistance to change is a problem that can be observed during many implementations. The reasons for such an attitude can significantly vary and depend for example on the system type (Jiang et al., 2000). Resistance to change is also identified by Hong and Kim as one of the critical success factors for ERP implementation (Hong & Kim, 2002). Researchers analyze the resistance from different perspectives (people-oriented, system-oriented and interaction-oriented) (Jiang et al., 2000). Different authors underline the role of proper change management, and claim that a troubled implementation may take place when the system is mandated by top management without preparing the organization and adequately managing the change (Motwani et al., 2002), (Beheshti et al., 2014). According to Govindaraju and Indriany (2012) especially top management support is important for mobilizing employees during the project. As a result, staff may adopt the implementation enthusiastically or may reluctantly consider the suggestions and not get involved with the phases of implementation. Users' acceptance of a new system is often recognized as a main aspect of the implementation and it influences the perception of resulted changes (Brito & Nogueira, 2009), (Kwak et al., 2012). System's individual characteristics, its usefulness and ease of use, prior expectations, and magnitude of the change are among the most important factors identified as sources of employees' attitudes toward change (Jiang et al., 2000). A communication between business and IT professionals can be supported by the systems analysis method developed by Alter (2011). It can be used for facilitating the business professionals, who don't possess sophisticated knowledge, their engagement in IT system development and improvement. Moreover the way of perceiving the IT system users should change from technological tool users to human participants in socio-technical work systems.

Two research questions are posed in this paper: (1) what factors facilitate a successful system implementation, and (2) what actions can be taken to increases the chance of the implementation succeeding? This paper attempts to answer the above questions by examining four implementation cases of the same system from both the client and the supplier perspective. In spite of equal experience and skills of the supplier company team, not all implementations were equally successful.

Fine recovery system and its implementation

The fine recovery system was developed with participation of Wroclaw Roads and City Maintenance Office and is destined for companies dealing with mass collection of debts coming from invalidated municipal transportation rides. The data can be introduced manually or via a mobile application that enables recording of data from the ticket inspectors' location. The inspectors can prepare the calls for payment and also verify the data of passengers who refuse ticket validation. The system can also exchange data with external systems like the National Debt Register (KRD) and e-court service.

The main units of the system are as follows (Marszałek, 2017):

- Request unit – enables to manage the data concerning invalidated rides, add new data, browse and analyze the already collected data.
- Renewed request (reminder) unit – enables mail merge pitched at debtors.
- Pre-court/pre-litigation request – the last conciliatory request can be generated and printed. Both successfully and unsuccessfully provided requests should be registered because this step of the debt collection processes is obligatory.
- Court case unit – a lawsuit can be generated automatically on a blanket accepted by Polish courts.
- Procedural path unit – includes all the stages after the lawsuit has been brought.
- Recovery unit – enables sending the requests to the debit collectors.
- National Debt Register unit – the information about the passengers who repeatedly shun from paying off fines can be electronically placed in the National Debt Register.
- Ticket inspectors – the efficiency of each ticket inspector can be determined and used to calculate commissions.

Implementation of a system requires close cooperation between the supplier company tram and the staff of the client company. There are seven following main steps of the implementation of the fine recovery system (Marszałek, 2017):

1. Presentation of the system – the content of the presentation varies depending on the previous stage (tendered contract or a request for proposal).
2. Requirements analysis – during the close cooperation with the client company, core functional and non-functional requirements are identified and described or elaborated and elucidated (according to the previous step). A specification document that has to be approved by both sides is prepared.
3. Installation of the trial version – a demonstrative version is configured in accordance with the recovering procedure applied in the client company and then introduced.
4. General training – a presentation of the units and their operation can be held for one big group of users or several smaller ones. The overall attitude towards the system can be disclosed together with some details of the recovering procedure that can bring about the necessary system modifications.
5. Data migration – the client company might have a set of recovering data from the previous system and want to use it in the new system. Data migration is usually a long-lasting and difficult process. It is repeated until all errors are corrected.
6. On-the-job training – in the form of workshops with individual users or a small group of users. The participants practice operations following their job description.
7. Launch of the system – a new system is launched; it can replace the previous system or work simultaneously with it for some time to compare the results.

System implementations in four companies

The computer system that support activities connected with recovering process was developed by the supplier company and implemented at different companies. Four implementations were taken into consideration and compared from the client as well as from the supplier perspective.

The case of company A

Company A, founded in 1992 in a city with a population of 250,000, was responsible for the organization and management of the public urban transport. The previous computer system was only adapted to support recovering operations and was not effective. Moreover, the external applications

like Excel spreadsheets and mail merge editors had to be used to fulfill a part of the operations. The executive board decided to introduce a new system to automatize part of the work and, for mostly, to avoid any losses caused by delayed prosecution and lapsing of cases. A contract for the new system has been tendered and the general requirements as well as the detailed timescale of the implementation were put in the contract. A certain reluctance towards the new system has been observed among the staff since the general training. They expressed distrust towards the functionalities of the new system and its user-friendly interface and insisted on adjusting it to match the previous system design. Such an attitude hindered the training and – in consequence – the whole implementation. In the end, it was possible to convince the staff to accept most solutions presented in the new system and only tiny modifications were introduced. Nevertheless, a big number of questions from the staff was a serious issue that resulted in the necessity of providing an additional training.

The case of company B

Company B, founded in 2008, was responsible for the organization and management of the public urban transport for one of Poland's largest cities and the surrounding urban region. The previous system was dedicated to this company and supported the basic functionalities of recovering but was not integrated with other entities. The development of this system was impossible, so its users made individual efforts to find a better solution that would allow them to collect debts better than before (especially important were the automated generation of lawsuits and the electronic placement of information in the National Debt Register). Company B has chosen the system basing on several presentations. The requirements for the new system were not listed earlier, thus it was necessary to carry out some interviews and consultations with future users and management. The collaboration was very fruitful due to the positive attitude of the company B staff.

The case of company C

Company C has been operating since 1990 and has dealt with ticket inspection and debt collection that resulted from invalidated rides in the public and municipal transport in one of Poland's largest cities. A supplier of the new system was selected in competitive bidding where partial offers were not accepted. The requirements for the new system were described in detail; they were very complex – the system was expected to enable control and mass debt collection and to be integrated with the ticket inspection system on mobile devices and with other external systems. A special department had been established just so there was no additional expectancies (apart from the description of the subject of the contract). Due to long recruitment process, not all staff members could work with the trial version. Therefore, on-job training had to be very detailed and profound.

The case of company D

Company D, established in 1996, was responsible for the organization and management of the public urban and suburban transport in one of the largest cities in Poland. This company was expected to take over the operations of ticket inspection and mass debt collection. The supplier was chosen based on an order and the client company did not have enough experience and knowledge to determine system requirements.

There was no time pressure in the system implementation at company D, hence all of its phases went calmly. However, there were disadvantages to this situation – the implementation was overrun with a host of suggestions and remarks that were taken into consideration. Quick installation of the trial version has facilitated discussion about the requirements. The activities the staff at company D learned were new for them, so the trainings often took the form of a workshop. Moreover, the employers did not have any previous experience or habits, so they quickly accustomed to the system. There was no data to be migrated, so the new system could start expeditiously and the trainings were organized prior to each phase of recovering process.

It is possible to indicate four main factors that differentiate all the implementations described above. They are presented in Table 1.

Table 1: Main factors differentiating described implementations

	A	B	C	D
Previous system	yes	yes	no	no
Board initiative	yes	no	no	no
Detailed system requirements	no	no	yes	no
Time pressure	yes	yes	yes	no

Source: own work

Research Methodology

Four cases of implementation of the fine recovery system were evaluated from the perspective of both the client and the supplier. In this study, two data collection instruments were used to assess clients' and supplier's experiences related to implementation of new systems. The first one was a user survey and the second – the interviews with the people who were involved in all the four implementation projects from the supplier's side. The staff (86 employees) who participated in the implementation at the clients' companies filled in a questionnaire that evaluated several aspects of the implementation process. The questionnaire consisted of 36 questions (most of them close-ended, with ordinal scale) and was divided into four parts that referred to:

- presentation of the system – raised the questions of the presentation comprehensibility and usefulness, as well as the assessment of skills and knowledge of the training officers.
- analysts' qualities presented during requirement analysis – the staff were asked to assess the level of analyst's expertise, responsiveness and involvement in the process. Later on, the qualities of the alternative solution and how analysts identified and anticipated clients' suggestions were evaluated
- trial version assessment – included questions about the functionality of the trial version (the advantages of the new system, necessary functions), whether it met expectations (was it adequate for the worksite), whether the duration of the trial version and the level of technical support during the tests were sufficient.
- evaluation of the trainings and documentation – the comprehensibility of the general training, as well as the utility of the on-the-job training (was it sufficient for starting unassisted work with the system) and its general assessment. Some questions about the documentation of the system were also posed (regarding its clarity and usefulness).

The supplier staff took part in interviews that were structured, with 34 questions, mostly open-ended. The questions asked concerned the methods of the new system requirements determination, fluctuation of the requirements, initial presentation (its preparation and impact), working with the trial version, data migration (scope, data verification methods), trainings. The analysts were asked about the problems they encountered, about users' behavior and engagement (point-making, questions) as well as about meeting those expectations.

Results

According to the results of the questionnaire, the staff from companies B and D assessed the usefulness of the system presentation positively (100% of participants), at company A the result was distinctly lower (50%). The staff complained that some of their questions were not answered or answered in an incomprehensive manner.

Fig. 1: The assessment of the analysts' qualities

Source: own work

The accuracy of the requirement analysis was assessed high in companies B and D (respectively 4.1 and 4.3 points on a 5-point scale) and low in company A (2.8 points). Requirement analysis was not conducted at company C due to a very detailed description of the subject of the contract. The opinions on the analysts' qualities also varied between companies (see Fig. 1) – the staff at company A evaluated all features distinctly more negative. The analysts' willingness to cooperate with the users was evaluated as the most negative, but the expertise and the involvement also got a very low rating.

The trial version provided functions required on the workplaces by most of the users and the trial version testing period was assessed as sufficient to familiarize with the system's functionalities (company C was the most unsatisfied). The trial version functionalities met the expectations of all the companies, except company A (see Fig. 2 for details). Technical support during the trial period was rated as the worst (especially at company A, however company C was also not satisfied).

Fig. 2: The assessment of the trial version

Source: own work

Apart from the company A staff, the comprehensibility of the general training was assessed well. The respondents complained about the large amount of information shared in short time and about the fact that most of it focused only on the theoretical aspects of the system. The on-the-job training was assessed slightly better – according to the respondents it was helpful in starting individual work with the system (see Fig. 3 for details).

Fig. 3: Training assessment

Source: own work

The documentation of the new system was well-rated but it was used only by a part of the users (mostly because of the technical language; some did not use it as the trainings provided were comprehensive enough). The respondents from companies A and B were also asked to compare the new system with the previous one. The opinion of the majority of the users from company A (67%) was that the old system was better than the new one. In the case of company B, most of the users (83%) appreciated the advantages of the new system.

The employees participating in the interviews mentioned problems that occurred during the implementation of the fine recovery system at company A. The staff members were very much used to the previous system, so a feeling of hostility and a pushback against the new system were observed which resulted in difficulties in determining the details of the functional requirements. The implementation at company B received best assessment and was also the most efficient. The friendly attitude of the staff was an important factor which helped in putting the record straight in a short time. Only at company D there was no time pressure on the implementation of the system (there was no deadline for the task). The users had the opportunity to slowly familiarize themselves with the fine recovery system which reduced their doubts concerning the new system.

Discussion

Although every among the four implementations described in this paper was successful eventually, they were differently assessed by clients. The authors attempt to discover the factors that are expected to improve how implementation process is perceived and assessed by the users of the implemented system. In order to achieve this, several steps have been taken into consideration and analysed: the situation at the company before the implementation, users' evaluation of particular implementation phases and the supplier's staff opinions.

The first identified factor is the source of the initiative behind the change of the system. A bottom-up initiative seems to influence the implementation positively. The implementation at company B was initiated by the employees, who felt the need to change the previous system and were visibly interested in achieving success with this project. The collaboration with the analysts and training specialists run smoothly and all the arrangements were completed flawlessly. The involvement of the above professionals was appreciated, which is reflected in the positive assessment (highest rank) of this implementation by the supplier's staff. Also the client's opinion regarding the analysts' qualities, the training and the trial version period was very positive and the new system was generally appreciated.
On the contrary, the implementation at company A, where the system exchange had been imposed by the management, was assessed as the worst by both the client as well as by the company that

implemented the system. The staff, used to the previous system, was reluctant and did not want to collaborate with the analysts and training specialists. The employees tried to force making adjustments to the new system interface to match the previous design. Their hostility might be the reason of the noticeable lower assessment of the system analysts' qualities as well as the trainings. Moreover, the staff was also dissatisfied with the trial version and technical support, saying their expectations were not met. In the end, they were still convinced about the supremacy of the old system over the new one. The second identified factor is the duration of the implementation. Scheduling sufficient time for the implementation (especially for working with the trial version of the system) eliminates the feeling of rush and may improve the perception of the whole system.

The lack of a set time-frame was observed during the implementation at company D. The staff had enough time for testing the trial version which meant that the users' could adequately familiarize themselves with the system and hence their bias was reduced. Finally, the results of the survey show that this implementation was assessed as the best. The differences could be clearly seen, especially in the evaluation of the trial version.

The results of the questionnaire survey were analysed statistically. The hypothesis concerning the lack of difference between the implementations in the four examined companies was rejected. Variance analysis at the 0.05 level showed significant differences related to the variables described as: technical support during working with a trial, fulfilment of the expectations by the trial, general training comprehensibility, assessment of the on-the-job training and usability of the on-job-training. A post-hoc analysis allowed to identify significant differences between some of the examined companies (see Table 2).

Table 2: Results of a post-hoc analysis

Variable	Pairs of significantly differing companies
fulfilment of the expectations by the trial	D-C
technical support during working with a trial	B-A C-A D-A
usability of the on-job-training	B-A C-A D-A
general training comprehensibility	B-A D-A D-C
assessment of the on-the-job training	D-C

Source: own work

Conclusion

Only four companies case studies were been used to observe how users react to issues associated with a new system implementation. Therefore, we cannot claim any generalisation of the results. Nevertheless, the lessons learned from analyzing four organizations may be helpful for others in their efforts towards a successful system implementation. The most important issue seems to be the attitude of the future users of the new system and their identification with the system. Obviously, when selecting the system a bottom-up initiative is not always possible, yet comprehending the necessity of system introduction (or change) is an essential factor that could help in the efforts of system implementation. Involving representatives of the future users in systems presentations and giving the possibility of expressing their opinion on the system's advantages and disadvantages seems to bring benefits to the process. The next problem to be avoided is allotting inadequate time period for the implementation resulting in undue haste. Special attention should be paid to working with the trial version and to providing training. Moreover, no questions posed (especially during training sessions) should remain unanswered.

Resistance to change as a problem during the implementation is brought up by many authors, who also analyse the importance of top management support and of generating awareness of why change is necessary. However, the relation between the source of system-choosing initiative (top-down versus bottom-up) and the perception of the implementation is not verified.

We would like to recommend that future research to examine the influence of this factor, although finding an appropriate set of companies poses some difficulties.

Planning the duration of implementation needs to be balanced, which the supplier can achieve in cooperation with the client. Taking too much time for the implementation will create unnecessary financial burdens, while too little may leave users unsatisfied. Nonetheless, it is impossible to determine a general rule for the estimation of implementation time.

The main limitation of this study is that it was focused on a relatively small number of companies (it ensured that the supplier's team was the same, so they could compare all the four implementations). The study was intended to set the direction for future research works planned at several IT system suppliers companies.

Decision Making Framework Enabling Sustainable Remanufacturing in Small and Medium Sized Enterprises in The Automotive Sector

Paulina GOLINSKA-DAWSON

Poznan University of Technology, Poznan, Poland
paulina.golinska@put.poznan.pl

Abstract

The main goal of this paper is to present the decision making framework which is based on the Sustainable Remanufacturing Maturity Model (SRMM). This framework supports the decision makers with actionable knowledge on how to reach the state of multidimensional (economic, ecological and social) resource efficiency in the remanufacturing process, so called sustainable remanufacturing (SR). The originality of the proposed framework results from relating the process maturity level (current state) to the appropriate improvement's actions which can be taken at each maturity level. The framework provides adequate tools that allow to identify the improvement potential and then to prioritize actions which are needed in order to improve the sustainability of the remanufacturing process. The tools are tailored for different levels of the process maturity in a company, namely: low, medium and high.

Keywords: Automotive Aftermarket, Maturity Profile, Sustainable Remanufacturing, Sustainability Assessment.

Introduction

Remanufacturing is an industrial process that transforms core (returned product) into "as good as new" product. Remanufacturing is the most resource efficient recovery option for end-of-use products (Steinhilper, 1998; Yan et al., 2018). Very few previous studies address the problem of the sustainability assessment of the remanufacturing process.

It is often assumed that remanufacturing is a sustainable practice without any further investigation. The previous studies on remanufacturing and sustainability have addressed the topics, as follows:

- remanufacturing, as enabler of Sustainable Operations Management (SOP) (Kleindorfer et al., 2017; Fatima & Biswas, 2016)
- remanufacturing, as enabler of the Sustainable Supply Chain (SSC) (Correia et al., 2017; Yan et al., 2018)
- remanufacturing as enabler of sustainable consumption (Matsumoto et al., 2018; Ardeshirilajimi & Azadivar, 2018)
- eco-design (Pigosso et al., 2013)
- choice of most sustainable recovery option for end-of-life and end-of-use products (Sundin & Lee, 2012; Warsen et al., 2011).

None of the above mentioned approaches focuses on a holistic assessment of the remanufacturing process, as a core business of a company.

Sustainable remanufacturing is defined here as: *a remanufacturing process which transforms a core in a product with as good as new functionality, when maximizing the material recovery rate at a feasible economic cost and minimizing the negative environmental and social impact*.
The sustainable remanufacturing has the characteristics, as follows:

- economically efficient use of resources,
- minimizing waste generation and emissions,

- maximizing the secondary use of car parts,
- ensuring safe and ergonomic work environment, supporting employee's development and generating minimal burdens for the surrounding community.

The operationalization of the sustainability goals at a company level is challenging, especially in small and medium sized enterprises (SMEs). Schrettle et. al. (2014) have stated that companies search for guidelines on how to develop sustainable capabilities and integrate them in their business goals at operational level and include them in their decision-making process.

The maturity model (MM) has been explored by a number of researchers with regard to its potential, as a framework for sustainability assessment in a company (Machado et al., 2017). Correira et. al. (2017), through systematic literature review have identified that most of the existing MMs in sustainability domain only describe the current state and that the application framework is missing.

This paper extends the previous author's studies (Golinska & Kuebler 2013; Golinska-Dawson & Kuebler, 2018) on the application of the MM, in order to provide sustainability assessment criteria of remanufacturing operations. The initial MM hasn't included the application framework, which allows to make changes in the current business practices and eliminate wasteful activities.

The main goal of this paper is to present the decision making framework which is based on the Sustainable Remanufacturing Maturity Model (SRMM). The framework aims for enabling SMEs in the automotive aftermarket the assessment their current maturity profile (as-is state) with regard to sustainable resource utilization. Further the framework provides adequate tools for each of the maturity level and that allows to identify the improvement potential and to prioritize actions which are needed in order to improve the sustainability of the remanufacturing process.

The main theoretical contribution of this paper is the proposal of the decision making framework which is specialized for the organizational conditions that appear in the remanufacturing SMEs in automotive sector. Three set of methods are presented which allow assessing the process in SMEs at: low, medium and high maturity level. The findings from the literature review are combined with the insights from the experts' panel and the case studies.

The remainder of the paper is organized, as follows, first the methodology is described. Then the decision framework is presented, the used tools and methods are described. That is followed by framework testing. Finally in conclusions, the benefits and limitations of the proposed approach, as well as further research are discussed.

Methodology

The previous related studies on the application of a maturity model (MM) for sustainability assessment, focus on the supply chain perspective or the sustainable operations management perspective. They partly include the remanufacturing aspects but they don't allow for a holistic assessment of the remanufacturing process with regards to the sustainability goals. During the literature review only one other maturity model has been identified, which is solely dedicated for the assessment of the remanufacturing process. The Remanufacturing Process Capability Maturity Model" (RPCMM) has been developed by Butzer et al. (2017). The RPCMM focuses on providing the benchmarking tool in assessment of the remanufacturing process efficiency but it has a very limited application framework.

The maturity models allow the decision makers to evaluate the current situations (as-is) with regard to sustainability and to guide them through the improvements path (Correia et al., 2017). They allow for the analyses of the current state of an organization to enable positive transformation towards reference state (to-be).

The design of the maturity models is challenging as "the nature of maturity models has not been theorized well in literature" (Kohlegger et al., 2009). Similar criticism is expressed by Poeppelbuss et

al. (2011) "academic articles often present new MMs, as a rough sketch that would not suffice for practical application".

Operationalization of the objectives of sustainable development at the enterprise level requires providing a framework for managerial decision-making with regard to the assessment of the current state (the level of resource utilization) in the remanufacturing process and then identifying potential for improvement's actions and prioritizing them.

The proposed framework is developed based on the literature review and the output of the case studies conducted in the SMEs in the automotive remanufacturing aftermarket, as presented in Fig.1

Fig. 1: Methodology, Source: Developed by the author

Based on the concerns about the limitations of the MMs, which have been expressed in the previous studies (Correia et al. ,2017; Marchado et al. 2017; Tarhan et al., 2016; Poeppelbuss et al., 2011) the research questions are formulated, as follows:

- RQ1: What form of the SRMM does allow assessing the current level of sustainability of the automotive remanufacturing process and identifying the areas for improvement?
- RQ2: How to support the decision makers to prioritize the actions which are necessary to transform towards sustainable remanufacturing in automotive SMEs?

In order to address the research questions the decision making framework is designed and it includes the elements as follows:

- the structuring of the SRMM – it provides definition of the maturity levels and it gives guidelines on how to calculate maturity level;
- an application framework – which relates the maturity level with relevant indicators and other sustainability assessment methods in order to identify the appropriate actions, that are necessary to improve the current situation.

Decision framework description

Introduction – Organizational Conditions in Automotive Remanufacturing SMES

Remanufacturing of automotive parts differs significantly from the primary production. The process constitutes of subprocesses, (Golinska-Dawson et al., 2018): core delivery; initial assessment; disassembly; cleaning; inspection and sorting; reprocessing of components; reassembly and testing.

For purpose of the design of the decision framework the organizational conditions in automotive remanufacturing are identified based on literature research and pilot studies among 40 SMEs (for details see: Golinska-Dawson et al., 2018). A summary of the results, which are obtained are presented in Table 1.

Table 1: The organizational conditions in automotive remanufacturing, Source: developed by the author based on (Golinska-Dawson et al., 2018)

	The factors identified based on the literature review	**Implications of a factor appearance in SMEs (based on an empirical study)**
External (core deliveries)	Uncertainty of the process' input (time, quantity, quality)	The uncertainty of the supply stream is limited by processing cores owned by the customer or diversification of sources of supply.
	Proliferation of cores and small size of deliveries	Most remanufacturing orders include only one car part (87.5% of orders).
	Variable Material Recovery Rate (MRR)	Most SMEs achieve the MRR required by APRA standards (82.5% of respondents).
Internal factors (organization & execution of the remanufacturing process)	Uncertain lead times	The duration of the regeneration cycle varies from hours to weeks, depending on the technical condition of the core and the availability of the necessary components.
	Small batches of wide range of product variants and generations	The high proliferation of models and the generation of car parts might cause difficulties in the automation of technological operations and limits the possibility of obtaining cost-effectiveness (scale effect).
	Materials matching restrictions,	Majority of the SMEs produce the missing components on their own.
	Time consuming disassembly, cleaning and reprocessing	SMEs perceived as time-consuming operations typical for remanufacturing process.
	Problems to meet variable quality requirements	Most SMEs do not perceived as significant problems resulting from the need to meet diverse customer requirements.

The definition of external and internal factors (theoretically and empirically) has become the starting point for designing the SRMM and developing a set of methods and tools in the application framework.

SRMM - Definition of The Maturity Levels and Maturity Scoring

Small and medium sized enterprises use ad hoc solutions and experts knowledge (Golinska et al., 2015). The processes have low standardization and the corporate reporting standards are rarely used. There is need for guidance on how to assess the current remanufacturing performance with regard to sustainability (current process maturity level) and how to improve the resource utilization to transform a core (used product) into a remanufactured product in a sustainable way.

The process maturity is defined here, as: *an extent to which processes are defined, managed, measured, controlled and optimized with regards to sustainable resource utilization.*

It is assumed that the model is used for self-assessment, so the Likert- like questioner is used. This assumption is also supported by previous research (Machado et al., 2017).

The initial MM of sustainability in remanufacturing (Golinska & Kuebler 2013; Golinska-Dawson & Kuebler, 2018) includes 5 stages which are created based on the ISO/IEC 15504. The current version is modified according to commonly used in the literature CMMI (Chrissis et al., 2003). The process maturity levels are defined, as follows:

- Level 0 (very low) – the sustainable practices in management of remanufacturing process are not applied or are applied incompletely by a company.
- Level 1 (low) – the sustainable practices in management of remanufacturing process are applied ad hoc (e.g. to solve current problem or to comply with specific customer requirements) in a company, processes are not formalized.
- Level 2 (medium) – the application of sustainable practices in the management of remanufacturing processes is formalized; there some indicators are defined in order to measure the performance towards sustainability.
- Level 3 (high) – the application of the sustainable practices in the management of remanufacturing process is formalized and controlled, the performance indicator are measured and monitored on a regular basis.
- Level 4 (very high) – the application of the sustainable practices in the management of remanufacturing process is used for continuous optimization.

Figure 2 presents the elements of the SRMM. The maturity levels are measure based on the appearance of a management practice in a company.

Fig. 2: Structure of the SRMM, Source: developed by the author based on (Golinska-Dawson & Kuebler 2018)

The 60 management practices are structured based on 3 in-depth case studies conducted by the author in remanufacturing SMEs, additional data from interviews with remanufacturing managers and the outputs of the review of the automotive remanufacturing cases described in the literature.

There is no practices' description at level 0 (very low), as if the practice at level 1 is not implemented, and then the maturity value 0 is carried out to maturity profile. All the codes of the management practices are tailored specially to reflect the organization conditions in SMEs in automotive remanufacturing sector.

The practices are assessed on the Likert-like scale in the Sustainable Management Practices Questionnaire (SMPQ). The managers answer the questions "Yes (1 pt.)/No (0pt)". The subsequent maturity level cannot be measured in a category if the previous level is not achieved (e.g. if the company does not apply practice from level 2 in an assessment's category then the question for level 3 is automatically assessed with value "0"). The example of the sustainable process management practices are presented in Table 2.

Table 2: An example of the sustainable management practice – extract from the SMPQ for remanufacturing, Source: developed by the author

Dimension	Code	Process management practice description	Corresponding maturity level
ECO …..	PE1	Ensure that energy usage is taken into consideration in management actives (management staff is aware of it)	1
	PE2	Formulate rules for energy usage measuring and monitoring (e.g. are there separate meters on the machines)	2
	PE3	Incorporate the energy usage monitoring in everyday routines of employees	3
	PE4	Implement an energy management system(e. ISO 50.001)	4

The maturity profile is constructed based on assessment from maturity questionnaire which allows the self-assessment of the current maturity level by the managers. The maturity profile is constructed in graphical form, as a radar diagram.

The Application Framework

Table 3 presents the summary of the developed application framework. The application framework consists of: assessment methods, method for improvements' identification and guidelines for giving priorities.

Table 3: The application framework, Source: developed by the author

SRMM's level	Assessment method	Method for improvements' identification	Method for giving priorities
Very low	Process mapping	ad hoc	ad hoc
Low	RPA and Leanness questionnaire (qualitative assessment) (Kosacka & Golinska-Dawson, 2018)	modified RPA (Kosacka & Golinska-Dawson, 2018)	RMC (Remanufacturing Muda Checklist) (Kosacka & Golinska-Dawson, 2018)
Moderate	Qualitative and quantitative indicators (Golinska et al., 2015)	normalization of indicators using the whitening function (Golinska et al., 2015	GDM (priority index) (Golinska et al., 2015
High	Quantitative indictors (Golinska &Pawlewski, 2015)	Process modelling (DES) (Golinska & Pawlewski, 2015)	Based on the analytics from DES simulation different variants of sustainable resource utilization (Golinska &Pawlewski,2015)
Very high	Systematic monitoring and control of the qualitative indicators	Combination of the optimization methods	Continuous improvement

In the brackets are indicated the author's previous works in each the respective individual methods are described in details. In the previous works these method were not linked to the maturity levels.

The originality of this paper results from categorizing the independent methods and lining them with the maturity level at the SMEs where they can be applied.

The Application Framework For Companies At The Low Maturity Level

For remanufacturing SMEs at a low level of process maturity (P = 1), a decision support approach is proposed based on the lean management concept. It allows for conducting the qualitative analysis of the process of automotive parts remanufacturing in SMEs where it is not possible to use the indicators-based method (quantitative assessment). The "green & lean" approach (Kleindorfer et al. 2005) postulates the use of lean management methods and tools to obtain more efficient use of resources and reduce waste in the remanufacturing process. The assumption is made here that achieving a state of „zero waste" (also called zero Muda) results in obtaining higher degree of sustainability in remanufacturing operations. The main elements of the proposed approach for qualitative assessment are presented in the Fig 3.

Fig. 3: Framework for low maturity level, Source: developed by the author

The tools LM (leanness matrix) and LQ (leanness questionnaire) are based on of the Rapid Plant Assessment (RPA) method (Goodson, 2002). They allow for a very quick scan of the current state of the remanufacturing process of a SME by internal or external expert. The tools translates expert's linguistic assessment into simple scoring system. The tools help to determine if the plant uses best practice in these categories and helps to identify the categories of strengths and weaknesses. For the identified weaknesses further analysis is conducted. The application of tool RMC (Remanufacturing Muda Checklist) allows translating the generic RPA's weakness into specific actions (so called "potential for improvement"). The final step (in Fig 3) is to develop priorities for the necessary actions.

The Application Framework for Companies at The Medium Maturity Level

SMEs with medium level of process maturity (P = 2) have formalized processes, so it is possible to use indicators-based assessment method. The main elements of the proposed approach for qualitative assessment are presented in the Figure 4.

Fig. 4: Framework for medium maturity level, Source: developed by the author

The proposed SIS (sustainable indicator system) uses heterogeneous data sources (numerical data, qualitative data, non-parameterized expert knowledge). The indicators in the SIS (Table 4) are qualitative and quantitative (if data is available). The assumption is made that the application should be possible without an additional reporting effort.

Table 4: Sustainable indicators system SIS, Source: adapted after (Golinska et al. 2015)

N	Indicator	Description	Indicator type and range		
Economic performance			type	range	ref. value
1	OEE	Overall Equipment Effectiveness	quantit.	0-100%	max
2	RPF	Remanufacturing process flow	qualitat.	1-5	max
3	Planning adequacy	Adequacy of reman process planning	quantit.	0-100%	max
4	AMT	Availability of machines and tools	qualitat.	1-5	max
5	Service level	Percentage of executed orders on time	quantit.	0-100%	max
6	OOS	Availability of materials (overall out of stock)	qualitat.	1-5	max
Environmental performance					
7	Energy consumption level (ECL)	Energy consumption per one core	qualitat.	1-5	min
8	Waste generation level (WGL)	Amount of waste generated	quantit.	0-100%	min.
9	MRR	Material recovery rate	quantit.	0-100%	max
10	Generated Emissions level (GEL)	Amount of emissions (CO2, water, sewage) per one regenerated core (product)	qualitat.	1-5	min.
Social performance					
11	Employment	Change in the level of employment in the period	quantit.	0-100%	max
12	Staff Training	Percentage of employees who participated in additional training	quantit.	0-100%	max
13	Harmfulness of the remanufacturing process (HRPP)	Refers to the consequences that are associated with threat to safe and health of workers in the remanufacturing process	quantit	5 intervals	min
14	Comfort level	Identification of waste (Muda) of time of workers due to inefficient workplace design	quantit.	0-100%	max

N	Indicator	Description	Indicator type and range		
15	Innovation level	The number of implemented innovations in the enterprise proposed by employees	quantit.	0-100%	max

The original approach to normalization of the values of indicators using the weighting function derived from the theory Grey Decision Making (GDM) has allow to integrate the heterogeneous sources (Yang & John, 2012).The main advantage of GDM is that the decision can be made when the phenomenon is only partially known (Liu &Forrest, 2010), as it happen in case of the remanufacturing (high uncertainty). The application of the GDM allows performing an integrated assessment of the indicator's value and it enables classification of the indicators values into one of the 3 categories, as follows:

- class 1- acceptable level of sustainability, the allocated resources are used in a sustainable (efficient) way,
- class 2- conditionally acceptable level of sustainability, the utilization of the allocated resources should be improved at the earliest convenience takin into consideration the economic and organizational conditions,
- class 3 - unacceptable level of sustainability, the utilization of the allocated resources is not sustainable and it should be improved immediately.

After the classification is performed then the priority is given to the corrective actions. First the actions should be taken which aim to improve the value of the indicators from class 3, then from class 2. The IT tool is developed for the SMEs, so the proposed framework works as a "black box" which allow assessment and prioritization of the improvement actions necessary in order to move towards sustainable remanufacturing.

The Application Framework for Companies at the High Maturity Level

In SMEs at high maturity level (P=3) the processes are formalized and the sustainable practices are implemented. Therefore the quantitative indicators can be calculated and the formalized optimization methods can be used (Fig.5).

Fig. 5: Application method for high maturity level, Source: developed by the author

The simulation model allows for a dynamic assessment of different process organization scenarios with regards to sustainable resource allocation. The detailed description of the DES simulation model is not presented in this paper due lack of space. The description of the modelling approach used in the framework is presented in (Golinska & Pawlewski, 2015). The simulation experiments are conducted following logic as presented in Figure 6.

Fig. 6: The logic of the simulation experiments, Source: adapted from (Golinska & Pawlewski, 2015).

The application of the DES model of the remanufacturing process allows for identification of the areas that don't comply with the SR. For these areas, the values of decision variables in the designed scenarios are modified. Then simulation experiments are carried out again and their results are reassessed. After obtaining satisfactory values of the analysed indicators, then the priorities are set for improvement measures to be implemented in the real remanufacturing process. The sustainability assessment is performed through dynamic testing of various variants of the organization of the remanufacturing process and resources allocation. As a result, the continuous improvement of the process allows transition towards of sustainable remanufacturing.

At very high maturity level (P=4) a company has achieved the desired state of the "sustainable remanufacturing". The continuous improvement approach is recommended to maintain the most efficient resource utilization but the "as-is" state is sufficient.

Decision Framework Description Testing

The proposed decision making framework has been tested through multimethod approach:

- case study,
- numerical experiments,
- simulation experiments
- experts' interviews.

Each of the proposed methods: assessment methods, method for improvements' identification and guidelines for giving priorities have been applied with usage of the real life data. The three SMEs are chosen, which refer to the low, medium and high maturity level. The proposed methods have proofed to be feasible accordingly to the existing organization conditions. In the Table 5 is presented the summary of the testing approach.

Table 5: Framework testing, Source: developed by the author

SRMM's level	Assessment method	Method for improvements' identification	Method for giving priorities
Company A (P=1)	RPA, Leanness questionnaire; tested by case study and experts' interviews Result: feasible	Modified RPA; tested by case study and experts' interviews Result: feasible	RMC (Remanufacturing Muda Checklist); tested by case study and experts' interviews Result: feasible
Company B (P=2)	Qualitative and quantitative indicators; tested by case study & experts' interviews Result: feasible	Normalization of indicators using the whitening function; tested by numerical experiments & experts' interviews Result: feasible	GDM (priority index); tested by numerical experiments and experts' interviews Result: feasible
Company C (P=3)	Quantitative indictors; tested by numerical experiments & experts' interviews Result: feasible	Process modelling (DES); tested by simulation experiments & experts' interviews Result: feasible	Prioritizing alternative scenarios of sustainable resource utilization; tested by simulation experiments & experts' interviews Result: feasible

In the next step the results from the application framework testing have been discussed with the 3 academic experts who have over 5 years' experience in automotive remanufacturing domain. They assess the benefits of applying the framework for decision making towards transition to sustainable remanufacturing. On the basis of the obtained results from real life data testing they have provided the scoring on the Likert scale (very low 1-5 very high). The obtain result is over 4, that means that it is high.

Conclusions

The paper presents the decision making framework which allows describing the current state of the remanufacturing process with regards to the sustainability. The focus is placed on the resource utilization. The framework takes into consideration the organization conditions which appear in the remanufacturing of automotive components in SMEs.

The proposed framework includes steps, as follows:

- the maturity scoring
- improvements' potential identification
- prioritization of the required actions.

The originality of the proposed framework results from relating the process maturity level (current state) to the appropriate improvement's actions which can be taken at each maturity level. The framework provides adequate tools that allow to identify the improvement potential and to prioritize actions which are needed in order to improve the sustainability of the remanufacturing process. The main theoretical contribution of this paper is the proposal of the application framework, which provides guidelines on how to improve to current management practices in order to make the remanufacturing process more sustainable. Most of the maturity models provide only the descriptive framework which allows assessing the current state (Gonçalves Machado et al., 2017). However they don't have sufficient prescriptive power, to guide towards improvement actions. The propose framework aims to address that limitation and provide not only the description of the maturity level

but also to propose the application methods which are relevant for each describe maturity level. The decision framework proposes relevant methods for:

- identifying in the synthetic way the current maturity level with usage of the SMPQ questionnaire, and then
- conducting in-depth analyses using methods tailored for the previously identified maturity level, and finally
- providing guideline which actions should be taken first in order to move towards more sustainable remanufacturing practices (prioritizing methods) taking into consideration the limited resources which appear in the SMEs.

The main limitation of this paper is that the proposed decision making framework is elaborated based on the case studies and interviews with the industrial and academia experts. Only the automotive remanufacturing sector is taken into consideration.

The further research will include testing of the proposed framework in remanufacturing SMEs indifferent sectors. The next step will also include elaboration of the catalogue of the improvement's actions which are suitable for automotive remanufacturing SMEs.

The paper has managerial implications. It provides the decision makers with actionable knowledge on how to reach the state of multidimensional (economic, ecological and social) resource efficiency in the remanufacturing process, so called sustainable remanufacturing. The proposed GDM tool is currently developed as web service which allows for the on-line assessment of the current situation and for the identification of the improvement potential. The tool provides also some general guidelines for the implementation of the improvement actions.

Abstract

The digital transformation of the industry, automation, robotics also known under the collective term Industry 4.0 have great potential not only in manufacturing processes, but also in business and support processes that are still strongly characterized by manual activities (as opposed to manufacturing processes). The new approach to automate processes manually performed in the administration and back-office brings the technology associated with artificial intelligence, namely robotic process automation (RPA). The aim of this paper is to explore literature and find out in which areas and processes it is possible to use RPA and what characteristics and features can be automated processes, also to determine the maturity of processes for automation and to assess the potential usability of maturity models for the implementation of robot process automation in industry.

Keywords: RPA, robotic process automation, business processes, maturity

Introduction

Industry 4.0 brings a change of the entire market environment. If companies want to be successful in the future, they must accept the innovation challenges and opportunities that brings trend. Enterprises implement especially in their production processes, new technologies and tools of the concept of industry 4.0.

Continuous digitization and automation have great potential not only in manufacturing processes, but also in business and support processes that are still strongly characterized by manual activities (as opposed to manufacturing processes). The new approach to automate processes manually performed in the administration and back-office brings the technology associated with artificial intelligence, namely robotic process automation (RPA). RPA is also called a robot, bot or software robot and is a technological imitation of a human worker to automate structured tasks quickly and efficiently. It is not a physical robot, but a software solution that is configured to work with current data and applications, to respond to events, to handle transactions without human intervention, and to communicate with existing systems. RPAs can automate business process activities that are routine, repetitive, and rule-based, ie where decisions can be made based on clear criteria (Slaby, 2012).

Gartner (Shetty, 2019) reports that the RPA tools are at the Peak of Inflated Expectations in the Gartner Hype Cycle for Artificial Intelligence, because organizations are looking for ways to reduce costs, link older applications, and achieve a high return on investment. There is a growing interest in RPA among software vendors and BPM suppliers who want to take advantage of this new feature. They also find the potential of this software to integrate with the Artificial Intelligence, Machine Learning, feature that enables multiple types of automation.

Methodology of Literature Review

The aim of the literature review is to map and evaluate relevant literature for future research. Literature has been searched through a wider Google Scholar database because RPA is a new technology, further through ResearchGate, Web of Science and Scopus. Key words "RPA" and "Robotic process automation" were selected for the literature mapping that deals with RPA and the automation of supportive, non-production processes. In total, 49 sources were found in the scopus database, 22 in the WoS database, and 20 fulltext sources from Google Scholar and ResearchGate. In the pictures below, you can see the analysis of searched publications (source). As a result, it was noticed that the largest share of publications falls or the years 2015−2019. Most publications have been included in the subject area as computer science, business, management and accounting, engineering see Figure 1. Figure 2 shows the countries that publish the most publications on the topic RPA. Mapped publications are mainly processed by university researchers and most often published at conferences and journals.

After reading the abstracts of the sources, 36 full-text sources were studied to select only those resources that are relevant to the topic. Based on the results of the analyses performed, a research gap was identified, consisting of a small number of publications on measuring process maturity for RPA implementation in the manufacturing industry.

Fig. 1: Publication by subject area (2015-2019), source: Scopus

Fig. 2: Number of publications in each country, source: own processing, 2019

Literature Review

Professors Leslie Willcocks and Mary Lacity at London Schoool of Economics, along with Andrew Craig, have published a series of their research work on RPA, then other large companies and researchers have become interested in RPA and RPA has become a trend. The most important RPA suppliers on the market include UiPath Studio (Romania), Automation Anywhere (USA), Blue Prism (UK) [6]. With increasing demand for RPA, smaller software vendors have entered the market, and also existing BPMS (business process management systems) suppliers have expanded their capabilities.

The first definition of the RPA is listed and described by author Slaby (Slaby, 2012) in the introduction.

Major RPA expert Leslie Willcocks defines RPA as follows (Lhuer, 2016): "RPA takes the robot out of the human. The average knowledge worker employed on a back-office process has a lot of repetitive, routine tasks that are dreary and uninteresting. RPA is a type of software that mimics the activity of a human being in carrying out a task within a process." Compared to humans, the robot can perform repetitive activities faster, more accurately, without errors, and actually 24/7 continuously without fatigue. Therefore, workers can focus on tasks that require significant human traits, such as thinking, judgment, emotional intelligence, and customer interaction.

The IEEE Standards Association defines RPA as ("IEEE Guide for Terms and Concepts in Intelligent Process Automation," 2017): „A preconfigured software instance that uses business rules and predefined activity choreography to complete the autonomous execution of a combination of processes, activities, transactions, and tasks in one or more unrelated software systems to deliver a result or service with human exception management."

As in manufacturing processes, the robot replaces the physical work of a person, so RPA as a software robot copies a person in administrative processes while working on a PC. Research (Lacity and Willcocks, 2016) has found that RPA is best suited to replace people in processes where people have received inputs from one set of systems (such as emails and spreadsheets), processed these inputs using rules, and then outsource systems like ERP or CRM. Robots can log into systems using their own usernames, interpret text, tables, drag and drop and click, fill in application forms, check quality, and correct data across systems.

Characteristics of RPA

RPA belongs to IT technology called "Lightweight IT" mainly because it does not interfere with basic computer systems. Lightweight IT is focused on new possibilities, fast pace, quick change, and is usually taken out of control by IT department (Grung-Olsen, 2017; L. Willcocks et al., 2015). RPA is easy to configure. Developers who design the process do not need programming skills (Anagnoste, 2017; Jovanović et al., 2018). The interface works like modeling processes in Visio, dragging and dropping icons that represent process activities. Workers with expert process knowledge, no

programming experience, can work with the robot and can be trained for process automation within a few weeks. If you need to change the process or automate it, it does not have to wait for the IT department to repair or develop (L. Willcocks et al., 2015).

RPA is not considered an isolated technology, it stands on top of existing systems. The robot accesses other enterprise systems as a human, through a user interface, with a user ID and password. RPA does not store any data (Lacity and Willcocks, 2016). RPA plays the role of data integration, process integration and data transformation (Fettke and Loos, 2018). RPA implementation does not require a large investment, after clarification of business processes is almost the only expense the software itself and implementation. RPAs can also be rented, which completely eliminates the input investment. The software can run on a regular PC, on a server, or on a virtualized environment.

Advantages of RPA

A general advantage of RPA is building enthusiasm for digitalization and building local ownership (Osmundsen et al., 2019). More specific benefits of RPA that help improve productivity are (Botar et al., 2018; Reddy et al., 2019), (Grung-Olsen, 2017):

- Easy and fast implementation
- 24/7 continuous operation
- Return on investment of 30-200% in the first year
- Elimination of human errors and greater accuracy
- Increase process speed
- Digitizing the process
- Integration of applications through the user interface, without complicated programming
- Fewer workers
- Easy to set up and change processes

No changes to existing application systems are required to implement RPA. Another advantage is that employees get rid of monotonous, demotivating, repetitive work and can devote themselves to creative, strategic tasks that lead to business development and growth. RPA also includes monitoring and analytics capabilities that enable users to monitor health of their processes (Devarajan, 2018). In the event of an unexpected error, the processes are configured to alert the requested worker to a problem that they will then resolve. All these benefits result in cost savings (despite initial costs), improved service quality, increased productivity and efficiency (Lacity and Willcocks, 2016; Ratia et al., 2018).

Disadvantager and Risks of RPA

The author Kirchmer (Kirchmer, 2017) focused mainly on risks that brings RPA. He claims that RPA has the potential to make mistakes faster and with greater certainty because no control by human is performed before the operation is performed (data quality or inadequate definition of business rules can lead, for example, to order wrong parts - quickly and in large quantities). he use of RPA may involve certain symptoms of the problem without removing the real reasons for the problem. Osmundsen in his article (Osmundsen et al., 2019) also talks about the lack of control mechanisms and Lack of end-to-end process view. Companies do not invest in RPA for the following reasons (Reddy et al., 2019):

- The costs and budget constraints of companies
- The lack of technical skills, as they think that the end user must have considerable technical expertise for RPA
- Fear of replace human workers

Another disadvantage of automation is that it runs across a user interface in multiple applications and is therefore prone to changes and failures in basic applications (Grung-Olsen, 2017).

Possibilities of Using RPA

A large part of mapped publications focuses on the use of RPA in various industry and functions (processes). Available publications provide either short examples of where a robot was used, or a full case study showing process models and effects from RPA deployment. Some publications may describe RPA recommendations for use in certain processes and industries (such as BPO providers and Shared Services –SS). To complete the view, in which industries, functions or processes the research has been addressed and implemented by RPA, a table below is created. It identifies the possibilities of RPA usability and the publications they deal with.

Table 1:An overview of publications showing the possibility of using RPA, source: own processing, 2019

Industry / function	Publications
Telecommunication	(Geyer-Klingeberg et al., 2018), (Lacity et al., 2015a), (Penttinen et al., 2018), (Slaby, 2012)
IT sector	(Zaharia-Radulescu et al., 2017), (Saha et al., 2018)
Finance (accounting, auditing, controling,..)	(Anagnoste, 2017), (Asatiani and Penttinen, 2016), (Botar et al., 2018), (Rozario and Vasarhelyi, 2018), (Devarajan, 2018), (Fernandez and Aman, 2018), (Moffitt et al., 2018), (Cheon, 2017)
Bank	(Reddy et al., 2019), (Devarajan, 2018), (Mager, 2019)
Insurance	(L. P. Willcocks et al., 2015), (Lacity and Willcocks, 2016), (Devarajan, 2018),
Healthcare	(Bhatnagar, 2019), (Lacity and Willcocks, 2016), (Ratia et al., 2018), (Schmider, 2018)
Human Resource	(Anagnoste, 2017), (Anagnoste, 2018a), (L. Willcocks et al., 2015), (Leopold et al., 2018), (Reddy et al., 2019), (Nawaz, 2019), (Gupta et al., 2018)
Energy	(Lacity et al., 2015b)
BPO provider / SS	(Aguirre and Rodriguez, 2017), (Lacity et al., 2015a), (Lacity and Willcocks, 2016), (Anagnoste, 2017), (Asatiani and Penttinen, 2016), (Slaby, 2012), (Lakshmi et al., 2019), (Suri et al., 2017), (Hallikainen et al., 2018), (Zaharia-Radulescu et al., 2017)
Public administration (sector)	(Houy et al., 2019), (Ranerup and Henriksen, 2019)
Manufacturing	(Devarajan, 2018), (Lin et al., 2018)
Education	(Issac et al., 2018)
Tourism	(Tsaih and Hsu, 2018)

The table below was developed by Everest Group, a management and research company. The table shows the industry in which there is a potential for automating of various functions by RPA. Manufacturing is a sector in which it is not yet widely developed the idea of the introduction of RPA and drawing benefits that brings. But the picture below shows that in the manufacturing industry there is a high potential for finance and accounting processes and growing potential in procurement processes. However, these processes differ in manufacturing from the approach to RPA utilization presented by the authors (Lin et al., 2018). Their expectation is that they can use RPA to achieve automatic remote control of the device, thereby achieving the goal of an unmanned factory.

Function	Finance & Accounting	Procurement	Human resource	Contact center	Industry specific processes	
Industry	Accounts receivables, accounts payable, general ledger	Invoice processing, requisition-to-purchase order	Payroll, hiring, candidate management	Customer service		
Banking & financial services						✓ Cards activation ✓ Frauds claims
Insurance						✓ Claims processing ✓ New business preparation
Healthcare						✓ Reports automation ✓ System reconciliation
Manufacturing						✓ Bills of material generation
Hi-tech & Telecom						✓ Service order management ✓ Quality reporting
Energy & utilities						✓ Account setup ✓ Meter-reading validation

Potential for RPA
Low High

Illustrative processes with higher potential

Fig. 3: RPA potential for industry and function, source: (Anagnoste, 2018a)

Specifics of Processes within RPA

The industries described above can use RPA for automation, given that their business processes are characterized by certain common characteristics. Before enterprises start with automation using the RPA must determine whether the process is appropriate for RPA, whether the process meets certain requirements for RPA deployment, or whether it has mature processes for RPA (to ensure that the RPA-mature process is). And this chapter is based on a literature review dealing with specific characteristics, criteria that processes must meet in order to automate and deploy a robot. At the same time, this chapter can serve as an input for identifying process properties for each level of maturity, as a tool for evaluating process maturity within RPA.

It is clear from the above definitions and literature research that the processes to be automated by RPA are characterized by routine, manual and repeatable activities that have digital, structured data and predictable outputs. According to available literature is identified for the simultaneous use of RPA several other key characteristics of business processes.

- The basic characteristics of the process that can be automated, include high levels of standardization and some low cognitive requirements(Aguirre and Rodriguez, 2017; Asatiani and Penttinen, 2016). The process should not require the intervention of a (human) worker to make decisions based on analysis, judgment, perception, or interpretation skills (Slaby, 2012). The author Geyer-Klingeberg (Geyer-Klingeberg et al., 2018) states that when processes are standardized, the highest potential for automation in an organization should be detected.
- It is also essential that the process was stable in a stable environment, without the expected significant changes (Slaby, 2012) These changes will not involve changes of features, updates and error fixes applied systems and applications.

- Minimum process exception handling is required. Process deviations are best manageable by humans. If there are many exceptions in the process, it should not automate the meaning (Lacity et al., 2015b; Slaby, 2012).
- The process and its activities must be based on a predefined business rule so that all process steps can be accurately enrolled, taking into account all possible events and results that occur on the way (Asatiani and Penttinen, 2016; Lacity et al., 2015b).
- Another requirement, which strongly supports the implementation of the robot is to access multiple systems and human interaction with the PC. Implementation is useful when employees are forced to work with two or more existing systems and software applications and transfer data between them (Anagnoste, 2018a; Harmon, 2017; Leopold et al., 2018; Slaby, 2012).
- Another requirement for efficient use of the robot is a large number of transactions and processed data. Thus, processes involving activities that are performed very often (Asatiani and Penttinen, 2016; Slaby, 2012).
- The robot is also recommended for processes and activities that are prone to human error due to manual work (Aguirre and Rodriguez, 2017).
- The suitability of using the robot for the process also depends on the complexity of the process, or the average time it takes to complete the process (Lacity et al., 2015a; Leshob et al., 2018).

Comprehensively we can say that the RPA can be used to automate or to copy the activities of workers in the digital process (Ratia et al., 2018). In this case, the digital process is characterized as a process whose inputs, input formats and data are digitally readable, and data transfer requires access to multiple applications, systems. The digital process can be controlled manually by a person (worker) or robot. At the same time, it is assumed that the process is optimized, standardized and stabilized before automation.

With such a characteristic process the growing importance of process modeling, which is included in the deployment and configuration of the robot. The process modeling also increases the importance of the process analyst (L. Willcocks et al., 2015), whose main functions are identifying, mapping or modeling processes, evaluating processes, process reengineering (Anagnoste, 2018b).

Assessment of process maturity in RPA implementation

Every institution that wants to implement RPA must have its "selected" processes ready for RPA deployment to achieve the highest efficiency. And it can be said that the processes must be mature for RPA. Therefore, it would be appropriate to specify the process levels leading to their automation, or to specify process properties leading to the intelligent process level. The question of whether there is a model of maturity or readiness of administrative processes (referred to as support processes in the industrial enterprises) for digital transformation and industry 4.0 has been addressed in my research (Hořánek and Basl, 2019). Of the reviewed maturity models, few publications dealt with supportive processes. None took into account RPA.

As part of the implementation of RPA, the publication by Willcocks et al. (L. P. Willcocks et al., 2015) pointed out that businesses build the foundations for RPA and use the benchmark for their ability to develop and increase business value. A comprehensive maturity model for RPA was presented and was created by RPA provider BluePrism in collaboration with Horses for Sources (HfS) - Enterprise RPA maturity model. The model consists of three levels. This model does not specialize in processes, but comprehensively to the institution and their RPA strategy and program. The RPA Maturity Assessment Tool created by Automation Anywhere and HfS (Sutherland, 2014) contains the same RPA maturity levels and their model evaluates 10 elements. These tools are designed for BPO providers, RPA software developers or advisors / consultants.

Close to the evaluation of process maturity for RPA is the work of Leshob et al. (Leshob et al., 2018), which focuses on creating business process methodology to identify the most appropriate processes for RPA. Their design consists of several successive steps to identify processes, based on their features

that are appropriate for RPA. The result is the assignment of processes to four groups, depending on how they fit the RPA.

As for the process maturity, in the mapped literature it appears several times as a requirement or property that the process must have in order to deploy RPA. As a mature process, the publication (Lacity et al., 2015a) considers a process that is stable, standardized, then measured and documented, and therefore its costs are also known. That is, a process that is part of BPM (business process management).

Houy, Hamberg and Fettke researchers (Houy et al., 2019) did not directly define the maturity of RPA, but they divided RPA into three successive categories that can also express RPA maturity and are as follows:

- Category 1 - Programmable RPA robots in which programmers must manually define the rules that a bot should perform.
- Category 2 - Self-learning RPA robots who use historical and current data to learn how a user typically interacts with a software system and mimics interaction to perform tasks automatically.
- Category 3 - cognitive RPA robots who can learn the rules of structured and unstructured data to perform the task automatically.

Similarly, the author Anagnoste (Anagnoste, 2018a) presents the development of RPA towards intelligent robotics - IRPA. Where at the beginning (since 2012) RPA stands, cognitive RPA follows and in the future IRPA containing artificial intelligence. The complementary technologies introduced by Grung-Olsen (Grung-Olsen, 2017), such as chatbots, image recognition, speech recognition, various types of machine learning, AI, along with technologies that enhance, augment and compliment human abilities such as big data, IoT / sensors and mobile devices could be part of higher maturity levels.

Summary and Evaluation

Given the large and strong trend of Industry 4.0 and robotics, RPA has great potential for automating supportive administrative processes even in manufacturing companies. Companies are trying to achieve intelligent factory. This includes not only production processes, but always those non-production processes. Software robots, complemented by cognitive tools or artificial intelligence, can help companies easily reach a intelligent factory. This high potential is reflected in the table above and the literature under review. So far, the mapped publications do not provide a case study or RPA assessment in these administrative processes of a manufacturing enterprise, but the publication lists more precise process activities where RPA can be used (see Table 1). Robots would not be massively implemented in this manufacturing industry, as is the case with BPO services and shared service centers. The implementation process RPA and the resulting effects would be significantly different, but with the integration of AI and cognitive tools RPA gaining its importance and effectiveness of the process for the company in the future. In particular, a process analyst would play an important role in this sector and company. A process analyst, as an expert with process knowledge, would also play a role as a developer, as RPA is easy to configure and there is no need for programming skills to design or make further changes.

RPA also plays an important role in the Czech market. Their implementation is growing every year, especially in the fast-growing business services sector. The survey of association ABSL (ABSL, 2019), which brings together business service providers on the Czech market, shows that more than 100,000 people work in this sector and is one of the most important sectors of the Czech economy (ICT Revue, 2019). Furthermore, the survey shows that 72% of companies have already introduced process automation to approximately 29% of their processes. In addition, 46% of companies test robots and the same 46% of companies plan to automate some of their processes. In total, the industry "employs" 4,000 full-time robots. In addition to RPA, companies implement OCR technologies, chatbots, AI tools.

In particular, RPA suppliers have developed maturity models for BPO and SS providers, in particular to help them identify all the elements to be considered in the RPA strategy and the activities they need to do to ensure that RPA is used effectively.

Helping with process automation can provide large and small and medium enterprises with a tool that evaluates their processes, assigns them to a level, and communicates RPA readiness, or steps to reach higher levels. In addition to complex models, there was no methodical tool (model) that specifically focused on assessing of process maturity or readiness of a process for implementing one robot. Based on the results of the analyses performed, a research gap was identified, consisting of a small number of publications on measuring process maturity for RPA implementation in the manufacturing industry. For these reasons, there is a place for the development of new tools generally acceptable.

When designing the model and defining the process properties in each maturity level, it is possible to use the process properties described in the third chapter. When designing a model of maturity can be inspirational publications that focus on the continuing ability of RPA as cognitive ability (Fettke and Loos, 2018) and the ability of artificial intelligence (Reddy et al., 2019), publications that RPA is divided into groups (Anagnoste, 2018a; Houy et al., 2019) or assess the level of process automation (Leopold et al., 2018).

Conclusion

Large companies and major multinational companies have already adopted the RPA to increase productivity and overall efficiency and reduce costs. RPAs implemented as the first banks, insurance companies and telecommunications services. RPA is widely used by business process outsourced (BPO) providers and business service centers, because they include activities with the highest potential for automation in finance, supply chain and human resources departments. The implementation of RPA is riddled with challenges related to both the reality of day-to-day business operations, from SMEs to the center of shared business services and beyond, and the social impacts of a changing labor market.

The aim of this work is review literature for introduction to the topic and for outline the main facts about RPA. The literature review chapter includes the possibilities of RPA usability and lists the industry and processes in which RPA implementation was conducted or recommend. The next chapter is focused on Specifics of Processes within RPA. The aim of this chapter was to identify all the features and characteristics that processes need to meet in order to implement RPA while creating the basis for creating process maturity levels for automation. The fourth chapter is also related to processes and is focused on assessment of process maturity for automation and assessment of company maturity for RPA implementation. The last chapter summarizes the conclusions from individual chapters and presents the possibility of further research.

Abstract

In flexographic printing technology, quality is measured mainly through correct depiction of color. Color quality is checked mainly manually, organoleptically by a person, and/or semi-automatically by measuring optical density with a spectrophotometer. Unfortunately, the effects are not immediately visible, only after the product has left the machine. Therefore it is a time-consuming and costly process. The printer is expected to identify perfectly the cause of the error, but that requires thorough analysis of the situation. A quick and reckless decision not only may not solve the problem, but also increase the costs related to further use of materials and production stoppage. Therefore the method is long-running and labor-intensive. In order to improve quality management it is necessary to automate the process. A cognitive agent can be used in this purpose. The aim of the paper is to develop an approach for cognitive agent's sensory memory and perceptual memory implementation. The agent will be used for improving quality management of the flexographic printing on packages. Such approach has not been developed before, therefore it is the main contribution of this paper. The main findings are as follows: Due to the use of Hierarchical Temporal Memory the Agent will analyze all parameters and their combinations with other parameters. Changes made by perceptual memory will gradually change the representations in a way that the 'winning' columns will be similar in similar signals, however this will occur after many modifications initiated by the learning process. Such approach can improve the quality of prints made and allow for increase in efficiency and decrease in cost of the entire process. It is necessary in the face of growing competition from digital printing. The approach presented in this paper allows for implementation of the remaining modules of LIDA cognitive agent – it is a subject of future works.

Keywords: Artificial Intelligence, Cognitive Agents, Sensory Memory, Perceptual Memory, Quality Management, Flexographic Printing, Printing on Packages

Introduction

In printing technology, quality is measured mainly through correct depiction of color. It is the most important quality of the printing process. In companies involved in flexographic printing, color quality is checked manually, organoleptically by a person, and/or semi-automatically by measuring optical density with a spectrophotometer. This method is closely connected with the knowledge and experience of the printer. Color quality inspection is performed at the end of the process, when the final product is obtained. The printer checks if color quality stays within the tolerance set out by the standard. If unsure, the printer checks the range of visible spectrum with a spectrophotometer. If color quality does not meet the customer's expectations, then a deduction stage begins to identify the process element to blame for the fault. There are several factors in printing technology that may cause a printing error. The main ones include Krzyzkowski et al (2015):

- parameters of order (printing profile),
- characteristics of printing units,
- properties of ink,
- properties of duct tape,
- type of anilox,
- type of printing matrix,

Each of the factors has a number of attributes that may influence print quality. Should color quality inspection reveal that color quality does not stay within the expected tolerance, the production process must be put on hold to investigate what exactly could produce the negative effect. Each of the aforementioned elements is checked. Unfortunately, the effects are not immediately visible, only after the product has left the machine. Therefore it is a time-consuming and costly process. The printer is expected to identify perfectly the cause of the error, but that requires thorough analysis of the situation. A quick and reckless decision not only may not solve the problem, but also increase the costs related to further use of materials and production stoppage. Therefore the method is long-running and labor-intensive. In order to improve quality management it is necessary to automate the process. According to the authors, a cognitive agent can be used to conduct a multi-dimensional analysis of quality much faster, with lower error probability than in the case of manual/semi-automatic analysis conducted by a person. The agent's task would be to improve the quality management process in the production of printed labels on products. It will support the decision making process of the printer, it will also have the authority to automatically correct process parameters in order to improve printing quality in real time. A significant advantage of cognitive agents is their ability to act on their gained experience. In the case of flexographic printing, the agents would remember the properties of each production batch, including those that were completed with no errors and those where color quality did not stay within the tolerance. It will allow for data to be gathered to create a set to be used for learning in order to increase the program's performance.

The aim of the paper is to develop an approach for cognitive agent's sensory memory and perceptual memory implementation. We are using The Learning Intelligent Distribution Agent architecture. The agent will be used for improving quality management of the flexographic printing on packages. Such approach has not been developed before, therefore it is the main contribution of this paper.

Related Works

The history of flexographic printing goes as far back as the 1920s, however some historians argue that it had already been known in the 1860s Hoekstra et al (2019). Subject literature states that flexography is a 'rotary printing process using flexible printing molds with convex relief, which can be attached to printing rollers of different circumference, with the use of liquid printing ink, applied with rollers with cellular surface structure, with or without the use of squeegees, onto various types of substrates' Olmos et al (2019). Picture 1 presents a simplified depiction of the process. The method includes making one imprint each time with the rotation of the printing roller. The squeegee is used to control the amount of transferred ink, specifically to scrape the excess amount of ink. This is an option. Dosing may be performed without the use of squeegees, then the amount of ink is controlled through proper calibration of pressure between anilox roll and the scoop roll.

Fig. 1: A simplified depiction of the flexographic printing

There is also a possibility to completely omit the scoop roll. In such case, the ink is dosed immediately to the anilox roll while it rotates, and a partial amount of it remaining in a sealed-off zone where ink is directed under pressure to ink carriers – chambers of correct size, according to the printing requirements, located on the surface of the anilox. The purpose of anilox rollers is to keep the printing molds continuously covered in ink in order to effectively generate new imprints. The molds are in turn located on the printing roller. A convex relief barely touches the anilox roller, transferring ink from one roller to another. The mold, also known as the matrix, is prepared for the process outside the machine, using double-sided duct tape, also known as 'foam', which attaches it to the printing roller. The last element is the pressure cylinder whose task is to create proper conditions for between the mold and the material Olmos et al (2019).

The printing mold, also known as the matrix, which receives the pattern from the design, is made of photopolymers. They are chemicals composed of unsaturated monomers, binders, and initiators of photochemical reactions. They are created in the polymerization process, with the participation of UV radiation. Thus the produced prints are characterized by high quality and accuracy of the depicted image, necessary hardness, high durability, and resistance to light and ozone Barone et al (2017).

The correctness of the print depends on the amount of information about the order to be made. The parameters, or profile, of the order determine the range of colors at the disposal of the printing company and the printing ruling to be made.

Another important factor that influences print quality are parameters of printing units. Depending on the order, cylinders with different diameter and substrate thickness are used. As a result, the machine must be adapted to changes in pressure settings of individual cylinders so that the cylinders are properly spaced against one another. The settings are usually controlled by a computer system that analyzes the location of printing molds against one another. The problem is, this a variable parameter, influenced by such values as foam thickness, type of photopolymer, or theme for given separation. The biggest problem is the increment of photopolymer which swells during the process, increasing its circumference. A change in pressure also influences color intensity. With longer printing processes, the double-sided duct tape is also 'tamped', which also changes the placement Hoekstra et al (2019). Therefore, foam hardness is an important parameter. The selection of foam level depends on the print. Hard tapes are used for large elements and inscriptions, soft tapes – for soft raster and photographs.

Another element influencing the coloring is the anilox roller that transfers a specified amount of ink onto the matrix. The selection of anilox must be compatible with the order. Printing with CMYK ink is done with raster method where small dots, visible under a magnifying glass, are printed, therefore

anilox should be engraved with more density (it should have high ruling), and ink transfer should be scarce, so that an ex-cess amount of ink does not distort the color. The situation changes when larger elements are printed, e.g. backgrounds. In this case, anilox with higher ink transfer and thinner structure should be used. Therefore, using the same ink, but different anilox rollers, extremely different effects may be obtained, that is why the selection of correct roller is so important in obtaining the desired coloring effect Olmos et al (2019). The roller is selected when the order profile is being created.

Another factor influencing the quality is the printing matrix. Normally, two types of technology are used: CTP and KODAK. CTP technology involves the problem of 'swelling', connected with duration of printing process and wear of matrix, resulting in enlarging the raster point which contributes to the intensification of printed raster colors. Thus, an important parameter is the wear of photopolymers. Small changes in print can be found after only an hour of printing. After several hours the changes are clearly visible. The wear is calculated with the number of imprints, because the number of strikes of the matrix against the surface is vital in the calculation.

The presented characteristics of factors influencing the quality of flexographic printing indicates high complexity of the process. In the face of ever increasing expectations from customers, action must be taken to improve the process and raise the quality of printing services.

One of the directions to take when improving the process is to use methods and tools of artificial intelligence whose continuous development has been witnessed in recent decades. They involve different approaches to the realization of a dream that many people have – so that a computer could match our relatively understood human intelligence. A computer has outrun us in many areas of skills, however humans re-main unchallenged in a lot of fields. Plenty of ideas and algorithms exist, but there is still a long way to go to meet such great requirements set for artificial intelligence. One of the attempts to reach closer to the goal is creating artificial intelligence based on cognitive architecture.

Cognitive architecture may be defined as organized structure of processes and knowledge attempting to model itself on cognitive dependence Albus et al (2004). The initial stimulus for building cognitive architectures was their ability to come to human's aid in complex situations where a computer has much quicker reaction time when a large number of variables must be considered in a given situation. Considering human capabilities, we would have a real chance for automated support in actions in which we ourselves are limited Hernes et al (2017).

Cognitive architectures are expected to be able not only to resolve one problem using a selected method, but also to have the ability to analyze the problem from a broader perspective, using a broader scope of solutions. Additionally, using the experience and knowledge, they will be able to implement new solutions in rapidly changing environment. The key here is to learn and use the gained knowledge.

An important common feature of cognitive architectures is the way their learning mechanisms are designed and the way their memory is organized. Different approaches to building cognitive architectures present diverse understanding of the role of memory Hernes et al (2017).

Learning mainly involves storing the gained knowledge and attributing opportunities and situations where it can be used. Efficient design and use of the process is an important step in building higher cognitive systems. The organization of memory is connected with the way the knowledge is represented Hernes et al (2017).

There are many cognitive agent programs that can be attributed to one of three types of architectures. Each type of cognitive architecture may be represented as a series of steps required by the architecture to perform the desired activity. The process of taking these steps is called a cognitive cycle. Although the term 'cognitive cycle' is used to describe most architectures, the cycles differ in terms of types of action taken during each step. This grouping de-pends on the type of presented and processed information, not on different possibilities, properties, and evaluation criteria for a given architecture Kotseruba et al (2018).

Flexography has become a standard used in the packaging industry in America and Europe alike. In the last forty years flexographic printing has experienced impressive growth in terms of quality and productivity Lorenz et al (2015). Flexography has moved from low-quality to high-quality print and at present it is widely used in the production of packaging, involving various applications: flexible packaging, labels, plastic bags, carton and cardboard packaging, shrink-wrap packaging, and many more. It is also used for printing the substrates of notebooks, forms, newspapers, and labels.

Due to its innovative nature and a wide range of possible applications, flexographic print is strengthening its position. According to the report by Smithers Pira, in the year 2017 the market for flexographic print has been valued to 164 billion dollars. It is estimated that it will experience an increase by 2.3% yearly and in 2023 it will reach a value of 187 billion dollars The Future of Flexographic Printing to 2023 et al (2018). Therefore it is legitimate to address the aspects of automation and improving the quality of flexographic print.

Research Methodology

In our researches we use the Design Science Research Process (DSRP) methodology Vaishnavi et al (2017). This methodology involves the realization of research works as process-dependent steps responsible for the implementation of basic tasks and the delivery of basic work artifacts. This methodology is based on five basic steps. The first, "Awareness of problem", focuses on the preparation of a preliminary proposal for a new research topic, which usually results from the analysis of already available achievements and results in related disciplines or disciplines, as well as in industry. The second, development of the proposal ("Suggestion"), follows the initial proposal, and is a creative step aimed at defining new models, methods, functionalities based on new configurations of existing or new elements. The third, development of the proposal ("Development"), is the stage where the initial research is developed and extended. The fourth, "Evaluation", is the stage where the prepared artefacts are evaluated according to the adopted criteria. The fifth, "Conclusion", can be the end of a given research cycle or is the end of the entire research undertaking. As outlined, each stage ends with a specific result, which then forms the basis and allows for the next step in the process. In addition, this methodology assumes that it is possible to return to the previous steps under the observed restrictions. The conception of using the DSRP methodology in this paper, is presented in Figure 2.

Fig. 2: Research methodology

We use mainly the literature of subject analysis, as research method in the Awareness of problem and the Suggestion stages. The development and evaluation stage are joined in our research. In the development stage, we use such research methods as modeling, design and implementation, and observation of phenomena.

Evaluation: we use case studies on examples. We based the Conclusion phase on synthesis, analysis, induction and deduction research methods.

Sensory memory and perceptual memory implementation

In order to improve efficiency in printing process, the key aspect is monitoring the color, its intensity and hue. This should be done on the final stage of production. It will be the main stimulus reaching sensory memory, based on which the system will attempt to increase efficiency.

The following modules of LIDA agent memory will be used:

- Sensory memory,
- Perceptual memory,
- Declarative memory,
- working memory,
- global working memory,
- procedural memory,
- sensory-motor memory and action structure.

Due to a limited number of pages, this paper will analyze methods of implementing sensory and perceptual memory.

Sensory Memory Implementation

In order to implement sensory memory, the Hierarchical Temporal Memory (HTM) will be used, also known as the automated learning technology that functions using o model of structural and algorithmic properties of neocortex. HTM networks are educated using a lot of data that changes in time and store large sets of patterns and sequences. The network has a hierarchical organization of memory and is based on variation in time. The information is stored in a dispersed manner Numenta Inc et al (2012). In HTM information is represented with Sparse Distributed Representations (SDR). They are bit maps where the bits are Numenta Inc et al (2012):

- dispersed, meaning only activation of many bits can represent something,
- sparse, meaning only a small number is active,

In printing process, input data is as follows:

- order parameters (attributes *Order, Standard*)
- properties of printing units (attributes *Position of pressure cylinder, Speed, Photopolymer wear, Tape wear;* the parameters are grouped in a hierarchy using the parameter *Pressure*),
- properties of ink (attribute *Ink*),
- spectrophotometer reading (attribute *Spectrophotometer*),
- time stamp (attribute *Time*),

Root is the parameter *Colour.*

Based on the data, the hierarchy and regions of HTM will be presented according to Figure 3.

Fig. 3: Simplified diagram of eleven regions of HTM laid out in a three-level hierarchy, relaying information within the levels, between levels, and to/from the hierarchy

Order is the attribute that contains data on the amount and optical density of colors used in print, as well as maximum acceptable tolerance. It is created on the basis of the profile, however optical density may be updated after the first print, should the color turn out to be different than initially assumed, but still satisfy the customer. The attribute *Standard* contains the following data:

- profile – conducted machine test for colors it can generate; therefore the system has the information on optical density of each color to be used in the order,
- printing perimeter – the perimeter of the prepared printing mold which includes: pressure cylinder, duct tape, and matrix; value range from 400cm^2 to 750cm^2.

Position of pressure cylinder is composed of two values: the positioning of the right and left side of the cylinder. They are positioned against the starting position and that involves the necessity to notify the system about a change in the position. System representation will be a combination of these two parameters.

Speed of printing is controlled by the printer processor. Average printing speed is between 200 and 300 meters per minute. Normally the range is between 250 and 280 m/min. Maximum speed is 400 m/min. Attributes *Photopolymer wear* and *Tape wear* are influenced by speed, or the number of imprints made to be exact. The tape is replaced with each change of matrix, however the photopolymer may be reused, so its wear will not be reset upon finishing the printing.

Pressure is an important attribute. It is a component of photopolymer and tape wear data, pressure cylinder position, and standard. This region will be analyzed thoroughly, so it should have a large bit map.

Ink parameter takes values based on the readings from the viscometer – a device that reads ink viscosity in real time. The importance of this information results from the fact that a change in viscosity affects color intensity and must be continuously monitored. The rate of viscosity change is important for the future forecast.

The most important attribute is *Spectrophotometer*. The device measures the optical density of control points located at the edge of the print.

Time is an attribute that enables the system to analyze the repeatability and gathering of data in the declarative memory, while specifying where it took place. It will be divided into time, day, month, and year reading.

The final attribute is color. This region is essential in HTM, because it is where the analysis of all values will take place.

Perceptual Memory Implementation

In perceptual memory the system conducts normalization of incoming input in relation to time so that it can begin learning sequences and patterns appearing in the stream in subsequent steps of the cognitive cycle, and begin drawing conclusions Franklin et al (2016). Algorithms of perceptual memory perform two main functions: keeping the constant of sparseness of incoming bits and the properties of superposition, which is essential for keeping the semantic meaning of signal. Therefore, having two different SDR with high coefficient of superposition, the output representation created in perceptual memory must also have high coefficient of superposition. This mechanism also works in reverse. If two signals are not similar, we will obtain two output representations with low coefficient of superposition. Using this mechanism, the agent attempts to keep the status or context from the past Numenta Inc et al (2012). In perceptual memory, data representation is done using active columns. Each column has many cells that go into three types of status Numenta Inc et al (2012):

- active – one active cell in the column is enough to activate the column which constitutes representation,
- active from side input – status that could be reached in the process of prediction; according to schematics learned by the system the agent awaits a pre-learned pattern,
- inactive – in a situation when all cells are inactive, the entire column remains inactive as well.

Due to the ability of inserting a large number of cells in the column, the system is able to interpret exactly the same input in different contexts. For instance, fifty active columns represents pressure, so if only one cells is required to activate the cells, and there will be four of such cells in each column, then the system has 504 possible interpretations of the same signal. The same input will always result in the activation of the same 50 columns, but in different contexts different cells will be activated in the columns. The agent can determine and remember a given value at a given moment in the process, considering all other parameters and their values in the current status Numenta Inc et al (2012).

Each time a new, unknown signal appears, a new representation of sparse set of active columns is created. Every column connected with all bits in SDR has a weight range of connection between 0.0 to 1.0. Initially, the values are distributed randomly. Regardless of the location of active bits in SDR, a column is able to establish connection with some bits, and unable to do the same with other bits. This is due to the threshold of superposition which indicates minimum value of the weight of connection to be reached for it to exist. If the threshold value is set to 0.7, the columns can only establish connection with bits whose value begins with 0.7. However, the most important connections are made with active bits. The number of active columns representing a specific SDR must be proportional to the active bits of the SDR, following the rule for creating output data of perceptual memory, discussed above. They are ranked from the largest to the smallest number of accurate connections (connections with active bits) (Fig 4) and an appropriate percentage becomes active (according to the proportion). If there are several columns with the same value, but not all of them may become active with proper proportion, then the system randomly activates the appropriate number of columns among those having the same number of active connections Numenta Inc et al (2012), McCall et al (2010).

The value of weight of connections is variable during the process of learning. New information arriving after the cognitive cycle make the connections change their weight, which may result in the occurrence of new possible connections or reduction of existing ones. The forecast created on the basis of input data changes the representation so that it fits the context pf previous input data. Learning makes the agent note the cause-and-effect relations and similarities in incoming stream of data. The system will need time to learn, however it can continue learning later on Numenta Inc et al (2012), Franklin et al (2016).

Fig. 4: Connections between the winning column (single selected, blue frame) and SDR representation. Grey bits represent all connections above weight 0.7, whereas green bits represent active connections, according to the SDR representation. The selected column has maximum number of active connections (5)

Conclusions

The authors proposed the implementation of sensory memory and perceptual memory for cognitive agents during the process of flexographic printing on packages. Due to the use of HTM the Agent will analyze all parameters and their combinations with other parameters. Changes made by perceptual memory will gradually change the representations in a way that the 'winning' columns will be similar in similar signals, however this will occur after many modifications initiated by the learning process. For instance, the Agent will be able to differentiate the course of the printing process in a specific configuration of the position of pressure cylinder against the wear of photopolymer and tape. Also, every color read be the spectrophotometer will be a representation of the sum of all relations of regions from lower hierarchies. The agent will remember which parameters affect the color and to what extent. Such approach can improve the quality of prints made and allow for increase in efficiency and decrease in cost of the entire process. It is necessary in the face of growing competition from digital printing.
The approach presented in this paper allows for implementation of the remaining modules of LIDA cognitive agent – it is a subject of future works.

Abstracts

The article deals with the findings of the study that reveals the investment cycles in the Russian economy 1989 to 2019 based on official statistics. This research has been performed in response to the need of theoretical development on interdependence between different kinds of economic cycles, the lack of common interpretation of the 'investment cycle' concept and agreed methods of its analysis; the need for assessment of its current state and forecasting of investment process development, and the need for specification of trends and methods of investment process management in the economic systems of different levels. We also suggest the interpretation of the investment cycle as an important part of business cycle in this article. The methods used to determine the investment cycles involving the spectral analysis techniques are provided in this study. Using the linear filtering methods, the investment cycles in the Russian economy development over two recent decades have been distinguished. The recommendations on the trends of further research in this field are given in the article.

Keywords: Investment Cycle, Business Cycle, GDP, Spectral Analysis Methods, Band-Pass Filter, Hodrick-Prescott Filter

Introduction

Coronavirus pandemic followed by the sharp decline of oil prices in the first quarter of 2020 reminded of the cyclic nature of the world and national economy development. Despite the fact that the economists and scientists recognized it, the research of cycling involving the small periods (15 to 20 years), particularly in the post-Soviet Russian economy, seems insufficient.

The principal research and development activities in Macroeconomics, that form the foundation of the current theory of economic cycles, were introduced at the beginning of the last century in the works of such famous scientists as V. Kondratieff, (Kondratieff waves with a period of 45–60 years), S. Kuznets (Kuznets swing with a period of 15–25 years), K. Juglar (Juglar cycles with a period of 7–9 years), J. Kitchin (Kitchin cycles with a period of 3–4 years), and etc.

Most publications in Microeconomics are devoted to cycles and determiners of investment activity, and perspectives of particular field, company or even project development. It can be easily seen that they have a narrow focus, in general. Herewith, the interpretation of the 'investment cycle' concept varies greatly depending on the goals of the particular study.

In practical terms the research and detection of the so-called business cycles and their components in the economy is of great interest.

The business cycle is a quasi-periodic oscillation characterized by periods of expansion and contraction of the economy, lasting on average from 4 to 40 quoters.

Correct identification of cycles in economy needs to determine its contraction and expansion stages, i.e.

it is based on fluctuations of the economic processes. As a rule, the business cycle consists of the expansion stage, observed in many economic activities, followed by recession and recovery stage, further developed into the next expansion stage. It is a recurrent sequence, although it is not strictly periodic.

Business cycles can be distinguished by their intensity and duration. For example, there was a severe recession in 1981 in the USA, but it did not last long, whereas in 2008 the recession was heavy and long-lasting.

The business cycle research has a long history. Primary definition of the term was given in the publication by Arthur F. Burns et al (1946) and remains valid today. According to this definition: "Business cycles are a type of fluctuation found in the aggregate economic activity of nations that organize their work mainly in business enterprises: a cycle consists of expansions occurring at about the same time in many economic activities, followed by similarly general recessions, contractions, and revival which merge into the expansion phase of the next cycle; in duration business cycles vary from more than one year to ten to twelve years; they are not divisible into shorter cycles of similar characteristics with amplitudes approximating their own."

Business cycle research has been widely conducted in the USA, also in the projects of scientists and specialists of National Bureau of Economic Research – NBER (http://www.nber.org/), and have been further developed in the works of the scientists of different countries.

The identification of business cycles and their components, study of their duration and other features, however, is still urgent, also in terms of timely forecasting of potential financial defaults.

Meanwhile, almost no attention is paid to representation and analysis of individual components of business cycles (investments in fixed assets, household and government consumption, import, export, and etc.) in many countries, and, particularly, in the Russian Federation. However, behavior, phases, duration and other characteristics of business cycles are determined by their dynamics.

The given study deals with the identification of the investment cycles in the Russian Federation economy over two recent decades (1998 to 2019). The study is based on the official statistical information about Russian GDP structure by quarterly expenditure in current prices according to Bloomberg system. GDP component measurement in current prices is used for data comparative analysis and repeatability of the study. The spectral analysis and time series filtering techniques were used to identify the investment cycle periods.

Analysis, processing, visualization, and statistical data modeling were performed in R software environments.

Results

The investment cycles form the most important and integral part of development and business cycles in economy. They produce direct influence on the final results measured by the GDP growth volume and rate.

The dynamics of the GDP (GDP) and investment in fixed assets (INV) reflected in the corresponding GDP expenditure item is provided below (Fig.1). Some statistical characteristics of INV time series are given in Table 1.

Table 1: Statistical characteristics of INV time series INV (mlrd rub)

Name	Data	Value
Min.	1998-03-01	73.6
1st Qu	2003-08-09	586.3
Median	2009-01-15	1975.2
Mean	2009-01-14	2418.7
3rd Qu	2014-06-24	3646.9
Max.	2019-12-01	8717.7

As one can see on Fig.1, the dynamics of change in the GDP and INV absolute values is of seasonal nature.

Since the full business and investment cycles cannot be directly observed on the basis of statistical data sets, the seasonal and trend components shall be provided for their identification and analysis.

The similar procedure was first implemented for the US economy using the method suggested by Bry and Boschan (1971), and, then, adopted for practical use by NBER specialists.

Fig. 1: Dynamics of the GDP and INV for the period 1998 – 2019 (mlrd rub)

The authors use X-13ARIMA-SEATS method (Fig 2) in this study to exclude the seasonal factor influence and detect the trend in the INV time series.

Fig. 2: Dynamics of the seasonal adjusted INV for the period 1998 – 2019 (mlrd rub)

This method is chosen, since it is rather common in the EU countries and it is used by the official statistical services of the Russian Federation. Whereas the statistical agencies in the USA and Canada use the different X11 technique, described in detail in the publication by Dagum et al (2016).

To provide the more detailed analysis of the seasonal component, its quarterly dynamics is plotted below (Fig. 3). Horizontal lines of the graph correspond to the average quarterly investment volume values.

Fig. 3: Dynamics of the seasonal component of INV for the period 1998 – 2019 (mlrd rub)

It can be easily seen that the largest investment volume is observed in Quarter 4 due to the considerable role of the government funds in the investment activity that underlines its specific character in the Russian Federation. Undrawn budget funds are expended and returned to the economy at the end of the year. It characterizes the investment policy of the government as uneven and partially ineffective.

However, the revealed uneven nature is also associated with the investment reporting of the private companies submitted at the end of the corresponding quarter (the financial year in the Russian Federation coincides with the calendar year).

Further research provides for the identification and analysis of the investment growth rate variations, and the initial set was transformed (logarithmic transformation) as appropriate. A periodogram of investment growth rate variations is provided below (Fig. 4).

Proceeding from the periodogram, the investment growth rate variation depends on frequency fluctuations mostly by 2 to 4 quarters (values 1 and 2 on the horizontal (x) axis).

Visual analysis (Fig. 2) suggest the trend as confirmed by growth rate of investments autocorrelation analysis (Fig. 5).

As showed in the book by Box et al (2015) if there is a trend of data, the autocorrelations (ACF) for small lags tend to be large and positive, and observations nearby in time are nearby in size. So, the ACF of trended time series, as a rule, tend to have positive values that slowly decrease as the lags increase. When data are seasonal, like in this case, the autocorrelations will be larger for the seasonal lags (at multiples of the seasonal frequency) than for other lags.

Such conversion in the scientific study often requires the spectral analysis. In particular, the linear filtering techniques are widely used in the economic research, and the so-called HP-filter suggested in the publication by Hodrick and Prescott (1997) is one of the most popular among them.

This filter is applied for decomposition of y_t variable into trend Y_t and cyclic x_t components:

$$y_t = Y_t + x_t, \tag{1}$$

by minimization of the following expression:

$$\sum_{t=1}^{N}[(y_t - Y_t)^2] + \delta[(Y_{t+1} - Y_t) - (Y_t - Y_{t-1})]^2. \tag{2}$$

Fig. 4: Periodogram (frequency 4/τ)

Fig. 5: ACF of quarterly growth rate

First addend in (2) calculates the cyclic component xt variation. Second addend shows the change in the trend Yt component increment in the long-term perspective.

Parameter δ defines the balance for the elements of both components. As Ravn et al. (2002) mentioned, parameter δ value can be calculated by formula:

$$\delta_\tau = 1600(\tau/4)^4, \qquad (3)$$

where τ is the monitoring rate.

It can be easily seen that this parameter is 1600 for quarterly measurement. As mentioned above, the values characterizing the investment growth rate variations were subject to log transformation for the analysis of the investment growth rate using some patterns (1-3). The results obtained are provided on a diagram below (Fig. 6).

Fig. 6: Cyclic fluctuations of investments in fixed assets in the GDP of Russia over the period 1998 - 2019

Conclusions

As we can conclude proceeding from the results (Fig. 6), the investments in the Russian economy over the period under consideration is considerably uneven. It reached its highest peak (18.3%) the year before the global financial crisis in 2008.

Hence, the biggest decline in the investment rate (-6.55%) was observed in Q1 2009 due to the global financial crisis in 2008.

The next drop in the investment rate (-5.73%) was recorded in Q1 2002 due to the negative impact of the external factors by the end of 2001, i.e. economic recession in developed countries and deterioration in foreign economic environment, primarily, due to a significant plunge in oil price. World price of 'URALS' crude oil dropped to $19.8 a barrel in October, 2011, and to $17.9 a barrel in November. Herewith, the deterioration of economic situation with the other traditional export commodities of the Russian Federation was observed. First of all, it affected ferrous metals (demand for rolled sheet products on the part of main consumers - auto manufacturers and some kinds of structural steel products on the part of machine-building and construction companies) and non-ferrous metals (nickel and aluminum, mostly).

It should be underlined, that this is the current situation (Q1 and Q2 2020), and we recommend business entities, investors and regulatory authorities to learn the lessons from it.

It is an interesting fact that both recession considered led to the drop in investments that exceeded the results of financial default in 1998 in the Russian Federation.

There is a set of full investment cycles of the Russian economy on the plot, e.g. from Q2 1998 to Q1 2002 (i.e. about eight quarters), from Q1 2009 to Q2 2015 (24 quarters), from Q3 2015 to Q2 2018 (12 quarters).

It can be easily observed that these cycles vary by duration and by nature. The reasons of these differences can be determined by various factors, both, external (e.g. global financial crisis, decline in the price of basic goods), and internal (monetary policy, actions of the regulatory authority, social and political processes and the economic reforms carried out, and so on).

Due to the analysis of the reasons of changes in the investment cycles we can better understand their nature and foresee their further behavior, or study the influence of factors, individual or total.

The findings obtained offer the great promises in development of the investment cycle forecasting approaches, that can contribute to more efficient business planning, and timely response to the negative processes and take preventive measures on the part of the regulatory authorities.

Acknowledgment

The publication is prepared upon the results of the research carried out according to the State Assignment given to the Financial University under the Government of the Russian Federation in 2019.

Abstract

The article discusses current issues of legislation and law enforcement practice regarding the establishment of the possibility of copyright protection of the result of intellectual activity by the criterion of its creative origin. In the literature, the corresponding problem is known as the "threshold of originality." The authors analyze approaches to establishing the “threshold of originality” in various legal systems (Anglo-American, continental); they are exploring doctrinal approaches to defining the boundaries of protection of works of science, literature and art; they are examining the current judicial practice in this area. On this basis, they offer their own approach to understanding the “originality” of a work, corresponding to the current legal regime of intellectual property in the Russian Federation. It is concluded that the general conditions for the protection of the result of intellectual activity as an object of copyright in modern Russian law is its attribution to works of science, literature or art created by the intellectual labor of a person acting in conditions of creative freedom.

Keywords: Intellectual Property, Copyright Protection, Creative Work, Protection Of Photographs, Sweat Of The Brow.

Introduction

One of the important issues of intellectual property law is the determination of which objects are eligible for protection and which are not. For different types of protected intellectual property (industrial property, trademarks, means of individualization), various rules are used. With regard to copyright, one of the essential requirements for objects that can be protected as works of science, literature and art is originality.

It is usually claimed that in order to become an object of copyright, a work must possess a sufficient degree of originality, which confirms its character as a creative result of intellectual activity.

In legal literature and judicial practice, the corresponding requirement is called the “threshold of originality”, which is rather arbitrary, since of course there is no quantitative indicator of the author’s creative contribution, therefore determining whether the work is original enough to “overcome” this threshold, is a fairly subjective process based on not arbitrary criteria. The relevant criteria are different

in different jurisdictions, can be quite flexible, evolving over time, and are fixed mainly in judicial practice and the works of legal scholars. There is no unity between the latter: according to Lavik and Gompel (2013), some are calling for an increase in the threshold of originality.

Modern reality poses quite complex tasks for lawyers, such as determining the possibility of copyright protection of works created by artificial intelligence – see Guadamuz (2017) or animals — see Guadamuz (2016). As mentioned by Hua (2017), questions of evaluation of the protection of works of arts and crafts arise as well.

As a result of this, the study of the modern approach to determining the threshold of originality has theoretical and practical importance. Given the processes of globalization in the modern world, the solution to this problem is relevant in a wider context, since it allows us to imagine a possible evolution of the criterion of originality in many legal systems.

Methods

General and special scientific methods, traditional for theoretical and applied legal research, were used, such as formal-legal, system-structural, content analysis of various publications, comparative legal method.

Results and Discussion

Despite the fact that copyright is the subject of regulation of a number of international treaties, the main among which is the Berne Convention of 1886, these documents do not contain clear guidelines on the threshold of originality, and therefore different legal systems use different approaches to determining which works can be considered original, and which are not.

It should also be noted that the question of originality does not apply to all categories of works, but only to those that are close enough to the "threshold of originality". Of course, in situations where the object of rights is a complex literary work, the text of which is not even remotely similar to existing ones and contains a significant number of clearly authorial elements, a picture or other image, when looked at which even an amateur in art will consider their creative work, a complex piece of music, there is not even a minimal doubt that they are original enough so that intellectual property rights may arise in relation to them and.

However, as stated by Kasharin (2010), in practice, often enough, the need arises to determine whether originality criteria for simpler intellectual activity correspond to originality criteria, in particular those representing a combination of elements, each of which is not protected in itself, as well as materials created on the basis of other intellectual activity results, including those in the public domain due to the expiration of the period of protection of intellectual property rights to them or for other reasons.

Based on the analysis of approaches to determining the originality of creative works in different countries of the world, three approaches to establishing the "threshold of originality" can be distinguished with a significant degree of conditionality.

The first, which can be conditionally called based on personal creative contribution, is used, for example, in US law. The guiding principles for establishing the originality of works in this country were determined by the US Supreme Court in a 1991 judgment in Feist Publications v. Rural Telephone Service, which concerned the intellectual rights to the telephone directory. Subject to a number of other court decisions, in particular in cases such as Morrissey v. Procter & Gamble, Bridgeman Art Library v. Corel Corp, Meshwerks v. Toyota Motor Sales U.S.A. etc., the essence of the approach used can be explained as follows.

Any work in relation to which the question of its originality may arise should contain the result of the creative activity of its author, going beyond the exact copying of the existing results of intellectual activity, or using obvious techniques, methods, calculations, actions, etc., aimed at connection or

transformation of already known or trivial elements. Moreover, as concluded by Matveev (2009), the laboriousness of creating a result in itself, the need to apply special knowledge, skills does not matter and cannot be considered a basis for recognizing the original nature of the created object.

For example, a logo consisting of text printed in a regular font and a combination of simple geometric shapes will not meet this criterion of originality, as it is a simple combination of trivial elements, which were not used to create any overlay beyond the obvious techniques of overlapping and relative positioning elements of creative methods. An image that faithfully copies, for example, a picture in the public domain, will not be an original work, since in this case the author does not pursue the task of making his own creative contribution, but focuses on copying someone else's result of intellectual activity as accurately as possible.

On the other hand, even a creative contribution that is quite simple in nature and does not require significant intellectual efforts, which reflects the personality of the author (for example, the almost unconscious choice of composition and angle of shooting for spontaneous photographing of an event) will be considered sufficient to ensure that the result. The activity, as described by Sviridova (2018), was recognized as an object of copyright.

Another possible approach is based on giving greater importance to the novelty of the work. So, for example, in Sweden the following general rule is used: original enough to become an object of protection will be a work for which it is unlikely or even impossible to simultaneously create independently two different people. Of course, this does not necessarily mean complete identity: substantial similarities may be sufficient — see What may be protected (2015). So, for example, the technical drawing was recognized by the Supreme Court of Sweden as a non-copyright item — see NJA 2004 s. 149.

This approach has especially noticeable consequences in relation to photographic works: taking into account the fact that, unlike works of fine art, capturing an image by a photographic method does not require any special creative skills (especially when it comes to modern photographic technique that automatically selects the mode shooting). In many countries of Europe, in order for a photo to be recognized as a protected object, it must have a significant degree of originality, which, as stated by Fisher (2016), is expressed in the choice of the subject, composition, lighting, and other actions that enable the photographer to create an image that could not under similar conditions received by another person. For example, this approach is used in Portugal — see “Bom registo…” (2017) and Switzerland — see “Auszug…” (2004).

Finally, the third approach transfers the consideration of the issue of the workability of a work from the plane of its originality to the plane of considering the nature of the person’s activities in the process of its creation. Usually this leads to an extremely low threshold for originality. For example, it can be said that any work created by creative labor is considered to be protected. Here we can also mention the classical doctrine of “sweat of the brow”, as mentioned by Ramalho and Gomez (2017), used in Anglo-Saxon law: if the creation of a work is time-consuming and requires special skills, it is considered protected, even if it is not in the least innovative. At the same time, another person can also claim protection if he creates a similar work with independent labor, even if it is almost identical to the previous one.

What approach was used in Russia? Until recently, normative acts did not contain any clear criteria for the originality of a work. E.P. Gavrilov (2004), one of the leading experts in the field of legal protection of intellectual property, argued in this regard: “the very fact of the appearance of two identical results, not copied from each other, is clear and indisputable evidence of the lack of originality and the impossibility of establishing legal protection for both of these results”. A similar opinion was expressed by other authors, in particular, A.V. Nesterov (2018) and V.A. Maximov (2017). It is easy to notice that this approach is very close to the model used in the USA.

Of course, this point of view was not the only one, although M.V. Labzin (2007) also notes that “the concept of Professor Gavrilov has not met with serious criticism until recently”. In particular, M.V.

Labzin (2008) justified a different position: according to his opinion, "the object of copyright is even such a work of creativity, in the creation of which the author, expressing himself, showed his own way of thinking, his inherent skills and abilities, but did not reflect their result, as a result of which he is not unique with parallel creativity ", and, therefore," originality is a consequence of creativity, and not a characteristic of the level of novelty of an object ".

Judicial practice was also not unambiguous, and if in the 2000s and early 2010s it was possible to find many examples in which the reason for the refusal to protect the work was the lack of its uniqueness or novelty, then after 2014, when the court intellectual rights, judicial practice has become almost uniform, and originality has been consistently rejected by the courts as a necessary condition for the protection of creative works.

The culmination of this was the adoption on April 23, 2019 by the Plenum of the Supreme Court of the Russian Federation of Decree No. 10 "On the application of part four of the Civil Code of the Russian Federation", which included paragraph 80, which establishes the following rules for resolving by the courts of the Russian Federation issues related to determining the creative nature of a work taking including its originality.

"When resolving the issue of attributing a specific result of intellectual activity to copyright objects, it should be borne in mind that, according to the meaning of Articles 1228, 1257 and 1259 of the Civil Code of the Russian Federation, in their interconnection this is only the result that was created by creative work. It should be borne in mind that, unless proven otherwise, the results of intellectual activity are assumed to be created by creative work.

It is also necessary to take into account that the lack of novelty, uniqueness and (or) originality of the result of intellectual activity alone cannot indicate that such a result was not created by creative work and, therefore, is not the object of copyright.

The creative nature of the creation of a work does not depend on whether the work was created by the author himself or using technical means. At the same time, the results created by technical means in the absence of the creative nature of human activities (for example, photo and video shooting with an automatic surveillance camera used to record administrative offenses) are not object of copyright."

Thus, at present, in Russia, any works created by the creative work of a living author are protected, regardless of their novelty, uniqueness and (or) originality. Moreover, as stated by Mansurova (2017), the definition of "creative work" can be very broad. At the same time, it cannot be argued that the Russian courts accepted the doctrine of "sweat of the brow".

The reason for the impossibility of such a perception is primarily that the legislation contains a list of objects, the creation of which, although it is time-consuming and requiring special skills, but which still cannot be protected by copyright. Their common name is "messages about events and facts that are purely informational in nature." As examples of such objects are named news of the day, television programs, timetables of vehicles and the like. As you can see, the list in the legislation is open, as a result of which recognition of other objects not specified in the law as having informational character is not excluded.

From time to time, courts (especially of the first instance) attempt to attribute various objects, including photographs, to such messages about events and facts. So, the decision of the Moscow Arbitration Court of April 7, 2017 in case No. A40-239418/16 regarding the recognition of photographs as a copyrighted object indicated the following: "the controversial photograph is the result of shooting an architectural structure, contains information about the architectural structure and is for informational purposes only. A shot of such an object is made by the person directly at its location, because the object is located in an area open for public shooting, taking into account the available photographic equipment, that is, in conditions independent of the will of the author, in which the photographer does not select and control neither the quality of the shooting, nor the angle, nor the lighting, nor the filling of the frame, nor the background and / or the context of the shooting, neither the behavior of the shooting

objects and other conditions, but only seeks to fix the structure, carrying out such fixation technically, without realizing an artistic (creative) intention, with a purely informational purpose. Based on the composition, identical photographs could be performed by several persons independently of each other and located in a similar place of photographing and able to capture the same angle of an architectural object. The faces in the frame, obviously, were not models and did not fulfill the plan of the photographer, but only accidentally fell into the frame."

In addition, the trial court noted that "the controversial photograph was not processed in any way, the lighting conditions were not taken into account when photographing, the settings corresponding to the lighting conditions were not selected; the photo does not contain signs of novelty and originality, since it represents a reproduction by photographic display of the famous Perm Gate project by Nikolai Polissky, and as a result, it is not an original work, and the photo angle used is one of the most common camera angles used to capture this artistic project".

However, this decision in this part did not pass the verification by the appellate and cassation instances (Resolution of the Intellectual Property Rights Court dated October 30, 2017 No. C01-812/2017 in the case No. A40-239418/2016), which recognized that despite these circumstances, the photograph is still It must be recognized as the object of copyright. There are other similar solutions by which any photographs taken by the photographer on their own, regardless of their artistic value, are recognized as the object of copyright.

In addition, it should be noted that for the type of objects most in need of protection, the creation of which is time-consuming and requires significant resources, but the protection of which is impossible using existing copyright institutes, Russian civil law provides for specific rules. This is the exclusive adjacent right of the database manufacturer. By default, legislation (art. 1334 of the Civil Code of the Russian Federation) requiring significant costs for creation is recognized as a database containing more than 10 thousand independent information elements. And although protection is provided on the basis of other legal norms, as mentioned by Kalyatin and Voynikanis (2007), the interests of the creator of the intellectual property object remain protected.

However, even taking into account all the above, it has to be noted that a rather unique situation has developed where, on the one hand, the criterion of originality is denied, on the other hand, rather complex works are not recognized as objects of copyright. An example is the Resolution of the Intellectual Property Court of 04.24.2015 No. C01-305/2015 in case No. A46-10011/2014, which recognized the text materials published on the Forbes website, which gave a brief description of Ukrainian cities, as non-copyright items. Despite the fact that these materials are quite voluminous and without a doubt are the result of the intellectual activity of a person who has compiled a selection of facts, the court ultimately came to the conclusion that they are not a work of science, literature or art that has a creative character.

Probably, the last thing played here was that for all the described settlements, the notes were built according to a given structure and have a strictly factographic character, which does not imply the use of any literary creative techniques. Based on this, we can draw certain conclusions regarding modern approaches to determining the threshold of originality in Russian copyright law, taking into account the explanations of the plenum of the Supreme Court of the Russian Federation on intellectual property issues.

Conclusion

It should be concluded that the use of the term "originality" in the context of the necessary property of a work protected by copyright is somewhat different from its commonly used meaning in the language as something unlike the others, peculiar, unusual, original. In the context of intellectual property law, "originality" means that the work is created as a result of independent creativity, comes from a particular author, reflects his personal creative approach to solving the problem.

At the same time, it cannot be said that the novelty of a work and the absence of its similarity with existing works should be completely ignored in the context of copyright. One of the legitimate questions that can be asked when examining whether a work is original is the question of the possibility of another solution to a similar intellectual problem. If several different people who will be assigned the same task, requiring intellectual efforts, cannot create solutions that are any significantly different from each other, the result is not original and cannot be considered the object of copyright.

In modern Russian judicial practice, as follows from the results of the study, just such an approach has been strengthened that differs from that used in other legal systems. Unlike other countries where the key importance may be given to the use of original creative techniques, the novelty of a work or the degree of laboriousness of its creation, the Russian law enforcer, when determining the creative nature of a work, asks whether its creator has creative freedom or is placed in a tight framework, including related to the purely utilitarian nature of the result, which should strictly comply with certain requirements. At the same time, even an object that is modest from the point of view of creative methods, the analogue of which can be independently created by another person, can be recognized as creative and protected, if in principle it was possible to create another, excellent result by a third person who is in the same conditions.

For example, photography, even in an absolutely typical perspective, without using artistic techniques of the composition and subsequent processing, is still an object of copyright, because even if the author did not use such techniques, he could use them as part of the task. On the other hand, if the subject is faced with the task of accurately and concisely fixing facts of a certain nature, then he does not have a proper degree of creative freedom. This does not mean the complete absence of differences between the results of the work of different people performing the same task, simply these differences will not be determined by the individuality of a personal creative approach, but by the available initial information, the degree of diligence of labor, used technical means, etc.

Thus, the general conditions for the protection of the result of intellectual activity as an object of copyright in modern Russian law is its attribution to the works of science, literature or art created by the intellectual labor of a person who acted in conditions of creative freedom. With regard to a number of objects, such as news of the day, television programs, timetables of vehicles, the lack of creative freedom is presumed. As regards other objects, this issue needs to be considered individually in relation to the particularities of each specific situation, however, in the absence of evidence of any other outside the presumption of law, any result of intellectual activity should be considered as created by the author.

Abstract

International Financial Reporting Standard (IFRS) 15, Revenue from Contracts with Customers, which was included in the system of international standards, replaces the previously existing IAS 11 Construction Contracts and IAS 18 Revenue. IFRS 15 introduces new rules for accounting for revenue and expenses under contracts with customers, other requirements for the presentation and disclosure of information about contracts in the financial statements. The paper discusses the costs (expenses) arising in connection with the fulfillment of obligations under contracts with customers for construction work in accordance with IFRS 15 Revenue from Contracts with Customers and the Russian standard PBU 2/2008 Accounting for Construction Contracts.

Keywords: Costs of Contracts with A Client, Costs of Concluding A Contract, Costs of Fulfilling A Contract, Groups of Contract Costs, Cost Recognition Criteria.

Introduction

Starting January 1, 2018, a new international financial reporting standard (IFRS) 15 Revenue from Contracts with Customers was introduced, which stipulated not only a different definition of revenue from contracts with customers, but also defined new regulation in accounting for costs of contracts with customers. This Standard supersedes the previously effective IAS 11 Construction Contracts. In the Russian practice of accounting, an analogue of this standard is PBU 2/2008 Accounting for Construction Contracts. In connection with the innovations there is a need to consider the main changes in cost accounting for contracts with customers in accordance with IFRS 15 (IFRS) Revenue from Contracts with Customers and with the current RSPBU 2/2008 Accounting for Construction Contracts.

Materials and Methods

Construction as an industry is one of the most difficult segments in terms of technical nuances of the implementation of construction work. Accountants in addition to the specifics of maintaining financial and tax accounting in this industry need to understand some specific issues of the construction industry. Such knowledge is necessary for the correct classification of facts of economic activity, organization of accounting work, reliable preparation of accounting (financial) statements.

The specifics of construction management is determined by the features of construction production, which include:

1. immobility and territorial dispersion of construction products;

2. mobility of performers and implements of labor, complication of coordination of activities of construction organizations on sites, sometimes decentralization;

3. long duration of the production cycle;

4. the variety of facilities being built and, consequently, variety of technological, organizational and management solutions, the need for their study and comparison;

5. a large influence of natural factors, which increases the probabilistic nature of the system, the necessary specific management decisions.

These features of the construction industry have a direct impact on the organization of accounting.

The main provisions of the organization of accounting for construction work are formulated in the Accounting Regulation "Accounting for Construction Contracts", approved by Order of the Ministry of Finance of Russia of October 24, 2008 No. 116n (PBU 2/2008). However, this provision applies to organizations acting as contractors (subcontractors) in construction contracts, or as subcontractors in construction contracts in one of the following cases:

1) the duration of the execution of contracts should be more than one reporting year (long-term nature);

2) the start and end dates of contracts fall on different reporting years.

In the event that the contractor performs work within one reporting year or has the right to apply simplified methods of accounting, the rules of this PBU are not applied and the records are kept in accordance with PBU 10/99 Organization Costs.

In the system of International Financial Reporting Standards (IFRS), starting January 1, 2018, IFRS 15 Revenue from Contracts with Customers came into force replacing the previously existing IAS 11 Construction Contracts and IAS (IAS)) 18 Revenue. The new standard regulates accounting rules not only for revenue from contracts with customers, but also for any contracts with customers. So PBU 2/2008 Accounting for Construction Contracts regulates cost accounting only for construction contracts, and PBU 10/99 does not contain any rules that would relate to cost accounting for contracts with customers. It turns out that in Russia at the moment there is no regulatory document accounting for such contracts.

In accordance with IFRS 15 Revenue from Contracts with Customers the costs of contracts with customers are divided into two groups:

1) the costs associated with the conclusion of the contract;

2) costs associated with the fulfillment of contractual obligations.

The standard defines the conditions for the recognition of costs associated with the implementation of the contract, which include:

- costs should be directly related to the existing or specific expected contract;

- costs should form or improve the organization's resources that will be used to fulfill the obligations stipulated by the contract;

- costs must be reimbursed.

Moreover, the costs associated with the contract are classified into two categories:

1. direct costs capitalized as assets if all the criteria listed above are met;

2. costs recognized at the time of their occurrence.

Figure 1 shows a detailed classification of costs for contracts with customers in accordance with the requirements of IFRS 15 Revenue from Contracts with Customers.

The grouping of expenses under construction contracts, set out in the Russian standard PBU 2/2008 Accounting for Construction Contracts differs significantly compared with the IFRS 15 Revenue from Contracts with Customers. The mismatch initially lies in the terminology of the concepts of "costs" and "expenses". Both in PBU 2/2008 Accounting for Construction Contracts and in PBU 10/99 Organization Costs the term "expenses" does not apply.

To date, in the Russian regulatory documents there is no officially fixed concept of "expenses", which is used in a number of other accounting standards. This leads to a variety of its interpretations, both in the economic literature and in various regulations. So, M.S. Koske and Yu.G.Mishuchkova quantitatively described the terms "costs" and "expenses" in Russian accounting standards. In their opinion, the frequency of use of the term "expenses" is equal to or greater than the frequency of use of the term "costs". Of the 24 PBUs currently in force, the term "expenses" is not used in 12 of them, as emphasized in the paper by Koske M.S. and Mishuchkova Yu.G. "Expenses in Russian accounting: the economic nature and regulatory consolidation."

It turns out that in the national accounting standards, the terms "costs" and "expenses", according to the author, are used as synonyms. Let's disagree with this.

In accordance with RAS 10/99 Organization Costs, costs are understood to mean a decrease in economic benefits resulting from the disposal of assets (cash, other property) and (or) the occurrence of obligations that lead to a decrease in the capital of this organization, with the exception of a decrease in deposits by decision of participants (property owners). Based on this definition, costs are one of the central factors influencing the financial result of the organization. It follows that the expenses appear before the costs, that is, at the time the organization acquires economic resources. They can be charged either to assets or to costs. If an entity has an intention to capitalize expenses in order to create an asset, then they are recognized as assets. If such an intention is absent, then the expenses that have arisen apparently reduce the economic benefits of the company without creating any asset and are recorded as costs.

Fig. 1: Classification of expenses for contracts with customers in accordance with IFRS 15 Revenue from Contracts with Customers

It should be noted that in international accounting there is no single standard governing expenses and their accounting, as well as in Russian accounting standards. Each element of expenses is reflected in a specific IFRS.

Returning to PBU 2/2008 Accounting for Construction Contracts, we present the proposed groups of contract costs and the rules for their recognition in accounting (Fig. 2).

Figure 2 shows that the first group of costs includes expenses directly related to the execution of the construction contract. In paragraph 12 of PBU 2/2008 Accounting for Construction Contracts these costs include: actually incurred costs and expected unavoidable costs (anticipated), which are reimbursed by the customer in accordance with the terms of the contract. Expected costs are accepted for accounting either as they arise in the course of construction work, or through the formation of a special reserve to cover such costs. A provision may only be made if such costs can be reliably determined.

Fig. 2: Groups of costs under a construction contract in accordance with PBU 2/2008 Accounting for Construction Contracts

The second group of costs under the contracts includes indirect costs for each contract with the help of their distribution. Methods of cost allocation are determined by the organization independently and are applied systematically and consistently. The method of distribution of indirect costs must be necessarily fixed in the accounting policies of the organization.

The third group of costs in accordance with PBU 2/2008 Accounting for Construction Contracts includes other costs, which may consist of certain types of costs for the general management of the company, for R&D, the reimbursement of which is provided for in the contract.

As IFRS 15 Revenue from Contracts with Customers PBU 2/2008 Accounting for Construction Contracts provides the costs associated with the preparation and signing of the contract which incurred before the date of signing. Such costs include the costs of developing a feasibility study, the costs of preparing a contract for insurance of risks of construction works, etc. However, in accordance with the Russian standard, such costs are included in the costs of a construction contract only if they can be reliably defined, and if in the reporting period in which they occurred, it is likely that the contract will be signed. If these conditions are not met, such expenses relate to other expenses of the reporting period in which they arose. Unlike PBU 2/2008 Accounting for Construction Contracts, in accordance with IFRS 15 Revenue from Contracts with Customers, the expenses of concluding a contract with a client are recognized as assets regardless of whether or not a contract is signed with the client. They will in any case be reimbursed by the client. To simplify the procedure in practice, the company has the right to recognize the expenses of concluding the contract as costs as incurred if the depreciation period of an asset that the organization would otherwise have recognized would have been no more than one year. We assume that organizations can choose this approach, fixing it in their accounting policies, and in this case, apply it consistently to all expenses of concluding short-term contracts.

Thus, comparing the classification of expenses of the international standard and the Russian one, we can conclude that a certain degree of compliance of the composition of expenses exists. This applies to expenses directly related to the contract.

PBU 2/2008 does not establish criteria for recognizing the expenses of fulfilling a contract. In accordance with paragraph 95 of IFRS 15 Revenue from Contracts with Customers, the following criteria for recognizing expenses are defined:

1) expenses relate directly to a specific contract;

2) the expenses create or improve the quality of the organization's resources that will be used to fulfill future performance obligations;

3) expenses will be reimbursed.

The above criteria are valid for those contracts that fall within the scope of this standard.

Thus, both PBU 2/2008 and IFRS 15 describe a general methodology for expense accounting for contracts with customers, not taking into account the industry-specific activities of organizations. The described regulatory documents have both general and distinctive features, as well as a number of issues that have not been worked out in them. Moreover, it is worth noting that the adoption of IFRS 15 removes Russian rules from international ones.

Having studied the differences between international and Russian rules for expense accounting, we paid special attention to the expenses that will be the basis for the cost of construction work as an asset of the organization. The general methodology for calculating the cost of finished products in accordance with IFRS and domestic accounting standards is almost the same. This relates to expense classification by element.

Much attention is paid to the problems of expense classification in Russian practice, but two signs of expense grouping are disclosed in regulatory documents, in particular, according to economic elements and costing items of labor products. The expense structure used by Russian enterprises is formed under the influence of regulations, industry instructions and the specific features of the business entity. In accordance with paragraph 8 of PBU 10/99 Organization Costs, Russian organizations apply a single expense grouping according to the following economic elements: material expenses, labor expenses, social security contributions, depreciation, and other expenses. Disclosure of information in the context of economic elements in accounting is mandatory regardless of the specifics of activity, industry and other factors of enterprise management.

Today in Russia there is not a single document regulating the composition of expenses and the cost of construction work. Previously, the principles of expense classification, as well as methods of planning and accounting for the cost of construction work were given in the Model guidelines for planning and accounting for the cost of construction work (approved by the Ministry of Construction of Russia on December 4, 1995 N BE-11-260 / 7). This document has now been canceled. However, for practical purposes, construction organizations today are guided by certain provisions of the Standard Methodological Recommendations only in that part that does not contradict PBU 9/99, PBU 10/99 and other documents of the system of accounting regulation. However, the above regulatory documents are common to all Russian organizations and do not reflect the industry-specific activities of organizations.

Taking into account industry instructions and production characteristics in Russian practice, expenses are classified according to calculation items. According to PBU 10/99 Organization Costs "for management purposes, cost accounting is organized according to cost items", each company can independently establish a list of costing items.

Research Results and Discussion

Thus, due to the lack of industry instructions for accounting for production expenses and calculating the cost of products (works, services) in the construction industry, business entities have to independently develop a procedure for accounting for the costs of labor products, fixing their decisions in the accounting policy. However, the lack of regulations does not always contribute to making the right decisions in practice, even if they are taken by qualified specialists.

The practice of construction organizations of the Chuvash Republic shows that in their approved accounting policies very little attention is paid to expenses, their classification, the applied method of cost accounting and calculation of the cost of construction work, the order of distribution of indirect expenses, etc. This is probably due to the fact that the current regulatory documents on cost accounting in the construction industry are absent. Therefore, according to the authors, in order to make the right decisions, at least the following information should be disclosed in the accounting policies of the construction organization:

1. Grouping expenses by costing items. Typically, construction organizations apply the following classification: materials, labor expenses, operating expenses of construction machinery and mechanisms, overhead expenses, other production costs. This list is not final, the organization has the right to expand the range of articles depending on the accepted objects of accounting and economic feasibility.

2. The procedure for accounting for direct and indirect expenses. It is preferable to indicate on which accounts direct and indirect expenses are accumulated.

3. The procedure for the distribution of indirect expenses. First of all, this concerns the costs of operating construction machinery and mechanisms, overhead costs and other production costs. In practice, organizations usually use the basic wages of the main production workers as the distribution base. The costs of operating construction machines and mechanisms should be apportioned by type of production in proportion to the hours worked by each group of machines (machine hours). Overhead costs may be allocated in proportion to direct expenses. The organization can use other bases of expense distribution, which would take into account the causal relationship between the cost item and the basis of their distribution. In addition, the company can organize analytical accounting of overhead expenses, combining them into cost groups and for each establish the appropriate basis for their distribution.

4. Accounting of work in progress. Here the construction company has two accounting options. Either the work is handed over as the entire volume of work is completed, or the work is handed over in stages. In the second case, each delivery to the customer of the work stage is reflected as an implementation. In this case, it is advisable for the company in the working chart of accounts to provide account 46 Completed Stages of Work in Progress.

5. The method of cost accounting and costing of construction costs. Cost accounting for construction work, depending on the cost accounting object, can be organized either using an ordering method, or by the method of cost accumulation for a certain period of time. The main method, of course, is the custom cost accounting method. But, if the construction organization performs homogeneous construction work, creates objects of the same type with a small production cycle, it is advisable for such an organization to keep track of costs using the cost accumulation method.

Conclusion

According to the results of the comparative analysis of IFRS 15 Revenue from Contracts with Customers and PBU 2/2008 Accounting for Construction Contracts, we can conclude that the IFRS regulation significantly alienates us from domestic rules for accounting for expenses under contracts with customers. The difference begins in the terminology used “expenses” and “costs”. It cannot be said that the International Standard and domestic regulatory documents distinguish similar groups of expenses under the contract and the rules for their recognition in accounting. In PBU 2/2008 there is no simplified condition for recognizing the expenses of concluding a contract, as well as criteria for recognizing the expenses of fulfilling a contract as an asset for those expenses that are not within the scope of other IFRS. IFRS 15 does not recognize future expenses as deferred costs. In PBU 2/2008 there are no rules for accounting for assets, which recognize the expenses of concluding and fulfilling contractual obligations that include depreciation of such assets. According to the author, IFRS 15 has

not yet been widely disseminated in practice and perhaps in the future it will be amended in terms of cost accounting for contracts with customers.

Abstract

The article considers the concept of competitiveness in healthcare. It analyzes the strengths and weaknesses of the organization under study compared with competing medical organizations and studies the structure of the Republican Center for Manual Therapy Autonomous Institution (AU RPVL) and competing enterprises in the medical services market for the researched period. The authors assess the competitiveness of medical services. The paper discusses the dynamics and structure of income from the provision of paid services. Recommendations are developed to increase the competitiveness of the medical organization under study.

Keywords: competitiveness, medical services, analysis, factors.

Introduction

The relevance of the chosen topic is determined by the need to increase the competitiveness of medical organizations on the basis of timely and competent analysis. The analysis allows us to study the current problems of the competitiveness of medical organizations, to identify the strengths and weaknesses of competing organizations. Based on the results obtained it becomes possible to develop a strategy to increase the organization's competitiveness.

Materials and Methods

The emergence of new medical organizations caused by the growing demand for their services and growing profitability due to the use of modern management methods and new technologies implies the free choice of their services by the consumer, and therefore higher demands are placed on the quality of services by customers. Health organizations are more often forced to resort to marketing tools in order to understand the needs of consumers not only in the field of treatment but also in services, and to develop a competitive enterprise development strategy.

In modern conditions the problems of the competitiveness of medical services are extremely relevant.

Competition in healthcare is the state and process of the relationship between health care providers and their consumers in which there is a rivalry between health care providers to meet the needs of patients.

From the point of view of the final result competition is divided into constructive and destructive.

Constructive competition provides for a positive outcome in which the patient's choice increases, prices for medical services are reduced without loss or improvement in the quality of medical care.

Destructive competition is aimed at improving financial well-being to the detriment of the quality of services. In healthcare these include: orientation of suppliers only to the local market, struggle for the maximum number of patients, monopolization of the medical market.

The emergence of competition in the modern market of medical services exacerbates the problem of competitiveness of medical organizations.

Competitiveness characterizes the level of development of one organization in comparison with competing organizations in terms of customer satisfaction and performance.

We can distinguish the following approaches to the analysis of the competitiveness of goods and organizations.

Terekhova E.Yu. suggested a method of polling and interviewing in assessing competitiveness. This method allows to determine the competitiveness of both public and private medical organizations; assess and give recommendations for each competitiveness factor; compare the requirements of consumers and experts of insurance organizations for the subjects of the supply in a particular market; determine deviations in the level of development of regional and urban healthcare in relation to national; account for problems in the management of this sphere at all levels. The disadvantages include the fact that competitiveness is evaluated from the perspective of consumers of services as well as insurance organizations.

According to Thompson A.A. and Strickland A.A. it is possible to assess the competitiveness of the organization through the use of indicators of key factors for the organization's success in the industry under study, as well as the main advantages and disadvantages of competitors. Later on the sum of such indicators is formed into a comprehensive indicator of the organization's competitiveness. The positive side of this approach can be considered the ability to assess the enterprise in direct comparison with its competitors in this industry however the methodology does not take into account the specifics of budgetary and paid organizations and there is no possibility of assessing competitiveness within the organization itself.

The American method of analyzing hierarchies is based on an expert assessment of the organization according to certain criteria of competitiveness which are added to the matrix of paired comparisons. In this case competitiveness is determined both separately for each criterion and for the general level based on all parameters. This method is both qualitative and quantitative, i.e. suitable for evaluating several organizations, and allows to organize the indicators in a hierarchical order.

Research Results and Discussion

In order to identify competitiveness factors an analysis of the competitiveness of a medical institution is carried out.

Further we analyze the competitiveness of the researched organization Republican Polyclinic of Rehabilitation Treatment (vertebrology and manual therapy) Autonomous Institution of the Ministry of Health and Social Development of Chuvashia (AU "RPVL"), whose activity is the provision of health services.

The main competitors are Doctor Shumakov Clinic LLC, Similia LLC.

In Table 1 we consider the strengths and weaknesses of competitive clinics.

Table 1: Factors of competitiveness of the AU "RPVL" and its competitors

Name of company	Factors	
	positive	negative
AU «RPVL»	low prices, high quality, flexible discount system	inconvenient location
Similia LLC	convenient location, good interior of the clinic	high prices for services
Doctor Shumakov Clinic LLC	wide range of services	inconvenient location, high prices for services

Level of quality of service as well individual approach to the client in providing discounts favorably differ AU "RPVL" from the competitive organizations. However, the inconvenient location of the organization under study reduces its competitiveness. Similia LLC and Doctor Shumakov Clinic LLC are characterized by a high price for medical services. The positive side of Similia LLC is the good interior of the clinic creating an atmosphere of calm and comfort. The advantage of Doctor Shumakov Clinic LLC is the provision of a wide range of medical services.

One of the components of the competitiveness of a medical institution is its share in the medical services market (Table 2).

The data in Table 2 indicate that in 2016 the share of AU "RPVL" in the medical services market was 23.2%. Doctor Shumakov Clinic LLC held a leading position in the competition, its share was 48.9%. Similia LLC had a 27.9% share.

Table 2: Share of the AU "RPVL" and competing enterprises in the medical services market in 2016-2018

Name of company	Medical services market share,%			Deviation (+,-)	
	years			2017 from 2016	2018 from 2017
	2016	2017	2018		
AU «RPVL»	23,2	27,7	34,3	4,5	6,6
Doctor Shumakov Clinic LLC	48,9	48,3	53,1	-0,6	-5,2
Similia LLC	27,9	24,0	12,6	-3,9	-1,4

Competitive position of AU "RPVL" in the market of medical services in 2016-2018 improved. In 2017 its share increased compared to 2016 by 4.5 percentage points and amounted to 27.7%. In 2017 compared with 2016 this indicator increased by 6.6 percentage points and amounted to 34.3%. The share of Similia LLC in the medical services market has noticeably decreased (from 0.279 to 0.126).

Table 3: Criteria for the competitiveness of the services of AU "RPVL" and its main competitors in 2018 * , (points)

Criteria	AU «RPVL»	Competitors	
		Similia LLC	Doctor Shumakov Clinic LLC
Service quality level	7	5	7
Service popularity	6	4	6
Service uniqueness	4	7	6
Price of services provided	7	5	6
The complexity of services	8	6	6
Total	32	27	31

** The assessment was carried out on a 10-point scale*

The competitiveness of an organization can also be assessed by such indicators as the quality of services, price, novelty of the services provided, etc. The indicator of the quality of services in LLC Similia is 2 points lower than in AU "RPVL" and Doctor Shumakov Clinic LLC. The popularity of the services of AU "RPVL" and Doctor Shumakov Clinic LLC has a rating of 6 points. At the price of the services provided the highest number of points belongs to AU "RPVL". This indicator in Doctor Shumakov Clinic LLC is 1 point lower.

Fig. 1 : Services competitiveness criteria

The advantage of the studied organization over competitors is a higher level of quality and flexible pricing of the services provided.

Table 4: Indicators for evaluating the competitive position of AU "RPVL" and competing clinics in 2018 *, (points)

Indicator	**AU "RPVL"**	**Competitors**	
		Similia LLC	**Doctor Shumakov Clinic LLC**
Availability of developed infrastructure	4	3	7
Information availability	3	2	5
Scientific and methodological documentation	3	2	8
Business and personal qualities of workers, specialists, medical personnel	8	5	6

Compliance of the quality and the range of services provided to customers	7	6	7
Advantages over existing potential competitors	5	4	10
The ability to withstand competition while maintaining benefits for a long time	5	4	6
Total	36	26	49

** The assessment was carried out on a 10-point scale*

According to the assessment conducted in Table 4 Doctor Shumakov Clinic LLC has competitive advantages. The stability of this clinic is due to the availability of developed infrastructure and scientific and methodological documentation worked out in accordance with the standards.

The enterprise AU "RPVL" has a high quality rating, which corresponds to the quality value of Doctor Shumakov Clinic LLC.

Fig. 2: Indicators for assessing the competitive position of AU "RPVL" and competitor clinics

Clinic activities are financed from budgetary funds and entrepreneurial funds. Recently the amount of budgetary funds received at the institution's account has been moving more and more towards a decrease and the implementation of medical and preventive activities is due to the provision of paid medical services.

Paid medical services are rendered annually at AU "RPVL" for children and adults from the regions of our republic (2/3 of the total) and cities of the republic (1/3).

In Table 5 we consider the dynamics of income from the provision of paid medical services of the AU "RPVL" for 2016-2018.

The data in Table 5 indicate that the income from the provision of paid medical services of the studied organization for 2016-2018 annually reduced. In 2017 compared with 2016 the largest reduction occurred in such revenue items as outpatient medical services, functional diagnostics and consulting medical services.

Table 5: Dynamics of income from the provision of paid medical services at AU "RPVL" for 2016-2018, thousand rubles

Indicators	Years			Deviation (+/-)	
	2016	2017	2018	2017 from 2016	2018 from 2017
Revenues from the provision of paid medical services - total, including	5560	4626	4487	- 934	- 139
- consulting medical services (advisement)	1120	1041	1092	- 79	51
- outpatient medical services (10 days treatment)	3894	3341	3147	- 553	-194
- functional diagnostics	497	201	211	- 296	10
- other	49	43	37	- 6	- 6

In 2018 compared with 2017 outpatient treatment services decreased by 194 thousand rubles, other services by 6 thousand rubles. Positive dynamics is observed in consulting medical services, they increased by 51 thousand rubles. Revenues from functional diagnostics increased by 10 thousand rubles and amounted to 211 thousand rubles.

In Table 6 we consider the structure of income from paid medical services provided to the population by AU "RPVL" in 2016-2018.

Table 6: The structure of income from paid medical services provided to the population by AU "RPVL" in 2016-2018, %

Indicators	**Years**			**Deviation (+/-)**	
	2016	**2017**	**2018**	**2017 from 2016**	**2018 from 2017**
Revenues from the provision of paid medical services - total, including	100	100	100	-	-
- consulting medical services (advisement)	20,1	22,7	24,3	+2,6	+1,6
- outpatient medical services (10 days treatment)	70,0	72,2	70,1	+2,2	-2,1
- functional diagnostics	8,9	4,3	4,8	-4,6	+0,5
- other	1,0	0,8	0,8	-0,2	-

According to Table 6 it can be concluded that for the researched period the main share in the total income from the medical services provided is occupied by the income from the provision of outpatient medical services (more than 70%). Revenues from consulting medical services (advisement) occupy more than 20% of the total income derived from the provision of paid medical services.

Fig. 3: Structure of paid medical services provided to the population by AU "RPVL" in 2016-2018,%

Less than 10% are income from functional diagnostics and from other services.

In modern conditions to improve the efficiency of the economic entity a timely and competent analysis of revenues, expenses and financial results is necessary.

In Table 7 and Figure 4 we consider the dynamics of the indicators of revenues and expenses of AU "RPVL" for 2017-2018.

Table 7: Indicators of revenues and expenses of AU "RPVL" for 2017-2018, thousand rubles

Indicators	Years		Deviation, (+,-)	Rate of change, %
	2017	2018		
Revenues	14997	16343	1346	109,0
Expenses	16415	17098	683	104,2
Net operating result	-1418	-755	663	-

Revenues of AU "RPVL" in 2018 amounted to 16343 thousand rubles, their increase compared to the same year was 9% or 1346 thousand rubles. Expenses also increased by 4.2% and amounted to 17098 thousand rubles in 2018.

In 2017 and 2018 expenses of AU "RPVL" exceeded revenues as a result of which the organization received a loss in the amount of 1,418 thousand rubles in 2017 and 755 thousand rubles in 2018.

In 2018 compared with 2017 the amount of loss decreased by 663 thousand rubles.

Fig. 4: Dynamics of indicators of revenues and expenses of AU "RPVL" for 2017-2018.

A positive aspect in the activity of the medical institution is the excess of the growth rate of revenues over the growth rate of expenses.

Conclusion

Competition in the medical services market requires improving approaches to competitiveness management and the search for new sources of competitive advantages.

To increase the competitiveness and effectiveness of the activity of AU “RPVL” it is necessary:
- to expand the list of paid medical services;
- to provide the public with information about the clinic and its benefits, about the services provided;
- to develop a system of discounts on paid medical services;
- to accept collective requests for the provision of paid medical services;
- to increase income from functional diagnostics by expanding the list of services provided;
- to optimize costs through the economical use of material, financial and labor resources.

Abstract

The prospect and relevance of corporate governance in Russia is explained by the fact that it is increasingly positioned as a factor in the stability and profitability of a business in difficult conditions of economic uncertainty caused by a series of global challenges. To objectify the choice of managers with the appropriate competence and to avoid principal-agent conflicts, it seems important to study the factors that prompt the process of delegation of company management to professional management and to reveal its specificity that is characteristic of Russian realities.
This study shows that the topic of achieving corporate governance effectiveness does not lose its relevance, its importance increases many times to achieve the strategic goals of the company, increase its competitiveness and investment attractiveness. The success of strategic development depends on many factors, including productive, responsible, and trusting relationships of all corporate governance entities, primarily owners and hired management. In the strategic plan, those companies that have chosen the path of improving corporate governance gain more chances of their own growth, reliable consolidation of previously won leading market positions and acquisition of a global scale.

Keywords: Corporate Governance, Strategic Development, Corporate Sector.

Introduction

Defining the development strategy and formulating the strategic goals of the company, representatives of Russian business are striving to increase profits and ensure business stability in a long-term horizon. Increasing operational efficiency and reducing costs continue to remain important tasks of the corporate sector - this trend has remained relevant almost from the beginning of corporate construction. Company executives note that the main external challenges to Russian business are: geopolitical instability which has a direct impact on the general economic situation; the development of competition in a hypercompetitive struggle; market instability caused by sanction wars; the impact of innovative technologies that increase the vulnerability of activities to new digital technologies and business models. An increasing part of the business community, including large and medium-sized businesses, began to realize that without professional management of the company it is impossible to achieve strategic goals and adequately answer the series of challenges of the current stage of development of society.

Materials and Methods

The object of the study is the corporate sector of the Russian economy, which is in a state of searching for effective tools for managing equity.

The subject of the study is corporate relations that develop between the owners of capital and professional management in the process of delegation of company management.

The paper is based on the conceptual provisions of the modern theory of corporate governance in relation to the study of agent relations taking shape in a company at different stages of its evolution. The authors generalize theoretical and methodological approaches to the organization and to the increase of corporate governance effectiveness described in the works of foreign (Mallin C., Jensen M., Meckling W., Gompers PA, Ishii JL, Metrick A. et al.) and domestic (Asaul A. N., Belikov I.V., Verbitsky V.K., Ivashkovskaya I.V. et al.) researchers.

To justify the applicability of conceptual approaches to building corporate relations in modern conditions of the economic environment, we used the results of empirical studies conducted by the Center for Political Technologies Independent Fund, the PwS audit network in Russia, the Center for Corporate Development with the support of the Moscow Exchange, and the Association of Professional Investors.

The methodological basis of the study was the methods of comparative and abstract logical analysis, as well as the following methods: general logical, formalization, inductive-deductive, statistical. The application of the methods of theoretical, functional and structural analysis made it possible to generalize and structure scientific material on research issues, determine the logical relationship of strategic and operational tasks in the corporate management system, and identify trends in the formation of the Russian corporate governance model.

Research Results and Discussion

In Russia at the present stage of corporate construction the problem of separation of ownership and management is increasingly becoming the focus of scientific discussions. Initially, ownership and management in Russia were strongly connected, at present the process of delegation of real management by owners to professional managers is underway.

It should be recognized that there are a number of objective reasons pushing owners (principals) to delegate management to professional management (agent). Among these determinants is, above all, the growth of companies. Increasing the size of the company and expanding its presence requires a clearer organization of business processes and the use of more standard management schemes - otherwise, a decrease in management efficiency is inevitable. The second important determinant is the continuous increase in the complexity of business processes - this circumstance requires higher qualifications of managers, the presence and constant growth of their professional knowledge corresponding to the specifics of the business and its organization in the current environment of economic uncertainty.

The need to transfer property management to professionals is reinforced by subjective factors. First of all, this is an age factor affecting the problem of generational change in property ownership, and such a psychological factor as fatigue is also quite pronounced. Moreover, only in relatively rare cases can a business be effectively transferred to the owner's children or relatives.

A study conducted in 2016 by PwS, in which more than 2800 owners and heads of companies from 50 countries, including Russia, took part, revealed that a wide list of problems of economic genesis in private and family business is inevitably supplemented by not only commercial, but also emotional problems of relationships. One of the main problems is the transfer of family business management to the next generation. Only 25% of respondents confirmed the active participation of children in the family business, while only 9% of owners plan to transfer control to the next generation. A large

number of companies are likely to change owners over the next 5 years, while a number of executives found it difficult to answer how they see the future of the business in terms of its succession. 39% of owners of Russian private companies plan to conduct an IPO or sell their business in the long term, which is significantly less than in 2014 (50%) (the same indicator in the world is only 17%). 36% of respondents found it difficult to answer about the fate of their business in the future - this is 17% lower than in 2014 (19%). 11% of respondents plan to transfer ownership to the next generation, but with the involvement of professional managers, in 2014 there were only 4%.

It should be noted that a restrained attitude towards family business (in the narrow sense of the word) was also manifested at the stage of the formation of new Russian entrepreneurship, and remains today, but basically, it is associated mainly with small business. Examples of domestic public companies that grew out of family businesses are extremely concise - they include Binbank, Vozrozhdenie Bank, Promsvyazbank, TRIO group of companies, ZAO August and others. In addition, due to the lack of official statistics for family business, their real size in Russia is difficult to imagine.

All of the above gives owners a reason to transfer control to hired professionals with specialized education, who often have diplomas from Western universities and business schools. So, according to PwS data, in 2018, the organization of more professional management of the company was identified as their key task by 50% of respondents, while maintaining business in the hands of family members by only 6% of respondents (in the world this figure reaches 30%). This is primarily due to the impact of modern challenges on business, requiring professional solutions (Fig. 1).

Figure 1: The main challenges for companies during 2020-2022. (in %)

At the same time, despite the increase in the number of professional managers, there is also an acute shortage of qualified managers due to overtaking growth in demand for them.

An analysis of the process of delegating authority to hired management indicates its slowness and high soreness. According to researchers, this characteristic is a consequence of several reasons.

The first reason should be called the fear of losing control of the business, and the loss of control can lead to opportunistic behavior of managers and their pursuit of their own interests which do not always coincide with the interests of the owners. The inevitable consequence of this is conflicts, which, according to studies by the Unity recruitment agency, are the second most frequent reason for the change of top managers - they make up 31%, low productivity (33%) is in the first place. The experience of previous years has constantly demonstrated that such fears are not unfounded.

The source of the second reason is the natural inertia of management processes, because over a fairly long period of time the company's existence, management mechanisms were set up for its leader, who established, maintained and expanded most of his business contacts with the external environment, since Russian business is heavily built on personal connections. Therefore, the transfer of powers cannot be reduced to purely technical procedures for the transfer of cases. And finally, the third reason: we should not forget that many owners do not just combine ownership with management. They are also the founders of their companies - this means that they not only know their company well from the inside, they have a high degree of personal identification with their business. As a result, psychological factors are superimposed on socio-economic motives and calculations, and given the fact that many of the owners are relatively young and fully capable the problem becomes even more tangible.

But despite the difficulties the delegation of authority although slow and inconsistent, but still occurs: in some cases, there is a frequent change of managers who do not fully meet the high requirements of the owner, in others - the owners, unable to stand it, return to the positions of general directors at critical moments. We emphasize that the process of delegation of managerial functions is inevitable, its outcome, speed and depth depend, first of all, on the main owner - his activity, interest in further business development. If the owner does not want to take the risk associated with the delegation the intention to abandon the management of the company is accompanied by its sale.

The degree of delegation of authority largely depends on the market situation in which the company is located. According to experts, during the restructuring period combining the functions of the owner and the manager is beneficial, but after building the system and entering the company in fierce competition in the market, it is necessary to delegate management functions to professionals to a greater extent.

It is important to note that even if the delegation of a substantial part of the powers has taken place the owners reserve the right to sufficiently tight control over the activities of hired managers. If there is a dominant owner of the company the independence of decision-making by top managers is significantly limited and their dependence on the owner grows. As practice shows in large domestic corporations often even very influential top managers cannot make their own decisions. Thus, Russian reality is quite far from the "managerial revolution" proclaimed back in the 1930s as applied to the American economy. Of course with the dispersal of ownership the grounds for the independence of managers are objectively expanding but since the process of such dispersal is not going very fast, this affects the management structure to a small extent.

To reduce pain and prevent negative consequences for the owner, the transfer of authority should be carried out using internal control and audit mechanisms. There is a need to objectify this process using independent external audit tools. In addition, we should also indicate the special status of the corporate secretary who should turn from a technical executor into a special control center, as well as be responsible for disclosing information to the investment community.

The role of independent directors, audit commissions and committees of boards of directors is also growing. At the same time studies conducted by the TopCompetence Corporate Development Center show a decrease in the share of independent directors in the Board of Directors to 3 people in 2017 compared to 2016. In 2018, this trend was suspended: the average number of independent directors in the boards of Russian companies increased slightly - to 3.8 people but this figure continues to be significantly lower compared to European countries. Only in Turkey this figure is even lower and amounts to 32.7%. In Finland, the Netherlands and Switzerland the highest percentage of independent directors on company boards is 84% (Table 1).

Table 1: Share of independent directors on the Board of Directors: by country (in %)

Russia	Belgium	Denmark	Finland	France	Germany	Italy	Netherlands	Norway	Poland	Spain	Sweden	Switzerland	Turkey	Great Britain	USA
36,7	45,9	77,2	84	69,1	60	51	83,6	76,3	49,4	44	69,6	84	32,7	61,4	85

Despite the significance of all the problems of delegation of authority considered, the main one should be recognized as the lack of trust between the owner and management, which has a significant impact not only on the delegation process itself, but also on the further relations developing between them. For this reason, the formation of a team of managers is based on the "friend or foe" principle, based on the experience of collaboration, personal relationships, recommendations of third parties - as a result, top managers and owners continue to be integrated into one team. It should be recognized that business, as a rule, used to be built on a team basis, and this team-based "partnership" principle has been preserved in corporate governance today. Despite the fact that far from all the original teams survived - as they scaled out, they displaced someone, someone left voluntarily as a result of the division of the business - but the team principle of making key decisions involving a limited circle of partners who know and trust each other saved and projected onto relationships with managers.

It should be noted that the selection of managers for purely professional qualities is becoming increasingly common: the ideal professional portrait of a professional manager consists in particular of the willingness to solve new problems (34%), visions of new prospects (21%), salary expectations (16%), stability of the company (11%), etc. This is especially true for large public companies: the general level of management in them is increasing, and in medium and small companies the structure of relations remains more or less the same. At the same time, the requirements of qualified managers are also increasing, more and more intense competition is taking place for them, they often change jobs dictating their conditions as a result of the adoption of more advantageous offers.

Each owner, forming a team of professional managers, must clearly understand what strategic goals the invited top managers should be guided by. The goals can be related both to the objective results of the company's work - increasing the company's capitalization, growth of its net revenue and profit level, shareholder incomes - and to the growth of reputation capital - the importance of achieving positive PR effects is increasingly being declared which was hardly addressed before any close attention.

Moreover the vast majority of researchers indicate that the main goal for most large companies at this stage is to increase capitalization (or increase the value of assets for non-public companies). Performance indicators are now rather in the background. There is certainly a profit orientation but this target is not without contradictions: since the prosperity of the shadow economy Russian companies have learned not to show a high level of profit - not only from the pursuit of tax optimization but also from business security considerations. We believe that a certain inertia in this respect persists today.

Regarding the development of corporate governance itself as a strategic goal the situation is even more controversial. Objectively managers have no interest in such development and it occurs rather as a result of external pressure on management. The obvious interest of top managers is caused by the issue of increasing their income level which has significantly risen in recent years due to the deficit of highly qualified managerial staff noted above.

These statements are based on the results of a study according to which the motivation of management and personnel to implement the principles of corporate social responsibility / sustainable development in the organization's activities, including the connection of remuneration with the results in the field of corporate social responsibility / sustainable development, is an unpopular principle of the Corporate Governance Code - only 19% of the 100 largest by capitalization of

Russian companies whose shares are listed on the Moscow Exchange comply with it.

In addition, one cannot exclude the possibility of opportunistic management behavior favorable conditions for which are created due to the difficulty of the owner to exercise full control over the management activities. In this regard, a large role is given to the Boards of Directors which are largely called upon to regulate relations between owners and management. The obvious manifestations of opportunistic behavior are:

1) withholding information about the real market position of the company;
2) theft;
3) work with low return;
4) inefficient use of company resources;
5) conclusion of high-risk or illegal transactions;
6) unfair performance of assigned obligations;
7) damage to the business reputation of the company;
8) transfer of insider materials to competitors.

An analysis of the managers' income structure confirms international practice: there is a tendency to more closely link the income level of top managers with the results of the company - these may be significant bonuses or option programs. These efforts are aimed, among other things, at overcoming the previous practice of seeking interest on the side of the counterparty and realizing it in the form of "kickbacks". Among the 25 largest Russian companies, the leader in payments for professional managers is Nornickel which in 2018 spent almost 7 billion rubles on remuneration. In total, these 25 companies spent 54.5 billion rubles to pay bonuses to management (Table 2). The most paid were representatives of the oil and gas sector (they accounted for 17.3 billion rubles), banks (9.6 billion rubles) and metallurgical companies (9.4 billion rubles).

Table 2: Leaders in the payment of bonuses to professional managers

Companies	Bonus volume		The number of managers who received bonuses
	2018	2017	
Nornickel	6,8 billion rubles	6 billion rubles	23
Sberbank	4,4 billion rubles	3,9 billion rubles	18
Gazprom	4,3 billion rubles.	4,5 billion rubles	17
Rosneft	4 billion rubles	4 billion rubles	17
VTB	3,7 billion rubles	3,8 billion rubles	24

Regarding the management style it can be stated with great certainty that most of the Russian companies retain the legacy of the Soviet period - an authoritarian management style that can take different variations, for example paternalistic form or bureaucratic management. In both variations authoritarianism remains a key indicator of the managerial style of most Russian companies. And this may seem like a paradox: how authoritarianism and the previously mentioned team principle of business organization can be combined. The fact is that the team principle does not mean collegiality: as a rule, the head of the company is able and entitled to make individual decisions and the team is only his direct support. Collegial forms can work when discussing various issues until the top manager has determined his position and is not ready to make a single decision.

In this regard it is important to answer the question about the quality of management decisions and its dependence on the degree of effectiveness of the corporate governance system that has developed in the company. Most experts respond positively to this question. But the processes — managerial decision making and corporate governance — go largely parallel and the relationship between them is not always direct. At least, it is noted that effective company management is quite possible with poor corporate governance. But nevertheless, it is assumed that in the medium and even longer term this can play a tangible role.

Corporate governance performance can be judged from multiple perspectives. Well-managed companies achieve high results in the long term; it is easier for them to access capital. High management standards reduce investment risks - this is primarily due to the presence in these companies of highly paid managers with high qualifications. For an investor a well-functioning corporate governance system is an motive to provide capital at a lower cost. Companies with established corporate governance provide an increase in resources for shareholders, employees and the country as a whole, contribute to the economy and ultimately help the progress of society.

In conclusion, we note a number of factors that can directly affect the increase in the efficiency and strategic stability of the corporate management system:

1. The presence of clearly formulated strategic guidelines. Innovations in production, marketing, resource management and other areas of activity should be justified by the desire to get ahead of competitors and prevent the loss of market positions. At the same time, it is important to constantly ensure that the economic effect of innovations is higher than the cost of their implementation.
2. Minimization of management expenses. In a situation where management costs are higher than a positive result the question should arise about the restructuring of the entire management system or its individual links.
3. Improving the internal structure. A tangible effect in practice is provided, for example, by a transition from a functional-structural model of a company to a process-role or matrix one. This is not always possible but if it succeeds the number of hierarchical levels reduces, a horizontal (network) type of management develops, the gap between the leader and the executor narrows - as a result, the mobility and speed of the entire system increases.
4. Institutional aspects, the development of the regulatory framework. This factor relates primarily to the competence of the state. For the development of economic systems that would meet world standards it is necessary to create technological and economic institutions that take into account both world business experience and Russian traditions that shape the nature of entrepreneurship in Russia. An innovation policy is also necessary especially in the era of the digital transformation of society.

In the strategic plan strategically minded corporate executives will win who themselves will begin to solve a wide range of problems working for the future and strengthening their reputation, in contrast to those leaders who will be forced to do this under pressure from the state. They will begin to seriously appeal to broader interests, one can hope not only in order to redistribute property and control in strategic sectors.

Conclusion

Predicting the future of corporate construction in Russia it should be recognized that in the process of forming the Russian model of corporate governance it is inevitable to borrow a number of elements of foreign models that require adaptation to Russian realities. The modern look of the Russian model of corporate governance will permanently evolve and undergo a transformation due to a number of reasons including: a gradual decrease in ownership concentration; increasing requirements for company transparency; the inability of owners to manage the company in difficult turbulent environments which will inevitably lead to the delegation of an increasing number of functions to hired management. But the corridor of opportunities, it should be recognized, still remains limited - there is a so-called dependence on previous development coupled with strong structural and institutional inertia.

In general, in Russia as well as throughout the world the leadership model is gradually changing, the life cycle of top management is shortening. Top managers are faced with ever-increasing challenges, it is necessary to adjust existing and build new business models, manage to keep track of the market situation, and be more effective. Professional managers with a fresh look and a new approach, flexible and energetic are required. Boards of directors need to understand in which cycle the teams are. If managers have been taking their seats for the past 5-7 years, they are used to a certain type of

work and may not be able to quickly adapt to a flexible horizontal model and will not be able to respond to unexpected changes.

Abstract

World experience convincingly shows that the functioning of a market economy is impossible without a variety of forms of management, the simultaneous existence and interaction of which in social production on the basis of competition among them ensures an increase in production and an increase in the quality of products, contributes to the search and rational use of advanced forms and methods of organizing production. Among the variety of all forms of farming in agriculture, a special place is held by private subsidiary farming of the population. In statistical publications, the abbreviated name of this area is used - "households". These include private subsidiary farming of the population (farmsteads), collective gardens and vegetable gardens, summer cottages. The owners of private subsidiary and peasant farms are mainly rural residents, the owners and users of garden farming - mainly urban dwellers, residents of urban-type settlements. The functioning of the private sector is characteristic of agriculture from the very inception of agricultural production to modern days.In the context of the reform of agricultural relations, the collapse of collective farm and state farm production, the duration and complexity of the process of establishing new forms of management in the agricultural sector, the role of private subsidiary farming as the most flexible, fairly stable legal form in agricultural production is significantly increasing. At present, private subsidiary farming are one of the main sources of income for the population, food supply, and one of the areas of employment in conditions of unemployment. Revenues from the sale of surplus agricultural products make up a significant share of the budget of rural families, private farms contribute to the preservation of rural lifestyles, are often the only place of employment for rural unemployed.

The ongoing changes in the system of agrarian relations in Russia affect the small commodity sector, in particular the private subsidiary farming of citizens. The relevance of the research topic is due to the importance of private household plots in maintaining the country's food security and the well-being of the rural population and is determined by the need to improve the conditions for the functioning of private farming.

Keywords: Private Subsidiary Farming, Small Forms Of Managing, Rural Area.

Introduction

Private Household Farming Is One Of The Most Important Production Functions Of Households In Rural Areas.

The Concept Of Private Household Plots Is Given In The Federal Law "On Private Subsidiary Farming" Of July 7, 2003, Which Determines That "Private Plots Are Maintained By A Citizen Or Citizen And Members Of His Family Living With Him And (Or) Co-Operating With Him For Private Plots Meet Personal Needs On The Land Provided And (Or) Acquired For The Management Of Private Household Plots". The Same Law Confirms That The Production, Processing Of Agricultural Products In Private Household Plots And Their Sale Are Not Entrepreneurial Activities And Are Not Taxed. However, The Law Does Not Specify Some Important Points: The Nature Of Employment In Private Household Plots And Income Received From Its Management Is Not Defined; Despite The Presence In The Law Of The Term "Subsidiary" It Does Not Specify What Exactly The Need Is, The Size Of The "Surplus" Of Agricultural Products Is Not Established.

These Are the Basic Statutes That Characterize the Very Concept of Private Subsidiary Farming. It Differs from Peasant (Farm) Farming, Primarily in That It Is Not Always An Entrepreneurial Activity, And Is Not Always Of A Commercial Nature, I.E. Has An Auxiliary, Consumer Character And Is Carried Out Mainly In Order To Meet The Private Needs Of Its Members On The Land Provided.

Thus, The Characteristic Features of Private Subsidiary Farming of Citizens That Distinguish It From Other Types Of Activities Are:

- Firstly, The Activity of Production and Processing of Agricultural Products. In This Way, It Differs from Other Types Of Activity That Are Not Related To Agricultural Production;
- Secondly, Such Activity Is Not Always Entrepreneurial, Is Not of The Main, But Subsidiary Nature to Other Types of Activities of Citizens Conducting Such A Farming;
- Thirdly, Such Activity Is Mainly Not Commodity, But Consumer in Nature And Is Carried Out In Order To Meet The Personal Needs Of Citizens Conducting Private Subsidiary Farming;
- Fourthly, The Main Means of Production Is the Pre-Granted or Acquired Land.

At Present, Personal Subsidiary Plots Are One of The Main Sources of Income for The Population, Food Supply, And One Of The Areas Of Employment In Conditions Of Unemployment.

Revenues from The Sale of Surplus Agricultural Products Make Up A Significant Share of The Budget Of Rural Families, Private Farms Contribute To The Preservation Of Rural Lifestyles, Are Often The Only Place Of Employment For Rural Unemployed.
According to the 2006 All-Russian Agricultural Census, There Are 17.9 Million Private Farms In The Russian Federation: 15.8 Million Families In Rural Areas And 2.1 Million Families In Cities And Urban-Type Settlements. Private Farms Play the Role Of Stabilizing The Socio-Economic Balance In The Countryside.

The Functioning Of Small-Scale Production In The Countryside, As Well As The Study Of The Economic Problems Of The Development Of Private Farms, Were Described In The Work And Research Of Statesmen Of The Pre-Revolutionary Period S.Yu. Witte, P.A. Stolypin, Scientists N.P.

Makarov, A.V. Chayanov, A. N. Chelintsev. The Problems Of The Functioning Of Private Household Plots, The Prospects For Their Integration With Other Subjects Of The Agricultural Economy, The Possibilities For The Development Of A Cooperative Movement Are Reflected In The Contemporary Works Of Such Scientists As I.I. Bezaev, V.A. Dergunov, V.M.Zherebin, A.P. Zinchenko, E.G. Lysenko, E.S. Stroev, S.O.Rubakhin And Others.

The Foreign Predecessors Of Domestic Scientists Are Considered To Be The German Economists T. Goltz, F. Erebo, The Swiss Agrarian E Laura. Great Influence On The Views Of Agricultural Scientists Was Also Exerted By The Work Of German Economists I. Thünen, A. Weber On The Rational Distribution Of Productive Forces On A Regional Scale, And On The National Economy As A Whole.

Foreign Experience In The Development Of Farms Is Presented In The Works Of M. Buckett, F.G. Ashbrooke And Others

Materials and research methods.

The research involved teachers and staff of the Chuvash State Agricultural Academy. The scientific problem was studied on the basis of the Department of Economics, Management and Agro-Consulting using available information resources, including reference networks, electronic library networks, official websites of government agencies of the Russian Federation and Russian enterprises. The objects of the study were households of the population of Russia and the Chuvash Republic.

In the course of the work, the following research methods were used - general scientific methods of dialectics, analysis, synthesis, induction, deduction, analogy.

The results of the study

A significant contribution to the production of many types of agricultural products is made by small-scale enterprises, which include citizens conducting personal subsidiary plots, agricultural consumer cooperatives, individual entrepreneurs working in the field of agriculture, and peasant (farm) enterprises.

Let's consider the dynamics of the state of these farms according to the results of the All-Russian Agricultural Census of 2006 and 2016.

Table 1: The number of objects and the total land area per one census object by category of farms based on the results of the All-Russian Agricultural Centers 2006 and 2016.

No.	The name of the categories of objects of agricultural enterprises	The number of objects of agricultural enterprises, thousand units		The total land area on average per agricultural enterprise, ha	
		2006 г.	2016 г.	2006 г.	2016 г.
1	Agricultural organizations	59,2	36,4	6930,1	6018,1
2	Peasant (farmer) enterprises and individual entrepreneurs	285,1	174,6	103,0	240,9
3	Private subsidiary and other individual households of citizens	22800	18200	0,4	0,7
4	Nonprofit organizations of citizens	79,8	76,3	15,1	14,6

The data in the table show that the number of private farms decreased, according to the 2016 census, compared with the 2006 census, from 22.8 million units to 18.2 million units, however, while their total number is the largest among all categories of farms, and the land area per one LPH object increased from 0.4 ha to 0.7 ha.

Let us analyze the contribution of this category of farms to the total volume of agricultural production over the past fifteen years.

Table 2: The structure of agricultural production by farm categories in the Russian Federation, 2003-2017,%

Household Categories	2003	2005	2010	2014	2015	2016	2017
Farms of all categories, including	100	100	100	100	100	100	100
Agricultural organizations	42,6	44,6	44,5	49,5	51,5	52,5	55,1
Households	52,5	49,3	48,8	40,5	37,4	35,4	32,4
Peasant (farm) enterprises, individual entrepreneurs in the field of agribusiness	4,9	6,1	7,2	10,0	11,1	12,1	12,5

The data in the table indicate that the combined contribution of households (private household plots), peasant (farmer) households and private enterprises in the agricultural sector decreased from 2003 to 2017 from 57.4% to 44.9%. Over the past fifteen years, there has been a tendency towards a decrease in the volume of production in private farms and an increase in peasant (farmer) and private sector enterprises, which is explained by the transfer of households to this sector as part of participation in receiving grants to support beginning farmers in accordance with state programs.

The Chuvash Republic is the smallest and most densely populated region of the Volga Federal District, in which 40.2 percent of the republic's population lives in 1720 rural settlements. The territory of the Chuvash Republic is 18.3 thousand square km, of which 1,009.9 thousand ha (55.1 percent) are agricultural land.

The Chuvash Republic, as well as the Russian Federation as a whole, is characterized by an increase in the number of small forms of farming in the countryside, and both the small business sector, consisting of peasant (farmer) farms and agricultural consumer cooperatives, and private subsidiary farms are dynamically developing.

In the Chuvash Republic, there are over 235 thousand private subsidiary farms (according to the 2016 All-Russian Agricultural Census). Owners of private farms produce 63% of potatoes, 69.6% of vegetables, 61.8% of milk, 32.5% of eggs from the total volume of the main types of agricultural products produced in the Chuvash Republic.

Table 3: Agricultural Products by Category (at actual prices; million rubles)

	2015	2016	2017	2018
Farms of all categories				
Agricultural products	39347,2	39338,3	38736,9	37370,9
including: plant growing	20191,7	19369,6	17467,6	17183,4
animal husbandry	19155,5	19968,7	21269,3	20187,5
Agricultural organizations				
Agricultural products	15479,4	16912,1	16893,8	16560,1
including: plant growing	5719,9	6253,3	5869,3	5328,8
animal husbandry	9759,6	10658,9	11024,5	11231,3
Households				
Agricultural organizations	20383,2	18338,9	17768,0	16941,8
including: plant growing	11732,6	9933,5	8608,4	9126,3
animal husbandry	8650,5	8405,4	9159,6	7815,5
Peasant (farmer) households				
Agricultural organizations	3484,7	4087,3	4075,1	3869,0
including: plant growing	2739,2	3182,8	2989,9	2728,3
animal husbandry	745,5	904,5	1085,2	1140,7

Table 4: Structure of agricultural products by farm category (at actual prices; percent of total)

	2015	2016	2017	2018
Farms of all categories	100	100	100	100
including: Agricultural organizations	39,3	43,0	43,6	44,3
Households	51,8	46,6	45,9	45,3
Peasant (farmer) households	8,9	10,4	10,5	10,4

In 2018, private household plots of the population of the Chuvash Republic produced agricultural products worth 16560.1 million rubles. or 45.3% of the total output, including crop production at 9126.3 million. rub. or 53.1%, livestock production by 7815.5 million rubles. or 38.7% of the production of relevant products in the republic (table 3). [2]

Thus, we see that private subsidiary farming plays a key role in the socio-economic development of the region. In this regard, the issue of the formation of a special economic mechanism aimed at their full support and development remains relevant. For objective historical reasons, private household plots for the rural population are the main and often non-alternative type of economic activity and employment.
To date, many private subsidiary farms are large-scale, focused on the production and sale of products in order to make a profit. The entrepreneurship of rural residents to expand their farms is supported.

To this end, programs are being implemented at the federal and republican levels to support start-up entrepreneurs, which allow obtaining budget funds for the registration of an entrepreneurial form of activity: individual entrepreneurship or peasant farms.

The advantages of peasant farms or individual entrepreneurship over private farms are that they can legally work in the legal field:

- Obtaining state support in larger volumes than private subsidiary farming, that is, on a par with agricultural producers;
- obtaining a land plot for rent for agricultural production with an area of over 1 ha;
- attracting and creating additional jobs legally;
-increasing the size of the pension after going on a well-deserved rest;
- obtaining social support measures from the Social Insurance Fund:
-reimbursement of sick leave benefits and in connection with motherhood;
- payment for the treatment of workers at the expense of the Social Insurance Fund in case of accidents, etc.

In the Chuvash Republic, a number of forms of state support for small businesses are being implemented:

1) a grant is provided to support a novice farmer in the amount of up to 3,000 thousand rubles - for those planning to breed milk and meat cattle; up to 1,500 thousand rubles - for other types of activities;

2) grants are allocated in the form of a grant for the development of family livestock farms. To farmers who have expressed a desire to build a farm in the countryside, up to 60% of the cost of building livestock buildings and equipment are reimbursed from budgetary funds. The maximum grant size per family livestock farm cannot exceed:

- 10 million rubles, but not more than 60 percent of the costs — for raising cattle for meat and dairy industries;
- 5 million rubles, but not more than 60 percent of the costs - for other activities.

3) grant support for agricultural consumer cooperatives for the development of material and technical base. The maximum grant amount provided to one agricultural consumer cooperative is an amount not exceeding 70 million rubles and not more than 60 percent of the costs of developing the material and technical base of the agricultural consumer cooperative.

In just seven years (2012-2018), 285 novice farmers, 56 family livestock farms and 6 agricultural consumer cooperatives benefited from state support.

During the implementation of the grant support project for small-scale farming (beginner farmers and the development of family livestock farms), 763 jobs were created, revenue from these farms increased 11 times, the area cultivated by farmers - 6.5 times, cattle stock - 7 times.

The Ministry of Agriculture of the Chuvash Republic accepts applications from peasant farms and private subsidiary farms for the provision of grants from Agrostartap.

Grants are provided as part of the regional project “Creating a Farmer Support System and Developing Rural Cooperation”. The maximum size of the Agrostartap grant is determined in an amount not exceeding:

- 4 million rubles - for heads of peasant farms planning to use the funds of the Agrostartap grant to form an indivisible fund of the agricultural consumer cooperative, of which this peasant farm is a member (funds of the Agrostartap grant allocated to the indivisible fund of the agricultural consumer cooperative cannot be less than 25 percent and more than 50 percent of the total amount of funds);
- 3 million rubles - for other heads of peasant farms or citizens of the Russian Federation.

At the same time, the size of the Agrostartap grant cannot exceed 90 percent of the costs indicated in the plan of expenses of the business plan, and is determined by the tender committee taking into account the applicant’s own funds and the plan of expenses of the business plan.

The development of private subsidiary farming is one of the important directions of the socio-economic development of the republic. Its main goals are: increasing the level of employment, increasing incomes, replenishing the domestic market for goods and services, strengthening the role of the family in raising children through joint work, moving away from measures that encourage dependency, supporting initiatives, independence of citizens, and others.

Currently, members of private subsidiary plots, who are of working age and are mainly employed in private household plots, in our opinion, can choose one of the following options in order to ensure the accumulation of seniority, retirement, sick leave, maternity benefits, etc.

Saving employment. This option is most suitable for the rural population. If it is impossible to maintain full employment, since the reasons stimulating citizens to expand private household plots, at the same time determine the reduction in production in collective agricultural enterprises, it is advisable to transfer the employed to private household plots:

- to work on a part-time basis;
- to perform seasonal or temporary work;
- for civil law contracts (work contracts). When working under a contract, work experience is maintained. In addition, the employer must transfer all payments to extrabudgetary funds.

Organization of private agricultural enterprises by private owners (individuals) for servicing private households and hiring them as hired workers. Consumer cooperatives have the right to hire workers from among their members. Working hours in a cooperative are counted in the general and continuous work experience on the basis of entries in work books. The able-bodied members of private household plots not accepted into the consumer cooperative may conclude a contract with him.

Early registration of pensions for unemployed citizens - members of private household plots. At the suggestion of the employment service authorities, in the absence of employment opportunities for unemployed citizens who were laid off due to liquidation of the organization, reduction in the number of employees or staff and who have work experience regardless of interruptions in their employment, giving the right to full retirement pension (old age), including retirement on preferential terms, with their consent, the pension is issued ahead of schedule, but not earlier than two years before the retirement period established by the legislation of the Russian Federation.

Registration of able-bodied members of private household plots as unemployed. The time during which a citizen receives unemployment benefits in the manner prescribed by law does not interrupt the length of service and is counted into the total length of service. Unemployed persons are also subject to compulsory health insurance (payments are made by executive authorities). However, the duration of the payment of benefits in each period of unemployment may not exceed 12 months, in total terms - 18 calendar months, except as otherwise provided by law.

Registration as an individual entrepreneur. If the owner of private subsidiary farming has a side job (production of handicrafts, sewing clothes, knitting, etc.), he can buy a patent for these types of activities and become an individual entrepreneur. This will provide him with seniority and retirement. And in his free time from entrepreneurial activity, he can engage in private household plots.

Registration by the farmer. The expansion of private household plots can become an advisable change in its status and the registration of a peasant (farm) farm. Such a change in status solves the problems of seniority, retirement benefits and access to other social funds.

Currently, owners of personal subsidiary plots within the framework of the State program have an additional opportunity to increase the production of agricultural products in the courtyard due to soft loans. These measures certainly contribute to the development of private household plots and increase labor costs for agricultural production and increase its profitability. However, with the increasing public importance of the development of private household plots in the framework of a

priority project, labor in private household plots remains socially unprotected, income from it is not only non-indexed, but, on the contrary, depreciated due to increasing price disparity, the working time and income of private plots are not counted for calculating pensions, household members do not enjoy social protection for temporary disability, vacations, etc.

Conclusion

Thus, we see that private subsidiary farming plays a key role in the socio-economic development of the region. In this regard, the issue of the formation of a special economic mechanism aimed at their full support and development remains relevant. For objective historical reasons, private household plots for the rural population are the main and often non-alternative type of economic activity and employment. The task of improving the well-being of the rural population, creating a qualitatively new standard of living in rural areas is directly related to the development of private household plots.

In our opinion, it is necessary to expand state support for personal subsidiary plots of the population, because: firstly, private plots are the basis on which local staff are trained to organize peasant (farm) farming; secondly, personal subsidiary plots are an integral part of the infrastructure of the village, a carrier of rural culture and the identity of peoples; thirdly, personal subsidiary plots show better results of the efficient use of land resources in comparison with other forms of management, they adapt more quickly to market situations.

The studies on this topic allow us to draw the following conclusions and suggestions:

1. At different periods of its development, the economy of agriculture was characterized by the presence of different styles of life. Among them, over the centuries-long history of our country, a special role has been played by the small peasant form households with a private form of ownership, which, by their nature, purpose and function can be combined by a common name - private subsidiary plots.

2. The high viability and stability of private farms of the rural population, due to which they can function in any economic conditions, is due to the maximum approximation, in many cases, the coincidence of the spaces of the private subsidiary plots and the place of residence of peasants, which helps to minimize all types of costs, including transport and labor related to the delivery of labor to places of work and products to places of storage; private subsidiary plots have no dependence on the circulation of money capital, they require cash in order to complete the circulation of resources in a much smaller amount than large agricultural enterprises, and replenishment of these funds is carried out to a greater extent from family income derived from core activities in large-scale production, pensions or scholarships.

3. One of the main tasks of the socio-economic policy of the Russian state at the present stage is to overcome the degradation of the social infrastructure of the village, the revival of rural settlements, their comprehensive development, ensuring the proper quality of life of the people living in them.

4. The experience of organizing agricultural production indicates that private farms have always developed in conjunction with collective enterprises. Therefore, the search for the most effective forms of relations between private household plots and other subjects of agricultural production is an urgent task for modern science and social practice.

5. Currently, the rural farmstead has become the main source of income for the majority of the rural population and an increasingly important supplier of raw materials for the processing industry. Private subsidiary plots are an integral part of the agrarian economy of the republic, the social and economic importance of which has grown significantly in recent years.

6. The main reason restraining the growth of agricultural production of private household plots is the lack of a structure capable of organizing its marketing on acceptable terms. The solution to this problem could be the creation of a consumer cooperative with the tasks of providing various services, including sales.

One of the factors hindering the marketing of manufactured products is the remoteness of many rural locations from markets that are primarily located in large cities.

As before, the problem in the activities of private household plots is the acquisition of feed, and especially forage. Practically no wholesale deliveries of compound feeds, mineral fertilizers and other resources are made.

In private farmsteads, low-mechanized technologies based on manual labor are used, which makes rural labor unattractive for rural youth.

Private farms also experience in their development a number of difficulties of a legal, organizational, economic, financial and technological nature. All of the above requires the adoption of a system of organizational and economic measures to support private household plots of the rural population and stimulate the development of rural cooperation, the development and adoption of regional and district programs for the development of personal subsidiary plots in rural areas.

7. The bulk of the economically active rural population works on the farmstead - a private subsidiary farm, where labor, first of all, requires clarification of the content and legal status of the workplace, determination of the main and additional activities, and accordingly its impact on the formation of rural families' incomes.

8. The increased role of household plots of the population, their expansion require solving issues of cooperation of private plots. Further development of production in private farms is possible through various types of cooperation between them and integration with the public sector, which already has a material and technical base capable of serving small-scale agricultural production.

9. Cooperation can be carried out according to one of the following options:

- Creation of a legal entity (consumer cooperative), the founders of which are the heads of private farms (individuals);
- creation of a legal entity, the founders of which, along with individuals are collective farms, processing, trading and serving enterprises; joint use of machinery, land, livestock through the conclusion of contracts.

10. The development of private subsidiary plots is one of the important directions of the socio-economic development of the republic. Its main goals are: increasing the level of employment, increasing incomes, replenishing the domestic market for goods and services, strengthening the role of the family in raising children through joint work, moving away from measures that encourage dependency, supporting initiatives, independence of citizens, and others.

Abstract

Modern mobile commerce enterprises of any format and dimension, due to their flexibility and technological efficiency, are able to adapt to the changing environmental conditions and form new areas of activity in accordance with the challenges of the time. Mobile commerce is a continuation of e-commerce, the transfer of e-commerce into the most diverse mobile forms. Forms of the implementation of mobile commerce and its innovative mobile communication technologies allow you to transfer the information flow to the most advanced mobile gadgets of users, giving them complete freedom in their movements in space. The article discusses the objects of mobile commerce, provides a classification and analysis of market activities of subjects of mobile commerce. National peculiarities of entrepreneurship in the mobile commerce market of Russia are revealed. The quartet of the largest federal players in a completely mature mobile commerce market created a unique situation of the classical oligopoly in the face of imperfect competition, which put the domestic antitrust authority in a difficult position. Although the appearance of reliable competition requires a reduction in the financial success of each member of this strategic group, a kind of quadriga, in particular a decrease in marginal service revenue, a decrease in the growth rate of net profit, the reality of cartel conspiracy, especially in terms of price and tariff formation for a range of services mobile communications, of harmonization of non-price instruments, more and more becomes convex and tangible. And the extremely high indicators and characteristics of market concentration and tension for the oligopoly structure of mobile operators can become the source material of the case study for analysts of the territorial administrations of the FAS RF. While working on a report for the IBIMA Conference, the authors pay special attention to the construction and testing of a statistical model for analyzing the revenue from advertising activity of oligopolistic quartet participants in the mobile communications market.

The world caught me, but did not catch.
Grigory Sckovoroda

Introduction

The main solution of the diverse and numerous economic problems that have arisen in the country recently seems to be the implementation of the promising program "Digital Economy of the Russian Federation"[1]. This program is aimed at creating conditions for the development of a knowledge society in Russia, improving the welfare and quality of life of our citizens, the availability and quality of goods and services produced in the digital economy and using modern digital technologies, the degree of awareness and digital literacy of users, improving accessibility and the quality of public services for citizens, as well as economic security both within the country and abroad.

The deadline for the implementation of such a large-scale project is indicated by the end of 2025. By this time, the Ministry of Communications and Mass Media of the Russian Federation intends to create a broadband Internet coverage of the most remote corners of the country. The government's plans included a significant reduction in the cost of Internet service providers. However, the famous intervened circumstances related mainly to the entry into force of the so-called "I. Yarovaya package", consisting of two federal laws, which are combined with the tasks of preventing terrorist activities [1, 2].

According to the regulations, from 01.07.2018, operators have become obliged to store conversations, text fragments, images, sounds, video recordings and other electronic messages of users. A resolution of the government of the Russian Federation, adopted in April of the same year, specifies that it is necessary to keep the content of negotiations and messages for 6 months, and messages transmitted via the Internet, for one month. The economic side of the "package" formed the need for purchasing new, naturally, import and, of course, expensive equipment, on which the intercepted information will be accumulated and stored [11]. Accordingly, only increased tariffs for the services of providers will allow to compensate the costs incurred for the strict execution of the specified sacred "package".

Of course, in the summer of 2018, Russian Internet providers together and everywhere raised their tariffs by about 8-10%. However, the horn press services of major companies try not to associate such a reactive pricing scheme with promulgated regulations and argue that their employers in these matters are guided solely by balancing the interests of customers and consumers and dictated by the characteristics of the competitive situation in communication services markets. In turn, independent market experts believe that by the end of 2020 the cost of these services should not increase on average by more than 10% from the corresponding regional base levels of 2018.

Official statistics show that the domestic mobile communications market of wireless technologies is showing steady growth due to the increased sales of tablets, music players, smart phones and other gadgets, which allows you to go online not only from computers and laptops. At the same time, as networks are deployed LTE standard (Long Term Evolution) as the initial version of the 4G standard (development started since 2008), 3G coverage expansion (mobile Internet communication standard has been used for more than 20 years) of significant areas of the country as new coverage areas appear directly from mobile operators2.

Without a doubt, the mobile Internet is a global information environment of a decentralized nature and turns out to be quite an effective means of providing business activities in the mode of application of advanced information technologies. Moreover, a modern and sensitive Russian business is gradually being digitized on the background and under the circumstances that foreign business has long acquired the status of, so to speak, "digitalized". Although both abroad and in the homeland, the main business process that is striving for digitalization, and other industrial production processes clearly need a new round of growth in their productive capabilities, which is especially important for Russia. Thus, at the International Labor Forum in St. Petersburg, A.L. Kudrin said on 02/28/2019 that in terms of labor productivity of $ 23 per hour on average in the national economy, we are noticeably behind even our neighbor and friendly Turkey3.

However, against the background of the unsatisfactory development of the infrastructure of basic communication devices, traditional skepticism and undisguised mistrust of Russian consumers of the older age groups to the newest information technologies, the state of the mobile communications market and mobile commerce can be considered as starting, h. e. with a low initial level of reference and a very narrow client segment. Therefore, the largest Russian operators brought down their impressive avalanches of advertising messages on the head of the domestic consumer through very powerful TV channel injectors.

Naturally, it is precisely on television channels as the largest media tool in reaching the audience that advertisers spend the most. And here, to the average user, constantly updated standards of available communication are not important; for him it is important that the connection is available. A slightly

more advanced and inquisitive user wants to actively download a variety of applications, quickly view the news feed in social networks and enjoy watching high-quality movies On-line.

Advertising messages from TV screens inform the consumer about the emergence of new types of services and about new content formats, as well as opportunities to get new entertainment and new quality of life. It is highly artistic and even, in a certain sense, talented advertising messages that explain to a potential buyer that, for example, thanks to the 5G standard, the Internet of Things, unmanned cars, smart houses, robotization of production and business processes, telemedicine (remote operations, including surgical) in real time, education (visual learning through VR-broadcast of the best practices of the educational process), advanced computer games and even interactive virtual reality will be transferred from the pages of technological media in the daily lives of Russians.

Russian telecom operators are not lagging behind the world trend and cooperate with the world's leading suppliers of network equipment – corporations Ericsson, Huawei, Nokia, which develop 5G devices. Most domestic analysts are convinced that the widespread introduction of 5G will begin after 2020. Today, the 5G level is more a concept than a technology, because there is no uniform standard yet. In order for the 5G connection to enter into wide consumer use, it is necessary to develop technical requirements, select frequencies and switch to fundamentally new equipment.

Potentially innovative resource elements of the existing communication systems can be assessed by the diversity of the latest basic production assets owned by the players of the mobile communication market, i.e. economic entities (EE), as well as in the quantity and quality of the information services they provide. At the same time, the quantity and quality of these services unambiguously depend on the quantity and quality of the communication facilities themselves, which are used by mobile operators when building their own information systems based on the elements developed by companies [11].

Here we note that an objective, and even more so, a quantitative assessment of the quality of communication services is extremely difficult, since every individual subscriber is clearly subjective about the relative level of quality of services provided under the influence of many explained and taken into account signs-factors, as well as covariance factors of a stochastic nature individually. However, the psychophysical state of the consumer of services and the peculiarities of his perception of external information in the advertising format become the decisive determinant of this impact [8].

To other specific features of the formation and development of the mobile communications industry is the following. It is here that industry innovations are characterized by genuine scientific and technical novelty, and the development and production of innovative products, works and / or services actually forms a new market for pioneer goods, inaccessible, and therefore free for some time from any industry competitors. However, high market competition for the first time declared economic good, which only in words and with great difficulty is recognized as innovation, however, and unfortunately, is the most important sign of the absence of noticeable innovations. Thus, in the author's understanding, radical, breakthrough innovations represent the true path to the commodity markets for the economic good [7].

Formulation of The Research Problem

Competition in commodity markets and advertising activity of market players in time go hand in hand. Traditionally, advertising has served as a marketing tool everywhere. To a certain extent, advertising allowed the FOrmation of customer Demand and STImulate Sales (for Soviet marketers and applied specialists, the FODSTIS system in the abbreviation of the 70s of the 20th century) products, works and services that the population needed, including our country, where, as you know, competition did not have. And classic marketing provided appropriate activities to promote the economic benefits of the end user in a well-studied and saturated market [12].

However, the movement of time is non-stop, and views on research subjects are fluid and changeable. And today: “The essence of marketing today is not at all in serving customers – it is necessary to outwit,

circumvent, and defeat your competitors. In short, marketing is a war in which a competitor is your opponent, and the buyer is a territory to be conquered" [4.5]. Consequently, in the newest marketing concept, the advertising tool turns into a weapon of war and begins an independent wingedly expressed militaristic terminology – "shooting at bastions", "Fire on headquarters!", Other jargon and turns of professional common vocabulary4.

In scientific use, advertising warfare now refers to a kind of verbal-visual rivalry of one or several brands in the advertising space in order to assert its superiority. And the meaning of the military-advertising confrontation of market players is to call the "attacking" brand and not at all a peaceful response an ambitious competitor [13]. Modern dynamics and trends in the development of global communications and PR technologies lead to the fact that EE is becoming increasingly difficult to successfully operate in its business areas without choosing a strategy that allows you to take an optimal and reliable position in the market space, while guaranteeing that all the benefits are rationally organized and calculated defense.

So, in innovative entrepreneurship, in modern business, a situation arises when the use of classic advertising communications becomes insufficient. An objective marketing need is being formed for the organization of an adversarial EE campaign. At the same time, the basis of the modern trade doctrines and concepts of promoting economic benefits is the struggle between the brands of these EEs. Of particular interest in this regard is the accumulated and interesting practice of advertising wars abroad [4.13]. But gradually, instructive and domestic experience is accumulating, where, in particular, the belligerent one is noticed, and for our case pattern, the person involved in the person of the operator Tele2 with its rather provocative content advertising billboards5.

The advertising war begins to act as an independent and self-sufficient strategy for practical application of general marketing tools, and it turns out to be aimed directly at supporting and promoting the brand in a competitive environment as on the real battlefield, without diverting to seemingly secondary considerations of economics and logistics. And such a verbal-visual duel of universally recognized brands in the advertising space has another combined goal – achieving unconditional and fixing long-term customer loyalty.

Such truly expensive, well-thought-out and planned information efforts are ultimately aimed at the final approval of real or retouching of imaginary competitive advantages. The local objectives of the advertising war are the desire to significantly break away from the nearest market rival, create their own specific and unique brand, and capture the largest segment of the target audience of consumers of economic benefits.

The difference between advertising and marketing wars lies in the fact that it concerns only aspects of advertising positioning, in its rigid variant, of an economic entity and does not concern pricing policies and pricing strategies. And, in particular, does not affect the tools of the procedure of price dumping. Today, the organizers of advertising wars are increasingly being used as a popular tool of psychological pressure on a competitor, down to psychedelic methods of influencing consumers on the economic good.

At the same time, it is extremely important for the market analyst and any official market controller (for example, Roskomnadzor – Federal Service for Supervision in the Sphere of Communications, Information Technologies and Mass Communications of the Russian Federation) to determine reliably whether this advertisement is misleading or not. It is especially important to investigate which claims are made in advertising about the properties of specific goods, works and services, which are about prices, tariffs, which are about the hedonic merits of the economic good [14], and which are about the terms of delivery or the benefits of a branded service.

Thus, in relation to the comparison of prices and tariffs, the legislation of most countries of the European Union and the Russian Federation (RF) prohibited the indication in the same advertising offer at the same time the price of the current (declared) and the price of the previous (old), as a rule, higher.

Was this practice of advertisers misleading the consumer, or was it really the case in such cases about sincerely informing those interested and wanting to know absolutely everything about the consumer? There is no answer to this question, since advertising can be really unfair, but not necessarily at the same time misleading the consumer. In connection with the adoption of new regulations in such cases, all kinds of inaccuracy, misleading the consumer can be the subject of a special trial and fall under strict law enforcement practice6.
In the 60s of the 20th century, the concept of bad faith was associated, by advocates of consumer rights, as a rule, with clients of advertising agencies (customers), and not with consumers or the public in general. Half a century later, the concept of unscrupulous advertising implies in most countries both market rivals (their guilt) and consumers or the public (the effect of their perception), regardless of how the advertising message is presented. At the same time, all actors of the market process, including the advertising industry itself, have long recognized that TV and the Internet are especially powerful sources and an effective medium of information (media) from all available.

Consequently, these sources of advertising messages must be subject to appropriate regulation and especially tight control over the content of the advertising offer as a message to an unidentified, not stratified and generally unidentified consumer of any economic benefit, including mobile services.
In recent years, the decline of the authority of most Russian television channels has led to a proportionate increase in the interests of the user of gadgets to the information capabilities of the Internet, which is still sluggishly regulated and ineptly controlled. However, against the background of the threats announced by the government structures of various tightening and in connection with the impending international sanctions against the blocking of the Russian Internet channels, the ideas of creating a sovereign, h. e. Autonomous RuNet7, where the control of Roskomnadzor, after the adoption of the relevant Federal Law on the protection of RuNet from external threats, will, of course, be absolute.

Setting the Research Tasks

Traditionally, the use of economic and mathematical methods was caused by the need for proper justification when making a rather limited timeframe of a management decision in an already functioning economic system or because of the need to obtain reliable forecast ideas about the effectiveness of projects, strategies and programs. The general scheme for implementing the strategy of sustainable development of a conditional EE in the external environment, taking into account the conditions of its operation, is shown in Figure 1.

The process of formation of the market status of a sectoral business structure is closely related to the analysis of the competitive environment in industry markets and actualizes the problems that determine the current functioning of the EE in the studied market, and to a much greater degree that information support the development of a development strategy for the market of services in its future parameters. Such well-developed strategies, as a rule, competitive in nature, are a set of marketing and production measures organized by the entrepreneurial structure itself on the principles of a flexible combination of the internal and external environments of the EE (see Fig. 1).

The performance of any entrepreneurial structure in the free and highly competitive mobile communications market in the context of globalization and the information network economy depends not so much on the available total production capacity of the structural business units, on the material, technical, technological and personnel characteristics, but on sustainable and equilibrium financial condition of units in the region. In the regions, rationality, the effectiveness of the chosen management system and ways of strategic development, economic justification and final management decisions play an exceptional role, especially in the Russian context.

Fig. 1: The components of the environment of functioning of the economic entity, forming the mechanism of interaction of competition factors in the mobile communication market[8] (developed by the authors)

According to the dominant concept of J. Schumpeter [29], all strategies of entrepreneurial structures in commodity markets provide for solving problems of maximizing profitability levels, which turns out to be strategic goals not only in an unstable economic environment resembling the Russian situation. The prosperous financial position of the company ensures the reliability of securities on the stock market, the preservation of jobs, the retention of market share and even the strengthening of competitive positions in consumer price segments and in innovative niches.

In these cases, economic-mathematical models of different complexity and dimension are constructed, representing some analogs of behavior in the market space of the studied economic system with different variants of the estimated model parameters, as well as possible sets of specified counting variables. Successfully constructed models will serve as the basis for the adoption, with the help of a selected or

assigned performance criterion, of the so-called optimal or close to optimal, required by any hierarchical level (center) of managerial decision responsibility.

When solving many economic problems, the analyst has to deal with the problem of choosing such a management decision in the context of explicit / implicit uncertainty. Under the problem situation is understood as the uncertainty of the conditions for the fulfillment of one or another supply, sales and service, etc. operations and the uncertainty of the manifestation (actions) of individual elements of the socio-economic system, the functioning of any components or even independent mechanisms for the implementation of business processes that affect the efficiency and effectiveness of the implementation of the adopted or in assessing management decisions already taken.

For the correct formalization of tasks in such uncertain situations, many mathematical methods are used, of which a well-developed tool is, by the way, game theory, which allows one to quantify the uncertainty level of a local economic situation, to accept both the proper (within the legal field) and (according to the chosen criteria) managerial decision, which, as is commonly believed, provides for obtaining the necessary effects of any nature that form the basis of goal setting [6], but importantly, the effects of the equilibrium state of EE.

One of the popular tasks of this class is the task of a stable and equilibrium market sales, associated with the capabilities of the FODSTIS system for products, works and services through fairly powerful means of *PR* and commercial advertising. And although the organization of advertising business in the marketing schemes of entrepreneurs paid enough attention, and techniques for creating advertising messages to the potential consumer have achieved some perfection, the economic rationale for the budget of advertising efforts, their basic analytics of many EEs in some cases are inconclusive. The latter entails known financial losses in the implementation of projects for the market activity of these EEs in the fight for ratings.

We will not touch on the organizational side of the advertising business, the essence of its business processes in the market promotion of economic benefits to the final consumer, who, under the influence of the advertising message as one of the essential factors, formed the corresponding solvent consumer demand. This demand is the target consumer and presents mobile services during the purchase and sale transaction. But to substantiate the required size of costs in the composition of the cost of services of mobile operators for advertising efforts, you can refer to the analysis methods that go back to the game theory with a nonzero amount9.

Suppose that the existence of only two, but very large companies (as was originally in the domestic mobile communications industry) in the local (federation subject) or commodity market of the enlarged region (federal district), or even the All-Russian market, along with the neighboring markets (CIS countries) and further afield, the market segments sufficiently provide goods, jobs, services equivalent to an unusually advanced, fully knowledge-intensive and innovative product mix.

Naturally, both designated EEs are interested in a constant increase in the volume of their market sales. And although, according to market rules and in accordance with a customer-oriented approach to business understanding, these EEs are considered to be competitors fighting for their loyal customers, their interests in the market space are not are completely or markedly opposed, h. e. In their mobile network business, these companies are not in the ordinary sense antagonists.

Suppose that both EEs dominate in a certain commodity market by aggregate volume of their sales, which is quite typical for collaborating and affiliated companies, for example, in the sphere of trade (well-known and popular trade networks), e-commerce (even more well-known and even more popular thanks to advertising leading domestic mobile and mobile service operators operating in all segments of the telecommunications market and others) and so on. The dynamics of the shares of the main players in the mobile communications market is shown in Figure 2.

Fig. 2: Dynamics of indicators of the market share of the main Russian mobile operators by the number of subscribers for the period 2006-2016, %. Source of information: open data J'son & Partners Consulting (handling date: 11.03.2019).

A common example of such mobile operators is the "quadriga" or the "big four" of the Russian format of oligopoly companies (PJSC VimpelCom, PJSC MTS, MegaFon and *Tele*-2) that work so smoothly and synchronously that the attentive market observer has certain ideas and there are serious suspicions that the owner of these seemingly different companies is the only but very highly qualified manager-organizer with the appropriate support at the highest level and with very strong but not advertise, foreign bonds.

However, the author of this material, even at the level of his own value judgment, does not say anything like that. Nevertheless, it is extremely interesting and useful to explore such assumptions and facts in the area of market-political analytics or even to assist the units of the Federal Antimonopoly Service of the Russian Federation (*FAS RF*). The start of this initiative can put someone voluminous journalistic investigation of the mobile market in the spirit of: company "A" *VS* of company "B"?[10]

Let their total sales (*m – mutual*) coincide with the value of realized customer demand (*Demand*) in the *t-th* period – $D_m^{(t)}$. Suppose also that for each company the coefficient of effectiveness of advertising efforts is determined. This ratio is able to take into account what proportion of the commodity market belongs commensurately with the company, depending on its cost of advertising offers. Accordingly, the total sales volume for the period of related (according to the working hypothesis of a conspiracy nature) adopted for service and discussed above is made up of their *i-th* volumes $D_i^{(t)}$, $i = \overline{1,n}$.

Russian viewers, for example, are impressed by the costs of expensive television advertising by such giants as PJSC VimpelCom, PJSC MTS, MegaFon, *Tele*-2, etc. It is enough to recall such entertaining and popular advertising memes of one of the well-known companies related to the cost of traffic services in rub. per unit of time, as "Not a tariff, but Tariff", "Unlimited", "Zabugorishche" and similar auditory tenacious memes, turning into the Russian newspeak. Suffice it to recall the catchy and optimistic slogan of Beeline – "Live on the bright side!".

Brand awareness of a company is achieved, firstly, by using color gamut. So, the red color fills the advertising messages of the MTS with purple bookmarks, the lilac-green colors are assigned to the Megaphone, the traditional yellow-black accompany Beeline, the gray-blue shades of the commercials with scenario and American Hollywood film company trick tricks accompany *Tele*-2.

Secondly, the use of celebrities in commercials is also regulated and fixed in time. Recognizable showmen D. Nagiyev, D. Malikov, M. Boyarsky, M. Gorban - this is MTS. The singer I. Labutenko, the

bench mark Vlady from the "Cesta" group and the footballer A. Miranchuk, sometimes the coach S. Cherchesov is a Megaphone. A very capable and expressive A. Revva, the mythological Deadpool from "not ours" comics, etc. – this, of course, Beeline with his system of tracking advertising campaigns over time. And the second-tier actors, but outwardly representative K. Samoukov, O. Nazarov and others provide the entire gamut of aesthetic demands of the viewers of most *TV* channels from *Tele*-2.

Methods and Tools of Research

As a research technique, the author used a group of problems from game theory. For further calculations on the case under study, we introduce the following notation for two companies of mobile operators, although in the most general case there are four major market players:

$C_1^{(t)}$, $C_2^{(t)}$ – costs of advertising the first and second company in the *t-th* year;

a_1, a_2 – the effectiveness of the promotional efforts of the first and second companies are fairly stable in size in the medium term;

the ratios in the volume of sales of services are determined by the accounting balance equation $D_m^{(t)} = D_1^{(t)} + D_2^{(t)}$.

The difference in the values of the efficiency ratios of the studied companies is explained by the fact that services, such as mobile communications, etc., are not in demand among consumers. And it is obvious that in the prevailing market conditions, the volume of sales of the services of the first company will be equal in *t-th* year equal to

$$D_1^{(t)} = D_m^{(t)} \frac{a_1 C_1^{(t)}}{a_1 C_1^{(t)} + a_2 C_2^{(t)}}, \tag{1}$$

and of the second company to

$$D_2^{(t)} = D_m^{(t)} \frac{a_2 C_2^{(t)}}{a_1 C_1^{(t)} + a_2 C_2^{(t)}}. \tag{2}$$

To simplify the economic situation in the industry and similar activities of the homogeneous companies under study, we will assume an approximate equality of the costs of both companies, with the exception of the costs of forming their advertising budget. In this case, the balance sheet profit from the sale of services by the first company, taking into account the prevailing industry average standards for the formation of profit η_{Π}, will be equal in *t-th* year[11]

$$\Pi_1^{(t)} = \eta_{\Pi} D_1^{(t)} = D_m^{(t)} \frac{\eta_{\Pi} a_1 C_1^{(t)}}{a_1 C_1^{(t)} + a_2 C_2^{(t)}}. \tag{3}$$

Similarly, the gross profit from the sale of services of the second the enterprise turns out to be numerically symmetrical by its algebraic notation of the calculation formula

$$\Pi_2^{(t)} = \eta_{\Pi} D_2^{(t)} = D_m^{(t)} \frac{\eta_{\Pi} a_2 C_2^{(t)}}{a_1 C_1^{(t)} + a_2 C_2^{(t)}}. \tag{4}$$

Taking into account the cost of advertising efforts, the first company's *net inc*ome (but not the planned net profit) $\Pi_1^{(t)}{}'$ will be

$$\Pi_1^{(t)\prime} = \Pi_1^{(t)} - C_1^{(t)} = D_m^{(t)} \frac{\eta_{\Pi} a_1 C_1^{(t)}}{a_1 C_1^{(t)} + a_2 C_2^{(t)}} - C_1^{(t)}. \tag{5}$$

Similar financial performance for a second company is defined as

$$\Pi_2^{(t)}{}' = \Pi_2^{(t)} - C_2^{(t)} = D_m^{(t)} \frac{\eta_\Pi a_2 C_2^{(t)}}{a_1 C_1^{(t)} + a_2 C_2^{(t)}} - C_2^{(t)}. \quad (6)$$

Suppose, by resorting to the methods of commercial intelligence or industrial espionage, the first company was informed (that is, it turned out to be quite familiar) about the cost of advertising efforts from the second company. Although in reality, knowing the market contingency in the activities of these twin companies, one could not resort to any clever conspiracy.

However, in this case, financial analysts of the first company may look for such a value $C_1^{(t)}$ (the size of the advertising budget) at which the net profit $\Pi_1^{(t)\prime}$ will have the maximum value. For a specific search for extremal values, it is necessary to differentiate the right-hand side of expression (5) by variable $C_1^{(t)}$ and equate the resulting first partial derivative of the resulting dependence to zero

$$\frac{\partial \Pi_1{}'(C_1^{(t)}, C_2^{(t)})}{\partial C_1^{(t)}} \equiv 0; \quad (7)$$

The partial derivative of the first order in a variable $C_1^{(t)}$ forms the corresponding equation with respect to the variable $C_1^{(t)}$.

$$D_m^{(t)} \frac{\eta_\Pi a_1 a_2 C_2^{(t)}}{(a_1 C_1^{(t)} + a_2 C_2^{(t)})^2} - 1 = 0. \quad (8)$$

From where

$$D_m^{(t)} \eta_\Pi a_1 a_2 C_2^{(t)} = (a_1 C_1^{(t)} + a_2 C_2^{(t)})^2. \quad (9)$$

Similarly, the second company, in order to maximize its net profit, mirrors the amount of advertising efforts $C_2^{(t)}$, based on the already familiar ratio given in the formula from (7)

$$\frac{\partial \Pi_2{}'(C_1^{(t)}, C_2^{(t)})}{\partial C_2^{(t)}} \equiv 0. \quad (10)$$

Taking into account the completed and understandable procedure, as well as the derived expression (6), the following entry was obtained

$$D_m^{(t)} \frac{\eta_\Pi a_1 a_2 C_1^{(t)}}{(a_1 C_1^{(t)} + a_2 C_2^{(t)})^2} - 1 = 0, \quad (11)$$

either

$$D_m^{(t)} \eta_\Pi a_1 a_2 C_1^{(t)} = (a_1 C_1^{(t)} + a_2 C_2^{(t)})^2. \quad (12)$$

The right parts in expressions (9) and (12) are the same, therefore, their left parts are equal, h. e.

$$D_m^{(t)} \eta_\Pi a_1 a_2 C_2^{(t)} = D_m^{(t)} \eta_\Pi a_1 a_2 C_1^{(t)}. \quad (13)$$

Thus, the correlation of the cost of advertising efforts EEs

$$C_2^{(t)} = C_1^{(t)}. \quad (14)$$

From expressions (9) or (12) equally after simple transformations and taking into account the relation from expression (14) it follows

$$C_1^{(t)} = C_2^{(t)} = \frac{D_m^{(t)} \eta_{\Pi} a_1 a_2}{(a_1 + a_2)^2}. \quad (15)$$

Substituting the obtained values into the formula from the expression (5) for the cleared profits of the first company, we find

$$\Pi_1^{(t)\prime} = D_m^{(t)} \frac{\eta_{\Pi} a_1 C_1^{(t)}}{a_1 C_1^{(t)} + a_2 C_2^{(t)}} - C_1^{(t)} = \frac{D_m^{(t)} \eta_{\Pi} a_1 C_1^{(t)}}{C_1^{(t)}(a_1 + a_2)} - \frac{D_m^{(t)} \eta_{\Pi} a_1 a_2}{(a_1 + a_2)^2} =$$
$$= \frac{D_m^{(t)} \eta_{\Pi} a_1^2 + D_m^{(t)} \eta_{\Pi} a_1 a_2 - D_m^{(t)} \eta_{\Pi} a_1 a_2}{(a_1 + a_2)^2} = \frac{D_m^{(t)} \eta_{\Pi} a_1^2}{(a_1 + a_2)^2}. \quad (16)$$

Similarly, the purified profit (operating) of the second company from the formula of expression (6) is equal to

$$\Pi_2^{(t)\prime} = D_m^{(t)} \frac{\eta_{\Pi} a_2 C_2^{(t)}}{a_1 C_1^{(t)} + a_2 C_2^{(t)}} - C_2^{(t)} = \frac{D_m^{(t)} \eta_{\Pi} a_2 C_2^{(t)}}{C_2^{(t)}(a_1 + a_2)} - \frac{D_m^{(t)} \eta_{\Pi} a_1 a_2}{(a_1 + a_2)^2} =$$
$$= \frac{D_m^{(t)} \eta_{\Pi} a_1 a_2 + D_m^{(t)} \eta_{\Pi} a_2^2 - D_m^{(t)} \eta_{\Pi} a_1 a_2}{(a_1 + a_2)^2} = \frac{D_m^{(t)} \eta_{\Pi} a_2^2}{(a_1 + a_2)^2}. \quad (17)$$

Behavior strategies of market players { $C_1^{(t)}, C_2^{(t)}$ }, that lead to reliable, in terms of the quality of calculations, the values of the purified profit $\Pi_1^{(t)\prime}$ and $\Pi_2^{(t)\prime}$ are considered fairly stable and balanced in the sense that if the first company applies the market strategy discussed above, and the second company uses any other conditional market), then the indicator of the purified profits of the second company will necessarily decrease in proportion, and vice versa.

Mathematically, it is easy to show, using the method of incomplete induction, that for the oligopoly quartet under study ("quadrigue", "big four") in general, the net operating profit of each of the *i-th* mobile operators that operate on the corresponding product market in synchronized link mode in the corresponding *t-th* year, takes in the relevant volume range for *a very small* sample – $\langle n \rangle \in \{N\}$ – the following form

$$\Pi_i^{(t)\prime} = \frac{(\sum_{i=1}^{n} D_i^{(t)}) \times \left[(\prod_{i=1}^{n} a_i^2) - a_i^2 \right] \eta_{\Pi}}{\sum_{i=1}^{n} (a_i)^2}, \text{ при } 2 \le n \le 5. \quad (18)$$

The formula from the expression (18) can be considered quite workable and make the necessary calculations on it for the mobile communications industry, including an assessment of financial indicators and market development directions telecommunication services. The authors of the article will use the formulas from expressions (16) ÷ (18) for calculating financial analytics in the second part of the article.

Results

Analysis of market share, financial indicators of cellular operators and directions of development of the telecommunications services market in the Russia. According to the results of 2016-2018, the mobile communications market has stagnated, although, starting in 2017, companies began to take decisive steps towards changing their strategy towards digitizing their global market activities. Such a turn in the long-term strategies of mobile communication development has become forced for operators,

since in order for the business to survive as an industry, really competing companies need to think about individual strategic changes.

Digitalization of business in the activities of each market player occurs in different ways, and in this competitive struggle, each company is obliged to choose its strategies for interacting with the country's digitalization policy. So far, we note from ourselves, all the main players are in the same starting conditions, which confirms the working hypothesis of a unified strategy for the development of the sectoral mobile communications market.

And what is the strategy of market behavior will actually «winning», yet difficult to say. On the one hand, if the market telecom operators had previously been associated exclusively with voice services, now the range and the list of services they sell has expanded considerably. On the other hand, it is becoming more and more difficult for market players to earn money in this business: in a competitive struggle, the cost of services decreases, the subscriber base is already distributed between operators, subscribers use instant messengers that allow them to communicate generally free of charge.

Separate results of economic activities of the main participants of the cellular communication market for 2017 are shown in Table 1. The reduction in the market share of small mobile operators shows one of the trends of the past ten years (see the graph lines in Figure 1). Today, they collectively own only 1% of the market share, while in 2007-2010 all other EEs occupied 10-12% of the market. The current situation also requires separate professional comments with the identification of special features.

Table 1: Indicators of financial and economic activities of the "big four" for 2017 *

Number in order	Name of indicator	PJSC MTS	MegaFon	PJSC Vimpel Com	*Tele*-2
1	2	3	4	5	6
1	Revenue, billion rubles	442,9	321,80	327,5	123,0
2	Net profit, RUB billion	56,0	20,52	7,6	-5,5
3	The change in revenue compared to with the previous year, %	1,70	1,80	19,80	16,20
4	Change in net profit / loss compared with the previous year, %	15,60	-29,00	-63,20	64,60

**Calculated by the author according to the Annual Report of the studied companies.*

The fight for the first position in the ranking unfolds between MTS and MegaFon. Some analysts believe that a large proportion belongs to MegaFon. Others insist that this operator is inferior to MTS, which is also developing steadily. Whichever analyst is right, the gap between competitors is insignificant – about 1%. Strengthening the position of MTS and MegaFon had a negative impact on the Beeline brand, which since 2006 has lost 12% of the market, and at the beginning of 2019 the share of the latter dropped to 23%. *Tele*2, which entered the market in 2003, has been demonstrating good momentum for several years in a row. Despite a shorter history than its competitors, by 2019 its share reached 15%, and further growth to 20% would not surprise.

Literature Review

Theoretical refinements to the working hypothesis of the study. Strategic management accounting is a relatively new area of accounting and analysis, so the boundaries of this area are not yet strictly defined and are quite vague. There are so far no restrictive prohibitions and unified regulations indicating what and how should be developed. And the available scientific literature in this area is heterogeneous, incomparable and contradictory. The definitions of the categories and terminology of the conceptual academic apparatus are verbose and not concrete.

For example, the term strategy in this article is not accidental at all and is not a tribute to frivolous fashion for the application of various innovative technologies, in particular, the use of the concept of so-called strategizing [27] everywhere, always and without much reason. But, nevertheless, it should be distinguished in relation to the topic of the stated research of the concept of competitive strategy and the strategic mission of the organization (as the strategy development).

So, a competitive strategy describes how an economic entity (EE), in the form of a company, is going to compete in its industry, and how it will try to gain a competitive advantage. The strategic mission of EE can be presented in conjunction with the continuous so-called spatially-temporal continuum (from lat. continuum – continuous, solid) – from the first to the last stages of the life cycle of the actual market product in time, including the creation, implementation, active use and, finally, its withdrawal from the market space [3].

In the first part of the article, the basic multi-agent variants of the market environment in which each specific agent, i.e. EE is forced to take into account the actions of other agents and to establish for themselves how they will affect his own well-being. The presence of various competitive variants of the environment in which the goals of agents are conflicting, leads to the emergence of a family of special search problems in real opposition, often called mathematical games.

In the mathematical theory of games as with a zero sum with an appeal to the Maximin|Minimax method (the Minimax von Neumann principle, 1928), and with full information, which is one of the branches of applied economics, any multi-agent versions of the functional environment are considered games, provided that the influence of each agent on others is significant, regardless of whether the agents are cooperative or competitive structures. However, it is better to consider variants of a specific market environment with a sufficiently large number of agents as certain economies, and not as purely mathematical games [15.240].

Applied economic aspects of game theory are widely used in the analysis of serious business situations related to decision-making, for example, in cases of insolvency and bankruptcy of electric power plants, when organizing a variety of auctions, in particular, on the distribution of the spectrum of radio frequencies of mobile operators, in projects for the development of innovative industrial products and in setting prices for them, as well as in developing national defense strategies, etc.

Returning to the object of our study, the behavior of the four main companies in the industry of means and operators of mobile communications (MTS, MegaFon, Beeline and *Tele-2*) in several recent economic episodes, such as a refusal to work in Crimea after 2014; almost simultaneous, for the same period of time refusal to withdraw roaming, surprisingly synchronized and equivalently funded, massive advertising campaign, etc., prompted the author to express a certain working hypothesis. Do not these companies make up a certain coalition managed from a single peculiar think tank of global strategic initiatives?

But, let's say, Mobile TeleSystems PJSC (MTS), which is a leading telecommunications operator in Russia and the CIS countries, has already been operating in Crimea since the end of June 2019, i.e. The operator's management is thinking about the development tactics of their company. But Megafon, Beeline and *Tele-2*[12] have not yet directly connected to network traffic, although by law they are

obliged to turn around and work in new federal subjects from June. Possibly, such an order from the administrative authorities does not quite fit and is coordinated in the development strategies of the other three operators.

In proposing and substantiating his working hypothesis, and then in constructing an analytical model of cost-effectiveness of advertising campaigns for mobile operators (see the report of the author at the 2019 Conference [28]), the author adhered to generally accepted canonical definitions from the field of game theory and probability theory [16, 17].

The subject / object, to which possible actions and interests are attributed, is called *the player*. The set of players will be denoted by n, (in our case $n = 4$), while the exhaustive set is N, $n \in N$. The subset $K \subset n$, $K \neq \varnothing$, will be called the so-called *coalition*[13]. A coalition can consist of one player and all n. Each K-coalition has a certain set of actions X_K, which we will call *the set of strategies* of K-coalition, and the elements of this set $x^K \subset X_K$ – strategies of K-coalition.
The global interests of the emerging coalition $K \subset X_K \neq \varnothing$ are set in the form of a transitive preference on the set of all outcomes of the decisions made S. The market preferences that arose for a player are usually denoted by a special mathematical sign – ⊢. More details on the strategies of socio-economic behavior used in best practices can be found in [18, 19]. The emerging individual preferences of specific players, essentially competing needs, can be represented by individual utility functions f_i, $i = \overline{1,n}$ on the set $\{S\}$, which are commonly called *payoff functions*, or simply winnings of a particular player. But not all *multi-agent* variants of the market environment include cooperating industry players.

On the one hand, players with conflicting utility functions are in a state of competition with each other. This actually means that any player in a competitive environment must, firstly, recognize the presence of other active players, secondly, predict some of the other player's possible plans, thirdly, determine how another player's plans will affect his own plans, and fourthly, to establish the best way of their behavior, taking into account competently identified and measured external and internal influences. Therefore, in conditions of real market competition, as well as in conditions of bona fide cooperation, a transparent statistical modeling procedure is needed with a description of the true plans of another player.

On the other hand, in a truly civilized competitive environment, player actions cannot be included in the joint plan and affect its periodic adjustment. In this sense, if in a multi-agent market environment of a similar product there are other active players of similar weight categories with whom you have to cooperate, compete or coordinate their market actions, then each player prepares an independent, not always overlapping plan, but necessarily reflecting the vision of their own household activity in the foreseeable or forecast period [11].

For the presentation and formation of considerations taking into account preferences, it is advisable to use the achievements of *the utility theory*, which indicates that each prevailing economic state of the market environment has a certain degree of usefulness for the player and that the player prefers an updated state with a higher utility for himself. Preferences, being expressed in terms of countable characteristics of utility, can be combined with probabilities given in the general theory of rational decisions or in best practices for making informed management decisions [20, 21].

There is experience in successfully combining the tools of utility theory with probability theory and mathematical statistics [15.778] in order to create such a market agent that is able to make rational decisions, thereby maximizing the utility function, taking into account what the agent is convinced of and aims for. How can one not recall the correct and pertinent observation of Jean-Baptiste Say (1767-1832): "Utility tells objects value, which is a measure of utility" [22.124]. Such an agent can make decisions with a claim to indisputable outcomes in situations where, due to information uncertainty and the existence of conflicting goals, the so-called *the logical agent* remains unable to successfully solve anything at all.

For example, an important risk factor of economic and legal nature – the so-called legal risks (as opposed to market risks) – may become tax legislation in force in the service markets in which agents operate. It is known that new domestic regulations are notable for their unpredictability and lead to significant uncertainty, which complicates the formation / processes and/or policies / planning of both financial and tax nature.

This, in turn, prevents the obtaining of acceptable results on the validity and reliability of decision-making regarding business development. An object of certain concern may also be the unpredictable interpretation by tax authorities of such fresh normative acts, for example, in relation to transfer pricing, controlled foreign companies, subsidiaries with uncontrolled participation interests, tax residency, and more.

Discussion

Market players in the domestic mobile communications industry. VimpelCom, the first domestic mobile operator, where Alfa Group was a controlling auctioneer for a long time (its share reached 44% at the time), had an undeniable advantage in extremely promising non fixed-line telephony markets[14]. As a rule, there were no problems with attracting equity capital back then. And as the author of the article presents, the auctioneers of large-scale projects are a heterogeneous set of investors, each of which is unlikely to fully understand, and most importantly, in detail, the concept of project financing, which is now very popular in the regulation of economic processes.

There are always different groups of investors who evaluate the real prospects of the recipient company differently depending on the composition and the degree of influence of various auctioneers. If you project what has been said on any market organization, then the increase in the administrative and economic influence of one auctioneer or the existing greater degree of control of another auctioneer can both attract various kinds of investors to finance and implement the project, and scare them equally.

When it comes to the development prospects of the company, it should be understood what kind of investors the EE is going to attract, and what strategy is being laid in the development of this EE. It should be borne in mind that both well-known basic strategies are absolutely viable. As for the structure of blocks of shares and other securities, the generally accepted, fairly objective judgment is this: it is always easier for the management of EE to work when there are no large shareholders, and EE is 100% a public joint-stock company (PJSC) with a dispersed investor base.

In such conditions, much greater strategic freedom of action is provided for EE. In other words, the choice of certain steps is less limited by some competitive features of the market good or by direct barriers that are associated with the presence of heavyweight shareholders who have their own interests that conflict or at least do not coincide[15] with the interests of other participants.

There is a certain opinion that with the beginning of the active introduction of new generation networks, the mobile communications market will return to a situation of fierce competition for subscribers between leading operators. But it’s not worth talking about any toughening of the competition – only its focus is changing. Competition is not at the expense of each other in a quartet format, i.e. in the battle for new subscribers – the competition of the participants takes place parallel to each other for their loyal subscriber base. And, as noted above (in this report), the competition does not come at the expense of a sophisticated mechanism of pricing and tariffs, but towards a significant increase in the quality, creativity of services, and the innovativeness of the service offered, which generally and friendly underpins the final quality of economic benefits for consumers.

At the same time, the individual breakthroughs ahead of someone from the quartet agreed upon, according to the author's judgment, form a gap in time factor of only three to five months, which disappears rather quickly. All operators have built approximately the same (technologically and in

terms of equipment) networks, offer similar sets of services in the product lines. And compared with foreign prices, low prices for one minute of the service and suspiciously close to each other tariffs in terms of their level, firstly, complicate their further decline for purely economic reasons. Secondly, prices and tariffs cannot fall out of the restrictive framework of special conciliation protocols on pricing, which, according to the author, the quartet participants adhere to. Analysts from the Federal Antimonopoly Service of the Russian Federation usually call these protocols exactly the cartel price conspiracy.

Analysis of the financial activity of mobile operators

In the process of operating the base stations of mobile operators, it is necessary to monitor the effectiveness of the facilities and units located, evaluating all the gross, technical, economic, financial and commercial indicators of the organization's business activity. To control the level of traffic, income and activity of subscribers, it is also necessary to take into account the number of subscribers, in particular, have the information necessary to study the level of operator presence in a particular administrative-territorial zone and / or geographical location. The coverage area of cellular communications by all market agents of the territory of the Russian Federation is shown in Figure 3, and the main indicators of the companies from the Big Four are shown in Table 2.

Fig. 3. 3G coverage area in the Russian Federation as of February 2019. All operators. Source of data [24].

According to analysts at *QBF*, a management investment company, the Russian telecommunications market has been static since the beginning of 2014[16]. The annual increase in the number of subscribers tends to zero, as the market for mobile services is oversaturated. For 2016, the positive dynamics of the IFRS net profit index $\Im_{\Pi_{N_{110}}}$ was recorded only for MTS[17]. As a rule, the national currency rate is an important factor taken into account when conducting a financial analysis, since a large share of the operating expenses of mobile operators is historically tied to the dollar exchange rate.

In addition, the weakening, in turn, of the Russian ruble reduces revenues from foreign roaming against the background of a noticeable drop in foreign tourist flow, as well as other categories of *VAS* revenue (*VAS – Value Added Services*)[18]. In combination with a decrease in real wages, disposable incomes of the population and a weakening of the Russian ruble by the moment in question, the mobile communications companies under review showed a record-breaking synchronized drop in margins (*ROS – Return On Sales*, in percent as the ratio of the difference between the wholesale price and cost of services to this very price).

In the conditions of a long and significant decrease in disposable income, domestic households showed a tendency not earlier characteristic for consumers to save on communication services. According to the Federal State Statistics Service, from 2013 to 2017, the share of relevant expenses decreased from 2.0% to 3.3%. At the same time, users switched to cheaper tariffs and refused additional *SIM*-cards. According to the results of 2018, as shown in the Table 2, MTS gross revenue fell nearly 6%, but net profit increased 34.62%[19]. The operator himself explains that the development of roaming in many respects influenced this situation[20]. According to analysts, about half of foreign roamers use the services of MTS, so the behavior of the "guest" network affects MTS more than other market operators.

In addition to the relatively good dynamics of other financial indicators, last year the operator recorded the most noticeable increase in customers, despite the fact that in the "quadriga" it has the largest consolidated subscriber base, exceeding 102 million subscribers. At the same time, Beeline PJSC, on the contrary, showed negative dynamics, having lost about 1 million customers over the analyzed period.

According to the results of 2018, PJSC *Tele-2* shows almost three-fold growth in gross revenue compared to the previous year, which is largely due to an increase in the monthly *ARPU* metric – *Average Revenue Per User* – average income from an active subscriber, which found its way reflection in the table 2, although such tariffs were provided in advance. Naturally, this company, together with Rostelecom, is developing

Table 2: Indicators of financial and economic activities of the "big four" according to the results of 2018*

Number in order	Name indicator	MTS	Mega-phone	VimpelCom-Communications (Beeline)	*Tele-2*

14	Operator Market Share, %	29,77	28,34	21,14	19,91

Notes:

** It is calculated by the author according to the Annual Report of the studied companies for the corresponding period (https://www.finanz.ru/balans/megafon, https://www.finanz.ru/balans/mobile_tele-systems_adrs, etc. by operators);*
*** Consolidated revenue according to the audit of PricewaterhouseCoopers Audit JSC in 2019;*
**** Together with the state holding Rostelecom;*
× – So far, according to the author, the reporting information for 2018 is not convincing.

several promising business areas at once. And if through the state holding network in 2018, 90% long-distance and 80% of international connections of users of *Tele-2*, then Rostelecom itself operates on the operator's networks as a virtual operator (*MVNO*). For example, in Moscow and St. Petersburg, *Tele-2* under the *Sky Link* trademark provides mobile services in IMT-VC-450 and LTE-450 standard [26]. An effective outcome of such cooperation was the inclusion of 1.19 million new subscribers by the beginning of 2019.

Formally, in an updated format, according to the author of the article, such a carrier duo of cellular communications is a strong and serious market competitor, capable of crowding out other members of the Quadriga in the coming years. The impressive dynamics of gross revenues, which almost completely turned into *EBITDA* and, together with the "dried up" characteristic of *CAPEX* [21], gave a forecasted "zero" in the operating cash flow, which makes it possible to objectively and professionally evaluate professional competencies financial and economic block of the company.

The restrictions on decryption of the financial statements of *Tele-2* do not allow for a more detailed analysis, however, it is obvious that the accumulated long-term debt decreased in the reporting year by about 22 billion rubles. It was redistributed along other lines of the balance sheet, which lowered the critical ratio of debt to *EBITDA* to an acceptable level. In other words, the financial condition of the operator was somewhat more stable than it was imagined two years earlier.

Since mid-2018, it can be cautiously noted that the domestic mobile communications market has become a full-fledged multi-agent market of four federal players in structure resembling an oligopoly (see the sector diagram in Figure 4), but in a spirit that claims to be a cartel with signs of cooperative behavior. Although the launch of *Tele-2* at the Moscow region, which is key for Russian operators, negatively affected the quality of market pricing schemes[22].

Over the past year, MegaFon PJSC lost about 1/3 of its retained earnings and became the leader in reducing this indicator, which is directly related to the increase in operator expenses due to stagnation of gross revenue. Nevertheless, some market analysts believe that such a low economic result was affected by the negative dynamics of the value of the operator's shares in the stock market. So, in order to support his quotes, he began to pay tangible, long-promised and long-awaited dividends. Directly, the representatives of the operator company justify their threatening drop in gross revenue by not completely convincing their dependence on the influx of migrants, which has significantly decreased, according to the Federal State Statistics Service, to the analyzed period (2018-2019).

Study limitations

Analysis of pricing policies, tariffs and methods competition of mobile operators. The standard strategy for the behavior of Russian operators in the cellular market in their competition over the past three years, practically until 2017, was a steady reduction in prices / tariffs and the offer of unlimited packages, as well as the offer of the so-called *converged services*. However, market specialists draw attention to the fact that schemes for a longer price reduction in the long term can also cause noticeable negative consequences in the form of a decrease in gross revenue, which was already observed in 2018. It seems that in the future, the most rational for the economic activities of operators will be the introduction of such a model of pricing and tariffs, when the unit of tariffing will be the unit amount of transmitted data, and not the time interval, say, the minute of voice communication, during which the signal will be served by the operator.

It turns out that convergent company offers, combining fixed (wired) and mobile services, are still a popular technique for maintaining revenue and retaining customers. In particular, it is possible to monetize this convergence due to additional paid accounting services in the *VAS* system. So, for example, Beeline collaborates with *Alfastrakhovanie*, offering subscribers, complete with the Internet, a service to protect their apartments from natural and other disasters. At the expense of lower prices, the MTS operator filled the retail network with data-generating devices, which are more cost-effective for the operator than push-button telephones.

And the participants of the quartet of operators adopted a tacit agreement on "reconciliation", deciding to abandon the dumping policy and switch to holding their subscribers. Market analysts immediately, but cautiously enough, characterized like an agreement the terms "price conspiracy", "price cartel" and other soft formulations. Attempts at non-market pricing are not uncommon everywhere. Thus, the Accounts Chamber of the Russian Federation in its operational report on the implementation of the federal budget for 2017 notes that mobile communication services are rising at an alarming rate, and the growth rate of prices and tariffs exceeds the corresponding average dynamics in other sectors of the national economy[23].

In particular, the supervisor indicates that among the types of services observed, communication rose in price in the first half of the year by 2.4%, which is significantly higher than the average cost of services, which amounted to 1.3%. A year earlier, the chain tariff index for communication services grew by 2.1%. Thus, the Accounts Chamber has included the communications sector in the group of the most dynamically growing sectors of the services sector, which includes medical services + 2.3%, pre-school education + 3.3%, passenger transport + 4.9% and some other types of consumer services. Moreover, the noted price gains exceed the corresponding level of inflationary expectations for the same period throughout the price range.

After a record drop in mobile revenue and margin contraction in 2016, market players began to almost simultaneously change their pricing strategy according to the marketing principle, known for its paradoxical nature, *more services, but at a higher price*, including providing them at archive rates. The first stage was the abolition of unlimited *data*-tariffs in early 2017, the second was the increase in prices for become limited *VAS*. The actions of the operators coincided with a local recovery of real wages and led to a noticeable acceleration in the growth rate of mobile revenue in the Russian Federation, as well as the expected improvement in the quality of margins. Nevertheless, these actions have interested specialists from the FAS bodies, and they may have a rather short effect as a result, in particular, due to the small number of conditionally independent players on the mobile communications market. In fact, the oligopoly model of market competition "quadriga" confidently steps towards monopolistic competition.

The authors of the article do not have reliable information about market shares and the main financial indicators of mobile operators for 2018, so the calculations for the proposed model will be limited to economic results until 2018. However, at the beginning of 2019, the mobile cellular market in Russia gained a stable configuration in terms of the number of subscribers and is now represented by four named quite equal players. They own more than 99% of the entire market (see the sector diagram in Figure 4), but none of the operators violates the antitrust laws. The largest market share was won by MTS. Despite the decrease in the number of subscribers by 2.13%, the operator was once again able to maintain a leading position. According to the results of the analyzed year, the share of MTS reached almost 30% of consumers, which amounted to 78.3 million subscribers.

The second position is occupied by MegaFon, which suffered less loss in the number of subscribers. Their number decreased by only 0.22%, however, this fact did not take MegaFon to the leading position, and the operator's share slightly exceeded 28.0%. The subscriber base of this provider was equal to 75.4 million people. Following MegaFon with an indicator of 21.14% comes VimpelCom (the Beeline market brand). This operator also suffered losses in the customer base due to a decrease in the number of subscribers by 0.25%, and it amounted to 58.16 million people. The last place in the quadriga so far belongs to the Tele-2 operator with a market share of about 20%.

Fig. 4: Sector chart of the market shares of Russian mobile operators of the number of subscribers as of the end of 2018 in the territory of the Russian Federation as a whole. Data Source: J`'son & Partners Consulting

The tasks of the largest mobile operators analyzed are not limited to the provision of cellular services. Their current innovation is already aimed at optimizing the business processes of various industries and the formation of *a smart* digital infrastructure. Technical features of the functioning of mobile networks existing innovative, as well as future technological generations, and specific aspects of the marketing work of mobile operators are described in detail in [26].

Prospective directions for the development of the cellular communications market

Almost everyone uses mobile gadgets and their services today, and, in connection with this circumstance, the possibilities of expanding the client base due to traditional services, which are becoming less popular, are essentially minimal. The launch of high-speed 5G standards, most likely, will not significantly change the situation. The best solution for mobile operators may be to expand the boundaries of the industry, for example, by offering to a market consumer media services in various formats of television, online music and the development of mobile commerce.

And here the video, as the most popular content in the near future, is recognized as one of the drivers for the development of the telecommunications services market. Firstly, the volume of these video media increases the average revenue per ARPU user. Secondly, as a widely demanded service, its provision affects the loyalty of subscribers. In addition, there are mainstream IT sectors that can open up new financial opportunities for operators and increase industry competitiveness. These include well-known projects in the field of M2M (Machine-to-Machine – literally in Russification – machine-to-machine interaction), BigData-based solutions, cloud services, the Internet of things, etc. So, "smart" cars, "smart" houses and cities need network, as well as services through which such things will communicate. According to MegaFon managers, in 2017 the number of M2M devices increased 2.2 times, and by 2020 38 million such devices are expected to appear.

Despite some partial loss of subscribers, the studied mobile operators demonstrate an increase in gross revenue, while the main revenues come from the sale of mobile services. The increase in revenues from the sale of mobile services is determined by the action of the following factors: refusal of operators from price competition schemes; avoiding unlimited tariffs; income from additional services provided to corporate clients.
However, for the purposes of statistical comparability of indicators, it is advisable to compare companies in the mobile communications sector at the level of the Russian business segment, a key source of gross revenue. According to VEON24, in the last year of the retrospective period, the entire

relevant segment generated slightly less than 50% of operating income. However, Megafon this share is 98.6% of revenue, and MTS – 93.0%.

Conclusion

Advertising activity of market players. Considering the specifics of the business of the mobile operator companies, in particular, the fact that almost every fourth Russian is a client of each company from quadriga, an advertising message for them is one of the key determinants of the promotion (promotion) of services. At the same time, with the improvement of the market and technologies, the range of services has significantly expanded and acquired a package nature. The number of mobile services today is impressive, their structure is diverse, the differentiation of prices and tariffs is noticeable even for individual operators by market niches, segments and consumer sectors.

The above distinguishes the specific market of consumers of mobile services from others and, of course, increases the advertising activity of players, forcing them to choose the optimal set of media channels for themselves to communicate with the consumer. In the Russian advertising market, and the total advertising costs of the largest mobile communication operators are measured in many billions, the Quadriga participants for a long period of time invariably occupy a leading place in the tops of the most advertised categories of goods, works and services. These advertisers determine the behavior of the category as a whole.

The total expenses of mobile communication companies on advertising activity are unevenly distributed across various media and advertising media. There is still an increase in the share and volume of television advertising purchases and a commensurate decrease in purchases from other media, more radio and the press, and less outdoor advertising. A special object of research is advertising efforts on the Internet. The advertising activity of the remaining players, comprising 0.84% (see Fig. 4), which are mainly represented by regional mobile operators, is extremely small compared to the listed companies and in most cases is inconstant.

Due to the fact that there is actually high competition in the Russian market of mobile services in conditions of its proximity to saturation, it can be assumed that the costs of direct advertising are unlikely to be seriously reduced. Most likely, in this case we need to talk about the dependence of sales of services on advertising costs. Preliminary results of statistical analysis indicate that the relationships between these indicators in the studied operators are in a measurably narrow confidence interval. The only exceptions are market neophytes, who in the current situation need not only serious financial investments to overcome the market entry barrier, but also much more significant investments in connection with the public and marketing efforts.

Specific calculations based on the developed analytical model of the net profit of the quadriga of mobile operators [28], as well as a quantitative assessment of the level of competition in the telecommunications market using O. Herfinadal – A. Hirschman[25] species concentration $\Im_{c}^{(HH)}$ and tension $\Im_{ten}^{(HH)}$ indices, index of R. Linda $\Im_{d}^{(Lin)}$, index of A. Salai $\Im_{d}^{(A)}$, measurements of the market capacity of these services and critical mass the author will spend upon receipt of updated reliable statistics for 2019.

In continuation of this study the model calculations from expression (18) will be given. After that analytical calculations will follow with a more detailed discussion of how mobile cellular operators plan to hold their positions in the market, improve financial performance and attract new customers. However, the recruitment of new customers is hampered by the fact that Russian consumers find themselves in extremely difficult economic conditions, much more complex than the mobile communications industry itself.

[6] The profile committee of the Council of the Federation on constitutional legislation and state construction recommended for approval by the Chamber a number of laws, including those aimed at combating the dissemination of false information. The first package of the two laws prescribes responsibility for the dissemination of inaccurate data, which created the threat of harm to the life or health of citizens, a massive violation of public order. According to the law on "fake news", the prosecutor's office may apply to *Roskomnadzor* if information found to be unreliable in the online media. 05/13/2019 The Federation Council approved the draft law on blocking "fake" news adopted by the State Duma of the *RF*.
[7] https://www.rbc.ru/technology_and_media/15/02/2019/5c666af39a79478787a38cd3. (the date of circulation: February 18, 2019).
[8] It provides for the full activity of all established functions of the market – regulating, stimulating, distributing, informational, intermediary, sanitizing [3].
[9] A game with a non-zero amount (*Nonzero sum games*) is a mathematical class of games in which not necessarily winning one player implies losing the other, as is observed in zero-sum games. In such a game, market agents have the ability to communicate to each other about their intentions, and in some cases even coordinate their market actions. In this case, the most sophisticated ways of exchanging information can be used – from fake commercial "threats" to primitive psychological bluff. It is mathematically proved that the game of n people with a nonzero amount can always be converted into a game of "n+1" people with a zero amount by adding a so-called. "Fake player". A finite non-zero-sum game is also called *a bi-matrix game* in the literature, which has obvious signs of searching for equilibrium states [10].
[10] *VS* – abbr. from lat. *Versus*, meaning – *against*.
[11] EBITDA (an abbreviation of Earnings before interest, taxes, depreciation and amortization) – an analytical indicator equal to the amount of profit before deducting expenses for interest payments, taxes and accrued depreciation, taking into account the impairment of assets of all kinds. The EBITDA indicator demonstrates the potential of an EE to make a real profit, which allows it to cover its expenses [9]. As a relative indicator of EBITDA to the total revenue of TR (Total Revenue), the share in% reflects the market efficiency of the analyzed object.
[12] Serious changes are expected in the independent status of the further existence of *Tele-2*, with which the state-owned company Rostelecom (today owns 45% of the operator’s shares) entered into a transaction (the parameters of which were not disclosed) on a consolidation basis of 100%, which will allow, according to President of the state holding M. Oseevsky, to achieve total gross revenue of half trillion rubles. Preliminary professional appraisers determined the market, fairly fair value of the operator at 240 billion rubles, which is equivalent to 5.5 annual *EBITDA*, and the purchase of the remaining stake in the upcoming Rostelecom transaction, which thereby returns to the Russian cellular

market after August 2014 communications are likely to be paid by quasi-treasury shares and other securities.

[13] The sign ∅ – means a set that does not contain a single element, that is, the so-called empty set is considered.

[14] PJSC VimpelCom was founded on 08/15/1992 by Russian radio engineer D. Zimin and American businessman E.O. Fabela II. Since September 1993, under the Beeline brand, it has been providing cellular services, becoming the first Russian mobile telephony company. Then it became the first company in the Russian Federation to place shares on the New York Stock Exchange back in November 1996.

[15] The author distinguishes between the terms auctioneer and shareholder. The first is a potential buyer / seller of securities, a person conducting an auction, a bidder – a public sale of assets [23]. The second is an already held holder of securities entitled to dividends.

Abstract

The authors start from the objectives of the 2020-2030 National Strategy for Sustainable Development and try to identify the public policies by which the transition towards circular economy in Romania may be accelerated. It is taken into account the preservation of natural capital and the increase of the efficiency of using resources.In the paper there are highlighted the reflections of the authors with regard to resource productivity. We insist on responsible production-consumption models and the stage of implementing of integrated waste management systems in each county.Appealing to EUROSTAT data, a multifactorial model of assessing the circularity of an economy is proposed. In the end of the paper there are underlined the concerns of certain romanian companies for assimilating the CIRCULYTICS tool for measuring circularity.

Keywords: sustainable development, secondary resources, recycling rate, circular economy, waste management, multifactorial model, Circulytics.

Introduction

A hundred years ago, by means of his works in the sphere of public relations, Edward Bernays (nephew of Sigmund Freud), fires the flame of consumerism in the world. This comprised all the developed West, and after the fall of the communist regime it moved also in the Central and Eastern European countries. Based on the linear model produce-distribute-consume-throw away, the present economic development becomes unsustainable. There is need of a rethinking of the economic science and a redesign of public policies. Consumerism led to an increase in waste volume and diversity. On this background, waste management becomes a substantial issue of future economic development. Following 2015 when the European Union adopted programmes and goals for adequate management of raw materials, waste, by-products, and energy, also in Romania these issues received a special attention. These are to be found under various forms on the agenda of public authorities, business environment, and academic and research institutions. Numerous campaigns to inform the public and raise awareness took place in Romania's counties, by which stakeholders were explained the importance of the transition towards circular economy. All communication programmes were oriented towards explaining the new way of viewing fluxes from the standpoint of sustainability: the value of products, materials and resources is to be held in the economy as long as possible, and the producing of waste is to be reduced to a minimum.

Circular economy – the solution for the future

Romania's Government puts at the base of the 2020-2030 Strategy for sustainable development the Objective no. 12: responsible consumption and production, more principles that are to be found in the philosophy of the "circle that closes". There is in view the triad production-consumption-environment. A couple of principles are formulated by McKinsey Center for Business and Environment, among which there are:

- The preservation and strengthening of natural capital;
- Optimizing the yield of resource use;
- Making the economic system more efficient by eliminating negative externalities.

The process of transition towards a circular economy in Romania is closely tight to reconsidering the unsustainable consumption and production models, in view of identifying future development opportunities. To this end, implementing the 2030 Agenda for sustainable development, especially by the 12th Objective, brings in front the need of an integrated promotion of environmental, social and economic elements.

Debates in the last years regarding the importance and role of circular economy concluded with the approval at European level of an ambitious action plan regarding circular economy (2018). This plan is considered the engine of the transitions towards the "circle that closes". Within the mentioned strategy, research and academic institutes from Romania work at drafting a list of synergies of circular economy. This aims at the scope of agriculture and waters, municipal waste, biodiversity, human health, renewable energy, resource efficiency, preventing and reducing food waste, etc. All these suppose making analyses in terms of costs and benefits.

In the Report towards the Club of Rome entitled "Bankrupting nature" is analyzed the opportunity of decoupling economic growth from continuous use of resources. The efficiency of using resources is also approached in depth under the aspect of effect – effort.

Resource efficiency in Romania

Global environmental issues that Romania also confronts with are to a great extent the result of overexploiting natural resources, i.e.: fuels (fossil), ores, water, soil and biodiversity. It becomes more clear that the prevailing model of economic development in Romania, based on the intensive use of resources, on waste generation and pollution is no longer sustainable. Many resources, especially the important ones, are used on the short term or represent a loss for the economy, being disposed in waste deposits or becoming compost. Also in Romania solutions are looked after for maintaining as long as possible in the economy the value of products, materials and resources. In this way, waste production is effectively diminished.

The use of resources and waste management puts significant pressures in the phases of extraction, production, consumption and at the end of the lifecycle. Through the National Strategy of Sustainable Development also in Romania there are in view a couple of main objectives:

- Reducing the quantity of materials used in the economy;
- Using resources more efficiently;
- Significant diminishing of waste production;
- Transforming (through recycling) waste into secondary resources.

The Europe 2020 Strategy was taken in also by the Romanian Government, following by specific programmes the three priorities:

- Intelligent growth – based on knowledge and innovation;
- Sustainable growth – building a more ecologic economy that would use resources more efficiently;
- Inclusive growth – based on a high rate of employment that would assure social and territorial cohesion.

Circular economy is in close relation to these priorities. In this way, also Romania prepares for 2030 when it will have an authentic social market economy. These priorities have been transposed in Romania into specific national objectives and action lines. The productivity of resources is being measured by the value in euro of the products obtained by processing one kilogram of raw materials.

In 2018 Romania was placed in a low position, marking a regress compared to the European average. According to EUROSTAT, although the average of the European Union was of 132.0 (where 100 represents the productivity of resources in 2000), Romania was ranking last with a coefficient of 78.9. In 2019 Romania's import totalled 86.24 billion euro and exports 69.0 billion euro, indicating that Romania registered a deficit of 17.28 billion euro. Up to today Romania is a net exporter of raw materials, semi-fabricated and products with a relatively low degree of processing (low added value). It has to be signaled that in Romania's case the rythm of improving the return of resources is slower that in the E.U. countries. To this adds also the unsatisfactory dynamic of the labour cost, with a constant difference between Romania and the E.U. average of over 6 times.

Responsible models of consumption and production

Decoupling the negative effects that economic growth has on the environment needs a new sustainable model of production and consumption. Sustainable development proposes the solution of a more efficient production, of a sustainable management of waste and activities in line with the principles of environmental protection. In terms of consumption, recycling is compulsory, this asking for the transition towards a circular economy and making citizen conscious of the limits of the planet.

Within the new E.U. approach there is an increasing highlight on competitiveness through ensuring the stability of production and consumption, increasing the efficiency in using resources (material and energetic), reviving the processing industry that has high added value and the relative balancing with the sector of services that saw an important development in the last decades. In Romania, industry (including constructions) had a contribution of 38% to the GDP in 2018, greater than the E.U. average of 24%, fitting within an increasing dynamic in favour of services (a trend observed in the majority of the European countries).

Integrated waste management fits naturally in the vision of sustainable development and represents the putting in practice of the concept of circular economy based on recycling and preservation. In 2017 we recycled approximately 740.000 tons of waste. The results are not at all enough having in view that Romania's target for 2020 is 50% degree of selective collection and recycling out of the total household waste that is produced. Through the Environmental Operational Programme 2007-2013 projects have been promoted for integrated waste management systems (IWMS) at the level of each county of Romania. These were finalised at the end of 2019. The recycling rate of municipal waste is still very low in Romania, of only 14% (comprising 7% from recycling of materials and 7% from composting). This situation is shown in the Country Report regarding the assessment from 2019 of the application of the EU environmental regulations (EIR), drafted by the European Commission. In 2017 the production of municipal waste per capita was 272 kg, much under the EU average which is of approximately 487 kg. Romania set a recycling target of 55% of the municipal waste until 2025 and 60% until 2030. There is in view the selective recycling of dangerous household waste until 2022, of biological waste until 2023 and of textile fabrics until 2025. In the 2020-2030 decade Romania will pass to a new model of rational, responsible and efficient development of resources. Also, the implementing of sustainable practice of green acquisitions will be accelerated according to national priorities and European policies.

A multi-factorial model for the circularity of the economy

At the beginning of 2018, the European Commission published the values upon which it will survey in the future the circularity of the economies of the member countries. Already by the package adopted in 2015, EU promoted the idea of circular economy in which nothing is wasted, in which products last as long as possible and at the end of their lifecycle they are recycled. The magazine "Politico" made an analysis regarding the way EU member countries adapt to the policies regarding circular economy. At the end of the analysis certain surprising conclusions resulted. Thus, northern countries, such as Sweden, considered having "green economy" are not in the top of transition towards circular economy. In turn, Center European countries, such as Poland and the Czech Republic, are in top of the countries with the most circular economy. Such economies are structured on the following fluxes (Fig. 1):

Fig. 1: Fluxes in circular economy

Source: own conclusion (2020)

One of the causes that is slowing transition towards circular economy is the tendency to produce a lot of waste. The values that the EC uses in order to determine the degree of circularity are mentioned in the following table:

Table 1: Values that the EC uses in order to determine the degree of circularity

No.	Explanation
1	Quantity of garbage and alimentary waste produced
2	Quantity of waste that is being recycled and how much of the recycled material is reused
3	The volume of traded recyclable materials
4	The number of registered patents related to circular economy
5	The number of jobs created in the sectors of circular economy, of which, mostly in repair and maintenance

Source: data gathered from magazine "Politico"

"Politico" magazine analysed 7 key values based on data from EUROSTAT and ranked each of the 28 member countries (before BREXIT). These key values are shown in Table. 2:

Table 2. 7 key values

No.	Explanation
1	Municipal waste (annual kg per citizen)
2	Alimentary waste (annual kg per citizen)
3	Municipal recycling rate
4	Rate of traded recyclable goods
5	Rate of reusing materials
6	Number of patents within circular economy (since 2000).
7	Investment in circular economy (million euro).

The ranking for circular economy differs also in relation to the Index of Performance for the Environment proposed in 2018. Through it is classified a larger range of environmental policies, from pollution to emissions from agriculture and to biodiversity. This is due also to the fact that practices that reduce the impact upon health and the environment do not necessarily contribute also to circularity. For example, burning waste to obtain energy, as happens in Austria, Germany or the northern countries reduces significantly waste deposits but does not contribute to the growth of the rates of recycling and reusing.

For dynamic empirical analysis, using EUROSTAT data, we may build matrixes of the dimensions 28 x 7 with elements $X_{ij}(t)$, where:

i = 1,2,…28 – the EU member countries;
j = 1,2,…7 – collected key values;
t = 1,2,…5 – time interval 2015 – 2019.

Based on these dynamic matrixes may be studied the evolution of economies circularity and their approach to the strategic targets of EU and of each member country.

A tool for Measuring Circular Economy

Recently, Ellen Mac Arthur Foundation launched the most comprising tool for assessing the circularity of an economy at global scale. Through this tool companies are being offered the possibility to assess their degree of circularity. With its aid material fluxes are measured, information in being given regarding circular operations within offer chains, opportunities for strategic innovation is highlighted. The tool called CIRCULYTICS uses data and parameters by which the transition of a country towards a high degree of circularity is highlighted, it allows economic agents to understand and monitor circular economy. By using CIRCULYTICS companies are able to design systems through which they dispose waste from production chains. At the same time, they develop strategies with a positive influence upon the environment, improve results and consolidate the brands on the market.

Although economy entered a decline due to the effects of the global pandemy, there are consultancy firms, but also companies that undergo clear analyses and collect data that is necessary for the intake of CIRCULYTICS. There are in view 7 key domains of the business evolution, recommended by Ellen Mac Arthur Foundation: strategy, people and skills, systems, processes and infrastructure, innovation, external involvement, input, output. The tool adopted at the beginning of the year has a great benefit: it measures the circularity of the economy in a comprehensive way as fields such as strategy, innovation, people and skills and networking are included in its values. This tool will allow Romanian companies to create circularity reports that can be forwarded to shareholders or to the public so as to maintain transparency and to keep the customers informed regarding data by which they are assured that the products acquired fit within a model based on circular economy.

Conclusions

In April 2019 Environment Implementation Review (EIR) published a report regarding Romania's application of the EU policy and regulations in the field of environment. Within the pack of measures adopted by the EC in January 2018 is stipulated also the design of a frame to monitor the progress towards a circular economy.

Circular (secondary) use of material resources in Romania is much under the EU-28 average and with a declining trend compared to previous years. With regard to the number of persons employed in the circular economy, Romania is close to the EU-28 average, with 1,54% of the total occupied persons. In an inquiry, ING International shows that 8 out of 10 Romanians wish to pass to a circular economy. Measuring the transition of a country towards a more circular economy is a complex task. In Romania's Sustainable Development Strategy is considered that the number of products with ecological label as well as the number of economic organizations (small and medium size enterprises) that are concerned about the environment offer an approximation of this transition. The two indicators show to what extent the private sector and other stakeholders at national level are involved in the transition to circular economy. At the end of 2018, Romania had 24 products and 19 licenses registered in the EU system of ecologic labelling. In turn, small and medium size enterprises from Romania continue to obtain results under the EU-28 average for the environment component. An efficient way to follow would be focusing the decisional factors upn the most interested enterprises

and the adoption of a certain "value chain" that could generate propelling effects at the level on the Romanian society.

Waste management continues to represent a major challenge for Romania. The national performance is still marked by a low rate of recycling municipal waste (14%). In the early warning report, the EC mentioned Romania among the states that risk failing in reaching its municipal waste recycling objective until 2020 and enter the infringement area. Also, on this background, using the special EU funds for improving waste management is still extremely low. With all this lack of accomplishments, numerous Romanian big enterprises started investing in the infrastructure for recycling and collecting used products, trying to profit from this business opportunity.

Abstract

The new conditions in which the largest states of the world were put by the COVID-19 pandemic, which required the broad masses of the population to stay at home, became a serious test for the education system, which was forced to reorganize as quickly as possible, urgently switching to distance learning. The article describes the experience of teaching the disciplines of the criminal law cycle for the students of the law faculty of Southwest State University (Kursk, Russia) in the context of an emergency transition to distance learning in connection with the COVID-19 pandemic and the introduction of high alert mode in the region. The main possible approaches to the implementation of educational programs in the context of the impossibility of personal contact between the teacher and students, as well as taking into account the need to work at home and use the available communication channels, are considered. It is concluded that although the emergency transition to the remote interaction of the teacher and students was successfully organized as a whole, the implementation of the training of lawyers completely on a remote basis is still undesirable. At the same time, the introduction of distance technology elements and the constant use by students of the university's electronic educational environment, encouraging the use of modern multimedia and communication technologies, interactive forms of discussion of lectures and practical classes, mutual verification of completed tasks, it is advisable to integrate into the normal educational process in order to increase its effectiveness.

Keywords: COVID-19, self-isolation, distance learning, legal education, electronic educational environment, video lectures, knowledge control, interactive training, digital footprint.

Introduction

The pandemic of the new coronavirus infection COVID-19 has become a serious challenge to the entire world community, including the modern education system. In conditions when the need to curb the spread of infection required students and teachers to stay home, the ability to continue their education using distance technology is one of the most important factors that allow the education system to stay "afloat" in the most difficult economic and epidemiological situation.

The proliferation of distance learning technologies is no longer a new trend; it is one of the fastest growing sectors of the education industry (Means et al., 2010). More and more universities both in the Russian Federation and abroad offer to receive education through the Internet. As noted (Davis D. et al, 2018), mass educational distance learning platforms are functioning quite successfully, offering

courses from leading universities in the world, such as Coursera, edX, as well as their Russian counterparts (for example, Universarium).
Initially, these platforms acted more as an advertising platform for universities participating in programs, offering only free electronic certificates that do not have any official status. However, gradually they began to offer paid certification of certified educational certificates, occupying an intermediate niche in the educational market: past training courses in such systems gained a competitive advantage in the labor market, since in those areas of special activity where higher university education is required, certificate holders, even about taking a distance learning course, they are more trusted by employers than people who do not have any formal documents at all in special education. As noted by E.A. Seregina (2018), distance learning allows education despite temporary and spatial barriers, as well as reduce the cost of education by increasing its availability.

The first distance learning courses focused on teaching technical disciplines. So, one of the first massive online courses created by Stanford University was devoted to the problems of artificial intelligence. However, over time, more and more courses in the humanities began to appear, including the legal cycle. The wide distribution of such courses, their support by leading world (Yale University, Stanford University, University of London) and Russian (the Higher School of Economics is the pioneer here) universities allow us to talk about the possibility of distance learning, including lawyers.

At the same time, in the Russian context, the emergence of distance learning faculties in many law schools, and far from always leading ones, raised reasonable doubts about the quality of knowledge received by students. I.V. Goncharova et al. (2018) Indicate that despite the growing interest of Internet users in distance learning, only a small number of the best universities in the country provide this opportunity, and most universities that still use distance learning do it purely on a commercial basis. It can be noted that for many universities, attracting students to distance learning is only a way of attracting additional funds, in the absence of real investments in the creation of high-quality distance learning courses. Moreover, as noted by G. Aglyamzyanova and R. N. Abaydulin (2018), often a distance education course is a direct adaptation of a traditional full-time or extramural (with training in sessions) training course, which includes lectures, practical exercises, implementation of control and term papers, as well as final control in the form of tests and exams.

As a result of this, the problem of finding acceptable forms of distance learning for students in legal education is becoming particularly relevant. It seems that this should focus on the requirement set forth in the educational standards of the third generation for the widespread use in the educational process of active and interactive forms of conducting classes, such as business and role-playing games, analysis of specific situations, psychological and other trainings, meetings with representatives of commercial, state and public organizations, master classes by experts and specialists. T. Markova, I. Glazkova and E. Zaborova (2017) note that only the joint work of students, teachers and administrative staff of educational institutions can ensure an adequate quality of education. The common goal of all these groups is the use of modern information technologies that allow remote interactive interaction between students and teachers at a high level (as indicated by Panigrahi R., Srivastava PR, Sharma D. (2018), the greatest involvement of students can be achieved through multi-user computer simulations or help of virtual worlds similar to those used in network games, but simulating a real situation).

Despite the fact that most Russian universities have been interested in the technologies described above for a long time, and were engaged in the creation of an electronic educational environment (hereinafter - EEE), a complete transition to distance learning was not planned, and these resources were considered mainly as having an auxiliary role. However, the COVID-19 pandemic sharply violated plans for the gradual introduction of distance learning technologies. Already on March 14, 2020, the Ministry of Education and Science recommended the transition to distance learning (Order of the Ministry of Science and Higher Education of the Russian Federation dated March 14, 2020 No. 397), and from March 16, 2020, many universities began to urgently switch to distance technologies.

In conditions of such a quick and hasty introduction of new forms of training, it is extremely important to analyze and generalize the experience of teaching legal disciplines in new conditions without the possibility of organizing contact forms of training.

Methods

An analysis of the distance learning methods of students was carried out under conditions of necessity to organize a contactless interaction of a teacher with students in a short time using technical means of communication. As part of the emergency transition to distance learning for students in connection with the COVID-19 pandemic and the introduction of a high-readiness regime in the region since March 18, 2020, the following disciplines using distance technologies were taught at Southwest State University (Kursk, Russia): “Criminal law”,“ Criminology”, “Crimes related to malfeasance”. Classes were held with full-time students. In total, remote interaction was carried out with more than 150 students. The established class schedule was kept as much as possible; all classes were held in full with the interaction of the teacher and students in the online mode.

Results.

Conducting classes was carried out in three main forms: lecture classes, practical exercises and test control.

The lecture classes were supposed to be held on the basis of the available Powerpoint presentation slides, which were used as the base material for face-to-face lectures. The following options for organizing interaction with students were considered:

1. Online broadcast using teleconferencing (such as Zoom, Skype and the like).

2. Online broadcasting using streaming services without using teleconferencing, with the organization of direct communication with the teacher through text chat.

3. Placing a video of the lecture on video hosting (Youtube) with transmitting the link to students for viewing at a convenient time, organizing direct communication with the teacher through a text chat.

4. Sending students presentations without accompanying audio / video materials for self-study, with the organization of the possibility of direct communication with the teacher through text chat.

The latter option seems to be the least attractive, since it uses less communication tools compared to a traditional lecture. Only the visual channel for perceiving information (reading) is used, while it is considered necessary that the student visual and auditory perception of information is combined during the lecture, as well as lecture notes (which with this method of conducting it becomes unnecessary). At the same time, this method has the undoubted advantage that it does not need to use communication channels with high bandwidth, which may not be available to the teacher or students.

The organization of teleconferencing seems to be the most attractive option from the point of view of interactivity, but the practical implementation of this option faces significant difficulties. Firstly, almost all teleconferencing services require a paid subscription to organize full-fledged communication: there are restrictions on the duration of the conference (in Zoom no more than 40 minutes), the number of participants, etc. It is rather difficult to quickly provide teachers with a paid subscription; moreover, it ties them to a specific service. It is possible to organize video conferencing using the university’s own services (BigBlueButton software), but this requires the university’s information infrastructure to withstand the necessary load, and it is usually not ready for this. Secondly, teleconferencing requires a stable communication channel that provides a sufficiently high flow rate for both downloading and downloading. Quite a lot of students, especially in rural areas, use mobile or xDSL connections that do not provide the necessary stability, are limited in the amount of transmitted traffic, and are asymmetric, making it possible to watch online video, but not broadcast their own video stream. Thirdly, a teleconference with 60-80 participants requires several moderators to be allocated in order to organize well, since uncontrolled interaction with so many participants risks quickly becoming chaos. Fourth,

there are certain concerns related to the security of personal data of participants in such teleconferences, as well as the possibility of unauthorized connection to them (which almost inevitably leads to class failure). This applies specially to Zoom, the practice of using which in various educational institutions has shown its inadequate safety - there have been cases of unauthorized connections (including using illegally obtained student credentials) with the subsequent disruption of the lesson (for example, by demonstrating pornographic videos).

Finally, it is necessary to take into account the special conditions in which teachers and students were placed in connection with the introduction of restrictive anti-epidemiological measures. In conditions when parents are both at the same time in a typical home, both working remotely and involuntarily unemployed, a university student and his brother or sister who are remotely taking school classes, there is simply no talk of any teleconferencing. Therefore, this option has also been discarded.

When choosing between the online broadcast and the pre-recording of the lecture, the choice was made in favor of the pre-recording, since the increase in the interactivity of interaction during the online broadcast is insignificant. It should be borne in mind that broadcasting in any case is delayed by a few seconds, as a result of which the chat questions are inevitably late and appear when the teacher has already switched to another material. In addition, it is quite difficult to conduct a lecture and follow a text chat at the same time. Thus, it was considered that this option creates an excessive load on the teacher, without giving significant advantages.

Modern versions of PowerPoint (using the version available by Office 365 subscription) allow you to fully record a lecture with audio / video accompaniment without the need for any additional software using a standard microphone and webcam, including a built-in laptop. The important thing is that the recording unit is one slide of the presentation, which allows you to quickly overwrite the failed fragment. In addition, during the lecture, you can make handwritten notes on the slide or highlight individual fragments of the text, use multimedia tools (for example, animation or videos). The result is a video lecture in the format of slides with a video of the teacher's story superimposed on them (in the corner of the screen) explaining the material presented on the slides. Such a lecture can be exported using standard PowerPoint functions to an MPEG4 video file, which can easily be uploaded to video hosting.

Video materials recorded in this way were posted on Youtube, a link to them was posted on the university's EEE and sent to students on the day of the lesson. Feedback with students was carried out in two forms. Firstly, in order to verify that the students attended the lecture and learned its material, they had to submit a handwritten summary of it. His photograph was uploaded by students in the EEE. This makes it possible to record lecture attendance using a point-rating system. The student who uploaded the synopsis at the scheduled time (not earlier than 10 minutes before the end of the lecture lesson on schedule and no later than 30 minutes from its end) is considered to be present at the lecture. Of course, the lecturer and his assistants should carry out spot checks of abstracts.

As a means of organizing text communication, various instant messengers (Viber, WhatsApp, Telegram, Discord, Skype) and social networks (VK, Facebook) were considered. It was found that all of them in one way or another provide the possibility of organizing a group chat with a sufficient number of participants, with the ability to send text messages, links, multimedia elements and audio messages. All of them have a mobile version and a desktop version, as well as a web version. Thus, the choice of a specific tool is not determined by their technical capabilities (which are almost the same), but only by which of these tools are most familiar to teachers and students. In the specific circumstances, it was preferable to use the VKontakte social network, since the vast majority of students have already used it for communication.

For direct communication with students, general chats were organized, in which all students were added. During the lesson, these chats were monitored, answers were given to questions arising on the topic of lectures. It can be noted that students were much more active in taking the opportunity to ask the teacher a question than during the in-person lecture, and participated in mutual discussions regarding the material presented by the teacher.

Practical classes were conducted on the basis of existing author's methodological developments designed to organize work under the conditions of applying a point-rating system for assessing knowledge, taking into account the need to involve the maximum number of students in the lesson.

The possibility of conducting classes in a teleconference format was also considered. Although the number of conference participants in a practical lesson is less than the limit for free use of most services, the remaining drawbacks of this method of conducting the lessons described above with regard to lectures remain relevant for practical exercises. In view of this, despite the attractiveness of this format, which is closest to the traditional face-to-face training, it was decided to abandon it. At the same time, it should be considered the possibility of its use in relatively small groups of students (up to 10 people), provided that there are no problems with communication channels and there is an organizational possibility of interaction.

Quite widespread in practice is a non-interactive format for conducting practical classes in remote form, which involves students completing written tasks of the teacher with their subsequent direction to the teacher for verification. It can hardly be called providing full involvement of students in academic work. In addition, non-individual task execution becomes very likely under such conditions.

As a result, an interactive format using text and multimedia communication tools (video messages, voice messages) was chosen for conducting classes. As noted above, almost any messengers or social networks can be used for this, taking into account specific conditions, the social network VKontakte was chosen.

Chats were created for each group of students. The actual conduct of classes took place within the established schedule as follows. At the beginning of the lesson, each student was given an individual task by surname.

The following task options were used: an oral answer to a question, an oral or written solution to a case problem, an oral report (preparation is entrusted as a homework in the previous lesson), a checklist for definitions (in writing), a test (in writing), and a summary of a scientific article (in writing) followed by an oral report), writing a short essay (in writing).

The student fixes the oral task in the form of a voice message. The written task is performed on a piece of paper, fixed on a photo and also sent to chat. In addition, students were told about the ability to accompany the answer with illustrative and other multimedia material (for example, links to videos), which many students actively used.

The teacher supervised the work of students, listening and viewing completed tasks. In order to stimulate the independent work of students, additional questions were asked (in text form, the answer to them also in text form). Students were reminded of the need to familiarize themselves with the answers of classmates during the lesson (view and listen), and were asked to ask questions to the teacher and classmates. As the used technologies became familiar to students, the request to ask questions to classmates was replaced by a mandatory requirement for some students.

At the end of the lesson, the students' work in the lesson was evaluated by the teacher, the assessment was brought to the attention of students. A digital trace of the lesson was also recorded. At the end of the lesson, screenshots of correspondence with students, other available for saving, were uploaded to the EEE so that students (including those who were not present at the lesson) and other teachers could familiarize themselves with them. It should be noted technical difficulties with the preservation of audio messages and other multimedia materials. Some instant messengers (Telegram, WhatsApp) allow them to be downloaded as a file using regular means, so if there is a need to include such materials in a digital footprint, you need to consider them as the preferred means of organizing interaction. At the same time, these technical difficulties are not insurmountable: for example, on the VKontakte social network, you can use the Video DownloadHelper extension for the Firefox browser

(https://www.downloadhelper.net/) and standard browser developer mode tools to save video messages and audio recordings. allowing you to get a direct link to the audio file for a voice message.

Discussion

In general, the distance interaction with students, despite the suddenness of the transition, was able to be organized quite quickly and without serious difficulties (in particular, due to the fact that I had previously trained students using distance technologies). Such a system was generally perceived positively by students, one can note a more creative than some students' traditional approach to completing assignments using multimedia tools. There were no significant technical problems in the interaction of teachers or students with the EEE of the university - there were only a few complaints about the temporary inaccessibility of the environment, these students were able to successfully upload materials after a few minutes.

However, it should be noted that none of the traditional forms of working with students can be losslessly adapted to the distance learning format.

So, lectures in their traditional form involve live communication between the teacher and the audience. A qualified teacher does not just present material in his discipline, he adapts it to the needs and level of a specific audience, explaining it with illustrative examples, including those of current interest; he has the opportunity to illuminate in more detail any aspect of the topic, if he aroused keen interest among the audience, or was not clear to them, to answer questions that the audience has. It is good practice for the lecturer to include dialogue elements in the lecture.

However, even in the form closest to the traditional form of remote lectures (using telepresence systems), the teacher is deprived of direct contact with the audience and is not able to assess the perception of his speech by the audience. Often, even at a fairly high level, distance courses are limited to providing pre-recorded video or audio lectures, or even a lecture course in text format. This, of course, cannot be recognized as an adequate replacement for the traditional lecture. In addition, the limitations of the used technical means, telecommunication channels and human resources lead to the fact that the use of fully interactive forms of interaction becomes impossible or difficult to implement.

The situation is even worse with practical exercises, which involve a joint solution by a group of students of tasks designed to consolidate the knowledge gained, as well as the current control of their performance. In the distance course, students are forced to work individually, without close contact between themselves and the teacher. This does not allow you to get teamwork skills, business interaction. Even if students are involved in collective forms of work (for example, by mutual verification of tasks), their interaction is still limited, in such conditions it is quite difficult to organize a truly interactive interaction, involving a general discussion of discussion issues, brainstorming and other similar forms of work.

There is no opportunity to control the familiarization of students with the work of classmates in practical classes. The student can ignore tasks that are not personally relevant to him, not get acquainted with their results and their assessment by the teacher.

The most serious questions are also caused by the organization of students' knowledge control during distance learning. First of all, this is due to the complexity of controlling the independence of tasks. The only more or less reliable way to control the student's personal performance of this or that work is to ensure his full-time presence at the university, its branch or a specially created center, however, the main advantages of the distance learning form over the usual part-time form are lost. If the assignment is carried out in the absence of full-time control of the student, wide opportunities for academic deception open up to the task of hired "specialists."

In part, this drawback can be mitigated by issuing an individual assignment to each student, offering to answer additional questions, constructed in such a way that a ready-made answer to them would be difficult to find, as well as cross-checking students' work.

The complexity of preparing for classes has increased due to the fact that all materials must be pre-translated into a form suitable for sending to students, specific students performing tasks, etc.

The complexity of evaluating the results of students' activities and providing them with feedback in connection with the need to fully listen to an oral answer without the possibility of interrupting a student, checking written answers, and also interacting primarily in the form of text messages as the most accessible to them, has increased. It also takes a lot of time to save the results of the lesson for the full fixation of its "digital footprint" in the EEE.

Separately, the laboriousness of preparing lectures should be noted. Recording video accompaniment to a presentation requires a much greater concentration of attention than a traditional lecture, since it is highly desirable not to allow interruptions and speech malfunctions, which often require rewriting “takes” of the same slide several times. In addition, even if the lecture is fully prepared in video format, for full-fledged work with students, it is still required that the teacher during the lecture be available online and be ready to answer students' questions (which they could also ask during the full-time lectures). In fact, the labor costs for lecturing increase threefold: approximately 4 academic hours for preparing (updating, clarifying) the presentation and recording video material and 2 academic hours for online consultation during the lecture, instead of 2 hours for lecturing in the classic non-interactive format.

It should be noted that all these shortcomings are not critical and can be smoothed out with varying degrees of success provided that distance learning technologies are introduced into the teacher’s daily work, as well as the possibility of combining full-time and distance learning under normal conditions when anti-epidemiological measures do not force the teacher and students avoid personal contact.

Conclusion

Although the emergency organization of distance learning in the context of the coronavirus infection pandemic at Southwestern State University was successful, taking into account the circumstances, the full implementation of educational programs in this form on an ongoing basis is undesirable.

However, the identified shortcomings cannot be called critical, at least in the framework of the teaching of individual disciplines of the industry cycle. Moreover, the revealed advantages in the form of increasing student engagement and encouraging them to use modern multimedia and communication technologies indicate the prospect of learning using distance technologies, including the possibility of organizing active and interactive forms of training sessions with their use.

For example, it was found that students are more willing to ask questions and discuss the lecture material in group text chat than verbally directly during or after the lecture. Therefore, it makes sense, regardless of the format in which the lecture is delivered, in remote or in-person mode, to create such a chat for students by highlighting in-person lectures to assist in organizing its work of assistants - like other teachers (for example, conducting practical classes at students in this discipline), as well as volunteers from among students who are good at mastering the material.

An important advantage is also the fixation of the digital footprint, which allows students and the teacher to use the recorded learning results when implementing the subsequent educational process, referring to them if necessary. In addition, it increases the objectivity of the current assessment of student knowledge.

Although many traditional forms of training are not applicable in distance learning, there are many educational technologies, the full potential of which is revealed precisely with distance learning. For example, this is a crosscheck of tasks (especially of a creative nature) performed by students: while in traditional education, its use is complicated by the possible overstatement for personal reasons, then in an online course, in the absence of direct communication between students, the influence of this factor is significantly reduced.

The aforesaid allows us to talk about the need to generalize the experience of using distance learning forms after removing the restrictions associated with the distribution of COVID-19, in order to integrate their individual elements into the usual educational process.

Abstract

This article focuses on the definition of transnational crime, as well as on the identification of the causes and conditions of transnational crimes. On the example of illegal sale of narcotic substances at the international level, the authors attempt to make a comprehensive analysis of the characteristics of transnational crime at the present stage of development of the international community.
Authors conclude that domestic methods of detection of transnational crimes are outdated and are not able to fully meet the needs of the investigation. Confronting transnational crime, which is complex in nature, requires interaction between the entire world community and individual regions. Cooperation between the European Union and Russia as the largest participants in international relations is particularly important. Despite the established regulatory framework for combating organized crime, in particular drug trafficking, there are problems that require immediate solutions. It should be noted that the need for work on which it is necessary to intensify in the near future: the development of a unified anti-drug policy, the harmonization of national legislation, the development and implementation of international operations to control narcotic and psychotropic drugs in legal circulation, further exchange of experience on drug demand reduction, prevention, treatment and rehabilitation of drug patients.

Keywords: Transnational Organized Crime, European Union, Interaction, European Police, Drug Trafficking.

Introduction

In the context of globalization, States interact with each other more actively every year. Humanity faces new challenges that require joint solutions from States. One of the global problems of the 21st century is the Commission of crimes at the interstate level. According to Valeev D.M. (2016), under transnational crime adopted to understand the social anti-legal phenomenon, which is a purposeful system of active operations of criminal groups organized on ethnic, kinship or professional signs, and operating on the territory of several States. The main international Treaty regulating the fight against transnational crime is the UN Convention against transnational organized crime of 15 November 2000. However, it is difficult to settle all relations in the field of combating various types of interstate crimes in one document, so States cooperate on these issues at the local level. A striking example of such cooperation is the cooperation of the Russian Federation and the European Union. Let us consider the features of the fight against transnational crimes on the example of identifying the illegal sale of drugs.

A serious problem of our time is the sale and distribution of drugs at the interstate level. According to data provided by the United Nations Office on drugs and crime, around 250 million people worldwide have experience in the use of drugs. At the same time 190 thousand people die of addiction, 8 thousand of whom are citizens of the Russian Federation. The scale of the problem of drug use is serious: according to the Ministry of health and law enforcement in 2017, the number of people suffering from drug addiction ranged from 640 thousand to 7.3 million people.The first figure reflects the data on those who applied for medical care, and the second expresses the number of detainees by law enforcement agencies during the use of drugs.

It is significant that both in Russia and in the world, the production of synthetic drugs is steadily growing. What are the reasons for this growth?

The first reason for the trend of growth in the production of synthetic drugs around the world is the simplicity of their production. In order to produce synthetic drugs, you do not need to have large reserves of natural resources, as well as attract a large number of people, spend money on expensive equipment, there is no dependence of the manufacturer on climatic conditions. That is why there is an increase in the consumption, storage and marketing of synthetic drugs. The second reason for the increase in the spread of synthetic drugs in society is the ease of their production, which can be established almost anywhere. The third reason for the manufacture of synthetic drugs is the low cost and high profitability of "business" in the market. The fourth reason is that the production of synthetic drugs does not require a specific precursor. Police Colonel Vyacheslav Dikarev (2019) believes that this circumstance makes it possible to obtain several types of synthetic drugs, including those not included in the list of prohibited, but having a similar negative impact. All of the above reasons are responsible for the increase in the number of people involved in the criminal sphere of drug distribution, and, accordingly, their use.

The victims of drug trafficking offences are drug users. According to the 2018 world drug report, young people remain the most vulnerable group to consumption and exposure. Studies show that there are two peak periods when a person is most likely to become addicted to drugs and psychoactive substances: early (12-14 years) and late (15-17 years) adolescence. The largest proportion of people who use psychoactive substances falls on the age of 18-25 years. The world report cites two opposite reasons that serve as the beginning of drug use. First, persons with sufficient means to pursue recreational purposes, wanting to make emotions brighter. Secondly, young people experiencing difficulties, on the contrary, want to relax and distance themselves from the extreme conditions in which they live. At the same time, there are two diametrically opposite consumption models, the so-called club and street consumption. Club drugs include ecstasy, methamphetamine, cocaine, ketamine, LSD - these types are used by young people with a high level of income. The peak of "club" consumption according to statistics occurs in 15-24 years. It should be noted that these drugs have a complex composition, so this fact should be taken into account when searching for sales channels in the framework of the seizure of drugs from young people. Street consumption is characterized by the low cost of narcotic or psychoactive substances, which usually include inhalants, which are paint solvents, gasoline, paint, corrective fluid and glue. It is evident that with this type of consumption, it is often impossible to identify the funds prohibited in circulation. States, taking into account international experience showing the causes and conditions of drug use, are developing a strategy to combat their spread.

Considering transnational crime as an example of the sale of drugs, we consider it important to establish the reasons and conditions for the involvement of young people in the distribution of drugs. It is no secret that there is a large turnover of money in the drug business, which, at first glance, is very easy to earn. According to the developers of the UN world drug report for 2018, the main reason for the involvement of young people in the cultivation, manufacture and production of drugs is social instability, poor economic situation in the country and, as a result, the inability to earn at all or receive extremely low wages. This group of people is "easy prey" for organized criminal groups, so they turn their attention to poor young people in order to obtain labor for the cultivation, manufacture, transportation and trafficking of drugs at the local level. In the system of transnational crime, this category of people acts as the" lowest link", performing the most rough work. Organized criminal

groups is beneficial to recruit children and young people in the criminal activity connected with illegal drug trafficking, because they are due to age are reckless, assisting organized group to give the youth any orders and the ability of the subordination of young people and children organized groups. In the investigation of illicit drug trafficking as a transnational crime of an international character, it is always necessary to pay attention to the most vulnerable category of citizens – young people, because it can help in uncovering a whole complex network of drugs in huge quantities.

Investigation of the committed interstate crimes in the sphere of drug trafficking and prevention of new criminal acts requires a detailed analysis of the concept of transnational organized criminal group. Note that the UN Convention against transnational crime of 2000 does not define a transnational organized group. The international instrument in the conceptual apparatus contains two terms: organized and structured criminal groups. The 2000 Convention identifies several characteristics of an organized criminal group: structure, membership of at least 3 persons, acting for a period of time to commit a serious crime within the meaning of the Convention, and the ultimate goal of obtaining direct or indirect financial or other benefits. Within the meaning of the 2000 Convention, a structured group is a group formed by a group that has no mandatory formal definition of the roles of group members or developed structure. The article of this Convention strictly regulates the responsibility for participation in an organized group, without paying attention to the fact of personal participation in criminal acts. N. I. Zelinskaya emphasizes that the definition of transnational organized groups laid two categories: 1) the group's operations beyond one state, the so-called "internationalization"; 2) the cohesion of the group members who are citizens of different States. E. B Serova (2013) gives a criminalistic definition of transnational organized group, understanding as such created for the purpose of committing criminal acts at least moderate system of interrelated elements, subject to common principles, traditions and United criminal purpose, the result of which is to obtain direct or indirect financial or other benefits.This system is branched and has a centralized hierarchical structure, headed by the organizer and has corrupt connections, since it cannot act with impunity without the preferences of some authorities, usually law enforcement. The distinctive features of transnational crimes include the following: they are national in nature of the criminal-legal prohibition and international in characterization of subjects or criminal activity. Transnational crimes thus fall under the jurisdiction of more than one state. In order to carry out full-fledged activities, the organized community, in addition to the sale of drugs, sometimes needs to commit other illegal acts: legalization of income, corruption crimes and so on. The difficulty of identifying such groups is that they receive support from the authorities, which discredits the work of law enforcement agencies, which "close" the way to expose a transnational organized group.

Results and Discussion

The scientific community has repeatedly attempted to develop a universal concept of transnational organized criminal group. The work of legal scholars was carried out on the basis of legal definitions enshrined in international instruments, the main of which is the UN Convention against transnational crime of 2000. However, there are legal gaps in its text. E. B. Serova (2013) rightly points out that article 2 contains the number requirement as "at least three persons", whereas article 5 of the above Convention refers to the presence of two or more persons in a transnational organized group. National legislation has tightened the conditions when deciding on the form of complicity, which is recognized as a transnational organized criminal group, it must consist of at least 2 people. It is important to distinguish a transnational criminal group from terrorist activities, the former becoming transnational by virtue of its interstate nature. The full list of characteristics of a transnational criminal group includes the receipt of direct or indirect, financial or other benefits, as well as the presence of prior collusion and a certain structure. In a transnational organized group, there is usually a foreign element. V. Nomokonov (2003) notes that this characteristic is decisive in terms of the characteristics of transnational criminal groups. It is worth noting that such criminal groups, as we mentioned above, are formed with selfish motivation. The activities of a transnational criminal group differ in that they are carried out in more than one state, and a significant part of the planning, preparation and control of the Commission of crimes takes place in another state. Thus, a transnational criminal group, with an extensive network, concentrates the main center in a country where, as a rule, the main criminal acts

are not committed. The 2000 UN Convention indicates other options for the activities of a transnational criminal group.

Thus, it can be committed in one state, but with the participation of an organized group that commits crimes in more than one state; crimes can be committed in one state, which entails significant harm to the public order of another state. Based on the analysis of the above, we propose our own version of the concept of transnational organized criminal group – a system of interrelated elements, including at least two persons, specially created for the purpose of obtaining direct or indirect financial or other benefits by committing a number of criminal acts of a cross-border nature, that is, on the territory of two or more States, as well as with the participation of persons with different nationalities.

Police Colonel Vyacheslav Dyukarev (2019) notes that the fight against transnational criminal groups that sell drugs is difficult and has certain problems, because there is a constant increase in the "professional skills" of participants in transnational organized criminal groups]. The relevance of operational and investigative measures carried out by law enforcement agencies is gradually decreasing. In particular, it is difficult in practice to carry out a controlled purchase or controlled delivery, as drug dealers understand how dangerous it is for them to interact directly with the client. Moreover, such measures are not enough, because the transnational criminal group is so difficult to weave into the social systems of countries that one detention of its lower levels will not give law enforcement officers the opportunity to find the organizer. This circumstance forces to look for new ways of obtaining evidence base, and only with their complex application it is possible to achieve the desired result. The complexity of the disclosure of transnational organized groups engaged in illicit trafficking in narcotic substances is that in the era of technology in the vast majority of cases for the interaction of parts of the criminal group used software, including information and telecommunication network "Internet".

An illustrative example of international drug trafficking via the website "Silk Road, the owner - administrator Ross Ulbrich, hiding under psuedonyms "dread Pirate Roberts". The site took orders for drugs for payment with bitcoins, which have recently become very popular in the world. At the time of arrest of the founder of the website according to research conducted in Traini College, the number of visits to the site daily reached 60 thousand, and the monthly turnover of profit in 2012 (a year before closing) was 1.2 million dollars. The service was arranged on the principle of the international trading platform eBay: the platform charged a Commission of 10 percent for all transactions, drugs were delivered by mail. Only by 2013 was it possible to arrest and then sentence the founder of the site to life imprisonment. Given the scale of silk road activities, it is difficult to measure the number of victims worldwide who have suffered from the use of narcotic drugs. This example shows that the fight against illicit trafficking in narcotic drugs is a world-class problem and constantly requires the search for new means and methods.

Before proceeding to a detailed analysis of the mechanisms of interaction between the European Union and Russia on the fight against illicit drug trafficking, we consider it necessary to pay attention to the situation on the sale and use of drugs in Europe in recent years.

Ivanova N. In. and Hismatova Z. G. (2017) give the following categories of groups of States according to the degree of rigidity of the legislation concerning drugs.

The first category is moderate control countries. These include Germany, France, Russia, Italy. These States are actively engaged in the fight against illicit trafficking in narcotic drugs, and criminal legislation provides for a penalty of imprisonment for crimes related to the illegal sale of narcotic and psychoactive substances. Punishment can be replaced by an alternative measure-referral to treatment for drug addiction by a court decision.

The second category – countries with a strict policy in the field of drug trafficking. Among them are the USA, Japan, China. For committing a crime in the specified areas there is a serious punishment, up to life imprisonment and the death penalty.

A special place in the classification is occupied by the Netherlands. According to the legislation of this state, drugs are divided into "light" and "heavy", with the latter being actively fought. Banned, for example, in Russia, drugs based on cannabis there legalized and responsibility for their cultivation, production, storage and marketing is not provided. In this regard, the Netherlands has become, without exaggeration, a real drug capital of the European Union. According to the Ministry of justice of the Netherlands for the year 2000, 5% used "light" drugs on a regular basis. Do not forget that in Russia these substances are prohibited, therefore, their supply is illegal and subject to the Criminal code of the Russian Federation.

The statement of the former Director of FSKN of the Russian Federation (it is transformed into Gosnarkokontrol of the Ministry of internal Affairs in 2016) Victor Ivanov that 90% of the drugs turned in Russia have foreign origin is indicative. Indeed, in Europe there is a problem with the increase in the production of narcotic drugs, as well as the emergence of fundamentally new drugs. This is evidenced by statistics. According to the European report on drugs: trends and changes in 2016, the evolution of the drug market was as follows: the markets of cannabis, amphetamines and heroin appeared in the 1970s of the 20th century, then in the 2000s the market was replenished with cocaine. Throughout the 21st century, the "range" of narcotic and psychoactive substances grew, in the process of globalization, the ways of smuggling drugs and their analogues became more complicated.

The European drug report 2016 indicates that drug markets generate huge revenues: according to the most conservative estimates in 2013, the volume of retail drug sales in the European Union amounted to 24, 3 billion euros. The volume of sales for certain types of drugs as follows: 38% - products of cannabis, 28% heroin 24% cocaine, 8% amphetamine, 2% - MDMA. Most seizures occur in Spain and the UK. According to the European report 2014, London has become the largest consumer of cocaine: 700 thousand people in the UK aged 12 to 59 years take it on a regular basis. Relatively high indications for seizures have Italy, Germany, Belgium. In France, the Netherlands, information on seizures is closed, and Turkey also records frequent cases of confiscation of narcotic drugs, as law enforcement agencies intercept drugs in transit to countries outside the European Union, in particular Russia, as well as countries of the Middle East. The report of the International narcotics control Board indicates that there are 4 smuggling routes through which heroin enters the European Union: the "Balkan route", the "southern route", the offshoot of the "Balkan route" and the "Northern route". The first two pass through the territory of Turkey, then crosses one of the countries: Romania, Bulgaria or Greece, then lead to Central, southern or Western Europe. Branch of the "Balkan route": drugs transit to Europe through Africa.

In General, the member States of the European Union have taken concerted action to combat transnational organized criminal groups engaged in the illicit sale of narcotic drugs. Each of the countries of the European Union undertakes to treat the smuggling of narcotic substances as a criminal offence, but the approach to the differentiation of punishment for their Commission in the countries of the European Union differs, based on the classification of the degree of rigidity of the legislation of States, given above.

In practice, there are cases of manifestations of transnational crime associated with illicit trafficking in narcotic substances in the system "European Union - Russian Federation".

Deputy Prosecutor General of the Russian Federation Alexander Zvyagintsev asked for the extradition of Russian citizen Vladimir Krasavchikov in order to bring to criminal responsibility for crimes that are associated with drug trafficking. As a result of the investigation, it was found that Vladimir Krasavchikov led an international (transnational) criminal group that exported cocaine from Ecuador to Russia in the period from 2003 to 2010. Until 2010, Krasavchikov was hiding from the investigation in Ecuador, but after the Prosecutor General's office of the Russian Federation sent a request for his extradition, which forced the offender to leave this state. Then Krasavchikov was detained in the Netherlands, where all the necessary materials for extradition were sent. The process of extradition of a Russian citizen was difficult: the interests of Krasavchikov were represented by a large group of Dutch lawyers, who strongly hindered the speedy extradition of the criminal. On July 13, 2012, the court of Amsterdam decided to extradite Krasavchikov, and on November 20 of the same year, the

Supreme court of the Netherlands approved it. Only in 2014 managed to extradite Krasavchikova in the Russian Federation, and the verdict of the Kirovsky district court of St.-Petersburg from 22.12.2017 in the case № 1-4/2017 (1-6/2016; 1-120/2015; 1-1024/2014;) he was sentenced to the penalty of deprivation of liberty for a period of 10 years with punishment serving in a corrective colony of a strict mode. The long process of transferring the organizer of a transnational criminal group to the territory of the Russian Federation shows the need for additional study of the processes of interaction between the European Union and Russia in the disclosure of such complex crimes in the field of illicit drug trafficking.

In 2017, the Russian interior Ministry managed to block a major channel of drug smuggling from Europe. Employees of the Department of transport in the Ural Federal district managed to stop the activities of the interregional group and to withdraw from illicit trafficking more than 100 kilograms of prohibited substances. Malefactors tried to create in the territory of the Ural and Volga Federal districts new channels of sale of drugs from Europe, at the same time employees of Chelyabinsk customs transferred information on a parcel with drugs which have to arrive from Europe. Parcels were sent from Germany, Belgium and Holland, and the recipients of batches of 1 to 10 kilograms of drugs were persons from Krasnodar, Ufa, Rostov-on-don, Moscow, Novosibirsk and Chelyabinsk. From the above information, it can be concluded how developed the transnational criminal group was. Only in Ufa, interior Ministry officials were able to find 240 caches in the city cemetery. In addition, an underground laboratory was discovered, where 50 kilograms of mephedrone were produced from precursors weighing 300 kilograms in one cycle. Drugs were passed through postal items in children's toys. A total of 8 contraband shipments of cocaine, hashish LSD, marijuana and other drugs from other countries in Russia were identified. As Urda M.N. (2018) informs, all operatively-search event was held with the cooperation of the MIA of Russia and of Interpol. As a result, 47 criminal cases were opened. The scale of criminal activity in this case is simply huge, which indicates the urgent need for cooperation between the European Union and Russia in combating transnational crime.

Member States of the European Union carry out activities aimed at the prevention of international drug trafficking, carried out by governments and law enforcement agencies. The implementation of the anti-drug strategy, as well as the action plans and policies of the European Union to combat organized crime, have helped in this endeavour.

Cooperation between Russia and the European Union in the fight against transnational crime is based on the International Treaty "on the plan of joint action of the European Union and Russia to combat organized crime" of 29 March 2000. This document sets out in detail the framework of cooperation between Russia and the European Union with the judiciary, law enforcement agencies, as well as with the bodies coordinating the framework of cooperation between the European Union and Russia. In section 2 "cooperation with law enforcement agencies" the document, defining the framework of such cooperation, the document instructs the participants of the action Plan to strengthen border control in order to suppress drug trafficking. According to Volevodz A.G. (2009), a common strategy of the European Union against Russia stipulates that the cooperation with Europol is in conformity with the Convention on Europol.

There is a set of measures that Express cooperation between Russia and the European Union in the fight against transnational crime: preparation of annual joint reports on the state of organized crime, exchange of technological and strategic information, training courses for law enforcement officers of the Russian Federation, exchange of experts, joint meetings, exchange of information on suspicious transactions. In our opinion, these measures should be implemented together, to use a comprehensive approach, but in this case, according to Sheveleva and Urda (2017) it is possible to achieve the desired result - if not complete eradication, a substantial reduction in the number of transnational organized criminal groups and crimes committed by them.

The action Plan for 2016-2020, prepared on the basis of the report "White paper on transnational crime", is interesting to study. The document identifies a range of actions, key areas that ultimately help to implement measures to combat transnational organized crime: strengthening international cooperation through the development of networks; the introduction of special investigative techniques,

witness protection and incentives for cooperation; administrative influence and cooperation with the private sector, as well as asset recovery. The document was adopted with the aim of structuring the mechanism for combating transnational organized crime, the task of developing a legal framework for combating transnational organized crime, and strengthening international police and judicial cooperation. According to the 2016 action Plan, the Committee of experts on the functioning of the European conventions on cooperation in criminal matters is the main body implementing the above goals and objectives. It has the following functions: to support the Committee's web page with a view to providing adequate information on the fight against transnational organized crime; to condemn the use of a safe and secure means for international legal cooperation; and to establish links between judicial networks. According to D.D. Shalagin (2018), taking into account the action Plan of 2000, as well as those transnational crimes (for example, trafficking of narcotic substances) the objectives and tasks set by the action Plan for 2016-2020 is an important aspect of combating transnational organized crime in light of the interaction between the European Union and Russia.

Cooperation between Russia and the European police (Europol) is important in the fight against international drug trafficking. A framework for the implementation of the cooperation is the cooperation Agreement between the Russian Federation and the European police office of 6 November 2003 the Purpose of the document is the expansion of cooperation in the fight against the most dangerous forms of transnational organized crime. The Agreement States that one of its subjects is the detection, disclosure and investigation of crimes that are associated with the illicit traffic in narcotic drugs, psychotropic substances and their precursors. In 2004, the Russian national contact point (RNCP) for interaction with Europol was established, it is a division of the national Central Bureau of Interpol at the Ministry of internal Affairs of the Russian Federation. RNCP interacts with Europol in the framework of its activities in the processing of requests of the latter, the direction of requests to Europol, the formation of reference materials, etc. Interaction of law enforcement agencies of Russia and Europol allows to exchange information more productively, thereby developing the most effective plans of investigation of transnational crimes and exposure of transnational organized groups.

Conclusion

Summing up the study, we note the following. The consequences of transnational crimes are harmful not to one state but to the whole of humanity, as they violate basic human rights: the right to life, the right to health, the right to work and others. Only by uniting will the international community be able to confront this serious threat. On the example of illegal sale of drugs, the authors showed the scale of the problem, identified the most effective mechanisms to combat this type of transnational crimes. It should be noted that domestic methods of detection of transnational crimes are outdated and are not able to fully meet the needs of the investigation. Confronting transnational crime, which is complex in nature, requires the interaction of both the entire world community and individual regions. Cooperation between the European Union and Russia as the largest participants in international relations is particularly important. Despite the established regulatory framework for combating organized crime, in particular drug trafficking, there are problems that require immediate solutions. It should be noted that the need for work on which it is necessary to intensify in the near future: the development of a unified anti-drug policy, the harmonization of national legislation, the development and implementation of international operations to control narcotic and psychotropic drugs in legal circulation, further exchange of experience on drug demand reduction, prevention, treatment and rehabilitation of drug patients. At the international conference "Russia-EU Partnership after enlargement: strategic planning and everyday implementation" Fedorov (2003) said that Russia shield protected Europe from the flow of drugs coming from the East. However, this can not continue permanently, because there are many examples of the elimination of drug smuggling channels from Europe, which caused significant harm to Russia. Only constructive cooperation between Europe and Russia will help to improve the situation regarding transnational organized crime in the field of illicit drug trafficking.

Abstract

This paper analyzes the relationship of credit growth to credit risk, namely the level of non-performing loans in 69 banks located in the ASEAN-5 countries (Indonesia, Malaysia, Thailand, Philippines, and Singapore). Bank credit risk is susceptible to financial constraints in which the relationship with the smooth running of the Bank in carrying out its core business. On the other hand, the growth of bank credit can affect the increase in NPLs, but at a certain point, credit growth can actually affect the decline in the level of NPLs. This indication of bad credit can arise if the related banks have constraints from the credit given and also the capacity of the assets owned by the Bank. This paper describes how the Bank's credit growth and the size of the firm can affect the risk related to the Bank's non-performing loan. In the context of this paper, the model used is the GMM estimator, which is suitable for research using lagged variables so that the influence of the previous period can be seen significantly. To take a more in-depth look at the effects of NPLs, using the selected variables can affect NPLs to be more specific influences. To illustrate the effect of this approach, research was conducted based on banks listed on ASEAN-5 countries. Analysis results prove that credit growth and firm size have a significant effect on non-performing loans. this is evidenced by the risk management development that occurred in ASEAN-5 countries.

Keywords: Non-Performing Loan; Credit Growth; Firm Size; Risk Management; GMM Estimator

Introduction

The 1997-1998 financial disaster, which has been hit the Asian economic system, has been affected the banking region. ASEAN-5 is a designation for 5 Southeast Asian countries, namely Indonesia, Thailand, Malaysia, the Philippines, and Singapore. Two countries, namely Indonesia and Thailand, were countries that had a significant impact during the Asian monetary crisis in 1997/1998 at that time. As for Malaysia and the Philippines, it is quite affected only by the decline in the value of their currencies. But not for Singapore, which only experienced a decline in investor confidence and demand from all investors in the Asian region. The 1997-1998 monetary crisis that once hit the country's economy in Southeast Asia, which has affected the banking sector, which began with the weakening of the exchange rate of the Thai state, which weakened the exchange rate of Bath (Yamazawa, 1998).

The crisis that began with the weakening of the nominal exchange rate in Southeast Asian countries against the United States dollar has caused a lot of bad credit and reduced public confidence in banking institutions, which in turn has weakened the banking intermediation function. At that time many people withdrew their funds (rush) in private banks and transferred them to banks that were considered safe (flight to safety), namely foreign banks and government banks or even abroad.

To prevent this, banks set high-interest rates for funds and then followed by adjustments to high lending rates. With these conditions, bank lending has stalled because the real sector is unable to absorb expensive funds. The impact of these conditions is the weakening of economic growth.

Banks always face the risk of Non-performing Loans (NPLs) because of their main function as intermediary financial institutions. Credit activities are said to be safe if the NPL ratio of the Bank concerned is less than 5%. Efforts to reduce the level of NPL ratios and eliminate the risk of bad credit

have certainly been made, as is the case with the credit application policy, the 5C principle, and others. But in reality the things that are policy and principle are still not perfect in its application. Not because of one of these policies, but there are factors that affect the level of NPL in the company.

Many previous studies have examined NPL, but with the aim to update and to strengthen the results of previous studies, this study was conducted, especially for the influence of the variable Credit Growth on NPL which is still very rarely examined. Besides that, in previous studies there were still inconsistencies in the results between the variables tested influence on NPL. This study seeks to fill these gaps so that more literature can be used as a reference for further research. The variables that will be used as control variables between Credit Growth and Bank Size to NPL in this study are Capitalization (CAR), Revenue Diversification, Debt to Asset Ratio, Return on Assets (ROA) and Operating Risk (SDROA).

The paper proceeds as follows. In section 2, a literature review related to this research is explored. Then, the methodology is presented in section 3. Data and result is studied in section 4. The final section 5 concludes the paper.

Literature Review

According to Kuncoro (2002), Asset Quality shows the quality of assets related to credit risk faced by banks due to lending and investment of bank funds in different portfolios. Every investment of bank funds in earning assets is assessed for quality by determining the level of collectibility, which is whether Current, Substandard, Doubtful, or Loss. Non-performing loans is one of the key indicators to assess the performance of bank functions. One of the functions of a bank is as an intermediary institution or a liaison between parties who have excess funds and those who need funds.

Credit growth illustrates the level of development of total loans extended to third parties in a given period. The higher the credit growth, the better the quality and quantity of credit. The higher the credit quality, the higher the chance for banks to channel the funds back to the public or debtors. With this in mind, the opportunity for banking is even greater in making profits (Vithessonthi, 2016)

According to Hammami and Lindahl (2014), credit growth defines as calculations of the natural logarithm of total bank credit with total bank assets. Total bank credit is the overall credit from loans provided by banks and all bonds issued by banks, less the allowance for impairment losses provided by banks in preventing bad loans.

This study will focus on looking at the effect of credit growth being an independent variable on bank credit risk, which in a previous study conducted by Vithessonthi (2016) found that there were different relationships between the two research periods. The variable is said to be significantly positive between credit growth and bank credit risk before the crisis in 2008, and the variable is said to have a significant negative relationship in the post-crisis 2008. as an indicator of non-systemic risk, which is the credit risk itself.

Kingu, Macha, and Gwahula (2018) said that Bank size has a positive effect on the non-performing loan dependent variable. This research was conducted at banks in Tanzania which incidentally have been effective in addressing credit risk and good loan portfolios. It was found that the greater the market share obtained by banks could reduce the level of non-performing loans while the research of Alexandri and Santoso (2015) said that it has a negative relationship to non-performing loans because of companies with a small market share, especially Rural Credit Banks (Bank Perkreditan Rakyat) that do not have a significant influence in influencing existing credit risk.

Research from Kingu et al. (2018) also says that the capital adequacy ratio is negative and statistically significant for the existence of non-performing loans. The results of his research show that the higher the capital ratio, the less non-performing loans, whereas Kumar and Kishore (2019) say that the relationship between the capital adequacy ratio is insignificant, due to policies in Indian banks.

Ferreira, Zanini, and Alves (2019) prove from his research that revenue diversification has a relationship with the non-systemic risk of banking. This is indicated by the diversified non-interest income, which has a positive and significant relationship to the Z-score, which in this diversification

activity reduces the risk of insolvency. This statement is in line with Sariartha and Husnan (2015), which states that revenue diversification can reduce non-systemic risk in banks in carrying out their business processes.

From previous research conducted by Vithessonthi (2016) shows that the deposit to asset ratio has a positive effect on non-performing loans. With high deposits as a percentage of total assets shows that the development of financial security. This shows that the deposit program is cost-efficient. Research conducted by Mwangi, Muturi, and Ombuki (2015) shows that the deposit to asset ratio has a significant contribution to financial security.

According to the research conducted by Ekinci and Poyraz (2019) on banks in Turkey, it shows that the increase in bank lending and the lack of management in carrying out monitoring and screening of borrowers results in a negative effect on return on assets. This is in line with the results of Probondani (2018), which shows that return on assets has a significant impact on the value of credit risk as measured by non-performing loans, which have an impact on reducing the profitability of government banks in Indonesia.

According to the research of Vithessonthi (2016), shows that banks in Japan have results related to operational risk from ROA having a positive correlation to non-performing loans. This calculation uses the standard deviation for the three sample years as the variability of return on assets.

Research Methodology

This research was conducted in public banking that includes ASEAN-5, namely Indonesia, Malaysia, Singapore, the Philippines, and Thailand, during the study period. The study was conducted through the websites of each company, the stock exchanges of each country, and by using the Eikon Thomson Reuters data stream. The time of the study was conducted from 2019 to 2020. The selection of the research period between 2013 - 2018 was due to the non-performing loan performance, which tended to decrease when it touched the year between the end of 2013 to the end of 2018. The purpose of this study is to determine the extent of internal factors in the banking sector that affect credit growth so that if the data are taken starting in 2014, it is likely that external factors that will predominantly influence the variable credit growth in ASEAN-5 countries.

Data is obtained by getting it from outside the company, which is called external data. Viewed from the time dimension, the data used is dynamic panel data; that is, the data obtained is a combination of time series data and cross-section data. Meanwhile, for the purposes of statistical analysis, the model testing will be used by the Bank's annual financial statement data. Bank data is the total data of government banks and private banks listed publicly.

The number of public banks covered is 83 (eighty-three) banks, consisting of 44 banks in Indonesia, 10 banks in Malaysia, 15 banks in the Philippines, 3 banks in Singapore, and 11 banks in Thailand. While there are banks included in the sample selection results that will be the subject of research are 34 (thirty-four) banks from Indonesia, 8 (eight) banks in Malaysia, 14 (fourteen) banks in the Philippines, 3 (three) Singaporeans banks and Thailand as many as 11 (eleven) banks. So that the actual amount can be used to become 69 (sixty-nine) banks. The number of observations used in the study was (6 x 69 = 414) 414 bank-years. Observations were taken from each bank's annual report for six years of observation. The sample size is used as a basis for testing the hypothesis

In this study, there are 7 (seven) variables that are grouped into three parts, namely the dependent variable, the independent variable, and the control variable. The dependent variable (Y) in this study is credit risk, as indicated by the non-performing loan (NPL) variable. Meanwhile, the independent variable is Credit Growth (BCG) (X1) and Size (X2). The control variables used are Capital Adequacy Ratio (X3), Revenue diversification (BRD) (X4), Deposit to asset ratio (DEPTA) (X5), Return on Assets (ROA) (X6), and Operational Risk (SDROA) (X7).

Table 1: Explanatory variables

No	Explanatory Variable	Equation	Definition
1	Non Performing Loan	$\frac{Non-Performing\ loan}{Total\ Credit}$	Y
2	*Credit Growth*	$\boldsymbol{Bank\ Credit\ Growth = ln\frac{Total\ Credit}{total\ asset}}$	X1
3	*Size*	$\boldsymbol{Size = \ln total\ assets}$	X2
4	*Capital Adequacy Ratio*	$\boldsymbol{CAR = \frac{Tier\ 1\ Capital + Tier\ 2\ Capital}{Risk-Weighted\ Assets}}$	X3
5	*Revenue Diversification*	$Revenue\ Diversification(HHI) = \left(\frac{INT}{NOR}\right)^2 + \left(\frac{NON}{NOR}\right)^2$	X4
6	*Deposit to asset ratio*	$Deposit\ to\ asset\ ratio = \frac{Total\ deposit}{Total\ Asset}$	X5
7	*Return on asset*	$Return\ on\ Asset = \frac{EBIT}{Total\ Asset}$	X6
8	*Operating risk of ROA*	$SHROA = {ROA_{i,t}}/{\sigma ROA_i}$	X7

The optimal Non-performing loan for banking I in period t is determined as NPL * it. Then Xit is symbolized as a collection of independent variables and control variables, which have been used as previous studies by Radivojević et al. (2019). The model used to sees a lagged variable to see its relationship within a one-year difference. The model is

$$NPL^*{}_{it} = \beta_0 NPL_{i,t-1} + \beta_i X_{i,t} + \varepsilon_{i,t} \quad (1)$$

by using lagged variables can cause errors in using too much lagged variable. In other words, the possibility of bias can occur in using panel data such as the use of OLS and FE methods. In addition, the model can also cause bias due to endogenous factors that arise due to the use of lagged variables. And to reduce these endogenous variables, the GMM method is used as a reference to minimize the endogenous factors that emerge. The modified model is shown below

$$NPL^*{}_{it} = \alpha + \beta_0 NPL_{i,t-1} + \beta_1 BCG_{i,t} + \beta_1 SIZE_{i,t} + \gamma_i X_{i,t} + \varepsilon_{i,t} \quad (2)$$

Where:

$NPL^*{}_{it}$: *Non-Performing Loan*

NPL_{it-1} : *Lagged one period of Non-performing loan*

BCG_{it} : *Credit Growth*

$SIZE_{it}$: *Firm Size*

X_{it} : *Control Variable*

ε_{it} : *Error terms*

Therefore in using the OLS method will get inconsistent results. By using two lagged variables will increase accuracy in calculating non-performing loan variables. Therefore, for independent variables and control variables, lagged variables are carried out in one period.

Arellano-Bond and Blundell-Bond estimators have one-step and two-step variants, but two-step is more efficient. Two-step standard errors tend to be biased downwards (Arellano & Bond, 1998). For that, there is a finite-sample correction for the two-step covariance matrix from Windmeijer (2005). This can make two-step robust estimates more efficient than one-step robust, especially for GMM systems.

After modeling the data and getting the estimated parameters, statistical testing to be performed are the parameters significance testing, the goodness of fit model testing, and the overdispersion model testing. After all of the testing are done, and the model is fit, best estimate of non-performing loan over in listed banking companies of ASEAN-5 Countries can be derived.

A regression model is said to have these characteristics if it has a minimum variance, if average, the estimated value will have the same value as the actual value, and the estimator used is not biased, and no estimator has a smaller variance. However, there are often regression problems that arise in regression models due to the use of several independent variables, such as serial correlation and other validity checks fo GMM methods.

Fig. 1: Research Methods Flowchart

Results

From the statistical results, it can be seen how the average of the variables used and see the most significant and smallest values of the data taken and the average and standard deviation to see the normality of the data to be used. With a total of 414 observations, the samples taken were those listed from the public financial statements with complete information for six years.

Table 2: Descriptive Statistics

	NPL	BCG	SIZE	CAR	REV	DEPTA	ROA	SDROA
Mean	0.0274	0.1194	20.7843	0.1866	0.3066	0.7685	0.0104	0.0036
Median	0.0231	0.0965	21.0630	0.1699	0.3024	0.7825	0.0108	0.0018
Maximum	0.3455	1.9988	26.7251	0.8749	0.8608	0.8977	0.0390	0.0728
Minimum	0.0000	-0.4394	14.1535	0.0802	0.0213	0.4808	-0.1173	0.0001
Std. Dev.	0.0251	0.2041	3.5576	0.0700	0.1649	0.0730	0.0122	0.0075
Observations	414	414	414	414	414	414	414	414

If we look at the results of the correlation tables that have been tested, it can be seen that the correlation coefficient between the independent variables does not have an enormous enough value. The highest value is 0.6252, and it does not reach 0.7. By looking at the results of the table above, we can conclude that this model does not have multicollinearity. This is because the correlation coefficient between independent variables is still under the condition of multicollinearity, which is 0.8 (Gujarati & Porter, 2008)

Table 3: Serial Correlation Test Tables

Correlation	NPL	BCG	SIZE	CAR	REV	DEPTA	ROA	SDROA
NPL	1.0000							
BCG	-0.2648	1.0000						
SIZE	-0.0772	-0.2349	1.0000					
CAR	0.1009	0.2152	-0.3255	1.0000				
REV	-0.0325	-0.1450	0.6252	-0.2167	1.0000			
DEPTA	0.0254	0.0751	-0.2573	-0.1441	-0.3067	1.0000		
ROA	-0.3345	0.1429	0.1978	0.0033	0.0588	-0.2197	1.0000	
SDROA	0.3266	-0.1262	-0.2952	0.1132	-0.0613	0.0405	-0.6146	1.0000

This first analysis uses a panel data regression type where the selected variables have been tested in several previous studies, where the value of Non-performing loans influences the selected instrument variables (Vithensonthii, 2016). The dependent variable (Y) in this study is credit risk, as indicated by the non-performing loan (NPL) variable.

By seeing the goodness of fit using the Wald test, the regression model conducted and estimated using the first difference generalized method of moments is already significant. This can be seen from the following table.

Table 4: Wald Test

Wald Test:			
Equation: EQ01			
Test Statistic	Value	df	Probability
F-statistic	6.039807	(7, 332)	0.0000
Chi-square	42.27865	7	0.0000

It can be seen that this condition has a p-value for F-statistics of 0,000. With a significance level of 1%, then the null hypothesis, which states that the chosen instrument variables do not have a significant effect on the dependent variable simultaneously, can be rejected. So overall, it can be said that the instrument variable has its own influence on the dependent variable.

Table 5: Arellano-Bond Test

Arellano-Bond Serial Correlation Test				
Equation: EQ01				
Date: 05/09/20 Time: 14:09				
Sample: 2012 2018				
Included observations: 345				
Test order	m-Statistic	rho	SE(rho)	Prob.
AR(1)	-0.429767	-0.009178	0.021356	0.6674
AR(2)	-1.772427	-0.013717	0.007739	0.0763

From the Arellano-Bond test, it can be concluded that there is no second-order autocorrelation in the regression model used. This is evidenced by the p-value of the m-statistic AR (2) of 0.0763, by using a significance level of 5%.

By using NPL as a dependent variable and looking at the effect of its lag variable, the regression results obtained with the Generalized Method of Moments (GMM) method use data from the previous period (t-1) to the next period. The regression model used is the Two-Step System Generalized Method of Moment (GMM).

This method is carried out to overcome bias results due to endogeneity problems that often occur in the OLS method. GMM is the most suitable method to be used in this study because GMM is used to overcome endogeneity problems that arise. After all, there is a possibility that the relationship between the dependent variable and the independent variable not only reflects the influence of that two variables, but also affects the dependent variable on the control variable. Following is a table of regression results using the GMM dynamic data panel model.

Table 6: GMM Dynamic Panel Data Results

Dependent Variable: NPL				
Method: Panel Generalized Method of Moments				
Transformation: First Differences				
Date: 05/09/20 Time: 14:08				
Sample (adjusted): 2014 2018				
Periods included: 5				
Cross-sections included: 69

DEPTA	-0.033659	0.015756	-2.136298	0.0334
ROA	-0.383596	0.140282	-2.734467	0.0066
SDROA	0.472304	0.314167	1.503353	0.1337
@LEV(@ISPERIOD("2014"))	-0.001485	0.000971	-1.528237	0.1274
@LEV(@ISPERIOD("2015"))	-9.15E-05	0.000790	-0.115791	0.9079
@LEV(@ISPERIOD("2016"))	0.004333	0.001098	3.945346	0.0001
@LEV(@ISPERIOD("2017"))	0.000526	0.001166	0.450533	0.6526
@LEV(@ISPERIOD("2018"))	-3.89E-05	0.000830	-0.046804	0.9627
	Effects Specification			
Cross-section fixed (first differences)				
Period fixed (dummy variables)				
Mean dependent var	0.002428	S.D. dependent var		0.022794
S.E. of regression	0.021989	Sum squared resid		0.160527
J-statistic	23.18214	Instrument rank		32
Prob(J-statistic)	0.229414			

The results of the Sargan test value listed above was obtained the j-statistic value of 0.229414. With a significance of 10%, it can be assessed that the number can be greater, so that the null hypothesis of no overidentifying restrictions fails to be rejected

T-test was conducted to test the effect of independent variables on the dependent variable individually. The results of the test can be seen by comparing the value of α with a p-value. If the P-value is smaller than the Alpha value of 0.05, then H0 is rejected, and H1 is accepted, which means that there is an influence between the independent variable and the dependent variable. Conversely, if the p-value is greater than the Alpha value of 0.05, then H0 is accepted, and H1 is rejected where it indicates that there is no influence between the independent variable and the dependent variable.

Discussion

Table 7: GMM Dynamic Panel Data Summary (One-tailed)

Variable	Coefficient	t-Statistic	Prob. (one-tailed)
BCG	-0.0105***	-2.9605	0.0016
SIZE	0.0078**	2.0138	0.0224
CAR	-0.0141	-0.7188	0.2363
REV	0.0109*	1.3869	0.0832
DEPTA	-0.0337**	-2.1363	0.0167
ROA	-0.3836***	-2.7345	0.0033
SDROA	0.4723*	1.5034	0.0668
***Significancy at 1%			
**Significancy at 5%			
*Significancy at 10%			

Based on Table 7, it can be seen that the p-value of the independent variable is 0.0016, where when the p-value is smaller than the significance value of Alpha 0.01, then H0 is rejected, and H1 is accepted. So it can be concluded that the independent variable in this study, namely Credit Growth (BCG), has a

significant influence, there is a dependent variable, namely Non-Performing loans (NPL), which indicates that credit growth can be a predictor of non-performing loans. Then the p-value of the independent variable that is size shows a value of 0.0224 which means that there is a significant influence between SIZE and the NPL dependent variable which means SIZE can indeed be a predictor to see non-performing loans which is also in line with previous studies.

By looking at the control variables, there are four control variables that indicate the significance of the Non-Performing Loan dependent variable, namely revenue diversification (REV) with a probability value of 0.0832 with a significance of 10%; Deposit to asset ratio (DEPTA) with a probability value of 0.0167 with a significance of 5%; then Return on Assets (ROA) with a value of 0.0033 using a 1% significance; and Operating Risk (SDROA) with a value of 0.0668 using 1% significance. These four control variables have a significant influence on Non-performing Loans, so that the chosen variables are in accordance with previous research journals.

Other control variable regression results, namely the Capital Adequacy Ratio (CAR) showed a p-value of 0.2363 where this value is greater than Alpha 0.05 and indicates that no significant effect was found between the CAR and the NPL dependent variable so that in this study indicated that the CAR could not be used as a predictor for predicting an increase in bad credit in this study.

Conclusion

After running some data analysis, Credit growth has a significant and negative effect on non-performing loans in public banks that include ASEAN-5. This indicates that in banks in Southeast Asian countries, credit growth can be used as a predictor to predict an increase in non-performing loans in the state. This can happen because the customer's sentiment towards credit demand is very dependent on the economic conditions in the state. It can be pointed out that the increase in NPLs in ASEAN-5 is related to the decrease in credit demand from customers as well as from monetary conditions such as inflation and changes in interest rates in the country.

Size as an indicator of asset capacity owned by banks has a significant and positive influence on non-performing loans of public banks, including ASEAN-5. This indicates that banks in ASEAN-5 countries with the majority of banks with large assets instead indicate an unfavorable credit cycle. This inadequate credit cycle shows that there is inadequate risk management for banks that have large assets in lending.

The selected control variables that have been chosen indicate a significant effect on the changes in Non-Performing Loan, except the Capital Adequacy Ratio (CAR). It can be seen that the minimum capital supply that has been provided by the bank did not affect the increase in NPL.

Acknowledgment

The author gratefully acknowledges the support of the Master of Management, the University of Indonesia to undertake his master studies, also acknowledges Mr. Imo Gandakusuma, for their constructive criticism of the manuscript, which led to important improvements being made to this paper.

Abstract

Indonesia issued Law Number 20 / 2016 on Trademark and Geographical Indication. This new law also introduces several significant changes that refine current practices; one of the most important amendments is the broadening scope of the trademark category including three- dimensional form, sound marks, and hologram marks, known as Non - Traditional Trademark. This provides broader progressivity in the term scope of protection although the requirement of visually perceptible for trademark remains to stand as a limitation in the name of legal certainty. This paper used juridical normative method, aims to examine the new scope protection of trademark according to Indonesia's new trademark law and how it impacts to the implementation of trademark protection in Indonesia compared to some countries that also applied the protection of Non - Traditional Trademark. The result shows that the requirement "graphically visible requirement" in Indonesia New Trademark Law provides certainty in its implementation of legal protection although its limiting the scope of trademark protection comparing to other jurisdictions where many countries perceived Non - Traditional Trademark as a progressive effort to comply with global trade tendencies for in recent years the industries keep registering more and more trademarks in an unconventional area like a hologram, three - dimensional trademark, sounds, scents and even taste and this potentially result in the limitation of protection for Indonesia's product in the global market.

Keywords*:* Non - Traditional Trademark, Legal Protection, Indonesia Trademark Law

Introduction

Statement of the Problem

Trademark plays a pivotal role in the modern economic world as an inevitable part of product identity. The main function of a trademark is to provide distinctiveness among products and services. Traditionally trademark limited to word, color, symbol, or design or a combination thereof. Over the years, the concept of a trademark has expanded along with the massive growth of the global market and international trading. The producer faces the urgencies to individualize their product and sharpen the distinctiveness from the competitor's products to give the clearer information about the product and services (Mauritius Research Council, 2003) by individualizing the signs and characteristic as the element of distinctiveness to strengthen product impression, not limited to traditional forms like word, color, and symbol, but also in broader scope and senses, for example, the scents have been used as the product identity in the commercial market to sharpen the product impression in the eye of the consumer. (Hawes, 1989)

Globally, the producers use many measures and resources to gain a distinctive impression of a product that can vary in a very wide range starts from color, sound, position, olfactory, taste, moving image, 3 - dimensional designs, and shapes. These market phenomena tend to broaden the trademark in the scope of definition and sharpen it in the scope of the use and function. The definition of the non-traditional trademark can be extremely wide appearing as a challenging issue in the matter of legal protection and verification in trademark registration. Considering the uptight intersection between the definition and scope of the non-traditional trademark in Indonesian Law Number 20 / 2016 on Trademark and Geographical Indication and the very real and factual main function of a trademark, the two most important statements of the problems in this paper are:

1. Has the approach of nontraditional trademark legal protection according to Indonesian Law Number 20 /2016 on Trademark and Geographical Indication meets the needs of Indonesian products?
2. How to create synchronized legal protection of non-traditional trademark for Indonesia's product concerning international regulations, comparative studies, and national needs?

Objectives

This paper aims to:

1. Identify the approach of nontraditional trademark legal protection according to Indonesian Law Number 20 / 2016 on Trademark and Geographical Indication and its implementation in protecting Indonesian products
2. Analyze the formulation of the synchronized legal protection of nontraditional trademark concerning international regulations, comparative studies and national needs

Significance of the Study

This research expected to be the reference for interested parties and institutions related to the legal framework protection for the non-traditional trademarks according to Indonesia new trademark law and how to formulate legal protection of non-traditional trademark for Indonesia's product taking international regulations, comparative studies and national needs as consideration to formulate appropriate and synchronous protection of trademark in the global scope.

Trademark Protection in Indonesia according to Law of the Republic Indonesia Number 20 /2016 on Trademark and Geographical Indication

Law of the Republic Indonesia Number 20 /2016 on Trademark and Geographical Indication has entered into force on October 27th, 2016 and took effect on November 28th, 2016 with some major changes where Indonesia now protecting non-traditional trademarks in certain form, limited to three - dimensional trademarks, sound marks, and hologram. This limitation is a direct consequence of the definition and requirement in article 1 verse (1). The trademark protection in Indonesia uses the visual approach with the "graphically visible" requirements. This main requirement excluded non-visual (non-traditional) trademark like olfactory / scent mark from protection for they are lack visual perceptibility.

However, the new definition of a trademark based on Indonesia new trademark law provides broader and better protection of trademark as the effort to accommodate the current development of trade and information technology where creativity becomes an ultimate necessity (Ahmad M. Ramli, Ranti Fauza Mayana and Tisni Santika,2020), which brought consequences to the ease and vary creative process of creating effective product marketing strategy including product identity development through branding.

According to the present Indonesia legal context, the broader scope of trademark protection potentially brought significant implications in providing legal protection for various forms of trademarks. As further implication downstream, this potentially results in chain reactions from encouraging the producers to be more creative in branding creation and strengthening the identity of products although this new scope of protection limited to Hologram, 3 Dimensional Trademark, and Sound Mark.

Indonesia grants legal protection of trademark based on registration (first to file principle), this puts trademark registration as paramount importance. The requirements regarding the form of trademark registration based on Article 4 of Indonesia Trademark Law are: the application must contain color(s) if the Mark being applied for registration use color elements, if the Mark is in 3 (three) dimensional shape, its Mark representation is supplemented in the form of characteristics of the Mark, for sound mark the application supplemented with musical notes and sound recording this strengthen the requirement of visual perceptibility of trademark protection.

The Vary Wide Scope of Non - Traditional Trademark

The Standing Committee on the Law of Trademarks, Industrial Design and Geographical Indications established by The World Intellectual Property Organization (WIPO) classified nontraditional trademarks into two categories: Visual trademarks for example 3 (three) dimensional marks, hologram and color marks and non - visual trademarks such as sound marks, olfactory/scent marks, and taste marks. In the term of nontraditional trademark, to define the criteria means to limit the scope of protection. This wide scope frame trademark not only limited to any word, name, or symbol but also including device (and any combination of thereof) used/utilized by manufacturer/merchant as product identification to differentiate and distinguish their goods from those made / manufacturers by others. This approach tends to focus on the function and the use of trademarks as the means of identifying a product, providing the information for consumer about the origin of the product and as the symbol of the reputation of the producer, manufacturer or merchant (Sullivan, 2016), further trademark broadly viewed as a sign, or any element that also represents something other than itself. (Sandri and Rizo, 2003).

Considering the difficulties and challenges in determining the definition of non - traditional trademark, any trademark that does not fall with within the traditional scope of a trademark shall be considered as non-traditional trademark (Carapeto, 2016) and as the consequences, the registration criteria for nontraditional trademark appear to be difficult to satisfy, and further, each country to regulate the limitation considering the scope of protection for nontraditional trademark by defining what nontraditional trademark is or strictly define the limits of trademark types that can be registered, the broader the definition of a trademark the broader the scope of trademark protection.

International instruments mostly leave the scope protection of trademarks to national sovereignty. The first example is Paris Convention for the Protection of Industrial Property of March 20, 1883, as last amended on Sept 28, 1979, does not provide the limitation of protection in the absence of any specific definition of trademark and leaves the state parties to define trademark and incorporate any relevant regulations in their domestic law. The condition and requirement for the filling and registration of trademarks shall be determined in each country of the Union by its domestic legislation. TRIPs Agreement also allows the contracting parties to provide not only visually perceptible signs that are eligible for protection. The registrations of non-visual trademarks are not expressly excluded. Article 15 verse (1) TRIPs Agreements states the broader definition as any signs as long as they are capable to conduct the function of distinctiveness for products and services ranging from personal names, figurative elements, numbers, letters, and colors also any combination of these signs, TRIPs Agreement emphasized Trademark as the sign of product and also implement the principle of free to determine by allowing member states to grant trademark protection based on use. Further, members may (and may not) require a trademark to be visually perceptible.

As the consequences of those international regulations, the protection of nontraditional trademark in the European Union has been progressively conducted through *European Trademark Reform* with the latest Amendment of Trademark Regulation from Community *Trademark Regulation* (CTM) to

European Union Trademark (EUTM). EUTM entered into force on March 23rd, 2016, this new regulation defines trademark broadly as signs that capable of distinguishing the goods or services whether its particular words, personal names, letters, numbers, colors or designs, including the shape of goods or sounds to differentiate goods/ services of one venture from those of other ventures. These signs are registered to enable the competent authorities to determine the exact and precise subject of the protection afforded and enable the public to identify these signs and the relations to the manufacturer. (Kulbaba, 2016)

The graphical representation requirement has removed in trademark registration (Gruebler, Disdier-Mikus, Fields, and Hoy, 2016). The definition tends to be flexible to allow the new type of fillings that may be possible in the future due to technological advancement. The basis protection approach is the function of the sign registered as a trademark can be any signs capable of distinguishing the goods and services (Kumar, 2016). This wide scope doesn't mean that anything can be registered as trademarks. Article 7 verse (1) point (e) states the absolute grounds for refusal in case the signs exclusively consist of the natural shape/characteristic of the goods themselves, came from the necessity to obtain technical function, or in case the shape / characteristic result substantial value of goods. The scope of trademark protection in the European Union consists of a wordmark, figurative mark, figurative mark with letters, 3D mark, color per se mark, and sound mark.

This wide scope of definition and protection brought a direct consequence in the term of registration. It will be necessary to ensure that all trademark offices are equipped to manage different kinds of nontraditional registration fillings and to formulate certain mechanisms for verification of proof. The adding of the phrase *"or another characteristic"* is a step to counterbalance the removal of the graphical representation requirements which allow the expansion types of registrable trademarks, the grounds of refusal should be in the balance position. The wide scope of non-traditional trademark leads to the variation of trademark protection between one country and another.

A broader scope of trademark protection in the United States of America (USA) regulates by the *Lanham Act*. Beside word, name, and symbol, *Lanham Act* also includes devices along with any combination of thereof). *Lanham Act* also emphasizes the functional aspect of a trademark as the instrument adopted by merchants, producers, or manufacturers to identify, personalize, and distinguish their products from others'. This functionality and distinctiveness approach opens the possibility of non-traditional trademark protection. The scope of trademark protection in the USA consists of Color Trademark, Sound Mark, Olfactory Mark, Taste Mark, Moving Image Trademark, and Three Dimensional Design and Shape.

Color marks are marks that consist solely of one or more colors used on particular objects (Stockell and Hickey, 2009). To gain the color trademark protection, the applicant must prove that the color brings distinctiveness as applied to particular objects. United States Patent and Trademark Office (USPTO) will identify the determinant factors such as the duration, color promotion, and the level of product knowledge among consumers. There is a certain number of the color marks that have gained the trademark protection, for example, Tiffany & Co.'s robbin's egg color for boxes and shopping bags. Since 1845 the color has used extensively on promotional materials, including boxes and shopping bags. The Tiffany & Co Blue Color known as "*Light-medium Robin egg blue color"* is protected as a color trademark based on Registration Number 2,359,351 for boxes and Registration number 2,416,795 for shopping bags. (Max, 2012). Sound can be registered as a **sound mark** when the sound gives a certain link with the associated product and services. The applicant should clearly describe such sound marks by attached the musical notation as require by *layman's term*, for example, Metro – Goldwyn-Mayer (MGM)'s iconic lion's roar. (Daniel, 2012). The applicants also require providing audio record as supporting evidence.

Olfactory mark protection in the USA based on the consideration that sensory element especially scent is a determinant factor for product recognition. Sensory marks for example scent is also a determinant factor of products. The first registered olfactory trademark was a *Plumeria blossom* – scented registered in 1990 by California Company OSEWEZ. In the olfactory mark registration, the applicant should be able to prove that the scent or fragrance is not related to the functional or practical use of the product. For the olfactory mark, there is no graphical visibility requirement;

however, the applicants still require providing a detailed description of a certain scent. The physical specimen of the scent also uses as the supporting prove in trademark registration. To be registered as olfactory marks the applicants have to show that the scent or fragrance serves the function to identify and distinguish a brand or product. This means that the product whose purposes merely smell related like perfume or air fresheners cannot be granted with olfactory marks (Greene, 2015).

Taste marks protection can only be applied to goods and not services. The example of the taste mark is the application for the "Taste of Strawberries for pharmaceutical" applied by Ely Lily and was represented using a verbal description. Lanham act does not exclude taste marks from protection, but it's still very challenging to prove the use of the taste is a non-functional purpose of a product. **Moving Image Trademark** is given the protection when the applicant provides the specimen describes the movement of the image and its correlation with the product. Such specimens can be video recording, serial images, or a set of screen shots and have to describe the whole movement or repetition. (George, Hardy, Mangan, Poulter, 2013). Three Dimensional Designs and Shape in Lanham Act known as Trade Dress. The trade dress of a product is essentially the total image of a product and may include features such as size, shape, color or color combinations, and texture, graphic or even particular sales technique. (Pattishall, Beverly W and Hilliards, 2013).

Methodology

This research using juridical normative methods preceded by studying and examining the legal regulation and literature on theories and concepts related to the subject matter of this research. Regulations placed as the primary sources that apply to a particular situation, the research enriched by viewing the question as a matter of synchronizations among different normative systems.

Result of Analysis

The Approach of Non-Traditional Trademark Legal Protection According to Indonesian Law Number 20 /2016 on Trademark and Geographical Indication and its Implementation in Protecting Indonesian Products

Law Number 20 /2016 on Trademark and Geographical Indication defines Trademark as the signs in form of drawing, logo, name, words, alphabets, numbers, color composition in two-dimensional form and/or three-dimensional form, sound marks, hologram or the combination of two or more elements which are graphically visible to differentiate goods and/or services produced by the person or legal entity in the commercial activity of goods and services. Indonesian trademark law does not clearly define sound marks, three-dimensional marks, and hologram marks although this law does state the requirement of protection for those marks. For example, for the registration of sound marks, the applicant must submit a notation or sound recording as supporting prove. For three-dimensional marks, the applicant obliged to submit the trademark label in the form of three-dimensional characters that can be seen from the front, side, top, and bottom. Indonesian Trademark law does not state the requirement of hologram mark registration. This raises the assumption that the requirement to register a hologram mark is in has the same requirement as the traditional mark.

The compulsory requirement of a trademark to be graphically visible put the big challenge for registration of the non-visual mark, except sound mark that can be easily described with musical notation composition. The requirement visual graphic for trademark protection in Indonesian law, however, very logic requirement since it's a tough thing to translate the intangible aspect like sounds, scent and tastes into a graphically captured format. (Burrel and Handler, 2003).

The compulsory obligation to describe the signs registered as trademark precisely in a visible graphic form is the effort to seek legal certainty, transparency, and publicity principle in trademark registration. (Kitchin, 2011). Legal certainty is one of the most measurable purposes of the law, but this should not be the reason to step aside the objective main function of a trademark to operate as source identifiers by distinguishing the products from those of another. Further trademark has a vital

role in facilitating consumer's buying decisions and as the symbol of a reputation for a producer to gain more economic incentives for their products.

The formulation of legal protection for a non-traditional trademark in Indonesia should be set as urgency since the nontraditional trademark such as scent, taste, and texture came as strong and determinant sensory branding for global products. Practically the acknowledgment of sensory branding as a trademark is given to well known or famous trademark. The purpose is the most basic function of law itself: to protect the righteous owners from the bad faith of others. The expansion of the trademark scope raises the possibility of overlap, for example between the three-dimensional mark and industrial design. When certain design registered as a trademark the validity of protection extends from 10 years to unlimited, as long as the trademark still performs the actual use in trade. For this very reason, the scope of protection and limitation is set clearly and precisely in achieving the certainty concerning the scope of protection, the procedure, and requirement of registration also the implementation of trademark protection.

Synchronized Legal Protection of Nontraditional Trademark: Suggestions Concerning International Regulations, Comparative Studies, and National Needs

The main function of trademark law is to protect the consumers from confusion about the source of products sold under a trademark, trademark as an indicator of the source plays an important role in trade and business (Roth, 2005), with the growing creativity of product development, trademarks appear in new and innovative context (Froomkin, 2004). Businesses show increasing interest in pairing pleasant sensory marks such as scent and taste with their products as smell and taste is said to be one of the most potent types of human memory. Olfactory marks and taste marks are the two hardest kinds of marks to meet the graphical visibility requirement, besides the distinctiveness. Practically, there are few possibilities methods to describe non-visual trademark but so far these methods haven't proved to be effective and precisely describe non-visual trademarks for example through chemical formula/ingredients used by the applicant to represent the olfactory mark and write the ingredients/composition to represent taste marks, although this methods perceived to be insufficient as chemical formula and ingredients represent the substance rather than the actual smell or taste.

Verbal description considers being an option to provide the description of smell and taste although this method lacks of accuracy for there a great possibility that the description will be different between subjects. Specimen sample of the scent/taste can also be attached to support the registration although the stability of this specimen sample has certain issues of consistency. Lyons (1994) introduced Gas Chromatography (GC) or High –Performance Liquid Chromatography (HPLC) method that claimed to be able to provide good qualitative and quantitative information about complex mixtures and produce a graphic output indicating a plot of the amount of each compound against the time taken for its separation (Lyons, 1994)

Besides the hardship in providing graphical visibility form of non-visual mark, the claim of certain scent or certain taste would create a broad scope of a trademark with a strong tendency to unfair competition and monopoly. The limitation scope in trademark registration needs to be set to prevent the broad – generic trademark (as well as the broad patent is prohibited in patent law) and also can be based on the function of the trademark itself as the distinctive factor of the products. In order to be protected, a trademark (especially non-visual trademark) should be affiliated with the products. For example, the scent or taste marks affixed to the product that is not normally scented or tasted. The uniqueness of the scent, taste, and "unique" collaboration with the product has a greater chance to be considered as distinctiveness.

There are few successful registrations of such combination in the United Kingdom and the United States for example "the smell of fresh-cut grass for tennis balls (Vennootschap Onder Firma Senta Aromatic Marketing's Application, Case R 156 / 1998-2 ETMR 429), the scent of roses applied to tires (U.K. Reg No.2000234/filling date Oct 31, 1994) the strong smell of bitter beer applied to flights for darts (U.K. Reg No.2001416/filling date Oct 31, 1994) and the scent of strawberry, grape or cherry for motor fuel (U.S. Reg No. 2,596,156, strawberry; U.S. Reg No. 2,568,512, grape; U.S. Reg No.2,463,044).

The solution for the invisibility of sensory marks like sounds, smell, or taste can be through the visualization of such marks in the form of product application and perform the distinctiveness function because traditionally trademarks are attached to goods. The distinctiveness should be measured on how many the sensory marks produce the distinctiveness on such goods/product they are attached. (De Carvalho, 2011). In other words, the attachments of the sensory marks with the products create the visibility of such invisible sensory marks to meet the graphically visible requirement in trademark law.

Broadly, the doctrine of secondary meaning can be the solution and intersection between sensory marks (non-visual marks) and graphically visible requirement. The secondary meaning gained by certain products through the process of marketing to build the consumer's perception of such products and then apply for trademark protection based on actual use according to article 15 verse (2) of TRIPs Agreement where Member state may make registrability depend on use. However, actual use of trademarks shall not be a condition for filling of application of registration"

Tyser (2015) proposed the existence of secondary meaning can be proved by both direct evidence and indirect evidence. Direct evidence gained from a consumer survey and the scope of product market, whereas indirect evidence gained based on use, exclusivity, advertisement methods, and the evidence that such product is a trendsetter and massively copied by the competitors. Protection based on secondary meaning aims to protect the unregistered - but popular or been used in a relatively long time from the bad faith of unfair competitors and as the recognition of any existing prior rights in accordance with Article 16 of TRIPs Agreements. Further, Indonesia Trademark Law also allows the unregistered well-known trademark owner to fill lawsuit for trademark annulations in case other party registers a similar trademark.

Conclusion

The protection of non – traditional trademark according to Indonesian Trademark Law limited to sound mark, hologram, and three-dimensional trademarks. This scope of protection is the direct consequence of the definition of the trademark which is limited by the graphically visible requirements. This approach took as the effort to guarantee the legal certainty in trademark registration and scope of protection.

Along with the massive development of global trade, in order to formulate synchronized legal protection of nontraditional trademark, it's important for Indonesia to continuously pursue progressivity in protecting nontraditional trademark by adopting some progressive methods and measure taking international regulations, comparative studies and national needs in accordance with the global tendency where trademarks appear in a new and innovative context.

Abstract

Food waste is a widespread issue posing a challenge to global food security and environmental governance. Causes of food waste on the level of wholesalers and retailers, food services, and households involve a wide range of issues including awareness, knowledge, attitudes, preferences, portion size, planning, socio-economic factors, labelling, packaging, handling, storage, stock management, logistics and expectations of a retail chain concerning product quality and shelf life. Among the key reasons for wasting food in households, first of all, non-consumption of the product in a timely manner is given, which results in its deterioration or expiration. In the article, the authors present the results of a study on consumer behavior regarding food waste in households in Poland (N=1070). The focus was on the analysis of the frequency of throwing out purchased food and on identifying the causes of throwing out food by consumers in Poland in relation to consumer segmentation variables (such as age, material status, education and the number of people in the household). The results of the study made it possible to carry out typologies of households that waste food in Poland. The frequency scale and reasons for throwing food out by Polish consumers clearly indicate that they have very low awareness of the problem of food waste. Food waste in Poland is a big ethical, economic and social problem. This study was supported by the National Science Centre (Narodowe Centrum Nauki), Poland [grant number 2017/27/B/HS4/00805].

Keywords: Food Waste; Food Labelling; Food Purchase; Shelf Life Labelling; Expiration; Food Waste Reducing; Consumption Behavior

Introduction

Food waste is a widespread issue posing a challenge to global food security and environmental governance. It is directly related to environmental, economic, ethical and social impacts (Jírovec and Calleja, 2015). It represents an inefficient use of resources such as land, water, labour, energy, emitted greenhouse gases, a decrease of the edible mass of food along the food supply chain, and also, loss of economic value of the food produced. According to the existing data, the food system is highly inefficient as a significant amount of food is quantitatively and qualitatively lost and wasted along the supply chain. Quantitative food loss refers to physical waste resulting in a decrease in the mass of food destined for human consumption. Qualitative food loss is related to the decrease in food value in terms of product usability and fitness for consumption as it may no longer have its intended sensory, physiochemical, nutritional characteristics or even safety. Non-compliance with quality standards have an impact on the economic value of food (FAO, 2019).

Food waste in Poland and the world

FAO estimates that one-third of edible parts of food produced for consumption is lost or wasted globally, which constitutes about 1.3 billion tons per year (FAO, 2011). The concepts of food loss and food waste have been worked out in many reports and papers. The definition of food waste was not universally agreed up, which lead to problems during data collection, analyses and interpretation (do

Carmo Stangherlin and de Barcellos, 2017; Thyberg and Tonjes, 2016). According to the most often used approach, the term 'food loss' refers to a decrease in edible food mass throughout the part of the supply chain (food suppliers in the chain, excluding retail, food service providers and consumers). Food losses occurring at the retail and consumption level are considered 'food waste'. This term refers to the cases when edible products are thrown away. This is a result of the decisions and actions of retailers, food services and consumers (Thyberg and Tonjes, 2016; FAO 2019). It was reported that the share of wasted food at the consumption stage rises with the increase in a society's wealth (European Commission 2010; Lipinski et al. 2013; Kowalska 2017). In low-income countries, mass of food decreases mainly at the production stage. In developing countries, the main reasons for throwing food away are low consumer awareness and a lack of knowledge about proper handling, transportation storage and preparation of foodstuffs, and a lack of technical facilities (Parfitt et al., 2010). In industrialized countries, over 40% of the food losses occur at retail and consumer levels, which is almost as high as the total net food production of sub-Saharan Africa (FAO, 2019).

According to the data collected in the EU under the FUSIONS project, annual food waste in member states was assessed at the level of 88 million tones, which equates to 173 kilograms of food waste per person and one-fifth of the EU food production. The sector contributing the most to food waste in Europe are households, and they are responsible for 53% of cases. The costs associated with food waste for member states were estimated at around 143 billion euros. Households cover two-thirds of this amount (Fusions, 2016). The highest amounts of wasted food were reported in the UK (14.4 million tons per year), then in Germany (10.4 million tons per year), Netherlands (9.5 million tons per year), France (9.1 million tons per year), Poland (9.0 million tons per year), Italy (8.8 million tons per year) and Spain (7.7 million tons per year) (European Commission, 2010). The share of the food lost in the production sector and households varies in particular state members, e.g. in Poland over 6.5 million tons come from the production sector, and over 2 million are attributable to households, whereas in Germany these amounts are 1.8 million tons and 7.7. million tons, respectively (European Commission, 2010).

Causes of food waste on the level of wholesalers and retailers, food services, and households involve a wide range of issues including awareness, knowledge, attitudes, preferences, portion size, planning, socio-economic factors, labelling, packaging, handling, storage, stock management, logistics and expectations of a retail chain concerning product quality and shelf life (European Commission 2010). At home, food can be wasted after purchasing, after preparation and after serving, therefore Wansink (2018) specified three distinct stages of food wasting in households: buying food which is never used, preparing food that is never served, serving food that is never consumed. There are several reasons for this. One of the most common reasons for food wastage reported in researches from many countries is lack of consumption at the right time, which results in its spoilage or expiration (Quested, Ingle and Parry, 2012; Aitsidou et al. 2019; Banki Żywności, 2019). Prior literature suggests that food-related routines related to decisions in the food provisioning process are the main contributors to food waste together with perceived behavioral control. The leftovers reuse routines were found to be the most important drivers of food waste but were closely followed by shopping routines. Planning routines contributed only indirectly as a result of shopping routines. These routines were closely associated with households' perceived skills (Stancu et. al. 2016). Aktas et al. (2018) who investigated the relationship between food waste and contextual factors proved that planning routines (e.g. making a shopping list) can help reduce the food surplus.

Another cause of food waste in households is improper storage or poor stock management. A frequent occurrence is the preparation of portions which are too big in relation to the actual need (Banki Żywności, 2019; Lipinski et al. 2013). Lanfranchi et al. (2016) reported that the main reasons for food waste in Italy are leaving food in the fridge, freezer or pantry for a too long (23%), buying too much in relation to the amount which was needed (13%), expiration (12%), cooking too much (10%) and food spoilage (10%). In the UK, 255 000 tonnes of food are discarded prematurely due to non-compliance with storage conditions information (Brook Lyndhurst, 2011). Household provisioning routines, time management, accounting for family preferences can also influence food waste (Evans, 2012). Consumer waste is often a result of confusion over labels and not understanding the difference between various types of shelf life labelling used around the world. This may result in throwing out

high-quality food due to unnoticed information, misunderstanding or sometimes – due to excessive safety concerns (Wilson et al. 2017; Brook Lyndhurst, 2011). Melbye et al. (2017) reported on the attitudes of Norwegian consumers toward wasting edible food. The researchers found that people with higher subjective knowledge of food (the consumer's beliefs about his or her knowledge) tend to show more negative attitudes toward wasting edible food. Also, respondents expressing a high level of environmental concern were inclined to be more negative toward wasteful behavior.

The study of van Geffen et al. (2020) conducted in Germany, Hungary, Netherlands, and Spain showed that the presence of competing goals, such as competition between health and food waste, competition between enjoyment and food waste, and between maintaining the budget and food waste, seems to have an impact on the intentions of consumers to reduce food waste. It was noted that low food prices do not motivate consumers to reduce food waste. On the other hand, consumers in Hungary reported that they would need more money to reduce food waste arguing that food waste was often caused by the low-quality food that spoils too fast.

The socio-economic and demographic characteristics of a household also influence the level of food waste it produces. In a study by Tucker and Farelly (2016) conducted in New Zealand, it was found that food waste increases with the number of people in a household and the number of younger people. Elder people are often less likely to throw out food (CBOS 2016; van Grasso, 2019; Melbye et al. 2017). The article by van Grasso et al. (2019) demonstrated that being unemployed or working part-time was associated with less food waste behavior in Denmark and Spain. In Denmark, being male was associated with more food waste behavior, and living in a household with four or more people was associated with less food waste behavior. The results of other authors' research show that food waste increases according to the number of individuals in a household, and in particular the number of younger people (Koivupuro et al., 2012; Tucker and Farrelly, 2016).

Goal 12.3 of the Sustainable Development Goals (SDG) which were set in 2015 by the United Nations General Assembly, calls for halving per capita global food waste at retail and consumer levels by 2030, and reduce food losses along production and supply chains (United Nations, 2015). Several interventions were undertaken and policies implemented both at the local and global levels (FAO, 2019; Kim et al. 2019; Schanes et al. 2018; Parfitt et al. 2010).

The methodology of the research

The main purpose of the study was to identify consumer behavior in Poland in terms of food waste. Specific research objectives included:

• recognition of the frequency of throwing out purchased food by consumers in Poland,
• identifying and analyzing the causes of food waste in households in Poland,
• identifying and analyzing the relationship between consumer behavior related to food waste and segmentation variables such as gender, household size, and consumer income. The results of the study also allowed us to determine the typology of households in Poland in the context of wasting purchased food. In addition, the conducted analyses of the collected research material constituted the basis for the development of the demographic and economic profile of the households in Poland with the largest and smallest predisposition to food waste.

The survey was conducted using the individual direct interview method throughout Poland in the period from April to May 2019. The research tool was an interview questionnaire prepared and verified in the pilot, containing questions about consumer behavior in terms of food waste, perception of health risk in food consumption after its shelf life, interpretation of information on food shelf life, and the birth certificate (gender, age, education, material status, household size, number of children in the household). As part of the analysis, descriptive statistics were used to determine the structure of the surveyed population: structure and intensity indicators (proportions, percentages). To measure the strength of the relationship between the features (on a nominal scale), the V - Cramer contingency coefficient was used (Akoglu, 2018; Croux and Dehon, 2010).

Sample

The research population was comprised of consumers who have declared the systematic purchase of food products. The selection of the research sample (N = 1145) was carried out by the quota method (selection criteria: sex, age, and place of residence), which met the demand for maintaining the relative representativeness of the research population. After verifying the completeness of the questionnaires, 1070 questionnaires were analyzed.

Results and Discussion

The key goal of the study was to identify consumer behavior related to food waste in households, and more precisely the frequency of throwing out purchased food in households in Poland. The surveyed consumers were asked to indicate how often they discard purchased food. The results of the study of the above-mentioned issue are presented in Table 1.

Table 1: Frequency of throwing out purchased food in the household (%)

How often do you throw out purchased food?		
Frequency	**Numbers of persons**	**Percentage**
everyday	14	1.3%
2-3 times a week	83	7.8%
once a week	172	16.1%
several times a month	337	31.5%
several times a year	341	31.8%
it doesn't happen to me	123	11.5%
total	1070	100.0%

Source: Own research

As the results in Table 1 indicate, the vast majority of consumers surveyed in Poland admit that to having thrown out purchased food (88.5% of indications) - only 11.5% of consumers declare that they do not happen to throw out purchased food. The above results are very worrying - any action related to the disposal of food is referred to as waste. Such behavior is unethical, uneconomical and socially unacceptable - especially when we consider the fact that, according to the report 'Global Hunger Index 2016' worldwide, 950 million people suffer from hunger (of which a significant part comes from Africa and Asia) (https: //www.ifpri.org/publication/2016-global-hunger-index-data). The largest percentage of consumers surveyed wastes food by throwing it away several times a year (31.8% of responses). Unfortunately, an equally high percentage of consumers throw out purchased food several times a month (31.5% of responses) - this is a relatively high frequency, very worrying in the context of the long-term social and economic effects of food waste. In turn, 16.1% of respondents declared they throw out purchased food even more often - once a week, and 7.8% of consumers throw out food 2-3 times a week. The smallest percentage of consumers in Poland indicate that they throw out food every day (1.3% of responses). The results of the study regarding the frequency of throwing out purchased food indicate that the phenomenon of food waste by consumers in Poland is quite common - more than half of the surveyed people throw out food more often than once a month. It can be assumed that consumers who discard food are not able to plan shopping rationally, buy too much food in relation to consumer needs, and also have low awareness of the importance of the food waste problem.

An important issue related to the wastage of food by consumers in Poland (manifested in the throwing out purchased food) is to identify the reasons for this behavior. The results of the survey on identifying the causes of food waste by Polish consumers are presented in Table 2.

Table 2: Reasons for throwing out food by consumers (%)

Reasons for throwing out food	Numbers of persons	Percentage
Food is out of date	663	62.0%
I am not sure if the food is suitable for consumption	300	28.1%
Shopping has been poorly planned	241	22.5%
I bought or prepared too much product	214	20.0%
Food is visually unattractive	209	19.5%
I bought a spoiled food	126	11.8%
I don't want to consume food	116	10.8%
I have no storage space	33	3.1%
I didn't know how to store food	26	2.4%
The product would expire soon	25	2.3%
I can't prepare food	18	1.7%

Source: Own research

Analyzing the data contained in Table 2, we can conclude that the only rational reason for consumers throwing out purchased food is the fact that the purchased food is spoiled. In such a situation, when the consumer notices that the product is spoiled taking into account the health risk associated with consumption, discarding the product seems to be the only obvious and reasonable solution. Therefore, the above reason for throwing out food (indicated by 11.8% of respondents) should not be treated as food waste. If we consider this a waste, the reason lies with the sales agents who improperly stored the product (allowing it to break down) or did not control the shelf life, allowing to sell the product, which has expired. The most common reason for consumers throwing out purchased food in Poland is the fact that the product is expired (62% of indications). Consumers, seeing that the shelf life of food has expired, throw it out in fear of health risks. In the case of perishable food, labelled with the term 'use by', such behavior is reasonable. But throwing out expired food which is microbiologically stable, and thus marked with 'best before' date, is not reasonable and contributes to food waste. Such food is still safe but it may not be at its best in terms of sensory quality. In the context of the above, it is worth paying attention to one more aspect related to the disposal of expired food - since food has expired, it may mean that consumers buy too much food in relation to their consumption needs. Brook Lyndhurst (2011) reported that approximately 50-80% of the decision to discard overdue eggs, ice-creams and desserts was dictated by the fact that the product was out of date. The same reason was given for 40-50% of the discards of convenient ready-to-eat foods, biscuits, sweets and snacks, dairy products, rice, pasta, noodles, meat, refreshing drinks, bakery products, and salads. The driver for this state can be excessive food purchasing. Also, promotions or bulk discounts may entice consumers to buy on impulse, which encourages waste (Wansink, 2018; Aschemann-Witzel et at. 2016; Wilson et al. 2017).

Another reason indicated by consumers for throwing out food is the fact that they are not sure if the product is suitable for consumption. As one can suppose, it is caused by the fact that the consumer is not able to correctly interpret the date marking or such information is missing (e.g. when the original

packaging or parts of it are removed). In view of the above, consumers, for fear of their health (and the health of other household members), throw out such food. It seems that social communication activities to increase consumer awareness of food durability labelling and educational activities to acquire food sensory assessment skills could contribute to reducing the percentage of food waste due to consumer uncertainty about its freshness.

Another reason indicated by consumers in Poland for throwing out purchased food includes errors in planning purchases and buying or preparing too much food - about a quarter of consumers indicated the above reasons. In order to avoid such behaviors and situations leading to food waste, consumers should be more aware of their consumption needs, should rationally plan purchases (e.g. by making a list of products needed) and should increase their awareness of the socio-economic effects of the problem of food waste in Poland and the world. About 10% of respondents declared that they throw out purchased food because they do not want to consume it. The above reason seems absurd and indicates a highly irresponsible consumer as a result of buying a product (perhaps under the influence of a sudden impulse or promotion). If the consumer does not intend to consume purchased food, he should (by following the economy of sharing) share with other people (family, neighbors), or hand over the product to those in need. Throwing out food in such a situation is extremely irresponsible behavior.

In turn, the least frequently indicated reasons for wasting food by throwing it out were: 'I have no storage space' - 3.1% of indications, 'I did not know how to store the product' - 2.4% of indications, 'the product would expire soon' - 2.3% of indications and 'I can't prepare food' - 1.7% of the responses. The above reasons were indicated by a small percentage of consumers surveyed in Poland, however, in analyzing them we can conclude that they also indicate irresponsible, irrational shopping behavior of consumers, carried out on impulse, without analysis of real consumption needs; in addition, they indicate low consumer awareness of the problem of food waste. An interesting issue is the analysis of the frequency of discarding food in relation to the reasons that consumers are guided by wasting food. The results of this study in are presented in Table 3.

Table 3: Reasons for throwing out food and frequency of throwing out (%)

Reasons for throwing out food	**Frequency of throwing out food**				
	everyday	2-3 times a week	once a week	several times a month	several times a year
Food is out of date	30.8%	28.2%	32.6%	34.7%	34.9%
I don't want to consume food	7.7%	8.8%	7.8%	5.1%	4.6%
I am not sure if the food is suitable for consumption	17.9%	17.2%	15.1%	15.6%	13.3%
Food is visually unattractive	12.8%	11.0%	9.1%	10.5%	11.8%
Shopping has been poorly planned	23.1%	14.5%	11.5%	13.7%	9.8%
I bought a spoiled food	5.1%	11.0%	13.3%	10.7%	9.8%
I bought or prepared too much product	0.0%	0.9%	1.6%	1.9%	1.8%
I have no storage space	0.0%	0.9%	1.8%	0.9%	0.6%
I can't prepare food	0.0%	2.2%	1.0%	0.9%	1.4%
I bought a spoiled food	2.6%	3.5%	5.0%	4.7%	10.2%
The product would expire soon	0.0%	1.3%	0.8%	1.1%	1.5%

Source: Own research

Analyzing the relationship between the frequency of throwing out purchased food and the reasons indicated by consumers, we can see that:

• Consumers who declare they throw out food every day mainly do so because of its expiry (30.8%), poorly planned purchases (23.1%) and lack of certainty as to whether food is suitable for consumption (17.9%);

• Consumers who very often throw out food (2-3 times a week) mainly point to their expiry (28.2%), uncertainty as to whether the food is suitable for consumption (17.2%) and poorly planned purchases (14.5%). In addition - food is thrown out for the absurd reason of being visually unattractive or involving too too much preparation as indicated the consumer (about 10%).

• 1/3 of consumers discarding food once a week do so because of their expiry date, as well as the uncertainty about its usefulness (17.2%); Consumers also indicate such reasons for throwing out as: preparing too much food, poorly planned shopping and visual unattractiveness of food (about 10%). Almost 8% of consumers discard food once a week because they simply do not want to consume it, even though they have bought it.

• Consumers who discard food the least often, i.e. several times a month and several times a year, also do so mainly because of its expiry (1/3 of respondents), lack of certainty whether food is useful for consumption and visual unattractiveness of food (12 - 13%), as well poorly planned purchases and poorly planned quantity of food prepared (about 10%).

To sum up the analysis of the frequency and reasons for throwing out purchased food by consumers in Poland, there are three main reasons for such behavior, namely:

• low consumer awareness of labelling food with shelf-life dates, or more precisely the possibilities of consuming the product after the shelf life has expired, as well as the inability to correctly interpret food labelling;

• irrational purchasing behavior, which results in buying excessive amounts of food or buying food that the consumer does not want to consume or cannot prepare;

• low consumer awareness of the problem of food waste, which results in its being thrown out when the food could be handed over to people in need.

It seems that in order to reduce food waste in Poland, it is necessary to educate consumers widely about the problem of food waste, as well as about the correct interpretation of information on packaging regarding food durability.

A highly interesting issue in the context of analyzing food waste in Poland is the identification of the relationship between food discarding and segmentation variables describing the consumer and his household and the reasons for discarding indicated by consumers. An important element of the analysis is also the issue of interdependence (strength of the relationship) between demographic, economic and social features that differentiate the examined population and the frequency of throwing out purchased food. Because these features have mainly qualitative and responses are represented on a nominal scale, the V-Cramer contingency coefficient was used to measure the strength of the relationship (Bergsma and Wicher, 2013; Liebetrau, 1983). It is not burdened with such restrictions as other contingency coefficients such as C-Pearson, Q-Kendall or T-Czuprow. The analysis of the strength of the compound included all the characteristics of the research unit included in the study did not generally show any strong relationship between the frequency of food ejection and individual features. Only for statistical correctness can it be emphasized that the highest strength of the frequency of food throwing occurred in the case of education (V-Cramer = 0.134), material status (V-Cramer = 0.091) and the age (V-Cramer= 0.089) and the number of persons in the household (V-Cramer = 0.076). V-cramer correlation coefficients were calculated using IBM SPSS Statistics version 25. Generally, the obtained coefficient values can be considered low and basically say that there is no relationship between the frequency of food thrown out by the surveyed consumers and their demographic, socio-economic characteristics. Despite the fact that the conducted contingency analysis using the V-Cramer factor did not show a clear correlation between the frequency of throwing out food by consumers and their demographic and economic features, it should be considered a fully justified cross-sectional analysis, which allowed to indicate the relationship and regularity between the profiled consumers and the phenomenon of food waste in households. The rest of the article will present the relationship between the frequency of discarding food and the indicated variables, which will allow for developing a demographic and economic profile of consumers in households that waste food to the greatest and least extent as a result of throwing it out.

When analyzing the frequency of throwing out purchased food by consumers in Poland (Table 4), it can be seen that the propensity to waste food varies in different age segments.

Table 4: Frequency of throwing out food and the age of consumers (%)

Frequency of throwing out food	Age segments					
	up to 19 years	20 - 29 years	30 – 39 years	40 – 49 years	50 – 59 years	60+ years
everyday	0.0%	1.6%	1.4%	0.0%	1.8%	1.6%
2-3 times a week	18.2%	8.9%	8.1%	8.7%	7.2%	6.3%
once a week	22.7%	2.0%	19.8%	18.8%	15.7%	11.0%
several times a month	31.8%	34.2%	36.5%	31.5%	31.9%	26.6%
several times a year	18.2%	26.3%	24.8%	31.5%	33.1%	38.6%
it doesn't happen to me	9.1%	8.9%	9.5%	9.4%	10.2%	15.9%

Source: Own research

The youngest consumers are dominated by consumers who throw out purchased food several times a month (31.8%) and those who throw it out once a week, 2-3 times a week and several times a year (about 20%). None of the youngest consumers surveyed in Poland discard purchased food every day, and about 10% of them do not throw out food at all. In turn, in the consumer segment of 20-29 years, the largest percentage discards purchased food several times a month (34.2%) and several times a year (26.3%). In the aforementioned analyzed age segment, a small percentage of respondents throw out food every day and once a week, and as in the group of youngest consumers, around 10% declare that they never throw out purchased food. In the next analyzed age segment (30-39 years), also a small percentage of consumers throw out food every day (1.4%), but the percentage of consumers throwing food once a week increases significantly (compared to the 20 – 29-year-old segment) and it amounts to almost 20%. The highest percentage - like among younger consumers - discards food several times a month (36.5%). In turn, the 40 - 49 age segment shows a tendency to throw food at a lower frequency than in younger age segments - none of the surveyed consumers declared that they throw out food every day, and the largest percentage of consumers throw out food several times a month and several times in the year (31.5%). In the oldest consumer segment, there is also a smaller tendency to throw out food - the frequency is decreasing. And so in the 50 – 59-year consumer segment, the largest percentage of respondents throw out food several times a year and several times a month (about 33%); in turn, among senior consumers (60+) almost 40% declare that they throw out food several times a year, and 16% declare that they do not throw out purchased food at all (which is the highest value among all the surveyed segments). Wansink (2018) explains this phenomenon by experienced hunger or food insecurity as a child. To sum up, it can be stated that as the age of the consumer increases, the frequency of throwing out purchased food decreases, so the older the consumer, the lower his tendency to consumption behavior leading to food waste. The most frequent discarding of food concerns the youngest consumer segment (72.7% discards food every day, several times a week, once a week and several times a month), the segment 30-39 years (67.3%) and the segment 40- 49 years and 50-59 years (59% and 57%). Thus, it can be concluded that consumers aged 60+ and aged 20-29 are the least wasteful with purchased food.

Another interesting area of analysis of the study results is the relationship between the tendency to throw out purchased food and the material status of the family (subjective assessment of the material level of the household).

Table 5: Frequency of throwing out food and the material status of the family (%)

Frequency of throwing out food	Material status of the family									
	definitely below the national average		slightly below the national average		the national average		slightly above the national average		definitely above the national average	
everyday	1.1%	42.3%	0.5%	47.5%	1.8%	62.7%	0.7%	59.3%	2.0%	59.0%
2-3 times a week	3.3%		5.6%		8.9%		8.2%		9.7%	
once a week	10.0%		12.2%		17.5%		18.3%		17.4%	
several times a month	27.9%		29.2%		34.5%		32.1%		29.9%	
several times a year	34.4%	57.7%	37.2%	52.5%	28.7%	37.3%	31.0%	40.7%	31.3%	41%
it doesn't happen to me	23.3%		15.3%		8.6%		9.7%		9.7%	

Source: Own research

Analyzing the frequency of food throwing out, i.e. de facto food wastage by consumers in Poland, depending on the subjectively assessed material status of the family, it can be seen that consumers from the poorest segments have the lowest tendency to throw out food. Almost a quarter of consumers assessing the material status of their family (household) well below the national level never throws out food, and a relatively high percentage throws out only a few times a year (34.4%). 42.3% of consumers in this segment are wasting food very frequently. In the segment of consumers assessing their material status at a level slightly below the national average, a relatively high percentage (compared to other segments) admits that they never throw out food (15.3%), and as much as 37.2% throw out only several times a year. Compared to the previous segment, the percentage of people who waste food frequently (47.5%) increases slightly. In the segments of consumers assessing the material status of their family at the level of the national average and above (slightly, definitely) the percentage of people throwing food with a high frequency (from 59.0% to 62.7%) clearly increases in relation to the less affluent segments, and thus the percentage of people who never throw out purchased food decreases(about 10.0%). Thus, in summary, it can be concluded that the propensity to waste food expressed by the high frequency of its disposal is low in the poorest consumers segment (material status below the national average), and definitely higher in the segment of consumers with good and very good material status (national average and above). The above is economically and socially justified - consumers from the poorest group in Poland are more prone to rational purchases, they do not buy beyond their needs, they try to optimally plan food expenditure and consumption of this food in their households.

Another area of analysis is the relationship between the frequency of discarding purchased food and consumer education. The results of this study are presented in Table 6.

Table 6: Frequency of throwing out food and consumer education (%)

Frequency of throwing out food	Consumer education							
	vocational education		secondary education		bachelor degree		master degree	
everyday	1.0%	45.2%	1.8%	52.1%	1.7%	62.9%	0.6%	65.5%
2-3 times a week	3.6%		9.1%		5.5%		11.1%	
once a week	12.7%		15.6%		14.3%		19.7%	

several times a month	27.9%		25.6%		41.4%		34.1%	
several times a year	35.0%	54.8%	34.4%	47.9%	29.1%	37.1%	28.8%	34.5%
it doesn't happen to me	19.8%		13.5%		8.0%		5.7%	

Source: Own research

Analyzing the frequency of throwing out purchased food in relation to the education of the surveyed consumers, we can conclude there is a clear relationship between the studied phenomenon and the analyzed variable. In the segment of consumers with the lowest level of education, the largest percentage of people (from all segments) declare that they do not throw out the purchased food at all (19.8%), while the lowest percentage of people declare that they throw out food with a high frequency (e.g., only 3.6% 2-3 times a week). Among people with secondary education, the percentage of consumers who do not discard food at all is 13.5%, and the percentage of people discarding with high-frequency increases by 5 percentage points compared to the previous segment (e.g., 9.1% 2-3 times a week). In the most educated consumers segment, the percentage of people who declare that they never throw out food (up to 5.7% in the segment of consumers with master's degree education) clearly decreases, and at the same time the percentage of people who throw out food with a high frequency (e.g., up to 11.1% discarding 2-3 times a week). Therefore, analyzing the data contained in Table 6, it can be clearly stated that the propensity of consumers to throw out purchased food (expressed in a higher frequency) increases with the level of education of the consumers in Poland. Van Geffen noticed that despite the fact that consumers report a widespread aversion to waste of food and are concerned with food waste, there is a gap between what consumers aim to do in order to reduce food waste and what they actually do (van Geffen et al. 2020). This conclusion is extremely worrying - it seemed that educated people are more aware of the economic and social threats associated with food waste, as well as the huge problem of malnutrition and hunger worldwide, which should be associated with restrictive attitudes and behaviors regarding food waste in households. However, it turns out that - according to the study - consumers with lower education levels are less likely to throw out purchased food products, and thus waste less food.

When analyzing the frequency of throwing out purchased food by consumers in Poland, it is also worth analyzing the relationship between the studied phenomenon and the size of the household (the number of people in the household). These results are presented in Table 7.

Table 7: Frequency of throwing away food and the number of people in the household (%)

Frequency of throwing out food	**Number of persons in the household**									
	1		2		3		4		5+	
everyday	0.7%	54.3%	2.1%	55%	0.9%	61.5%	0.9%	62%	2.7%	53.5%
2-3 times a week	11.4%		5.6%		6.8%		10.9%		7.1%	
once a week	13.6%		13.9%		18.8%		15.4%		19.6%	
several times a month	28.6%		33.4%		35.0%		34.8%		24.1%	
several times a year	33.6%	45.7%	32.9%	45%	26.5%	38.5%	30.3%	38%	34.8%	46.5%
it doesn't happen to me	12.1%		12.1%		12.0%		7.7%		11.7%	

Source: Own research

Analysis of the data contained in Table 7 indicates that there is no clear relationship between the size of households (number of persons in a household), and the frequency of wasting food as a result of throwing it out. It turns out that the highest percentage of people who declare that they do not throw out purchased food is about 12% and occurs in all separate households except for 4 persons - in these households this percentage is lower by 5 percentage points. In turn, analyzing people who declare that they throw out purchased food every day, it turns out that most of them belong to two-person households and the largest of 5 people or more. Consumers are the least likely to dispose of purchased food from the smallest (1 and 2 persons) and largest (5+) holdings - the percentage is around 45%.

In turn, the highest frequency of throwing out purchased food can be seen in households of 3 and 4 people - the percentage is 62%. Thus, to sum up, it can be stated that the highest frequency of throwing out purchased food, i.e. wasting it in Poland, concerns consumers being members of 3 and 4-person households.

Conclusions and Recommendations

The results of the study on the diagnosis and analysis of the frequency and causes of consumer disposal of purchased food provide interesting conclusions regarding the problem of food waste in households in Poland. The basic conclusion that comes to mind is awareness of the problem of food waste. The frequency scale and reasons for throwing food out by Polish consumers clearly indicate that they have very low awareness of the problem of food waste, and thus its social and economic effects. Another important conclusion that can be made based on the conducted study (in particular based on the analysis of the causes of throwing away food) concerns the awareness of consumers in Poland in the field of marking food with information regarding its durability. It turns out that consumers are not able to correctly interpret and assess whether the product is useful for consumption (28.1% of consumers discard food because of this). In addition, consumers are not educated on labelling systems - they do not distinguish between the terms 'use by' and 'best before', which results in waste products that can be consumed beyond their shelf-life. A disturbing conclusion drawn from the research pertains to the purchasing and consumption behaviors contributing to food waste. The analyzed reasons for throwing away food indicate that Polish consumers make ill-considered purchases, buy more food than they need, and buy products that they do not want to consume later. In addition, consumers prepare more food than they can consume, which also contributes to food waste. The frequency with which Polish people dispose of purchased products is also alarming - well, more than half of the respondent’s waste food very often (up to several times a month).

In addition to the conclusions presented, the key achievement of the study is the ability to identify and describe the demographic and economic profile of the consumer in Poland and the household that wastes food the most by throwing it away. Analyses of the relationship between the frequency of throwing away food and the segmentation variables (structure indicators) indicate that the youngest consumers - under 20 years old and consumers aged 30 to 59 - are the most wasteful of food (therefore the age range is quite wide). They are also people with a bachelor’s degree or a master's degree (the higher the education, the greater the frequency of throwing away food), and those with good and very good material status (national average and above). In terms of the number of people in the household, 2 and 3-person households are the most wasteful with food.

To sum up, the results of the conducted study are worrying, they point to the large scale of the problem of food waste in Polish households. In view of the above, it seems necessary to have a broad educational social campaign that would increase the level of public awareness both within the problem of food waste itself, as well as in the field of food labelling and making rational purchasing decisions.

Management of The Customer Portfolio and The Competitive Strategy of a Packaging Industry Enterprise

Dariusz KRZYWDA

Czestochowa University of Technology (CUT), Poland
dariusz.krzywda@pcz.pl

Abstract

As a result of market instability, the economy is experiencing a rapid rate of change, which is contributing to an increase in competition. Managing a company in such conditions must be a continuous process of analyzing the business environment and potential of the company from the perspective of customers and designing and implementing strategies to secure its sustainable competitive position and effectiveness of its operations. An important area in this process is an analysis and assessment of values and establishing an optimal structure of customers. The article presents an analysis of the portfolio of active clients of a packaging industry company existing on the market since 2006. The research has made it possible to divide the customers into groups according to their individual characteristics. The assessment of the customers of a packaging company is very important and complex due to the type of dependent demand that characterises this industry and its exceptional susceptibility to economic fluctuations. The results of the research allow us to understand better the complex dependencies between the customer and the company in situations when companies change their strategies aiming at reducing costs of packaging and facing changes introduced in legal regulations concerning this specific business area.

Keywords: Customer Portfolio, Packaging, Dependent Demand

Introduction

Customer portfolio management is one of the key issues faced by company managers on a daily basis. Having initially devoted a period of time on building up a portfolio of customers, at the following stages, companies strive to increase their efficiency and thus improve the performance of the entire company. It is of crucial importance that then the profitability of customers is analysed and decisions are taken to deal with unprofitable customers.

Portfolio analyses, known since the 1980s, are an invaluable aid in customer portfolio management. Among them, the research into the customer portfolio, like CLV or CPA, is particularly important (Rudawska, 2016; Čermák, 2015), and the concept of customer relationship management is increasingly growing in popularity. The information that comes from estimating the value of customer portfolio allows for a better planning of the company's marketing strategy, shows the benefits of building lasting relationships with the client and is a helpful tool in choosing the most effective way of reaching out to the client. (Żak, 2015). At the same time, when building customer relationships, the company needs to answer the following questions: Are all customers equally important to the company? Can the company afford to meet the needs and expectations of all its customers? How to choose those clients in which it is worth, or even needed to invest?

The literature on the subject offers numerous methods of customer portfolio analysis. As well as deciding on a given method, the conclusions and decisions based on the method itself are also extremely significant, as regards further handling of customers and shaping relations with them in practice. This is particularly important in the modern economy, which is characterised by intense competition, the phenomenon of global competition and, above all, individualised and increasingly sophisticated customer needs. In situations where managers become aware of arising problems, they not infrequently take inadequate actions, which may not necessarily have an adequate impact. The most common of these are cost reductions. (Skowronek-Mielczarek, 2016) This approach may have negative consequences for the future operations of the company. In this context, it would be advisable to consider other solutions, perhaps such that go a little further and require, for example, a

modification of the company's strategy and ways of achieving a competitive advantage. Thus, a customer portfolio analysis may prove to be a kind of research which, if properly conducted, may enable the company's management to thoroughly verify the adopted strategy of gaining a competitive advantage and make a decision to change such strategy.

In this regard, a certain research gap emerges in the literature on the subject and in research. While there are many theoretical studies on strategy and portfolio analysis, there is a certain lack of considerations that would provide implications for economic practice to be followed. There is also very little reflection on how to verify competitive strategies by means of a portfolio analysis in specific cases.

Literature Review

A fundamental goal for business is to develop means by which it can perform better than their competitors (Čiarnienė, Stankevičiūtė, 2015; Troshani & Rao, 2007) Competitiveness can be described as comparative social, economic, political, technological and other positions of companies, sectors and countries. It means entity's ability to sustain and strengthen its position in the market through improvement of key competences. (Čiarnienė, Stankevičiūtė, 2015) Competitive advantage is defined as something what separates the enterprise from others and keep it alive and growing. (Smith & Flangan, 2006)

Research on business competitiveness and strategies for achieving competitive advantage has a rich and long tradition in the management science literature. It features numerous concepts of a business's competitive advantage and shows that new concepts are constantly being developed, which is probably a result of the complexity of the nature of such advantage, diversity of its sources and different types of approach to its identification and sizing (Stankiewicz, 2002). Competitive advantage is achieved by applying an appropriate competitive strategy, which can be defined as "a set of coordinated ways of achieving the company's objectives, tailored to the company's situation and environment". (Pierścionek, 1992)

In the traditional approaches, the most common sources of competitive advantage include cost advantage, quality leadership, leadership and the marketing concept of competitiveness. More recent concepts of a company's competitiveness take into account challenges resulting from sudden changes in its environment. Their distinguishing features primarily include innovation, entrepreneurship, the network connections of companies in a given sector (Włodarczyk, 2013) and also human capital (Coleman, 2007).

Some researchers emphasize the importance of resources in creating business competitiveness. Barney (1991), for example, asserts that a firm develops sustainable competitive advantage by leveraging the resources that it posses. These resources are described as unique, rare, non-substitutable and difficult to imitate by rival firms, and included all assets and capabilities (Ismail et. Al, 2014)

One of the most popular concepts of competition is the concept developed by Michael E. Porter, who identified three strategies that can be adopted by an enterprise in order to build a competitive strategy. These are the strategies of differentiation, (qualitative leadership), cost-effectiveness and focus. (Porter, 1998) Philip Kotler has also made a major contribution to the study of competitive strategies, distinguishing between the following types of strategies: leader strategy, contender strategy, follower strategy, niche strategy and alliance strategy. However, there are also other concepts in the literature on the subject. One of them is a concept based on resources and core competencies developed by Gary Hamel and Coimbatore Krishnarao Prahalad. As it is often emphasized, in practice Porter's concepts of competitiveness and core competencies complement each other, because, when combined, they comprehensively characterize the internal aspects of businesses and their environment. (Beyer, 2012)

Another concept of competitive advantage is the relational approach, which is based on the assumption that this type of advantage is based on the relations of the company. The source of advantage in this approach is the specialization of the participants in a given network, as well as unique relationships allowing for better use of specific resources of collaborating partners. Another contemporary approach to competitive advantage is the knowledge-based concept, which has its roots in a concept based on resources and core competencies. Knowledge is regarded here as a strategic resource of the company, determining its development, survival and generating a lasting competitive advantage. (Beyer, 2012).

Against such numerous strategies for achieving competitive advantage, the concept of customer service deserves - from the point of view of the objectives of this study - a very special attention. Customer service started to be of interest as early as in the 1980s, when managers pointed out that in the face of growing competition, when many companies offer products and services of similar quality, a perfectly organised customer service can be a distinguishing feature, thanks to which it is possible to win customers and encourage them to continue cooperation. (Coyle et al. 1996) It is stressed, however, that customer service is not only an area of interest for marketing specialists, but also for experts in logistics. The level of customer service offered by a given company largely depends on a number of decisions taken by the logistics team in the field of transport, inventory, warehousing, forecasting the demand, and supply orders. Therefore, it can be said that if this system is managed efficiently and the service together with the product meets their expectations, customers are fully satisfied. (Godziszewska-Nowicka, 2014) The main objective of the logistics strategy is to provide customers with the level of service they expect at a cost that is as low as possible from the point of view of the entire logistics chain. As the literature emphasizes, it is not an easy task to find the level that will allow to maximize the turnover of the company and at the same time minimize the costs. (Godziszewska-Nowicka, 2014) An adequate level of logistic customer service in industrial, commercial or service companies entails certain costs resulting from achieving specific effects of the logistics system.

Research Hypotheses and Methodology

The aim of the study was to verify the most important element of customer service as a strategy of achieving a competitive advantage by means of a portfolio analysis. This is one of the varieties of customer service strategy singled out by D. Kempny, alongside the low service cost strategy, customer selection strategy, core logistics skills strategy and trade-offs strategy (i.e. "one step ahead of the competition"), i.e. a group of strategies for achieving competitive advantage through customer service logistics strategies. The strategy of the most important element of customer service is to provide deliveries in the shortest possible time, availability of the product from stock, reliability of deliveries, flexibility, accuracy, completeness, etc. (Kempny, 2001)

The subject of the survey was a commercial enterprise offering auxiliary packaging materials (packaging tapes, polyester tapes, stretch film and packaging accessories). It is a small company located in the southern part of the Silesian Voivodeship which has now been present on the market for 15 years. The company's clients are manufacturing companies representing various industries, located mainly in the Silesian Voivodeship. They are mostly manufacturing companies of various sizes - from large manufacturing plants to small family businesses. The suppliers of the company under study are large companies with high economic power which manufacture packaging aids, both in Poland and in various countries of the European Union (France, Croatia, Turkey, Germany, and Spain).

The company's strategy was established at the very beginning of its existence and is based - in accordance with the intention of its owners - on achieving a competitive advantage thanks to an exceptionally efficient logistics service. Two assumptions were made at the time. First of all, it is extremely difficult to achieve a competitive advantage in the packaging sector in terms of product quality or innovation, as there are many importers and manufacturers of packaging and packaging materials on the market who apply aggressive pricing policies. The second assumption stipulates that the demand for packaging materials and auxiliary packaging means is a dependent demand, which

means that its size depends on the production volume in the enterprise. It is also a company operating on a B2B market. B2B markets differ from B2C markets in the structure and demand, the nature of the bought unit, the types of decisions and the purchase decision process itself. In addition, the arising demand in B2B markets is mostly derived from the demand for consumer foods. (Rebentisch, 2016) The founders of the company in question originally intended that their offer should be addressed to those companies which do not implement regular material planning, do not include packaging materials in material planning or operate in the area of large fluctuations in demand, and hence are unable to forecast demand with a sufficient accuracy. The market analysis showed that there were many such businesses in the region. The advantage of the company in question was therefore to rely on a truly efficient logistics service, i.e. immediate processing and completion of urgent orders, even relatively small ones, with a diversified range of products. That was expected to be possible thanks to the maintenance of appropriate warehouse stocks, which were supposed to ensure high availability of products and short order completion time, which in turn was to be made possible thanks to the efficient handling of orders made, mainly ad hoc, over the phone.

During the years of its economic operation, the company had to analyse the value of its customers and their profitability. While it was possible to maximize the value of the company for its customers and secure a high repeat customer business rate, the company proved to be generating too low revenues.

The research used primarily the method of examining customer profitability, which - in order to triangulate the study - was extended by a qualitative method in the form of an in-depth interview with the management of the company. During the analysis and as a result of the research in the field of the literature on the subject, a hypothesis was put forward, according to which the strategy of the most important element of service may lead to a decrease in the customer portfolio profitability. Therefore, it requires constant monitoring and analyses of the actions taken in order to be profitable.

The study was based on an analysis using a customer profitability matrix developed by M. Christopher and H. Peck. These authors proposed a matrix of customer profitability, taking into account the costs generated by customers, which is shown in table 1.

Table 1: Customer profitability matrix

Net sales value of the customer	high	Protect zone	Cost Engineer zone
	low	Build zone	Danger zone
		low	high
		Service costs	

Source: M. Christopher, H. Peck (2003) Marketing Logistics, Butterworth-Heinemann; 2 ed.

The build zone comprises relatively cheap customers with low net sales value. In their case, the possibility of increasing the turnover without a proportionate increase in service costs is considered. Customers in the danger zone should be given special attention in terms of medium- and long-term opportunities to improve sales value or reduce the cost of service, as well as strategic reasons for their

maintenance. The cost engineer zone is used to calculate the chances of increasing profitability while reducing the service level and finding new ways of securing orders. Special opportunities are being sought with customers in the protect zone in order to develop relationships so that they do not use the services of new suppliers, as these customers represent a high value for the company (Christopher, Peck, 2003).

Results and Discussion

The analysis carried out on the basis of the customer profitability matrix allowed us to locate the company's customers in the four zones.

Fig. 1: Customer profitability matrix developed for the company under study

Source: author's own compilation

The approach developed by Christopher and Peck has revealed the following situation in the company's client portfolio.

There was only one large company in the protect zone, a zone where service costs are relatively low and net profit on sales is relatively high. According to an interview with the managers of the company in question, the business relationship between the two companies is long-standing and is based on a very good knowledge of the client's needs, advice and personalized orders. The companies are testing new products (specialized heavy-duty straps) together, and the employees of both companies are thinking about the best solutions. It is also important that the structure of the customer's company has allowed for the development of personal relationships: the management of the company has not changed for many years, which means that there are no barriers with regard to communication with the company and this cooperation takes place on a truly partner-like basis, with the unity of objectives of both companies.

The situation is slightly similar in the case of three companies: one of the cost engineer zone and two of the build zone. Here, too, these are large companies.

The company from the cost-engineer zone is a company which has recently recorded a large growth, and therefore its demand for raw materials, semi-finished products and thus for packaging and auxiliary packaging materials has increased. As a result, the values of individual orders from this company have increased, which can be completed in one delivery. This means that the company is approaching the protect zone, i.e. moving to the left in the graph. Due to the development of this client, there was a certain risk that it would decide to change its supplier and thus fall out of the client portfolio of the company under study. In practice, however, it turned out that the customer had become accustomed to a high level of logistical service combined with speed and flexibility of deliveries. The fact that the supplier company in question is small makes it possible for decisions to be made quickly and on an ongoing basis by its owners, in a flexible and customer-oriented manner. In this case, it is possible to speak of good results in applying the strategy of the most important element of service.

Two companies from the build zone which are close to the protect zone are long-standing customers of the supplier, and they also have recently developed rapidly expanding their customer base and increasing the value of orders. The cost of servicing them has not been very high, but the individual orders are increasing in terms of value and the companies are moving up in the graph. These companies operate according to certain patterns, in which the supplier must fit in. With the growth of these two companies, the qualifications of their employees, who are well aware of the supply needs of their companies, have improved. Here, too, the managers of the supplier company in question were concerned about whether these companies would wish to continue their cooperation, but here too, the customer's familiarity with certain standards of logistics service combined with the appropriate quality of goods played an important role.

In the cost engineer zone, theoretically, ways of handling services should be analysed in order to reduce their costs. Such a dilemma was faced by the managers of the studied company in relation to two companies from this zone. The recommended revision of the service methods in this situation could consist, for example, in less frequent deliveries higher in value. Unfortunately, in both cases it turns out to be impossible, due to the lack of standardised ways of collecting data in relation to demand in both these companies. Although they are large companies, they do not use electronic systems and place orders by telephone. The companies are not equipped with computer systems for processing demand data or planning materials needs. At the same time, they operate in a very unstable market, acting as an emergency service themselves. Also, they do not pay much attention to packaging, and do not store it. The relations of the examined supplier company with these two companies from the cost engineer zone are good, but it is impossible to discipline their managers to place orders on a more systematic and predictable basis. The chances of moving them to the protect zone (to the left in the graph) were assessed by the managers of the studied company as being low.

The build zone includes the largest group of companies, both large and small. This group comprises companies which have not recorded any growth for many years and thus, as customers, do not increase the volume or value of orders. They are often family businesses focused on their core competencies. Packaging and packaging materials are supplied on an ongoing basis, without

preparing specific demand plans as a result of which they place orders spontaneously, often modifying them after they have been already placed, order only the necessary quantities and do not store packaging. This is an extremely difficult group, as the managers of the investigated company do not see the possibility of changing the formula of cooperation with these particular companies. Of course, the examined company implements its strategy here and acts as an emergency service, but in the case of smaller companies this strategy does not generate sufficient sales value. It is significant that this value increases with the company size, as can be seen in the graph: larger companies are a little closer to the protect zone here.

Not many companies are in **the danger zone**, where high service costs are combined with low sales value (4 large and 2 small companies). Two of the large companies are nearing the cost engineer zone. The task of the managers of the studied company should be to move them to the protect zone, i.e. to the left and upwards in the graph, which may be achieved by reducing the cost of service and increasing the net sales value. In practice, the companies should be "disciplined" for this purpose, i.e. they should be compelled to order less frequently and with a higher value or they could be expected to develop into larger companies with a higher demand in the future. At the same time, however, there is a concern that by becoming larger players on the market and thus increasing their bargaining power, they might choose to resign from the services of their current supplier.

The remaining companies in the danger zone are two large and two small companies. In particular, the two small companies in this group, generating low sales value at relatively high costs at the same time, are particularly worrying from the point of view of the analysis. Similarly as in the case of the small companies from the build zone, the managers of the examined company do not see any possibility of working out a new formula of cooperation with these companies, which would allow them, e.g. to reduce their costs of service. This is also an area where the strategy of achieving a competitive advantage does not work.

Conclusions

The conducted analysis allows us to confirm the hypothesis set at the beginning of the research part, according to which the strategy of the most important element of the service may result in a decrease in the profitability of the customers' portfolio and therefore requires constant monitoring and analysis of the profitability of actions taken. The approach developed by Christopher and Peck reveals that the effectiveness of the strategy of achieving a competitive advantage through extremely efficient logistics service and acting as an " emergency service" has its limits. Net sales profit is correlated with company size, i.e., the bigger the company, the higher the profit and lower the service costs. However, it seems that companies could move in the graph to the protect zone if they were more disciplined in planning their materials needs and placed fewer orders of higher value. In this way, however, the company in question would not be implementing its competitive strategy, which its managers has chosen to follow.

Theoretically, as many companies as possible should be included in the protect zone. The only way in the current situation is to optimize routes, order volumes and routes, orders, customer discipline. First of all, however, this is not possible and as the reality shows small companies, in particular, do not systematically forecast demand and plan materials needs, and , what seems rather clear in this situation, do not use IT systems designed for these purposes. In many cases, these are family businesses, where there is also a lack of clearly defined competences of the staff responsible for purchasing. Orders are placed spontaneously and irregularly, and are often adjusted while being completed. As experience shows these companies understand "just-in-time" deliveries in this way. What is more, this also proves to be the case with large companies, as can be seen in the chart.

The company in question is dependent on the growth and corporate culture of its customers. It acts by taking on the currency risk and the risk related to fluctuations in raw material prices on the market. The packaging that the company sells contains oil-based materials whose prices fluctuate up to 10% on a quarterly basis, while product prices remain relatively stable. In conclusion, it should be stated that the strategy of the most important element of customer service described in the

literature does not prove to work. Understood as an "emergency service" does not bring the desired sales value while generating high costs. The management of the surveyed company is considering abandoning this strategy. The best solution is, of course, the economic growth of the customers' companies which would increase the value of their orders; however, the managers of the examined supplier company have absolutely no influence on that. A situation in which a specific employee responsible for purchases is appointed in the customers' companies is also extremely desirable; however, this is not always the case. In addition, it is necessary to consider individual analysis and forecasting of demand for a given customer on the basis of previous records, and encouraging the demand, e.g. by placing inquiries about orders and executing orders taking into account delivery routes. In some cases it may be recommended to move away from personal deliveries and own transport in favour of couriers and shipping.

Résumé

La compétitivité est l'aptitude pour un secteur ou l'ensemble des entreprises d'une économie à faire face à la concurrence effective ou potentielle à travers deux composantes complémentaires, à savoir la compétitivité-prix et la compétitivité hors-prix. Une multitude des instruments ont été utilisés dans la littérature pouvant évaluer la compétitivité. Cependant, cette évaluation a été dans la plupart des cas statique et se change selon le niveau d'analyse.

La compétitivité se trouve souvent réduite à la notion des prix, qui ne permet pas de dégager l'ensemble des caractéristiques des produits exportés. Ainsi, se baser seulement sur des avantages-prix, cache autant de justifications liées à l'échange extérieur. A titre d'illustration, les États-Unis et l'Allemagne qui occupent les premiers rangs au niveau des exportations mondiales, malgré les importants coûts salariaux qu'ils supportent. Leurs succès s'expliquent bien par l'utilisation des facteurs autres que le prix, le (hors-prix).

Le présent article propose de débattre l'alignement des facteurs de la compétitivité avec les exigences de la globalisation et l'importance de suivre l'évolution des facteurs de compétitivité pour chaque économie, encore plus pour une économie en voie de développement comme celle du Maroc.

Ce papier est décliné en trois grandes sections. La première présentera les déterminants de la compétitivité –prix, la deuxième est réservée à la définition de la compétitivité hors-prix dans les modèles théoriques, avant d'analyser. Dans une troisième section, l'analyse qualificative portera sur comment la compétitivité peut être améliorée à travers le développement de la capacité d'innovation, la qualité, la productivité de travail et l'adaptation à la demande internationale. La quatrième section portera sur une analyse quantitative portera sur un diagnostic de la compétitivité des exportations marocaines à travers l'évaluation de certains indicateurs clés de la compétitivité au Maroc.
Mots clés : compétitivité-prix, compétitivité hors prix, exportation, concurrence.

Introduction

L'environnement économique international a connu au cours des dernières décennies des mutations profondes, à la faveur de la dynamique des exportations et l'évolution de la perception de la compétitivité celle-ci est un concept vaste et à multiples facettes. Elle couvre des aspects aussi divers que la capacité à conquérir des parts de marché, maitriser le coût des exportations, saisir les mouvements du taux de change et garantir l'innovation, la qualité des infrastructures, le respect du droit ou bien encore la performance des services publics. La recherche de la compétitivité est devenue un souci majeur et permanent aussi bien de la part des pays développés qu'en développement.

De plus en plus, la compétitivité est liée à de nombreux facteurs comme la spécialisation géographique, la spécialisation sectorielle, les politiques de soutien des pouvoirs publics (subventions et autres aides aux exportateurs, accès au crédit et à l'assurance, etc.). Le taux de change joue aussi un rôle puisqu'il influence le prix des produits importés et exportés.

Dans cet article on essaie de déterminer les deux types de compétitivité et leurs caractéristiques d'évolution pour l'économie marocaine :

- La compétitivité-prix qui est la capacité à conquérir des parts de marché grâce à des prix plus faibles que ses concurrents ;
- La compétitivité hors-prix (ou compétitivité structurelle) qui est la capacité à conquérir des parts de marché en produisant avec une meilleure qualité et/ou un meilleur service que ses concurrents.

La compétitivité-prix se mesure par le rapport entre les prix des exportations des pays partenaires avec le prix des exportations du pays national. Dans un sens plus large, la compétitivité-prix est liée à l'évolution des coûts unitaires de production (coût du travail, prix de l'énergie, coût du capital, prix des consommations intermédiaires, etc.) nets de gains de productivité. Elle dépend donc aussi des comportements de marges des entreprises ou de l'évolution du taux de change.

La compétitivité hors-prix, de nature qualitative, est la partie de la demande non expliquée par le prix restent difficile à appréhender et il est peu aisé d'évaluer la dimension variété (cf. différenciation horizontale des produits) et la dimension qualité (cf. différenciation verticale des produits).

Par ailleurs, la Direction des études et de la prévision financière (DEPF) explique que pour le cas du Maroc, la part des exportations présentant un positionnement prix déficient est passée de 12,3% en 1998 à 20,8% en 2014. Ainsi, «le changement notable dans le modèle de croissance de l'économie, en faveur des branches industrielles émergentes à forte valeur ajoutée (automobile, électrique, électronique, produits chimiques…), a entraîné un renforcement de la contribution de produits à plus haute qualité. Ces Evolutions mettent l'accent sur l'importance de la détermination, de la mesure et de suivie des facteurs de la compétitivité propres pour chaque économie, éventuellement une économie en vois de développement comme celle du Maroc.

Les Déterminants De La Compétitivité-Prix

Le Taux De Change

Est considéré comme l'élément fondamental de l'économie des échanges, par conséquent sa gestion recouvre une place importante dans le commerce et la finance internationaux, cette caractéristique permet à la politique de change d'être un propos débattu au niveau national et international. Cet élément est déterminé par la confrontation de l'offre et de la demande relatives d'une monnaie à une autre. Il peut être défini comme suit : « le taux de change d'une zone monétaire, mesuré comme une somme pondérée des taux de change avec les différents partenaires commerciaux et concurrents ».

On distingue entre le taux de change effectif nominal (TCEN), mesuré en se basant sur les parités nominales et qui ne tient pas compte des différences de pouvoir d'achat entre les deux devises respectives, et le taux de change effectif réel (TCER), qui prend en considération les indices de prix et leurs évolutions. Le taux de change peut avoir un impact important sur la compétitivité-prix à l'exportation et sur le marché intérieur d'un pays, dans la mesure où une dévaluation ou une surévaluation peuvent influer directement la compétitivité externe du pays.

En effet, une surévaluation du taux de change effectif déprécie directement la compétitivité-prix, en renchérissant les exportations et en baissant le prix des importations. De même, une dépréciation du taux de change effectif (dévaluation en parités fixes) favorise la compétitivité-prix en diminuant le prix des exportations, ainsi en augmentant le prix des importations. Cette situation contribue à l'amélioration du solde commercial, en provoquant un déplacement de la demande étrangère et nationale vers les biens nationaux.

Pour comparer la compétitivité de deux pays dans un secteur donné, (Gallagher et al, 2006) propose de confronter leurs coûts de production, qui seront calculés en rapportant les salaires

nationaux et la productivité de la main d'œuvre. Le pays où les coûts de production sont les plus faibles bénéficie d'un avantage comparatif sur l'autre pays considéré. Toutefois, (Sharples, 1990) fait valoir que la compétitivité ne peut pas être évaluée sur la seule base des coûts de production et que les chercheurs devraient aussi prendre en compte les coûts de commercialisation, autrement dit, les coûts supplémentaires liés au fait d'apporter le produit à un acheteur étranger.

1-2 Les Couts De Production

La compétitivité-prix renvoie à la capacité de l'entreprise ou de l'industrie à gagner des parts de marché en raison d'un niveau de prix plus faible que celui des concurrents. C'est un concept de l'ordre du court terme, puisque toute variation de prix va pousser les concurrents à réagir immédiatement.

La compétitivité est déterminée par le coût de production tel que le coût des matières premières ou intrants, des frais financiers, des coûts de la main d'œuvre ainsi que de transport. Toutefois, Or, elle est considérée comme le levier d'action des pays développés pour améliorer leur compétitivité face aux pays en développement dont les coûts de la main d'œuvre sont très faibles.

A titre d'illustration, les automobiles japonaises ont mis du temps à percer en Europe, du fait d'une qualité jugée suspecte malgré leurs prix plus faibles que ceux des voitures européennes comparables; le fait que Toyota offre une garantie illimitée de trois ans a totalement modifié les conditions de la compétitivité de l'industrie automobile japonaise sur les marchés européenne. L'évolution de la compétitivité prix demeure insuffisante pour expliquer les performances d'un pays vis-à-vis du commerce extérieur.

Au niveau macroéconomique, la compétitivité d'une économie nationale désigne la capacité de son secteur productif à satisfaire la demande intérieure et étrangère. De fait, les parts de marché relatives à l'exportation sont souvent utilisées comme indicateur de la compétitivité commerciale d'un pays. Les coûts fixes sont des coûts qui ne varient pas lorsque les quantités produites augmentent ou diminuent. Ils regroupent les loyers des immeubles, les amortissements des machines, les intérêts à verser, et les dépenses administratives ... etc. Les coûts variables contiennent les dépenses qui évoluent de façon plus ou moins proportionnelle aux quantités produites, ils rallient les salaires des travailleurs, l'achat des matières premières, de l'énergie ... etc.

Par ailleurs, l'analyse de la position compétitive en fonction de l'avantage prix et avantage qualité, révèle que la part des exportations marocaines en concurrence prix à hauteur de plus de 70% en 2002 a cédé le pas à celle des ventes en concurrence qualitative.

La Compétitivité Hors-Prix Dans Les Modèles Théoriques

Pour justifier les points de différence des performances commerciales entre les pays, de nombreux modèles économétriques sont mis en place en vue d'expliquer ce phénomène, ainsi de prendre des décisions à propos des politiques structurelles. Pour certains économistes, l'avantage comparatif représente le déterminant clé de l'échange commercial. L'analyse de ce concept repose sur la comparaison entre les coûts dans un ensemble des pays, de telle sorte qu'il y ait une différence entre ces coûts comparés qui seront adoptées pour améliorer ses performances à l'export. Les modèles d'équations d'exportation à l'Armington sont la base de toute étude élaborée pour interpréter cette différence.

En fait, lorsqu'ils sont appliqués sur le cas de la France, l'étude a abouti au fait qu'ils expliquent bien l'évolution des exportations françaises avant les années 1990. Pourtant, (Bessone (A.-J.) et Heitz (B.) (2005) [1] ont conclu que les équations d'exportations traditionnelles ne peuvent pas expliquer les évolutions des parts de marché liées aux exportations françaises et allemandes. (Artus. p

et L. Fontagné, 2006)[2] confirment également ces résultats et ajoutent d'autres variables explicatives en vue de capter les facteurs d'offre et la qualité des produits. Or, (Junz, H. et Rhomberg, R.R. (1973)[3] ont déduit que les prix seuls ne peuvent refléter l'évolution des parts de marché à l'export des pays. En effet, les prix constituent l'élément important dans les transactions commerciales, et ils ne reflètent que partiellement la capacité d'un pays à imposer ses produits sur le marché mondial.

(Krugman, 1989 ; Grossman et Helpman, 1989), en tant que des pionniers des théories récentes, ont soutenu l'importance des facteurs d'offre dans l'évolution des exportations, notamment, leur forte influence sur la demande des biens et que les performances des exportations d'un pays ne dépendent pas seulement de l'élément prix mais aussi des phénomènes de qualité et de la différentiation de produit. (Murata et al, 2000) incluent une tendance non linéaire aux équations d'exportation afin d'appréhender l'effet des facteurs hors-prix de la compétitivité sur l'évolution des exportations des pays membres de l'OCDE. Ils estiment un Modèle à Correction d'Erreur MCE pour chaque pays de l'échantillon sur des données trimestrielles. Ils aboutissent à des résultats très hétérogènes selon les pays de l'échantillon. Par exemple, la tendance pour le cas de la France et l'Allemagne a un impact négatif sur les exportations, pourtant pour l'Espagne elle est positive, et pour d'autres pays comme l'Italie, elle n'est plus significative. Ensuite, (A. Rouabah, 2005) estime un modèle similaire pour le cas de Luxembourg, il a conclu la tendance a un impact significatif et positif sur les exportations de Luxembourg.

L'utilisation d'une tendance pour capter l'aspect hors-prix enrichit le modèle d'Armington et permet de mieux modéliser l'évolution des exportations mais sans discriminer les facteurs d'offre. La tendance tient en compte des variables d'offre très hétérogènes telles que la qualité des produits, la variété proposée, l'investissement direct, l'investissement immatériel ainsi que d'autres facteurs tels que l'entrée sur le marché des pays émergents. Les limites de cette approche se manifestent à l'utilisation des variables proxy pour visualiser l'effet hors-prix de la compétitivité sur les performances commerciales d'un pays donné, puisqu'il y'a un risque de divergence des résultats. Certains économistes considèrent l'innovation comme étant un facteur clé de la qualité et de la compétitivité et qui peut mieux éclaircir les différences de performances entre les pays.

(J. Fagerberg, (1988)[4] calcule un indice de la compétitivité technologique basé sur les dépenses de R&D et les brevets déposés, il stipule que si un pays possède un indice de la compétitivité technologique élevé, alors ses performances commerciales sont jugées appréciables. Toutefois, (Marnier, A ; Toujas-Bernate J (1994)[5] utilisent un proxy qui se base sur les dépenses relatives de R&D pour montrer qu'à long terme, l'augmentation des dépenses de R&D a un effet positif sur l'évolution des parts de marché.

Pamiès-Sumner (2005) [6] puis Blot et Cochard (2008) appliquent un modèle similaire en séries chronologiques et panel pour montrer les différences entre les exportations françaises et allemandes. Après, ils aboutissent à des résultats similaires, qui s'énoncent que les produits français sont moins innovants que les produits allemands, ce qui explique un décalage entre le deux pays.

A la suite, Hummels et Klenow(2002) utilisent également un indicateur des dépenses de R&D pour mesurer la variété des produits proposée par les pays. Amable et Verspagen (1995) pensent aux brevets déposés comme variable proxy de l'innovation.

Toutefois, la littérature empirique cite d'autres proxy de l'innovation, à savoir la part des secteurs de haute et moyenne technologique dans la production totale du pays (Barrellet Pomerantz 2007), le stock du capital fixe net dans le secteur manufacturier (Athanasogluet Bardaka 2008), ou

encore l'effort d'investissement (Erkel-Rousse 1992). Toutes ces mesures peuvent enrichir les équations d'Armington, mais elles ont un défaut de rétrécir la compétitivité hors-prix à l'innovation.

Plusieurs études empiriques ont été effectuées afin d'appréhender l'effet de la compétitivité hors-prix sur les exportations des pays de la zone euro par le biais de l'indicateur de compétitivité globale.

L'Institute for Management Development (IMO) donne une mesure appelée le World Competitiveness Yearbook (WCY), qui fait partie des indicateurs les plus connus de la compétitivité internationale, et elle est publiée chaque année depuis 1989, elle sert à analyser et classer les pays en fonction de leur capacité à créer et à maintenir un environnement qui permet aux entreprises d'être compétitives. Les nations doivent, en effet, fournir un environnement macroéconomique qui encourage la compétitivité qui se fait à travers les infrastructures, les institutions, et les politiques efficientes.

Quelques Déterminants De La Compétitivité Hors Prix

Les déterminants de la compétitivité hors-prix, notamment dans le contexte où la qualité et l'innovation deviennent des instruments centraux d'une concurrence efficiente à l'échelle internationale. La compétitivité hors-prix correspond à la capacité à conquérir des parts de marché indépendamment du niveau de prix grâce à la différenciation des produits, à la qualité réelle ou supposée du produit, à l'image de marque, aux délais de livraison, etc .... Cette compétitivité est de l'ordre du long terme puisqu'elle demande du temps pour se construire.

Dans le contexte actuel du commerce international, la nouvelle logique de la compétitivité est essentiellement basée sur l'exploitation des avantages hors-prix.

Ces avantages permettent à un pays de conquérir des parts de marché, de faire face au concurrence, ainsi d'améliorer l'attractivité des produits locaux en se basant sur des facteurs qualitatifs difficilement quantifiables. Ces facteurs autres que le prix, peuvent être l'apport de l'innovation, et donc de la R&D, d'amélioration de la qualité des produits, d'adoption des techniques de marketing avancé, d'une différenciation des produits ...etc

Parmi les avantages hors-prix déjà cités, la capacité d'innovation et de différentiation restent parmi les principaux éléments influant la compétitivité hors-prix.

Capacité D'innovation

L'innovation est un outil primordial de la compétitivité nationale, puisqu'elle permet de renforcer la position concurrentielle du pays à l'international. Elle permet également d'augmenter sa productivité, d'améliorer la qualité de ses produits et ses services ainsi de développer ses compétences clés. M. Porter souligne que l'innovation est le pivot de la compétitivité de n'importe quelle entité économique. Parce qu'elle conditionne sa capacité à maintenir des avantages concurrentiels durables sur les marchés.

L'innovation peut prendre deux formes, celle de produits qui renvoie à l'introduction des nouveaux produits sur des différents marchés ou bien des produits déjà présentés sur le marché intégrant un nouveau procédé, et celle de processus qui réfère au nouveau procédé de production ou une organisation novice dans l'entreprise. Or, ces deux formes ont une relation de causalité entre eux dans le sens où l'une provoque l'autre.

Qualité

La qualité est un appui important pour la compétitivité hors-prix, elle représente aussi, un pari pour les politiques qui, visent à réaliser une montée en gamme dans les secteurs à forte valeur ajoutée. La qualité d'une entité (bien ou service) se définit comme l'ensemble des caractéristiques qui lui confèrent l'aptitude à satisfaire des besoins exprimés et implicites des différents utilisateurs (AFNOR, cité par Collignon et Wissler, 1984). Elle représente la première condition d'accès au marché pour un produit, même à l'existence de ce dernier. Des économistes, toutefois soulignent que « faire de la qualité apparaît comme le prix à payer aujourd'hui pour être encore sur le marché de demain ». (Valceschini 1991).

Etant donnée une stratégie de différenciation de produits (pour certains secteurs) et dans un marché mondial en concurrence monopolistique, la qualité contribue énormément à l'amélioration de performances de pays en terme d'exportation, ainsi qu'au terme de gain de part de marché.

Productivité Du Travail

Peut être définie comme la valeur des biens produits ou la valeur ajoutée du secteur manufacturier par heure de travail. Il s'agit donc de la valeur ajoutée à la production réalisée par un travailleur. Une telle valeur dépend de plusieurs facteurs:

- Mise en place des équipements perfectionnés.
-La qualification et la formation adéquate de la main d'œuvre.
-L'amélioration des conditions de travail de la main d'œuvre et de la situation sanitaire de la population active.

La prise en compte de la productivité du travail est déterminante dans l'analyse de l'effet du coût de la main d'œuvre sur la compétitivité. L'effet de la productivité et du coût de la main d'œuvre sur la variation du coût de la main d'œuvre unitaire s'exprime sous la formulation suivante :

$$\Delta \text{ CMOU} = \Delta \text{ CMO} / \Delta \text{ PTV}$$

Ou :

Δ CMOU : variation du cout de la main d'œuvre unitaire
Δ CMO : variation du cout de la main d'œuvre globale
Δ PTV : variation de la productivité

Une augmentation des coûts de la main d'œuvre ne peut affecter l'état compétitif du pays par rapport à ses concurrents, que si la productivité relative du travail enregistre, simultanément, un accroissement notable. Alors, ceci réduit voire annule les effets pervers de la hausse des coûts salariaux sur la compétitivité. Par conséquent, la variation unitaire du coût de la main d'œuvre est un indicateur pertinent pour évaluer la compétitivité d'un pays par rapport à ses concurrents. Or, la productivité s'avère une source non négligeable de la dynamique industrielle, en favorisant l'innovation et le développement des avantages hors-coûts.

L'adaptation A La Demande Internationale

L'aptitude de répondre à la demande internationale représente un facteur déterminant de la compétitivité d'un pays.

Certes, la notion de la compétitivité exige aux pays qui veulent maintenir ou accroître leurs parts de marché, d'adapter leurs produits offerts à la demande mondiale. En effet, plusieurs travaux prouvent que les flux des exportations d'un pays dépendent en grande partie de

l'évolution du niveau de la demande extérieure qui lui est adressée, ainsi de sa capacité à s'orienter et à se positionner sur des marchés dynamiques à forte croissance.
L'ouverture mondiale ne demeure suffisante, pour stimuler la croissance du pays, qu'avec une spécialisation et diversification des échanges. Pourtant, celles-ci peuvent entraîner des risques sur la conjoncture mondiale.

La meilleure stratégie dépend de la capacité du pays à satisfaire un ensemble des conditions dont l'aptitude et la flexibilité pour suivre l'évolution de demande internationale et se prêter à la réorientation de la structure des exportations en anticipant l'évolution de la demande internationale.

D'après l'analyse effectuée ci-dessus et en se basant sur les différentes études théoriques, nous pouvons résumer les différents déterminants des exportations dans le schéma suivant :

Figure1 : les déterminants associés aux performances des exportations

La mesure de la compétitivité hors prix (le cas du Maroc)

Rappel sur la Situation Des Exportations

Les exportations ont une tendance haussière durant la période 1980- 2014, mais à un rythme plus faible comparativement aux importations durant la même période. Ce qui implique une détérioration du déficit commercial d'une année à l'autre. Ce déficit s'est multiplié, allant de 7,15 Milliards de DH en 1980 jusqu'à 186,11 Milliards de DH en 2014. Il a néanmoins diminué en 2012 pour atteindre -202,3 Milliards de DH, ce qui résulte des effets de la crise économique et financière sur le Maroc et sur ses partenaires commerciaux.

Par extension, le tissu des exportations a été marqué, depuis le début de la décennie de 1980, par un manque de dynamisme, qui s'est expliqué essentiellement par la sensibilité élevée de l'offre exportable eu égard aux facteurs exogènes, notamment avec les fluctuations des prix de phosphates

et la succession des phases de repli de l'activité économique dans la zone euro. En effet, avec le recul de la demande adressée par cette zone à notre pays, la concentration de nos exportations sur le marché européen est devenue vulnérable aux effets de retournement du cycle conjoncturel dans la zone.

Quant aux importations, leur progression est maintenue à un taux de croissance moyen de 14,61%, 7,26%, 10,05%, et 7% durant les périodes 1981-1990, 1991-2000,2001-2010 et 2011-2014 respectivement. Cette progression est expliquée par la hausse des achats des biens d'équipement, des produits énergétiques et des intrants nécessaires. Pour relancer l'investissement, ainsi que le renchérissement des matières premières notamment le pétrole brut et les céréales, et également par les effets néfastes de la crise de 2008.

Les Indicateurs De Mesure Pratiqués

Suite à la mutation perpétuelle de l'économie mondiale, et pour suivre les tendances du développement de reste du monde, le Maroc se trouve face à la nécessité d'adopter une politique de la libéralisation des échanges commerciaux qui lui permet d'attirer des nouveaux débouchés extérieurs pour ses produits locaux.

En effet, la mise en œuvre de cette politique a provoqué l'intensification des investissements directs étrangers", ce qui a contribué à l'amélioration du degré d'ouverture de l'économie marocaine

Quant au taux de couverture qui traduit le pourcentage des exportations dans les importations, il est estimé à 51,8% en 2014. Ce taux a connu un fléchissement durant les dernières décennies passant de 66,43% en moyenne, durant la période 1995-2004 à 49,16% durant la période 2005-2014. Ceci est dû aux vulnérabilités structurelles de tissu industriel vis-à-vis des importations stratégiques, surtout celles des produits énergétiques depuis 2009, ainsi à la reprise depuis 2007 de celles des produits alimentaires. Ajoutons à cela, la flambée de cours des matières premières.

Les demi-produits

La part des demi-produits trace une tendance à la hausse, passant de 14% à 24,1% durant la période 1980- 2014. Cette évolution est tributaire de l'augmentation principalement, de la part des engrais naturels et chimiques et celle d'acide phosphorique, puisqu'ils prédominent les exportations des demi-produits.

Leurs parts dans celles-ci s'établissent conjointement à 62,24% en 2014 contre 70% en 1980. Or, dans les exportations totales leurs parts se situent respectivement à 8,2% en 1980 contre 6,4% en 2014, et à 1,6% en 1980, contre 8,6% en 2014.

Les produits finis d'équipement

Leurs parts dans les exportations globales s'accentuent durant la période 1980- 2014, soit un taux de croissance annuel moyen de 12,15%. Cela est dû essentiellement à l'augmentation des parts de produits finis industriels, dont la part allant de 0,3% en 1980 à 16,6% en 2014.

Evolution De La Part De Marché A L'exportation

Un des indicateurs' les plus importants pour évaluer le niveau de la compétitivité des exportations d'un pays sur un marché donné est l'évolution de sa part du marché. La hausse de cet indicateur implique une hausse des exportations du pays en question par rapport au reste du monde

Finalement, les produits manufacturiers, les biens d'équipement, et le textile qui clôturent la liste avec une part de marché à l'exportation qui est quasiment stable et qui n'excède pas 0,06%.

Quant à l'automobile, il débute à s'accroître à partir de 2008, et surtout avec le lancement de pacte d'Emergence industriel en 2012.

Durant la période 2000- 2014, les exportations des produits vestimentaires occupent le premier rang par rapport à d'autres produits. Leur part à l'exportation s'est inscrite dans une tendance baissière pour atteindre 0.67% en 2014, soit la part la plus faible observée sur l'horizon. Ce recul s'explique autant que par les crises de la consommation en Europe que par l'absence d'intégration industrielle.

Le second rang est occupé par les produits agricoles, dont la part de marché à l'exportation oscille aux alentours de 0,2% et 0,3% et qui demeure tributaire des aléas climatiques.

Adaptation des indicateurs de mesure pour la compétitivité hors prix

La Part De Marché Relatives

Elle est définie comme l'une des mesures fondamentales de la compétitivité hors-prix. Cet indicateur permet d'évaluer les performances d'un produit ou d'une industrie par rapport à ses concurrents sur le marché mondial.

L'indicateur de la part de marché en valeur permet de calculer la part des exportations d'un pays en un produit dans la demande mondiale. Comparativement à l'indicateur en volume, il présente l'avantage de tenir compte des éléments de la qualité et de la différenciation des produits soumis à la concurrence.

$$XMS_{ik} = (X_{ik} / X_{iw}) \times 100$$

Avec :

XMS ik : la part de du marché du pays dans l'industrie i au niveau mondial
X ik : la valeur des exportations du pays k pour l'industrie i
X iw : la valeur des exportations mondiales de l'industrie i

Il est à noter que si un pays présente une part de marché en valeur supérieure à celle en volume, cela indique que le prix d'exportation de ce pays est plus élevé que celui des concurrents

Indice de l'avantage comparatif révélé de Balassa

«Chacun des pays trouvant l'avantage à se spécialiser et à exporter les biens pour lesquels il dispose de plus fort avantage comparé, et à importer les autres biens de ses partenaires. Il s'avère difficile de mesurer directement ce concept, pour cette raison, de nombreuses études empiriques élaborées en référence à l'indicateur de l'avantage comparatif révélé, en tant qu'une mesure de spécialisation internationale

II existe plusieurs approches visant à mesurer cet indicateur. La plus pratique consiste à comparer la structure des exportations d'un pays *k* par rapport au reste du monde. La formule de calcul de cet indicateur se présente comme suit :

$$XRCA_{ik} = X_{ik} / \left[X_k \quad / \quad X_{iw} / X_w \right] \times 100$$

Avec:

$XRCA_{ik}$: représente l'avantage comparatif révélé, du pays *i* par rapport au reste du monde, pour un produit *k.*

X_{ik} : La valeur des exportations du pays k pour une industrie *i.*

X_k : La valeur des exportations mondiales d'une industrie i.

X_{iw} : La valeur des exportations de toutes les industries du pays *k.*

X_w: La valeur des exportations mondiales

Si le calcul de l'indicateur pour un pays *k,* dégage une valeur supérieure à 1 (l00), cela implique un avantage comparatif du pays *k* sur le commerce du produit i. De même, il indique que la part des exportations du pays *k* pour le produit. i par rapport à ses exportations totales est supérieure à la moyenne mondiale.

Productivité Apparente Du Travail

La productivité du travail ou production par actif occupé, qui, selon l'approche de la comptabilité de croissance, est la résultante à la fois du volume de capital mis à la disposition d'un actif (intensité capitalistique) et de la Productivité Globale des Facteurs (PGF). Cette dernière n'est autre que l'augmentation de l'efficacité globale du processus de production et d'une utilisation plus efficace de la combinaison capital-travail, permise par une réorganisation du travail ou bien par l'introduction de plus d'innovations.

Le coût de la main d'œuvre, a été considéré depuis longtemps comme la clé de la compétitivité des exportations marocaines. En fait, les salaires réels au Maroc, étaient faibles par rapport aux pays concurrents, ce qui lui a permis de se spécialiser dans les industries dites à forte intensité de la main d'œuvre, en particulièrement: le secteur agroalimentaire et le textile.

Cependant, cet avantage compétitif basé sur le coût salarial est devenu un désavantage en termes de la compétitivité dans la mesure où le niveau de SMIG actuel au Maroc, est classé parmi les salaires les plus élevé en Afrique, notamment dans les industries agroalimentaire et textile nécessitant le recours intense à la main d'œuvre.

La période (1999-2014) a été caractérisée par une augmentation de la productivité fortement corrélé à l'augmentation du stock d'emploi industriel.

En effet, les coûts salariaux ne constituent désormais le facteur déterminant de la compétitivité sur les marchés internationaux, pourtant, la différentiation des produits et l'amélioration de la productivité le sont. C'est pour cette raison que notre choix s'établit sur la variable de la productivité apparente du travail. Ajoutons à cela l'hypothèse qui stipule que le Maroc est doté en facteur travail.

La productivité apparente du travail se présente comme le rapport de la valeur ajoutée et les moyens mis en œuvre pouf l'obtenir. Elle peut être calculée soit par tête, soit par heure de travail effectué. Si nous procédons par l'approche par tête, la formule sera comme suit :

Productivité (t) = PIB non agricole (t) nombre de travailleurs dans le secteur industriel (t)

Hors, le surplus de productivité ne joue qu'un rôle marginal dans la croissance de la valeur ajoutée non agricole. Son taux de croissance n'a été que 0,5% en moyenne annuelle en 2000-2014 au lieu de 5,8% dans le secteur agricole.

Partant du constat que la compétitivité ne peut se réduire au coût du travail. Sans parler de la compétitivité hors-prix fondée sur la qualité et l'innovation. Celle basée sur le prix dépend aussi du coût du capital et des coûts de transactions liés aux complexités des cadres juridique et réglementaire. Par ailleurs, suite aux différentes réévaluations du SMIG au Maroc, cet avantage comparatif du bas salaire ne cesse de s'effriter au point que le travailleur marocain est devenu plus cher comparativement à d'autres pays tels que la Corée du Sud, Taïwan, la Malaisie ou encore la Turquie.

S'il est vrai que l'on peut obtenir des produits compétitifs grâce à des salaires bas, il est tout à fait possible de réduire le coût total avec des travailleurs plus productifs, qui permettront non seulement d'avoir une production plus élevée, mais aussi de faire des économies dans l'utilisation des autres facteurs de production, grâce justement à leur efficacité. Ainsi, dans l'hypothèse d'une convergence, c'est-à-dire d'un rapprochement, des salaires dans tous les pays, et c'est ce qui arrivera à terme, ce qui va faire la différence ce n'est pas le coût de travail mais c'est la productivité de travail.

Conclusion

En conclusion, compter uniquement sur les bas salaires pour attirer des investisseurs étrangers dans le but de relancer la croissance économique, revient à croire qu'il existe une course au bas salaire. Sauf que, si le bas salaire était le seul critère, comment expliquer alors que les pays développés, où le coût du travail est plus élevé, attirent plus d'IDE que les pays moins développés ? Si cette course existe, c'est uniquement pour des biens bas de gamme. Pour les autres biens, des critères supplémentaires pèsent dans la balance.

L'évaluation des principaux indicateurs de compétitivité du Maroc montre que, malgré les efforts des pouvoirs publics et en dépit de certaines réussites ponctuelles ou sectorielles, le pays n'arrive pas encore à atteindre le niveau adéquat pour affronter la concurrence mondiale et ce, en raison de la persistance de plusieurs handicaps structurels. Il s'agit en particulier de l'inertie de l'offre exportatrice nationale, sa concentration sur quelques produits et sur quelques marchés, la prédominance des produits à basse technologie et à forte intensité de ressources naturelles et de main-d'œuvre, la faible qualification et scolarisation des employés ainsi qu'une faible productivité comparativement à des pays concurrents particulièrement asiatiques. Le contexte mondial actuel, marqué par l'accélération du démantèlement des barrières à l'échange international et les co-localisations, offre, certes, des opportunités en matière d'extension du commerce extérieur. Cependant, malgré ces opportunités, les risques et les défis restent nombreux. Dans ce contexte, marqué, également, par une crise économique profonde qui affecte la zone euro, le renforcement de la compétitivité devient pour le Maroc un impératif pour relever le défi de la croissance et du bien-être, ce qui nécessite l'association des efforts de tous les acteurs socio-économiques pour développer une économie performante et compétitive.

Les pouvoirs publics ont joué un rôle important dans la promotion de la compétitivité et de l'attractivité de l'économie. Ils ont, en particulier, lancé un programme ambitieux de modernisation et de renforcement des infrastructures routière, autoroutière, ferroviaire et aéroportuaire. Ils ont même identifié, dans le cadre du ''Plan Emergence'', de nouveaux métiers mondiaux.

Ces efforts gagneraient, toutefois, à être complétés par la mise en place des conditions propices à l'amélioration des performances des exportations et la consolidation de l'attractivité. Remporter le pari de la compétitivité reste tributaire aussi du rôle de l'Etat et de l'Entreprise. Si l'Etat demeure sollicité pour assurer les conditions de la compétitivité de l'économie, il est important de souligner le rôle important que l'entreprise est appelée à jouer pour réussir le défi de la compétitivité. L'entreprise doit ainsi améliorer la qualité de ses produits, développer des techniques de management modernes, investir plus dans l'innovation et la Recherche & Développement. Elle doit aussi intégrer dans sa stratégie de développement la valorisation du capital humain comme facteur central de compétitivité et de promotion économique et social.

Analysis of The Y Generation's Advertising Perception

Jakub HORVÁTH

Faculty of Management, University of Prešov, Prešov, Slovakia
jakub.horvath@smail.unipo.sk

Abstract

The article focuses on the perception of advertising and its evaluation by the generation of the Millennials. The basic population for the purpose of the survey is the millennials of the East Slovakian region. 180 respondents were surveyed and it was possible to include 154 respondents' answers based on the criterion of completeness of completed questionnaires. Data collection was conducted through simple random sampling in January and February 2019. To verify the hypotheses, we used the StatSoft SPSS software. Due to the nature of the analysed variables we used Cronbach´s alpha and Mann Whitney U test. Based on the research findings, the respondents did not know or did not want to rate the internet advertising (banner, context, advertising on social networks, e-mail advertising). The generation of the Millennials evaluate internet advertising as more negative than the traditional advertising. This output suggests to some extent the so-called "advertising blindness". The result of the hypothesis verification is that there is a significant difference between the ranking of traditional and internet advertising in the generation of the Millennials. These results are very interesting if we confront them at the level of the global tendency of advertising perception by Y generation representatives.

Keywords: advertising, advertising perception, ad ranking, the Millennials.

Introduction

People are hit by an enormous amount of ads trying to get their attention from various media - television, print media, radio, and now even the Internet. With this number of promotional messages, businesses that do not use marketing communication are in the shadows of those who use it (Hagyari, Bačík and Fedorko 2016). Every company that builds its promotional activities only on the recommendations of its customers does not very often achieve what we call magnetism (Turner and Shah 2014; Lizbetinová et. al. 2019). However, if the company wants to achieve it, it should focus on developing the right strategy for marketing communication (Bačík, Mihal and Fedorko 2015). Marketing is an activity, a set of institutions and processes that have been created to communicate, deliver and exchange offers that are valuable not only to customers but also to other stakeholders and the general public (Lamb, Hair and McDaniel 2012; Mura and Kljucnikov 2018). In traditional marketing theory, we should be familiar with McCarthy's 4P model, which deals with product, price, placement and promotion (Dann and Dann 2011). Marketing communication is, according to Ferencová and Butoracová Šindleryová (2009) "any form of controlled communication used by organizations to inform, persuade or influence consumers, intermediaries and even certain groups of the public". In the traditional marketing theory, marketing communication tools include advertising, public relations, personal sales, sales promotion, direct marketing and etc. (Armstrong et al. 2009). E-marketing is a form of marketing where the application of IT tools and the Internet allows marketing tools and activities to focus on the defined relationships (Molenaar 2012). Molenaar further claims that e-marketing consists of three sub-areas: marketing, information technology and Internet. E-marketing helps to create customer demand by using the power of the Internet (Mudrík and Fedorko 2010). It gives businesses the opportunity to exchange attention for value (attention economy) (Frankovský and Birknerová 2014). E-marketing tools help building a long-term customer relationship. Moreover, the e-marketing environment is very well measurable (Stokes 2013; Mura, Marchevská and Dúbravská 2018). Dorčák (2012) states that traditional forms of e-marketing communication include: website, contextual advertising, banner advertising, search engine advertising; PPC advertising, e-catalogues, e-mail marketing and public relation (Štarchoň et. al.

2018). A website is a document containing hypertext, images, and other multimedia elements stored on a web server that is displayed to the user when entering a specific web address in the selected search engine (Fedorko and Kakalejčík 2015). For businesses, it is one of the proprietary media that allows it to communicate with its potential customer (Dorčák 2012). In an ideal world, any Internet user would immediately become a customer (Kovaľová, Frankovský, Birknerová and Zbihlejová 2019). As the real world differs greatly from the ideal, businesses need to think about the steps that the customer takes before and after the purchase to offer the customer enough information transforming them to customers as soon as possible. The funnel is the best choice for defining a purchasing cycle.

Fig. 1 : Purchasing funnel

The purchasing funnel is the purchasing process that the customer is conducting during the purchase cycle. It usually consists of several phases (Halligan Shah 2014). The definitions of the funnels vary with the author. However, for the purposes of this article, we will use Carter's (2013) purchasing funnel, which is shown in chart 1. The displayed funnel consists of 3 phases and 4 types of people involved in it. We can define these people as follows: stranger – represents an internet user who has not previously visited the business website (Halligan and Shah 2014); visitor – represents the internet user who previously visited the business website (Carter, 2013); lead - represents a visitor who has expressed a deeper interest in the website by providing their contact information in exchange for the content of the website (Scott, 2013; Štefko, Bačík and Fedorko 2014).

Methodology

The main objective of this article is to find out if there are differences in the ranking of traditional and online forms of advertising. Based on this objective, a research question is formulated as to whether: "Are there any differences in the evaluation of internet and traditional Y generation advertising?" Based on this research question, a research hypothesis is formulated:

H1: We assume that there are significant differences between the ranking of traditional and internet advertising in the generation of the Millennials.

The deeper relationships of the conducted research show a portion of inference statistics and part of the analytical processing. In this section, Cronbach's alpha and Mann Whitney U test were used.

For the purpose of this research, the research sample was defined as a new generation of customers represented by the Millennials. As for the definition of the age group of the Millennials, the article follows the methodology of Young (2017) from Ogilvy & Mather. The Millennials are referred to as "Y generation" from the age 18 to 34.

- C Centennials (1995-2012),
- Y Millennials (1977-1994),
- X Generation (1966-1976),
- S Generation (1955-1965).

The inputs to the analyses were obtained through the implementation of primary research, which was carried out using CAWI (Computer Assisted Web Interview). Data collection via an electronic questionnaire was conducted in January and February 2019. It was a quota selection based on the ROD variable, where were efforts to maintain the population ratio, i.e. 52% representing women and 48% representing men. It was an electronic inquiry, where the questionnaires were distributed on the Facebook pages to the groups of the University of Prešov and to other groups of people living in the Prešov and Košice regions. E-mails (from the private address database of the authors) were subsequently sent to identify the gender characteristics. The research was conducted in January and February 2019. Thus, based on the selection, the research has a limitation and therefore it can be generalised only to Eastern Slovakia. 180 answers were collected and in case of the question identifying their generation (how old are they) 26 respondents were eliminated, i.e. the number of selection proceeding to the investigation is 154.

Results

The examined issue points to the perception of advertising and its evaluation by the generation of the Millennials. The following chart shows the gender characteristics ratio.

Fig. 2 : Gender characteristics – Advertising Rank

The previous chart points to the fact that the selection consists of 55.84% women (86 respondents) and 44.16% men (68 respondents), thus we can talk about the selection approximating the actual population of Eastern Slovakia. The questionnaire for the survey variables (the ranking of individual types of ads) also offered the possibility of not filling out the items. The following table shows the actual frequencies found.

Table 1 : Advertising Rank - Frequency

Advertising type	**TV Advertising**	**Banner advertising**	**Contextual Advertising**	**Advertising on Social Network**	**E-mail Advertising**
Valid	152	136	134	152	136
Not filled out	2	18	20	2	18
Advertising type	**Radio Advertising**	**Leaflet Advertising**	**Newspaper Advertising**	**Billboards**	**Posters**
Valid	152	150	154	154	154
Not filled out	2	4	0	0	0

It is noteworthy that the respondents did not know or did not want to rate the internet advertisement (banner, contextual, advertising on social networks, e-mail advertising).

Table 2: Descriptive Statistics - Advertising Rank

Advertising Type	**TV Advertising**	**Banner Advertising**	**Contextual Advertising**	**Advertising on Social Network**	**E-mail Advertising**
Negatively					
Rather negatively	62	36	36	34	58
Rather positively	44	42	46	44	58
Positively	32	46	36	54	8
	14	12	16	20	12
Median	2.00	2.00	2.00	2.00	2.00
Mean	1.99	2.25	2.24	2.39	1.81
Std. dev.	1.00	0.95	0.98	0.98	0.90
Advertising Type	**Radio Advertising**	**Leaflets**	**Newspaper Advertising**	**Billboards**	**Posters**
Negatively	26	12	8	16	10
Rather	52	32	16	30	26

negatively	56	70	88	66	74
Rather positively	18	36	42	42	44
Positively					
Median	2.00	3.00	3.00	3.00	3.00
Mean	2.43	2.87	3.06	2.87	2.99
Std. dev.	0.91	0.87	0.76	0.93	0.85

The previous table shows the outputs of descriptive statistics on the subject. Looking at the characteristics of the central tendency it is possible to note that the internet advertising of the generation of the Millennials is rated as more negative than the traditional one. This output suggests to some extent the so-called "advertising blindness". The following sections will be devoted to exact confirmation of the significance of the differences.

H1: We assume that there are significant differences between the ranking of traditional and internet advertising in the generation of the Millennials.

The assumption defined by the previous H1 hypothesis will be verified on average values of traditional and internet advertising. The possibility of average individual items is determined by an acceptable level of reliability. The following table illustrates this.

Table 3 : Cronbach's α - Reliability

Traditional advertising		**Internet advertising**	
α	N	α	N
0.788	6	0.830	4

The threshold for applying the selected item adjustment procedure (arithmetic mean) in terms of reliability is 0.7 (70%), thus the condition can be considered fulfilled. Data were adjusted by arithmetic mean. The following table shows the Mann-Whitney Wilcoxon U test output, and thus the significance of the difference in ranking between traditional and internet advertising.

Table 4: Test - Difference in Ad Rank

Ad rank	
Mann Whitney U	2 949.000
Wilcoxon W	5 577.000
Z	- 5.683
Asymp. Sig. (2-tailed)	0.00

H0: there is no significant difference between the variables.

H1: there is significant difference between the variables.

Based on the p value, which is equal to zero to three decimal places, it is advisable not to reject the alternative H1 hypothesis and to adopt an opinion on the significant difference in the ranking of traditional and internet advertising. The presented output also recommends adopting the basic H1 hypothesis, that there is a significant difference between the evaluation of traditional and internet advertising in the generation of the Millennials. The following chart shows the difference.

Fig. 3 : Rating of traditional and internet advertising

From the above it is clear that the Y generation (the Millennials) evaluate better the classical/traditional advertising. This fact can be a cause of advertising blindness, i.e. the given generation is ignoring the ads on the screen of their smartphones and they are somehow immune to it.

Conclusion

Until recently, businesses have implemented their marketing activities based on traditional marketing communication tools. However, since these tools often required a considerable budget, they were not available for every business. In addition, they only provided one-way communication. However, the arrival of the Internet as a network of networks and the emergence of social media has changed the situation. Using modern marketing communication tools, even small businesses with limited budgets have the ability to reach out to their target audience, often with minimal cost. In addition, they have the option of two-way communication.

Based on the above analysis, we can say that the Millennials do not know or do not want to evaluate the internet advertising. Representatives of the Y generation rated the internet advertising more

negatively than the traditional one. This output suggests to some extent the so-called "advertising blindness". Based on the hypothesis we have established, we note that there is a significant difference between the evaluation of traditional and internet advertising in the generation of the Millennials. The y generation (the Millennials) rated traditional advertising as better. This fact can be a cause of advertising blindness, i.e. the given generation is ignoring the ads on the screen of their smartphones and they are somehow immune to it.

Women's Activity in Selected Political Structures in Poland In the Years 1989-2015

Magdalena NOWAK-PARALUSZ

Department of Social Sciences, WSB Universities, Poland,
E-mail: magdalena.nowak-paralusz@wsb.torun.pl

Abstract

The subject of this article is the modern political activity of women in Poland after the year 1989. It concerns particularly issues of the participation of women in the sphere of the politics. A creature of the recognition of the phenomenon is the behavior not only in the relation with the sex in political structures, but also conditioning of both external and internal of internalized by the society and the participation of women in decision processes. The article is sacrificed to statistics devoted to the participation of women in political structures on chosen levels of the political life. The author analyses the statistical presence of women in individual decision bodies: the government, State-institutions and parties. A small percentage of women in decision-making bodies is a result of traditional rules according to which political structures in Poland function, but women themselves are also an obstacle to women's participation in decision-making structures. A decisive factor about the attempt of the analysis of the political participation of women in Poland after 1989 was the scarcity research and works devoted to these problems, especially in the area of analyses of the Polish political sphere. The participation of women in the Polish politics still has not had the complex elaboration, though more and more often some works, making an attempt analyses of the phenomenon from detailed scientific perspectives, appear. Undoubtedly, this issue requires deepened research.

Keywords: Gender, Political Participation, Social Psychology, Political Psychology, Women In Poland

Introduction

The main axis of the article is the participation of women in Poland in the decision-making process analyzed through their involvement in political structures over the last few decades. The following considerations concern the degree of women's political involvement in certain areas of the political sphere – in the legislative body (the parliament – in the decision-making body of the Parliament, Parliament committees), in the executive body (the government – a woman as the Prime Minister and as a Minister) after 1989.

The decision-making process is an integral part of human existence. An individual makes decisions almost from the beginning of its existence in each field of its functioning. Along with social development, the decision-making process was moved from the individual level to the group level, when people began to form communities (including political communities). Thomas Hobbes points out that along with the creation of the idea of the state, competences shifted from the private to the public sphere. As a result of the transfer of decision-making power, a significant social problem arose: decisions made by the community are largely unable to satisfy each member of a given community (regardless of how they make decisions within the community; whether in the form of an authoritarian decree of the ruler or through democratic voting). The degree of participation of an individual or group representing the interests of a particular environment in the political decision-making process implies their superior-subordinate relationship towards other individuals and groups. Subordinate position of one group and the superiority of another in the political sphere were explained by numerous researchers of the political activity aspect. Lester W. Milbrath and others emphasized the need to have certain means to undertake political activity. Milbrath also pointed to

the time that should be devoted to political activity as one of the main elements determining political commitment. Pierre Bourdieu believed that by having or lacking political capital we determine the degree of political participation: the smaller the political capital one has, the less influence on the sphere of political action they can have.

The fundamental aspect of participation in the political decision-making process is being a part of decision-making structures or having representatives in the system of power1. The right to elect is a tool that allows an individual to participate in decision-making processes. Today, in most political systems, after achieving the so-called electoral age and if the requirement of no criminal record is met, citizens have the right to be candidates in elections to representative bodies regardless of their gender. Contemporary electoral registration procedures do not differentiate candidates in terms of their gender. One of the most important components of electoral rights is the passive voting right.

There is a large gap between the participation of women and men in key political structures, including decision-making bodies. According to a report from a conference in Beijing devoted to the situation of women in the world, one of the main problems is enabling women's access to decision-making bodies at all levels of political life and making it possible for them to play leadership roles. The inability to participate equally in the decision-making process affects the disproportion in the representation of social structures, as well as the functioning of the democratic system. Equal participation of women in the decision-making process is a prerequisite for representing women's interests to an appropriate degree. At present, the interests of at least 50% of the population are not represented to such an extent and the lack of active participation of women results in the lack of a women's point of view in the decision-making process, not to mention the principles of social justice and equality. In Poland, the situation of women in the decision-making process and leadership roles is similar to that in the world, there is a large disparity between the genders in the participation in decision-making bodies at all levels of political life. After 1989 in Poland, the number of women in decision-making bodies at certain levels of government has been changing; a certain upward tendency in the percentage share in decision-making bodies can be noticed, but we cannot say that participation is equal. Women in Poland are largely underrepresented at all levels of government structures and in other bodies of executive power, with a smaller disparity at the level of legislative bodies.

The representation of each gender in authority bodies and in decision-making processes should not be lower than 40-50% - then you can talk about the representativeness of power, because – as researchers indicate – a share of 30-35% does not provide equality of gender [Norris, Lavenduski, 2004; M. Fuszara, 2010; and P. Oliver, G. Marwell, R. Teixeira. 1985]. The number of women in elected bodies, in public administration and in political parties (with particular emphasis in highest positions), is not proportional to the number of men in these institutions. This essentially translates into women's decision-making possibilities and the possibility to represent their interests on the political arena. There is a high probability that women in political and decision-making positions in governments and legislative bodies will contribute to the redefinition of political priorities and the implementation of completely new programs related to the marginalized interests of women. From the point of view of proper execution of democratic principles it is important to introduce the women's point of view to the mainstream politics (gender mainstreaming).

Woman – country leader

President

After 1989, four women ran for the office of the president: Hanna Gronkiewicz-Waltz (1995), Henryka Bochniarz (2005), Magdalena Ogórek (2015) and Anna Grodzka (2015). Hanna Gronkiewicz-Waltz was a candidate supported by Stronnictwo Ludowo Chrześcijańskie (People's Christian Party), Zjednoczenie Polskie (Polish Union), Partia Konserwatywna (Conservative Party), Koalicja Konserwatywna (Conservative Coalition), Zjednoczenie Chrześcijańsko-Narodowe (Christian-National Union), Niezależne Zrzeszenie Studentów (Independent Students' Association) and Stowarzyszenie Rodzin Katolickich (Association of Catholic Families). H. Gronkiewicz-Waltz

and an expert in her field received 2.76% of the population votes in the first round of elections, which was the seventh best result out of 13 candidates running for the office of the president. Henryka Bochniarz ran for the 2005 election as an independent candidate and expert in her field. The candidate's election was supported by the Democratic Party and the young Center. In the first round of elections, she received 1.26% of votes, which was the seventh result out of twelve candidates. Maria Szyszkowska initially declared her availability in the 2005 election as an independent candidate, but she failed to collect the necessary number of signatures necessary to submit her candidacy despite the support she received form Demokratyczna Unia Kobiet (Democratic Union of Women), Antyklerykalna Partia Postępu „Racja" (Anti-Clerical Progress Party 'Racja'), as well as small left-wing organizations and parties. Three women ran for the office of the president of the Republic of Poland in 2015, similar to the year 2005 as independent candidates, Magdalena Ogórek, supported by the Left Wing (SLD), Wanda Nowicka (NGO expert) supported by Unia Pracy (Labor Union Party) and Anna Grodzka supported by Zieloni (Green Party). Wanda Nowicka and Anna Grodzka did not collect enough signatures of support for their candidacy. Magdalena Ogórek managed to do that and received 2.38% of votes in the first round of elections.

Election campaigns of all the female candidates were incoherent and not very expressive. The political offer of female candidates (1995 and 2005) addressed to voters was not very characteristic and at the same time resulted in an image distrust. It was an image of women in important decision-making positions on one hand, and of housewives performing traditional female roles on the other. Both candidates relied on an image of an expert and referred to strong family traditions that they cultivate along with their simultaneous activity and professional career[2] Creating such an image of a female politician according to research carried out by Renata Siemieńska increases the chances of women's electoral success [R. Siemieńska 1997]. Hanna Gronkiewicz-Waltz received more votes from women than from men (3.9% of women compared to 2.2% of men) and from voters with higher education (4.7% of voters had higher education, 3.4% secondary education, 2.3 vocational education and 1.8% primary education [M. Mazur 2002]).

Political marketing specialists could not find a way to promote women[2], present their offer, their advantages and abilities, and change the quality of politics that choosing them would bring[3]. Among 55 candidates for the office between 1989 and 2010 there were three women, representing 5.45% of the total number of candidates. The reasons for underrepresentation of women on the list of candidates for the office of the President of the Republic of Poland should be considered from the perspective of numerous factors, emphasizing four elements:

- political calculations,
- lack of a woman with social support on the Polish political scene,
- lack of a woman with party support on the Polish political scene,
- low social support for women as president.

One of the factors having a decisive significance for putting up a female candidate is political calculation – you do not put up candidates who have little chance of being elected. Women in Poland competed as independent candidates and/or with the support of organizations and political parties of little importance on the Polish political scene. Another causative factor is the fact that since 1989 there has not been a charismatic woman who has public support in the area of Polish politics, which also negatively correlates with women's chances of being elected in the presidential election. The reasons for the low support of voters for women candidates for the office of the president be sought in the way they are presented by mass media during election campaigns, in the distribution of emphasis in the presented programs, as well as in political rivalries between individual political forces [R. Siemieńska 1997.]. Moreover, women in the Polish public sphere who are recognizable, are rarely popular in the society.

In the recent history of the Republic of Poland, any major party or one enjoying considerable social support, has not put up a female candidate for president. It seems that nowadays not only there is no political will to do it, but above all there are no women who meet the requirements necessary to

achieve a satisfactory result in elections. In the present shape of the political market in Poland, with the prevailing stereotype of a female politician and inconsistent creation of images of politically active women, it is impossible to put a woman in the highest position in the country. Nevertheless, if a woman politician was built an appropriate political image based on political experience, competence and successes in the professional field, this could become a significant impulse for the electors and introduce unexpected commotion on the potentially stable electoral market.

Parliamentary Decision-Making Structures

Apart from a few exceptions, underrepresentation of women in democratically elected parliaments is an undeniable fact [J.A Karp, S.A Banducci 2008]. This disproportion is the reason for women's interests not being properly represented in political decisions [A.M Holli, H. Wass. 2010]. Numerous scientific papers indicate that proportional electoral regulations contribute significantly to increasing the representation of women in political elites, among others, parliamentary elites [M. Duverger, 1956; E. Lakeman. 1976; F. G. Castels. 1981; P. Norris. 1985].

The presence of women in parliamentary structures in Poland is not surprising, although there is an unquestionable disproportion between the representation of women and men in legislative bodies [see Siemieńska 2000; Moser 2001; Kunovich 2003]. Since women in Poland obtained electoral rights [Walczewska 1995]4, their permanent presence in parliament can be seen.

One of the factors that increased the representation of the fair sex in the parliament were discussions about the introduction of the quota system to the electoral law. Initially, it was an unsuccessful attempt to apply affirmative actions in Poland. Despite this, on the wave of political discussion, three parties voluntarily used instruments to support women: Unia Demokratyczna (Democratic Union), Partia Pracy (Labor Party) and Sojusz Lewicy Demokratycznej (Democratic Left Alliance) introduced a quota system on their electoral lists. It is worth noting that in 2001 the most Polish women were introduced to the Sejm by Liga Polskich Rodzin (League of Polish Families), which did not use any tools to support women's participation in politics. Th phenomenon of this situation was brought by the support given to Liga Polskich Rodzin by the radio station Radio Maryja. This statistic was maintained until 2011, when slightly less than 24% of women were elected in the 7th term of the Sejm; this was the second time when attempts were made to increase women's political participation through instrumental activities. The downward trend reversed in 2015, when the number of women increased to 27% in the 8th term of the Sejm. As a result of actions taken, among others, by the Congress of Women in 2009, a draft parity bill was submitted to the Sejm and the quota law introduced before the parliamentary elections has been in force since 2011. Since 1997, Poland has been classified on the list of the Interparliamentary Union5 presenting the participation of women in world's parliaments. Poland currently occupies 55th (in reality 59th) place among 190 classified countries, although at the beginning of the term it was 42nd.

The Speaker Female and the Deputy Speaker

Since 1989 two women have been elected the Speaker of the Parliament Lower House (Ewa Kopacz, Małgorzata Kidawa-Błońska), the position of Deputy Speaker was held eight times. Statistically, the function of the Marshal of the Sejm was held by 7.14% of women, and the Deputy Speaker by 14.28%. During three terms of the Parliament Lower House, there was no woman in the position of Deputy Speaker (1st, 3rd and 4th term). The position of the Speaker is not only a prestigious office due to the fact that the one who holds it is the second most important person in the country, but it is also significant due to the wide range of powers assigned to this position. The symbolic participation of women in the decision-making body of the Parliament Lower House primarily affects the significant reduction of the influence of women politicians on shaping the legislative activity of the state and is the cause of underrepresentation of initiatives related to issues relevant to the pursuit of women's interests.

In the Parliament Upper House after 1989, the function of the Speaker was held once (Alicja Grześkowiak), and Deputy Speaker was held eight times. Statistically, 12.5% of women held the function of the Speaker of the the Parliament Upper House, and 25% held the Deputy Speaker position. During two terms, no woman held the Deputy Speaker position (4th and 6th term).

The prestige and competences of the persons holding the function of the Speaker of the Senate are much smaller than those holding the position of the Speaker of the Sejm of the Republic of Poland, but they still remain relevant in the legislative process. The lack of women in the presidium of the Senate implies a significant reduction in the influence of female politicians on shaping the legislative activity of the state and eliminating a woman's point of view on the organization of legislative processes in the Senate.

Prime Ministers and Deputy Prime Ministers

Women's participation in government structures relates to the problem of gender asymmetry in decision-making processes as an element of political commitment [R. Inglehart, P. Norris, 2003]. In the short history of Polish democracy, Poland was led by 17 governments and two politicians held the position of the Prime Minister twice. So far, three women have served as the Prime Minister, and the position of Deputy Prime Minister has been entrusted to women four times. The number of women in the ministerial position ranged from zero to six in particular offices. Two governments were fully masculine: the government of Jan Olszewski and the first government of Waldemar Pawlak; one government, apart from the position of the Prime Minister, consisted of men only, it was the government of Hanna Suchocka.

Since building a new political system started in Poland, 15 politicians have held the position of Prime Minister (two were the head of government twice). Among them there were three women (Hanna Suchocka, Ewa Kopacz and Beata Szydło) (see Chart 9) and two women served as Deputy Prime Minister (Izabela Jaruga-Nowacka and Zyta Gilowska – twice and Elżbieta Bieńkowska) . For 15 months in 1992-93 the position of Prime Minister was held by Hanna Suchocka. Ewa Kopacz also held this position for 15 months in 2014-2015. Beata Szydło held the office from December 2015 to December 2017. For 18 months in 2004-2005 Izabela Jaruga-Nowacka was the Deputy Prime Minister in the government of Marek Belka, while Zyta Gilowska was the Deputy Prime Minister in the government of Kazimierz Marcinkiewicz for 5 months of 2006 and for 14 months in the years 2006-2007 in the government of Jarosław Kaczyński. Elżbieta Bieńkowska was the Deputy Prime Minister in the second government of Donald Tusk for 9 months in the years 2013-2014 .

It is worth emphasizing that Hanna Suchocka became the Prime Minister by accident, according to the politicians from the party which put out her candidacy, as a result of a coalition trade, because from the candidates for the Prime Minister only she found relative acceptance of all the parties forming the government. However, she had no influence on the composition of the government, nor was she the author of the expose. Hanna Suchocka held the position of Prime Minister in the atmosphere of continuous conflicts of the coalition parties for 15 months. Ewa Kopacz was "anointed" for Prime Minister by Donald Tusk, who took office of the President of the European Council in December 2014. After the 2015 election, the winner party PiS (Law and Justice) designated Beata Szydło as Prime Minister. None of the women were the Prime Minister for more than two years.

Women in the position of the Minister

Since 1989 in Poland, women have held the position of a Minster 51 times, representing 11.72% of all ministerial positions during this time .

Most often, ministerial positions were held by independent women (23.53%), followed by those connected with PiS (20.59%) and PO (Civic Platform) (17.65%), and the least often those representing the PSL (Polish People's Party). The largest number of women were entrusted with the

function of a Minister by Donald Tusk during the second term of his government (7 women throughout the entire term – there were a maximum of 5 at the same time) and Jarosław Kaczyński (6 women throughout the entire term – there were a maximum of 5 at the same time), followed by Prime Ministers: Jerzy Buzek, Leszek Miller, Kazimierz Marcinkiewicz, Donald Tusk (1st term of his government), Ewa Kopacz and Beata Szydło appointing 5 women as members of the government. Three Prime Ministers did not entrust any women with a position of a Minister to: Jan Krzysztof Bielecki, Jan Olszewski and Hanna Suchocka. Women were entrusted with ministries related to areas stereotypically considered as fields of women's activity, these were ministries mainly dealing with social issues and areas perceived as women's spheres. Usually, Ministers' competencies were closely correlated with the roles played by women in private or professional spheres.

Most frequently women were appointed the head of the Ministry of Labor and Social Policy (5 times), followed by the Ministries of Regional Development and Finance (4 times), and once were appointed the head of the following Ministries: Health, State Treasury as well as Industry and Trade. Furthermore, women held the office of the Minister of Justice, Sport and Tourism, Culture and Art as well as Science and Higher Education (each ministry was entrusted to a female Minister twice). Women were the head of the Ministry of National Education and Spatial Planning and Construction three times, and received the function of a Minister without Portfolio four times. Women in Poland after 1989 have never held a function in the so-called hard ministries, stereotypically perceived as an area of male activity: at the Ministry of National Defense and the Ministry of Internal Affairs.

Expert Ministers include Halina Wasilewska-Trenkner, Zyta Gilowska (both independent) managing the Ministry of Finance, Teresa Kamińska (AWS) a Minister without Portfolio, Elżbieta Bieńkowska (independent) managing the Ministry of Regional Development, and Barbara Piwnik (independent) – Ministry of Justice. Women who run their Ministries as experts in their field were usually from outside the party having an image of a professional. Expert female Ministers transcend the stereotypical perception of women in politics. The political, social and media circles perceive them through the perspective of their skills and knowledge, not their gender. Some women in governments, despite their qualifications, were appointed to positions that did not guarantee the possibility of presenting and using their knowledge. The best example of a minister who received a Ministry because of the need to raise gender statistics is Joanna Mucha, who managed the Ministry of Sport and Tourism in the second government of Donald Tusk but did not have any qualifications to run the Ministry. She is known for wanting to be called a "Ministra" (previously unused female form of "Minister") and for lack of basic knowledge on subjects related to the Ministry she was managing. Mucha does not appear in the rankings of qualifications, but in those of beauty and fashion. This is worth mentioning, especially because Elżbieta Bieńkowska, who was a member of the same government, was perceived through the prism of professionalism and competence and was very often indicated as one of the best Ministers and a contender to take the position of Deputy Prime Minister. The appointment of Mucha may have been a good political move, due to low participation of women in Tusk's second government, but it caused political damage to both the person concerned and the potential subsequent female candidates for high decision-making positions. If Mucha had not been there, only 4 women would have been members of Tusk's government, which considering the political postulates of Platforma Obywatelska (Civic Platform) and above all, considering the promises of the Prime Minister, would have proven the failure of the government's pro-equality policy and the failure to fulfill the basic promises made by Tusk. Mucha's incompetence at her office was gross and also damaged her image as a competent and professional person. Joanna Mucha has long emphasized her activities to increase women's participation in political life and it seems that she would have definitely better managed the function of the Government Representative for equal treatment affairs rather than the office she managed.

The position of the Minister without Portfolio has been functioning in the Polish public sphere since 1989, Polish legal regulations give the Prime Minister the possibility to appoint the so-called Minister of Special Affairs, who does not manage any of the existing Ministries. A Minister without Portfolio is a special task Minister competences include working on issues that are important from the point of view of government interests, but which do not fall under the competence of any Ministry.

There were 31 Ministers without Portfolio during 17 government terms, out of which 6 women were appointed to this position (accounting for 15.38%): Małgorzata Niezabitowska, Teresa Kamińska – social reform coordinator, Izabela Jaruga-Nowacka – Minister for equal status for women and men and Danuta Hübner – Minister for European integration, secretary of the European Integration Committee, Elżbieta Witek and Beata Kempa.

The first Minister without Portfolio in 1989-91 – the spokesperson was Małgorzata Niezabitowska, a member of Tadeusz Mazowiecki's government. One of the most important Ministers without Portfolio was Teresa Kamińska, who was responsible for introducing four social reforms in 1997-99. Her significance in making political decisions was all the more important because she was one of the closest associates of the Prime Minister. Danuta Hübner was another woman in the position of a special task Minister. She formed the structures of the Polish administration, which was to prepare Poland for membership and accession negotiations in the European Union7. She was the first Polish Minister for European affairs in 2003-04 (as a Minister without Portfolio). She was the first Polish woman to become the EU Commissioner for Regional Policy (2004-09). In 2004, Izabela Jaruga-Nowacka became the next Minister without Portfolio. Her duties included, coordinating the work of the Council of Ministers in the field of social policy, monitoring the functioning of the Government Center for Strategic Studies and holding the office of the government's representative for equal status of women and men. The position entrusted to Jaruga Nowacka was supposed to be facade, due to the EU requirements regarding the government's responsibility for introducing equality postulates, but it became a flagship example of the pursuit of gender equality and determination in transforming the socio-political system. Her political activities contributed to the creation of a program of activity for the benefit of women, adoption of the law on the prevention of domestic violence, establishment of definitions of discrimination, mobbing and sexual harassment terminology as well as changes in the labor code to protect against discrimination and mobbing.

Most women in ministerial positions were independent (23%), followed by PiS (20%) and PO (17%). The relatively large number of independent female politicians (almost every fourth female Minister) holding the position of Minister indicates they were selected for the office through the prism of their competence and achievements in their fields. The fewest women among the Ministers represented the PSL affiliation – a tendency also reflecting the situation in the parliament, where PSL traditionally has the lowest number of representatives.

Conclusions

A small percentage of women in decision-making bodies is a result of traditional rules according to which political structures in Poland function, but women themselves are also an obstacle to women's participation in decision-making structures. There are many obstacles limiting political activity (discussed in more detail in previous parts of the work). In cyclically presented reports on gender equality, including equality in the decision-making process, the emphasis is put on the fact that in government bodies men and women often function differently, in accordance with the traditional division of roles. Men act as experts, and women perform a supporting function. There is also a significant obstacle related to informal decision making during men's meetings which women do not participate in, this applies to unofficial situations where binding arrangements and decisions are most often made. An analysis of the positions occupied by women indicates two key inclinations in the appointment of women to decision-making bodies. First of all, according to paternalistic patterns – areas requiring "typical female skills and predispositions" are put at the disposal of women. Second of all, the decisive element in the designation is the professionalism of the candidates (specialists in their area), which also affects the asexual perception of women in these positions. It is also worth mentioning two additional trends – the party line and the so-called filling in gender statistics.

The progress that took place in women's activity in decision-making structures in Poland after 1989 is noticeable, although there is still a relevant disproportion in the participation of women and men in decision-making bodies. This trend is forced by EU programs which assume equal political participation of women at all levels of the decision-making process. To balance gender representation in political structures, various institutional solutions are introduced in the European Union, i.e. quota

or parity systems, which is currently impossible to implement in Poland. Equal participation of women and men in decision-making processes is important not only from the point of view of implementing the principles of equality and social justice, but above all because it is a promise to take into account the point of view of women in all spheres of political life.

Footnotes

[1] In Poland, the issues of political decision-making were studied by, among others: Ziemowit Jacek Pietraś: (1990), (1997), (1998) and Jerzy Sielski (1983) and (1998); Andrzej Bodnar (1985) and (edited together with W. Szczepański) (1987).

[2] One of the four election campaign slogans of Hanna Gronkiewicz-Waltz referred to her activity and successes in the professional field "Hanna Gronkiewicz-Waltz. It was her who strengthened the zloty". Its perception in the society collided with another slogan "We will take care of Poland", which introduced a dissonance between a successful woman and a stereotypical woman-guardian. The reference to professional success in the electoral slogans of Henryka Bochniarz was not used, and the slogans constructed for the campaign were hardly suggestive and to a small extent related to the candidate or her achievements – "Presidential candidate" or "My presidential candidate" or "I choose concretes."

[3] The campaigns of both candidates tried to convince voters that the candidates were most of all women (mothers, wives), and the secondary focus was their professional success and political qualifications. During the election campaigns of both candidates, to a higher extent in the campaign of H. Gronkiewicz-Waltz, the proportions between the image of a Polish Mother and a successful woman were distorted, which led to the dysfunction of the election message. Moreover, professional competences and predispositions for political activity of both candidates were outweighed by the presented qualifications in the private sphere of both women. During the campaign Hanna Gronkiewicz-Waltz strongly publicly emphasized that she is religious, trying to win the support of the Catholic electorate. In her election campaign, Henryka Bochniarz emphasized the importance of acting to improve the situation of women in Poland.

[4] In 1995, for the first time in the short history of Polish democracy, while preparing election campaigns, the committees used the advice of specialists in the field of electoral marketing or image creation. The staff of Hanna Gronkiewicz-Waltz was one of the three pioneer teams that for the first time in the history of Polish election campaigns used paid election advertising.

[5] After Poland regained independence in 1918, women on an equal rights with men, were given the right to vote, both passive and active.

[6] The Interparliamentary Union is a supranational union of parliamentarians. It was established in 1889 in Paris. Its main goal is to promote peace and international cooperation. As part of its activity, statistics of individual sex participation in world parliaments have been kept since 1997.
[7] She organized the Committee for European Integration and she was the head of it in 1996-1997 and 2001-2004.

Abstract

The success of product innovations introduced to the market depends on many different factors, among which two seem particularly important. The first is the degree to which a given product innovation meets the expectations of its customers, and the second is the level of consumer innovativeness. Wanting to build and maintain a competitive advantage, companies around the world are increasingly engaging customers in value co-creation, which should lead to the introduction of products to the market that better meet the needs of customers. In the subject literature, a lot of research has been devoted to topics of both consumer innovativeness and customer engagement in value co-creation, but there are few studies that show the (possible) relationship between them. Therefore, the main goal of the article is to supplement knowledge in this area by empirical recognition of the relationship between consumer innovativeness and their level of engagement in co-creating the offer with enterprises. The research part of the article presents the process of segmentation of the inhabitants of the Poznań agglomeration due to their innovativeness and shows the relationship between innovativeness and the predispositions and behaviours of the respondents towards engaging in value co-creation with enterprises. The study was conducted by means of direct interviews using an interview questionnaire, on a sample of 795 inhabitants of the Poznań agglomeration, and its results confirm the hypothesis of the existence of a clear relationship between consumer innovativeness and engagement in value co-creation.

Keywords: consumer innovativeness, consumer behaviour, value co-creation, customer engagement (CE), motives, consumer segmentation

Introduction

As the market role of customers shifted from being only the recipients of firms' offers to now being a part of value creation process, the concept of consumer engagement has gained popularity in the academic research and is widely recognized by marketers. Today's customers communicate not only with firms but also with other consumers and are influencing each other's decision making process. Nowadays, value is created not only inside enterprises but co-created with external stakeholders, primarily with clients. It needs to be highlighted that they participate not only in the process of creating value but also in communicating and distributing it to the market. The level of customer (consumer) engagement affect firm performance – it directly and indirectly contributes to enterprises profits (for example through purchases and customer referrals) (Kumar and Pansari 2016).[1] "Engaged customers" are a great company asset – they are more loyal and profitable than average customers. One Gullup study found that in the banking industry "fully engaged" customers maintained balances that were 26% greater than less engaged ones (McEwen 2004). Another Gullup research indicated that "engaged consumers" bring 37% more annual revenue than "actively disengaged customer" (Adkins and Sorenson 2014). Nowadays customer engagement is one of the keys determinants of firms market success and is therefore getting more attention from academic researchers and practitioners. Customer

(consumer) engagement is very important in relation to both, the process of new product development and modification of existing ones in terms of adapting them to consumer requirements, increasing their chances of market success. Adapting products to the needs and expectations of customers obviously increases the chances of their acceptance by customers, but it is not the only important factor in this regard. Acceptance depends on a number of other determinants, including the characteristics of potential customers, and more precisely, on the degree of their innovativeness. The main goal of the article is to recognize the relationship between consumer innovativeness and customer engagement.

The concept of consumer innovativeness

Changes in market behaviour of consumers, emerging new trends, as well as the pace of technological development, force enterprises around the world to develop and market product innovation. They are currently one of the key factors to stand out from the competition, or more broadly – to gain and maintain a competitive advantage. Most new products introduced to the market do not gain consumer acceptance and must be removed from it. The level of acceptance depends not only on the characteristics of the innovation itself, but also, among others, on the degree of innovativeness of the consumers themselves. Despite the lack of unanimity in defining consumer innovativeness, its particular significance is emphasized. Hirschman (1980) stated that, "few concepts in the behavioural sciences have as much immediate relevance to consumer behaviour as innovativeness. The propensities of consumers to adopt novel products (…) can play an important role of theories of brand loyalty, decision making, preference, and communication".

For Rogers (1983) consumer innovativeness is "the degree to which an individual or other unit of adoption is relatively earlier in adopting new ideas than the other members of a system". In this behavioural perspective on innovativeness (called "actualized innovativeness" or "innovative behaviour"), the time of product adoption is the main (only) criteria of innovativeness and people who adopt new products earlier are seen as more innovative than others. Innovative behaviour is also manifested by acquiring new information about new products (Hirschman 1980). On the basis of consumer innovativeness Rogers (1983) classified five adopter categories: (1) innovators, (2) early adopters, (3) early majority, (4) late majority and (5) laggards. In Midgley and Dowling (1978) view innovativeness in a construct at a high level of abstraction, that is by definition unobservable. They proposed a refined definition of innate innovativeness as "the degree to which an individual is receptive to new ideas and makes innovation decisions independently of the communicated experience of others". In this proposal innovativeness is based on the personality trait possessed (more or less) by every member of society. Steenkamp, Hofstede and Wedel (1999) also defines consumer innovativeness based on the personality trait "as the predisposition to buy new and different products and brands rather than remain with previous choices and consumer patterns". Hirschmann (1980) linked innovativeness to novelty seeking by stating that "the desire to seek out the new and different (…) is conceptually indistinguishable from willingness to adopt new products (i.e. inherent innovativeness)". Im, Bayus and Mason (2003) described innate consumer innovativeness as a generalized unobservable predisposition toward innovations applicable across product classes. On the other hand, the domain-specific innovativeness approach posits that innovators are not likely to adopt all new products (Truong 2013). Goldsmith and Hofacker (1991) stated that "domain or product category specific innovativeness reflects the tendency to learn about and adopt innovations (new products) within a specific domain of interest", so the adoption of innovations can vary across different product categories. Venkatraman and Price (1990) proposed that "innovativeness is comprised of cognitive innovativeness (the desire for new experiences with the objective of stimulating the mind) and sensory innovativeness (the desire for new experiences with the objective of stimulating the senses)". We acknowledge that on the one hand, consumer innovativeness is a personality trait, but the level of new product adoption is dependent on product category. It should be highlighted that consumer innate innovativeness is an important determinant of acceptance of innovations, but there are of course many more determinants in this matter. It means that in regard to some product categories consumers with high level of innate innovativeness can adopt innovations relatively later than consumers with lower level of innate innovativeness.

Systematic literature review on consumer innovativeness carried out by Bartels and Reinders (2010) and Kaushik and Rahman (2014) on one hand have shown ambiguous (positive or non-existing) relationships between innate innovativeness and new product adoption, but on the other hand, the reviews have shown a positive relationship between innate innovativeness and purchase and usage intention, so it seems to have a stronger effect on adoption intention than actual adoption. Innate innovativeness affects the product adoption with the help of some mediating variables, therefore indirectly (Kaushik and Rahman 2014). Several authors have also examined the positive relationship between innate innovativeness and domain-specific innovativeness. Most studies found that domain-specific innovativeness has a positive and significant relationship with new product adoption behaviours (Bartels and Reinders 2010). It should be emphasized that the scope of research on consumer innovativeness is extremely wide (Kaushik and Rahman 2014; Bartels and Reinders 2010). The variables used in the research carried out for the purposes of this article, which were used to determine the level of innovativeness, concerned such issues as – the rate of absorption of product innovations, propensity to take risks, searching for new products (novelty seeking), degree of interest in product innovations, opinion leadership, or broadly understood attitudes towards innovation and towards changes.

The Concept of Customer Engagement

The concept of customer engagement has been arousing the interest of the academic community and practitioners for several years. Despite numerous studies and presented concepts, there is no single, generally accepted definition of the concept in question (Table 1). The differences in views are visible both in terms of its nature and its scope. For some authors, this is a psychological state (Brodie et al. 2011), or a reflection of the bond between clients and the company (McEwen 2004), while others emphasize the behavioural aspects of consumer-enterprise relations (Van Doorn et al. 2010; Jakkola and Alexsander 2014). There is also no consensus as to whether customer engagement covers all behaviours towards the company (Kumar et al. 2010) or only those that go beyond the transaction (Van Doorn et al. 2010). Vivek, Beatty and Morgan (2012) state, that customer engagement can be manifested cognitively, affectively, behaviourally, or socially.

Table 1: Selected definitions of customer engagement (behaviour)

Authors	**Defintion**
McEwen (2004)	**Customer engagement** is a measure of the overall strength of a company's customer relationships; it reflects the degree to which customers have formed emotional as well as rational bonds to the brands they buy and own.
Patterson, Yu and de Ruyter (2006)	**Customer engagement** – the level of a customer's various "presence" in their relationship with a service organisation. The presences include physical presence, emotional presence and cognitive presence. Customer engagement is a higher-order construct, and it comprises of four components, namely, vigor, dedication, absorption, and interaction
Bowden (2009)	**Customer engagement** - psychological process that models the underlying mechanisms by which customer loyalty forms for new customers of a service brand as well as the mechanisms by which loyalty may be maintained for repeat purchase customers of a service brand.
Van Doorn et al. (2010)	**Customer engagement behaviours** go beyond transactions, and may be specifically defined as a customer's behavioural manifestations that have a brand or firm focus, beyond purchase, resulting from motivational drivers.
Brodie et at. (2011)	**Customer engagement (CE**) is a psychological state that occurs by virtue of interactive, co-creative customer experiences with a focal agent/object (e.g., a brand) in focal service relationships. It occurs under a specific set of context dependent conditions generating differing CE levels; and exists as a dynamic, iterative process within service relationships that cocreate value.
Hollebeek,(2011)	**Customer brand engagement** the level of an individual customer's motivational, brand-related and context-dependent state of mind characterised by specific levels of cognitive, emotional and behavioural activity in direct brand interactions.
Vivek, Beatty and Morgan (2012)	**Customer engagement (CE**) is the intensity of an individual's participation in and connection with an organization's offerings or organizational activities, which either the customer or the organization initiates.
Jaakkola and Alexander (2014)	**Customer engagement behaviours -** behaviours through which customers make voluntary resource contributions that have a brand or firm focus but go beyond what is fundamental to transactions, occur in interactions between the focal object and/or other actors, and result from motivational drivers.
Harmeling et al. (2017)	**Customer engagement** - a customer's voluntary resource contribution to a firm's marketing function, going beyond financial patronage
Pansari and Kumar (2017)	**Customer engagement -** the mechanics of a customer's value addition to the firm, either through direct or/and indirect contribution**.**

Source: McEwen (2004); Patterson, Yu and de Ruyter (2006); Bowden (2009); Van Doorn et al. (2010); Brodie et at. (2011); Hollebeek,(2011); Vivek, Beatty and Morgan (2012); Jaakkola and Alexander (2014)Harmeling et al. (2017); Pansari and Kumar (2017).

We recognize the different approaches in defining the term customer (consumer) engagement. We acknowledge that customer engagement behaviour is related to the purchase so it contributes to firms profitability directly, but also goes beyond transactions and generates value and positively contributes to the profits of the firm indirectly – through non-purchase reactions (Kumar and Reinartz 2016).

Customer engagement behaviours can be initiated by both clients (current and potential) and companies (Vivek, Beatty and Morgan 2012), both in the real world and in a virtual environment (Brodie et al. 2013) and they can be both positive and negative (Van Doorn et al. 2010).

Kumar et al. (2010) state that the value of customer engagement is comprised of four core dimensions – customer lifetime value (CLV), customer referral value (CRV), customer influencer value (CIV), and customer knowledge value (CKV). The last one is related to customer behaviour regarding feedback for ideas for innovations and improvements, and contributes to knowledge development.

According to Bijmolt et at. (2010), the three key behavioural manifestations of customer engagement are: word-of-mouth (WOM), co-creation and complaining behaviour. An example of behaviour related to co-creation, and hence customer engagement, is making suggestions to improve the consumption experience (Van Doorn et al. 2010). The desire to share opinions with companies is the subject of research, the results of which are presented in the article.

While many studies on consumer innovativeness and customer engagement can be found in the literature on the subject, relatively few (not many) studies were conducted to determine whether and to what extent there is a relationship between the level of consumer innovativeness and the degree of engagement in value co-creation.

Goldsmith's, Flynn's and Korzenny's (2015) research has found a positive relationship between brand engagement and consumer innovativeness. Sarmah's, Kamboj's and Rahman's (2017a) study carried out on a sample of luxury hotels guests revealed that consumer innovativeness is positively related to their willingness to co-creation. Another study conducted by those authors indicated that tourist's innovativeness positively influences their degree of co-creation with service providers (Sarmah, Kamboj and Rahman 2017b). Handrich and Heidenreich (2013) found that consumer technological innovativeness highly correlates with consumer's willingness to co-create. Based on those findings we also hypothesize that there is a relationship between consumer innovativeness and consumer engagement (or willingness to engage) in value co-creation.

Research Design

An empirical study on the assessment of the relationship between consumer innovativeness and their engagement in co-creating the offer with enterprises was conducted in the first half of 2019 using the direct interview technique (face to face interviews). The areas of empirical research included: respondents – residents of Poznań and the Poznań poviat, subject – assessment of innovativeness and customer engagement, spatial – the city of Poznań, cities and villages of the Poznań poviat, and temporary – the first half of 2019. The main purpose of empirical research was to identify the relationship between consumer innovation and customer engagement and the research hypothesis is that there is a relation between them. The research objectives include:

1. an analysis of the relationship between innovativeness and customer engagement in value co-creation on the example of the inhabitants of Poznań and the Poznań poviat,
2. identification of innovative predispositions of the inhabitants of Poznań and the Poznań poviat,
3. definition of segmentation criteria and isolation of segments of the inhabitants of Poznań and the Poznań poviat due to innovative predispositions,
4. assessment of the relative shares of the segments of the inhabitants of Poznań and the Poznań poviat due to innovative predispositions,
5. assessment of engagement in value co-creation in terms of segments of residents of Poznań and the Poznań poviat.

In the sample selection process, quota selection was used. In the quota selection of the sample, it is assumed that the study is representative if the structure of the sample coincides with the structure of the studied population. The comparison of the studied population and the research sample is presented in the table 2 below.

Table 2: Comparison of the studied population and the research sample

Source: Based on Statistics Poland and own study.

The size of the research sample was 795 observations (N = 795). In the process of selecting a sample for the study, quota selection was used, taking into account the criteria of sex, age, and the respondents' place of residence. In the process of empirical data analysis, the IBM SPSS Statistics tool was used, which allowed the analysis of the results of the statistical description, correlation analysis, exploratory factor analysis (EFA), and analysis of variance.

The research tool was built on the basis of variables used in international research, the scope of which covered, among others, attitude and pace of absorption of technological innovations (Filová, 2015), openness to technological innovations (Rosen, 2005), or generally understood in the broad sense of consumer innovativeness (Kuswati and Irmawati 2018; Goldsmith., 2011). The research tool constructed on the basis of the literature analysis, as well as the subjective premises of the authors, consisted in total of 23 variables (A01-A23), for which the Likert scale was used (Table 3).

Table 3: Variables in the area of innovativeness of respondents

Research question: Please specify whether the following statements are in line with your predispositions for product innovations.
A01. As soon as I hear that an innovative product has appeared on the market, I am looking for information about it and seek to try it.
A02. I start using innovative products only when most of my friends / family members already use them.
A03. I like taking risks when it comes to trying new things.
A04. When it comes to product innovations, I often need the support of others in learning how to use them.
A05. My friends and family often turn to me for opinions on product innovations and help in using them.
A06. I like to use only proven products.
A07. Among my friends / family, I am usually one of the first people to try / use innovative products.
A08. I prefer to wait until others (friends, family, etc.) try product innovation before I do.
A09. I like to be one of the first people to try an innovative product as soon as it appears on the market.
A10. I like to experiment with innovative products.
A11. I absorb technological innovations very quickly.
A12. I like to provide information on product innovations and teach my friends / family how to use them.
A13. Generally, I have barriers in using innovative products.
A14. I am interested in technological innovations.
A15. I like to use innovative products.
A16. I often check if there are new ways to do something / solve a problem.
A17. I think it's best to reach for the proven methods for doing something / solving a problem.
A18. I know more about innovative products than other people.
A19. I am distrustful of innovative products and new ways of doing something.
A20. I am usually one of the last people in my environment in terms of acceptance of innovative products.
A21. I try to get as much information as possible about new innovative products from many sources.
A22. I systematically encourage family and friends to use new innovative products.
A23. I regularly buy innovative products.

Source: Own study.

While measuring the engagement in value co-creation, the actual participation of respondents and their propensity to participate in this process were verified. The Likert scale (Table 4) was used to assess the answers to research questions (B1-B2).

Table 4: Variables specifying engagement in value co-creation

Research Questions:
B1. Do you give companies opinions / ratings about their offers? (participation)
B2. Would you like to participate in cocreating companies' offers? (propensity)

Source: Own study.

Results

The first step in the research process is to assess the relationship between innovativeness and engagement in value co-creation of the residents of Poznań and the Poznań poviat (Table 5). Spearman's rank coefficient was used in the analysis of correlation relationships.

Table 5: The results of the correlation between innovativeness and engagement in value co-creation of the residents of Poznań and the Poznań poviat

	customer engagement[(a)]

(a) – Spearman rank correlation coefficients (rs); **p≤0,01, *p≤0,05		

Source: Own research.

The obtained results (Table 5) allow for the identification of statistically significant correlations between the engagement in value co-creation (both actual participation and propensity to participate in this process) and all variables in the scope of innovativeness of the respondents.

The strongest, clear, positive correlation relationships include, first of all, relationships related to taking risks associated with new products ($rs_{(A03,B1)}$=0.348; $rs_{(A03,B2)}$=0.373), verification of new products earlier compared to the environment ($rs_{(A07,B1)}$= 0.345; $rs_{(A07,B2)}$=0.368), information search and immediate testing of new products ($rs_{(A01,B1)}$=0.335; $rs_{(A01,B2)}$=0.365), testing of new products ($rs_{(A10,B1)}$=0.325; $rs_{(A10,B2)}$=0.352) and passive opinions on new products in the environment ($rs_{(A05,B1)}$=0.315; $rs_{(A05,B2)}$=0.371).

In turn, the strongest, indistinct, negative relationships include, in particular, relations regarding the occurrence of barriers related to the use of new products ($rs_{(A13,B1)}$=-0.272; $rs_{(A13,B2)}$=-0.231), late acceptance of product innovations ($rs_{(A20,B1)}$=-0.268; $rs_{(A20,B2)}$=-0.202), expectations of support of the environment in using new products ($rs_{(A04,B1)}$=-0.254; $rs_{(A04,B2)}$=-0.258), distrust of new products ($rs_{(A19,B1)}$=-0.239; $rs_{(A19,B2)}$=-0.255) and verification of new products in the environment ($rs_{(A08,B1)}$=-0.225; $rs_{(A08,B2)}$=- 0.233).

The results of the research indicate that there are statistically significant relationships between the innovativeness of the inhabitants of the city of Poznań and the Poznań poviat and their engagement in value co-creation. Obtained values of correlation coefficients may indicate the occurrence of other potential dependencies determining the studied phenomena – they include scope of cooperation between enterprises and clients, time and frequency of relationships, risk related to participation,

analysis of costs and benefits of the entities involved, types of problems to be solved, etc. Nevertheless, the above results allow positive verification of the hypothesis according to which there is a relationship between consumer innovativeness and their engagement in value co-creation.

Then, using the exploratory factor analysis method, the identification of innovative predispositions of the inhabitants of Poznań and the Poznań poviat was identified (Table 6) – the number of distinguished components was based on the Kaiser criterion, according to which each of the new components explains more than a single variable.

Table 6: Results of exploratory factor analysis in the set of innovativeness factors of the inhabitants of Poznań and the Poznań poviat

component	measurable variables	factor loadings
component 1 - **pro-innovation predisposition**	A01. As soon as I hear that an innovative product has appeared on the market, I am looking for information about it and seek to try it.	0.779
	A03. I like taking risks when it comes to trying new things.	0.689
	A05. My friends and family often turn to me for opinions on product innovations and help in using them.	0.690
	A07. Among my friends / family, I am usually one of the first people to try / use innovative products.	0.686
	A09. I like to be one of the first people to try an innovative product as soon as it appears on the market.	0.749
	A10. I like to experiment with innovative products.	0.743
	A12. I like to provide information on product innovations and teach my friends / family how to use them.	0.686
	A14. I am interested in technological innovations.	0.694
	A15. I like to use innovative products.	0.687
	A16. I often check if there are new ways to do something / solve a problem.	0.644
	A18. I know more about innovative products than other people.	0.757
	A21. I try to get as much information as possible about new innovative products from many sources.	0.582
	A22. I systematically encourage family and friends to use new innovative products.	0.768
	A23. I regularly buy innovative products.	0.750
component 2 – **orthodox predisposition**	A13. Generally, I have barriers in using innovative products.	-0.752
	A19. I am distrustful of innovative products and new ways of doing something.	-0.652

	A20. I am usually one of the last people in my environment in terms of acceptance of innovative products.	-0.697
component 3 – **conservative predisposition**	A02. I start using innovative products only when most of my friends / family members already use them.	0.644
	A06. I like to use only proven products.	0.772
	A08. I prefer to wait until others (friends, family, etc.) try product innovation before I do.	0.654
	A17. I think it's best to reach for the proven methods for doing something / solving a problem.	0.501
KMO=0.862; p=0.000; rotation method: VARIMAX with Kaiser standardization explanation of total variance=61,327; min. factor load value 0.500		

Source: Own research.

The obtained results allowed for the identification of three innovative predispositions – 1.pro-innovative, 2.orthodox, and 3.conservative. Pro-innovative predisposition (component No. 1) is characterized by, among others, searching for and immediately testing new products, taking risks related to new products, giving opinions and encouraging others to new market solutions, priority in verifying these solutions, showing interest in technological innovations, their adoption and gathering knowledge related to them. Orthodox predisposition (component No. 2) is characterized by, among others, the occurrence of barriers related to the use of new products and distrust, and their late acceptance. In turn, conservative predisposition (component No. 3) manifests itself, among others, in the use of new products after prior verification by the environment and preferring proven products.

Due to similar ranges of components 2 – orthodox predisposition and component 3 – conservative predisposition, a decision was made to carry out the method of exploratory factor analysis with the limitation of the number of isolated components to two (Table 7).

Table 7: Results of exploratory factor analysis in the set of innovativeness factors of the inhabitants of Poznań and the Poznań poviat

component	measurable variables	factor loadings
component 1 - **pro-innovation predisposition**	A01. As soon as I hear that an innovative product has appeared on the market, I am looking for information about it and seek to try it.	0.767
	A03. I like taking risks when it comes to trying new things.	0.688
	A05. My friends and family often turn to me for opinions on product innovations and help in using them.	0.702
	A07. Among my friends / family, I am usually one of the first people to try / use innovative products.	0.693
	A09. I like to be one of the first people to try an innovative product as soon as it appears on the market.	0.728
	A10. I like to experiment with innovative products.	0.737
	A11. I absorb technological innovations very quickly.	0.666

	A12. I like to provide information on product innovations and teach my friends / family how to use them.	0.732
	A14. I am interested in technological innovations.	0.733
	A15. I like to use innovative products.	0.733
	A16. I often check if there are new ways to do something / solve a problem.	0.690
	A18. I know more about innovative products than other people.	0.760
	A21. I try to get as much information as possible about new innovative products from many sources.	0.628
	A22. I systematically encourage family and friends to use new innovative products.	0.771
	A23. I regularly buy innovative products.	0.742
component 2 - **orthodox and conservative predisposition**	A02. I start using innovative products only when most of my friends / family members already use them.	0.635
	A04. When it comes to product innovations, I often need the support of others in learning how to use them.	0.709
	A06. I like to use only proven products.	0.643
	A08. I prefer to wait until others (friends, family, etc.) try product innovation before I do.	0.690
	A13. Generally, I have barriers in using innovative products.	0.599
	A17. I think it's best to reach for the proven methods for doing something / solving a problem.	0.514
	A19. I am distrustful of innovative products and new ways of doing something.	0.601
	A20. I am usually one of the last people in my environment in terms of acceptance of innovative products.	0.621

Source: Own research.

Analysis of the results (Table 7) confirms the validity of limiting the number of components to two – all the variables that originally defined the components of the orthodox predisposition and conservative predisposition (cf. Table 6), make up the new component 2 – orthodox and conservative predisposition. In addition, limiting the number of components will allow simplification (reduction) of segmentation criteria of the inhabitants of Poznań and the Poznań poviat due to their innovative predispositions.

The next step of the research procedure was to define the criteria for segmentation of the respondents due to their predisposition to product innovations. Due to the range of the used measuring scale <1.5>, it was assumed that respondents representing a given predisposition (pro-innovative or orthodox-conservative) are qualified entities for which the value of a given component is greater than 3.00 ($Comp_{(n)}>3.00$). Otherwise, when the value of this component is less than or equal to 3.00 ($Comp_{(n)}\leq 3.00$), the respondents are not treated as representatives of the extracted predisposition. Based

on the results of the exploratory factor analysis (Table 6) and the assumptions made, the population of respondents was divided into four segments (S1-S4) (Table 8).

Table 8: Criteria for segmentation of the inhabitants of Poznań and the Poznań poviat according to innovative predispositions

components	component value	segments			
		S1	**S2**	**S3**	**S4**
P1 **– pro-innovative predisposition**	+ (Comp1 > 3.00) – (Comp1 ≤ 3.00)	+	+	–	–
P2 – **orthodox and conservative predisposition**	+ (Comp2 > 3.00) – (Comp2 ≤ 3.00)	+	–	+	–
	Sum N=100%	12.3%	30.9%	42.0%	14.8%

Legend:
S1 – **hybrid segment**–pro-innovative (+), orthodox and conservative (+) predisposition
S2 – **pro-innovation segment**–pro-innovation (+), orthodox and conservative (-) predisposition
S3 – **orthodox and conservative segment**–pro-innovative (-), orthodox and conservative (+) predisposition
S4 – **neutral segment**–pro-innovative (-), orthodox and conservative (-) predisposition

Source: Own research.

The results of the research procedure allowed the identification of four segments differing in values of the components separated after the use of the method of exploratory factor analysis. The most represented segment in the studied population is the orthodox and conservative segment ($P1 \leq 3.00 \cap P2 > 3.00$ – share of S3=42.0%). The characteristics of its representatives include, first of all, caution in the use of new products, distrust and late acceptance of new products, the use of new products after their verification by the environment, and the preference for proven products. The second segment in terms of representation is S2 the pro-innovation segment ($P1 > 3.00 \cap P2 \leq 3.00$ – share of S2=30.9%). The characteristics of its representatives include, first of all, the search for and as soon as possible to test new products, accepting the risk associated with new products, giving opinions and encouraging others to new market solutions, and priority in verifying these solutions. The representation of subsequent segments is definitely smaller – the neutral segment ($P1 \cap P2 \leq 3.00$ – both predispositions equal to or below the average – the share of S4=14.8%) and the hybrid segment ($P1 \cap P2 > 3.00$ – both predispositions above the average – the share of S1=12.3%).

The next step in the research process was to assess the engagement in value co-creation due to the innovative predispositions of the inhabitants of Poznań and the Poznań poviat. In the research process, analysis of variance was used – the one-way ANOVA method (Table 9).

Table 9: Assessment of engagement in value co-creation in terms of segments of residents of Poznań and the Poznań poviat

co-creating customer value	**total average**	**segment** **S1 | S2 | S3 | S4**	**ANOVA**
B1. participation (actual share)	2.52	$2.73^3 < 3.09^4 > 2.10^1 < 2.36^2$	46.619^{***}
B2. propensity – willingness to participate (willingness to co-create)	2.52	$2.87^2 \approx 3.04^2 > 2.12^1 \approx 2.31^1$	43.912^{***}

S1 – hybrid segment; S2 – pro-innovation segment; S3 – orthodox and conservative segment; S4 – opportunistic segment
Test post hoc – S-N-K Student-Newman-Keuls

Source: Own research.

The results obtained (Table 9) allow us to compare the engagement it co-create customer value due to the respondents' innovative predispositions. The actual share in co-creating customer value is the highest in the S2 segment – pro-innovative (M=3.09), then in S1 – hybrid (M=2.73), and then in S4 segments – opportunistic (M=2.36) and S3 – orthodox and conservative (M=2.10). On the other hand, the propensity to participate in value co-creation is highest in the S2 – pro-innovative (M=3.04) and S1 – hybrid (M=2.87) segments; propensity is lower in the other two segments – i.e. S4 – opportunistic (M=2.31) and S3 – orthodox and conservative (M=2.12).

Limitations and Future Research

The study was not national in nature, hence its results can only be referred to hybrids of the Poznań agglomeration. In the next stages of research, an interesting idea seems to be to examine the level of innovativeness, segmentation in this area, recognize both the willingness to engage in value co-creation, as well as activities in this field among the general population of Poland, as well as residents of other countries and comparing results internationally.

Analysis of the results of correlation relationships indicates the presence of clear relationships (rs>3.00) and indistinct relationships (rs≤3.00). It should be noted that both consumer innovativeness and customer engagement are complex and heterogeneous phenomena. This may indicate the existence of other dependencies, whose identification and empirical verification will allow the construction of more complex theoretical models, the verification of which will be used, among others, methods of confirmatory factor analysis, regression analysis, and structural equation modelling (SEM). In this context, the key problem is the definition of endogenous variables, which in the case of consumers will constitute broadly understood benefits, both tangible and intangible, while in the case of enterprises they will be elements related to both economic results as well as market position and the image of these organizations.

Conclusions

The presented results have confirmed the relationship between innovativeness and customer engagement. The results of exploratory factor analysis and the adopted segmentation criteria allowed the identification of segments of the inhabitants of Poznań and the Poznań poviat according to their innovative predispositions. In turn, the use of variance analysis allowed for a comparison of engagement in value co-creation between individual segments. This allows to indicate further directions of research and confirms the need to explore the identified compounds.

Endnotes

[1]We acknowledge that not every customer is a consumer and not every consumer is a customer. In most market transactions the customer paying for the product also consumes it. Being aware that there are some differences between these entities, due to the scope of the article and the context of their use, they will be treated as synonyms. Whenever the term 'customer' is used in an article, it means a customer who is also a consumer.

Abstract

The article deals with the problem of spatial diversity of selected organic crops in Poland. The purpose of this study was to verify the hypothesis of convergence in the development of organic farming in Poland by voivodship. The research was based on cross-sectional data covering 16 voivodships of Poland and concerned the years from 2006 to 2018. The research was conducted on the theoretical and empirical level. In the theoretical part, the current research related to the issues discussed was presented. The empirical measurement was made using statistical analysis methods, i.e. sigma (σ) convergence analysis and the Czekanowski average difference method. The study assumed that we deal with various development paths resulting from the diversified allocation of resources, including in particular land resources and disproportions in long-term production structures. The conducted analyses revealed the unevenness of the organic farming development process in Poland by individual voivodships. In economic practice, this would mean using various instruments to support the development of agriculture and rural areas in a regional perspective.

Keywords: Convergence, Regional Economics, Agricultural Economics

Introduction

Organic farming is a farming method based on natural soil fertility and the effective use of agronomic techniques. Soil is the basis for organic farming. Therefore, all cultivation operations must be directed at maintaining and increasing soil fertility [Neuerburg 1994, p. 11] as well as preventing its erosion. The development of this way of farming in Poland is determined by both the natural conditions of the region and the Common Agricultural Policy of the EU, which aims to develop organic production and support it with financial aid [Kacprzak, Kołodziejczak 2011, p. 121]. Organic farming is part of the idea of sustainable agriculture aimed at equal treatment of the three social, economic and ecological spheres. According to Smith, Cohen, Reganold et al.[2020, pp. 2870-2878], these multi-functional benefits of organic farms for sustainable development result from the landscape context. Based on the research, they came to the conclusion that ecological areas were characterized by greater biodiversity and profits than conventional areas, despite lower yields. Research has shown that the benefits of biodiversity from organic farming vary depending on the landscape context compared to the benefits of yields and profitability. It has been found that ecological, but not economic, benefits resulting from the sustainability of organic farming are most evident in more intense agricultural landscapes, and therefore under the influence of intensive human activity, demonstrating a shaky capacity for self-regulation and requiring protection [Smith, Cohen, Reganold et al., 2020]. Bengtsson, Ahnstrom, Weibull [2005, pp. 261–269], Tuck, Winqvist, Mota, Ahnstrom, Turnbull, Bengtsson [2014, pp. 746–755] as well Katayama, Bouam, Koshida, Baba [2019, pp. 125-133] raised in their research the issue

of the impact of organic farming on biodiversity and the number of varieties. The research has shown that organic farming increases biodiversity in the agricultural landscape, supports greater organism wealth and abundance (by 30% on average) than conventional agriculture [Bengtsson, Ahnstrom and Weibull, 2005; Tuck et al., 2014; Katayama et al. 2019]. This study addresses the problem of uniformity in the development of organic farming in Poland in terms of time and space covering the division into voivodships. This problem is a contribution to further assessment of the conditions for the development of this activity. However, this requires an indication whether we are dealing with one or many models of its development and whether to support it is enough to use one universal policy or should we use different instruments? The achieved research results are both important for the theory of agricultural economics and application values.

Organic agriculture in the concept of sustainable development

Organic farming, unlike conventional farming, focuses largely on such production for which the use of most inorganic compounds for fertilization, pest control, diseases and weeds as well as the production of genetically modified varieties is forbidden for cultivation. On the other hand, this concept encourages crop rotation and catch crops to increase soil fertility, improve crop nutrition, and reduce production problems associated with pests, diseases and weeds [Connor 2008, p. 187]. Many definitions of organic farming have been created, which are used by various organizations, but they show the similarity of the research area and the analysed subject. The National Organic Standards Board treats organic farming as *an ecological production management system that promotes and strengthens biodiversity, biological cycles and soil biological activity. It is based on the minimal use of production means and management practices that restore, maintain and strengthen ecological harmony* [National Organic Standards Board 2000, p. 1]. The Codex Alimentarius Commission, in turn, defines organic farming as *a comprehensive production management system that promotes and improves the condition of the agro-ecosystem (...). It emphasizes the use of sound management practices instead of non-agricultural measures, given that regional conditions require locally adapted systems. This is achieved by using, where possible, cultural, biological and mechanical methods, rather than synthetic materials, to perform any specific function in this system* [Organically Produced Foods 2007]. Also, consumer preference studies confirm that organic food is associated with the natural process, care for the environment and animal welfare, and the non-use of pesticides and fertilizers. However, the price factor still plays an important role in shaping the demand for organic products [Shafie, Rennie 2012, pp. 360-367; Kułyk, Michałowska 2019, pp. 59-72]. Still, as noted by Jun and Xiang [2011, p. 1530], modern agriculture improves productivity while reducing the costs of excessive use of resources and energy, and generating damage to the environment.

Organic farming is part of the idea of sustainable development. Sustainable development should be understood here as a concept based on intergenerational equality - that is, the current generation cannot threaten the ability of future generations to meet their "material needs" and enjoy a healthy environment [Batie 1989, p. 1084]. It is an idea covering equivalent social, economic and environmental goals, referred to as the idea of eco-social justice. This can be considered a necessary condition and the goal of expanding democratic participation in ownership and control of resources [Gertler 2001, pp. 2-3]. Due to the fact that organic farming implements economic (providing income to farmers from the sale of agricultural products), environmental (rural development, animal welfare, landscape shaping) and social (provision of public goods, leisure places) goals, it is part of the concept of sustainable development. Economically, it can be observed that organic farming systems are achieving equal or even higher yields in developing countries compared to current conventional practices, which translates into a potentially important option for food safety and sustainable livelihoods of poor rural areas in times of climate change. Certified organic products meet the needs of farmers with higher incomes and therefore can serve as shaping climate friendly agricultural practices around the world [Scialabba, Müller-Lindenlauf 2010, pp. 158-169]. In addition, compared to conventional agriculture, organic products do not introduce so many harmful substances to the nutritional system.

There are several areas where the potential of organic farming is contained [Kilcher 2007, p. 32]:

1) improving soil fertility, biodiversity and the sustainability of agricultural production,
2) protection of natural resources,
3) improving agronomic and economic results,
4) providing access to attractive markets through certified products,
5) creating new partnerships along the entire value chain as well as strengthening farmers' confidence and autonomy.

The links with the concept of sustainable development are evident in the potential of organic farming. Moreover, it is favoured by the growing interest of consumers and a healthy lifestyle. It is also worth noting that the factor supporting organic farming is the EU subsidy system, which complements farmers' income. The aim of the research was to determine the direction of organic farming development in Poland, taking into consideration its spatial division into 16 voivodships.

The development of organic farming in Poland was three-stage. The first stage is the time before 1998, when organic farming did not benefit from any financial form of national support. The second stage is 1998-1999, when the state budget partly covered the costs of certification. At that time, subsidies for the costs of farm inspections were introduced in Poland [Luty 2014, p. 75], and after 1999, payments for the area of arable land were also introduced. The third stage is the period after Poland's accession to the European Union in 2004, when Polish farmers were included in the instruments of the CAP and the national agri-environmental program [Jończyk 2014, p. 131]. There are several key factors that have caused an increase in interest in organic production, which include a lower threat to the natural environment compared to intensive production, unused labour factor in agriculture [Siedlecka 2015, p. 240], concern for production potential, reduction in the level of agriculture intensification, limiting the use of fertilizers and plant protection products, respecting the natural environment, taking into consideration the specificity of local rural farms [Kułyk, Kowalewicz 2016, p. 151], growing interest in organic food and increasing demand for agricultural products of ecological origin, possibilities of exporting organic products [Komorowska 2015 , p. 119-120], an increase in consumer awareness of organic food and healthy nutrition, an increase in consumer purchasing power [Golik, Żmija 2017, p. 126] as well as an impact on public interest by caring for good animal breeding and rural development [Jończyk 2014, p. 130].

Material and Research Method

The empirical analyses of the convergence phenomenon carried out in the paper are based on cross-sectional and temporal data covering 16 voivodships of Poland in the years from 2006 to 2018. The aim of the study was to verify the hypothesis of convergence in the development of organic farming in Poland by voivodship. It was assumed that we are dealing with various development paths resulting from the diversified allocation of resources, including in particular land resources and disproportions in long-term production structures. In this article, sigma (σ) convergence analysis and the Czekanowski average difference method were used to achieve the assumed goal. Sigma convergence consists in the fact that the dispersion of the studied phenomenon tends to decrease over time, i.e. $\sigma_{t+T} < \sigma_t$ [Sala-and-Martin 1995, p. 3]. The idea of sigma convergence is associated with answering questions about long-term trends in the degree of diversity of the examined feature in a particular group of countries. During its measurement, the dispersion measure of the standard deviation of the natural logarithms of a given feature is used at some point *t* [Malaga 2004, p. 57]:

$$\sigma = \sqrt{\sum_{i=1}^{n}(lny_{it} - ln\bar{y}_t)^2}, \qquad (1)$$

where:
i- country index,
n- number of countries,
y_{iy}- level of convergence variable in the country *i* and at time *t*,
$\bar{y}$- average level of convergence in the examined group of countries.

If the standard deviations of the natural logarithms for the examined feature show a decreasing tendency, this indicates the occurrence of sigma convergence. This concept is derived from the neoclassical growth theory. Sigma convergence is defined as the effect of catching up over time [Dvorokova 2014, pp. 89-90]. In its original understanding, the sigma convergence analysis mainly concerned GDP per capita, but over time it was also used for research in agriculture [Czyżewski, Kułyk 2010, pp. 196-208; Kułyk, Augustowski 2017, pp. 44-53; or Somasekharana, Prasad and Nirmal Roy 2011, pp. 211-216]. The variable subjected to the convergence analysis (y) was the area of organic agricultural land converted into the number of certified organic farms in 16 voivodships in Poland. This variable is justified by changes in the size of arable land, the creation of new organic farms and permanent farms during the conversion period. The time range covered the years from 2006 to 2018 (Tab. 1).

Table 1: Sigma convergence results in Poland

Time	Sigma	Δ Sigma
2006	0,659	-
2007	0,609	**-0,076**
2008	0,459	**-0,247**
2009	0,562	0,225
2010	0,525	**-0,066**
2011	0,487	**-0,073**
2012	0,466	**-0,042**
2013	0,439	**-0,059**
2014	0,429	**-0,023**
2015	0,442	0,031
2016	0,432	**-0,024**
2017	0,440	0,019
2018	0,480	0,091

Source: own study based on BDL data (https://bdl.stat.gov.pl/BDL/dane/podgrup/temat), access: 05.04.2020.

The presented results show that the phenomenon of convergence did not occur in every period. Therefore, it is difficult to talk about equalizing the examined feature in all voivodships. Complementing the analysis was building a regression equation in the analysed time period (Tab. 2). The OLS estimation method was used, the observations 2006-2018 used (N = 13) and the dependent variable (Y) were the sigma parameters estimated each year.

Table 2: OLS model for the sigma parameter

Variables	Coefficient	Standard error.	t-Student	p-value	R^2
const	0,595300	0,0292701	20,34	<0,0001***	0,58
time	−0,0144158	0,00368769	−3,909	0,0024***	

Source: own calculations using the Gretl 2017d program.

A negative value of *time* parameter indicates the occurrence of sigma convergence. Both parameters are statistically significant at 99%, although the most important indicator of convergence is the value of the time variable parameter. The model fit factor for R^2 variables is 0,58.

Another used method was the Czekanowski average difference method. To perform this analysis, it is necessary to use the input data set, consisting of a series of objects of the same type (i.e. having the same variables), and then measure the distance between all possible pairs of objects. In practice, there are many methods for measuring distances in multidimensional space. The measurement is made using the formula [Soltysiak and Jaskulski 1999, p. 175]:

$$DD = \frac{1}{n}\sum_{j=1}^{n} |M_{1j} - M_{2j}|,$$

where DD indicates the average difference between two objects, resulting from elementary differences between their attributes, n number of variables (attributes) taken into account, M_{1j} attribute value for the first object; M_{2j} attribute value for the second object. The grouping procedure is to make the differences between units belonging to the same group as small as possible. Based on the scale of similarities, the Czekanowski diagram is built, which allows separating regions similar to each other in terms of the studied features [Mruk 2003, p. 204]. The larger the symbol at the intersection of the diagram's row and column, the more similar the regions are in terms of the studied features [Wójcik 2013, p. 359]. In the study, the area (in ha) of grain, potato, vegetable and fruit crops was analysed. The data came from the *report on the state of organic farming in Poland in 2017-2018* and concerned 2018. This category of crops was selected because, as Rembiałkowska [2007, p. 2761]. observes, plants grown in organic systems usually have significantly (on average 20%) lower yields than conventionally produced crops. This increases their price and creates a barrier for many consumers when buying organic food [Rembiałkowska 2007, p. 2761]. Due to the fact that all attributes were expressed in the same units, there was no need to standardize the features [Dzieciuchowicz 2007, p. 132]. In the first stage, the distance matrix was made using the Euclidean method (Tab. 3).

Source: own calculations using the MaCzek program 3.3.44.

Based on the distance matrix, the Czekanowski diagram was constructed. For this purpose, two modules were used: Simple auto algorithm and Simple genetic algorithm (Fig. 1-2). The simple genetic algorithm requires two parameters before starting to run: Number of generations and Number of variants. These parameters have an impact on the quality and time consumption of calculations. Their growth increases the likelihood of a more optimal variant of diagram arrangement. However, it should be noticed that due to the randomness of this type of algorithms, there is no guarantee of better ordering

of diagrams than in the case of simple ordering. Therefore, both methods are used in this study. After starting the procedure, the program displays the progress of calculations, their duration and the value of the ordering function F (the smaller the value, the better the order).

Figure 1: The Czekanowski diagram obtained with the use of Simple auto algorithm method
Source: own calculations using the MaCzek program 3.3.44.

Based on the ordering with the use of Simple auto algorithm, 4 groups of similar voivodships were identified. In the analysed case, the F value was 0,002, which indicates a high quality of ordering. The first group includes the following voivodships: Dolnośląskie, Podlaskie, Wielkopolskie and Lubuskie, the second group includes: Pomorskie, Kujawsko-Pomorskie, Małopolskie, Śląskie, Opolskie, Świętokrzyskie and Łódzkie, the third group consisted of the following voivodships: Lubelskie, Mazowieckie and Podkarpackie, while the fourth group are Warmińsko-Mazurskie and Podkarpackie provinces. This typology was then compared with the Simple genetic algorithm grouping method (Fig. 2). In this case, the maximum parameter values used were: Number of generations = 2000 and Number of variants = 50.

Figure 2: The Czekanowski diagram obtained with the use of Simple genetic algorithm method
Source: Own calculations using the MaCzek program 3.3.44.

Grouping with the use of Simple genetic algorithm revealed the occurrence of 3 similar groups of voivodships. The first group includes the following provinces: Zachodniopomorskie, Warmińsko-Mazurskie, Dolnośląskie, Podlaskie, Wielkopolskie and Lubuskie, the second group includes the following provinces: Świętokrzyskie, Pomorskie, Kujawsko-Pomorskie, Małopolskie, Opolskie, Śląskie and Łódzkie. The third group was represented by Lubelskie, Mazowieckie and Podkarpackie. The introduction of the Simple genetic algorithm method therefore reduced the analysed groups and moved Warmińsko-Mazurskie and Zachodniopomorskie voivodships from group 4 to group 1.

Conclusions

The convergence study allows assessing the development paths of a particular phenomenon and identifying possible gaps between the units under consideration. The aim of this study was to verify the hypothesis of convergence in the development of organic farms. The conducted analyses revealed the unevenness of the organic farming development process in Poland by individual voivodships. The results confirmed the occurrence of sigma convergence simultaneously, however, we did not deal with one convergence point, but with four different development models, characteristic for four groups of voivodships. The convergence process is long-term and if we take into consideration the diversity of labour productivity resulting from different positions of voivodships in relation to sustainable growth paths, we will obtain different growth models. The achieved results are in line with the adopted assumptions, and the differences are the result of disproportions in the size and structure of resources allocated in individual territorial units, including in particular land resources, production structures and environmental conditions. In this situation, it is possible to talk about conditional convergence, because the achieved disproportions are permanent and result from a number of structural (also historical – structure of the division of the land) differences. Conditional convergence means that the location of the point of long-term equilibrium of the size of capital and product per unit of effective work depends on many factors that to some extent may be shaped by economic policy. The identified different types of convergence of Polish regions are also independent of each other. This is help for the future in conducting economic policy and undertaking activities aimed at the development of agriculture and

rural areas on a regional basis. It also means that policies supporting changes in agriculture should be different due to the found disproportions and different development models.

Abstract

The main aim of the article is to indicate the possibilities, scale and scope of application of alternative technologies such as Cloud Computing to shape informational continuity of operations and provide safety and security for modern public and private organizations. The study has used the CAPI method as well as statistical analysis of empirical data. The research was conducted for various entities representing public services, local government administration as well as entities running business activities. The subject of the study were problems related to the functioning of a given organization in circumstances of crisis and threats. One of the important areas of research was the problem to use the tools and services of the CC platform, which enables strengthening the level of information security and informational continuity of operations. The range of research and analysis and study work undertaken leads to the conclusion that the increasing use of cloud computing can foster security and informational continuity of operations.

Keywords: Informational Continuity, Cloud Computing (CC), Security, Risk.

Introduction

The criterion of systemic, including informational, continuity of operations, understood as the ability to function in a modern organization in circumstances of threats and crises becomes a key requirement of its safety and security. Achieving the appropriate value level of this attribute is a complex task, requiring multidimensional evaluation and coordination of the activities of many people with appropriate, individual executive and management competences. Based on literature studies and theoretical analyses and also empirical analyses and studies, it has been confirmed that it is possible to identify risk factors for the loss of informational continuity of operations (Zaskórski, 2011, pp. 67-105). This creates the premises for building a comprehensive system to counteract disruptions and the risk of loss of informational continuity of operations, by using alternative solutions that increase the level of reliability of informational services. On this basis, it can be concluded that proposals for model solutions should take into account the various systemic dimensions of informational continuity of operations, including safety, security and also mobility and alternative capacity of ICT infrastructure. Being aware of these attributes allows to build a comprehensive system that provides informational continuity of operations of a modern organization functioning not only in normal situations, but also in crisis situations.

The main aim of the editorial is to indicate the possibilities, scale and scope of application of Cloud Computing technology in shaping the informational continuity of an organization - in the context of ensuring safety and security of contemporary public and private organizations. Therefore, the research problem has been decomposed into the following research questions (sub-problems):

RQ1: *What actions are taken to shape infrastructure ensuring safety and security and information continuity of operations for various classes of organizations?*
RQ2: *What are the possibilities to apply Cloud Computing in shaping the safety and security of an organization and its informational continuity of operations in circumstances of crisis and threats?*
RQ3: *What is the scale and scope to apply Cloud Computing in public and private organizations to shape their safety and security and informational continuity of operations in circumstances of crisis and threats?*

The study has used the CAPI method as well as statistical analysis of empirical data. The article is structured in four essential parts relating to the following problems: (1) specification of the essence of the informational continuity of organization's operations - with particular emphasis on safety and security management elements and the use of Cloud Computing (CC) technology, (2) definition of research assumptions and limitations, (3) presentation of the results of empirical research in the scope of shaping the informational continuity of organization's operations with the use of Cloud Computing infrastructure, as well as (4) the re-summit of research results in the context of continuity of information and decision making processes in circumstances where Cloud Computing solutions are applied.

The essence of informational continuity of operations

Information continuity of operations is one of the attributes of informational safety and security (see: da Veiga et al., 2020, pp. 2-20). An organization's information resources may have an impact both on the way in which work processes are carried out and on management effectiveness, including its position on the market. The continuity of organization's operations means the ability to carry out basic tasks at a certain quality level. However, an organization's sense of safety and security is variable and depends on both external and internal threats. The sources of these threats can be both natural forces and human activity (Fans, Subriadi, 2019, p. 276 et seq.). Each organization is a system of activity that aims at achieving its objectives with a particular focus on the criterion of safety and security and the risk stemming from a variety of threats that may intensify in crisis situations. Continuity of operations in systemic terms can be determined by the level of safety and security of individual sub-systems and threats appearing in one sub-system affect others and can threaten the whole (Niemimaa et al., 2019, pp. 209-215). The potential source of a discontinuity of operations and crisis situation may quite often be the environment of a given system. Every modern organization as a system is open in a strong relationship with its external environment. Multilateral links between an organization and its environment can have a significant impact on the organization's safety and security and on the achievement of its goals in circumstances of risk, indeterminacy and uncertainty of activity (see: Kostera, 2008; Xing, Zeng, Zio, 2019).

The size of the organization and its importance in the economic and social system of a country or region may have a strong impact on the effective management of safety, security and the risk to lose continuity of operations. The research and analysis of the safety and security of each organization taking into account the possible consequences of the threats indicates the need to identify individual vulnerability to a given threat (based on: Fans, Subriadi, 2019). This problem can be analysed in many aspects, including the ease of unauthorized access to the organization's resources, including information resources (Järveläinen, 2013, pp. 583-590). In addition, one of the important determinants of the safety and security of modern organizations is the use of information and communication technologies both within the organization and in relations with the wider environment (Rose et al., 2012, pp. 445-456; Di Caprio, Santos-Arteaga, Tavana, 2014, pp. 108-124; Basole, Park, 2019, pp. 369 et seq.). Modern information technologies affect the level of information safety and security and affect the level of informational continuity of operations (Zaskórski, 2011, pp. 107-144). The loss of informational continuity of operations may also have consequences related to the loss or depreciation of the entire potential of a given organization and the loss of ability to effectively manage its own resources. However, modern IT technology platforms and their flexibility may be conducive to ensuring continuity of operations and reducing the level of vulnerability of an

organization to crises and threats, but unfortunately new threats arise here. Therefore, each organization should (ISO 9001:2015; ISO 31000:2018):

- successively identify risk management processes and ensure their monitoring,
- determine methods for effective risk management, taking into account the criteria for its unambiguous evaluation,
- ensure the availability of adequate resources and information necessary to execute these processes,
- monitor and measure the key values in the processes organization and implement the actions necessary to achieve the planned results and continuous improvement of these processes.

Information continuity of operations (Fig. 1) is one of the dimensions of the operations' continuity of contemporary entities (da Veiga et al., 2020). Continuity of operations can be seen in terms of personnel, logistics, finance and similar continuity (Gallagher, 2003). It is important to note that a violation of information continuity may generate effects in other areas of the operations' continuity. Moreover, the informational continuity of operations is conditioned by the safety and security of information resources, including the risk of violation of the confidentiality criterion, integrity or reliability of data (see: Di Caprio, Santos-Arteaga, Tavana, 2014). The realization of such a risk may cause losses proportional to the importance of resources used especially in so-called critical processes (Liderman, 2007).

Fig. 1: Selected determinants of informational continuity of operations
Source: own elaboration based on (Miszalski, Zaskórski, 2014)

Every present-day organization should have an appropriate state of situational awareness (Endsley, 2015, pp. 101-111) of its operating conditions, and also of the needs of its stakeholders and of its capabilities (Artofmanliness, 2018). For this reason, when preparing to address the risks, the accepted standards and procedures for risk management should be followed, which should lead to the desired state (Management lexicon, 2004). The safety, security and crisis management system in any organization (including the state/country as a whole and any other entity) is therefore a system of coherent measures and coordinated undertakings, applied to ensure its smooth functioning (Białas, 2007, p. 182). Preparing an organization for crisis situations therefore requires linking many elements, including (Borodzicz, 2005; Crandall, Parnell, Spillan, 2014):

- procedures for monitoring and identifying threats and procedures for counteracting them (e.g. fire, hacking a computer system etc.),
- threat notification systems, as well as principles and forms of public relations and response methods appropriate to the nature of a given threat,

- evacuation and emergency solutions (back-up workstations, copies of data) and the principles of eliminating negative effects, taking into account the rules of cooperation with external entities according to established procedures.

The undertakings concerned with ensuring the security of the organization, including information security, should consist in recognizing, detecting and preventing situations that generate threats. Therefore, organizational and preventive procedures ensuring informational continuity of operations in crisis situations and the limitation of potential disruptions as well as the compensation of their negative effects are of great importance (Krzyżanowski, 1992). The safety and security policy is usually related to specific projects and requires the definition of the objectives, as well as the subject matter and area of impact of a given procedure and the conditions to use such a procedure. It is necessary to identify the persons responsible for carrying out the activities provided for by a given procedure. The organization's preparation to provide safety and security indicates the need to develop action plans and review it in several phases (see: Fans, Subriadi, 2019), including adequacy of actions in relation to needs and capabilities and identification of alternative solutions that would allow for continued emergency response (Gallagher, 2003, pp. 13-15).

In the information safety and security plans, a key role is played by the process of maintaining informational continuity of operations as the ability to effectively circulate useful information about incidents, threats and their consequences and the possibilities (forces and means) of actions to ensure overall continuity of operations, seen in different dimensions (based on: Järveläinen, 2013, p. 585 et seq.). This involves the effective and efficient exchange of information within the organization and its environment in all phases of crisis management, ensuring that the effects of information disruption are minimized and therefore the risk of loss of informational continuity of operations is minimized (based on: Rose et al., 2012, p. 447 et seq.). This may also mean providing situational awareness (including business awareness) for all links in crisis management.

An important assumption for effective management of a modern organization prepared for threats and crises is to develop and use the plans for information continuity of operations with the use of alternative information resources available not only in autonomous IT systems, but also with the use of services in cyberspace (based on: Basole, Park, 2019). Therefore, the use of the Cloud Computing (CC) information service platform (see: IDC MarketScape, 2019) may be an alternative solution that increases their reliability and thus reduces the risk of losing informational continuity of operations. This way of ensuring information safety and security with utilization of strong, professional mechanisms to protect data and services (based on: DaSilva et al., 2013, pp. 1161-1173; Vijayakumar, Arun, 2017, pp. S129-S136; Mishra, Umrao, Yadav, 2018, pp. 5980-6032) can foster:

- the integration of procedures of informational continuity of operations and the use of alternative procedures of informational continuity of operations, taking into account the various risks,
- preparing procedures for preventive, emergency and recovery activities, including the possibility of simulating the course of a crisis by using the CC platform,
- allowing access to resources, services and procedures without space and time constraints, and in particular in the event of failure (destruction) of the owned (autonomous) information resources,
- continuous and adequate analysis of risks for the updates of procedures.

The problem of developing and implementing organizational procedures for ensuring organizational security and responding to threats and crises is multi-faceted and difficult to fully formalize and unify. Therefore, research has been undertaken in relation to the evaluation and analysis of the condition and possibilities to provide informational continuity of operations of selected business entities and the government administration. These tests were carried out on a representative sample with many different assumptions and limitations.

Research Assumptions and Constraints

The essence and conditions of crisis management require the identification of information procedures for the informational continuity of organization’s operations in a specific task, organizational and,

above all, technological context (Miszalski, Zaskórski, 2014). This is primarily due to the particular importance of the attribute of continuity of operations for each entity in the face of the aware and unaware possible consequences of loss of continuity, both through the chaotic operation of individual services and the lack of coordination, and through the destruction and mutual obstruction of various activities, including the loss of control over the local and global situation.

In the article, the authors focus on the informational dimension and possibilities of counteracting the risk of lowering the level of informational continuity of operations. It is therefore assumed that the sign of ensuring informational continuity of operations is ultimately the pursuit to increase the level of information safety and security and preventing the risk of its reduction, and above all preventing the effects of such a phenomenon through the use of selected ICT platforms and tools in specific crisis situations.

The research was conducted for various entities representing public services, local government administration as well as entities running business activities. The subject of the study were problems related to the functioning of a given organization in circumstances of crisis and threats. One important area of research was the problem of using alternative tools such as the CC class services, which should enhance information safety and security and also informational continuity of operations. The population adopted in the research was evaluated according to various statistical parameters for selected attributes of operations' continuity.

The significance of differences in distributions between more than two variables of a ranked or quantitative nature was checked by a single-factor analysis of variance. The importance of differences between qualitative (nominal) variables was checked using the chi-quadrant independence test. Correlations between variables were checked using the Spearman's rank correlation coefficient. The analyses were based on the results of the questionnaire surveys by the questionnaire questions (Table 1).

The statistical analyses assumed the significance level of p=0.05. The analysis was carried out by using SPSS software. 77 representatives of organizations: public (27% of the total), non-governmental (22%) and commercial (51%) were surveyed. The public sector included organizations dealing with: health care (27%), science (23%), uniformed services (18%), local governments (14%) and central administration (9%). The NGO sector accounted for 34% of organizations. The private sector includes: services (33%), retail (17%), hotel and entertainment (15%), automotive (13%), telecommunications (10%), finance and insurance (6%), logistics (4%) and education (2%).

Table 1: The set of the questionnaire questions

No.	Question	The possible answers
1	Type of organization.	Public/NGO/Commercial
2	Sector.	Public: Uniformed governmental public services (e.g. the police), Health Care, Science, Central Governmental Administration, Local Government Administration, Others.
3		NGO
4		Commercial sector: Finance & Insurance, Retail, Logistics, Automotive, Telecommunications, Education, Services.
5	The quantity of staff employed.	Small: 0-50; Medium: 50-250; Big: 250+.
6	The age of the organization.	Startup: 0-2 years; The medium age: 2-5 years; The mature

No.	Question	The possible answers
		organization: over 5 years.
7	Geographical dispersion.	Small: 0-5 locations; Medium: 5-20 locations; Big: over 20 locations.
8	Security expenditure in relation to revenue.	Small: 0-0.4%; Medium: 0.4%-0,8%; Big: over 0.8%.
9	Expenditure priorities for the safety and security budget.	Prevention (1-5); Detection (1-5); Audit (1-5); Trainings (1-5); Safety and security policy management (1-5).
10	Is cloud computing used?	No; Private cloud; Public cloud; Hybrid cloud.
11	Security incidents detected within the last two years.	Please provide a number.
12	Is there a security or safety strategy?	Yes/No.
13	Is there an organizational level responsible for crisis management?	One-man position/Team/None.
14	Have key processes for the organization been identified?	Yes/No.
15	Have key resources for the organization been identified?	Yes/No.
16	Have the existing procedures allowed for the identification of materialized risk?	Yes/No.
17	Have the existing procedures allowed for the assessment of the materialized risk?	Yes/No.
18	Have the existing procedures allowed for continuity of operations for materialized risks?	Yes/No.
19	Priorities for keeping continuity of operations for materialized types of risks.	Information (1-3); Procedures & education (1-3); Infrastructure (1-3).
20	Sources of materialized types of risks.	Force majeure; Conscious destructive activity; Human errors and mistakes; Information system failure.
21	Does cloud computing affect business continuity?	Yes/No.
22	Is the organization testing its crisis management processes?	Yes/No.
23	Does the organization monitor the status of key processes and resources?	Yes/No.

Organizations employing up to 50 people accounted for 33% of the total number, while medium-sized organizations employing between 50 and 250 people accounted for 29% of the total number. The research group was supplemented by organizations employing over 250 people (39%). Most organizations have operated for more than 5 years (49%), medium in terms of age organizations accounted for 32% of the total, the least numerous were young organizations, which have existed for

two years at most (20%). In terms of geographical dispersion, small organizations with no more than 5 locations (39%) and large organizations with more than 20 locations (36%) dominated, the research group was supplemented by medium-sized organizations with 5 to 20 locations (25%).

It has been assumed in the conducted research that the entities that will be representative are enterprises and public administration entities. The population of entities subject to the research was 5751. In the research the formula for minimum sample size was adopted (see: Hoekstra, 2014, pp. 1157-1164):

$$Nmin=NP.(\alpha 2{\cdot}f(1-f))NP.\cdot e2+\alpha 2{\cdot}f(1-f)$$, where:

Nmin – minimum sample size,
NP. – the size of the population from which the sample is taken,
α – level of confidence in the results,
f – fraction size,
e – assumed maximum error, expressed as a fractional number.

Therefore, using the value of 5751 entities, 90% confidence level (10% uncertainty of the result was allowed), 0.5% fraction level (recommended default value), 10% error (assumed that there were up to 10% unintentionally misfilled questionnaires), the result of 67 entities was obtained as a minimum. A certain margin of safety was therefore adopted and a representative sample of 77 entities was determined.

Results of empirical research on informational continuity of the organization's operations, including cloud computing infrastructure (CC)

Nearly 45% of the respondents declared that the organization's expenditures on safety and security in relation to revenue are small, while the medium expenditures were declared by 18% of the respondents, about 37% declared that the expenditures are big and constitute over 0.8% of revenue (Table 2). Organizations with a small number of employees experienced relatively small expenses (75% of indications), the increase in expenses occurred with the size of the organization, large associations also experienced big expenses (63% of indications). The differences are statistically significant ($p<0.001$).

The vast majority of young organizations experienced small safety and security expenses (93% of them), organizations with internships from 2 to 5 years experienced small (48%) and medium (30%) expenses, while the majority of organizations operating above 5 years experienced relatively big expenses (60%). The differences between groups are statistically significant ($p<0.001$). Organizations having a big number of locations also experienced high safety and security expenses (75%), these expenses decreased with the number of locations, most organizations with small dispersion also experienced small expenses (69%). Analysis with the chi square independence test showed that the discussed differences are statistically significant ($p<0.001$).

The respondents also evaluated the spending priorities for the security budget, on a scale from 1 score to 5 scores, the scores were averaged and ranked from the highest to the lowest, i.e. from the highest priority to the lowest priority. The highest priority was given to expenditure related to the management of the safety and security policy (the mean score of 3.4, at least half of the people gave a score of 4) and expenditure related to training (the mean score=3.3; the median=4). Slightly lower priority was given to audit (the mean score=2.9; median=3), the least priority was expenditure related to prevention (the mean score=2.4; median=2) and detection (the mean score=2.3; median=2).

A one-factor analysis of the variance showed a statistically significant differences in assessments of safety and security policy management expenditures between different types of organizations (p=0,005). The highest mean scores was recorded for NGOs (4.1), slightly lower for public organizations (3.6), while the lowest for commercial institutions (2.9). No differences were found for the other priorities. In addition, statistically significant correlations between age (p=0.001),

geographical dispersion (p=0.020) and prioritization evaluation of audit expenditures were confirmed. Older organizations with a large number of locations valued this type of expenditures higher.

Most organizations used cloud computing: private one (34%), public one (9%) and hybrid one (25%). However, 33% of organizations did not use cloud computing services (Table 2).

The average number of security incidents within the last two years was 7.3, with a standard deviation of 15.6. At least half of the respondents stated that there were no more than 3 incidents in the organizations. The highest number of incidents was 123. It was found that statistically significant correlations between the number of detected safety or security incidents and the size of employment (p=0.032), age (p=0.004), dispersion of the organization (p<0.001), its safety and security expenditures (p<0.001). The higher the number of employees in the organization, the older and more dispersed the organization, the higher the safety and security expenditure and the higher the number of incidents detected.

Most of the respondents claimed that there was a safety and security strategy in their organizations (71%) (Table 2). Indeed, more often such a strategy was pursued by organizations with a larger number of employees (p<0.001), operating for a longer period of time (p<0.001) and having a large number of locations (p<0.001).

Most of the respondents stated that their organizations lacked a level of responsibility for crisis management (53%), in 32% of organizations a team was responsible for it (32%) and in 16% of cases a specific person was responsible (Table 2). Public and non-governmental organizations most often had no crisis level, 60% and 65% of cases respectively. The remaining public organizations had a crisis team, and most NGOs had one-man positions (29%). In the case of commercial organizations - 18% of them had a one-man position, 39% had a team, and nearly 44% did not have an organizational level responsible for crisis management. These differences are statistically significant (p=0.025).

Small and medium-sized organizations most often did not have organizational levels responsible for crisis management, large organizations most often had teams (69%) or one-person positions (21%). The differences are statistically significant (p<0.001). Also start-ups and middle-ranking organizations did not have such levels, 93% and 71% of cases respectively; organizations over 5 years old had most often teams responsible for crisis management (56%). The differences are statistically significant (p<0.001). Moreover, organizations with no more than 5 locations most often did not have a level responsible for crisis management (73%), the higher the number of locations, the more often organizations had a team or one-person positions responsible for crisis management (p=0.045).

Table 2: Summary results of the empirical research

Categories of responses	Percentage of respondents' indications
Problem: Safety and security expenditures in relation to income (relative to the size of the organization), n = 77	
Small; 0-0.4%	44.7%
Medium; 0.4-0.8%	18.4%
Big: over 0.8%.	36.8%
Problem: Use of cloud computing services (CC), n = 77	
Public cloud	9.1%
Hybrid cloud	24.7%
Private cloud	33.8%
No	32.5%

Categories of responses	Percentage of respondents' indications
Problem: Existence of security strategy, n = 77	
Yes	71.4%
No	28.6%
Problem: Existence of organizational level responsible for crisis management in the organization, n = 76	
One-man position	15.8%
Team	31.6%
No position or team	52.6%
Problem: Identification of key processes for the organization, n = 77	
Yes	75.3%
No	24.7%
Problem: Use of existing procedures for identification of materialized risk, n = 77	
Yes	58.4%
No	41.6%
Problem: Impact of existing procedures on the assessment of materialized risk, n = 77	
Yes	54.5%
No	45.5%
Problem: Impact of existing procedures on operations' continuity for materialized risk, n = 77	
Yes	66.2%
No	33.8%
Problem: Sources of materialized types of risks, n = 77	
Conscious destructive activity	31.1%
Human errors and mistakes;	28.4%
IT system failure	27.0%
Force majeure	10.8%
All above-mentioned causes	2.7%
Problem: Effect of cloud computing (CC) on continuity of operations, n = 77	
Yes	49.4%
No	50.6%
Problem: The testing of crisis management processes (systems) by the organization, n = 77	
Yes	57.1%
No	42.9%
Problem: The monitoring by an organization of states of key process and resource, n = 77	
Yes	61.0%
No	39.0%

In most cases (75%), key processes for the organization were identified (Table 2). More often such cases occurred in organizations employing a large number of people (p=0.035) and those operating for longer time period (p=0.018). However, the distribution of responses was not significantly affected by geographical dispersion (p=0.071). Key resources were identified among 70% of organizations (Table 2). This was most often the case among organizations with a large number of employees (p=0.007), operating for more than 5 years (p<0.001), with a large dispersion (p=0.001).

In more than half of the cases, the existing procedures allowed for the identification of materialized risk of loss of information security (58%). A slightly smaller percentage of respondents considered that the existing procedures allowed for the assessment of materialized risk (55%). More than 66% of the respondents considered that the existing procedures allowed for keeping the informational continuity of operations for a materialized risk (Table 2).

The empirical study also collected evaluations of priorities to keep continuity of operations for materialized types of risks on a scale from 1 score to 3 scores, the evaluations were averaged and ranked from the highest to the lowest, i.e. from the highest priority to the lowest priority. The most important priorities are information (the mean=2.2) and procedures and education (2.0). However, it was characteristic that the infrastructure was a little less prioritized (1.7). In the opinion of the respondents, the most frequent source of materialized risks were: conscious destructive actions (31%), human errors and mistakes (28%) and IT system failures (27%). Force majeure occurred less often (11%). At this point, it is also worth noting that almost half of the respondents (over 49%) believed that cloud computing had a fairly significant impact on the continuity of the organization (Table 2).

It is also worth noting that half of the respondents claimed that the organization is testing its crisis management processes (57%) (Table 2). They were most often tested by organizations employing between 50 and 250 people (64%), less frequently by institutions employing a smaller (36%) or larger (36%) number of people. The differences are statistically significant (p=0.031). More often such tests were also implemented by mature organizations (p=0.001) and with a large number of locations (p=0.003). Most of the respondents considered that their organizations monitored the status of key processes and resources (61%) (Table 2). Most often such monitoring was implemented by companies with a large number of employees (p=0.010), operating for longer period of time (p=0.008), and with a larger geographical dispersion (p=0.008).

Studies have shown significant gaps and inconsistencies in business continuity information systems and an insufficient level of perception of the problem, which may ultimately reinforce the legitimacy of the use of the CC services in ensuring informational continuity of operations in the crisis management systems of selected business entities.

Discussion: re-summit of research results in the context of continuity of information and decision making processes in circumstances of cloud computing application

The results presented confirm the relevance of the identified research problem. There is a need to increase the level of situation awareness that information safety and security of each organization is an important component of its effective operation and of the assurance of continuity of information and decision making processes and forecasting (including simulation) its condition (see: Zacharias et al., 2008, pp. 89-118). This can be facilitated by modern technologies and information platforms (Woźniak, Zaskórski, Pawlak, 2018). The virtualization of modern entities is connected with the process of “converting resources into data”, i.e. the process of collection, maintenance and manipulation of large volumes of data. Therefore, the use of cloud services not only increases flexibility in the face of a changing environment, but also increases the security and safety of the necessary services. Today's public and business entities, both public and business, should plan their activities in a context of threats and crises, where large amounts of data from heterogeneous sources can be processed. Therefore, in order to ensure high reliability of information processes it is worthwhile to refer to alternative services on the CC platform. This has also another aspect, namely reducing information exclusion of SMEs due to their weaker potential (see: Kostyńska, 2019). This is evident in studies where smaller organizations see lesser the loss of their value due to lack of access to certain services and cost barriers (see: Lei et al., 2018, pp. 3375-3388; Liu, Farouk, Zhen, 2019, pp. 3373-3380).

The demand for IT resources and services is constantly growing due to the continuous growth of collected and processed data (Lebens, 2013). Therefore, in order to increase the quality, and mainly

reliability, of information and decision making processes, the possibility of migration of implemented information processes to the cloud and organization of related resources in the cloud, is advised. The decision to operate through usage of the cloud is quite often made because of the short-term nature of a specific process and the low cost to enter the cloud environment (Chowdhury, 2018). However, the problem arises when considering the transfer of already existing resources and processes for various crisis situations and various options for scenarios of actions. In such situations, the quality of processes and resources may be determined by the time and amount of financial resources and the involvement of contractors and, above all, managers (based on: DaSilva et al., 2013, pp. 1162 et seq.).

The article therefore attempts to link the need for informational continuity of operations with the possibilities to use alternative solutions residing on the CC platform. Virtualization of information services does not have to be ultimately associated with the cost of purchasing your own servers and workstations, and resource consumption is automatically scaled to actual demand. The risk of physical destruction of resources and total loss of data can be monitored on an ongoing basis and the reliability of the system increases when potentially defective components are inspected and eliminated or replaced by other technical and technological components on an ongoing basis (see: Chowdhury, 2018). Cloud computing allows management to focus exclusively on the substantive aspects of their activities, especially in the crisis response phase. Effective monitoring and controlling the state of implementation of each process at any time and place - directly affects the quality and effectiveness of management (see: Basole, Park, 2019, pp. 370-379).

Empirical research has shown that without unrestricted access to automatically scalable resources it may not be possible to implement some key processes throughout the information and decision making process. To ensure informational business continuity, it may often be enough to invest a small amount of money to access the resources of the chosen platform (e.g. MS Azure with a Microsoft® PaaS model), with the possibility of secure use of resources without the risk of losing the continuity of processes.

Conclusions

In the processes of managing modern organizations in crisis situations, it is important for whom, when, where and what data and information services are necessary. The CC environment enables the integration of standard solutions with stand-alone solutions that support a given organization. This is particularly important for processes with strong time constraints. It becomes important to be able to report on-line by using an appropriate, up-to-date set of data, with availability on demand from any level of process execution. Moreover, for the quality of information and decision making processes, the selective availability of data from any device equipped with an Internet connection is quite often emphasized. Working on a common repository encompassing the information needs of a given process and of its territorially dispersed contractors provides an opportunity to use resources effectively. The efficiency and overall effectiveness of various working and management processes by using information services available in cyberspace can also be improved.

The undertaken scope of research and analysis as well as studies leads to the conclusion that the use of cloud computing may strengthen the level of safety and security and informational continuity of operations and have a positive impact on, among others (see: Chowdhury, 2018):

- the integration of processes implemented in many areas and places of operations conducted by the organization,
- flexibility and reliability of operations in a rapidly changing environment,
- dynamic change management and shortening the response time to changes in operational conditions,
- reduction of fixed/permanent and investment costs,
- increase in the scalability of resources, which can increase the efficiency of their allocation and usage.

- lowering the risk of losing continuity of operations of the entire organization, in which security and information continuity are the important attributes.

Therefore, the CC services can improve the effectiveness of information and decision making processes and their quality in modern process-oriented organizations, especially in crisis situations. The overall area of research will continue to explore other alternatives without excessive cost increases by assessing the suitability and effectiveness of the services available in Big-Data systems (ERP24, 2019; Zaskórski, Zaskórski, 2017) and in the IoT platform (Ogórek, Zaskórski, 2018). Information processes implemented in modern organizations therefore require information structuring in order to identify actual information needs determined by time and place and methods of access to resources. These determinants condition the quality of decision-making processes in the long-term perspective and in the operational dimension, with particular emphasis on contemporary possibilities (Satechnologies, 2018) to create an appropriate level of situational awareness.

Abstract

This research started from the interest of exploring the landscape as a tourist resource and understanding its role, performance, and importance in the current tourist context. This article aims to understand the role of the landscape as a tourist resource relating the characteristics of the landscape with the choice and motivation of the visitor and interpret the factors that influence the valorization of the landscape. In this sense, four research hypotheses were proposed for the northern region of Portugal: Tourists visiting the region of Porto and northern Portugal give importance to the characteristics of the rural landscape, to the aesthetics of the rural landscape, to the characteristics of the urban landscape, and to the aesthetics of the urban landscape; There are differences regarding the importance of the characteristics of the rural and urban landscape by sociodemographic variable; There is a relationship between the length of the average stay and the visit to the northern regions of Portugal; and finally, there is a relationship between the reason for the trip and the visit to the northern regions of Portugal: Porto Metropolitan Area; Trás-os-Montes; Minho, and Douro. These research results evidence that visitors from the region of Porto and Northern Portugal attach importance to the characteristics and aesthetics of the landscape

Keywords: Landscape, Tourism, Tourism Destination, Regions, Portugal

Introduction

The literature that addresses the function of the landscape as a tourist resource is limited. The relationship between landscape and tourism is vaguely explored. However, recent studies explore the connection between the landscape and its aesthetics and its influence on tourists, that is, the attractiveness factor of a landscape (De Aranzabal, Schmitz and Pineda, 2009; Carneiro, Lima & Silva, 2015; Breiby, 2015; Cébrian & Sánchez, 2016; Todorović, 2016; Serrano-Montes, Martínez-Ibarra, Arias-García, 2019; Lontai-Szilágyi, Bertalan-Balázs, Zsiros, Vasvári, Kumar, Nilanchal, Martonné Erdős, & Szabó, 2019; Lee, 2020). Terkenli (2004) argues that studies focusing on the relationship between tourism and the landscape emerged in the 1990s, also mentioning the distinction between three perspectives. The first perspective addresses the impact of tourism on the landscape, due to the growth and development of tourism activity. The second perspective covers the interest and awareness of the sustainability of the landscape by European and international bodies, which value the conservation of the landscape, the environment, and historical-heritage values. Finally, the third perspective presents a more complex approach by adopting structuralist perspectives that deepen the issue of tourism and landscape interactions and their impacts and changes that may arise: their consumption, conservation

and performance in everyday life and in the tourist context. The tourism destinations are places where it is possible to carry out and practice the tourist activity, through the available resources. Landscape tourism is the activity practiced in the tourist space, in this specific case, in the formerly called "tourist landscape". Beauty, aesthetics, and authenticity are some of the main attractive factors of a tourist destination. Tourist attractions, whether of a natural nature or human intervention, are essential components of a region tourism offer. The landscape scenario influences the attractiveness of a destination, since this is an element that inevitably is part of a tourism journey and experience. These points should be considered, regarding the management and planning of landscape sustainability as a tourist resource. The landscape establishes links between people and nature and should be recognized and valued on the basis of this vision, as the landscape is not simply a resource, but also plays the role of intermediary for the sustainable development of a region.

The Institute for Conservation of Nature and Forests (Instituto para a Conservação da Natureza e Florestas, ICNF, IP), in Portugal, explains through its online platform the concept of geosites: "The concept of geosite applies to the elements of geological heritage that constitute an occurrence of recognized scientific value, compared to the rest surrounding; it may, however, present more than one type of importance, namely didactic, cultural or aesthetic." Although "considered by the Legal Regime for Conservation of Nature and Biodiversity a natural value, such as the elements of biodiversity and landscapes, geosites have not enshrined at national level a specific classification regime". However, regarding its protection and conservation, its classification figure frames it as a "Monument of the National Network of Protected Areas". The rural environment and the rural landscape are understood as the most "genuine", because one of the most attractive factors is authenticity, often related to the surrounding culture and nature. The main motivation of visiting in rural areas is the search for tranquility, proximity to nature and the "authenticity" factor (Chambers, 2009). In another perspective, Cullen (1983) states that the urban landscape aims to combine the coherence and organization of urban space, through the management of the streets, spaces, and buildings planning, improving, and promoting the urban environment. Cullen (1983) adds that a very simplified street or avenue can become monotonous for visitors from a visual point of view, highlights the need to enhance some characteristics of the urban landscape: the optics, that is, the sequential perception of urban space (different views from different perspectives at the visual level); the place, in which different sensations are provoked in the individual according to the type of place where he is (closed places, open places); and the content, that is, the elements present in the urban landscape commonly associated with urban spaces (lights, buildings, skyscrapers, among others). Landscapes in the urban context contribute to the sustainability and biodiversity of the urban landscape with the inclusion of green spaces (urban parks, gardens) (Zárate, 2013). The urban landscape is in most cases the business card of a city, developed by city marketing whose goal is to appeal to aesthetic sense and emotions, and consequently contribute to the attractiveness of a destination.

We can say that the landscape is the element that is at the forefront of tourist demand, which reflects its attractiveness in this context (Cruz, 2002). According to Terkenli (2004), "as an image or representation of a place, the landscape represents the main and most durable means of contact between the tourist and the consumed place". Thus, we can consider the landscape a tourist resource, part of a tourist product and an identity element of the tourist destinations, the business card of a destination. The landscape is not only an element of attractiveness on the part of the visitor (and the population itself), but it is also an element that is shaped according to the needs that the tourist activity requires, that is, we can say that the perception of the landscape is modified and reinvented by the consumer himself. Kaplan & Kaplan, (1989) agree that nature develops a stimulating effect on people. Bourassa (1990) and Strumse (2001, 2002) point out other characteristics such as the landscape itself, the scenery, the harmony that end up influencing the state of mind and the well-being of the individuals who visit these places.

Breiby (2015) defined parameters regarding the aesthetic dimension of the landscape, which are harmony, scenery/view, purity, genuineness, and variety/contrast. Breiby (2015) still argues that there is a direct link between the aesthetics of a landscape and the satisfaction of the tourist, that consequently influence the desire to repeat the visit again, reinforcing that to better understand the experience of

tourists, research in this area should focus on the aesthetic dimensions of the anthropic and natural environment.

Destination Management Organization's (DMO) should seek to enhance the landscape as a tourist resource to achieve tourists' maximum satisfaction. Another concern of The DMO's is to manage and plan the available resources of a tourist landscape in order to achieve two purposes: to add tourist value to the place (taking into account its sustainability in the various dimensions) and use it as a resource that distinguishes itself as a competitive advantage over other destinations.

This paper is divided in three parts. The first part, the literary review, emphasizes the important influence of the landscape characteristics in the destination choice and visitor's motivation. The second part describes the research methodology, the methodology of data collection, presents and discusses the results of the research. The third and final part, the conclusion, discusses the innovative perspective introduced in the analysis of the landscape characteristics concerning the Northern region of Portugal.

Literature Review. Defining Landscape and Landscape Tourism

The cultural landscape plays a strong role in the identity and perception of a tourist destination, being considered a tourist product that holds value and meaning providing individual and collective emotions (Baudry and Paquot, 2003). The landscape is an indispensable tourist resource of a destination and that is naturally present regardless of its typology, the surrounding scenery is increasingly valued nowadays. As mentioned earlier, the literature that addresses the function of the landscape as a tourist resource is limited. The relationship between landscape and tourism is vaguely explored. However, there are studies that explore the connection between the landscape and its aesthetics and its influence on tourists, that is, the attractiveness factor of a landscape. Studies relating to tourism and the landscape are relatively recent. As already mentioned, the relationship between tourism and the landscape is a subject that began to be addressed at the end of the 20th century.

The cultural landscape plays a strong role in the identity and perception of a tourist destination, being considered a tourist product that holds value and meaning providing individual and collective emotions (Baudry and Paquot, 2003). The landscape is an indispensable tourist resource of a destination and that is naturally present regardless of its typology, the surrounding scenery is increasingly valued today.

The landscape can also be recognized as a tourist product, as it is a tourist resource that can exercise/provide services or functions commonly associated with a tourist product. According to Castro (2002), the use of the landscape to enjoy these activities "is possible due to the previous symbolic content of which it [landscape] is covered". That is, the changes made due to the tourist activity must pay attention to the historical-patrimonial context in which it is inserted and respect its requirements or conditions. However, this doesn't imply the total loss of the heritage and identity of a place, the tourist landscape can in some cases convey a greater sense of belonging (Tuan, 1979). The landscape as a tourist resource can be transformed into a tourist product through appropriate marketing techniques and allocation of infrastructure and services associated with tourism. The landscape can contribute to the sustainability of the environment where it is inserted to the extent that, if it reaches a certain level of popularity and attractiveness, it can condition excessive urbanization. In this way, we can reinforce the idea that the landscape acts as a tourism enhancer resource that, if properly planned, can contribute to the sustainability and conservation of the environment where it is inserted. The landscape contributes to the coherence and identity of the destination, especially if it presents property values. Concerning the promotion and development of landscapes, a new question arises regarding the artificiality of a landscape, which is created because of its significant exploitation and the growing popularity of the destination. Some actors take advantage of this phenomenon to promote a destination through landscape marketing, whose goal is to redefine landscapes as a tourist product to meet the expectations of visitors. "Tourist landscapes are, artificially, the translation into space of the consumers-tourists' spatial expectations of, whose tastes have already been properly worked by the media" (Cruz, 2002). Cruz (2002) adds that artificial landscapes are not products of the history or heritage of a place, but rather a tourism result. According to Pires (2001), "landscape and tourism are two closely related

realities. The landscape is a substantial element of the tourist phenomenon and therefore a resource of great value in the development and consolidation of the tourist offer".

The landscape and tourism are inseparable, especially when nature is assumed as a central qualification of the tourist product. Tourist experiences through the landscape, passive or active, gain a growing meaning in the tourist offer and are assumed as a central element of demand. However, to find a balance in the relationship between landscape and tourism, we cannot rule out the social context in which it is inserted and the local population. Tourist landscapes should be explored, planned, and developed with care and coherence, considering their values and the population where it is inserted. The landscapes convey historical and cultural significance; however, they also reflect the result of factors such as economic, social, and environmental policies.

To enrich the visitor's experience, the challenge is to enhance the landscape through their experiences, available information, and accessibility. One way to promote the landscape is the dissemination through interactive methods, in the emotional and imaginative dimensions, which allows awakening the sensations of amazement and admiration for the natural characteristics of the landscape (Gordon, 2012; Gordon, 2016; Pralong 2006; Dyer, 2007; Staiff 2014; Macadam, 2018). The landscapes have several distinct attributes, being then considered as a tourist resource of complex motivation (Jovičić, 1989), and at the same time manifest a complementary character to the tourist offer (Jovičić, 2008). These motivations are associated with the practice of cultural tourism, so the motivation that leads tourists to visit places of landscape beauty is a cultural need (Jovičić, 1989; 2008). Thanks to their attractiveness attributes, landscapes can respond to the needs of tourists (Todorović, 2016).

It is necessary a strong investment in the landscape as a potential tourist resource, thus allowing to belong to the range of the tourist offer of a destination. Thus, after its economic exploitation, its tourist value can be considered as a demand-motivating resource (Todorović, 2016). The motivation on the part of tourists can be influenced by the landscape of a destination or by the activities associated with it. The landscape plays an important role in the tourist offer also in terms of the tourist products available in this region, such as hospitality. Although the influence of the landscapes does not act properly through direct participation in tourist activities, indirectly adds value to a tourist destination. That is why we can consider the landscape as a tourist resource rather than a tourist product (Todorović, 2016). According to Pacheco & Oliveira (2011) "The landscape plays a fundamental role in the attractiveness of a tourist destination due to its intrinsic power of beauty, well-being, pleasure and satisfaction, has a high degree of representativeness at the time of the choice of the tourist/visitor as a spectator". That is, the landscape is a representative element of the destination and functions as a business card, eventually influencing and determining the visitor's choice.

Methodology

Following this investigation, the application of a questionnaire survey was adopted as a method. The purpose of the application of surveys is the collection of valid and reliable information through a set of questions asked to a representative group of respondents that can thus translate into the generalization of the universe of the population under study (Thayer-Hart et al., 2010). The planning and construction of the survey starts from the formulation of a problem that will answer the starting question of an investigation (Quivy & Campenhoudt, 1998) or through the implementation of objectives.

Part of the applied survey was based on an existing questionnaire conducted by the research of De Aranzabal, Schmitz and Pineda (2009) whose objective is to explore the relationship between visitor preferences and landscape characteristics with the support of an integrated spatial method for landscape analysis. Another study that served as the basis for the preparation of this questionnaire was that of Breiby (2015), "Exploring aesthetic dimensions in nature-based tourist experiences", whose results demonstrated that the aesthetic dimension influences the preferences of tourists in places of natural landscapes.

Table 1: Sample individual profile

Gender	Frequency	Percentage
Male	134	44,4%
Female	168	55,6%
Age	Frequency	Percentage
18-24	40	13,2%
25-34	82	27,2%
35-44	45	14,9%
45-54	57	18,9%
55-64	41	13,6%
+65	37	12,3%

Oceania	11	3,6%
Income level	Frequency	Percentage
Up to 1500€	61	20,2%
1501-3000€	72	23,8%
3001-5000€	30	9,9%
+ 5001€	24	7,9%
Don't know/Don't answer	115	38,1%

Source: Compiled by the authors

In the study by De Aranzabal, Schmitz and Pineda (2009), the authors intend to relate the different types of landscape with the visitor's profile, so the idea that the demand and impact of the visit require specific measures in terms of destination management is reinforced. Several studies, already presented, are in line with the objectives of this research, and the general objective is to understand the role of the landscape as a tourist resource relating the characteristics of the landscape with the choice and motivation of the visitor and interpret the factors that influence the valorization of the landscape. In this sense, four research hypotheses were proposed for the Northern Region of Portugal:

- **H1:** Tourists visiting the Region of Porto and Northern Portugal give importance: To the characteristics of the rural landscape; To the aesthetics of the rural landscape; To the characteristics of the urban landscape; To the aesthetics of the urban landscape;
- **H 2:** There are differences regarding the importance of the characteristics of the rural and urban landscape by sociodemographic variable: Gender; Age; Civil Status; Qualifications; Country of origin; Income; And as to the degree of importance of: To the characteristics of

the rural landscape; To the aesthetics of the rural landscape; To the characteristics of the urban landscape; To the aesthetics of the urban landscape;

- **H3:** There is a relationship between the length of the average stay and the visit to the northern regions of Portugal: For the region of the Metropolitan Area of Porto; To the Trás-os-Montes region; To the Minho region; To the Douro region.
- **H4:** There is a relationship between the reason for the trip and the visit to the northern regions of Portugal: Metropolitan Area of Porto; Trás-os-Montes; Minho, and Douro.

The sampling method used was simple random sampling with the application of the survey to national and international visitors/tourists. The survey was applied at the *Porto Welcome Center* and the interactive store of Francisco Sá Carneiro airport. The questionnaires were applied between March and July 2019, obtaining a total of 302 valid questionnaires.

Throughout the analysis, a significance level of 5% will be assumed to make decisions about the validation of the investigation hypotheses. The sampling error was calculated based on the number of visitors/tourists in the Northern region, a total of 4,334,202, for the year 2018 (INE). It should also be noted that for the calculation of the final sample, was considered the non-violation of the assumptions for the application of a multivariate analysis. Thus, a final sampling error of 5.6% was assumed for a 95% degree of confidence.

Table 2: Sample technical data

Universe under study	Tourists from the North region
Geographic coverage	Northern Region of Portugal
Thematic coverage	Motivation; landscape
Sample Size	302 tourists/visitors
Sample Error	5,6%
Trust level	95%
Sample Type	Simple random sampling
Study	Quantitative
Data collection method	Non-documentary; Non-participant observation; Survey by Questionnaire
Data processing method	SPSS version 25
Data collection period	March to July 2019

Source: Compiled by the authors

To verify the reliability of the questionnaire, the internal consistency was analyzed using Cronbach's Alpha coefficient. Internal consistency is the specific reliability estimate for questionnaires. According to Pestana and Gageiro (2003) Cronbach's Alpha value varies between 0 and 1, and the internal consistency is better the closer it is to the value 1, i.e.: Values below 0.6 make the scale "Inadmissible"; Between 0.6 and 0.7 internal consistency "Weak"; Between 0.7 and 0.8 internal consistency "Reasonable"; Between 0.8 and 0.9 internal consistency "Good"; Greater than 0.9 internal consistency of "Very Good" scale; In this study, Cronbach's Alpha obtained to measure the latent variable, characteristics of the rural and urban landscape, was 0.950, which indicates a degree of internal consistency "Very Good" (Table 3).

Table 3: Cronbach's Alpha coefficient

	N	%	Cronbach's Alpha
Valid	277	91,7%	0,950
Excluded	25	8,3%	

Source: own elaboration based on SPSS outputs

Twenty-five questionnaires were excluded for partial non-response and thus the sample was 277 valid questionnaires. After the data collection was completed, the Statistical Package for Social Science

(SPSS 25.0) program was used to create the database. The processing of data focuses on the use of statistical techniques such as exploratory descriptive analysis and inferential analysis. In the first analysis and in order to present the data, we use the production of absolute and relative frequency tables, graphs and measures of location (mean) and dispersion (standard deviation), with the purpose of characterizing the sample under study and helping to identify the visitor's profile. With the inferential analysis, it is intended to validate the established research hypotheses. Parametric tests, in particular t-Student, will be applied to this end to examine whether there are differences between means for two independent samples. One-Way ANOVA, to compare means between three or more independent samples, in turn, if one of the assumptions for the application of this test is violated, uses the Kruskall-Wallis nonparametric test, and finally, Pearson's correlation coefficient to analyze the relationship between variables. To achieve the objectives of this investigation, the hypotheses were developed according to the structure of the questionnaire. All hypotheses were tested with a 95% confidence level.

Table 4: Research hypotheses and statistical tests used

Chance	Statistical tests
H1: Tourists visiting the Region of Porto and Northern Portugal give importance:	
1. To the characteristics of rural landscape	One sample Student's t-test
2. To the aesthetics of the rural landscape	One sample Student's t-test
3. To the characteristics of the urban landscape	One sample Student's t-test
4. To the aesthetics of the urban landscape	One sample Student's t-test
H2: There are differences regarding the importance of rural and urban landscape characteristics by sociodemographic variable:	
Gender	Mann-Whitney U
Age	Kruskal-Wallis H
Marital status	Kruskal-Wallis H
Qualifications	Kruskal-Wallis H

Results

H1: Tourists visiting the Region of Porto and Northern Portugal give importance: to the characteristics of the rural landscape, to the aesthetics of the rural landscape, to the characteristics of the urban landscape, to the aesthetics of the urban landscape.

Table 5: Empirical global average of degrees of importance

	Landscape features	Aesthetics of the rural landscape	Characteristics of the urban landscape	Aesthetics of the urban landscape
Average	3,4122	3,8390	3,2976	3,70776
Standard deviation	0,72971	0,73302	0,62431	0,78150

Source: own elaboration based on SPSS outputs

To calculate the degree of global importance it was necessary to calculate the empirical global average of importance for the characteristics of the rural landscape (mean 3.41 and standard deviation 0.73), the aesthetics of the rural landscape (mean 3.84 and standard deviation 0.73), the characteristics of the urban landscape (mean 3.29 and standard deviation 0.62) and the aesthetics of the urban landscape (mean 3.71 and standard deviation 0.78). which encompasses the 33 items measured on a 5-point Likert scale and assesses the degree of importance visitors place on the characteristics of the landscapes.

Table 6: Validation of hypothesis 1

Hypothesis	Test	Value	P-Value, New American	Conclusion
H1: Tourists visiting the Region of Porto and Northern Portugal give importance:				
To the characteristics of the countryside		9,041	0,000	Confirmed
To the aesthetics of the rural landscape	One Sample Student's T Test	19,049	0,000	Confirmed
To the characteristics of the urban landscape		7,933	0,000	Confirmed
To the aesthetics of the urban landscape		15,069	0,000	Confirmed

Source: own elaboration based on SPSS outputs

To respond to this research hypothesis, the T-Student test was used for a sample and the theoretical reference mean was 3 points. From this application, a test value of 276 (freedom degrees) and the test value (p-value) were lower than 0.001. Since the test value is lower than the level of significance assumed, the hypothesis of investigation is corroborated and it can be affirmed that there is statistical evidence to indicate that visitors from the Region of Porto and Northern Portugal attach importance to the characteristics and aesthetics of the landscape.

H2: There are differences regarding the importance of the characteristics of the rural and urban landscape by sociodemographic variable: Regarding the characteristics of the rural landscape; regarding the aesthetics of the rural landscape; regarding the characteristics of the urban landscape; regarding the aesthetics of the urban landscape. To respond to this research hypothesis, the Mann Whitney U test and the Kruskal-Wallis H test were applied for independent samples. Table 7 shows the results obtained for each sociodemographic variable.

Table 7: Hypothesis 2.1. Test value for statistical tests - Characteristics of the rural landscape

Variables	Test	p-value	Significance
Gender	Mann-Whitney U	0,728	NS
Age group	Kruskal-Wallis H	0,493	NS
Civil Status	Kruskal-Wallis H	0,285	NS
Qualifications	Kruskal-Wallis H	0,720	NS
Country of origin	Kruskal-Wallis H	0,233	NS
Income	Kruskal-Wallis H	0,524	NS

Source: own elaboration based on SPSS outputs

In all variables there are no statistically significant differences, since the test value is higher than 0.05 (p-value), that is, there are no differences by sociodemographic variable regarding the degree of importance given the characteristics of the rural landscape.

Table 8: Hypothesis 2.2 Test value for statistical tests of rural landscape aesthetics

Variables	Test	p-value	Significance
Gender	Mann-Whitney U	0,828	NS
Age group	Kruskal-Wallis H	0,484	NS
Civil Status	Kruskal-Wallis H	0,440	NS
Qualifications	Kruskal-Wallis H	0,423	NS
Country of Origin	Kruskal-Wallis H	0,714	NS
Income	Kruskal-Wallis H	0,448	NS

Source: own elaboration based on SPSS outputs

In all variables there are no statistically significant differences, since the test value is higher than 0.05 (p-value), that is, there are no differences by sociodemographic variable regarding the degree of importance given the elements of the aesthetics of the rural landscape.

Table 9: Hypothesis 2.3 Test value for statistical tests of urban landscape characteristics

Variables	Test	p-value	Significance
Gender	Mann-Whitney U	0,735	NS
Age group	Kruskal-Wallis H	0,988	NS
Marital status	Kruskal-Wallis H	0,450	NS
Qualifications	Kruskal-Wallis H	0,975	NS
Country of Origin	Kruskal-Wallis H	0,011	S
Income	Kruskal-Wallis H	0,102	NS

Source: own elaboration based on SPSS outputs

In all variables except for the country of origin there are no statistically significant differences, since the test value is greater than 0.05 (p-value), that is, there are no differences by sociodemographic variable regarding the degree of importance given the characteristics of the urban landscape.

Table 10: Hypothesis 2.4 Test value for statistical tests of urban landscape aesthetics

Variables	Test	p-value	Significance
Gender	Mann-Whitney U	0,710	NS
Age group	Kruskal-Wallis H	0,745	NS
Civil Status	Kruskal-Wallis H	0,104	NS
Qualifications	Kruskal-Wallis H	0,747	NS
Country of Origin	Kruskal-Wallis H	0,411	NS
Income	Kruskal-Wallis H	0,585	NS

Source: own elaboration based on SPSS outputs

It is verified that in all variables there are no statistically significant differences, since the test value is higher than 0.05 (p-value), that is, there are no differences by sociodemographic variable regarding the degree of importance given the elements of the aesthetics of the urban landscape.

H3: There is a relationship between the length of the stay and the visit to the northern regions of Portugal: For the Region of Porto Metropolitan Area; For the region of Trás-Os-Montes; For the Minho region; For the Douro region.
Pearson's Coefficient (Chi-Square) test was used to validate this research hypothesis.

Table 11: Hypothesis 3 - Test value for statistical tests by northern region of Portugal for chi-square test (Pearson coefficient)

Variables	Value	Df	p-value	Significance
Porto	5,942	4	0,204	Ns
Trás-os-Montes	8,134	4	0,087	Ns
Minho	12,663	4	0,013	S
Douro	7,794	4	0,099	Ns

S - Significant NS- Not significant Source: own elaboration based on SPSS outputs

As for the analysis of the results of statistical tests on the research hypothesis 3, we can conclude that:

- The inferential statistical analysis allows us to conclude that the relationship between the length of stay **is independent** of the visit to the " Porto Metropolitan Area" region (α=0.204; proof value<0.05; N=299);
- The inferential statistical analysis allows us to conclude that the relationship between the length of the stay **is independent** of the visit to the region "Trás-Os-Montes" (α=0.087; test value>0.05; N=299);
- The inferential statistical analysis allows us to conclude that the relationship between the length of the stay **is not independent** of the visit to the "Minho" region (α=0.013; test value<0.05; N=298);
- The inferential statistical analysis allows us to conclude that the relationship between the length of stay **is independent** of the visit to the "Douro" region (α=0.099; test value;0.05; N=299).

It's possible to conclude that for all regions of northern Portugal except for "Minho" there is no relationship regarding the length of stay.

H4: There is a relationship between the reason for the trip and the visit to the northern regions of Portugal. For the regions: Porto Metropolitan Area; Trás-Os-Montes; Minho; Douro.

Table 12: Hypothesis 4 - Test value for statistical tests for chi-square test (Pearson coefficient)

Variable "Porto Metropolitan Area"	Value	Df	p-value	Significance Value
Vacation/Leisure	0,182	1	0,669	NS
Touring Cultural	11,664	1	0,001	S
Shopping tourism	0,101	1	0,751	NS
Wine and gastronomy Tourism	0,416	1	0,519	NS
Business tourism	2,123	1	0,145	NS
Visit to family and friends	0,351	1	0,554	NS
Other(s)	0,029	1	0,864	NS

S - Significant NS- Not significant Source: own elaboration based on SPSS outputs

Based on the results of the statistical test we can observe that:

- The inferential statistical analysis allows us to conclude that the relationship between the visit to the region of "Porto Metropolitan Area" **is independent** of the reason "Vacation/leisure"(α=0.669; test value>0.05; N=240);
- The inferential statistical analysis allows us to conclude that the relationship between the visit to the region of the "Porto Metropolitan Area" **is not independent** of the reason "Cultural Touring" (αα=0.001; test value<0.05; N=240);
- The inferential statistical analysis allows us to conclude that the relationship between the visit to the region of the "Porto Metropolitan Area" **is independent** of the reason "Shopping tourism"(α=0.751; proof value>0.05; N=240);
- The inferential statistical analysis allows us to conclude that the relationship between the visit to the region of the "Porto Metropolitan Area" **is independent** of the reason "Gastronomic tourism"(α=0.519; test value>0.05; N=240);

- The inferential statistical analysis allows us to conclude that the relationship between the visit to the region of the "Porto Metropolitan Area" **is independent** of the reason "Business tourism"(α=0.145; proof value<0.05; N=240);
- The inferential statistical analysis allows us to conclude that the relationship between the visit to the region of the "Porto Metropolitan Area" **is independent** of the reason "Visit to family and friends" (αα=0.554; test value>0.05; N=240);
- The inferential statistical analysis allows us to conclude that the relationship between the visit to the region of the "Porto Metropolitan Area" **is independent** of the reason "Other(s)" (αα=0.864; proof value>0.05; N=240).

Based on these conclusions, we can affirm that there is only a statistical relationship between the "Cultural Touring" reason and the visit to the Porto region. Which means that the main motivation of the visit to this region is "cultural touring".

Table 13: Hypothesis 4.2 - Test value for statistical tests for chi-square test (Pearson coefficient)

Variable "Trás-Os-Montes"	Value	Df	p-value	Significance Value
Vacation/Leisure	0,545	1	0,460	NS
Touring Cultural	0,000	1	0,991	NS
Shopping tourism	0,730	1	0,393	NS
Wine and gastronomy Tourism	3,940	1	0,047	S
Business tourism	0,730	1	0,393	NS
Visit to family and friends	0,063	1	0,801	NS
Other(s)	0,228	1	0,633	NS

S - Significant NS- Not significant Source: own elaboration based on SPSS outputs

Based on the results obtained for the variables related to the “Trás-Os-Montes region” we can verify that:

- The inferential statistical analysis allows us to conclude that the relationship between the visit to the region of "Trás-Os-Montes" **is independent** of the reason "Vacation/leisure" (α=0.460; test value>0.05; N=17);
- The inferential statistical analysis allows us to conclude that the relationship between the visit to the region of "Trás-Os-Montes" **is independent** of the reason "Cultural Touring" (α=0.991; test value>0.05; N=17);
- The inferential statistical analysis allows us to conclude that the relationship between the visit to the region of "Trás-Os-Montes" **is independent** of the reason "Shopping tourism" (α=0.393; proof value>0.05; N=17).
- The inferential statistical analysis allows us to conclude that the relationship between the visit to the region of "Trás-Os-Montes" **is not independent** of the reason "Wine and gastronomy tourism" (αα=0.047; test value;0.05; N=17);
- The inferential statistical analysis allows us to conclude that the relationship between the visit to the region of "Trás-Os-Montes" **is independent** of the reason "Business tourism" (α=0.393; test value>0.05; N=17);
- The inferential statistical analysis allows us to conclude that the relationship between the visit to the region of "Trás-Os-Montes" **is independent** of the reason "Visit to family and friends" (α=0.801; test value>0.05; N=17);
- The inferential statistical analysis allows us to conclude that the relationship between the visit to the region of "Trás-Os-Montes" **is independent** of the reason "Other(s)" (αα=0.633; proof value>0.05; N=17).

We can say, based on these results, that the only reason for travel that is correlated with the visit to the region of "Trás-Os-Montes" is the reason "Wine and gastronomy tourism".

Table 14: Hypothesis 4.3. Test value for statistical tests for chi-square test (Pearson coefficient)

Variable "Minho"	Value	Df	p-value	Significance Value
Vacation/Leisure	10,475	1	0,001	S
Touring Cultural	0,589	1	0,443	NS
Shopping tourism	0,944	1	0,331	NS
Wine and gastronomy tourism	0,001	1	0,973	NS
Business tourism	0,043	1	0,836	NS
Visit to family and friends	0,063	1	0,801	NS
Other(s)	5,030	1	0,025	S

S - Significant NS- Not significant Source: own elaboration based on SPSS outputs

Based on Pearson's coefficient test results, it's possible to draw the following conclusions:

- The inferential statistical analysis allows us to conclude that the relationship between the visit to the "Minho" region **is not independent** of the reason "Vacation/leisure"(α=0.001; test value<0.05; N=31).
- The inferential statistical analysis allows us to conclude that the relationship between the visit to the "Minho" region **is independent** of the reason "Cultural Touring"(α=0.443; test value>0.05; N=31).
- The inferential statistical analysis allows us to conclude that the relationship between the visit to the "Minho" region **is independent** of the reason "Shopping tourism"(α=0.331; proof value>0.05; N=31).
- The inferential statistical analysis allows us to conclude that the relationship between the visit to the "Minho" region **is independent** of the reason "Wine and gastronomy tourism" (αα=0.973; test value>0.05; N=31).
- The inferential statistical analysis allows us to conclude that the relationship between the visit to the "Minho" region **is independent** of the reason "Business tourism"(α=0.836; proof value>0.05; N=31).
- The inferential statistical analysis allows us to conclude that the relationship between the visit to the "Minho" region **is independent** of the reason "Visit to family and friends" (αα=0.810; test value>0.05; N=31).
- The inferential statistical analysis allows us to conclude that the relationship between the visit to the "Minho" region **is not independent** of the reason "Other(s)" (αα=0.025; proof value<0.05; N=31).

Based on these conclusions, the reasons "Vacation/leisure" and "Other(s)" are directly correlated with the visit to the Minho region.

Table 15: Hypothesis 4.4. Test value for statistical tests for chi-square test (Pearson coefficient)

Variable "Douro"	Value	Df	p-value	Significance Value
Vacation/Leisure	0,000	1	0,985	NS
Touring Cultural	12,765	1	0,000	S
Shopping tourism	1,667	1	0,197	NS
Wine and gastronomy tourism	4,362	1	0,037	S
Business tourism	2,656	1	0,103	NS
Visit to family and friends	4,157	1	0,041	S
Other(s)	2,145	1	0,143	NS

S - Significant NS- Not significant Source: own elaboration based on SPSS outputs

Based on Pearson's coefficient test results it's possible to verify that:

- The inferential statistical analysis allows us to conclude that the relationship between the visit to the "Douro" region **is independent** of the reason "Vacation/leisure" (α=0.985; test value>0.05; N=122).
- The inferential statistical analysis allows us to conclude that the relationship between the visit to the "Douro" region **is not independent** of the reason "Cultural Touring" (α=0.985; test value<0.0001; N=122).
- The inferential statistical analysis allows us to conclude that the relationship between the visit to the "Douro" region **is independent** of the reason "Shopping tourism" (α=0.197; proof value>0.05; N=122).
- The inferential statistical analysis allows us to conclude that the relationship between the visit to the "Douro" region **is not independent** of the reason "Wine and gastronomy tourism" (α=0.985; test value>0.037; N=122).
- The inferential statistical analysis allows us to conclude that the relationship between the visit to the "Douro" region **is independent** of the reason "Business tourism" (α=0.103; proof value>0.05; N=122).
- The inferential statistical analysis allows us to conclude that the relationship between the visit to the "Douro" region **is not independent** of the reason "Visit to family and friends" (αα=0.041; proof value<0.05; N=122).
- The inferential statistical analysis allows us to conclude that the relationship between the visit to the "Douro" region **is independent** of the reason "Other(s)" (αα=0.143; proof value<0.05; N=122).

According to these conclusions, there is a relationship between the reasons "Cultural Touring", "Wine and gastronomy tourism" and "Visit to family and friends" and the visit to the Douro region, which shows that this is the region of Northern Portugal with greater significance in terms of the motivation of the traveler.

Conclusion

Based on recent literature that addresses the landscape role as a tourist resource, exploring the connection between the landscape and its aesthetics and its influence on tourists, that is, the attractiveness factor of a landscape (De Aranzabal, Schmitz and Pineda, 2009; Carneiro, Lima & Silva, 2015; Breiby, 2015; Cébrian & Sánchez, 2016; Todorović, 2016; Serrano-Montes, Martínez-Ibarra, Arias-García, 2019; Lontai-Szilágyi, Bertalan-Balázs, Zsiros, Vasvári, Kumar, Nilanchal, Martonné Erdős, & Szabó, 2019; Lee, 2020), this study proposed four research hypotheses for the northern region of Portugal: Tourists visiting the region of Porto and northern Portugal give importance to the characteristics of the rural landscape, to the aesthetics of the rural landscape, to the characteristics of the urban landscape, and to the aesthetics of the urban landscape; There are differences regarding the importance of the characteristics of the rural and urban landscape by sociodemographic variable; There is a relationship between the length of the average stay and the visit to the northern regions of Portugal; and finally, there is a relationship between the reason for the trip and the visit to the northern regions of Portugal: Porto Metropolitan Area; Trás-os-Montes; Minho, and Douro.

Some of the main results showed a statistical evidence to indicate that visitors from the Region of Porto and Northern Portugal attach importance to the characteristics and aesthetics of the landscape; the only reason for travel which is correlated with the visit to the region of "Trás-os-Montes" is the reason "Wine and gastronomy tourism"; a statistical relationship between the "Cultural Touring" reason and the visit to the Porto region; the reasons "Vacation/leisure" and "Other(s)" are directly correlated with the visit to the Minho region; there is a relationship between the reasons "Cultural Touring", "Wine and gastronomy tourism" and "Visit to family and friends" and the visit to the Douro region, which shows that this is the region of Northern Portugal with greater significance in terms of the motivation of the traveler.

Considering these results, Destination Management Organization's (DMO) should seek to enhance the landscape as a tourist resource to achieve tourists' maximum satisfaction, to manage and plan the available resources of a tourist landscape in order to achieve two purposes: to add tourist value to the

place (taking into account its sustainability in several dimensions) and use it as a resource that distinguishes itself as a competitive advantage over other destinations.

The measures to be taken to foster the growth of landscape tourism according to this research, must consider further analysis about the visitors motivations and categorize the landscape into different classifications (e.g. urban, wine, cultural), analyze the appreciation of the landscape by visitors to make an assessment of the landscape and viewpoints and identify those who are most valued, invest in infrastructure, access and equipment present in viewpoint locations (information panels, secure structures), define landscape routes to disseminate the landscape and viewpoints as a tourist resource and place signage and information panels as a guide in viewpoint locations.

Energy Demand in The Hierarchy of Households' Socio-Economic Needs

Jolanta WITEK

The Jacob of Paradies University, Gorzów Wlkp., Poland

Abstract

Energy needs are all activities that consume rather heat or electricity and are necessary for the daily functioning of households. Energy is very important for modern lifestyles and social inclusion: it is essential for education, health, safety and well-being. Today, energy constitutes the basic necessity for all households. However, research on energy demand is a complex area that covers physical availability of energy sources, income and housing conditions, as well as individual and social factors in households. This is an important and complex issue that is part of the current EU energy policy, described, inter alia, in the latest package of solutions entitled "Clean energy for all Europeans", prepared by the European Commission in 2019. On the basis of theoretical findings regarding the issue of human needs and empirical research of households, there has been developed a research concept enabling the study of the place of energy demand in the hierarchy of household needs. It takes into account the conclusions from the analysis of energy demand in households taking into consideration consumption, sources and energy commodities used, as well as the results of public opinion surveys. The study, including statistical data analysis and public opinion reports, was conducted in regards to the Polish market. The proposed model presents the determinants of energy demand for households in the context of their place in the hierarchy of needs by A.H. Maslow.

Keywords: Energy, Energy Consumption, Households, Hierarchy of Needs, Energy Poverty

Introduction

Energy needs are all activities that use either heat or electricity, necessary to maintain a decent standard of living, i.e. heating the apartment and water, lighting, preparing meals and using basic home electronics and household appliances. Energy is very important for modern lifestyles and social inclusion: it is essential for education, health, safety and well-being. At the same time, energy policy and environmental policy of the state are often treated as decision areas requiring specialized technical knowledge, reserved for a narrow circle of experts. However, one should be aware of the fact that the effects of decisions in these areas have a direct impact on the state of health and sense of security of citizens (Gwiazda & Ruszkowski 2016). On average, energy expenditure accounts for 6% of the annual expenditure of 200 million households in the EU. The lowest-income households spent almost 9% of their total expenditure on energy in 2014. This represents a 50% increase over the past ten years, which is much more than in the case of average households (European Commission, 2019). Therefore, the energy transformation cannot be separated from socio-economic issues. This is reflected in the new Clean Energy for All Europeans package prepared by the European Commission in 2019.

Today, energy constitutes the basic necessity for all households. However, research on energy demand is a complex area that covers physical availability of energy sources, income and housing conditions, as well as individual and social factors in households. The aim of this article is to develop a research model indicating the scope of conditions for placing energy demand in the hierarchy of household needs. Research problems were formulated in the form of the following questions:

- How do households consume energy, taking into account the consumption purpose, technical means used and energy sources?
- What components should research on the place of energy demand in the hierarchy of household needs include?
- In what categories of needs should energy demand be classified?

For the purpose of the work, desk research was conducted in relation to households operating in Poland. Domestic and foreign statistical data and public opinion reports were used to this end.

The needs of consumers in A. Maslow's hierarchy of needs

The concept of need is inseparably linked to humankind. Defining *needs* is difficult due to the inherent complexity of the concept of 'need', so it is not surprising that numerous definitions have been proposed depending on the scientific discipline (including psychology, sociology, economics). According to J.F. Tobar Arbulu (1987), a challenging problem of needs research is how to define a need. *Needs* are theoretical constructs. The truth of those needs cannot, therefore, be proven in a direct physical way. The existence of a need can be concluded indirectly either from postulation or from the respective satisfiers that a person uses and strives for, or from symptoms of frustration caused by any kind of nonsatisfaction.

In economic literature, a need for the most part, is defined as some kind of state of an individual when he or she misses or feels a shortage. In positive form, an individual needs something and is interested in it. M. Pohorille (1985) defines need by claiming that shortage arouses an organism to action toward removing it. Similarly, L. Rudnicki (1996) believes that a need is a factor that activates the function to act towards an appropriate change of this state. The state of deficiency is felt as distress and inclines to take actions aimed at its "reduction", i.e. satisfying the need. Need is also defined by P.T. Beatty (1981) as a measurable discrepancy existing between a present state of affairs and a desired state of affairs, as asserted either by an "owner" of need or an "authority". In the former instance, need is described as a motivational need; in the latter instance, need is described as a prescriptive need. Therefore, the sources of needs are the human body (its biological and psychological structure) and human social environment. In most cases, a condition for meeting the need is its prior recognition. In the context of consumer behaviour, this occurs as a result of (Garbarski 1998):

- Lack of product or service (physical absence of the product in most cases prompts purchase);
- Obtaining information about a new product (may change existing habits);
- Emergence of new needs (caused e.g. by observing other people);
- Emergence of new financial opportunities (a change in material situation often changes the perception of previously consumed products and services);
- Changes in expectations for a product or service.

The complexity of needs is affected, among others, by the fact that satisfying them is of temporary nature, and that satisfying some needs often creates others. The number of needs is unlimited. Furthermore, they can be both complementary and substitutable, i.e. mutually replaceable. In the literature on the subject, attempts are made to group needs, however, it should be noted that due to their diverse nature, there is no way of classification that is universal and adequate for all individuals and their needs. The hierarchy of needs by A.H. Maslow (1943) is one of the best known ways of classifying needs. It is a motivational theory comprising a five-tier model of human needs, often depicted as a pyramid (Figure 1).

A. H. Maslow (1943) divided needs in accordance with the degree of necessity to satisfy them. Using this criterion, he established a list of innate needs, ranging from the lowest to the highest:

- physiological needs - e.g. hunger, thirst, sleep, providing protection against atmospheric influences;
- safety needs - regarding e.g. protection against injury, death or loss of own belongings, providing care during illness;
- belongingness and love needs - e.g. belonging to a family;
- esteem needs - regarding e.g. prestige, success, respect;
- self-actualization (self-realization) - e.g. the need to realize dreams, life plans, etc.

Fig.1: Maslow's hierarchy of needs

Source. (McLeod 2018)

A.H. Maslow (1943) initially stated that individuals must satisfy lower level deficit needs before progressing on to meet higher level growth needs. In his theory, he argued that human needs are unlimited, after a need is satisfied, another need will arise, needs have a certain hierarchical order, no need or drive can be considered independently, every need is related to satisfaction or dissatisfaction of other needs, and unsatisfied needs are a great source of motivation for humans (Maslow, 1943, 1954). For example, the most basic human need is physical survival, which will be the first factor to motivate their behaviour. After reaching this level, people are motivated by further categories of needs located at higher levels of the pyramid. Table 1 presents selected products that meet individual categories of consumer needs.

Table 1: Motivation focused on consumers' behaviour in context of Maslow's conception

Needs according to Maslow	The examples of consumers' behaviour – product categories
Self-actualization needs	Products enabling one's development , e.g. trips, education, hobbies, entries to museums and theaters
Esteem needs	Products „helping' gain the recognition of the other people by making the person look wealthy, e.g. designer's clothes, cars, furniture, credit cards, exclusive sport centers located outsider the town, high-proof spirits, cars etc.
Belongingness needs	Products making the buyer look like an outstanding person in the eyes of other people, e.g. luxury products, new products also clothes, beauty products, clubs and drinks
Safety needs	Buying the sufficient number of products which ensure „financial collateral', e.g. insurances, alarm systems, pension, investments and also products which ensure physical safety (in order to avoid damage), e.g. seat belts
Biological and physiological needs	Medicines, elementary and essential products such as food or beverages

Source. (Hanna 1980).

However, the evolution of A.H. Maslow's opinions over the years (1943, 1962, 1987) should be noted. As a consequence of further research, his concept of hierarchy of needs was improved. In his later works (Maslow 1987), he clarified that satisfaction of needs is not an "all-or-none" phenomenon,

admitting that his earlier statements may have given “the false impression that a need must be satisfied 100 percent before the next need emerges”. A. H. Maslow noted that the order of needs may vary depending on external conditions as well as individual differences. Furthermore, he stated that most behaviours have many motivations and pointed out that “any behaviour tends to be determined by several or all of the basic needs simultaneously rather than by only one of them" (1987). Due to the fact that A.H. Maslow’s hierarchy of needs is a frequent research tool (Tikkanen 2007), it will be used to explain the complexity of household energy needs.

Research Concept

Civilization development resulted in energy demand becoming one of the main human needs. Already in 2012, the OECD report (International Energy Agency 2012) clearly indicated that three classes of resources are considered critical in modern societies, i.e. energy, water and food. The order of their listing is not accidental and results from the hierarchy of importance for the functioning of societies:

- energy sufficiency allows the use of energy-consuming technologies for desalination, treatment and transport of water,
- energy and water abundance ensures the production of food in quantities that meet the needs.

Therefore, there occurs a mechanism of secondary goals as, in modern economy, access to energy makes it possible for individual and institutional buyers to meet the basic needs, like food production and satisfying hunger, as well as providing access to clean water. It is therefore a truism to say that energy is an essential good, which conditions the satisfaction of both lower and higher needs of buyers. This obvious statement does not explain the complexity of the problem. Therefore, a broader understanding of the determinants of energy demand in the hierarchy of social needs of households is required. Otherwise, simplifications affecting their operating conditions may be used. The indicated simplifications relate both to the relativization of social needs in the field of access to energy sources, and ways of satisfying needs based on access to energy.

The literature includes stands against the prioritization of energy needs in line with the initial version of A. Maslow's hierarchy of needs, which assumes the order of appearance and implementation of individual categories of needs. An example is the opinion of T. Michalak (2016)), who points out that in Poland, according to the Energy Law, energy security is "a state of the economy that can cover the current and long-term demand of consumers for fuels and energy in a technically and economically justified manner, while maintaining the environmental protection requirements" (Energy Law Act 1997). Thus, the statutory definition treats three aspects, that is technical, economic and ecological, which are critical for a positive assessment of the state of energy security, equally, assuming that they are fulfilled in a mutually harmonized way. The author, while analysing Polish energy policy, noted the use of argumentation to hierarchize the mutual relations of the above-mentioned aspects of energy security towards its users. In the proposed discourse, the technical aspect is presented as fundamental. This means that highest importance is attributed to the fact of energy provision, as its deficiencies are the most expensive. Next is the economic aspect, albeit treated as secondary. This means that in the accepted argument, any price is justified, as long as it allows access to electricity, since the lack thereof is the most expensive. Finally, the ecological aspect is treated as a higher need that should be implemented in the situation where the first two categories of needs are met, and in particular when the implementation of the ecological need does not threaten the technical and economic aspect (Kowalak 2016).

Therefore, when considering the place of energy demand in the hierarchy of socio-economic needs, attention should be paid to the complexity of this issue. Figure 2 proposes components for building the concept of energy demand conditions in the hierarchy of household needs.

In order to build a model of household energy demand conditions, an in-depth analysis of the selected market in terms of energy consumption by a given user segment is necessary. For the purposes of the article, desk research was conducted in relation to households operating in Poland. Domestic and foreign statistical data and public opinion report were used to achieve this objective.

Fig. 2: Components of the research concept

Source. Own elaboration.

In order to present the research context, it should be clarified that the specificity of the Polish energy market lies in the very high share of coal in electricity production, which constituted as much as 78.4% in 2017. Primary energy consumption in Poland was 94.3 Mtoe in 2017. Renewable energy in gross final energy consumption amounted to 11.3% in 2016 (Atlas energii 2018). According to the data presented by EUROSTAT and the Statistics Office (2019), the population of Poland represented 7.4% of the total population of the EU-28 countries in 2018. Poland occupied the 6th place among the European Union countries; after Germany (16.2%), France (13.1%), Great Britain (12.9%), Italy (11.8%) and Spain (9.1%). There were 14.4 million households in Poland. The number of households in Poland represented 6.5% of total households in the EU-28. In terms of the number of households, Poland also came 6th among European Union countries. The average number of people per household in Poland was 2.6 and was higher than the EU average of 2.3.

Energy Demand of Polish Households

Reasons for energy demand in Polish households by energy sources and commodities used

According to research conducted by the Statistics Office (2019), Polish households use energy for the following reasons:

- Space heating,
- Water heating,
- Cooking,
- Lightning,
- Using household appliances and audio/video devices,
- Forced ventilation and air conditioning
- Use of private means of transport.

The characteristics of energy consumption by households are broken down below in accordance with the purpose of energy consumption, as well as the sources and energy commodities used.

Space Heating

Almost half of all households, i.e. 45.4%, applied heating equipment that used solid fuel, among which the most common were double-function central heating boilers used to generate thermal energy and heat water (Table 2). Electricity-powered heating appliances were used by 5.3% of households, while electric heating was more often treated as additional heating than primary one.

Table 2: Space heating by technologies

Devices	Households using a given device
Double-function boiler – solid fuels	19%
Single-function boiler – solid fuels	17%
Stoves in rooms – solid fuels	5%
Fireplace – solid fuels	2%
Double-function boiler – natural gas	10%
Single-function boiler –natural gas	3%
Non-portable and portable heaters, underfloor heating - electricity	3%
Other techniques	1%
District heat	40%

Source. (Statistics Poland, Energy consumption in households in 2018, Warsaw 2019)

There has been an increase in the number of solar devices and heat pumps used for the purpose of heating living spaces. The study identified that 0.13% of households were heated by solar energy. Households using heat pumps constituted 0.28%.

Analysis of energy sources used for space heating indicates that the leading role was played by solid fuel and district heating. Solid fuel is the basic commodity of heating energy for single-family houses, whereas district heating is used in multi-family buildings (blocks of flats). The two most important and most commonly used solid fuels are hard coal and firewood, while other fuels (other types of biomass, lignite, coke) were less frequently used. Hard coal and firewood were usually consumed simultaneously or interchangeably in the same boiler and furnace. Fewer households used only coal (15.3% of households) or wood (7.3%). Two typical strategies are:

- both fuels are burned interchangeably, depending on current availability conditions and prices,
- wood is burned in warmer periods, while coal, as fuel with higher calorific value, in colder periods.

District heating was used to heat spaces by 40.4% of households. Natural gas was placed third among energy commodities used for this purpose, as it was used by 14.0% of households, including 13.1% of households where it constituted the primary commodity. Another medium used in space heating was electricity, which was used by 5.1% of households (and being the primary commodity for 2.6% of households). The least number of households used liquid fuels to heat spaces. Only 0.45% of households used heating oil.

Water Heating

As in the case of space heating, methods of heating water for domestic purposes also varied. The share of individual methods is presented in Table 3, following the principle of class inseparability, i.e. the use of two or more different water heating devices by many households (this applies to 17.2% of households).

Table 3: Water heating by technologies

Devices	Households using a given device
District heating installation	32%
Boiler or water heater - electricity	24%
Bathroom heater – natural gas	17%
Double-function boiler – natural gas	10%
Double-function boiler or water heater – solid fuels	15%
Other techniques	1%
Lack of running hot water	1%

Source. (Statistics Poland, Energy consumption in households in 2018, Warsaw 2019)

The position "no hot running water" in practice means the possibility of heating water only in kitchen appliances, and most often on a solid fuel stove. Such living conditions concerned 1.0% of households, i.e. 144 thousand households, which constitutes over 400 thousand inhabitants of the country.

In order to heat water for living purposes, households most often used: district heating - 31.6% of households, natural gas - 26.0%, electricity - 23.9%, and solid fuel, the least often source - 23.8% of households.

Cooking

Cooking meals is the third most important, after heating spaces and water, process of energy consumption in Polish households (Table 4).

Table 4: Equipment of households with cooking appliance

Devices	Households using a given device
Electric-only cooker with oven	9.90 %
Electric-only cooker without oven	5.65 %
Separate electric oven	9.16 %
Combined gas-electric cooker	56.88 %
Gas-only cooker	29.41 %
Solid fuel fired cooking stove	3.49 %
Microwave oven	49.87 %

Source. (Statistics Poland, Energy consumption in households in 2018, Warsaw 2019)

The most popular type of stove in Poland is a gas-electric stove with gas burners and an electric oven. More than half (56.9%) of all households had such a stove, while 29.4% used a gas stove. Whereas, 20.2% of households were equipped with an electric stove. Half of the households, i.e. 49.9%, apart from the main stove, had a microwave used as an additional device for preparing meals.

LPG fired stoves were another device used to cook meals. Whereas, solid fuel stoves, often called "charcoal burner", were found in 3.5% of households, and in many cases they were not the only device used for cooking meals. They can also be used to heat spaces, as well as boil and heat water through a heat exchanger or a heating plate. This type of stove is built of ceramic or metal material and has a hating plate where pots are placed. Coal, wood and other types of biomass can be burned in this type of stove. In small apartments and small single-family houses, it can act as the only source of heat. In old housing stock, where liquid gas stoves were used, old solid fuel stoves were often treated as back-up appliances, e.g. when one is temporarily unable to buy gas.

In accordance with the analysis of energy sources used by households, the most common energy sources used for cooking meals included: electricity (75.5% of households), natural gas (51.9%) and LPG (33.8%).

Forced Ventilation and Air Conditioning Equipment

Due to the prevailing climatic conditions in Poland, air conditioning devices were not included in the category of popular household appliances. Only 2.8% of all households have this type of appliance, with their resources being presented in Table 5.

Table 5: Households equipped with mechanical ventilation and air conditioning equipment

Devices	Households using a given device
Central air-conditioning	1.42%
Air-conditioners installed in rooms	1.20%
Air-conditioners installed outside of the building	0.20%
Fan heaters	0.14%
Evaporative coolers	0.04%
Forced ventilators	9.68%
Recuperators	0.26%

Source. (Statistics Poland, Energy consumption in households in 2018, Warsaw 2019)

Lighting of Dwellings

Households used lighting mainly for indoor residential purposes. Over 1/3 of respondents also illuminated the exterior. The energy commodity in this case were the appropriate types of bulbs, as shown in Table 6. Most households used LED bulbs, whereas traditional bulbs came second, and halogen bulbs third.

Table 6: Equipment of households with bulbs

Types of bulbs	Households using specific type of bulbs
All bulbs inside dwelling	100.00 %
– Incandescent bulbs	56.55%
– Compact fluorescent lamps	29.60%
– Fluorescent tubes	15.03%
– Halogen bulbs	36.93%
– LED bulbs	70.14%
– Other bulbs	11.82%
Bulbs located outside the building	37.60%

Source. (Statistics Poland, Energy consumption in households in 2018, Warsaw 2019)

Household appliances and audio/video devices

Households use a wide spectrum of home appliances and electronics (Table 7). The categories of household appliances tested are: refrigeration equipment, washing machines, dishwashers and vacuum cleaners, and the categories of audio/video devices are: television sets, sound and image reproduction equipment and computers.

Table 7: Equipment of households with household appliances and audio/video devices

Devices	Households using a given device
Refrigerator (1-door)	16.06 %
Combined fridge-freezer (2-door)	82.27%
Freezer	11.68 %
Automatic washing machine without dryer	92.14%
Combined washer-dryer	2.08 %
Clothes dryer	0.92 %
Non-automatic washing machine	2.56 %
Dishwasher	31.82 %
TV set	93.92 %
– CRT	9.78 %
– flat screen (able to receive digital broadcasts)	69.49%
– other	20.73 %
Home cinema set	9.24 %
Radio or radio/tape-recorder with CD player	57.49%
Mobile computer (laptop)	56.82 %
Printer or multifunction device	21.66%
Desktop computer	18.87%

Source. (Statistics Poland, Energy consumption in households in 2018, Warsaw 2019)

Appliances commonly owned by households included: television sets (93.9% of households, where 64.2% of households had only one set, and 29.7% two or more), automatic washing machines (92.1% of households), combined fridge-freezers (82.3% of households) and radios or radio-cassette players (57.5%). 56.8% of households were in possession of portable computers (laptops). Nearly half of households, i.e. 45.6%, used one laptop, whereas the others used two or more. 18.9% of households used desktop computers, with 17.8% using one computer, while the remaining households used two or more.

Passenger cars in households

Table 8 presents households having passenger cars. In 2018, they were used by 66.2% of all households. Almost half of the households (46.9%) had only one car, 16.7% had two cars, and almost 2.7% of households made use of three cars. About 1/3 of households (33.8%) did not own or use a passenger car.

Table 8: Passenger cars in households

Cars	Households using cars
Passenger cars, of which:	66.19 %
– petrol powered without LPG-system	38.86 %
– petrol powered with LPG-system	10.44 %
– diesel oil powered	24.90 %
– hybrid cars	0.12 %
– electric cars	0.02 %

Source. (Statistics Poland, Energy consumption in households in 2018, Warsaw 2019)

On average, one household used 1.33 cars. About 2/3 of passenger cars (64.9%) used by households were cars with petrol engines (including 13.2% of vehicles adapted to burn LPG), 34.9% were cars with diesel engines (diesel oil) and 0.17% were modern hybrid or fully electric cars.

Assessment of energy sources used in the opinion of Polish households

To assess Polish households' opinions on the used energy sources, a research report "Poles on Energy Sources, Energy Policy and Environmental", conducted in 2016 by Centre for Public Opinion Research (CBOS 2016) on a representative national research sample, was employed. The study covered the overall functioning of the energy sector in Poland, understood as the generation, transmission and distribution of energy.

In the survey, respondents assessed public confidence in energy sources in terms of their safety and prospectiveness (Table 9). In both spheres, the highest confidence values, i.e. over 80%, were obtained by renewable energy sources (RES). Coal (both hard coal and lignite) holds the dominant position in conventional power engineering, but with significantly lower values: in the aspect of safety - about 50%, and in terms of prospectiveness - about 30%.

Table 9: Public assessment of energy sources in Poland

Scope of assessment	Energy sources				
	Coal	Petroleum	Natural gas	Nuclear fuel	RES
Safety	52%	47%	60%	24%	87%
Prospectiveness	29%	38%	55%	52%	82%

Source. (CBOS 2016)

In the above context, respondents were asked to indicate the strategy that Poland should adopt in the next few years (until 2030) in the field of power engineering development. It turns out that Poles strongly focus on renewable energy sources: as many as 89% of the respondents share the view (over half - strongly) that during this period *it is necessary to significantly increase electricity production from renewable energy sources (RES), which will raise clean environment standards in Poland and strengthen the impact of citizens and local communities on decisions regarding energy.*

For almost two-thirds of Poles, it is also important to know *which source (conventional or renewable) the electricity used in the apartment comes from.* Declarations of great importance in this matter are the more frequent, the better the assessment of one's own material living conditions. Slightly over half of the respondents (52%) say that they would be willing to pay more for energy if it came from renewable sources. Among these, the majority (34% of all respondents) are ready to accept an increase in the renewable energy fee by no more than 5%. In total, nearly one in five respondents would agree to pay at least 6% more for "green energy" than today. Readiness to pay higher fees for energy from renewable sources is most often declared by people for whom it is important to know the source of energy they use in everyday life. The vast majority (81%) of Poles are aware of their personal impact on the state of the environment.

Therefore, Polish households understand the relation between energy policy and the state of the environment. Nearly three-quarters of respondents believe that environmental hazards associated with global warming and carbon dioxide emissions into the atmosphere are a very important problem. Only 5% of Poles downplay this issue, considering it to be of little importance (Figure 3).

Fig. 3: Assessment of the importance of global warming problems, carbon dioxide emission into the atmosphere and the associated environmental risk
Source. (CBOS 2016)

Fig. 4: Risk assessment from occurring phenomena (three answers possible)
Source. (CBOS 2016)

Furthermore, the problem of environmental pollution (58%) was most often indicated as the greatest threat among the phenomena and threats of civilization development. Slightly more than half of the respondents (51%) mentioned the threat of diseases of affluence (Figure 4).

The research results presented above are in line with the assessment of Poles regarding the use of energy sources and production methods in the context of carbon dioxide emissions. Generating energy is usually accompanied by carbon dioxide emissions that negatively affect the climate. In the opinion of the vast majority of Poles, the most harmful raw materials used for energy production are: hard coal, lignite and crude oil. In the opinion of the vast majority of respondents, the sources of energy that do not emit carbon dioxide at all are renewable sources. According to the respondents, solar, wind, hydro and geothermal energy that does not emit carbon dioxide is climate-friendly (Table 10).

Table 10: Public assessment of the impact of selected energy sources and energy production methods on climate (in%)

Energy sources - production methods	High carbon dioxide emission, harmful to the climate	Low carbon dioxide emission, neutral to the climate	Does not emit carbon dioxide, climate friendly	Hard to say
Hard coal	78	11	1	9
Lignite	68	15	1	16
Crude oil	54	21	3	22
Natural gas	20	44	12	24
Nuclear energy	15	16	42	27
Biofuels	6	38	34	23
Water energy	1	7	83	10
Wind energy	1	6	85	8
Solar energy	1	4	87	8
Geothermal energy	0	4	75	21

Source. (CBOS 2016)

The unequivocalness of self-assessment of Poles' knowledge on energy-related topics that is visible in the research results may be surprising. When asked directly how they assess their knowledge about the functioning of the power industry, understood as the generation, transmission and distribution of electricity in Poland, the respondents in the vast majority said that they knew little (62%) or nothing (24%) at all. Therefore, the presented opinions of Poles should be interpreted in the context of their sensitivity in terms of interest in their own health and the state of the environment at the local and global level. An analysis of the consistency of research results has allowed to assume that Poles have general awareness about energy, including preferences regarding the development of energy sources as well as opinions related to climate policy. The presented results of the sociological research are considered to be the first approach to the state of energy awareness of the Polish society of such broad and comprehensiveness, and indicate the complexity of the studied issues in the context of building a hierarchy of social needs regarding energy demand. Furthermore, they indicated a great interest of Polish households in energy issues in the broader context of caring for the climate and concern for the state of the environment.

The concept of examining the place of energy demand in the hierarchy of social needs of households

To describe the complexity of placing energy demand in the hierarchy of needs of households, the research model presented in Figure 5 was developed.

Fig. 5: The concept of examining the place of energy demand in the hierarchy of social needs of households

Source. Own elaboration.

The model was based on theoretical findings regarding human needs and empirical research on households. It takes into account the conclusions from the analysis of energy demand in households taking into consideration consumption, used energy sources and commodities, as well as the results of public opinion surveys. The proposed model schematically shows the conditions of household energy demand. The analysis makes it possible to place the energy needs of households in the hierarchy of needs divided into two main categories in accordance with the theory presented by A.H. Maslow:

- Deficiency needs,
- Being (growth) needs.

Energy demand in households based on deficiency needs

Energy needs are all household activities that use either heat or electricity for everyday operation. If a household has difficulties in satisfying its energy needs due to low income or housing characteristics, then energy poverty occurs.

According to this approach, a household is energy poor if it simultaneously meets two criteria: low income and high hypothetical energy expenditures, i.e. those that on average would allow it to meet standard energy needs. Hypothetical energy expenses are a derivative of the features of the inhabited building (apartment area, building age, heating method) and energy prices.

The scale of energy poverty in Poland is significant (Sałach & Lewandowski, 2018). In 2016, 4.6 million Polish residents, i.e. 12.2%, were affected by it (Figure 6). Half of them had a low income, which indicates that energy poverty should not be seen as an aspect of income poverty, but rather as a phenomenon affecting people with relatively low income and living in buildings that require relatively high energy expenditure. The energy poverty rate decreased by 2.2 percent points between 2012 and 2016, mainly due to the growing income of the population. However, this phenomenon invariably concerned mainly the inhabitants of single-family homes, especially in villages and in small towns. Energy-poor households more often than low-energy households used boilers or stoves for solid fuels as heat sources, and less often were located insulated buildings.

Fig. 6: Energy poverty in the years 2012-2016 in Poland

Source. (Sałach, Lewandowski 2018)

There is no common definition of energy poverty in the EU (Energy Atlas 2018). Only a third of countries officially recognize it, and just four of them - Cyprus, France, Ireland and the United Kingdom - have introduced a legal definition of this phenomenon. Still, it is estimated that 50-125 million EU citizens (10-25% of the population) are at risk of energy poverty, as shown in Figure 7.

Fig. 7: Energy poverty in EU 28

Source. (Energy Atlas 2018)

Energy poverty has significant consequences for both individual households and society as a whole. It causes low quality of life and health problems. Furthermore, it has economic and environmental effects, such as illegal logging or air pollution from the combustion of unsuitable fuels.

Energy demand in households based on being (growth) needs

Energy demand as a higher order need is mainly visible in the survey of households' opinions on the used energy sources and their consequences. According to the presented research (CBOS 2016), households understand the relation between the type of energy used and the state of the environment, climate change and their health. Support for both renewable energy sources and individual energy production in Europe is constantly growing. However, there is no European database, and thus it is difficult to estimate the number of citizens involved in this process across the EU (Atlas Energy 2018). Analyzes for the most developed countries such as Denmark and Germany indicate a positive trend. Central and Eastern European countries lack adequate political conditions, while fossil fuels and nuclear energy are preferentially favoured by governments. However, these countries have great potential. For example, Polish society expects the state to carry out an energy transformation. It is increasingly recognizing the danger resulting from poor air quality, rising energy costs, and climate change. The preferred direction of energy development in Poland is not coal and fossil fuels, but renewable energy sources. Figure 8 presents the results of social research carried out by various research laboratories over the years 2014-2018. They prove constant high support for the implementation of renewable energy sources.

Fig. 8: Social support for renewable energy development in Poland in 2014-2018
Source. (Atlas Energii 2018)

The desire to use renewable energy sources is dictated not so much by securing basic energy needs, but results from ecological awareness and responsible civic attitude towards all people on Earth and future generations.

Summary

The presented concept of examining the place of energy demand in the hierarchy of needs of households takes into account all the conditions related to both the psychological nature of a person, their economic conditions and the availability of energy sources and their commodities. However, it does not indicate the location of specific energy consumption goals in the hierarchy of needs. In model terms, this is consistent with A.H. Maslow's final approach to individual and flexible appearance of needs. Nevertheless, the presented concept may form the basis for designing studies that will examine

the described issues in more depth. The study of placing energy demand in the hierarchy of household needs is an important and complex issue that is part of the current EU energy policy. Solutions included in "Clean energy for all Europeans" package sets the right balance between making decisions at EU, national, and local level. For the first time, the focus is put on European energy consumers. The new rules increase universal access to energy, by combating the causes of energy poverty and protecting vulnerable consumers. Under the new rules on energy efficiency, Member States must prioritize social housing households and take energy poverty into account in their long-term renovation strategies (European Commission 2019). Summing-up, energy is important for the competitiveness of Member State economies as it affects production costs of industries and services and the purchasing power of households.

Abstract

CSR stands for corporate social responsibility and is based on four dimensions - economic, legal, ethical and philanthropic. The growing popularity of CSR manifests itself both in real actions taken by enterprises and in published reports on these actions. However, during the COVID-19 pandemic, it is reasonable to ask the question - were these CSR activities based on the mission and goals of the company, or were they just a PR tool? The purpose of this article is to outline the problems associated with the implementation of CSR activities during the COVID-19 pandemic and to identify future research directions in this area.

Keywords: Corporate Social Responsibility, COVID-19 Pandemic, Crisis.

Introduction

CSR is a concept assuming that enterprises do not operate in isolation and its activities have an impact on the social, economic and natural environment. More and more companies are undertaking CSR activities and presenting them to stakeholders in the form of separate reports. As indicated in the further part of this paper, CSR can give many benefits to the company and its employees. A balanced way of running a business allows for further development of the economy, taking into account the needs of various social groups and natural environment. However, in times of crisis, and such time is now due to the COVID-19 pandemic, there is doubt as to how much CSR activities resulted from the mission of the companies, and how far they were only a PR tool.

Therefore, this article reviews the literature on CSR, including critical research on CSR. Based on the current situation in Poland and the reaction of companies to this crisis, future research areas have been outlined.

The concept of CSR

CSR is an abbreviation for corporate social responsibility. The general meaning of CSR described Carroll by selecting four dimensions of CSR – economic, legal, ethical and philanthropic responsibilities (Carroll 1991). Wagner-Tsukamoto described Carroll's dimensions briefly as follows (Wagner-Tsukamoto 2019, p.471-472):

"At the base of his framework, Carroll located economic responsibilities; the firm is meant "to be profitable". Can ethics be drawn upon to justify such a recommendation, and if so, which kind of ethics? Equally, can the idea of economics be restrained to the bottom dimension only? One level higher, Carroll discussed legal responsibilities, again normatively: The firm is expected "to obey laws". Again, critical questions include why should a firm obey laws? How could ethics be drawn upon to ground this argument? Would economic considerations come into play? One level higher Carroll placed ethical responsibilities, which reflect in his reading ethical expectations of society that go beyond the fulfilling of laws. The top dimension reflects philanthropic (voluntary, discretionary) responsibilities: The normative recommendation to the firm is "to be a good corporate citizen" through making donations, volunteering, engaging in charitable acts, etc. As it was for the bottom dimensions, the questions are why would a firm be expected to fulfil ethical and philanthropic responsibilities, and can economic argument play any role here?"

So, each of the dimensions can be described by a simple phrase:

- Economic: being profitable.
- Legal: obeying the law.
- Ethical: being ethical.
- Philanthropic: being good corporate citizen.

There are several approaches to CSR research, some of which are listed below.

Nowadays, CSR must be associated as an international tool, not only as a local initiative that does not go beyond the borders of the country or region in which the company operates. According to Amo-Mensah and Tench (2018, p.140) "As corporate social responsibility (CSR) becomes more relevant, the activities of transnational corporations, sometimes referred to as multinational corporations (MNCs), in host countries have received considerable attention in recent years. Due to global economic integration, liberalisation and technological advancements, a large number of transnational companies (TNCs) usually based in Europe and the USA have extended their activities across national borders".

A lot of research has been done on the relationship between CSR, management commitment and stakeholders activities. For instance, according to Jones, Bowd and Tench (2009, p.306) "It can be argued that there has been a paradigmatic shift from a business model and way of working in which shareholder interests and issues such as return on investment reign supreme, to one whereby different stakeholders compete to influence and shape the business agenda, so that shareholder interests are simply one of many". It can therefore be concluded that profit maximization is no longer the main goal of stakeholders. Of course, you can't do business without profit, but that profit is no longer the only criterion. This approach is consistent with the statement of Kilcullen and Ohles Kooistra (1999) that "corporate social responsibility have centered on the long-term advantages of socially responsible behavior, advantages such as greater customer and employee loyalty and a more supportive external environment".

According to Tetrault Sirsly (2009) "Most of the business classics reviewed have provided the underpinnings of what has become stakeholder management and corporate social responsibility. The overwhelming importance of top management's values, ethics and morals in setting the tone of organizational culture is the foundation upon which corporate social responsibility is also built". More about the relationship between corporate social responsibility and managements' activities in O'Dwyer (2003).

Recently, many "varieties" of CSR and new approaches have been described in the literature. According to Carroll and Brown (2018) there is a: political CSR, upstream/downstream CSR, CSR in emerging economies, corporate social activism, and corporate social *ir*responsibility. For instance, CSR comparison of the emerging economy with the developed economy presented Garstecki, Kowalczyk and Kwiecinska

(2019) and political perspective in CSR research presented Rehbein, Hond and Bakker 2018 or Lin, Sambasivan Ho and Law (2019). According to Amodu (2018) "an efficient corporate social responsibility (CSR) framework in many economies has been linked with human capital development, social and financial inclusion, environmental protection and better stakeholder management".

One of the latest topics in CSR-related papers is the relationship between corporate social responsibility and circular economy, which is gaining popularity due to limited sources and environmental problems (Scarpellini, Marin-Vinuesa, Aranda-Uson and Portillo-Tarragona 2020; Zhao 2018; Li, Meng, Leung, Zuo, Tang and Wang 2018) and improves business sustainability by reinserting waste into the supply chain in order to manufacture products on demand in different industries (Nascimento, Alencastro, Quelhas, Caiado, Garza-Reyes, Rocha-Lona and Tortorella 2019; Hvass and Pedersen 2019; Sandvik and Stubbs 2019). According to the recent studies circular economy has four main benefits: environmental, economic, social and operational (Sehnem, Vazquez-Brust, Pereira and Campos 2019). As we can see, the concept of CSR has evolved and has helped several industries find new ways of doing business in more sustainable way.

The purpose of this article was not a detailed analysis of the beginnings of the CSR concept, for this we refer to other papers, for instance (Gomez-Carrasco, Guillamon-Saorin and Garcia Osma 2016; Moura-Leite and Padgett 2011).

Benefits of CSR

There are many benefits of CSR in the literature. Some studies focus on benefits for employees, others focus on benefits for the company.

In connection with benefits for employees Bauman and Skitka (2012) presented four employee needs in the CSR area: 1) safety and security, 2) distinctiveness, 3) belonging and 4) meaningful existence. Bauman and Skitka perceive these needs as four different ways by which a given company could influence employees' relationships. Alhouti and D'Souza (2018) conducted extensive research on the benefits of corporate social responsibility. According to them "CSR influences spiritual, status, efficiency and aesthetic benefits equally and (…) study finds that in most cases spiritual benefit is more likely to lead to a stronger consumer outcome than other benefits" (p.283).

In terms of benefits for the company McDonald, Svensson and Galbreath (2010) discussed three potential benefits of CSR activities: reduced employee turnover, increased customer satisfaction and improved reputation. In the summary of their research we can read that "as a result, this study offers some level of confirmation for scholars who have theorized that CSR is a value creating activity important to firms beyond direct financial benefits, such as those measured by traditional accounting-based measures" (p.422).

Lenssen, Bevan, Fontrodona and Drews (2010) divided the benefits into two groups: monetary and non-monetary. Among the monetary benefits they include direct financial effects such as revenue increases, cost decreases and benefits that do not directly lead to cash inflow but can be measured in monetary terms like an increase in brand value. Non-monetary benefits include repurchase rates, improved access to capital or retaining investors.

Undoubtedly, CSR activities bring benefits for the company and its employees. However, in times of crisis, such as the current pandemic associated with the COVID-19, it is reasonable to ask the following question - will CSR activities before the crisis continue after it?

Selected problems concerning CSR in disruptive times

As indicated in the previous section, the implementation of the CSR strategy can bring benefits to the company. But there are also some doubts both on the idea of CSR and CSR reporting.
